The command returns properties that show whether the policy configuration of the resource can be shared with clients through a WS-MetadataExchange request or through Web Services Description Language (WSDL) that is obtained by a `?WSDL` HTTP Get request.

Target object

None.

Required parameters

`-applicationName`
The name of the application for which you want to find out how it shares its policy configuration. The application must be a service provider. (String)

Optional parameters

`-resource`
The name of the resource for which you want to find out how it shares its policy configuration. If you specify this parameter, only the properties for that resource are returned. To retrieve information for the application, specify `WebService:/`. Alternatively, you can specify a service, endpoint or operation. However, policy sets are attached only at the application or service level, so the properties returned for an endpoint or operation are the settings that are inherited from the service. (String)

Return value

Returns a list of properties that include the resource name and that show whether the policy configuration of the resource can be shared. The following properties can be returned:

`wsMexPolicySetName`
The name of the policy set that specifies message-level security when the resource shares its policy configuration through a WS-MetadataExchange request. This property is returned if the value of the **`sharePolicyMethods`** property is `wsMex` and a policy set to provide message-level security was specified.

`wsMexPolicySetBinding`
The name of the binding that is applied when the resource shares its policy configuration through a WS-MetadataExchange request. This property is returned if the value of the **`sharePolicyMethods`** property is `wsMex` and a binding to provide message-level security was specified.

`resource`
The resource that you specified.

`directSetting`
How the properties apply to the resource. Valid values for this property are:

`true`
The properties apply directly to the resource.

`false`
The properties are inherited from the parent application or service.

`sharePolicyMethods`
How the policy configuration of the resource can be shared. Valid values for this property are:

`httpGet`
The resource shares its policy configuration through an HTTP Get request.

`wsMex`
The resource shares its policy configuration through a WS-MetadataExchange request.

Example

The following command displays the policy sharing configuration properties for the EchoService service in the WSSampleServices application. The provider is configured to share its policy through an HTTP Get request, and a WS-MetadataExchange request with message-level security. Message-level security for the WS-MetadataExchange request is provided by using the SystemWSSecurityDefault policy set and the "Provider sample" general binding.

```
AdminTask.getProviderPolicySharingInfo(['-applicationName', 'WSSampleServices',
'-resource', 'WebService:/SampleServicesSei.war:{http://example_path/}EchoService'])
.
.
[ [wsMexPolicySetName SystemWSSecurityDefault] [wsMexPolicySetBinding [Provider sample]]
[resource WebService:/SampleServicesSei.war:{http://example_path/}EchoService/]
[directSetting true] [sharePolicyMethods [httpGet wsMex]] ]
```

Policy sharing settings:

Use this pane to view and change whether the policy configuration of a web services service provider is shared. You can configure the service provider to include the policy configuration in its Web Services Description Language (WSDL) so that it can be accessed using an HTTP Get request, or published. You can also make the policy configuration available to a Web Services Metadata Exchange (WS-MetadataExchange) request.

To view this administrative console page for an application or service, complete the following steps. The application must be a web services service provider.

1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***service_provider_application_name*** > **[Web Services Properties] Service provider policy sets and bindings**.
2. Select the link in the Policy Sharing column for the application or service you require. The link is available if the application or service has a policy set attached.

To view this administrative console page for a service, complete the following steps.

1. Click **Services** > **Service providers** > ***service_name***.
2. Select the link in the Policy Sharing column for the service. The link is available if the service has a policy set attached.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Exported WSDL:

Select **Exported WSDL** to include the policy configuration of the service provider in the WSDL. The policy configuration is in WS-PolicyAttachments format in the WSDL so that it is then available to other clients, service registries, or services that support the Web Services Policy (WS-Policy) specification. The policy configuration will be available in published WSDL, or a client can use an HTTP Get request that is targeted at the target URL followed by `?WSDL` to obtain the provider policy.

WS-MetadataExchange request:

Select **WS-MetadataExchange** to make the policy configuration of the service provider available to a WS-MetadataExchange GetMetadata request. The policy configuration is in WS-PolicyAttachments format in the WSDL so that it is then available to other clients, service registries or services that support the Web Services Policy (WS-Policy) specification and the WS-MetadataExchange GetMetadata request.

When **WS-MetadataExchange** is selected, the **Attach a system policy set to the WS-MetadataExchange** option is available.

Attach a system policy set to the WS-MetadataExchange:

Select **Attach a system policy set to the WS-MetadataExchange** to set message-level security for the WS-MetadataExchange request. By default, this option is not selected and the transport policy of the application is used. This option is available only when **WS-MetadataExchange** is selected.

When **Attach a system policy set to the WS-MetadataExchange** is selected, the **Policy set** and **Binding** lists are available.

Policy set:

Select the policy set you require from the list to provide message-level security for the WS-MetadataExchange request. You can select from system policy sets that contain only WS-Security policies, only WS-Addressing policies, or both. The default policy set is SystemWSSecurityDefault.

System policy sets are used for system messages that are not business-related, for example, messages that apply qualities of service (QoS), including the messages that are defined in the WS-MetadataExchange protocol.

Note that any transport policy of the application is always used.

This option is available only when **Attach a system policy set to the WS-MetadataExchange** is selected.

Binding:

Select the binding you require from the list to provide message-level security for the WS-MetadataExchange request. You can select from general bindings that are scoped to the global domain, or scoped to the security domain of this service.

This option is available only when **Attach a system policy set to the WS-MetadataExchange** is selected.

Configuring the client policy to use a service provider policy

An application that is a web service client can obtain the policy configuration of a web service provider and use this information to establish a policy configuration that is acceptable to both the client and the service provider.

Before you begin

You have developed a web service client that contains all the necessary artifacts, and deployed your web services application into your application server instance. If you require them, you have attached the policy sets and managed the associated bindings.

The service provider must publish its policy in its Web Services Description Language (WSDL) and that policy must contain its policy configuration at run time in WS-PolicyAttachments format. The client must be able to support those provider policies.

For a list of WS-Policy assertion specifications and WS-Policy domains that are supported, see the WS-Policy topic.

About this task

You can administer the client to configure itself dynamically at run time, based on the policy of the service provider in the standard WS-PolicyAttachments format. You can administer the client to apply dynamically the provider policy at the application or service or service reference level. By default, endpoints and

operations inherit their policy configuration from the relevant service. However, it is possible to configure a service reference to override the service, in which case the endpoints and operations inherit their policy configuration from the service reference.

If the provider policy uses multipart WSDL, you can use an HTTP GET request to obtain the policy of the provider, but you cannot use the WS-MetadataExchange protocol. For more information about multipart WSDL, see the topic about WSDL.

Policy intersection is the comparison of a client policy and a provider policy to determine whether they are compatible, and the calculation of a new policy, known as the effective policy, that complies with both their requirements and capabilities.

This topic describes how to configure the client policy to use a service provider policy by using the administrative console. You can also configure the client policy to use a service provider policy by using wsadmin commands.

Procedure

1. From the navigation panel of the administrative console, click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***service_client_application_instance*** > **[Web services properties] Service client policy sets and bindings**.
2. In the row for the application or service where you want to apply the policy, click the link in the Policies Applied column. The Policies Applied panel is displayed.
3. Select one of the following options from the drop-down list:
   - Provider policy only. Configure the client based solely on the policy of the service provider. This option is available when a client policy set is not attached.
   - Client and provider policy. Configure the client based on both the client policy set and the policy of the service provider. This option is available when a client policy set is attached.

   The other options in the list do not apply to this task.
4. Use the radio buttons to select which method to employ to obtain the provider policy: an HTTP GET request (see step 5) or a WS-MetadataExchange request (see step 6).
5. Optional: To obtain the provider policy by using an HTTP GET request, click **HTTP GET request**. By default, the HTTP GET request is targeted at the URL for the service endpoint followed by `?WSDL`. For example:

```
http://myhost:9080/WSSampleSei/EchoService?WSDL
```

   When the policy set attach point is at the application level you cannot change this value.
   a. Optional: If you are applying a policy to a service and the provider policy is located at the service endpoint, ensure that **Use the default request target** is selected.
   b. Optional: If you are applying a policy to a service and the provider policy is not located at the service endpoint, click **Specify request target**, then enter the URL for the location of the provider policy in the field. For example, you might change the target of the HTTP GET request if the provider policy is located in a repository.
   c. Optional: If you select **HTTP GET request** as the method to be used to obtain the provider policy and if you select **Specify request target** and you want to configure transport-level security, select **Attach a system policy set to the HTTP GET request**, then select a suitable policy set and binding from the drop-down lists. Select the policy set you require from the Policy set list to provide transport-level security for the HTTP GET request. Select from system policy sets that contain solely HTTP transport policies, solely SSL transport policies, or both; the policy set cannot contain other policy types. Select the binding you require from the Binding list for the HTTP GET request. You can select from general bindings that are scoped to the global domain or scoped to the security domain of this service.
6. Optional: To obtain the provider policy by using a Web Services Metadata Exchange (WS-MetadataExchange) GetMetadata request, click **WS-MetadataExchange request**.

a. Optional: If you select **WS-MetadataExchange request** and want to use message-level security, select **Attach a system policy set to the WS-MetadataExchange request**, then select a suitable policy set and binding from the drop-down lists. See Configuring security for a WS-MetadataExchange request.

7. Click **OK**.
8. Save your changes to the master configuration.

Results

The web application client-side policy is calculated when it is required at run time, based either on the policy of the service provider, or on the client policy set and the policy of the service provider, depending on which option you selected. This calculated policy is known as the “effective policy” and is cached as a runtime configuration. The effective policy is used for subsequent outbound web service requests to the endpoint or operation for which the dynamic policy calculation was performed. The policy set configuration of the client does not change.

The provider policy that the client holds for a service is refreshed the first time that the web service is invoked after the application is loaded. After that, the provider policy is refreshed when the application restarts, or if the application explicitly invokes a refresh. When the provider policy is refreshed, the effective policy is recalculated.

Configuring the client policy to use a service provider policy by using wsadmin scripting:

An application that is a web service client can obtain the policy configuration of a web service provider and use this information to establish a policy configuration that is acceptable to both the client and the service provider.

Before you begin

You have developed a web service client that contains all the necessary artifacts, and deployed your web services application into your application server instance. If you require them, you have attached the policy sets and managed the associated bindings.

The service provider must publish its policy in its Web Services Description Language (WSDL) and that policy must contain its policy configuration at run time in WS-PolicyAttachments format. The client must be able to support those provider policies.

For a list of WS-Policy assertion specifications and WS-Policy domains that are supported, see the WS-Policy topic.

About this task

You can administer the client to configure itself dynamically at run time, based on the policy of the service provider in the standard WS-PolicyAttachments format. You can administer the client to dynamically apply the provider policy at the application or service or service reference level.

Note: If you specify client dynamic policy control at the service reference level, you must use the new name-value paired list format of the resource string. If you are not specifying client dynamic policy control at service reference level, you can use either format.

Table 141. How to specify policy control at different levels of the application. For each applicable level of the application, the table lists the relevant string format command and name-value pair format command needed to specify policy control and summarizes the associated behavior.

Level	String format	Name-value pair list format (NEW)	Behavior
Type	`"WebService:/"`	`"type=WebService:/"`	Indicates all artifacts in the application

Table 141. How to specify policy control at different levels of the application (continued). For each applicable level of the application, the table lists the relevant string format command and name-value pair format command needed to specify policy control and summarizes the associated behavior.

Level	String format	Name-value pair list format (NEW)	Behavior
Service	"WebService:/*myModule*:{*namespace*}*myService*"	"type=WebService:/,module=*myModule*,service={*namespace*}*myService*"	Indicates all artifacts within the web service
Endpoint (under this service)	"WebService:/*myModule*:{*namespace*}*myService*/*endpointA*"	"type=WebService:/ ,module=*myModule*,service={*namespace*}*myService*,endpoint=*endpointA*"	Indicates all operations for this endpoint (under the service)
Operation (under this service)	"WebService:/*myModule*:{*namespace*}*myService*/*endpointA*/*operation1*"	"type=WebService:/ ,module=*myModule*,service={*namespace*}*myService*,endpoint=*endpointA*, operation=*operation1*"	Indicates a specific single operation (under the service)
Service reference	[Not possible]	"type=WebService:/ ,module=*myModule*,service={*namespace*}*myService*,serviceRef=*myServiceRef*"	Indicates all artifacts within the web service reference
Endpoint (under this service reference)	[Not possible]	"type=WebService:/ ,module=*myModule*,service={*namespace*}*myService*,serviceRef=*myServiceRef*, endpoint=*endpointA*"	Indicates all operations for this endpoint (under the service reference)
Operation (under this service reference)	[Not possible]	"type=WebService:/ ,module=*myModule*,service={*namespace*}*myService*,serviceRef=*myServiceRef*, endpoint=*endpointA*,operation=*operation1*"	Indicates a specific single operation (under the service reference)

If the provider policy uses multipart WSDL, you can use an HTTP GET request to obtain the policy of the provider, but you cannot use the WS-MetadataExchange protocol. For more information about multipart WSDL, see the topic about WSDL.

Policy intersection is the comparison of a client policy and a provider policy to determine whether they are compatible, and the calculation of a new policy, known as the effective policy, that complies with both their requirements and capabilities.

This topic describes how to configure the client policy to use a service provider policy by using wsadmin commands. You can also configure the client policy to use a service provider policy by using the administrative console.

Procedure

1. Start the wsadmin scripting client if it is not already running.
2. Use the **SetClientDynamicPolicyControl** command. For example:

```
AdminTask.setClientDynamicPolicyControl('[-applicationName WebServiceClientApplication
-resource WebService:/ClientApplication.war:{http://example_path/}Service1
-acquireProviderPolicyMethod [httpGet ]
-httpGetProperties [httpGetTargetURI http://example_path]]')
```

3. Save your changes to the master configuration.

   To save your configuration changes, enter the following command:

```
AdminConfig.save()
```

Results

The web application client-side policy is calculated when it is required at run time, based either on the policy of the service provider, or on the client policy set and the policy of the service provider, depending on which option you selected. This calculated policy is known as the “effective policy” and is cached as a runtime configuration. The effective policy is used for subsequent outbound web service requests to the endpoint or operation for which the dynamic policy calculation was performed. The policy set configuration of the client does not change.

The provider policy that the client holds for a service is refreshed the first time that the web service is invoked after the application is loaded. After that, the provider policy is refreshed when the application restarts, or if the application explicitly invokes a refresh. When the provider policy is refreshed, the effective policy is recalculated.

Configuring the client policy to use a service provider policy from a registry:

An application that is a web service client can obtain the policy configuration of a web service provider from a registry, such as WebSphere Service Registry and Repository (WSRR), and use this information to establish a policy configuration that is acceptable to both the client and the service provider.

Before you begin

You have developed a web service client that contains all the necessary artifacts, and deployed your web services application into your application server instance. If you require them, you have attached the policy sets and managed the associated bindings.

The Web Services Description Language (WSDL) for the policy of the service provider, and its corresponding policies and policy attachments, are stored in a registry such as WSRR. That policy must contain its policy configuration in WS-PolicyAttachments format. The client must be able to support those provider policies.

The registry must support the use of HTTP GET requests to publish WSDL that contains WS-Policy attachments, for example WSRR Version 6.2 or later.

For a list of WS-Policy assertion specifications and WS-Policy domains that are supported, see the WS-Policy topic.

About this task

You can administer the client to configure itself dynamically at run time, based on the policy of a service provider that is held in a registry. You can administer the client at the service or service reference level to dynamically apply the provider policy that it obtains from a registry. By default, endpoints and operations inherit their policy configuration from the relevant service. However, it is possible to configure a service reference to override the service, in which case the endpoints and operations inherit their policy configuration from the service reference. You cannot administer the client to apply dynamically the provider policy that it obtains from a registry at the application level.

You can configure the client policy to use a service provider policy that is stored in a registry by using the administrative console. You can also configure the client policy to use a service provider policy that is stored in a registry by using wsadmin commands.

Procedure

1. From the navigation pane of the administrative console, click **Applications** > **Application Types** > **WebSphere enterprise applications**.
2. Click the web service client application that you want to configure.
3. Click **[Web services properties] Service client policy sets and bindings**.
4. In the row for the service where you want to apply the policy, click the link in the Policies Applied column. You cannot apply the policy at application level. The Policies Applied pane is displayed.
5. Select one of the following options from the drop-down list:
   - Provider policy only. Configure the client based solely on the policy of the service provider. This option is available when a client policy set is not attached.
   - Client and provider policy. Configure the client based on both the client policy set and the policy of the service provider. This option is available when a client policy set is attached.

   The other options in the list do not apply to this task.
6. Click **HTTP GET request**.
7. Click **Specify request target**, then enter the URL for the location of the provider policy in the field, that is, the address in the repository for the WSDL and policy. For information about using WSRR to

retrieve a WSDL document with embedded policies, and therefore obtain the required URL, see the WSRR documentation. The following example shows a typical URL:

```
https://www.wsrr.host/WSRR/6.2/PolicyService/
WSDL?bsrURI=3b9b493b-278f-4f64.ba3f.dabd30da3f7e
```

8. Click **OK**.
9. Optional: If there is a secure connection that uses the Secure Sockets Layer (SSL) protocol between the client and the registry, ensure that trust is established between the application server and the registry server. To access the registry, the client uses the SSL transport policy that is part of its service-level application policy. For example, for WSRR, you can enter the URL for the WSRR server in a browser window. If the WSRR server is not already trusted, a message is displayed stating that the security certificate is not trusted. To establish trust, use the following steps:
   a. Retrieve and store the X509 certificate from the WSRR server. Use the options on the message to view details of the certificate and save those details to a file, using distinguished encoding rules (DER) encoded binary format.
   b. Find out the key store that the client uses, that is, the key store that is shown by the SSL security transport bindings of the client application policy set. See Configuring the SSL transport policy. For example, the key store might be the default trust store for the node.
   c. Add the signer certificate that you saved in step a. to the key store that the client uses. See Adding a signer certificate to a keystore.
10. Optional: To access the registry, the client uses the transport policy that is part of its service-level application policy. If the registry requires authentication using the HTTP protocol, configure a valid user name and password as part of the application-level transport policy binding configuration. It is advisable to secure any authorization credentials, because they are used for interactions with both the web service endpoint and the registry.
    a. Ensure that the client has a policy set that contains the HTTP transport policy attached to the application or service level. See the relevant steps in Managing policy sets and bindings for service clients at the application level using the administrative console .
    b. Configure the HTTP transport client bindings for the binding named Client sample and enter the user name and password that the registry requires to authenticate outbound service requests. See the relevant steps in Configuring the HTTP transport policy.
11. Save your changes to the master configuration.

Results

The web application client-side policy is calculated when it is required at run time, based either on the policy of the service provider, or on the client policy set and the policy of the service provider, depending on which option you selected. This calculated policy is known as the “effective policy” and is cached as a runtime configuration. The effective policy is used for subsequent outbound web service requests to the endpoint or operation for which the dynamic policy calculation was performed. The policy set configuration of the client does not change.

The provider policy that the client holds for a service is refreshed the first time that the web service is invoked after the application is loaded. After that, the provider policy is refreshed when the application restarts, or if the application explicitly invokes a refresh. When the provider policy is refreshed, the effective policy is recalculated.

Policies applied settings:

Use this panel to view and change whether the policy configuration of a WebSphere Application Server service client is configured dynamically, based on the policies supported by its service provider. You can view or change how the client obtains the policy of the service provider; the client can use an HTTP GET request or a Web Services Metadata Exchange (WS-MetadataExchange) request. You can specify a policy set and binding to provide message-level security for WS-MetadataExchange requests or to specify HTTP transport and SSL transport configuration for HTTP GET requests.

To view this administrative console page for an application or service, complete the following steps. The application must be a web services service client.

1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***service_client_application_name*** > **[Web Services Properties] Service client policy sets and bindings**.
2. Select the link in the **Policies Applied** column for the application or service you require.

To view this administrative console page for a service, complete the following steps:

1. Click **Services** > **Service clients** > ***service_name***.
2. Select the link in the **Policies Applied** column for the service. The link is available if the service or the parent application has a policy set attached.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Apply the following policies:

Specifies whether the client policy is based on the policy of the service provider, and how that policy is used.

Select from the following options:

- Client policy only. Configure the client based solely on the client policy set. Do not use the policy of the service provider. This option is available when a client policy set is attached to the resource.
- Client and provider policy. Configure the client based on both the client policy set and the policy of the service provider. This option is available when a client policy set is attached to the resource.
- Inherit application attachment. Inherit the setting of the parent application. This option is available for a service when a client policy set is not attached to the service. If there is a policy set attached to the parent application, the inherited properties are displayed on this panel, but you cannot change them. If there is no policy set attached to the parent application, when you return to the Service clients policy sets and bindings panel, the Policies applied column shows a value of **None**.
- Provider policy only. Configure the client based solely on the policy of the service provider. This option is available when a client policy set is not attached to the resource.

HTTP GET request:

Click **HTTP GET request** to obtain the policy of the service provider by using an HTTP GET request. The policy configuration must be in WS-PolicyAttachments format in the WSDL of the service provider.

This option is available when **Apply the following policies** is set to Client and provider policy or Provider policy only.

By default, the HTTP GET request is targeted at the URL for each service endpoint followed by ?WSDL.

Use the default request target:

When you apply a policy to a service, click **Use the default request target** to target the HTTP GET request at the URL for each service endpoint followed by ?WSDL.

If the attach point is for the service, then you can either select this default request target or you can choose to specify an alternative request target using the **Specify request target** option.

If the attach point is for the application then the default request target will be used.

Specify request target:

When you apply a policy to a service, click **Specify request target** to change the target for acquiring provider policy using an HTTP GET request. Enter the URL for the location of the provider policy in the field.

This option is available when **HTTP GET request** is selected and you apply a policy to a service.

When you apply a policy to an application, this option is not available.

Attach a system policy set to the HTTP GET request:

Select **Attach a system policy set to the HTTP GET request** to set HTTP transport and SSL transport configuration for the HTTP GET request. This option is available when **HTTP GET request** is selected as the method to be used to obtain the provider policy and when **Specify request target** is selected and completed.

If you do not specify a policy set you will inherit the HTTP transport and SSL transport configuration from the application.

Policy set (for the HTTP GET request):

Select the policy set you require from the list to provide HTTP transport and SSL transport configuration for the HTTP GET request. Select from system policy sets that contain solely HTTP transport policies, solely SSL transport policies, or both; the policy set cannot contain other policy types.

This option is available when **Attach a system policy set to the HTTP GET request** is selected and the **Specify request target** is selected and completed.

Binding (for the HTTP GET request):

Select the binding you require from the list for the HTTP GET request. You can select from **Global Default Bindings** or **General client/provider policy set bindings**, which are specific to the individual service.

This option is available when **Attach a system policy set to the HTTP GET request** is selected and the **Specify request target** is selected and completed.

The value of **Default** will result in the Global Default Binding being used.

WS-MetadataExchange request:

Click **WS-MetadataExchange** to obtain the policy of the service provider by using a WS-MetadataExchange GetMetadata request. The policy configuration must be in WS-PolicyAttachments format in the WSDL of the service provider.

This option is available when **Apply the following policies** is set to Client and provider policy or Provider policy only.

Attach a system policy set to the WS-MetadataExchange request:

Select **Attach a system policy set to the WS-MetadataExchange request** to set message-level security for the WS-MetadataExchange request. By default, this option is not selected and the transport policy of the application is used. This option is available when **WS-MetadataExchange request** is selected.

When **Attach a system policy set to the WS-MetadataExchange request** is selected, the **Policy set** and **Binding** lists are available. If you select **Attach a system policy set to the WS-MetadataExchange request**, you must also select a policy set and a binding.

Policy set (for the WS-MetadataExchange request):

Select the policy set you require from the list to provide message-level security for the WS-MetadataExchange request. You can select from system policy sets that contain only WS-Security policies, only WS-Addressing policies, or both. The default policy set is SystemWSSecurityDefault.

System policy sets are used for system messages that are not business-related, for example, messages that apply qualities of service (QoS), including the messages that are defined in the WS-MetadataExchange protocol.

Note that any transport policy of the application is always used.

This option is available when **Attach a system policy set to the WS-MetadataExchange** is selected.

Binding (for the WS-MetadataExchange request):

Select the binding you require from the list to provide message level security for the WS-MetadataExchange request. You can select from **Global Default Bindings** or **General client/provider policy set bindings**, which are specific to the individual service.

This option is available when **Attach a system policy set to the WS-MetadataExchange** is selected.

The value of **Default** will result in the Global Default Binding being used.

Enabling Web Services Addressing support for JAX-WS applications using deployment descriptors

For JAX-WS applications, you can enable WS-Addressing support during the packaging of either a service or client application, by editing the deployment descriptor for that application.

About this task

To modify WS-Addressing behavior by using deployment descriptors, add an `<addressing>` element to the deployment descriptor file for the application. The `<addressing>` element has optional child elements as described in the following table.

The `<addressing>` element functions in the same way as the Addressing annotation. The child elements of the `<addressing>` annotation function in the same way as the parameters of the Addressing annotation.

Table 142. Child elements of the addressing deployment descriptor element. The table lists the different child elements with their possible values and a description of each one.

Element name	Possible values	Description
`enabled`	`true` (default) `false`	Whether WS-Addressing support is enabled.
`required`	`true` `false` (default)	Whether WS-Addressing headers are required.

`responses`	`All` (default)
	`ANONYMOUS`
	`NON_ANONYMOUS`
		Whether to use a synchronous or an asynchronous message exchange pattern. Specify `ANONYMOUS` to send messages in a synchronous message pattern; use `NON_ANONYMOUS` to send messages in an asynchronous message exchange pattern.

Procedure

- To modify the behavior of the WS-Addressing support in the service application, add the <addressing> element, and optional child elements as required, to the service deployment descriptor under the <port-component> element within the <webservice-description> element. In the following example, the Addressing deployment descriptor fragment specifies that WS-Addressing is enabled and required, and that the asynchronous message exchange pattern is used.

```
<port-component>
     <port-component-name>MyPort1</port-component-name>
        <addressing>
         <enabled>true</enabled>
         <required>true</required>
         <responses>NON_ANONYMOUS</responses>
        </addressing>
        <service-impl-bean>
           <servlet-link>MyPort1ImplBean</servlet-link>
        </service-impl-bean>
</port-component>
```

- To modify the behavior of the WS-Addressing support in the client application, add the <addressing> element, and optional child elements as required, to the client deployment descriptor under the <port-component-ref> element within the <service-ref> element. For example, the following deployment descriptor fragment indicates that WS-Addressing is enabled:

```
<service-ref>
        <service-ref-name>service/MyPortComponentRef</service-ref-name>
        <service-interface>com.example.MyService</service-ref-interface>
        <port-component-ref>
           <service-endpoint-interface>com.example.MyPortType</service-endpoint-interface>
           <addressing>
              <enabled>true</enabled>
           </addressing>
        </port-component-ref>
</service-ref>
```

Results

WS-Addressing properties are now included in the SOAP message header, and are processed by the server on receipt of the message.

Enabling Web Services Addressing support for JAX-WS applications using addressing annotations

For JAX-WS applications, you can enable WS-Addressing support during development of a service application, by using addressing annotations in the code. You can also use this method in a client application that uses an injected web service proxy reference.

About this task

Use one of the following addressing annotations in your service code:

- Addressing - use this annotation if you want to use the 2005/08 WS-Addressing specification.
- SubmissionAddressing - use this annotation if you want to use the 2004/08 WS-Addressing specification.

On clients, use the Addressing annotation only; the SubmissionAddressing annotation is not supported. You must specify the Addressing annotation in combination with the WebServiceRef annotation. The WebServiceRef annotation specifies a reference to the web service proxy that is injected by the client container.

Annotation settings override settings in the WSDL document. Annotation settings might differ from WSDL settings if you create the WSDL document manually rather than generating it from the code.

Specify up to three optional parameters for each annotation:

Table 143. Parameters for the addressing annotations. The table lists the different parameters with their possible values and a description of each one.

Parameter name	Possible values	Description
`enabled`	`true` (default) `false`	Whether WS-Addressing support is enabled.
`required`	`true` `false` (default)	Whether WS-Addressing headers are required.

`responses`	`Responses.All` (default)
	`Responses.ANONYMOUS`
	`Responses.NON_ANONYMOUS`
		Whether to use a synchronous or an asynchronous message exchange pattern. Specify `Responses.ANONYMOUS` to send messages in a synchronous message pattern; use `Responses.NON_ANONYMOUS` to send messages in an asynchronous message exchange pattern. **Note:** This parameter is not supported on the SubmissionAddressing annotation.

Note: You can use the Addressing annotation only with a SOAP (1.1 or 1.2) over HTTP binding. If you use the class with another binding, such as XML over HTTP, an exception is thrown on clients, and on servers the web service fails to deploy.

Procedure

- To modify the behavior of the WS-Addressing support programmatically in the service application, use one of the addressing annotations, with optional parameters as required, in the code. In the following example, the Addressing annotation is used with no parameters, so the default settings apply.

```
import javax.xml.ws.soap.Addressing;

@Addressing
@WebService(endpointInterface =
   "org.apache.axis2.jaxws.calculator.Calculator",
   serviceName = "CalculatorService",
   portName = "CalculatorServicePort",
   targetNamespace = "http://calculator.jaxws.axis2.apache.org")
```

  In the following example, the SubmissionAddressing annotation is used with parameters that specify that WS-Addressing is enabled and required. The `responses` attribute is not supported on this annotation.

```
import com.ibm.websphere.wsaddressing.jaxws21.SubmissionAddressing;

@SubmissionAddressing(enabled=true, required=true)
@WebService(endpointInterface =
   "org.apache.axis2.jaxws.calculator.Calculator",
   serviceName = "CalculatorService",
   portName = "CalculatorServicePort",
   targetNamespace = "http://calculator.jaxws.axis2.apache.org")
```

- To enable WS-Addressing support on clients that use an injected web service proxy reference, use the Addressing annotation, with optional parameters as required, in combination with the WebServiceRef annotation. The SubmissionAddressing annotation is not supported for this method.

  For example, the following code fragment specifies that WS-Addressing is enabled and that the synchronous message exchange pattern is used:

```
public class MyClientApplication {

            // Enable Addressing for a port-component-ref resource injection.
            @Addressing(enabled=true, responses=Responses.ANONYMOUS)
            @WebServiceRef(MyService.class)
            private MyPortType myPort;
            ...
       }
```

Results

If you use an addressing annotation in the service application, the server processes any WS-Addressing headers that conform to the relevant specification in inbound SOAP messages. If you specify that WS-Addressing is required, and an inbound SOAP message does not include any WS-Addressing headers, or includes WS-Addressing headers that do not conform to the specification indicated by the

annotation, the server returns a fault message. For example, if a client sends a message that includes 2004/08 WS-Addressing headers, and the server requires 2005/08 headers, the server returns a fault message.

If you use the Addressing annotation and generate a WSDL document from the code, a UsingAddressing element and WS-Policy assertions are created in the WSDL document. Clients that use this WSDL document will include WS-Addressing information in their messages. The SubmissionAddressing annotation is not understood by current WSDL generation tools. However, the WSDL document does not distinguish between the 2005/08 specification and the 2004/08 specification, so if you want to generate a WSDL document from code that contains a SubmissionAddressing annotation, use both the Addressing and SubmissionAddressing annotations together.

If you specify the responses attribute, the corresponding message exchange pattern will be used.

Enabling Web Services Addressing support for JAX-WS applications using addressing features

For JAX-WS applications, you can enable WS-Addressing support during development of a client application, by using addressing features in the code.

About this task

Use one of the following addressing feature classes in your client code:

- AddressingFeature - use this class if you want to send messages that include WS-Addressing headers that conform to the 2005/08 WS-Addressing specification
- SubmissionAddressingFeature - use this class if you want to send messages that include WS-Addressing headers that conform to the 2004/08 WS-Addressing specification

If you use both feature classes, the specification that is used depends on the type of endpoint reference that you also specify. For example, if you specify a W3CEndpointReference object, the specification that is used is the 2005/08 specification. If you specify an endpoint reference whose type conflicts with that indicated by the feature class, for example a W3CEndpointReference object with a SubmissionAddressingFeature instance, an error is thrown. If you do not specify an endpoint reference, the default specification is the 2005/08 specification.

Specify up to three optional parameters for each addressing feature instance:

Table 144. Parameters for the addressing features. The table lists the different addressing feature parameters as well as their possible values and a description of each one.

Parameter name	Possible values	Description
`enabled`	`true` (default) `false`	Whether WS-Addressing support is enabled.
`required`	`true` `false` (default)	Whether WS-Addressing headers are required.

`responses`	`Responses.All` (default)
	`Responses.ANONYMOUS`
	`Responses.NON_ANONYMOUS`
		Whether to use a synchronous or an asynchronous message exchange pattern. Specify Responses.ANONYMOUS to send messages in a synchronous message pattern; use Responses.NON_ANONYMOUS to send messages in an asynchronous message exchange pattern.
		Note: This parameter is not supported for the SubmissionAddressingFeature class.

Note: You can use the addressing feature classes only with a SOAP (1.1 or 1.2) over HTTP binding. If you use the class with another binding, such as XML over HTTP, an exception is thrown on clients, and on servers the web service fails to deploy.

Procedure

Create an instance of one of the addressing feature classes, with parameters as required. For example, to specify that WS-Addressing is enabled and required, and that the 2005/08 specification and the asynchronous message exchange pattern is used, use the following code:

```
AddressingFeature feat = new AddressingFeature(true, true, AddressingFeature.Responses.NON_ANONYMOUS);
```

To specify that WS-Addressing is disabled for the 2004/08 specification, use the following code:

```
SubmissionAddressingFeature feat = new SubmissionAddressingFeature(false);
```

Results

If you specify that WS-Addressing is enabled, the client includes WS-Addressing headers in SOAP messages. The headers conform to the WS-Addressing specification indicated by the type of feature class used. If the server does not use annotations, or uses policy sets to enable WS-Addressing, the server accepts both the 2005/08 and 2004/08 specifications.

If you specify that WS-Addressing is required and the client receives a message that does not include WS-Addressing headers, the client returns a fault.

If you specify the responses attribute, the corresponding message exchange pattern will be used.

Enabling Web Services Addressing support for JAX-WS applications using WS-Policy

For JAX-WS applications, you can enable WS-Addressing support during the development of a client or service application by adding WS-Policy assertions into the WSDL document.

About this task

The JAX-WS 2.2 specification introduces functionality that enables WS-Policy assertions in the application WSDL document to be mapped to and from Java annotations in the code.

There are several ways of enabling WS-Addressing support for JAX-WS applications. The method of using WS-Policy will be effective unless it is overridden by another method with greater precedence, such as if you are using AddressingFeature classes or using Addressing annotations. See the parent topic: Enabling Web Services Addressing support for JAX-WS applications for full details about the order of precedence used by WebSphere Application Server.

Note: WebSphere Application Server version 8 supports the JAX-WS 2.2 specification. One of the differences between the JAX-WS 2.1 and JAX-WS 2.2 specifications is that whereas the presence of WS-Policy in an application's WSDL was formerly ignored, if WS-Addressing support is defined within the WS-Policy, this will now be used by WebSphere Application Server in the configuration of the application. As the presence of WS-Policy in an application's WSDL is now checked for WS-Addressing configuration, you may notice a change in behavior in applications formerly run in previous versions of WebSphere Application Server.

If you add an Addressing annotation to your provider code and use the **wsgen** command-line tool to generate the WSDL document, it will contain WS-Policy assertions specifying the WS-Addressing support. However, if you are looking at the published WSDL document for the provider service, it is possible that policy defined in policy sets is showing, as this would overwrite any annotations defined in the code.

If you are using an existing WSDL document to create Java code, when WebSphere Application Server reads the WSDL, if any WS-Policy assertions specifying WS-Addressing support are present, the generated Java code will contain Addressing annotations.

Procedure

- To enable WS-Addressing support on clients, use WS-Policy assertions in the code, with optional attributes as required. The `wsam:Addressing` assertion indicates that WS-Addressing is required. If you want to indicate that WS-Addressing is supported but not mandatory, add the `wsp:Optional` attribute. In the following example, WS-Addressing is supported, but is not mandatory and the messaging format to use has not been specified.

```
<wsp:Policy>
    <wsam:Addressing wsp:Optional="true">
        <wsp:Policy/>
    </wsam:Addressing>
</wsp:Policy>
```

  This example is equivalent to the policy set configuration of WS-Addressing being set to non-mandatory and the messaging style being set to synchronous and asynchronous.
- To specify the message exchange pattern to be employed, use the `wsam:AnonymousResponses` assertion for synchronous message exchanges and the `wsam:NonAnonymousResponses` assertion for asynchronous message exchanges. In the following example, WS-Addressing support is set as mandatory and a synchronous message exchange pattern has been specified.

```
<wsp:Policy>
    <wsam:Addressing>
        <wsp:Policy>
            <wsam:AnonymousResponses/>
        </wsp:Policy>
    </wsam:Addressing>
</wsp:Policy>
```

  This example is equivalent to the policy set configuration of WS-Addressing being set to required and the messaging style being set to synchronous only.

  For more information, see the Web Services Addressing 1.0 - Metadata specification document.

Results

If you add WS-Addressing annotations to the application code specifying that WS-Addressing is enabled, when you generate the WSDL it will contain WS-Policy assertions.

When WS-Policy assertions specifying WS-Addressing support are included in the WSDL, WS-Addressing headers are included in the generated SOAP messages.

If you specify that WS-Addressing is required and an inbound SOAP message is received that does not include any WS-Addressing headers, an exception occurs.

Web Services Addressing annotations

The WS-Addressing specification provides transport-neutral mechanisms to address web services and to facilitate end-to-end addressing. If you have a JAX-WS application you can use Java annotations in your code to specify WS-Addressing behavior at run time.

You can use WS-Addressing annotations to enable WS-Addressing support, to specify whether WS-Addressing information is required in incoming messages, to control the message exchange pattern the service supports, and to specify actions to be associated with a web service operation or fault response.

The following WS-Addressing annotations are supported in WebSphere Application Server. These annotations are defined in the JAX-WS 2.2 specification unless otherwise stated. The JAX-WS 2.2 specification supersedes and includes functions within the JAX-WS 2.1 specification. See the Java API for XML-Based Web Services 2.2 specification for full details.

javax.xml.ws.Action
: Specifies the action that is associated with a web service operation.

- When following a bottom-up approach to developing JAX-WS web services, you can generate a WSDL document from Java application code using the **wsgen** command-line tool. However, for this attribute to be added to the WSDL operation, you must also specify the @Addressing annotation on the implementation class. The result in the generated WSDL document is that the Action annotations will have the `wsam:Action` attribute on the `input message` and `output message` elements of the `wsdl:operation`. Alternatively, if you do not want to use the @Addressing annotation you can supply your own WSDL document with the Action attribute already defined.
- When following a top-down approach to developing JAX-WS web services, you can generate Java application code from an existing WSDL document using the **wsimport** command-line tool. In such cases, the resulting Java code will contain the correct Action and FaultAction annotations.

If this action is not specified in either code annotations or in the WSDL document, the default action pattern as defined in the Web Services Addressing 1.0 Metadata specification is used. Refer to this specification for full details.

Note: Whilst the WebSphere Application Server runtime environment supports the deprecated `wsaw:Action` attribute, if you try to generate Java code from an old WSDL document containing the deprecated `wsaw:Action` attribute, this attribute will be ignored.

javax.xml.ws.FaultAction

Specifies the action that is added to a fault response. When you use this annotation with a particular method, the WS-Addressing FaultAction extension attribute is added to the fault element of the WSDL operation that corresponds to that method. For this attribute to be added to the WSDL operation, you must also specify the Addressing annotation on the implementation class. If you do not want to use the Addressing annotation you can supply your own WSDL document with the Action attribute already defined. This annotation must be contained within an Action annotation.

WSDL documents generated from Java application code containing the WS-Addressing FaultAction annotation will have the `wsam:Action` attribute on the `fault message` element of the `wsdl:operation`.

Note: To ensure that any custom Exception classes you write are successfully mapped to the generated WSDL document, extend the java.lang.Exception class instead of the java.lang.RuntimeException class.

javax.xml.ws.soap.Addressing

Specifies that this service is to enable WS-Addressing support. You can use this annotation only on the service implementation bean; you cannot use it on the service endpoint interface.

com.ibm.websphere.wsaddressing.jaxws21.SubmissionAddressing

This annotation is part of the IBM implementation of the JAX-WS specification. This annotation specifies that this service is to enable WS-Addressing support for the 2004/08 WS-Addressing specification. You can use this annotation only on the service implementation bean; you cannot use it on the service endpoint interface.

For more information about the Addressing and SubmissionAddressing annotations, including code examples, see Enabling Web Services Addressing support for JAX-WS applications using addressing annotations.

The following example code uses the Action annotation to define the invoke operation to be invoked (input), and the action that is added to the response message (output). The example also uses the FaultAction annotation to specify the action that is added to a response message if a fault occurs:

```
@WebService(name = "Calculator")
public interface Calculator {
   ...
    @Action(
      input="http://calculator.com/inputAction",
      output="http://calculator.com/outputAction",
```

```
      fault = { @FaultAction(className=AddNumbersException.class,
                value="http://calculator.com/faultAction")
      }
   )
   public int add(int value1, int value2) throws AddNumbersException {
      return value1 + value2;
   }
}
```

If you use a tool to generate service artifacts from code, the WSDL tags that are generated from the preceding example are as follows:

```
<definitions targetNamespace="http://example.com/numbers" ...>
   ...
   <portType name="AddPortType">
      <operation name="Add">
         <input message="tns:AddInput" name="Parameters"
                        wsam:Action="http://calculator.com/inputAction"/>
         <output message="tns:AddOutput" name="Result"
                         wsam:Action="http://calculator.com/outputAction"/>
         <fault message="tns:AddNumbersException" name="AddNumbersException"
                         wsam:Action="http://calculator.com/faultAction"/>
      </operation>
    <portType>
     ...
<definitions>
```

Web Services Addressing security

It is essential that communications that use Web Services Addressing (WS-Addressing) are adequately secured and that a sufficient level of trust is established between the communicating parties. You can achieve secure communications through the signing of WS-Addressing message-addressing properties and the encryption of endpoint references.

Undertake these actions for both the supported addressing namespaces, http://www.w3.org/2005/08/addressing and http://schemas.xmlsoap.org/ws/2004/08/addressing, even if you intend to use only one of those namespaces.

Signing of WS-Addressing message-addressing properties

You can use an assembly tool to specify the message-addressing properties, and therefore the WS-Addressing message elements, that require signing, or that require signature verification on inbound requests. The receiver of the message might rely on the presence of this verifiable signature to determine that the outbound message originated from a trusted source. Similarly, the lack of a verifiable signature that is associated with the specified inbound message addressing properties causes the rejection of the message with a SOAP fault.

Encryption of endpoint references

You can encrypt endpoint references as part of the SOAP header or SOAP body. Alternatively, you can remove the need for encryption by not including sensitive information in the address or reference parameters properties of the endpoint reference.

Use of the synchronous message exchange pattern

This method applies to JAX-WS applications only.

If you do not secure the WS-Addressing information in the SOAP message by using one or more of the previous methods, and you do not have WS-Security enabled, the ReplyTo and FaultTo elements of the SOAP message could be used to send messages to a third party, potentially taking part in a Denial of Service attack. To prevent such attacks, apply a WS-Addressing policy type and configure it to specify synchronous messaging only. You should also enable WS-Policy so that this requirement is communicated to clients.

Invoking JAX-WS web services asynchronously

Java API for XML-Based Web Services (JAX-WS) provides support for invoking web services using an asynchronous client invocation. JAX-WS provides support for both a callback and polling model when calling web services asynchronously. Both the callback model and the polling model are available on the Dispatch client and the Dynamic Proxy client.

Before you begin

Develop a JAX-WS Dynamic Proxy or Dispatch client. When developing Dynamic Proxy clients, after you generate the portable client artifacts from a Web Services Description Language (WSDL) file using the **wsimport** command, the generated service endpoint interface (SEI) does not have asynchronous methods included in the interface. Use JAX-WS bindings to add the asynchronous callback or polling methods on the interface for the Dynamic Proxy client. To enable asynchronous mappings, you can add the `jaxws:enableAsyncMapping` binding declaration to the WSDL file. For more information on adding binding customizations to generate an asynchronous interface, see chapter 8 of the JAX-WS specification.

Note: When you run the **wsimport** tool and enable asynchronous invocation through the use of the JAX-WS enableAsyncMapping binding declaration, ensure that the corresponding response message your WSDL file does not contain parts. When a response message does not contain parts, the request acts as a two-way request, but the actual response that is sent back is empty. The **wsimport** tool does not correctly handle a void response. To avoid this scenario, you can remove the output message from the operation which makes your operation a one-way operation or you can add a `<wsdl:part>` to your message. For more information on the usage, syntax and parameters for the **wsimport** tool, see the wsimport command for JAX-WS applications documentation.

About this task

An asynchronous invocation of a web service sends a request to the service endpoint and then immediately returns control to the client program without waiting for the response to return from the service. JAX-WS asynchronous web service clients consume web services using either the callback approach or the polling approach. Using a polling model, a client can issue a request and receive a response object that is polled to determine if the server has responded. When the server responds, the actual response is retrieved. Using the callback model, the client provides a callback handler to accept and process the inbound response object. The `handleResponse()` method of the handler is called when the result is available. Both the polling and callback models enable the client to focus on continuing to process work without waiting for a response to return, while providing for a more dynamic and efficient model to invoke web services. Polling invocations are valid from Enterprise JavaBeans (EJB) clients or Java Platform, Enterprise Edition (Java EE) application clients. Callback invocations are valid only from Java EE application clients.

Using the callback asynchronous invocation model

To implement an asynchronous invocation that uses the callback model, the client provides an `AsyncHandler` callback handler to accept and process the inbound response object. The client callback handler implements the `javax.xml.ws.AsyncHandler` interface, which contains the application code that is run when an asynchronous response is received from the server. The `javax.xml.ws.AsyncHandler` interface contains the `handleResponse(java.xml.ws.Response)` method that is called after the run time has received and processed the asynchronous response from the server. The response is delivered to the callback handler in the form of a `javax.xml.ws.Response` object. The response object returns the response content when the `get()` method is called. Additionally, if an error was received, then an exception is returned to the client during that call. The response method is then invoked according to the threading model used by the executor method, `java.util.concurrent.Executor` on the client's `java.xml.ws.Service` instance that was used to create the Dynamic Proxy or Dispatch client instance. The executor is used to invoke any asynchronous callbacks registered by the application. Use the `setExecutor` and `getExecutor` methods to modify and retrieve the executor configured for your service.

Using the polling asynchronous invocation model

Using the polling model, a client can issue a request and receive a response object that can subsequently be polled to determine if the server has responded. When the server responds, the actual response can then be retrieved. The response object returns the response content when the `get()` method is called. The client receives an object of type `javax.xml.ws.Response` from the `invokeAsync` method. That Response object is used to monitor the status of the request to the server, determine when the operation has completed, and to retrieve the response results.

Using an asynchronous message exchange

By default, asynchronous client invocations do not have asynchronous behavior of the message exchange pattern on the wire. The programming model is asynchronous; however, the exchange of request or response messages with the server is not asynchronous. To use an asynchronous message exchange, the `com.ibm.websphere.webservices.use.async.mep` property must be set on the client request context with a boolean value of `true`. When this property is enabled, the messages exchanged between the client and server are different from messages exchanged synchronously. With an asynchronous exchange, the request and response messages have WS-Addressing headers added that provide additional routing information for the messages. Another major difference between asynchronous and synchronous message exchange is that the response is delivered to an asynchronous listener that then delivers that response back to the client. For asynchronous exchanges, there is no timeout that is sent to notify the client to stop listening for a response. To force the client to stop waiting for a response, issue a `Response.cancel()` method on the object returned from a polling invocation or a `Future.cancel()` method on the object returned from a callback invocation. The cancel response does not affect the server when processing a request.

Procedure

1. Determine if you want to implement the callback method or the polling method for the client to asynchronously invoke the web service.
2. (Optional) Configure the client request context. Add the

```
com.ibm.websphere.webservices.use.async.mep
```

property to the request context to enable asynchronous messaging for the web services client. Using this property requires that the service endpoint supports WS-Addressing which is supported by default for the application server. The following example demonstrates how to set this property:

```
Map<String, Object> rc = ((BindingProvider) port).getRequestContext();
 rc.put("com.ibm.websphere.webservices.use.async.mep", Boolean.TRUE);
```

3. To implement the asynchronous callback method, perform the following steps.
   a. Find the asynchronous callback method on the SEI or `javax.xml.ws.Dispatch` interface. For an SEI, the method name ends in *Async* and has one more parameter than the synchronous method of type `javax.xml.ws.AsyncHandler`. The `invokeAsync(Object, AsyncHandler)` method is the one that is used on the Dispatch interface.
   b. (Optional) Add the `service.setExecutor` methods to the client application. Adding the executor methods gives the client control of the scheduling methods for processing the response. You can also choose to use the `java.current.Executors` class factory to obtain packaged executors or implement your own executor class. See the JAX-WS specification for more information on using executor class methods with your client.
   c. Implement the `javax.xml.ws.AsyncHandler` interface. The `javax.xml.ws.AsyncHandler` interface only has the `handleResponse(javax.xml.ws.Response)` method. The method must contain the logic for processing the response or possibly an exception. The method is called after the client run time has received and processed the asynchronous response from the server.
   d. Invoke the asynchronous callback method with the parameter data and the callback handler.
   e. The `handleResponse(Response)` method is invoked on the callback object when the response is available. The `Response.get()` method is called within this method to deliver the response.
4. To implement the polling method,

a. Find the asynchronous polling method on the SEI or `javax.xml.ws.Dispatch` interface. For an SEI, the method name ends in *Async* and has a return type of `javax.xml.ws.Response`. The `invokeAsync(Object)` method is used on the Dispatch interface.

b. Invoke the asynchronous polling method with the parameter data.

c. The client receives the object type, `javax.xml.ws.Response`, that is used to monitor the status of the request to the server. The `isDone()` method indicates whether the invocation has completed. When the `isDone()` method returns a value of `true`, call the `get()` method to retrieve the response object.

5. Use the `cancel()` method for the callback or polling method if the client needs to stop waiting for a response from the service. If the `cancel()` method is invoked by the client, the endpoint continues to process the request. However, the wait and response processing for the client is stopped.

Results

You have enabled your JAX-WS web service client to asynchronously invoke and consume web services. See the JAX-WS specification for additional information regarding the asynchronous client APIs.

Example

The following example illustrates a web service interface with methods for asynchronous requests from the client.

```
@WebService

public interface CreditRatingService {
       // Synchronous operation.
       Score getCreditScore(Customer     customer);
       // Asynchronous operation with polling.
       Response<Score> getCreditScoreAsync(Customer customer);
       // Asynchronous operation with callback.
       Future<?> getQuoteAsync(Customer customer,
              AsyncHandler<Score> handler);
}
```

Using the callback method

The callback method requires a callback handler that is shown in the following example. When using the callback procedure, after a request is made, the callback handler is responsible for handling the response. The response value is a response or possibly an exception. The `Future<?>` method represents the result of an asynchronous computation and is checked to see if the computation is complete. When you want the application to find out if the request is completed, invoke the `Future.isDone()` method. Note that the `Future.get()` method does not provide a meaningful response and is not similar to the `Response.get()` method.

```
CreditRatingService svc = ...;

Future<?> invocation = svc.getCreditScoreAsync(customerTom,
       new AsyncHandler<Score>() {
              public void handleResponse (
                     Response<Score> response)
                  {
                     score = response.get();
                     // process the request...
                  }
    }
);
```

Using the polling method

The following example illustrates an asynchronous polling client:

```
CreditRatingService svc = ...;
Response<Score> response = svc.getCreditScoreAsync(customerTom);

while (!response.isDone()) {
       // Do something while we wait.
}

score = response.get();
```

Enabling Web Services Addressing support for JAX-RPC applications

The Web Services Addressing (WS-Addressing) support provides mechanisms to address web services and provide addressing information in messages. To enable the WS-Addressing support for JAX-RPC applications, either configure the Web Services Description Language (WSDL) file for a service that runs on WebSphere Application Server, or use the WS-Addressing application programming interface (API) or system programming interface (SPI) to add WS-Addressing properties in a WebSphere Application Server client.

About this task

Complete this task to enable the WS-Addressing support, either as a service provider or as a client of a service provided by another party. This task also describes how to disable the WS-Addressing support, which can improve performance for those applications that do not use WS-Addressing or any protocol that depends on the WS-Addressing support.

If you are creating a web service, you can enable the WS-Addressing support during development of the service, by including the UsingAddressing extensibility element in the WSDL binding element for the service. This element contains a **required** attribute that has a value of either `false`, which specifies that WS-Addressing information is accepted but not required in incoming messages, or `true`, which specifies that WS-Addressing information is required in incoming messages. The default value is `false`. Messages from WebSphere Application Server clients always include WS-Addressing information if your service WSDL file includes the UsingAddressing element, regardless of the value of the **required** attribute.

If you are creating a client application to use a service from another provider, you might not have access to the WSDL file for the service, or the service might use a version of WSDL that does not support the UsingAddressing element (if the service is not running on a current version of this product). However, you can still enable WS-Addressing support, during run time, by setting WS-Addressing properties on the JAX-RPC stub or call object that you use to communicate with the service.

The following table summarizes the behavior of the WS-Addressing support in each of the scenarios mentioned previously.

Table 145. The behavior of the WS-Addressing support in the product. The table details the resulting behavior of different `UsingAddressing` settings when an application server client sends a message.

	The WSDL for the service specifies `UsingAddressing required = "false"`	**The WSDL for the service specifies**	**The WSDL for the service does not specify UsingAddressing**
A client sends a message that contains WS-Addressing information	The WS-Addressing information is processed by the product.	The WS-Addressing information is processed by the product.	The WS-Addressing information is processed by the product.
A non-WebSphere Application Server client sends a message that does not contain WS-Addressing information	The message is accepted.	The service returns a fault.	The message is accepted.
A WebSphere Application Server client sends a message, without specifying addressing properties	The message automatically contains the mandatory WS-Addressing information, as defined in the WS-Addressing specification. The information is processed by the product.	The message automatically contains the mandatory WS-Addressing information, as defined in the WS-Addressing specification. The information is processed by the product.	WS-Addressing information is not added. The message is accepted.

Procedure

- To enable WS-Addressing support from the server by configuring the WSDL file, complete the following steps:
  1. Ensure that the WSDL file for the service contains the UsingAddressing extensibility element on the binding element. If you generated the WSDL file by using the Java2WSDL tool, this element is

automatically added for you. If you created the WSDL file yourself, for use with the WSDL2Java tool, you must add the extensibility element. The UsingAddressing element has a **required** attribute with a default value of `false`. For example:

```
<wsdl:binding name="TestServiceSoapBinding" type="intf:TestService">
     <wsaw:UsingAddressing wsdl:required="false"
                           xmlns:wsaw="http://www.w3.org/2006/05/addressing/wsdl"/>

     <wsdlsoap:binding style="document" transport="http://schemas.xmlsoap.org/soap/http"/>

     <wsdl:operation name="invokeInstance">
       ...
     </wsdl:operation>

  </wsdl:binding>
```

This code indicates that the endpoint will process WS-Addressing information, but that this information is not required.

2. Optional: To specify that WS-Addressing information is required, change the value of the **required** attribute to `true`. If the endpoint receives a message that does not contain the mandatory WS-Addressing elements within the message header, the endpoint returns a fault message, as defined in the WS-Addressing specification.

   WebSphere Application Server clients and Proxy Server for IBM WebSphere Application Server always send WS-Addressing conformant messages to endpoints with bindings that specify the UsingAddressing element.

- To enable WS-Addressing support from a WebSphere Application Server client, use the IBM proprietary WS-Addressing API or SPI to associate one or more WS-Addressing properties with the JAX-RPC stub or call object that is used to send messages to the endpoint.

  These properties become message-addressing properties (MAPs) in the SOAP message header. If the node that receives the message is a WebSphere Application Server node, it processes the incoming MAPs in accordance with the WS-Addressing specification, even if the service does not have a UsingAddressing element in its WSDL file.

  Use this method when communicating with endpoints that use earlier versions of the WS-Addressing specification (for example: http://schemas.xmlsoap.org/ws/2004/08/addressing) that do not support the UsingAddressing element, or when the WSDL file for the target endpoint is not available to the client.

Results

WS-Addressing properties are now included in the SOAP message header, and are processed by the server on receipt of the message.

Disabling Web Services Addressing support

The Web Services Addressing (WS-Addressing) support provides mechanisms to address web services and provide addressing information in messages. WS-Addressing support is disabled by default on clients. The method for disabling WS-Addressing support on servers depends on whether your application is based on JAX-RPC or JAX-WS.

About this task

You do not have to disable WS-Addressing support even if your application does not require it, because in most cases WS-Addressing support does not have a negative impact on the running of applications. For JAX-RPC applications, disabling WS-Addressing support can be risky as this action also disables support for other specifications such as Web Services Atomic Transactions.

Procedure

- Disable WS-Addressing support for JAX-WS service providers using one of the following ways:
  - Use both the Addressing and SubmissionAddressing annotations in the service code, with the **enabled** parameter set to `false`; for example:

```
import javax.xml.ws.soap.Addressing;

@Addressing(enabled=false)
@SubmissionAddressing(enabled=false)
@WebService(...)
```

  - Use the `<webservice-description>/<port-component>/<addressing>` deployment descriptor element in the deployment descriptor for the service application; for example:

```
<port-component>
   <port-component-name>MyPort1</port-component-name>
   <addressing>
      <enabled>false</enabled>
   </addressing>
   <service-impl-bean>
      <servlet-link>MyPort1ImplBean</servlet-link>
   </service-impl-bean>
</port-component>
```

- You do not have to take any action to disable WS-Addressing support for JAX-WS clients, because WS-Addressing support is disabled by default. However, you can programmatically specify that WS-Addressing is disabled by using one of the following ways:
  - Use both the AddressingFeature and SubmissionAddressingFeature classes in the client code, with the **enabled** parameter set to `false`; for example:

```
AddressingFeature feat = new AddressingFeature(false);
SubmissionAddressingFeature feat = new AddressingFeature(false);
```

  - Use the Addressing annotation for an injected web services proxy reference; for example:

```
public class MyClientApplication {
   // Disable Addressing for a port-component-ref resource injection.
   @Addressing(enabled=false)
   @WebServiceRef(MyService.class)
   private MyPortType myPort;
   ...
 }
```

  - Use the `<service>/<port-component>/<addressing>` deployment descriptor; for example:

```
<service-ref>
   <service-ref-name>service/MyPortComponentRef</service-ref-name>
   <service-interface>com.example.MyService</service-ref-interface>
   <port-component-ref>
      <service-endpoint-interface>com.example.MyPortType</service-endpoint-interface>
      <addressing>
         <enabled>false</enabled>
      </addressing>
   </port-component-ref>
</service-ref>
```

- To disable WS-Addressing support for JAX-RPC service providers or clients, set the **com.ibm.ws.wsaddressingAndDependentsDisabled** system property to `true`. For example:

```
java -Dcom.ibm.ws.wsaddressingAndDependentsDisabled=true ... application_name
```

  Attention: Use this property with care because applications might require WS-Addressing message addressing properties to function correctly. Setting this property also disables support for the following specifications, which depend on the WS-Addressing support: Web Services Atomic Transactions, Web Services Business Agreement, Web Services Notification and Web Services Reliable Messaging.

Results

By completing this task, you disabled the WS-Addressing support. Disabling WS-Addressing on clients prevents WebSphere Application Server sending WS-Addressing message addressing properties in the SOAP header of outbound web service messages. Disabling WS-Addressing on servers additionally prevents WebSphere Application Server processing WS-Addressing MAPs in incoming SOAP headers.

Chapter 30. Developing web services - Invocation framework (WSIF)

The Web Services Invocation Framework (WSIF) is a Web Services Description Language (WSDL)-oriented Java™ API. You use this API to invoke web services dynamically, regardless of the service implementation format (for example enterprise bean) or the service access mechanism (for example Java Message Service (JMS)). Using WSIF, you can move away from the usual web services programming model of working directly with the SOAP APIs, towards a model where you interact with representations of the services. You can therefore work with the same programming model regardless of how the service is implemented and accessed.

Using WSIF to invoke web services

You invoke a web service dynamically by using the WSIF API directly.

About this task

You specify the location of the Web Services Description Language (WSDL) file for the service, the name of the operation to invoke, and any operation arguments. All other information needed to access the web service (the abstract interface, the binding, and the service endpoint) is available through the WSDL.

This kind of invocation does not require stub classes and does not need a separate compilation cycle.

Note: You should not use WSIF for new applications in WebSphere Application Server, unless you are supporting an existing WSIF configuration. You should instead adopt a more recent open standard, such as the Java API for XML-Based Web Services (JAX-WS) programming model.

For more information about using the Web Services Invocation Framework (WSIF) to invoke web services, see the following topics:

Procedure

- “Linking a WSIF service to the underlying implementation of the service.”
- “Developing a WSIF service” on page 1385.
- “Using complex types” on page 1393.
- “Using WSIF to bind a JNDI reference to a web service” on page 1394.
- “Example: Passing SOAP messages with attachments by using WSIF” on page 1396.
- “Interacting with the Java EE container in WebSphere Application Server” on page 1398.
- “Invoking a WSDL-based web service through the WSIF API” on page 1399.
- “Running WSIF as a client” on page 1405

Linking a WSIF service to the underlying implementation of the service

A Web Services Invocation Framework (WSIF) service is linked to the underlying service through a WSIF provider. A provider is an implementation of a Web Services Description Language (WSDL) binding that can run a WSDL operation through a binding-specific protocol. Providers implement the interface between the WSIF API and the implementation of a service.

About this task

Providers are pluggable within the WSIF framework, and are registered according to the namespace of the WSDL extension that they implement. Some providers use the Java Platform, Enterprise Edition (Java EE) programming model to use Java EE services. If a provider is available, but its required class libraries are not, then the provider is disabled.

To use the providers that are supplied with WebSphere Application Server, see the following topics:

Procedure

- Link a WSIF service to a SOAP over HTTP service.
- Link a WSIF service to a JMS-provided service (SOAP over JMS, or native JMS).
- Link a WSIF service to a local Java application.
- Write the WSDL extension that lets your WSIF service invoke an enterprise bean.

Linking a WSIF service to a SOAP over HTTP service

The SOAP provider allows WSIF stubs and dynamic clients to invoke SOAP services. Add Web Services Description Language (WSDL) extensions to your web service WSDL file so that the service can use the SOAP provider.

Before you begin

Note: The current WSIF default SOAP provider (the IBM Web Service SOAP provider) does not fully interoperate with services that are running on the former (Apache SOAP) provider. This is because the IBM Web Service SOAP provider is designed to interoperate fully with a JAX-RPC compliant web service, and Apache SOAP cannot provide such a service. For more information see "WSIF SOAP provider: working with existing applications."

About this task

The Web Services Invocation Framework (WSIF) SOAP provider supports SOAP 1.1 over HTTP.

The SOAP provider is JSR 101/109 compliant and uses Web Services for Java EE for parsing and creating SOAP messages.

The SOAP provider supports:
- SOAP-ENC encoding.
- RPC style and Document style SOAP messages.
- SOAP messages with attachments.

The SOAP provider is not transactional.

The SOAP provider does not support the WSIF synchronous timeout. The SOAP provider uses the default client timeout value that is set for Web Services for Java EE.

To link a WSIF service to a SOAP over HTTP service, you write extensions to the service WSDL file.

Procedure

- Optional: If you have a web service that you expect multiple clients to use to connect over SOAP, before you deploy the service set up your application deployment descriptor file `dds.xml` to handle multiple connections. For more information, see the troubleshooting tip Using WSIF with multiple clients causes a SOAP parsing error.
- Write the WSDL extension that lets your WSIF service access a SOAP over JMS service.

  Note: The WSDL binding extension for SOAP over JMS varies only slightly from the SOAP over HTTP binding.
- Write the WSDL extensions for SOAP attachments.

WSIF SOAP provider: working with existing applications:

The current WSIF default SOAP provider (the IBM Web Service SOAP provider) does not fully interoperate with services that are designed to run on the former (Apache SOAP) provider. This is because the IBM Web Service SOAP provider is designed to interoperate fully with a JAX-RPC compliant web service, and Apache SOAP cannot provide such a service.

About this task

As a result of the change from the Apache SOAP provider to the IBM Web Service SOAP provider, previous WSIF clients might not work in either of the following cases:

1. The web service uses any of the following parameter types: `xsd:date`, `xsd:dateTime`, `xsd:hexBinary` or `xsd:QName`. For more information, see the **Type Mappings** section of WSIF - Known restrictions.
2. The web service was built upon the Apache SOAP provider.

To get your existing services working again, you have two options:

Procedure

- Change the default WSIF SOAP provider back to the former Apache SOAP provider (in which case any future invocations to a JAX-RPC compliant web service will not work if that web service uses parameter types `xsd:date`, `xsd:dateTime`, `xsd:hexBinary` or `xsd:QName`).
- Modify your web services to use the IBM Web Service SOAP provider.

Changing the default WSIF SOAP provider:

The WSIF default SOAP provider (the IBM Web Service SOAP provider) is designed to interoperate fully with a JAX-RPC compliant web service, and therefore the default provider does not fully interoperate with services that are running on the former (Apache SOAP) provider. To get your existing services working again, you can either modify your web services to use the current IBM Web Service SOAP provider, or you can change the WSIF default provider back to Apache SOAP as described in this topic.

About this task

WSIF uses a properties file named `wsif.properties` to choose what SOAP provider to use. The SOAP provider is a node-wide setting, so all servers on the node must be restarted for any changes to take effect. The `wsif.properties` file is shipped in the `com.ibm.ws.runtime.jar` file that is located in the *app_server_root*`/plugins` directory (where *app_server_root* is the root directory for your installation of IBM WebSphere Application Server), and the “as shipped” properties file is accessed in this location by being put on the class path. However when you make changes to the file, you do not replace the original copy in the `com.ibm.ws.runtime.jar` file. Instead, you save the modified version in the *app_server_root*`/lib/properties` directory.

To change the WSIF default SOAP provider back to Apache SOAP, complete the following steps:

Procedure

1. Extract the `wsif.properties` file from the `com.ibm.ws.runtime.jar` file that is located in the *app_server_root*`/plugins` directory (where *app_server_root* is the root directory for your installation of IBM WebSphere Application Server).
2. Open the `wsif.properties` file in a text editor.
3. Remove the leading “#” character from the following lines:

```
# wsif.provider.default.org.apache.wsif.providers.soap.ApacheSOAP.WSIFDynamicProvider_ApacheSOAP=1
# wsif.provider.uri.1.org.apache.wsif.providers.soap.ApacheSOAP.WSIFDynamicProvider_ApacheSOAP=\
# http://schemas.xmlsoap.org/wsdl/soap/
#
```

After the update, the preceding lines should look like this:

```
wsif.provider.default.org.apache.wsif.providers.soap.ApacheSOAP.WSIFDynamicProvider_ApacheSOAP=1
wsif.provider.uri.1.org.apache.wsif.providers.soap.ApacheSOAP.WSIFDynamicProvider_ApacheSOAP=\
http://schemas.xmlsoap.org/wsdl/soap/
#
```

4. Save the updated `wsif.properties` file in the *app_server_root*`/lib/properties` directory.
5. Stop then restart all application servers on the node.

Example

Modifying web services to use the IBM Web Service SOAP provider:

The current WSIF default SOAP provider (the IBM Web Service SOAP provider) is designed to interoperate fully with a JAX-RPC compliant web service, and therefore the current default provider does not fully interoperate with services that are running on the former (Apache SOAP) provider. To get your existing services working again, you can either modify your web services to use the current IBM Web Service SOAP provider as described in this topic, or you can change the WSIF default provider back to Apache SOAP.

About this task

To modify an existing web service, use the assembly tool to complete the following steps and thereby generate new deployment artifacts for access to the service from the IBM Web Service provider:

Procedure

1. Import into the Workspace the project that contains your existing web services.
2. For every existing SOAP service in the project, repeat the following steps :
   a. From the pop-up menu for *your_service*`.wsdl`, select **Generate Deploy Code**.
   b. In the Generate Deploy Code window, change the **Inbound Binding Type** from `SOAP` to `IBM Web Service`.
   c. Click **Finish**.
3. Export the EAR file that contains all of the deployment artifacts for the IBM Web Service web service.

Linking a WSIF service to a JMS-provided service

The JMS providers enable a WSIF service to be invoked through either SOAP over JMS, or native JMS. Add Web Services Description Language (WSDL) extensions to your web service WSDL file so that the service can use the JMS providers.

About this task

The Java Message Service (JMS) is an API for transport technology. The mapping to a JMS destination is defined during deployment and maintained by the container.

The JMS destination endpoint for a web service can be realized in any of the following ways:
- The JMS destination for the queue can be the web service implementation.
- The JMS destination can be (but is not required to be) associated with a message-driven bean by the EJB container, thereby allowing the message-driven bean to be the web service implementation.
- For SOAP over JMS, the JMS destination can unwrap the JMS message and route the SOAP message to a web service that is implemented as a stateless session bean.

The JMS destination endpoint must respect the interaction model expected by the client and defined by the WSDL. It must return a response if one is required.

When the JMS destination endpoint creates the JMS response message the following rules must be followed:
- The response message must be sent to `JMSReplyTo` from the incoming request.

- The JMSCorrelationID value of the response message must be set to the JMSMessageID value from the request message.
- The response must be sent with a deliveryMode value equal to the JMSDeliveryMode value of the request message.
- The response must be sent with a priority value equal to the JMSPriority value of the request message.
- The TimeToLive/JMSExpiration value must be set to a value that equals the JMSExpiration value of the request message.

The client does not see any of these headers. The container receives the JMS message and (for SOAP over JMS) removes the SOAP message to send to the client.

To link a WSIF service to a JMS-provided service, use the following information and code examples:

Procedure

- Link your WSIF service to a SOAP over JMS service.
- Link a WSIF service to a service provided at a JMS destination.
- Enable a WSIF client to invoke a web service through JMS.

Writing the WSDL extension that lets your WSIF service access a SOAP over JMS service:

You can write a Web Services Description Language (WSDL) extension that enables your Web Services Invocation Framework (WSIF) service to access a SOAP service that uses the Java Message Service (JMS) as its transport mechanism.

Before you begin

This topic assumes that you chose and configured a JMS provider when you installed WebSphere Application Server (either the default messaging provider, or another provider such as the WebSphere MQ messaging provider). If not, do so now as described in Choosing a messaging provider.

About this task

If a SOAP message contains only XML, it can be carried on the Java Message Service (JMS) transport mechanism with the JMS message body type **TextMessage**. The SOAP message, including the SOAP envelope, is wrapped with a JMS message and put on the appropriate queue. The container receives the JMS message and removes the SOAP message to send to the client.

Use the following procedure, and associated code fragments, to help you to write the Web Services Description Language (WSDL) extension that enables your WSIF service to access a SOAP over JMS service.

Note: You can also use this procedure as a guide to writing the WSDL binding extension for SOAP over HTTP, because the SOAP over JMS binding is almost identical to the SOAP over HTTP binding.

Procedure

- Select the SOAP over JMS binding.

  You set the transport attribute of the <soap:binding> tag to indicate that JMS is used. If you also set the style attribute to rpc (Remote Procedure Call), then the Web Services Invocation Framework (WSIF) assumes that an operation is invoked on the web service endpoint:

  ```
  <soap:binding style="rpc" transport="http://schemas.xmlsoap.org/soap/jms"/>
  ```

- Set the JMS address.

  Note: See also the alternative method for specifying the JMS address that is given in the next step.

For SOAP over JMS, the <wsdl:port> tag must contain a <jms:address> element. This element provides the information required for a client to connect correctly to the web service by using the JMS programming model. Typically, it is the stubs generated to support the SOAP over JMS binding that act as the JMS client. Alternatively, the web service client can use the JMS programming model directly.

The <jms:address> element takes this form:

```
<jms:address

    destinationStyle="queue"
    jmsVendorURI="http://ibm.com/ns/mqseries"?
    initialContextFactory="com.ibm.NamingFactory"?
    jndiProviderURL="iiop://something:900/wherever"?
    jndiConnectionFactoryName="orange"
    jndiDestinationName="fred">

    <jms:propertyValue name="targetService" type="xsd:string"
                       value="StockQuoteServicePort"/>

</jms:address>
```

where attributes marked with a question mark (?) are optional.

The optional jmsVendorURI attribute is a string that uniquely identifies the JMS implementation. WSIF ignores this URI, which is used by the client developer and perhaps the client implementation to determine if it has access to the correct JMS provider in the client runtime environment.

The optional attributes initialContextFactory and jndiProviderURL can only be omitted if the runtime environment has a default Java Naming and Directory Interface (JNDI) provider configured.

The jndiConnectionFactoryName attribute gives the name of a JMS ConnectionFactory object, which can be looked up within the JNDI context given by the jndiContext attribute. This ConnectionFactory object is used to create a JMS connection to the JMS provider instance that owns the queue. In a simple configuration, the same ConnectionFactory object is used by the server message listener and by the clients. However the server and the clients can use different ConnectionFactory objects, provided that they all create connections to the same JMS provider instance.

The value attribute of the targetService <jms:propertyValue> element is the name of the port component for the target service as defined in the <port-component-name> element of the webservices.xml file for the target service.

- Set the JMS address (alternative method).

  For the SOAP over JMS provider you can instead specify the JMS address using the <soap:address> tag in the following format:

  jms:/[*queue*|*topic*]?<*property*>=<*value*>&<*property*>=<*value*>&...

  where the specification of *queue* or *topic* corresponds to the JMS address destinationStyle attribute.

Table 146. Properties that are valid for use with the <soap:address> tag. Column 1 specifies the property name, column 2 describes the property, and column 3 specifies the corresponding JMS address value.

Property name	Property description	Corresponding JMS address value
destination	The JNDI name of the destination queue or topic	jndiDestinationName
connectionFactory	The JNDI name of the connection factory.	jndiConnectionFactory
targetService	The name of the port component of the target service	targetService jms:propertyValue within jms:address
JNDI-related properties (optional):		
initialContextFactory	The name of the initial context factory.	initialContextFactory
jndiProviderURL	The JNDI provider URL	jndiProviderURL
JMS-related properties (optional):		
deliveryMode	An indication as to whether the request message should be persistent or not. The valid values are DeliveryMode.NON_PERSISTENT (default) and DeliveryMode.PERSISTENT	JMSDeliveryMode

Table 146. Properties that are valid for use with the <soap:address> tag (continued). Column 1 specifies the property name, column 2 describes the property, and column 3 specifies the corresponding JMS address value.

Property name	Property description	Corresponding JMS address value
password	The password to be used to gain access to the connection factory.	JMSPassword
priority	The JMS priority associated with the request message. Valid values are 0 to 9. The default value is 4.	JMSDeliveryMode
replyTo	The JNDI destination queue to which reply messages should be sent.	JMSReplyTo
timeToLive	The lifetime (in milliseconds) of the request message. A value of 0 indicates an infinite lifetime.	JMSTimeToLive
userid	The userid to be used to gain access to the connection factory.	JMSUserid

Here is an example of this format:

<jms:address> format:

```
<wsdl:port name="StockQuoteServicePort"

        binding="sqi:StockQuoteSoapJMSBinding">

    <jms:address destinationStyle="queue"
        jndiConnectionFactoryName="myQCF"
        jndiDestinationName="myQ"
        initialContextFactory="com.ibm.NamingFactory"
        jndiProviderURL="iiop://something:900/">

        <jms:propertyValue name="targetService"
                           type="xsd:string"
                           value="StockQuoteServicePort"/>

    </jms:address>

</wsdl:port>
```

<soap:address> format:

```
<wsdl:port name="StockQuoteServicePort"
        binding="sqi:StockQuoteSoapJMSBinding">
    <soap:address location="jms:/queue?connectionFactory=myQCF&destination
=myQ&initialContextFactory=com.ibm.NamingFactory&jndiProviderURL
=iiop://something:900/&targetService=StockQuoteServicePort" />

</wsdl:port>
```

- Set the JMS headers and properties.

  You use the <jms:property> tag to set the JMS headers and properties. This tag maps either a message part, or a literal value, into a JMS property:

  ```
  <jms:property name="Priority" {part="requestPriority" | value="fixedValue"}/>
  ```

  If the <jms:property> has a literal value, then it can also be nested within the <jms:address> tag:

  ```
  <jms:property name="Priority" value="fixedValue" />
  ```

  This form of the <jms:property> tag is also used in the native JMS binding.

Example of a WSDL that defines a SOAP over JMS binding

```
<!-- Example: SOAP over JMS Text Message -->

<?xml version="1.0" encoding="UTF-8"?>
<wsdl:definitions
        name="StockQuoteInterfaceDefinitions"
        targetNamespace="urn:StockQuoteInterface"
        xmlns:tns="urn:StockQuoteInterface"
        xmlns:xsd="http://www.w3.org/2000/10/XMLSchema"
        xmlns:soap="http://schemas.xmlsoap.org/wsdl/soap/"
        xmlns:jms="http://schemas.xmlsoap.org/wsdl/jms/"
        xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/">
```

```
    <wsdl:message name="GetQuoteInput">
        <part name="symbol" type="xsd:string"/>
    </wsdl:message>
    <wsdl:message name="GetQuoteOutput">
        <part name="value" type="xsd:float"/>
    </wsdl:message>

    <wsdl:portType name="StockQuoteInterface">
        <wsdl:operation name="GetQuote">
            <wsdl:input message="tns:GetQuoteInput"/>
            <wsdl:output message="tns:GetQuoteOutput"/>
        </wsdl:operation>
    </wsdl:portType>

    <wsdl:binding name="StockQuoteSoapJMSBinding" type="tns:StockQuoteInterface">
        <soap:binding style="rpc"
                  transport="http://schemas.xmlsoap.org/soap/jms"/>
        <wsdl:operation name="GetQuote">
            <soap:operation soapAction="urn:StockQuoteInterface#GetQuote"/>
            <wsdl:input>
                <soap:body use="encoded" namespace="urn:StockQuoteService"
                           encodingStyle="http://schemas.xmlsoap.org/soap/encoding/"/>
            </wsdl:input>
            <wsdl:output>
                <soap:body use="encoded" namespace="urn:StockQuoteService"
                     encodingStyle="http://schemas.xmlsoap.org/soap/encoding/"/>
            </wsdl:output>
        </wsdl:operation>
    </wsdl:binding>
    <wsdl:service name="StockQuoteService">
        <wsdl:port name="StockQuoteServicePort"
                    binding="sqi:StockQuoteSoapJMSBinding">
            <jms:address destinationStyle="queue"
                     jndiConnectionFactoryName="myQCF"
                     jndiDestinationName="myQ"
                     initialContextFactory="com.ibm.NamingFactory"
                     jndiProviderURL="iiop://something:900/">

                     <jms:propertyValue name="targetService"
                                        type="xsd:string"
                                        value="StockQuoteServicePort"/>

            </jms:address>

        </wsdl:port>
    </wsdl:service>
</wsdl:definitions>
```

Writing the WSDL extensions that let your WSIF service access a service at a JMS destination:

Using the native Java Message Service (JMS) provider, Web Services Invocation Framework (WSIF) clients can treat a service that is available at a JMS destination as a Web service. Use this information, and associated code fragments, to help you to write the Web Services Description Language (WSDL) extensions.

Before you begin

This topic assumes that you chose and configured a JMS provider when you installed WebSphere Application Server (either the default messaging provider, or another provider such as the WebSphere MQ messaging provider). If not, do so now as described in Choosing a messaging provider.

About this task

The WSDL extensions for JMS are identified with the namespace prefix `jms`. For example, `<jms:binding>`.

The supported operations are either one-way operations (`send` for JMS point-to-point messaging, or `publish` for JMS publish and subscribe messaging) or request-response operations (`send` and `receive` for JMS point-to-point messaging). The WSDL operations therefore specify either an input message only, or an input and an output message.

Operations that describe message interfaces with a native JMS binding do not have fault messages. No assumptions are made about the message schema or the semantics of message properties, therefore no distinction can be made between output and fault messages.

Use the following procedure, and associated code fragments, to help you to write the Web Services Description Language (WSDL) extensions that enable your WSIF service to access an underlying service at a JMS destination.

Procedure

- Set the JMS message body type.

  You use the `<jms:binding>` extension to specify the JMS message body type:

```
<wsdl:binding ... >
   <jms:binding type="messageBodyType" />
    ...
</wsdl:binding>
```

  where *messageBodyType* is either `ObjectMessage` or `TextMessage`.

- Specify the parts to use for the input and output messages.

  For JMS text messages and JMS object messages created from one or more WSDL message parts, you use the `<jms:input>` and `<jms:output>` extensions to specify the message parts to use for the JMS messages:

```
<wsdl:input ... >
   <jms:input parts="part1 part2 ..." />
</wsdl:input>

<wsdl:output ... >
   <jms:output parts="part1 part2 ..." />
</wsdl:output>
```

  In the next example, the WSDL message has just one part that contains the complete message body. This message body might result from a mapping of some other representation (see the next step “Map the data types”).

```
<wsdl:input ... >
   <jms:input parts="part1" />
</wsdl:input>
```

  If no parts are defined, then all the message parts are used.

- Map the data types.

  You use the `<format>` extensions to map data types:

```
<wsdl:binding ... >
   <jms:binding type="..." />

   <format:typeMapping encoding="Java" style="Java">
      <format:typeMap typeName="..." formatType="targetType"/>
   </format:typemapping>
   ...
</wsdl:binding>
```

  The value of *targetType* is dependent on the JMS message body type (see the step “Set the JMS message body type”). For JMS object messages, the target data type implements the java.io.Serializable class. For JMS text messages, the target data type is always java.lang.String.

  The `<format>` extensions are also used in other bindings that deal with Java interfaces.

- Set the JMS headers and properties.

JMS does not make assumptions about message headers. For example, if the JMS provider is MQSeries then each JMS message carries an RFH2 header. However you can access data in this message header indirectly, by getting and setting JMS message properties.

When you want your application to pass a property into the Web Services Invocation Framework (WSIF) as a part on the WSIF message, you use a <jms:property> tag. When you want to hard code a property value into the WSDL, you use a <jms:propertyValue> tag. The <jms:propertyValue> tag contains a specification of a literal value and its associated XML schema type.

You can specify <jms:property> and <jms:propertyValue> extensions within the <wsdl:input> tag in the binding operation, and also within the <jms:address> tag. For the<wsdl:output> tag in the binding operation, you can only specify the <jms:property> extension. Property values that are set in the <jms:property> tag take precedence over values set in the <<jms:propertyValue> tag, and property values that are set in the binding operation (in the <input> and <output> tags) take precedence over values set in the <jms:address> tag.

Here is an example of the <jms:property> and <jms:propertyValue> tags nested within the <input> and <output> tags:

```
<wsdl:input ... >

    <jms:property name="propertyName" part="partName" />

    <jms:propertyValue name="propertyName"
               type="xsdType" value="actualValue" />

</wsdl:input>

<wsdl:output ... >

    <jms:property name="propertyName" part="partName" />

</wsdl:output>
```

where *propertyName* identifies the JMS property that is associated with the header field, and *partName* identifies the message part that is associated with the property.

The JMS property identified by *propertyName* can be user-defined, or it can be one of the following predefined header fields:

Table 147. Predefined JMS message header fields.

Column 1 specifies the header field value, and column 2 specifies the data type for that header field value.

Value	Java type
JMSMessageId	java.lang.String
JMSTimeStamp	long
JMSCorrelationId	byte [ ] or java.lang.String
JMSReplyTo	javax.jms.Destination
JMSDestination	javax.jms.Destination
JMSDeliveryMode	int
JMSRedelivered	boolean
JMSType	java.lang.String
JMSExpiration	long
JMSTimeToLive	long

See the JMS specification for restrictions that apply when setting JMS header field values. Attempts to set restricted values are ignored.

For application-defined JMS message properties, the Java types used in the native JMS binding implementation (used for calls to the corresponding JMS methods) are derived from the XML schema type in the abstract interface (<wsdl:part> tag), and from the type mapping information in the format binding (<format:typemap> tag).

- Handle transactions.

  Independent of other JMS properties, the asynchronous processing of request-response operations has implications for callers running in a transaction scope. The send request part and the receive response part are separated into two transactions, because the send needs to be committed in order for the request message to become visible. Implementations that process WSDL for asynchronous request-response operations (such as WSIF) must therefore take the following additional actions:
  - They must ensure that the send request transaction returns a correlation ID to the user, and provides a callback with which users can pass in the response message to process the receive response transaction.
  - They might implement their own response message listener in order to recognize the arrival of response messages, and to manage the correlation to the request message.

Example 1: JMS Text Message

The JMS text message contains a java.lang.String. In this example, the WSDL message contains only one part that represents the whole message body:

```
<wsdl:definitions ... >

   <!-- simple or complex types for input and output message -->
   <wsdl:types> ... </wsdl:types>

   <wsdl:message name="JmsOperationRequest"> ... </wsdl:message>
   <wsdl:message name="JmsOperationResponse"> ... </wsdl:message>

   <wsdl:portType name="JmsPortType">
      <wsdl:operation name="JmsOperation">
         <wsdl:input name="Request"
                     message="tns:JmsOperationRequest"/>
         <wsdl:output name="Response"
                      message="tns:JmsOperationResponse"/>
      </wsdl:operation>
   </wsdl:portType>

   <wsdl:binding name="JmsBinding" type="JmsPortType">
      <jms:binding type="TextMessage" />

      <format:typemapping style="Java" encoding="Java">
         <format:typemap name="xsd:String" formatType="String" />
      </format:typemapping>

      <wsdl:operation name="JmsOperation">
         <wsdl:input message="JmsOperationRequest">
            <jms:input parts="requestMessageBody" />
         </wsdl:input>
         <wsdl:output message="JmsOperationResponse">
            <jms:output parts="responseMessageBody" />
         </wsdl:output>
      </wsdl:operation>
   </wsdl:binding>

   <wsdl:service name="JmsService">
      <wsdl:port name="JmsPort" binding="JmsBinding">
         <jms:address destinationStyle="queue"
                      jndiConnectionFactoryName="myQCF"
                      jndiDestinationName="myDestination"/>
```

```
      </wsdl:port>
   </wsdl:service>

</wsdl:definitions>
```

As an extension to the previous JMS message example, the following example WSDL describes a request-response operation in which specific JMS property values of the request and response message are set for the request message and retrieved from the response message.

The JMS properties in the request message are set according to the values in the input message. Likewise, selected JMS properties of the response message are copied to the corresponding values of the output message. The direction of the mapping is determined by the appearance of the <jms:property> tag in the input or output section, respectively.

```
<wsdl:definitions ... >

   <!-- simple or complex types for input and output message -->
   <wsdl:types> ... </wsdl:types>

   <wsdl:message name="JmsOperationRequest">
      <wsdl:part name="myInt" type="xsd:int"/>
      ...
   </wsdl:message>

   <wsdl:message name="JmsOperationResponse">
      <wsdl:part name="myString" type="xsd:String"/>
      ...
   </wsdl:message>

   <wsdl:portType name="JmsPortType">
      <wsdl:operation name="JmsOperation">
         <wsdl:input name="Request"
                     message="tns:JmsOperationRequest"/>
         <wsdl:output name="Response"
                      message="tns:JmsOperationResponse"/>
      </wsdl:operation>
   </wsdl:portType>

   <wsdl:binding name="JmsBinding" type="JmsPortType">
      <!-- the JMS message type might be any of the above -->
      <jms:binding type="..." />

      <format:typemapping style="Java" encoding="Java">
         <format:typemap name="xsd:int" formatType="int" />
         ...
      </format:typemapping>

      <wsdl:operation name="JmsOperation">
         <wsdl:input message="JmsOperationRequest">
            <jms:property message="tns:JmsOperationRequest" parts="myInt" />
            <jms:propertyValue name="myLiteralString"
                           type="xsd:string" value="Hello World" />
            ...
         </wsdl:input>
         <wsdl:output message="JmsOperationResponse">
            <jms:property message="tns:JmsOperationResponse" parts="myString" />
            ...
         </wsdl:output>
      </wsdl:operation>
   </wsdl:binding>

   <wsdl:service name="JmsService">
      <wsdl:port name="JmsPort" binding="JmsBinding">
         <jms:address destinationStyle="queue"
                      jndiConnectionFactoryName="myQCF"
                      jndiDestinationName="myDestination"/>
```

```
    </wsdl:port>
   </wsdl:service>

</wsdl:definitions>
```

Enabling a WSIF client to invoke a web service through JMS:

The ways in which the Web Services Invocation Framework (WSIF) interacts with the Java Message Service (JMS), and the steps to take to enable a service to be invoked through JMS by a WSIF client application.

Before you begin

This topic assumes that you chose and configured a JMS provider when you installed WebSphere Application Server (either the default messaging provider, or another provider such as the WebSphere MQ messaging provider). If not, do so now as described in Choosing a messaging provider.

About this task

Here are the ways in which WSIF interacts with JMS:
- WSIF only supports input JMS properties.
- WSIF needs two queues when invoking an operation: one for the request message and one for the reply.
- The replyTo queue is by default a temporary queue, which WSIF creates on behalf of the application. You can specify a permanent queue by setting the **JMSReplyTo** property to the JNDI name of a queue.
- WSIF uses the default values for properties set by the JMS implementation.

To enable a service to be invoked through JMS by a WSIF client application, complete the following steps:

Procedure

1. Use the administrative console to create and configure a queue connection factory and a queue destination for your chosen messaging provider.

   For more information, see Configuring resources for the default messaging provider, Configuring JMS resources for the WebSphere MQ messaging provider or Managing messaging with a third-party messaging provider.

   Note: In WebSphere MQ and some other JMS implementations, messages are persistent by default. The WSIF replyTo temporary queue is of type `temporary dynamic` by default, which means that your JMS provider cannot write a persistent response message to this queue. If you are using the WebSphere MQ messaging provider, create a temporary model queue that is of type `permanent dynamic`, then pass this model as the **tempmodel** of your queue connection factory. This ensures that persistent messages are written to a temporary replyTo queue that is of type `permanent dynamic`.
2. Use the administrative console to add the new queue destination to the list of JMS destination names for your application server. Ensure that the **Initial State** is `started`.
3. Put the JNDI names of the queue destination and queue connection factory, as well as your JNDI configuration, in the Web Services Description Language (WSDL) file.
4. Optional: If your client is running on an application server that has been migrated from WebSphere Application Server Version 5, you might get basic authentication errors and therefore have to modify your security settings. For more information see Web Services Invocation Framework troubleshooting tips.

JMS message header: The TimeToLive property reference:

The range of permitted values for the TimeToLive property of a JMS message that WSIF puts onto a queue.

The JMS message header property `JMSTimeToLive` is of type `long`. It sets the time to live of a message put onto a queue, in milliseconds. A value of `0` means live indefinitely.

The factors that determine the time to live of a JMS message are as follows:

- For a one-way (input only) operation, the default time to live is `0`, so the message remains on the queue indefinitely or until the server end-processes the message. The `JMSTimeToLive` value, if specified in the service endpoint URL or the JMS Address, is used for one-way messages. The client never waits for a response to a one-way operation and so it never times out. During a one-way operation, the client fails only if the queue itself is unavailable.
- For a two-way (request and response) operation the `JMSTimeToLive` value, if specified in the service endpoint URL or the JMS Address, is used for two-way messages. When the time to live is not specified, the default value is determined by the client response timeout setting.

Writing the WSDL extension that lets your WSIF service invoke a method on a local Java object

Using the Web Services Invocation Framework (WSIF) Java provider, WSIF can invoke Java code. This means that, in a thin-client environment such as a Java virtual machine (JVM) or Tomcat test runtime environment, you can define shortcuts to local Java programs. Use this procedure to help you to write the Web Services Description Language (WSDL) extension that links your WSIF service to a local Java application.

Before you begin

The WSIF Java provider is not intended for use in a Java Platform, Enterprise Edition (Java EE) environment. There is a difference between a client using the WSIF Java provider to invoke a Java component, and implementing a web service as a Java component on the server side.

About this task

The WSIF Java binding exploits the format binding for type mapping. Using the format binding, your WSDL can define the mapping between XML schema types and Java types.

The WSIFJava provider requires the targeted Java classes to be on the class path of the client. The Java method is invoked synchronously, in-process, in-thread, with the current thread and Object Request Broker (ORB) contexts.

The WSIF Java provider is not transactional.

The WSIF Java provider does not support the WSIF synchronous timeout. The Java provider will not time out waiting for a Java method to complete.

Use the following procedure, and associated code fragments, to help you to specify the WSDL extension that enables your WSIF service to invoke a method on a local Java object.

Procedure

- Specify the Java binding.

  To use the Java provider, you need the following binding specified in the WSDL file:

```
<!-- Java binding -->
<binding .... >
    <java:binding />
    <format:typeMapping style="Java" encoding="Java"/>?
        <format:typeMap name="qname" formatType="nmtoken"/>*
    </format:typeMapping>
```

```
    <operation>*
        <java:operation
            methodName="nmtoken"
            parameterOrder="nmtoken"
            returnPart="nmtoken"?
            methodType="instance|constructor" />
        <input name="nmtoken"? />?
        <output name="nmtoken"? />?
        <fault name="nmtoken"? />?
    </operation>
</binding>
```

In this example:

- A question mark (?) means optional, and an asterisk (*) means 0 or more.
- The `name` attribute of the `<format:typeMap>` element is a qualified name of a simple or complex type used by one of the Java operations.
- The `formatType` attribute of the `<format:typeMap>` element is the fully qualified class name for the Java class to which the element specified by `name` maps.
- The `methodName` attribute of the `<java:operation>` element is the name of the method on the Java object that is called by the operation.
- The `parameterOrder` attribute of the `<java:operation>` element contains a white space-separated list of part names that define the order in which they are passed to the Java object method.
- The `methodType` attribute of the `<java:operation>` element must be set to either `instance` or `constructor`. The value specifies whether the method that is invoked on the object is an instance method or a constructor for the object.

- Specify the `<java:address>` element.

  The `className` attribute of the `<java:address>` element specifies the fully qualified class name of the object containing the method to invoke:

```
<service ... >
    <port>*
        <java:address
            className="nmtoken"/>
    </port>
</service>
```

Writing the WSDL extension that lets your WSIF service invoke an enterprise bean

Using the EJB provider, WSIF clients can invoke enterprise beans through Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP). Use this information, and associated code fragments, to help you to write the Web Services Description Language (WSDL) extension that links your WSIF service to a service implemented as an enterprise bean.

Before you begin

Although you can use the EJB provider for EJB(IIOP)-based web service invocation, it is recommended that you instead invoke RMI-IIOP web services by using JAX-RPC.

The EJB client JAR file must be available in the client runtime environment with the current provider.

The EJB provider does not support the WSIF synchronous timeout. The EJB provider will not time out waiting for a Java method to complete.

About this task

Your WSIF client can invoke an enterprise bean by using RMI-IIOP, with the current security and transaction contexts. If the EJB provider is invoked within a transaction, the transaction is passed to the onward service and the standard EJB transaction attribute applies.

If there are multiple implementations of the service, it is up to the service providers to make sure that every implementation offers the same semantics. For example, for transactions, the bean deployer must specify TX_REQUIRES_NEW to force a new transaction.

Use the following procedure, and associated code fragments, to help you to write the Web Services Description Language (WSDL) extension that enables your WSIF service to invoke an enterprise bean.

Procedure

- Specify the EJB binding.

```
<!-- EJB binding -->
<binding .... >
    <ejb:binding />
    <format:typeMapping style="Java" encoding="Java"/>?
        <format:typeMap name="qname" formatType="nmtoken"/>*
    </format:typeMapping>
    <operation>*
        <ejb:operation
            methodName="nmtoken"
            parameterOrder="nmtoken"
            returnPart="nmtoken"?
            interface="remote|home" />
        <input name="nmtoken"? />?
        <output name="nmtoken"? />?
        <fault name="nmtoken"? />?
    </operation>
</binding>
```

  In this example:
  - A question mark (?) means optional, and an asterisk (*) means 0 or more.
  - The name attribute of the <format:typeMap> element is a qualified name of a simple or complex type used by one of the EJB operations.
  - The formatType attribute of the <format:typeMap> element is the fully qualified class name for the Java class to which the element specified by name maps.
  - The methodName attribute of the <ejb:operation> element is the name of the method on the enterprise bean that is called by the operation.
  - The parameterOrder attribute of the <ejb:operation> element contains a white space-separated list of part names that define the order in which they are passed to the EJB method.
  - The interface attribute of the <ejb:operation> element must be set to either remote or home. The value specifies the interface of the enterprise bean on which the method named by the methodName attribute is accessible.

- Specify the <ejb:address> element.

```
<service ... >
    <port>*
        <ejb:address
            className="nmtoken"
            jndiName="nmtoken"
            initialContextFactory="nmtoken" ?
            jndiProviderURL="nmtoken" ? />
    </port>
</service>
```

  In this example:
  - The className attribute of the <ejb:address> element specifies the fully qualified class name of the home interface class of the enterprise bean.
  - The jndiName attribute of the <ejb:address> element specifies the full Java Naming and Directory Interface (JNDI) name that is used to look up the enterprise bean.
  - The initialContextFactory attribute of the <ejb:address> element is optional and specifies the initial context factory class.
  - The jndiProviderURL attribute of the <ejb:address> element is optional and specifies the JNDI provider web address.

Developing a WSIF service

A Web Services Invocation Framework (WSIF) service is a web service that uses WSIF.

About this task

To develop a WSIF service, develop the web service (or use an existing web service), then develop the WSIF client based on the Web Services Description Language (WSDL) document for that Web service.

There are also two pre-built WSIF samples available for download from the WebSphere Application Server samples page of the developerWorks website:

- The Address Book sample.
- The Stock Quote sample.

For more information about using the pre-built samples, see the documentation that is included in the developerWorks download package. Note that these samples were written to work with WebSphere Application Server Version 5.

To develop a WSIF service, complete the following steps:

Procedure

1. Implement the web service.

   Use web services tools to discover, create, and publish the web service. You can develop Java bean, enterprise bean, and URL web services. You can use web service tools to create skeleton Java code and a sample application from a WSDL document. For example, an enterprise bean can be offered as a Web service, and use Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP) as the access protocol. Or you can use a Java class as a web service, with native Java invocations as the access protocol.

   You can use the WebSphere Studio Application Developer to create a web service from a Java application, as described in its StockQuote service tutorial. The Java application that you use in this scenario returns the last trading price from the Internet website www.xmltoday.com, given a stock symbol. Using the web service wizard, you generate a binding WSDL document named `StockQuoteService-binding.wsdl` and a service WSDL document named `StockQuoteService-service.wsdl` from the `StockQuoteService.java` bean. You then deploy the web service to a web server, generate a client proxy to the Web service, and generate a sample application that accesses the StockQuoteService through the client proxy. You test the StockQuote web service, publish it by using the IBM UDDI Explorer, and then discover the StockQuote web service in the IBM UDDI Test Registry.

2. Develop the WSIF client.

   Use the following information to help you develop a WSIF client:

   - “Example: Using WSIF to invoke the AddressBook sample web service dynamically” on page 1386 gives example code to show how you define a web service in WSDL.
   - “Linking a WSIF service to the underlying implementation of the service” on page 1369 describes the available providers, and gives example code of how their WSDL extensions are coded.
   - “Invoking a WSDL-based web service through the WSIF API” on page 1399 defines the main interfaces that your client uses to support the invocation of Web services defined in WSDL.

   The AddressBook sample is written for synchronous interaction. If you are using a JMS provider, your WSIF client might have to act asynchronously. WSIF provides two main features that meet this requirement:

   - A correlation service that assigns identifiers to messages so that the request can match up with the (eventual) response.
   - A response handler that picks up the response from the web service at a later time.

   For more information, see “WSIFOperation - Asynchronous interactions reference” on page 1403.

Example: Using WSIF to invoke the AddressBook sample web service dynamically

This is example code for dynamic invocation of the AddressBook sample web service by using WSIF:

```
    try {
        String wsdlLocation="clients/addressbook/AddressBookSample.wsdl";

        // The starting point for any dynamic invocation using wsif is a
        // WSIFServiceFactory. Create one through the newInstance
        // method.
        WSIFServiceFactory factory = WSIFServiceFactory.newInstance();

        // Once you have a factory, you can use it to create a WSIFService object
        // corresponding to the AddressBookService service in the wsdl file.
        // Note: because you only have one service defined in the wsdl file, you
        // do not have to use the namespace and name of the service and can pass
        // null instead. This also applies to the port type, although values have
        // been used below for illustrative purposes.
        WSIFService service = factory.getService(
            wsdlLocation,    // location of the wsdl file
            null,            // service namespace
            null,            // service name
           "http://www.ibm.com/namespace/wsif/samples/ab", // port type namespace
            "AddressBookPT" // port type name
        );

        // The AddressBook.wsdl file contains the definitions for two complexType
        // elements within the schema element. Map these complexTypes
        // to Java classes. These mappings are used by the Apache SOAP provider
        service.mapType(
            new javax.xml.namespace.QName(
                "http://www.ibm.com/namespace/wsif/samples/ab/types",
                "address"),
            Class.forName("com.ibm.www.namespace.wsif.samples.ab.types.WSIFAddress"));
        service.mapType(
            new javax.xml.namespace.QName(
                "http://www.ibm.com/namespace/wsif/samples/ab/types",
                "phone"),
            Class.forName("com.ibm.www.namespace.wsif.samples.ab.types.WSIFPhone"));
            // You now have a WSIFService object. The next step is to create a WSIFPort
            // object for the port you want to use. The getPort(String portName) method
            // allows us to generate a WSIFPort from the port name.
        WSIFPort port = null;

        if (portName != null) {
            port = service.getPort(portName);
        }
        if (port == null) {
            // If no port name was specified, attempt to create a WSIFPort from
            // the available ports for the port type specified on the service
            port = getPortFromAvailablePortNames(service);
        }

        // Once you have a WSIFPort, you can create an operation. Execute
        // the addEntry operation and therefore attempt to create a WSIFOperation
        // corresponding to it. The addEntry operation is overloaded in the wsdl i.e.
    // there are two versions of it, each taking different parameters (parts).
    // This overloading requires that you specify the input and output message
    // names for the operation in the createOperation method so that the correct
    // operation can be resolved.
        // Because the addEntry operation has no output message, you use null for its name.
        WSIFOperation operation =
            port.createOperation("addEntry", "AddEntryWholeNameRequest", null);

        // Create messages to use in the execution of the operation. This should
        // be done by invoking the createXXXXXMessage methods on the WSIFOperation.
        WSIFMessage inputMessage = operation.createInputMessage();
```

```
WSIFMessage outputMessage = operation.createOutputMessage();
WSIFMessage faultMessage = operation.createFaultMessage();

// Create a name and address to add to the addressbook
String nameToAdd="Chris P. Bacon";
WSIFAddress addressToAdd =
    new WSIFAddress (1,
        "The Waterfront",
        "Some City",
        "NY",
        47907,
        new WSIFPhone (765, "494", "4900"));

// Add the name and address to the input message
inputMessage.setObjectPart("name", nameToAdd);
inputMessage.setObjectPart("address", addressToAdd);

// Execute the operation, obtaining a flag to indicate its success
boolean operationSucceeded =
    operation.executeRequestResponseOperation(
        inputMessage,
        outputMessage,
        faultMessage);

if (operationSucceeded) {
    System.out.println("Successfully added name and address to addressbook\n");
} else {
    System.out.println("Failed to add name and address to addressbook");
}

// Start from fresh
operation = null;
inputMessage = null;
outputMessage = null;
faultMessage = null;

// This time you will lookup an address from the addressbook.
// The getAddressFromName operation is not overloaded in the
// wsdl and therefore you can specify the operation name
// without any input or output message names.
operation = port.createOperation("getAddressFromName");

// Create the messages
inputMessage = operation.createInputMessage();
outputMessage = operation.createOutputMessage();
faultMessage = operation.createFaultMessage();

// Set the name to find in the addressbook
String nameToLookup="Chris P. Bacon";
inputMessage.setObjectPart("name", nameToLookup);

// Execute the operation
operationSucceeded =
    operation.executeRequestResponseOperation(
        inputMessage,
        outputMessage,
        faultMessage);

if (operationSucceeded) {
    System.out.println("Successful lookup of name '"+nameToLookup+"' in addressbook");

    // You can get the address that was found by querying the output message
    WSIFAddress addressFound = (WSIFAddress) outputMessage.getObjectPart("address");
    System.out.println("The address found was:");
    System.out.println(addressFound);
} else {
    System.out.println("Failed to lookup name in addressbook");
```

```
        }

    } catch (Exception e) {
        System.out.println("An exception occurred when running the sample:");
        e.printStackTrace();
    }
}
```

The preceding code refers to the following Sample method:

```
    WSIFPort getPortFromAvailablePortNames(WSIFService service)
            throws WSIFException {
        String portChosen = null;

        // Obtain a list of the available port names for the service
        Iterator it = service.getAvailablePortNames();
        {
            System.out.println("Available ports for the service are: ");
            while (it.hasNext()) {
                String nextPort = (String) it.next();
                if (portChosen == null)
                    portChosen = nextPort;
                System.out.println(" - " + nextPort);
            }
        }
        if (portChosen == null) {
            throw new WSIFException("No ports found for the service!");
        }
        System.out.println("Using port " + portChosen + "\n");

        // An alternative way of specifying the port to use on the service
        // is to use the setPreferredPort method. Once a preferred port has
        // been set on the service, a WSIFPort can be obtained through getPort
        // (no arguments). If a preferred port has not been set and more than
        // one port is available for the port type specified in the WSIFService,
        // an exception is thrown.
        service.setPreferredPort(portChosen);
        WSIFPort port = service.getPort();
        return port;
    }
```

The web service uses the following classes:

WSIFAddress:

```
public class WSIFAddress implements Serializable {

    //instance variables
    private int streetNum;
    private java.lang.String streetName;
    private java.lang.String city;
    private java.lang.String state;
    private int zip;
    private WSIFPhone phoneNumber;

    //constructors
    public WSIFAddress () { }

    public WSIFAddress (int streetNum,
                        java.lang.String streetName,
                        java.lang.String city,
                        java.lang.String state,
                        int zip,
                        WSIFPhone phoneNumber) {
          this.streetNum = streetNum;
          this.streetName = streetName;
          this.city = city;
```

```
        this.state = state;
        this.zip = zip;
        this.phoneNumber = phoneNumber;
    }

    public int getStreetNum() {
        return streetNum;
    }

    public  void setStreetNum(int streetNum) {
        this.streetNum = streetNum;
    }

    public java.lang.String getStreetName() {
        return streetName;
    }

    public  void setStreetName(java.lang.String streetName) {
        this.streetName = streetName;
    }

    public java.lang.String getCity() {
        return city;
    }

    public  void setCity(java.lang.String city) {
        this.city = city;
    }

    public java.lang.String getState() {
        return state;
    }

    public  void setState(java.lang.String state) {
        this.state = state;
    }

    public int getZip() {
        return zip;
    }

    public  void setZip(int zip) {
        this.zip = zip;
    }

    public WSIFPhone getPhoneNumber() {
        return phoneNumber;
    }

    public  void setPhoneNumber(WSIFPhone phoneNumber) {
        this.phoneNumber = phoneNumber;
    }
}
```

WSIFPhone:

```
public class WSIFPhone implements Serializable {

    //instance variables
    private int areaCode;
    private java.lang.String exchange;
    private java.lang.String number;

    //constructors
    public WSIFPhone () { }

    public WSIFPhone (int areaCode,
```

```
                    java.lang.String exchange,
                    java.lang.String number) {
          this.areaCode = areaCode;
          this.exchange = exchange;
          this.number = number;
    }

    public int getAreaCode() {
          return areaCode;
    }

    public  void setAreaCode(int areaCode) {
          this.areaCode = areaCode;
}

    public java.lang.String getExchange() {
          return exchange;
    }

    public  void setExchange(java.lang.String exchange) {
          this.exchange = exchange;
    }

    public java.lang.String getNumber() {
          return number;
    }

    public  void setNumber(java.lang.String number) {
          this.number = number;
    }
}
```

WSIFAddressBook:

```
public class WSIFAddressBook {
    private Hashtable name2AddressTable = new Hashtable();

    public WSIFAddressBook() {
    }

    public void addEntry(String name, WSIFAddress address)
    {
        name2AddressTable.put(name, address);
    }

    public void addEntry(String firstName, String lastName, WSIFAddress address)
    {
        name2AddressTable.put(firstName+" "+lastName, address);
    }

    public WSIFAddress getAddressFromName(String name)
        throws IllegalArgumentException
    {

        if (name == null)
        {
            throw new IllegalArgumentException("The name argument must not be " +
                                               "null.");
        }
        return (WSIFAddress)name2AddressTable.get(name);
    }

}
```

The following code is the corresponding WSDL file for the web service:

```
<?xml version="1.0" ?>

Using complex types

WSIF supports user-defined complex types through the mapping of complex types to Java classes. You can specify this mapping manually or automatically.

About this task

Any calls to the WSIFService mapType and mapPackage methods used for manual mapping override any equivalent mapping information that is produced automatically. This override helps to maintain backwards compatibility, and also accommodates less standard mappings.

To map your user-defined complex types to Java classes, complete either of the following steps:

- Manually map complex types.
- Automatically map complex types.

Procedure

- Manually map complex types.

  The method to use when you create these mappings manually depends on the provider. For the Java and EJB providers, the mappings are specified in the Web Services Description Language (WSDL) file in the binding element. The following example provides the syntax for specifying the mapping:

```
<binding .... >
    <ejb:binding|java:binding/>
      <format:typeMapping style="Java" encoding="Java"/>?
          <format:typeMap typeName="qname" formatType="nmtoken"/>*
      </format:typeMapping>
 ...
</binding>
```

  In this example:

  – A question mark (“?”) means “optional” and an asterisk (“*”) means “0 or more”.

  – The format:typeMap **typeName** attribute is a qualified name of a complex type or simple type used by one of the operations.

  – The format:typeMap **formatType** attribute is the fully qualified class name for the Java class to which the element specified by **typeName** maps.

  If you use the Apache SOAP provider then you specify the mapping of a complex type to a Java class in the client code through two methods on the org.apache.wsif.WSIFService interface:

```
public void mapType(QName elementType, Class javaType)
```

  and

```
public void mapPackage(String namespaceURI, String packageName)
```

  Use the **mapType** method to specify a mapping between an XML schema element and a Java class. The method takes a QName representing the complex type or simple type, and the corresponding Java class to which it maps.

  Use the **mapPackage** method to specify a more general mapping between a namespace and a Java package. Any custom, complex or simple type whose namespace matches that of the mapping is mapped to a Java class in the corresponding package. The name of the class is derived from the name of the complex type using standard XML to Java naming conventions.

- Automatically map complex types.

  For complex types defined in the WSDL, where a generated bean is used to represent this type in Java, the Web Services Invocation Framework (WSIF) programming model requires that a call is made to the WSIFService.mapType() method. This call tells WSIF the package and class name of the bean representing the XML schema type that is identified with a QName. To make things easier, the WSIFService.mapPackage() method provides a mechanism to specify a wildcard version of this, where any class within a specified package is mapped to the namespace of a QName. This is a mechanism for manually mapping an XML schema type to a Java class and back again (one mapping entry provides a bidirectional mapping).

  There are many ways to convert a QName representing an XML schema type name to a Java package name and class. To enable automatic type mapping, set the WSIF_FEATURE_AUTO_MAP_TYPES feature on the WSIFServiceFactory instance:

```
WSIFServiceFactory factory = WSIFServiceFactory.newInstance();
factory.setFeature(WSIFConstants.WSIF_FEATURE_AUTO_MAP_TYPES, new Boolean(true));
```

  WSIF maps types by converting the URI part of the XML schema type QName to a package name, and converting the local part to a class name. WSIF does this mapping by using the WSIFUtils methods getPackageNameFromNamespaceURI and getJavaClassNameFromXMLName.

Using WSIF to bind a JNDI reference to a web service

You can use the Web Services Invocation Framework (WSIF) to bind a reference to a web service, then look up the reference by using JNDI.

About this task

You access a web service through information provided in the Web Services Description Language (WSDL) document for the service. If you do not know where to find the WSDL document for the service, but you know that it has been registered in a UDDI registry, then you look it up in the registry. Java programs access Java objects and resources in a similar manner, but using a JNDI interface.

The code fragments in the following steps show how, by using WSIF, you can bind a reference to a web service then look up the reference by using JNDI.

Procedure

- Specify the argument values for the web service.

  The web service is represented in WSIF by an instance of the org.apache.wsif.naming.WSIFServiceRef class. This simple Referenceable object has the following constructor:

```
public WSIFServiceRef(
        String WSDL,
        String sNS,
        String sName,
        String ptNS,
        String ptName)
{
    [...]
}
```

  In this example
  - *WSDL* is the location of the WSDL file containing the definition of the service.
  - *sNS* is the full namespace for the service definition (you can specify `null` if only one service is defined in the WSDL file).
  - *sName* is the local name for the service definition (you can specify `null` if only one service is defined in the WSDL file).
  - *ptNS* is the full namespace for the port type within the service that you want to use (you can specify `null` if only one port type is available for the service).
  - *ptName* is the local name for the port type (you can specify `null` if only one port type is available for the service).

  For example, if the WSDL file for the web service is available from the web address `http://myServer/WSDL/Example.WSDL` and contains the following service and port type definitions:

```
  <definitions targetNamespace="http://hostname/namespace/example"
               xmlns:abc="http://hostname/namespace/abc"
[...]
    <portType name="ExamplePT">
      <operation name="exampleOp">
        <input name="exampleInput" message="tns:ExampleInputMsg"/>
      </operation>
    </portType>
[...]
    <service name="abc:ExampleService">
[...]
    </service>
[...]
  </definitions>
```

  You can specify the following argument values for the WSIFServiceRef class:
  - *WSDL* is `http://myServer/WSDL/Example.WSDL`
  - *sNS* is `http://hostname/namespace/abc`
  - *sName* is `ExampleService`
  - *ptNS* is `http://hostname/namespace/example`
  - *ptName* is `ExamplePT`
- Bind the service by using JNDI.

To bind the service reference in the naming directory by using JNDI, you can use the com.ibm.websphere.naming.JndiHelper class in WebSphere Application Server:

```
[...]
    import com.ibm.websphere.naming.JndiHelper;
    import org.apache.wsif.naming.*;
[...]
    try {
       Context startingContext = new InitialContext();
       WSIFServiceRef ref = new WSIFServiceRef("http://myServer/WSDL/Example.WSDL",
                                               "http://hostname/namespace/abc"
                                               "ExampleService",
                                               "http://hostname/namespace/example",
                                               "ExamplePT");
       JndiHelper.recursiveRebind(startingContext,
            "myContext/mySubContext/myServiceRef", ref);

    }
    catch (NamingException e) {
       // Handle  error.
    }
[...]
```

- Look up the service by using JNDI.

  The following code fragment shows the lookup of a service by using JNDI:

```
[...]
    try {
[...]
       InitialContext ic = new InitialContext();
       WSIFService myService =
        (WSIFService) ic.lookup("myContext/mySubContext/myServiceRef");
[...]
    }
    catch (NamingException e) {
       // Handle error.
    }
[...]
```

Example: Passing SOAP messages with attachments by using WSIF

Information and example code for using the Web Services Invocation Framework (WSIF) SOAP provider to pass attachments within a MIME multipart/related message in such a way that the SOAP processing rules for a standard SOAP message are not changed. This includes how to write the Web Services Description Language (WSDL) extensions for SOAP attachments, and how to work with types and type mappings.

The W3C SOAP Messages with Attachments document describes a standard way to associate a SOAP message with one or more attachments in their native format (for example GIF or JPEG) by using a multipart MIME structure for transport. It defines specific use of the “Multipart/Related” MIME media type, and rules for the use of URI references to entities bundled within the MIME package. It thereby outlines a technique for carrying a SOAP 1.1 message within a MIME multipart/related message in such a way that the SOAP processing rules for a standard SOAP message are not changed.

WSIF supports passing attachments in a MIME message using the SOAP provider to link a WSIF service to a SOAP over HTTP service. The attachment is a javax.activation.DataHandler object. The mime:multipartRelated, mime:part and mime:content tags are used to describe the attachment in the WSDL.

- “Example: Writing the WSDL extensions for SOAP attachments” on page 1397
- “Example: Using WSIF to pass SOAP attachments” on page 1397
- “SOAP attachments - Working with types and type mappings” on page 1398
- “SOAP attachments - scenarios that are not supported” on page 1398

Example: Writing the WSDL extensions for SOAP attachments

The following example WSDL illustrates a simple operation that has one attachment called `attch`:

```
<binding name="MyBinding" type="tns:abc" >
  <soap:binding style="rpc" transport="http://schemas.xmlsoap.org/soap/http"/>
  <operation name="MyOperation">
    <soap:operation soapAction=""/>
    <input>
      <mime:multipartRelated>
        <mime:part>
          <soap:body use="encoded" namespace="http://mynamespace"
            encodingStyle="http://schemas.xmlsoap.org/soap/encoding"/>
        </mime:part>
        <mime:part>
          <mime:content part="attch" type="text/html"/>
        </mime:part>
      </mime:multipartRelated>
    </input>
  </operation>
</binding>
```

In this type of WSDL extension:

- There must be a `part` attribute (in this example `attch`) on the input message for the operation (in this example `MyOperation`). There can be other input parts to `MyOperation` that are not attachments.
- In the binding input there must either be a `<soap:body>` tag or a `<mime:multipartRelated>` tag, but not both.
- For MIME messages, the `<soap:body>` tag is inside a `<mime:part>` tag. There must only be one `<mime:part>` tag that contains a `<soap:body>` tag in the binding input and that must not contain a `<mime:content>` tag as well, because a content type of `text/xml` is assumed for the `<soap:body>` tag.
- There can be multiple attachments in a MIME message, each described by a `<mime:part>` tag.
- Each `<mime:part>` tag that does not contain a `<soap:body>` tag contains a `<mime:content>` tag that describes the attachment itself. The `type` attribute inside the `<mime:content>` tag is not checked or used by the Web Services Invocation Framework (WSIF). It is there to suggest to the application that uses WSIF what the attachment contains. Multiple `<mime:content>` tags inside a single `<mime:part>` tag means that the backend service expects a single attachment with a type specified by one of the `<mime:content>` tags inside that `<mime:part>` tag.
- The `parts="..."` attribute (optional) inside the `<soap:body>` tag is assumed to contain the names of all the MIME parts as well as the names of all the SOAP parts in the message.

Example: Using WSIF to pass SOAP attachments

The following code fragment can invoke the service described by the example WSDL in “Example: Writing the WSDL extensions for SOAP attachments”:

```
import javax.activation.DataHandler;
. . .
DataHandler dh = new DataHandler(new FileDataSource("myimage.jpg"));
WSIFServiceFactory factory = WSIFServiceFactory.newInstance();
WSIFService service = factory.getService("my.wsdl",null,null,"http://mynamespace","abc");
WSIFOperation op = service.getPort().createOperation("MyOperation");
WSIFMessage in = op.createInputMessage();
in.setObjectPart("attch",dh);
op.executeInputOnlyOperation(in);
```

The associated type mapping in the `DeploymentDescriptor.xml` file depends upon your SOAP server. For example if you use Tomcat with SOAP 2.3, then the `DeploymentDescriptor.xml` file contains the following type mapping:

```
<isd:mappings>
<isd:map encodingStyle="http://schemas.xmlsoap.org/soap/encoding/"
 xmlns:x="http://mynamespace"
 qname="x:datahandler"
```

```
 javaType="javax.activation.DataHandler"
 java2XMLClassName="org.apache.soap.encoding.soapenc.MimePartSerializer"
 xml2JavaClassName="org.apache.soap.encoding.soapenc.MimePartSerializer" />
</isd:mappings>
```

In this case, the backend service is invoked with the following signature:

```
public void MyOperation(DataHandler dh);
```

You can also use stubs to pass attachments into the Web Services Invocation Framework (WSIF):

```
DataHandler dh = new DataHandler(new FileDataSource("myimage.jpg"));
WSIFServiceFactory factory = WSIFServiceFactory.newInstance();
WSIFService service = factory.getService("my.wsdl",null,null,"http://mynamespace","abc");
MyInterface stub = (MyInterface)service.getStub(MyInterface.class);
stub.MyOperation(dh);
```

Attachments can also be returned from an operation, but only one attachment can be returned as the return parameter.

SOAP attachments - Working with types and type mappings

By default, attachments are passed into WSIF as DataHandler objects. If the part on the message that is the DataHandler object maps to a `<mime:part>` tag in the WSDL, then WSIF automatically maps the fully qualified name of the WSDL type to the DataHandler class and sets up that type mapping with the SOAP provider.

In your WSDL, you might have defined a schema for the attachment (for instance as a `binary[]` type). WSIF silently ignores this mapping and treats the attachment as a DataHandler object, unless you explicitly issue a `mapType()` method. WSIF lets the SOAP provider set the MIME content type based on the type of the DataHandler object, instead of the `type` attribute specified for the `<mime:content>` tag in the WSDL.

SOAP attachments - scenarios that are not supported

The following scenarios are not supported:
- Using DIME.
- Passing in `javax.xml.transform.Source` and `javax.mail.internet.MimeMultipart`.
- Using the mime:mimeXml WSDL tag.
- Nesting a mime:multipartRelated tag inside a mime:part tag.
- Using types that extend `DataHandler`, `Image`, and so on.
- Using types that contain `DataHandler`, `Image`, and soon.
- Using Arrays or Vectors of `DataHandlers`, `Images`, and so on.
- Using multiple in/out or output attachments.

The MIME headers from the incoming message are not preserved for referenced attachments. The outgoing message contains new MIME headers for Content-Type, Content-Id and Content-Transfer-Encoding that are created by WSIF.

Interacting with the Java EE container in WebSphere Application Server

How, and to what extent, WSIF interacts with the Java EE container that is provided in WebSphere Application Server.

About this task

You can interact with a container in any of the following ways:

Procedure

- Use the application server administrative console to define web services to WebSphere Application Server. This task is described in “Using WSIF to bind a JNDI reference to a web service” on page 1394. As part of the definition of a service, the administrator might define a “preferred port”.
- Use the Web Services Invocation Framework (WSIF) to make log and trace calls to the JRAS services in WebSphere Application Server, as described in Tracing and logging WSIF.
- Use WSIF providers to access Java Platform, Enterprise Edition (Java EE) services. For example, use the EJB provider to access the Java Naming and Directory Interface (JNDI) and make calls to remote enterprise beans.
- Use WSIF to wrap the use of container services so that, when WSIF is run in an unmanaged (thin) environment, the operation can succeed.

Invoking a WSDL-based web service through the WSIF API

The Web Services Invocation Framework (WSIF) provides a Java API for invoking web services, independent of the format of the service, or the transport protocol through which it is invoked.

Before you begin

WSIF includes an EJB provider for EJB invocation that uses the Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP). However, for EJB(IIOP)-based web service invocation, invoke RMI-IIOP Web services using JAX-RPC instead.

Ensure that your application uses only one thread to call WSIF.

About this task

The WSIF API supports the invocation of Web Services Description Language (WSDL)-defined web services. WSIF is intended for use in both WSIF clients and web service intermediaries.

The WSIF API is driven by the abstract service description in WSDL; it is completely independent of the binding used. This independence makes the API more natural to work with because it uses WSDL terms to refer to message parts, operations, and other items.

The WSIF API was designed for the WSDL usage model:

1. Select a port that supports the port type that you need.
2. Invoke the operation by providing the necessary abstract input message consisting of the required parts, without worrying about how the message is mapped to a specific binding protocol.

Other web service APIs, for example SOAP APIs, are not designed on WSDL, but for a specific binding protocol with its associated syntax; for example, target URIs and encoding styles.

The main WSIF API interfaces are described in the following procedure. For additional technical details of the WSIF API, see the generated API documentation that is supplied with WSIF (see the Apache WSIF website).

Procedure

- Create a message for sending to a port through the WSIFMessage interface.

  In WSDL, a message describes the abstract type of the input or output to an operation. The corresponding WSIF class is WSIFMessage, which represents in memory the input or output of an operation. The WSIFMessage interface separates the representation of the data from the abstract type defined by WSDL.

  A WSIFMessage class is a container for a set of named parts. WSIFMessage classes can be sent between Java Virtual Machines (JVMs).

1. Choose whether to represent the WSIF message at run time as a Java class or as XML.

   There are two natural ways to represent a WSDL message in a runtime environment:
   – The generated Java class, based on a WSDL to Java mapping such as that provided by a Java API for XML-based remote procedure call (JAX-RPC).
   – The XML representation of the data, for example using SOAP Encoding.

   Each option offers benefits in different scenarios. The Java class is the natural approach when WSIF is used in a standard Java client. However, in other scenarios where WSIF is used in an intermediary, it might be more efficient to keep a WSDL message in the SOAP encoded format. The style used to define messages must be consistent within the message, so all the parts in one message must be consistent. A string - `getRepresentationStyle()` - always returns `null`. This indicates that parts on this WSIFMessage class are represented as Java objects.

2. Get and set the parts of the WSIF message.

   You add parts to a WSIFMessage class with the setObjectPart or set*Type*Part methods. Each part is named. Part names within a message are unique. If you set a part more than once, the last setting is the one that is used.

   You retrieve parts by name from a WSIFMessage class with the getObjectPart or get*Type*Part methods. If the named part does not exist, the method returns a WSIFException error.

   You can use Iterators to retrieve parts from the message through the getParts() and getPartNames() methods.

   The order in which you set the parts is not important, but the message implementation might be more efficient if the parts are set in the parameter order specified by WSDL.

   WSIFMessage classes are cloneable and serializable. If the parts set are not cloneable, the implementation can try to clone them using serialization. If the parts are not serializable either, then a CloneNotSupportedException exception is thrown if cloning is attempted.

3. Set the WSIF message name.

   In addition to the containing parts, a WSIFMessage class also has a message name. This is required for operation overloading, which is supported by WSDL and WSIF.

For more information about the WSIFMessage interface (/wsi/org/apache/wsif/WSIFMessage.html) see the generated API documentation that is supplied with WSIF.

- Find a port factory or service through the WSIFService interface and the WSIFServiceFactory class.

  The WSIFService interface is a port factory that models and supports the WSDL approach in which a service is available on one or more ports. The factory hides the implementation of the port. WSIF supports dynamic ports that are based on a particular protocol and transport and configured using the WSDL at run time. For example, the dynamic SOAP port can invoke any SOAP service based on the WSDL description of that service, so you can hide and modify the set of available ports at run time.

  To find a service from a WSDL document at a web address, or from a code-generated code base, use the WSIFServiceFactory class.

- Invoke an operation through the WSIFPort interface and the WSIFOperation interface.

  A WSIFPort interface handles the details of invoking an operation. The port provides access to the implementation of the service.

  A WSDL document can provide many different WSDL bindings, and these bindings can drive multiple ports. The client can choose a port, the service stub can choose a port, or WSIF can choose a default port.

  The port offers an interface to retrieve an Operation object. A WSIFOperation interface offers the ability to run the given operation.

  If the port is serialized and deserialized at a later time, WSIF ensures that the client provides the correct information to the server to identify the instance. If the server instance is no longer available, the server must decide whether to create a fault or provide a new instance. That behavior can depend on the type of service. For example, for an enterprise bean, the WSIFPort interface stores the EJB Home and uses

it to select the bean before each invocation. The client is responsible for serializing or maintaining the port instance if it requires instance support. The client must create a new operation and messages for each invocation.

WSIFService interface

The WSIFService interface can generate an instance of the WSIFOperation interface to use for a particular invocation of a service operation.

The Web Services Invocation Framework (WSIF) service stores a list of providers that can each generate a WSIF operation for a particular Web Services Description Language (WSDL) binding. This service looks up providers by the provider type. For example, the service knows about one provider that handles SOAP ports, and other providers that handle Java ports that you define. In a managed environment, the container can configure the WSIFService interface.

For more information about the WSIFService interface, see the generated API documentation that is supplied with WSIF (see the Apache WSIF website).

A WSIFService implementation can choose a preferred port based on a number of criteria. The WSIFService implementation can set the preferred port, or it can be set by calling the setPreferredPort method.

The getPort method returns an instance of the WSIFPort class that is used to invoke a service on the port. Variants of the getPort method are used to define the characteristics of the port to be created:

- the getPort method with no arguments returns the preferred port.
- the getPort method with a string argument returns the port named by the string containing the WSDL identifier for the selected port.

The return value is `null` if the port name is not valid.

If a port is chosen (either by the WSIFService implementation, or by the setPreferredPort method), then the WSIFService implementation validates that the relevant provider exists and is configured. If the provider fails this validation check, the WSIFService interface chooses any other port for which a provider is defined. For example, if the preferred port is SOAP over JMS but the JMS libraries are not available, then WSIF chooses another port. If no preferred port is set, or the preferred port is not available, the WSIF implementation chooses the first available port listed in the WSDL.

The getAvailablePortNames() method returns, as an iteration of strings, the list of WSDL port names filtered by the set of available providers.

The getDefinition() method returns the WSDL definition for the service. If the WSDL definition is not available, this method returns `null`.

WSIFServiceFactory class

To find a service from a Web Services Description Language (WSDL) document at a web address, or from a code-generated code base, you can use the WSIFServiceFactory class.

Note: When you create a WSIFService interface from a WSIFServiceFactory class, you can specify a ClassLoader object to use in locating the WSDL file. You must specify this object when the WSDL file is in a JAR file. In such a case, specify the location of the WSDL file relative to the root of the JAR file, and use forward slashes (/) with the preceding slash removed.

For example:

```
com/myCompany/wsdl/MyWSDLFile.wsdl
```

rather than

```
/com/myCompany/wsdl/MyWSDLFile.wsdl
```

For more information about the WSIFServiceFactory class, see the generated API documentation that is supplied with WSIF (see the Apache WSIF website).

The WSIFServiceFactory class returns `null` if no service is found with that identifier.

WSIFPort interface

The port implements a factory method for the WSIFOperation interface.

For detailed information about the WSIFPort interface, see the generated API documentation that is supplied with WSIF (see the Apache WSIF website).

The createOperation(String) method returns a new instance of a WSIFOperation object. If the operationName value is not valid, or the operation is overloaded, the method throws an exception.

The createOperation(String, String, String) method supports overloaded Web Services Description Language (WSDL) operations. You can overload based on the input parameters, but not on the output parameters.

The client must call the close method when a port is no longer in use. In many cases, where the transport is sessionless, such as HTTP, this has no effect. However, if the port is using a session-based protocol such as MQSeries, Java Message Service (JMS), or External Call Interface (ECI), this supports the port in caching an open connection to the server and then closing it as required. Responsibly-written applications will call the close method if appropriate.

WSIFOperation interface

You use the WSIFOperation interface to invoke a service, based on a particular binding.

The WSIFOperation interface is the runtime representation of an operation. This interface provides methods to create input, output, and fault messages, and to invoke the operation.

For more information about the WSIFOperation interface, see the generated API documentation that is supplied with WSIF (see the Apache WSIF website).

createInputMessage, createOutputMessage and createFaultMessage
: These are factory methods to create the messages required by the invocation methods. All invocation methods require an input message.

executeRequestResponseOperation
: This method invokes “In Out” operations.

executeInputOnlyOperation
: This method invokes “In only” operations.

executeRequestResponseOperation
: If this method is used for invocation, an output and a fault message are instantiated and passed on the call to the method. If the method returns `true`, the output message contains the response message. If the message returns `false`, a fault occurred and is returned in the fault message.

executeRequestResponseAsync
: This method allows “In Out” operations to be invoked with the reply handled by using an alternative thread. Use of this method is discussed further in “WSIFOperation - Asynchronous interactions reference” on page 1403.

setContext and getContext
: Use of these methods is discussed in “WSIFOperation - Context” on page 1403.

All of the **execute*Nnnn*** methods fail with an exception if there is an error in processing the request in the WSIF provider.

Setting the timeouts for synchronous and asynchronous operations is discussed in “WSIFOperation - Synchronous and asynchronous timeouts reference” on page 1404.

WSIFOperation - Context:

Although Web Services Description Language (WSDL) does not define context, a number of uses of the Web Services Invocation Framework (WSIF) require the ability to pass context to the port that is invoking the service.

For example, a SOAP over HTTP port might require an HTTP user name and password. This information is specific to the invocation, but is not a parameter of the service. In general, context is defined as a set of name-value pairs. However, because web services tend to define the types of data by using XML schema types, WSIF represents the name-value pairs of the context by using the same representation that WSIFMessage classes use; that is, a set of named parts, each of which equates to an instance of an XML schema type.

You use the WSIFOperation interface setContext and getContext methods to pass context information to the binding. The port implementation can use this context, for example to update a SOAP header. There is no definition of how a port can use the context.

The parameter of the setContext and getContext methods is a WSIFMessage interface, and this interface has named parts defining the context information. The WSIFConstants class defines constants for the part names that can be set in a context WSIFMessage interface.

The following code fragment shows how to set the user name and password for HTTP basic authentication:

```
// set a basic authentication header
   WSIFMessage headers = new WSIFDefaultMessage();
   headers.setObjectPart( WSIFConstants.CONTEXT_HTTP_USER, "user name" );
   headers.setObjectPart( WSIFConstants.CONTEXT_HTTP_PSWD, "password" );
   operation.setContext( headers );
```

The WSIFOperation interface ignores context parts that it does not support. For example, the previous code is ignored by the WSIF Java provider.

The WSIFConstants class includes the following constants that can be used for context part names:
- CONTEXT_HTTP_USER
- CONTEXT_HTTP_PSWD
- CONTEXT_SOAP_HEADERS

The HTTP header values are expected to be of type String, and the SOAP header value is expected to be of type java.util.List, which should contain entries of type org.w3c.dom.Element.

WSIFOperation - Asynchronous interactions reference:

The Web Services Invocation Framework (WSIF) supports asynchronous operation. In this mode of operation, the client puts the request message as part of one transaction, and carries on with the thread of execution. The response message is then handled by a different thread, with a separate transaction.

Asynchronous operation is supported by the WSIF providers for SOAP over JMS and native JMS.

The WSIFPort class uses the supportsAsync method to test whether asynchronous operation is supported.

An asynchronous operation is initiated with the WSIFOperation interface executeRequestResponseAsync method. This method lets a Remote Procedure Call (RPC) method be invoked asynchronously. The method returns before the operation is completed, and the thread of execution continues.

The response to the asynchronous request is processed by the WSIFOperation interface fireAsyncResponse or processAsyncResponse methods.

To initiate the request, there are two forms of the executeRequestResponseAsync method:

- `public WSIFCorrelationId executeRequestResponseAsync (WSIFMessage input, WSIFResponseHandler handler)`
- `public WSIFCorrelationId executeRequestResponseAsync (WSIFMessage input)`

executeRequestResponseAsync(WSIFMessage input, WSIFResponseHandler handler)

This method takes an input message and a WSIFResponseHandler handler. The handler is invoked on another thread when the operation completes. When using this method, the client listener calls the fireAsyncResponse method, which then calls the WSIFResponseHandler interface executeAsyncResponse method.

For more information about the WSIFResponseHandler interface, see the generated API documentation that is supplied with WSIF (see the Apache WSIF website).

executeRequestResponseAsync(WSIFMessage input)

This method only takes an input message, and does not use a response handler. The client listener processes the response by calling the WSIFOperation interface processAsyncResponse method. This process updates the WSIFMessage output and fault messages with the result of the request.

WSIF supports correlation between the asynchronous request and response. When the request is sent, the WSIFOperation object is serialized into the WSIFCorrelationService object. The executeRequestResponseAsync methods return a WSIFCorrelationId object that identifies the serialized WSIFOperation object. The client listener can use this to match a response to a particular request.

The correlation service is located with the WSIFCorrelationServiceLocator class getCorrelationService() method in the org.apache.wsif.utils package.

In a managed container a default correlation service is defined in the default Java Naming and Directory Interface (JNDI) namespace by using the name: java:comp/wsif/WSIFCorrelationService. If this correlation service is not available, WSIF uses the WSIFDefaultCorrelationService.

For more information about the WSIFCorrelationService interface, see the generated API documentation that is supplied with WSIF.

This is the correlator ID:

```
public interface WSIFCorrelator extends Serializable {
   public String getCorrelationId();
}
```

The client must implement its own response message listener or message data base so that it can recognize the arrival of response messages. This client implementation manages the correlation of the response message to the request and call of one of the asynchronous response processing methods. As an example of the requirement for a client listener, the following code fragment shows what can be in the onMessage method of a Java Message Service (JMS) listener:

```
public void onMessage(Message msg) {
     WSIFCorrelationService cs = WSIFCorrelationServiceLocator.getCorrelationService();
           WSIFCorrelationId cid = new JmsCorrelationId( msg.getJMSCorrelationID() );
           WSIFOperation op = cs.get( cid );
           op.fireAsyncResponse( msg );
}
```

WSIFOperation - Synchronous and asynchronous timeouts reference:

When you use the Web Services Invocation Framework (WSIF) with the Java Message Service (JMS) you can set timeouts for synchronous and asynchronous operations.

Default values for these timeouts are defined in the wsif.properties file:

```
# maximum number of milliseconds to wait for a response to a synchronous request.
# Default value if not defined is to wait forever.
wsif.syncrequest.timeout=10000

# maximum number of seconds to wait for a response to an async request.
# if not defined or invalid defaults to no timeout
wsif.asyncrequest.timeout=60
```

If you use these default values, a synchronous request (such as a WSIFOperation interface executeRequestResponseOperation method call) times out after ten seconds, and an asynchronous request (such as a WSIFOperation interface executeRequestResponseAsync method call) times out after sixty seconds.

Note:

> The code that processes both of these timeout values uses milliseconds as its unit of time. The WSIFProperties class getAsyncTimeout method multiplies the wsif.asyncrequest.timeout value by 1000, to convert the value from seconds to milliseconds.

You can override these default values for a given request by writing a WSDL extension that sets a JMS property on the operation request with the `<jms:property>` and `<jms:propertyValue>` WSDL elements. Set the name of the property to be the name of the timeout from the WSIF properties file.

The following example sets synchronous requests to time out after two minutes (120 seconds):

```
<jms:propertyValue name="wsif.syncrequest.timeout" type="xsd:string" value="120000"/>
```

and the following example disables asynchronous timeouts (a value of zero means wait forever):

```
<jms:propertyValue name="wsif.asyncrequest.timeout" type="xsd:string" value="0"/>
```

When an asynchronous timeout expires, no listener or message data base waiting for the response is notified. The asynchronous timeout is only used to tell the correlation service that the stored WSIFOperation can be deleted. For more information about the correlation service, see “WSIFOperation - Asynchronous interactions reference” on page 1403.

Running WSIF as a client

You can run the Web Services Invocation Framework (WSIF) in the Application Client for WebSphere Application Server, and in similar clients from other suppliers.

Procedure

To simplify the process of launching client applications in the Application Client for WebSphere Application Server, use the `launchClient` tool as described in “Running a Java EE client application with launchClient” on page 2015.

Chapter 31. Developing web services - Notification (WS-Notification)

WS-Notification enables web services to use the publish and subscribe messaging pattern.You use publish and subscribe messaging to publish one message to many subscribers. In this pattern a producing application inserts (publishes) a message (event notification) into the messaging system having marked it with a topic that indicates the subject area of the message. Consuming applications that have subscribed to the topic in question, and have appropriate authority, all receive an independent copy of the message that was published by the producing application.

Developing applications that use WS-Notification

You can code a single application to undertake several WS-Notification tasks. These topics provide sample code for common tasks that your WS-Notification applications can perform.

Before you begin

Most of these examples use the Java API for XML-based remote procedure call (JAX-RPC) APIs and WebSphere Application Server APIs and SPIs. These JAX-RPC examples can interact successfully with Version 6.1 or Version 7.0 WS-Notification service points. However if you want to use WS-Notification with policy sets, for example to enable composition with WS-ReliableMessaging, then your WS-Notification applications must be encoded to use the Java API for XML-based Web Services (JAX-WS) programming model and must interact with Version 7.0 WS-Notification service points. If you are new to programming JAX-WS client applications, see the following topics:

- JAX-WS
- JAX-WS client programming model
- Implementing static JAX-WS web services clients
- Writing JAX-WS applications for WS-Notification
- Web services hints and tips: JAX-RPC versus JAX-WS, Part 1

If you have an existing Version 6.1 WS-Notification configuration, and you want to use WS-Notification with policy sets, work through the following tasks:

1. Migrating a Version 6.1 WS-Notification configuration from WebSphere Application Server Version 6.1 to Version 7.0 or later.
2. Preparing a migrated Version 6.1 WS-Notification configuration for reliable notification.
3. Configuring WS-Notification for reliable notification.

Your applications can also use WS-Notification to receive event notifications generated by other clients of the service integration bus such as JMS clients. This is described in Topology for WS-Notification as an entry or exit point to the service integration bus and Providing access for WS-Notification applications to an existing bus topic space. For information about developing applications for a mixed clients solution, including cross-streaming from a JMS client, see Interacting with JMS message types.

About this task

A single application can be coded to undertake several WS-Notification tasks. Use the examples to help you code these tasks into your WS-Notification applications.

For an overview of how applications can use the notification broker, see WS-Notification: How client applications interact at runtime.

WS-Notification applications divide into two broad types: those that expose a Web service endpoint (for example a WS-Notification consumer application that receives notifications of stock valuation changes),

and those that do not expose a web service endpoint (for example applications that generate notifications of stock valuation changes). For broad guidance on the steps you take to develop each of these application types, see the following topics:

- "Writing a WS-Notification application that exposes a web service endpoint."
- "Writing a WS-Notification application that does not expose a web service endpoint" on page 1409.

Rather than receiving all messages on a topic to which you have subscribed, your consuming application can use XML Path (XPath) selectors to filter the messages based upon the contents of each message as described in "Filtering the message content of publications" on page 1410.

The code examples listed in this topic use the following WebSphere Application Server APIs and SPIs:

```
com.ibm.websphere.sib.wsn.AbsoluteOrRelativeTime;
com.ibm.websphere.sib.wsn.CreatePullPoint;
com.ibm.websphere.sib.wsn.CreatePullPointResponse;
com.ibm.websphere.sib.wsn.Filter;
com.ibm.websphere.sib.wsn.GetMessages;
com.ibm.websphere.sib.wsn.GetMessagesResponse;
com.ibm.websphere.sib.wsn.NotificationMessage;
com.ibm.websphere.sib.wsn.TopicExpression;
com.ibm.websphere.webservices.soap.IBMSOAPFactory;
com.ibm.websphere.wsaddressing.EndpointReference;
com.ibm.websphere.wsaddressing.WSAConstants;
com.ibm.wsspi.wsaddressing.EndpointReferenceManager;
```

Procedure

- For examples of client applications, see the following topics:
  1. "Example: Subscribing a WS-Notification consumer" on page 1411.
  2. "Example: Pausing a WS-Notification subscription" on page 1414.
  3. "Example: Publishing a WS-Notification message" on page 1415.
  4. "Example: Creating a WS-Notification pull point" on page 1417.
  5. "Example: Getting messages from a WS-Notification pull point" on page 1418.
  6. "Example: Registering a WS-Notification publisher" on page 1419.
- For example XML code illustrating message content filtering by using XPath selectors, see "Filtering the message content of publications" on page 1410.
- For an example WSDL document describes a web service that implements the NotificationConsumer portType, see "Example: Creating a Notification consumer web service skeleton" on page 1421.

Writing a WS-Notification application that exposes a web service endpoint

Write a Java EE application, containing a web service definition, that can be deployed to the application server and act as a NotificationProducer, NotificationConsumer or demand-based publisher.

Before you begin

This task assumes that you have the following resources:

- An installed and functioning copy of IBM Rational Application Developer, Rational Software Architect or equivalent tooling.
- The WSDL file for the endpoint that is to be exposed.

About this task

To write a WS-Notification application that exposes a Web service endpoint, follow the method provided by your tooling for creating a web service implementation from a WSDL file. For example in Rational Software Architect there is a wizard in the Tutorials Gallery under "Create and deploy a WS-I compliant web service

and an enterprise bean skeleton from a WSDL document by using the WebSphere Application Server runtime environment". This wizard guides you through the following steps for writing a JAX-RPC application. The steps are very similar for writing a JAX-WS application. For an example of a JAX-WS NotificationConsumer client application that exposes a web service endpoint, see Writing JAX-WS applications for WS-Notification.

Procedure

1. Create a Dynamic Web Project.
2. Import and validate the WSDL file.
3. Create the web service. Select **File** > **New** > **Other** > **Web services** > **Web service wizard** > **Skeleton EJB web service**.
4. Implement the business methods in the generated EJB class. The methods you choose depend upon the type of endpoint that you are exposing (NotificationProducer, NotificationConsumer or demand based publisher).
5. Export the application.

What to do next

You are now ready to deploy the application to WebSphere Application Server as described in Installing enterprise application files with the console. In the Select installation options panel, ensure that the **Deploy web services** option is enabled.

Writing a WS-Notification application that does not expose a web service endpoint

Write a Java EE application that can be run outside of the application server to make web service invocations against an external web service. This application acts as a lightweight publisher, or a pull type consumer by invoking web service operations against another web service such as the NotificationBroker provided by WebSphere Application Server.

Before you begin

This task assumes that you have the following resources:

- An installed and functioning copy of IBM Rational Application Developer, Rational Software Architect or equivalent tooling.
- Knowledge of where to find the WSDL file for the service that is to be invoked.

About this task

To write a WS-Notification application that does not expose a web service endpoint, follow the method provided by your tooling for creating a web service implementation from a WSDL file. As an illustration, the following steps describe the method provided by Rational Software Architect for writing a JAX-RPC application. The steps are very similar for writing a JAX-WS application. For examples of JAX-WS publisher and subscriber client applications that do not expose a web service endpoint, see Writing JAX-WS applications for WS-Notification.

Procedure

1. Get the WSDL files for the service that you want to invoke. If the target service is the notification broker service that was generated by WebSphere Application Server, use the administrative console to publish the WSDL files for the service to a compressed file.
2. Create a Dynamic Web Project with a name of your choice.
3. Choose **File > New > Other > Web services > Web services Client**.
4. Select **Java Proxy**.

5. Enter or select the WSDL you obtained earlier.
6. Choose a Client Type of “Application Client” or “Java” depending upon your requirements.
7. Select your required security configuration.
8. Click **Finish**.
9. Use the generated proxy and stubs to make calls against the remote web service. For detailed coding examples, see “Developing applications that use WS-Notification” on page 1407.

What to do next

You are now ready to deploy the application for use in the Java EE application client container as described in “Running a Java EE client application with launchClient” on page 2015.

Filtering the message content of publications

Rather than receiving all messages on a topic to which you have subscribed, your consuming application can use XML Path (XPath) selectors to filter the messages based upon the contents of each message. This content-based subscription gives you greater flexibility in defining the type of information that you want to receive, and your applications do not need to handle their own filtering. Performance is improved because messages that are not relevant are not sent unnecessarily from the server to the application.

About this task

The WS-Notification publish and subscribe messaging model is topic-based. Each publication is classified as belonging to one of a fixed set of topics. Publishers label each publication with a topic name and consumers subscribe to all publications on a particular topic. For example a stock trading notification system might define a topic for each issue: Publishers post information labeled with the appropriate issue as the topic name, and subscribers subscribe to information regarding some issue.

You can use XPath selectors to filter messages for a given topic, by using a Boolean expression that is evaluated over the XML message content of the message body. For example, a subscriber to a topic-based publish and subscribe system for stock trading might use XPath selectors to specify constraints against three message attributes at the same time:

- issue name
- price
- volume of shares

The resultant Boolean statement might be as follows:

```
(issue="IBM") and (price<120) and (volume>1000)
```

You code your XPath 1.0 message content filters in the subscribing applications, by using XML Path (XPath) language, Version 1.0..

Note: If your subscriber applications use message content filtering, and are coded to specify the XPath Version 1.0 SelectorDomain, they can also filter publications from other WS-Notification providers that are of type JMS TextMessage or BytesMessage. For more information about these JMS message types, see Topology for WS-Notification as an entry or exit point to the service integration bus.

To filter the message content of publications by using XPath selectors, complete the following steps.

Procedure

1. Create a new application that subscribes a WS-Notification consumer.
2. Code an XPath message content filter in the subscribing application. For example code for doing this, see “Example: Subscribing a WS-Notification consumer” on page 1411. For an example of message content filter usage, see the example at the end of this task.

3. Code error handling for cases where the filter is not valid.
4. Invoke the application.

Example

This example XML code illustrates message content filtering by using XPath selectors. In this example a business, represented by a NotificationConsumer application, wants to be notified of bank transfers of over $1,000,000. The monitoring application subscribes on behalf of the NotificationConsumer specifying a valid XPath Version 1.0 message content filter, in the following WS-Notification subscribe message:

```
<wsnt:Subscribe>
  <wsnt:ConsumerReference>
    wsa:EndpointReference
  </wsnt:ConsumerReference>
  <wsnt:Filter>
    [ <wsnt:TopicExpression Dialect="xsd:anyURI">
        {any} ?
      </wsnt:TopicExpression> |
      <wsnt:ProducerProperties Dialect="xsd:anyURI">
        {any} ?
      </wsnt:ProducerProperties> |
      <wsnt:MessageContent Dialect="xsd:anyURI">
        /bankTransfer[value %gt; 1,000,000]
      </wsnt:MessageContent> |
      {any} *
    ] *
  </wsnt:Filter> ?
  <wsnt:InitialTerminationTime>
    [xsd:dateTime | xsd:duration]
  </wsnt:InitialTerminationTime> ?
  <wsnt:SubscriptionPolicy>
    [ <wsnt:UseRaw/> |
      {any}
    ] *
  </wsnt:SubscriptionPolicy> ?
  {any}*
</wsnt:Subscribe>
```

The WS-Notification service stores the subscription and its filter.

Another WS-Notification application then publishes a notification in which the message body contains the following information:

```
<bankTransfer origin="123456 87654321" target="224466 88664422">
  <originName>IBM Corporation</originName>
  <targetName>Matt Roberts</targetName>
  <date>02/02/2006</date>
  <value currency="USD">100,000,000</value>
</bankTransfer>
```

The WS-Notification service in the application server matches this publication to the earlier subscription and delivers the notification to the consumer specified in the subscription.

Example: Subscribing a WS-Notification consumer

Use this task to write the code for a JAX-RPC client acting in the publisher registration role, registering a publisher (producer) application with a broker, based on the example code extract provided.

About this task

This example is based on using the Java API for XML-based remote procedure calls (JAX-RPC) APIs with code generated by using the WSDL2Java tool (run against the Notification Broker WSDL generated as a result of creating your WS-Notification service point) and WebSphere Application Server APIs and SPIs.

In WebSphere Application Server there are two implementations of the WS-Notification service: Version 6.1 and Version 7.0. This JAX-RPC example can interact successfully with Version 6.1 or Version 7.0 WS-Notification service points. However if you want to use WS-Notification with policy sets, for example to enable composition with WS-ReliableMessaging, then your WS-Notification applications must be encoded to use the Java API for XML-based Web Services (JAX-WS) programming model and must interact with Version 7.0 WS-Notification service points. If you are new to programming JAX-WS client applications, see the following topics:

- JAX-WS
- JAX-WS client programming model
- Implementing static JAX-WS web services clients
- Writing JAX-WS applications for WS-Notification
- Web services hints and tips: JAX-RPC versus JAX-WS, Part 1

The article Writing JAX-WS applications for WS-Notification includes an example of a JAX-WS subscriber client application.

Raw subscriptions:

In this example, the first optional code block shows you how to create a *raw subscription*. This concept is defined in section 4.2 of the Web Services Base Notification specification.

In the normal case, a wrapped subscription causes the Notify operation of the NotificationConsumer to be driven when matching event notifications become available. If the Subscriber instead creates a raw subscription, then only the application specific content of the event notification (that is, the contents of the NotificationMessage element) are sent to the target consumer endpoint. Note that the web service endpoint specified in the ConsumerReference of the Subscribe request that also specifies **UseRaw** (that is, a raw subscription request) does not have to implement the NotificationConsumer port type because the Notify operation will not be used to deliver event notifications.

This means that the consumer must be able to accept operations for each of the types of application content that will be published on the specified topic. This pattern allows WS-Notification to invoke a group of existing web service applications that are not WS-Notification aware, but that want to receive the same information.

JAX-WS supports action-based dispatch, and JAX-WS raw consumer applications must accept the `http://docs.oasis-open.org/wsn/bw-2/NotificationConsumer/Notify` action URI. For more information, see the troubleshooting tip A JAX-WS application that is a raw consumer of brokered notifications must recognize a notification broker SOAP action.

To write the code for a JAX-RPC client acting in the publisher registration role, registering a publisher (producer) application with a broker, complete the following steps, referring to the example code extract for further information.

Procedure

1. Look up the JAX-RPC service. The JNDI name is specific to your web services client implementation.
2. Get a stub for the port on which you want to invoke operations.
3. Create the ConsumerReference. This either contains the address of the consumer web service that is being subscribed to, or a reference to a pull point. Specifying a pull point EPR indicates that the consumer is to use pull-based notifications.
4. Create the filter. This provides the name of the topic to which you want to subscribe the consumer.

5. Create a topic expression and add it to the filter. The prefixMappings are mappings between namespace prefixes and their corresponding namespaces for prefixes used in the expression.
6. Create an XPath 1.0 message content filter. For example you could select a subset of the available messages in the topic, based upon salary level. For an example of message content filter usage, see “Filtering the message content of publications” on page 1410.
7. Create the InitialTerminationTime. This is the time when you want the subscription to terminate. For example, you could set a time of 1 year in the future.
8. Create the Policy information.
9. Optional: Construct a policy indicating that the consumer is to receive raw style notifications.
10. Create holders to hold the multiple values returned from the broker:
    - The subscription reference
    - The current time at the broker
    - The termination time for the subscription
    - Any additional elements
11. Invoke the Subscribe operation by calling the associated method on the stub.
12. Get the returned values:
    - An endpoint reference for the subscription that has been created. This is required for subsequent lifetime management of the subscription, for example pausing the subscription.
    - The current time at the broker.
    - The termination time of the subscription.
    - Any other information.

Example

The following example code describes a subscriber client application that can subscribe a consumer application with a broker:

```
// Look up the JAX-RPC service. The JNDI name is specific to your web services client implementation
InitialContext context = new InitialContext();
javax.xml.rpc.Service service = (javax.xml.rpc.Service) context.lookup(
    "java:comp/env/services/NotificationBroker");

// Get a stub for the port on which you want to invoke operations
NotificationBroker stub = (NotificationBroker) service.getPort(NotificationBroker.class);

// Create the ConsumerReference. This contains the address of the consumer web service that is being
// subscribed, or alternatively is a reference to a pull point (see alternative below). Specifying a
// pull point EPR indicates that the consumer is to use pull-based notifications.
EndpointReference consumerEPR =
    EndpointReferenceManager.createEndpointReference(new URI("http://myserver.mycom.com:9080/Consumer"));

/*
// Alternative ConsumerReference for pull-based notifications:

EndpointReference consumerEPR = pullPointEPR;

*/

// Create the Filter. This provides the name of the topic to which you want to subscribe the consumer
Filter filter = new Filter();

// Create a topic expression and add it to the filter. The prefixMappings are mappings between namespace
// prefixes and their corresponding namespaces for prefixes used in the expression
Map prefixMappings = new HashMap();
prefixMappings.put("abc", "uri:example");
TopicExpression exp =
    new TopicExpression(TopicExpression.SIMPLE_TOPIC_EXPRESSION, "abc:ExampleTopic", prefixMappings);
filter.addTopicExpression(exp);

//Create an XPath 1.0 message content filter
//This example selects a subset of the available messages in the topic, based upon salary level
String filterExpression = "/company/department/employee/salary > 10000";
URI xpathURI = new URI(http://www.w3.org/TR/1999/REC-xpath-19991116);
```

```
QueryExpression qexp =
    new QueryExpression(xpathURI, filterExpression);

filter.addMessageContentExpression(qexp);

// Create the InitialTerminationTime. This is the time when you want the subscription to terminate.
// For example, set a time of 1 year in the future.
Calendar cal = Calendar.getInstance();
cal.add(Calendar.YEAR, 1);
AbsoluteOrRelativeTime initialTerminationTime = new AbsoluteOrRelativeTime(cal);

// Create the Policy information
SOAPElement[] policyElements = null;

/*
Optional
--------
The following lines show how to construct a policy indicating that the consumer is to
receive raw style notifications:

    javax.xml.soap.SOAPFactory soapFactory = javax.xml.soap.SOAPFactory.newInstance();
    SOAPElement useRawElement = null;

    if (soapFactory instanceof IBMSOAPFactory) {
        // You can use the value add methods provided by the IBMSOAPFactory API to create the SOAPElement
        // from an XML string.
       String useRawElementXML = "<mno:UseRaw xmlns:mno=\"http://docs.oasis-open.org/wsn/b-2\"/>";
        useRawElement = ((IBMSOAPFactory) soapFactory).createElementFromXMLString(useRawElementXML);
    } else {
        useRawElement = soapFactory.createElement("UseRaw", "mno", "http://docs.oasis-open.org/wsn/b-2");
    }

    policyElements =  new SOAPElement[] { useRawElement };
*/

// Create holders to hold the multiple values returned from the broker:
// The subscription reference
EndpointReferenceTypeHolder subscriptionRefHolder = new EndpointReferenceTypeHolder();

// The current time at the broker
CalendarHolder currentTimeHolder = new CalendarHolder();

// The termination time for the subscription
CalendarHolder terminationTimeHolder = new CalendarHolder();

// Any additional elements
AnyArrayHolder anyOtherElements = new AnyArrayHolder();

// Invoke the Subscribe operation by calling the associated method on the stub
stub.subscribe(consumerEPR,
                       filter,
                       initialTerminationTime,
                       policyElements,
                       anyOtherElements,
                       subscriptionRefHolder,
                       currentTimeHolder,
                       terminationTimeHolder);

// Get the returned values:
// An endpoint reference for the subscription that has been created. It is required for
// subsequent lifetime management of the subscription, for example pausing the subscription
com.ibm.websphere.wsaddressing.EndpointReference subscriptionRef = subscriptionRefHolder.value;

// The current time at the broker
Calendar currentTime = currentTimeHolder.value;

// The termination time of the subscription
Calendar terminationTime = terminationTimeHolder.value;

// Any other information
SOAPElement[] otherElements = anyOtherElements.value;
```

Example: Pausing a WS-Notification subscription

Use this task to write the code for a JAX-RPC client acting in the subscriber role, pausing a subscription for a consumer application, based on the example code extract provided.

About this task

This example is based on using the Java API for XML-based remote procedure calls (JAX-RPC) APIs with code generated by using the WSDL2Java tool (run against the Notification Broker WSDL generated as a result of creating your WS-Notification service point) and WebSphere Application Server APIs and SPIs.

In WebSphere Application Server there are two implementations of the WS-Notification service: Version 6.1 and Version 7.0. This JAX-RPC example can interact successfully with Version 6.1 or Version 7.0 WS-Notification service points. However if you want to use WS-Notification with policy sets, for example to enable composition with WS-ReliableMessaging, then your WS-Notification applications must be encoded to use the Java API for XML-based Web Services (JAX-WS) programming model and must interact with Version 7.0 WS-Notification service points. If you are new to programming JAX-WS client applications, see the following topics:

- JAX-WS
- JAX-WS client programming model
- Implementing static JAX-WS web services clients
- Writing JAX-WS applications for WS-Notification
- Web services hints and tips: JAX-RPC versus JAX-WS, Part 1

Procedure

1. Look up the JAX-RPC service. The JNDI name is specific to your web services client implementation. The PauseSubscription operation belongs to the SubscriptionManager service.
2. Get a stub for the port on which you want to invoke operations.
3. Associate the request with the subscription you want to pause. The subscriptionEPR is the EndpointReference returned by the invocation of the Subscribe operation.
4. Create any optional information.
5. Invoke the PauseSubscription operation by calling the associated method on the stub.

Example

The following example code describes a JAX-RPC client acting in the subscriber role, pausing a subscription for a consumer application:

```
// Look up the JAX-RPC service. The JNDI name is specific to your web services client implementation.
// The PauseSubscription operation belongs to the SubscriptionManager service
InitialContext context = new InitialContext();
javax.xml.rpc.Service service = (javax.xml.rpc.Service) context.lookup("java:comp/env/services/SubscriptionManager");

// Get a stub for the port on which you want to invoke operations
SubscriptionManager stub = (SubscriptionManager) service.getPort(SubscriptionManager.class);

// Associate the request with the subscription you want to pause. The subscriptionEPR is the
// EndpointReference returned by the invocation of the Subscribe operation
((Stub) stub)._setProperty(WSAConstants.WSADDRESSING_DESTINATION_EPR, subscriptionEPR);

// Create any optional information
SOAPElement[] optionalInformation =  new SOAPElement[] {};

// Invoke the PauseSubscription operation by calling the associated method on the stub
SOAPElement[] additionalReturnedInformation = stub.pauseSubscription(optionalInformation);
```

Example: Publishing a WS-Notification message

Use this task to write the code for a publisher client application that can publish a notification message to a broker, based on the example code extract provided.

About this task

This example is based on using the Java API for XML-based remote procedure calls (JAX-RPC) APIs with code generated by using the WSDL2Java tool (run against the Notification Broker WSDL generated as a result of creating your WS-Notification service point) and WebSphere Application Server APIs and SPIs.

In WebSphere Application Server there are two implementations of the WS-Notification service: Version 6.1 and Version 7.0. This JAX-RPC example can interact successfully with Version 6.1 or Version 7.0 WS-Notification service points. However if you want to use WS-Notification with policy sets, for example to enable composition with WS-ReliableMessaging, then your WS-Notification applications must be encoded to use the Java API for XML-based Web Services (JAX-WS) programming model and must interact with Version 7.0 WS-Notification service points. If you are new to programming JAX-WS client applications, see the following topics:

- JAX-WS
- JAX-WS client programming model
- Implementing static JAX-WS web services clients
- Writing JAX-WS applications for WS-Notification
- Web services hints and tips: JAX-RPC versus JAX-WS, Part 1

The article Writing JAX-WS applications for WS-Notification includes an example of a JAX-WS publisher client application.

To write the code for a publisher client application that can publish a notification message to a broker, complete the following steps, referring to the example code extract for further information.

Procedure

1. Look up the JAX-RPC service. The JNDI name is specific to your web services client implementation.
2. Get a stub for the port on which you want to invoke operations.
3. Create the message contents for a notification message.
4. Create a notification message from the contents.
5. Add a topic expression to the notification message. The topic expression must indicate to which topic or topics the message corresponds.
6. Create any optional information.
7. Optional: If the broker requires publisher client applications to register, associate the request with a particular publisher registration. The registrationEPR is the ConsumerReference EndpointReference returned by the broker in relation to an invocation of the RegisterPublisher operation.
8. Invoke the Notify operation by calling the associated method on the stub.

Example

The following example code represents a publisher client application that can publish a notification message to a broker:

```
// Look up the JAX-RPC service. The JNDI name is specific to your web services client implementation
InitialContext context = new InitialContext();
javax.xml.rpc.Service service = (javax.xml.rpc.Service) context.lookup(
    "java:comp/env/services/NotificationBroker");

// Get a stub for the port on which you want to invoke operations
NotificationBroker stub = (NotificationBroker) service.getPort(NotificationBroker.class);

// Create the message contents for a notification message
SOAPElement messageContents = null;
javax.xml.soap.SOAPFactory soapFactory = javax.xml.soap.SOAPFactory.newInstance();
if (soapFactory instanceof IBMSOAPFactory) {
    // You can use the value add methods provided by the IBMSOAPFactory API to create the SOAPElement
    // from an XML string.
    String messageContentsXML = "<xyz:MyData xmlns:xyz=\"uri:mynamespace\">Some data</xyz:MyData>";
```

```
    messageContents = ((IBMSOAPFactory) soapFactory).createElementFromXMLString(messageContentsXML);
} else {
    // Build up the SOAPElement using the standard javax.xml.soap APIs
    messageContents = soapFactory.createElement("MyData", "xyz", "uri:mynamespace");
    messageContents.addTextNode("Some data");
}

// Create a notification message from the contents
NotificationMessage message = new NotificationMessage(messageContents);

// Add a topic expression to the notification message indicating to which topic or topics the
// message corresponds
Map prefixMappings = new HashMap();
prefixMappings.put("abc", "uri:example");
TopicExpression exp =
    new TopicExpression(TopicExpression.SIMPLE_TOPIC_EXPRESSION, "abc:ExampleTopic", prefixMappings);
message.setTopic(exp);

// Create any optional information
SOAPElement[] optionalInformation =  new SOAPElement[] {};

/*
Optional
--------
The following line will cause the request to be associated with a particular publisher registration.
You must do this if the broker requires publishers to register. The registrationEPR is the
ConsumerReference EndpointReference returned by the broker in relation to an invocation of the
RegisterPublisher operation.

    ((Stub) stub)._setProperty(WSAConstants.WSADDRESSING_DESTINATION_EPR, consumerReferenceEPR);
*/

// Invoke the Notify operation by calling the associated method on the stub
stub.notify(new NotificationMessage[] { message }, optionalInformation);
```

Example: Creating a WS-Notification pull point

Use this task to write the code for a JAX-RPC subscriber client. This client creates a pull point for use by consumer applications that use pull style notifications.

About this task

This example is based on using the Java API for XML-based remote procedure calls (JAX-RPC) APIs with code generated by using the WSDL2Java tool (run against the Notification Broker WSDL generated as a result of creating your WS-Notification service point) and WebSphere Application Server APIs and SPIs.

In WebSphere Application Server there are two implementations of the WS-Notification service: Version 6.1 and Version 7.0. This JAX-RPC example can interact successfully with Version 6.1 or Version 7.0 WS-Notification service points. However if you want to use WS-Notification with policy sets, for example to enable composition with WS-ReliableMessaging, then your WS-Notification applications must be encoded to use the Java API for XML-based Web Services (JAX-WS) programming model and must interact with Version 7.0 WS-Notification service points. If you are new to programming JAX-WS client applications, see the following topics:

- JAX-WS
- JAX-WS client programming model
- Implementing static JAX-WS web services clients
- Writing JAX-WS applications for WS-Notification
- Web services hints and tips: JAX-RPC versus JAX-WS, Part 1

To write the code for a JAX-RPC client acting in the subscriber role, creating a pull point for use by a consumer application that is to use pull style notifications, complete the following steps, referring to the example code extract for further information.

Procedure

1. Look up the JAX-RPC service. The JNDI name is specific to your web services client implementation.
2. Get a stub for the port on which you want to invoke operations.
3. Create the request information.
4. Invoke the CreatePullPoint operation by calling the associated method on the stub.
5. Retrieve the reference to the pull point from the response.
6. Retrieve any additional information from the response.

Example

The following example code describes a JAX-RPC client acting in the subscriber role, creating a pull point for use by a consumer application that is to use pull style notifications:

```
// Look up the JAX-RPC service. The JNDI name is specific to your web services client implementation
InitialContext context = new InitialContext();
javax.xml.rpc.Service service = (javax.xml.rpc.Service) context.lookup(
    "java:comp/env/services/NotificationBroker");

// Get a stub for the port on which you want to invoke operations
NotificationBroker stub = (NotificationBroker) service.getPort(NotificationBroker.class);

// Create the request information.
SOAPElement[] optionalInformation = null;
CreatePullPoint cpp = new CreatePullPoint(optionalInformation);

// Invoke the CreatePullPoint operation by calling the associated method on the stub
CreatePullPointResponse response = stub.createPullPoint(cpp);

// Retrieve the reference to the pull point from the response
EndpointReference pullPointEPR = response.getPullPoint();

// Retrieve any additional information from the response
SOAPElement[] additionalInformation = response.getElements();
```

Example: Getting messages from a WS-Notification pull point

Use this task to write the code for a JAX-RPC client acting in the pull style consumer role, requesting messages from a pull point, based on the example code extract provided.

About this task

This example is based on using the Java API for XML-based remote procedure calls (JAX-RPC) APIs with code generated by using the WSDL2Java tool (run against the Notification Broker WSDL generated as a result of creating your WS-Notification service point) and WebSphere Application Server APIs and SPIs.

In WebSphere Application Server there are two implementations of the WS-Notification service: Version 6.1 and Version 7.0. This JAX-RPC example can interact successfully with Version 6.1 or Version 7.0 WS-Notification service points. However if you want to use WS-Notification with policy sets, for example to enable composition with WS-ReliableMessaging, then your WS-Notification applications must be encoded to use the Java API for XML-based Web Services (JAX-WS) programming model and must interact with Version 7.0 WS-Notification service points. If you are new to programming JAX-WS client applications, see the following topics:

- JAX-WS
- JAX-WS client programming model
- Implementing static JAX-WS web services clients
- Writing JAX-WS applications for WS-Notification
- Web services hints and tips: JAX-RPC versus JAX-WS, Part 1

To write the code for a JAX-RPC client acting in the pull style consumer role, requesting messages from a pull point, complete the following steps, referring to the example code extract for further information.

Procedure

1. Look up the JAX-RPC service. The JNDI name is specific to your web services client implementation.
2. Get a stub for the port on which you want to invoke operations.
3. Associate the request with a pull point. The pullPointEPR is the EndpointReference returned from invoking the CreatePullPoint operation.
4. Specify the number of messages you want to retrieve.
5. Create any optional information.
6. Create the request information.
7. Invoke the GetMessages operation by calling the associated method on the stub.
8. Get the messages returned from the response.

Example

The following example code describes a JAX-RPC client acting in the pull style consumer role, requesting messages from a pull point:

```
// Look up the JAX-RPC service. The JNDI name is specific to your web services client implementation
InitialContext context = new InitialContext();
javax.xml.rpc.Service service = (javax.xml.rpc.Service) context.lookup(
    "java:comp/env/services/NotificationBroker");

// Get a stub for the port on which you want to invoke operations
NotificationBroker stub = (NotificationBroker) service.getPort(NotificationBroker.class);

// Associate the request with a pull point. The pullPointEPR is the EndpointReference returned
// from invoking the CreatePullPoint operation
((Stub) stub)._setProperty(WSAConstants.WSADDRESSING_DESTINATION_EPR, pullPointEPR);

// Specify the number of messages you want to retrieve
Integer numberOfMessages = new Integer(2);

// Create any optional information
SOAPElement[] optionalInformation =  new SOAPElement[] {};

// Create the request information
GetMessages request = new GetMessages(numberOfMessages, optionalInformation);

// Invoke the GetMessages operation by calling the associated method on the stub
GetMessagesResponse response = stub.getMessages(request);

// Get the messages returned from the response
NotificationMessage[] messages = response.getMessages();
```

Example: Registering a WS-Notification publisher

Use this task to write the code for a subscriber client application that can subscribe a consumer application with a broker, based on the example code extract provided.

About this task

This example is based on using the Java API for XML-based remote procedure calls (JAX-RPC) APIs with code generated by using the WSDL2Java tool (run against the Notification Broker WSDL generated as a result of creating your WS-Notification service point) and WebSphere Application Server APIs and SPIs.

In WebSphere Application Server there are two implementations of the WS-Notification service: Version 6.1 and Version 7.0. This JAX-RPC example can interact successfully with Version 6.1 or Version 7.0 WS-Notification service points. However if you want to use WS-Notification with policy sets, for example to enable composition with WS-ReliableMessaging, then your WS-Notification applications must be encoded to use the Java API for XML-based Web Services (JAX-WS) programming model and must interact with Version 7.0 WS-Notification service points. If you are new to programming JAX-WS client applications, see the following topics:

- JAX-WS

- JAX-WS client programming model
- Implementing static JAX-WS web services clients
- Writing JAX-WS applications for WS-Notification
- Web services hints and tips: JAX-RPC versus JAX-WS, Part 1

To write the code for a subscriber client application that can subscribe a consumer application with a broker, complete the following steps, referring to the example code extract for further information.

Procedure

1. Look up the JAX-RPC service. The JNDI name is specific to your web services client implementation.
2. Get a stub for the port on which you want to invoke operations.
3. Create a reference for the publisher (producer) being registered. This contains the address of the producer web service.
4. Create a list (array) of topic expressions to describe the topics to which the producer publishes messages.
5. Indicate that you do not want the publisher to use demand based publishing.
6. Set a value for the initial termination time of the registration. For example, you could set a value 1 year in the future.
7. Create holders to hold the multiple values returned from the broker:
   - **PublisherRegistrationReference** defines the endpoint reference for use in lifetime management of the registration.
   - **ConsumerReference** defines the endpoint reference for use in subsequent publishing of messages.
8. Invoke the RegisterPublisher operation by calling the associated method on the stub.
9. Retrieve the PublisherRegistrationReference.
10. Retrieve the ConsumerReference.

Example

The following example code represents a JAX-RPC client acting in the publisher registration role, registering a publisher (producer) application with a broker.

```
// Look up the JAX-RPC service. The JNDI name is specific to your web services client implementation
InitialContext context = new InitialContext();
javax.xml.rpc.Service service = (javax.xml.rpc.Service) context.lookup(
    "java:comp/env/services/NotificationBroker");

// Get a stub for the port on which you want to invoke operations
NotificationBroker stub = (NotificationBroker) service.getPort(NotificationBroker.class);

// Create a reference for the publisher (producer) being registered. This contains the address of the
// producer web service.
EndpointReference publisherEPR =
    EndpointReferenceManager.createEndpointReference(new URI("http://myserver.mysom.com:9080/Producer"));

// Create a list (array) of topic expressions to describe the topics to which the producer publishes
// messages. For this example you add one topic
Map prefixMappings = new HashMap();
prefixMappings.put("abc", "uri:mytopicns");
TopicExpression topic =
    new TopicExpression(TopicExpression.SIMPLE_TOPIC_EXPRESSION, "abc:xyz", prefixMappings);
TopicExpression[] topics = new TopicExpression[] {topic};

// Indicate that you do not want the publisher to use demand based publishing
Boolean demand = Boolean.FALSE;

// Set a value for the initial termination time of the registration. For example, set a value 1 year in
// the future
Calendar initialTerminationTime = Calendar.getInstance();
initialTerminationTime.add(Calendar.YEAR, 1);

// Create holders to hold the multiple values returned from the broker:
// PublisherRegistrationReference: An endpoint reference for use in lifetime management of
// the registration
```

```
EndpointReferenceTypeHolder pubRegMgrEPR = new EndpointReferenceTypeHolder();

// ConsumerReference: An endpoint reference for use in subsequent publishing of messages
EndpointReferenceTypeHolder consEPR = new EndpointReferenceTypeHolder();

// Invoke the RegisterPublisher operation by calling the associated method on the stub
stub.registerPublisher(publisherEPR, topics, demand, initialTerminationTime, null, pubRegMgrEPR, consEPR);

// Retrieve the PublisherRegistrationReference
EndpointReference registrationEPR = pubRegMgrEPR.value;

// Retrieve the ConsumerReference
EndpointReference consumerReferenceEPR = consEPR.value;
```

Example: Creating a Notification consumer web service skeleton

Use this example when creating a web service that implements the NotificationConsumer portType defined by the Web Services Base Notification specification.

About this task

This task provides two code examples:

- An example WSDL document that describes a web service that implements the NotificationConsumer portType defined by the Web Services Base Notification specification.
- A basic implementation of the Service Endpoint Interface (SEI) generated from the preceding WSDL document using the WSDL2Java tool.

Note: The article Writing JAX-WS applications for WS-Notification also includes an example of a consumer Web service.

Procedure

If you are creating a Notification consumer web service skeleton, see the following code examples.

Example

The following example WSDL document describes a web service that implements the NotificationConsumer portType defined by the Web Services Base Notification specification:

```
<?xml version="1.0" encoding="utf-8"?>

<wsdl:definitions xmlns="http://schemas.xmlsoap.org/wsdl/"
    xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"
    xmlns:xsd="http://www.w3.org/2001/XMLSchema"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xmlns:wsn-bw="http://docs.oasis-open.org/wsn/bw-2"
    xmlns:wsdlsoap="http://schemas.xmlsoap.org/wsdl/soap/"
    xmlns:tns="uri:example.wsn/consumer"
    targetNamespace="uri:example.wsn/consumer">

    <wsdl:import namespace="http://docs.oasis-open.org/wsn/bw-2"
                         location="http://docs.oasis-open.org/wsn/bw-2.wsdl" />

    <wsdl:binding name="NotificationConsumerBinding" type="wsn-bw:NotificationConsumer">
        <wsdlsoap:binding style="document" transport="http://schemas.xmlsoap.org/soap/http" />
        <wsdl:operation name="Notify">
            <wsdlsoap:operation soapAction="" />
            <wsdl:input>
                <wsdlsoap:body use="literal" />
            </wsdl:input>
        </wsdl:operation>
    </wsdl:binding>

    <wsdl:service name="NotificationConsumerService">
        <wsdl:port name="NotificationConsumerPort" binding="tns:NotificationConsumerBinding">
            <wsdlsoap:address location="http://myserver.mycom.com:9080/Consumer" />
```

```
        </wsdl:port>
    </wsdl:service>

</wsdl:definitions>
```

The following example shows a basic implementation of the Service Endpoint Interface (SEI) generated from the preceding WSDL document using the WSDL2Java tool:

```
public class ConsumerExample implements NotificationConsumer {

    public void notify(NotificationMessage[] notificationMessage, SOAPElement[] any)
                                                                    throws RemoteException {
        // Process each NotificationMessage
        for (int i=0; i<notificationMessage.length; i++) {
            NotificationMessage message = notificationMessage[i];

            // Get the contents of the message
            SOAPElement messageContent = message.getMessageContents();

            // Get the expression indicating which topic the message is associated with
            TopicExpression topic = message.getTopic();

            // Get a reference to the producer (this value is optional and so might be null)
            EndpointReference producerRef = message.getProducerReference();

            // Get a reference to the subscription (this value is optional and so might be null)
            EndpointReference subscriptionRef = message.getSubscriptionReference();

            // User defined processing ...

        }
    }
}
```

Chapter 32. Developing web services - Reliable messaging (WS-ReliableMessaging)

To configure a web service application to use WS-ReliableMessaging, you attach a policy set that contains a WS-ReliableMessaging policy type. This policy type offers a range of qualities of service: managed persistent, managed non-persistent, or unmanaged non-persistent.

Developing a reliable web service application

Develop a Java API for XML-Based Web Services (JAX-WS) provider or requester application that can compose with a WS-ReliableMessaging-enabled policy set.

Before you begin

At any stage - that is, before or after you have built your reliable web service application, or configured your policy sets - you can set a property that configures endpoints to only support clients that use reliable messaging. This setting is reflected by WS-Policy if engaged.

About this task

You can develop a Java API for XML-Based Web Services (JAX-WS) web service requester application that sends messages reliably, or a web service provider application that requires reliable messaging. Your client application can also take programmatic control of WS-ReliableMessaging sequences.

Procedure

1. Develop your JAX-WS web service application.

   For a Web service requester application that sends messages reliably:

   a. Get an implementation WSDL document, and select the SOAP over HTTP binding. The WSDL should be WS-I Basic Profile compliant.

   b. Build the JAX-WS application from the WSDL implementation document.

   c. (Optional) Enable transaction support for outbound (requester) one-way message sends. For more information, see “Providing transactional recoverable messaging through WS-ReliableMessaging” on page 1426.

   d. (Optional) Use the waitUntilSequenceCompleted method on the sequenceManager to ensure that reliable messaging state is released after the client finishes messaging, as described in the “Controlling WS-ReliableMessaging sequences programmatically” on page 1424 topic.

   e. (Optional) If you want to use in-order delivery (that is, you want WS-ReliableMessaging to make messages available to your requester application in the order that they were sent), then you must also configure your requester application to poll for the messages in the order in which it should receive them. For more information, see Configuring the WS-ReliableMessaging policy.

   For a web service provider application that requires reliable messaging:

   a. Write or get an interface WSDL document that describes the service interface. The document should be compliant with the WS-I Basic Profile.

   b. Write or get an implementation WSDL document, and select the SOAP over HTTP binding. The WSDL should remain WS-I Basic Profile compliant.

   c. Build the JAX-WS application from the WSDL implementation document.

2. Enable your client application to take programmatic control of WS-ReliableMessaging sequences.

   This helps manage resources on the server, for example by removing sequences after a client application has finished messaging. You can add code to create sequences, send acknowledgement

requests, close sequences, terminate sequences and wait until sequences are complete. For more information, including example code, see “Controlling WS-ReliableMessaging sequences programmatically.”

What to do next

You are now ready to configure a policy set instance to enable WS-ReliableMessaging.

Controlling WS-ReliableMessaging sequences programmatically

Your client application can use the WSRMSequenceManager, part of the WebSphere Application Server SPI for reliable messaging, to gain programmatic control over reliable messaging sequences. This helps manage resources on the server, for example by removing sequences after a client application has finished messaging. You can add code to create sequences, send acknowledgement requests, close sequences, terminate sequences and wait until sequences are complete.

Before you begin

The WebSphere Application Server SPI for reliable messaging always uses the static policy set configuration that is applied to the client from which the SPI is called. It does not use any alternative policy set that is subsequently configured by WS-Policy to meet the requirements of a WS-Policy intersection.

About this task

By closing sequences programmatically, you limit the number of open sequences a single client has to support in a single JVM at one time.

For your client application to gain programmatic control over reliable messaging sequences, it needs access to a WSRMSequenceManager instance. Use the following code fragment to achieve this:

```
import com.ibm.wsspi.wsrm.WSRMSequenceManager;
import com.ibm.wsspi.wsrm.WSRMSequenceManagerFactory;

.........

     // Get the factory
     WSRMSequenceManagerFactory factory = WSRMSequenceManagerFactory
         .getInstance();

     // Get the sequence manager instance
     WSRMSequenceManager sequenceManager = factory.createWSRMSequenceManager();
```

All WSRMSequenceManager methods take the following parameters:

- The client instance object. This is either a **Dispatch client** instance, or the **Dynamic proxy client**. For details of the client types, see the JAX-WS client programming model topic.
- The **Port QName** instance for the target endpoint.

To control WS-ReliableMessaging sequences programmatically, add code to your client application as described in the following steps:

Procedure

- Add code to create a sequence.

  To set the available properties use the following methods:

```
/**
 * Sets the target provider endpoint.
 * A null value will cause a NullPointerException when the WSRMSequenceProperties object is used.
 *
 * @param providerEndPoint The target service endpoint URI
 */
public void setTargetEndpointUri(String providerEndPoint);

/**
 * This is used to indicate that a response flow is required between the provider and requester and the response
 * flow will be established at create sequence time
```

```
 *
 * By calling this method it will indicate that a response flow is required.
 */
public void setUseOfferedSequenceId();

/**
 * Set the Soap version for RM protocol messages.
 * The default value for this property is WSRMSequenceProperties.SOAP_11
 *
 * @param soapVersion
 */
public void setSoapVersion(int soapVersion);

/**
 * If the Sequence Acknowledgement messages are to be sent back asynchronously call this method.
 *
 */
public void useAsyncTransport();
```

To create the reliable messaging sequence use the createNewWSRMSequence method on the WSRMSequenceManager:

```
/**
 * Initiates a new sequence handshake between this client and the target EPR specified in the
 * WSRMSequenceProperties instance.
 *
 * This sequence will only be valid for the client issuing the createNewWSRMSequence call.
 *
 * When returning from this call, there is no guarantee that the sequence has been established.
 *
 * @throws NullPointerException if the sequenceProperties object is null, or the target EPR is null
 *
 * @param clientObject The JAX-WS Dispatch instance, or the Dynamic Proxy client instance.
 * @param sequencePropeties The properties for creating the reliable messaging sequence
 * @throws WSRMNotEnabledException
 * @throws WSRMSequenceAlreadyExistsException
 */
public void createNewWSRMSequence(Object clientObject, QName portQName, WSRMSequenceProperties sequencePropeties)

throws WSRMNotEnabledException,
       WSRMSequenceAlreadyExistsException;
```

- Add code to send an acknowledgment request.

  To send an acknowledgment request for a WS-ReliableMessaging sequence, use the following method on the WSRMSequenceManager:

```
/**
 * Sending an acknowledgement request sends the ACK requested message to the specified target endPointUri.
 * The target will respond with a range of messages that can be acknowledged for the current reliable messaging
 * sequence.
 *
 * @param clientObject The JAX-WS Dispatch instance, or the Dynamic Proxy client instance.
 * @param portQName
 * @param endPointUri The target endpoint uri
 * @throws WSRMNotEnabledException
 * @throws WSRMSequenceUnknownException
 * @throws WSRMSequenceTerminatedException
 * @throws WSRMSequenceClosedException
 */
public void sendAcknowledgementRequest(Object clientObject, QName portQName, String endPointUri)

throws WSRMNotEnabledException,
       WSRMSequenceUnknownException,
       WSRMSequenceTerminatedException,
       WSRMSequenceClosedException;
```

- Add code to close a sequence.

  To close a WS-ReliableMessaging sequence use the following method on the WSRMSequenceManager:

```
/**
 * Closes the web services reliable messaging session from this application to
 * the endpoint url specified.
 *
 * Throws a WSRMSequenceTerminatedException if the session between this application
 * and the target endpoint url is already closed
 *
 * Throws a WSRMSequenceTerminatedException when the session between this application
 * and the target endpoint has already been terminated.
 *
 * Throws WSRMSequenceUnknownException exception when either reliable messaging is not engaged to
 * the specified endpoint url or the sequence has previously been terminated and removed.
 *
 * @param clientObject The JAX-WS Dispatch instance, or the Dynamic Proxy client instance.
 * @param endPointUri The target endpoint url
 *
 * @throws WSRMNotEnabledException
```

```
   * @throws WSRMSequenceUnknownException
   * @throws WSRMSequenceClosedException
   * @throws WSRMSequenceTerminatedException
   */
  public void closeSequence(Object clientObject, QName portQName, String endPointUri)

  throws WSRMNotEnabledException,
         WSRMSequenceUnknownException,
         WSRMSequenceClosedException,
         WSRMSequenceTerminatedException;
```

- Add code to terminate a sequence.

  To terminate a WS-ReliableMessaging sequence use the following method on the WSRMSequenceManager:

```
  /**
   * Terminates web services reliable messaging session from this application to
   * the endpoint url specified.
   *
   * Throws a WSRMSequenceTerminatedException when the session between this application
   * and the target endpoint has already been terminated.
   *
   * Throws WSRMSequenceUnknownException exception when either reliable messaging is not engaged to
   * the specified endpoint url or the sequence has previously been terminated and removed.
   *
   * @param clientObject The JAX-WS Dispatch instance, or the Dynamic Proxy client instance.
   * @param endPointUri The target endpoint url
   * @throws WSRMNotEnabledException
   *
   * @throws WSRMSequenceTerminatedException
   * @throws WSRMSequenceUnknownException
   */
  public void terminateSequence(Object clientObject, QName portQName, String endPointUri) throws WSRMNotEnabledException;
```

- Add code to wait for a sequence to complete.

  To wait for a reliable messaging sequence to complete, you use a method call that ensures that all messages have been sent and acknowledged by the target service. After the sequence is completed, it is terminated and cleaned up.

  There are two ways of using the waitUntilSequenceCompleted method:

  –

```
public boolean waitUntilSequenceCompleted(Object clientObject,
QName portQName, String endPointUri, long waitTime)
```

    This method call waits for the specified **waitTime** for the reliable messaging sequence to complete. If the sequence does not complete in the specified time, the method returns false. If the sequence does complete in time, the method returns true.

  –

```
public boolean waitUntilSequenceCompleted(Object clientObject,
QName portQName, String endPointUri)
```

    This method call does not return until the reliable messaging sequence is completed.

Providing transactional recoverable messaging through WS-ReliableMessaging

If your WS-ReliableMessaging application runs inside the web container and uses a managed quality of service, you can use WS-ReliableMessaging to provide transactional recoverable messaging.

About this task

The WS-ReliableMessaging transactional model is as follows:

- On the web service requester side, the transaction is between the application and the local managed store.
- The WS-ReliableMessaging protocol delivers the message to the web service provider side, where a different transaction is used between the second managed store and the application being dispatched.

For the outbound (requestor) case on a one-way message send, if the **enableTransactionalOneWay** property is set to `true`, then the send is performed under any transactional context currently held by the application thread. (Note that transactions are not supported under an outbound two-way message exchange).

For the inbound (provider) case, if the **inOrderDelivery** property is set to `true`, then an inbound message is dispatched to the application under a transaction. For an inbound two-way message exchange, the response is also generated under that transaction and is not sent until that transaction has committed.

Note:

WS-ReliableMessaging transactions do not use the WS-AtomicTransactions protocol. The relationship between these two protocols is as follows:

- WS-AtomicTransactions and WS-ReliableMessaging are mutually exclusive when WS-ReliableMessaging is being used, with a managed store, to provide transactional recoverable messaging.
- If WS-ReliableMessaging is configured to use an in-memory store, then there are cases where a WS-AtomicTransaction can be flowed between the reliable messaging source and the reliable messaging destination for two-way invocations. In this situation, WS-ReliableMessaging only protects against network failures, not against server failure.

For more information, see WS-AtomicTransactions.

To provide transactional recoverable messaging through WS-ReliableMessaging, work through the steps described in Adding assured delivery to web services through WS-ReliableMessaging and also complete the following additional steps:

Procedure

- To enable transactional messaging for outbound (requester) one-way message sends, when you develop your JAX-WS web service application set the **enableTransactionalOneWay** property to `Boolean.TRUE` (or the string `true`) in the jaxWS request context map.
- To enable transactional messaging for inbound (provider) one-way and two-way message exchanges, when you configure your WS-ReliableMessaging policy either use the administrative console to select the option **Deliver messages in the order that they were sent** or use the wsadmin tool to set the **inOrderDelivery** property to `true`.

Configuring endpoints to only support clients that use WS-ReliableMessaging

By default, when a WS-ReliableMessaging enabled policy set is attached to an endpoint, the server supports clients that use reliable messaging and clients that do not use reliable messaging. In this version of the product, you can configure endpoints to only support clients that use reliable messaging.

About this task

You configure endpoints to only support clients that use reliable messaging by setting a property in either of the following ways:

- Set a property when packaging the application.
- Set a property as a JVM argument for the server.

This setting is reflected by WS-Policy if engaged. For information about how to engage WS-Policy, see Using WS-Policy to exchange policies in a standard format.

Procedure

- When packaging the application, configure endpoints to only support clients that use reliable messaging by setting the **strictlyEnforceWSRM** property in the META-INF/MANIFEST.MF of a WAR file or EJB module.

- Using a JVM argument for the server, configure endpoints to only support clients that use reliable messaging by defining the Java virtual machine custom property **com.ibm.ws.websvcs.rm.strictlyEnforceWSRM** on the server. For more information, see Configuring the JVM.

Chapter 33. Developing web services - RESTful services

You can use Java API for RESTful Web Services (JAX-RS) to develop services that follow Representational State Transfer (REST) principles. RESTful services are based on manipulating resources. Resources can contain static or dynamically updated data. By identifying the resources in your application, you can make the service more useful and easier to develop.

Planning JAX-RS web applications

Planning to use JAX-RS to enable RESTful services

By using the Java API for RESTful Web Services (JAX-RS) API, application developers can quickly develop RESTful applications. When planning to use JAX-RS to enable RESTful services, consider how to best implement the capabilities and characteristics of a RESTful application with JAX-RS.

Before you begin

Read the overview of JAX-RS information to learn about REST services and the advantages of using JAX-RS to build RESTful services.

About this task

JAX-RS is a programming model that provides a mechanism for developing services that follow Representational State Transfer (REST) principles. Using JAX-RS, development of RESTful services is simplified.

JAX-RS is a Java API for developing REST applications quickly. While JAX-RS provides a faster way for developing web applications than servlets, the primary goal of JAX-RS is to build RESTful services. JAX-RS 1.0 defines a server-side component API to build REST applications. IBM JAX-RS provides an implementation of the JAX-RS (JSR 311) specification.

By using JAX-RS technology, REST applications are simpler to develop, simpler to consume, and simpler to scale when compared to other types of distributed systems. Many popular and widely used Internet services have successfully provided RESTful APIs to their applications. Third parties have used various REST APIs to build their own businesses and applications.

Due to the simple consumption of RESTful services, you can write clients in many languages on different platforms. Most languages require no third-party libraries as long as there is a method to use an HTTP connection. Because of the pervasiveness of web browsers, the most prevalent clients are typically web browsers. For example, many Web 2.0 properties use a JavaScript framework such as Dojo toolkit for developing a client in a browser in conjunction with a RESTful server-side application that provides the data for the client.

Procedure

1. Review existing business and middleware applications in your environment to determine which services you want to implement as REST services.
2. Define the resources in your RESTful applications.
3. Determine the URL patterns, operations, and media type formats to use for each resource.
   a. Define the URI patterns for resources in RESTful applications.
   b. Define the client capabilities for RESTful applications using HTTP methods .
   c. Define the HTTP headers and response codes for RESTful applications using HTTP methods.

Results

You have a design plan for using JAX-RS to implementing REST services.

Defining the resources in RESTful applications

You can use Java API for RESTful Web Services (JAX-RS) to develop services that follow Representational State Transfer (REST) principles. RESTful services are based on manipulating resources. Resources can contain static or dynamically updated data. By identifying the resources in your application, you can make the service more useful and easier to develop.

Before you begin

After you have identified the application that you want to expose as a RESTFUL service, you must first define the resources for your RESTful application. When defining the resources for your application, consider the type of data do you want to expose. Perhaps you already have a relational database that contains information that you want to expose to users using REST technology. Do you already have a set of Java classes defined for accessing that data?

For example, consider the case of an application defined to support a book store. This application currently has a database with several tables that define the various items in the collection of books and the inventory of each book. In this example, there are a number of ways to represent the data in the database in a RESTful application. One approach is to consider each table as an individual resource, so that each of the verbs in the RESTful request maps to the actions that the database supports on that table such as select, insert, update, delete. This example is a simple approach to creating a RESTful application. This approach using the book store example is also used in the documentation that describes defining URL patterns for resources, resource methods, HTTP headers and response codes, media types, and parameters for request representations to resources

In support of this database for the book store application, there might already be existing code that is responsible for accessing the database and retrieving the data from each table. Even though the rows in each of the tables logically represents each resource, the accessor classes are used to define the resources. The implementing JAX-RS applications documentation provides more details on how these classes are incorporated into your JAX-RS application.

Alternately, you might have more static content that does not reside in a database that you want to distribute as resources. Whether it is a collection of documents in various formats or a resource-based facade for other remote systems, using JAX-RS, you can distribute content from multiple sources.

About this task

Resources are the basic building block of a RESTful service. Examples of a resource from an online book store application include a book, an order from a store, and a collection of users.

Resources are addressable by URLs and HTTP methods can perform operations on resources. Resources can have multiple representations using different formats such as XML and JSON. You can use HTTP headers and parameters to pass additional information that is relevant to the request and response.

With JAX-RS, you can annotate existing or new Plain Old Java objects (POJO) with JAX-RS specific annotations. JAX-RS annotated resource classes and the annotated methods are invoked depending on the URI patterns. You can use the annotated resource classes after these resource classes are added to the list of resources returned by the overridden methods in the JAX-RS application class.

Procedure

1. Identify the types of resources in the application.
2. (optional) Identify existing Java classes that you can use as resource classes.

3. Create new Java classes for resources that do not have an existing Java class.

Results

You have defined the content that you want to expose as a collection of resources in your application.

What to do next

Based on the resources that you have defined, read about defining URL patterns for resources, resource methods, HTTP headers and response codes, media types, and parameters for request representations to resources to learn more about additional steps you can take to define the resources for your JAX-RS application.

Defining the URI patterns for resources in RESTful applications

Representational State Transfer (REST) services are based on manipulating resources. Resources for RESTful services are addressable, and URLs are the primary way of achieving addressability in REST.

Before you begin

Identify the resources in the application that you want to expose as a RESTful service.

About this task

URLs are used to specify the location of a resource. Interaction between the server and client is based on issuing HTTP operations to URLs. Defining URL patterns is important because URLs often have a long lifetime so that clients can directly address a resource long after the resource is initially discovered.

URLs are typically used when you enter addresses to web browsers, such as `http://www.ibm.com/` or `http://www.example.com/bookstore/books/ISBN123`. Although URLs are not required to be understandable by users, RESTful services that provide logical URLs in understandable patterns enable client application developers to work efficiently.

RESTful clients use URLs to manipulate resources. Each resource must have its own unique URL. Some URL patterns have a collection path with a unique identifier appended. For example, you can use `http://www.example.com/bookstore/books` as the collection resource URL, `http://www.example.com/bookstore/books/ISBN123` as a unique book resource URL, and you can use `http://www.example.com/bookstore/books/ISBN123/authors` to retrieve a collection resource describing `ISBN123` authors.

The application developer must carefully consider the granularity of URLs because it can affect usage of the application and performance. For example, you can include the author information of a book as part of the book resource or you can define the author information as a unique resource with its own URL that is referenced in the book resource. Depending on the reuse of resources, it might be more efficient to define a separate resource for the author information that is referenced in a hyperlink of the book resource for cases when the author writes a different book.

After an initial URL is given to a client, subsequent related requests are discoverable by parsing the current resource. In the book example, a GET request to `http://www.example.com/bookstore/books/` retrieves a list of book URLs that can include `http://www.example.com/bookstore/books/ISBN123`.

Because systems rely on resources being available, URLs typically have longevity. Because HTTP has built-in status codes for redirection, such as the 301 moved permanently code and the 307 temporarily redirected code, users and clients with caches often reuse previously discovered URLs first. You can additionally consider including a version identifier in the URL pattern, such as `http://www.example.com/bookstore/v2/books/ISBN123`. Like the planning involved to define an interface using Java code, be sure to carefully choose your URL patterns because of expected longevity.

In Java API for RESTful Web Services (JAX-RS), you must add @Path annotations to the Java class files or the Java methods to define the relative URL of the resource. You can use JAX-RS subresource locators and subresource methods to define resources. Use parameters, such as the path parameter or matrix parameter, in the URL to identify the resource.

The value in the @Path annotation defines the relative part of the full URL to your resource. The base URL is derived from the domain, port, application module context root, and any URL pattern mappings in the web.xml file of the application module. For example, if the domain is `www.example.com`, the port is `9060`, the module context root is `example`, the servlet URL pattern is `store/*`, and the value of the @Path annotation is `/bookstore/books`. The full URL is: `http://www.example.com:9060/example/store/bookstore/books`.

Procedure

1. Identify the types of resources in the application. Suppose that you have two types of resources, a BooksCollection and an individual Book object which have the following class definitions:

```
public class BooksCollection {
    public BooksCollection() {
        /* no argument constructor */
    }

}

public class Book {
    public Book(String ISBN) {
        /* This constructor has an argument that will be annotated with a JAX-RS annotation.
         See the JAX-RS specification for information on valid constructors. */
    }
}
```

   As defined in the JAX-RS specification, by default, resource instances are created per request. For the JAX-RS runtime environment to create a resource instance, you must have either a constructor with no argument or a constructor with only JAX-RS annotated parameters present.

2. Add a @javax.ws.rs.Path annotation to each resource class. For each @javax.ws.rs.Path annotation, set the value as the part of the URL after the base URL of the application.

```
/*
 * BooksCollection.java
 * This Java class represents the books collection URL at /bookstore/books.
 */
@javax.ws.rs.Path("/bookstore/books/")
public class BooksCollection {

}
```

   After completing the application, you can use the resource by visiting `http://<host_name>:<port>/<context_root>/<servlet_path>/bookstore/books`. For this URL, specify the context root value as the part of the URL after the context module. Specify the servlet path as any URL patterns in the web.xml file, if it exists.

3. (optional) Determine if a resource needs to use part of the URL as a parameter. If a resource needs to use part of the URL as a parameter, such as an identifier, you can use the @javax.ws.rs.Path annotation with a regular expression. You can then add a @javax.ws.rs.PathParam annotation in either the resource constructor or the resource method.

```
/*
 * Book.java represents individual books.
  */
@javax.ws.rs.Path("/bookstore/books/{bookID}")
public class Book {
   public Book(@javax.ws.rs.PathParam("bookID") String ISBN) {

   }
}
```

   When an HTTP request is made to `http://<host_name>:<port>/<context_root>/<servlet_path>/bookstore/books/ISBN_number`, a Book instance is created with *ISBN_number* passed in to the ISBN parameter of the constructor.

For more information about other possible parameters, read about defining parameters for requests to resources in RESTful applications.

4. Create the javax.ws.rs.core.Application subclass to define to the JAX-RS runtime environment which classes are part of the JAX-RS application. The resource classes are returned in the getClasses() method; for example:

```
public class BookApplication extends javax.ws.rs.core.Application {
    public Set<Class<?>> getClasses() {
        Set<Class<?>> classes = new HashSet<Class<?>>();
        classes.add(BooksCollection.class);
        classes.add(Book.class);
        return classes;
    }
}
```

By defining the javax.ws.rs.core.Application subclass, classes returned from its methods are registered to the JAX-RS runtime environment. When configuring the web.xml file, you must specify the javax.ws.rs.core.Application subclass as a parameter to the servlet or filter. For more information, read about configuring the web.xml file for JAX-RS applications.

Results

You have created a URL to identify your resources for your RESTful service. By considering issues with URL patterns early in the application design, the RESTful service increases its usability and value over an extended time.

What to do next

The resource at the defined URL exists. However, the resource does not yet have any methods to handle HTTP method actions such as GET, POST, PUT, or DELETE. See the defining resource methods for RESTful applications to learn more about defining capabilities of resources using supported HTTP methods.

Defining resource methods for RESTful applications

Individual resources can define their capabilities using supported HTTP methods. In Representational State Transfer (REST) services, the supported methods are GET, PUT, DELETE, and POST. All operations are typically conducted by using one of the predefined HTTP methods with a resource.

Before you begin

Understand the predefined HTTP methods and their known attributes. Some HTTP methods are meant to be safe, meaning that issuing the request does not change the resource, or idempotent, meaning that multiple invocations of the operation do not change the result. While HTTP methods are defined to have certain attributes, the service implementation follows the definitions. See the HTTP method definitions information to learn more about the common set of methods for HTTP.

About this task

Clients use HTTP methods to perform certain operations. Unlike other distributed systems where unique interfaces are defined by each system, RESTful systems based on HTTP mainly rely on predefined methods. The four most common methods are GET, PUT, DELETE, and POST. Resources are not required to permit all HTTP methods for all clients.

The HTTP GET method retrieves a resource representation. It is safe and idempotent. Repeated GET requests do not change any resources.

The HTTP PUT method is often used to update resources or to create a new entity at a known URL. When a resource must be updated or created, an HTTP PUT method is issued at the resource URL with the new resource data as the request entity, also known as the message body. The HTTP PUT method is

idempotent so multiple identical PUT requests with the same entity to the same URL yields the same result as if only one PUT request was issued. This method assumes that no other relevant requests were made.

The HTTP DELETE method removes a resource at a given URL. It is also idempotent.

The HTTP POST method is often used when creating a resource in a collection when the final resource URL is not known. For instance, an administrator issues a POST request to a `/users` collection resource that creates a user with a unique ID such as `1234567890`. The unique ID is then used as part of the URL path to describe the new user resource, such as `/users/1234567790`. It is not safe and is not idempotent. In this case, the multiple POST requests to the `/users` collection can continue creating a new unique ID and adding this new ID to the users collection even if the user has the same information.

Because most RESTful services use well-known HTTP methods that provide expected results, you can more easily create clients. RESTful service developers can take advantage of the expected behaviors of HTTP methods. Resource methods can also use parameters, such as path parameters, query parameters, or matrix parameters to identify the resource. Read about defining the use of parameters for request representations to resources to learn more.

(optional) If you have a sub-resource method and a sub-resource locator method that have an `@Path` annotation with the same value in the same resource class, the sub-resource locator is not considered when determining the method to invoke by default. This is in compliance with the JAX-RS specification.

Use the `wink.searchPolicyContinuedSearch` property with a value of `true` to modify this behavior. This results in sub-resource locators being used if no sub-resource methods match the request.

To enable the property, include a properties file in the `WEB-INF` directory of the module that has the `wink.searchPolicyContinuedSearch` property and value specified. In the `web.xml` file of the application module, include an `init-param` element with the `propertiesLocation` value for the `param-name` element. The `param-value` element specifies the location of the properties file, for example, `WEB-INF/my_wink.properties`.

The following example illustrates the `web.xml` file:

```
<servlet>
    ...
    ...
    <init-param>
        <param-name>propertiesLocation</param-name>
        <param-value>/WEB-INF/my_wink.properties</param-value>
    </init-param>
</servlet>
```

The following example illustrates the `WEB-INF/my_wink.properties` properties file:

```
wink.searchPolicyContinuedSearch=true
```

Procedure

1. Identify the types of resources in the application.

   For each resource class, identify an existing method or create a method that you want to invoke for each supported HTTP method. Methods that respond to HTTP requests are also known as resource methods. For each resource method in the resource class, annotate the Java method with a single JAX-RS HTTP method annotation such as @javax.ws.rs.GET, @javax.ws.rs.POST, @javax.ws.rs.DELETE or @javax.ws.rs.PUT. For example, if an HTTP GET method is supported by the BooksCollection class, then you can create and annotate a method like the following snippet:

```
@javax.ws.rs.Path("/bookstore/books/")
public class BooksCollection {
    @javax.ws.rs.GET
    public String getBooksCollection() {
        String str = /* Construct a String representation of the resource. */
        return str;
    }
}
```

When issuing an HTTP GET request to `http://<host_name>:<port>/<context_root>/<servlet_path>/bookstore/books` URL using a web browser or another HTTP client, the previous getBooksCollection() method is invoked.

2. Ensure that the resource supports the required HTTP methods.

   Each resource typically has multiple resource methods; for example:

```
@javax.ws.rs.Path("/bookstore/books/{bookID}")
public class Book {
    /* This is a database key. */
    private String ISBN;

    public Book(@javax.ws.rs.PathParam("bookID") String ISBN) {
        this.ISBN = ISBN;
    }

    @javax.ws.rs.GET
    public String retrieveSpecificBookInformation() {
        /* This code retrieves a book resource based on the ISBN key. */
    }

    @javax.ws.rs.PUT
    public String updateBookInformation(String updatedBookInfo) {
        /* This code updates the book resource based on ISBN key and the entity (message body) sent
         in the request that is stored in updatedBookInfo. */
    }

    @javax.ws.rs.DELETE
    public void removeBook() {
        /* This code deletes a book resource based on ISBN key. */
    }
}
```

   When issuing an HTTP GET request to the `http://<host_name>:<port>/<context_root>/<servlet_path>/bookstore/books/<isbn_number>` URL using a web browser or another HTTP client, the retrieveSpecificBookInformation() method is invoked. Sending an HTTP PUT request to the same URL invokes the updateBookInformation method and any content in the request message body is passed as the value of the `updatedBookInfo` object. Finally, sending an HTTP DELETE request to the same URL invokes the removeBook() method.

   Note: According to the JAX-RS specification, you must not put multiple HTTP method annotations, such as @javax.ws.rs.POST or @javax.ws.rs.PUT on the same resource method Because HTTP methods have uniquely defined semantics, do not use a resource method for multiple HTTP methods.

Results

You have defined valid operations for the resources.

Defining the HTTP headers and response codes for RESTful applications

HTTP headers and status codes are useful to help intermediary and client programs understand information about requests and responses for applications. HTTP headers contain metadata information. HTTP status codes provide status information about the response.

Before you begin

See the HTTP 1.1 specification to become familiar with HTTP headers and HTTP status codes.

About this task

HTTP headers contain metadata information such as security authentication information, the user agent that is used, and cache control metadata. Standard HTTP headers are defined in the HTTP specification; however, you can use custom HTTP headers, if necessary.

You can read HTTP headers from the request and set the headers in the response. There are a set of common request and response headers, but there are also unique request and unique response headers. JAX-RS provides the HttpHeaders injectable interface and the @HeaderParam parameter annotation for reading HTTP headers. If a javax.ws.rs.core.Response object is returned from a resource method, you can set HTTP headers on the response. Also, you can set HTTP headers when an entity is written using the MessageBodyWriter interface.

You can set HTTP response status codes to help client programs understand the response. While responses can contain an error code in XML or other format, client programs can quickly and more easily understand an HTTP response status code. The HTTP specification defines several status codes that are typically understood by clients.

Procedure

- To read a specific request header, add a @javax.ws.rs.HeaderParam annotated parameter.

```
@javax.ws.rs.Path("/bookstore/books/{bookID}")
public class Book {
    @javax.ws.rs.GET
    public String retrieveSpecificBookInformation(@javax.ws.rs.HeaderParam("User-Agent") String theUserAgent) {
        /* The book ID was sent in a HTTP request header with the name "bookID". */
    }
}
```

- To read any request header, use the @javax.ws.rs.core.Context javax.ws.rs.core.HttpHeaders injected object.

```
@javax.ws.rs.Path("/bookstore/books/{bookID}")
public class Book {
    @javax.ws.rs.GET
    public String retrieveSpecificBookInformation(@javax.ws.rs.core.Context HttpHeaders requestHeaders) {
        /* Call methods on "requestHeaders" to get any request header sent by the client. */
        List<String> bookIdValues = requestHeaders.getRequestHeader("User-Agent");
    }
}
```

- To set a response status code or header, return a javax.ws.rs.core.Response object and build the response with the appropriate status code and headers.

```
@javax.ws.rs.Path("/bookstore/books/{bookID}") public class Book {
    @javax.ws.rs.GET public javax.ws.rs.core.Response retrieveSpecificBookInformation() {
        return Response.status(200).header("responseHeaderName", "responseHeaderValue").header("anotherResponseHeaderName", "foo").build();
    }
}
```

Results

You have used HTTP headers to read request headers and set response status codes and headers for JAX-RS web applications.

Defining media types for resources in RESTful applications

Resources are represented by multiple formats. XML, JavaScript Object Notation (JSON), Atom, binary formats such as PNG, JPEG, GIF, plain text, and proprietary formats are used to represent resources. Representational State Transfer (REST) provides the flexibility to represent a single resource in multiple formats.

Before you begin

Define the resources in the JAX-RS web application.

About this task

Resources have representations. A resource representation is the content in the HTTP message that is sent to, or returned from the resource using the URI. Each representation that a resource supports has a corresponding media type. For example, if a resource is going to return content formatted as XML, you can use `application/xml` as the associated media type in the HTTP message.

Depending on the requirements of your application, resources can return representations in a preferred single format or in multiple formats. For example, resources that are accessed using JavaScript clients might prefer JSON representations because JSON is easy to consume.

JAX-RS provides @Consumes and @Produces annotations to declare the media types that are acceptable for a resource method to read and write.

JAX-RS also maps Java types to and from resource representations using entity providers. A `MessageBodyReader` entity provider reads a request entity and deserializes the request entity into a Java type. A `MessageBodyWriter` entity provider serializes from a Java type into a response entity.

Table 148. Standard entity providers and basic Java types. This table includes the standard entity providers and basic Java types that are included in the JAX-RS runtime environment, along with the corresponding supported content types.

Java type	MessageBodyReader	MessageBodyWriter	Supported Content types
byte[]	X	X	*/*
java.io.InputStream	X	X	*/*
java.io.Reader	X	X	*/*
java.lang.String	X	X	*/*
java.io.File	X	X	*/*
javax.activation.DataSource	X	X	*/*
javax.xml.transform.Source	X	X	text/xml, application/xml, application/*+xml
javax.ws.rs.core.MultivaluedMap	X	X	application/x-www-form-urlencoded
JAXB types	X	X	text/xml, application/xml, application/*+xml
javax.ws.rs.core.StreamingOutput		X	*/*

If a `String` value is used as the request entity parameter, the `MessageBodyReader` entity provider deserializes the request body into a new `String`. If a JAXB type is used as the return type on a resource method, the MessageBodyWriter serializes the Java Architecture for XML Binding (JAXB) object into a response body.

If you need a custom mapping from a Java type to a specific representation, see the information for using an application-defined entity provider.

If your client can handle multiple formats and you want the server to determine the best resource representation to return, read about using content negotiation in JAX-RS applications to serve multiple content types.

The specifications for XML, JSON, and Atom provide details regarding the formats of resource representations for applications. See the specifications to learn more about the formats of resource representations.

Procedure

1. Determine the resource representation format such as XML, JSON, or ATOM to use for either the request or the response.
2. Add the @Consumes and @Produces annotations appropriately to the resource method.
3. If the resource needs to read the content of the request, add a request entity parameter to the resource method. The request entity parameter is a single Java parameter on the method that does not have an annotation.

4. If the resource method returns content in the response, return a Java object that is writable by a JAX-RS entity provider. This Java object is mapped to the response entity in the HTTP response. The returned object must be a JAX-RS supported Java type or wrapped in a javax.ws.rs.core.Response or javax.ws.rs.core.GenericEntity type.

Results

You have mapped the request entities to the resource method entity parameter and any response objects that are returned are mapped to the response entity for the resource representation.

Example

The following example illustrates defining XML as the resource representation for a RESTful bookstore application.

1. Identify the resource methods that you want to read the request entity or return a response entity.

   In the retrieveSpecificBookInformation method example that follows, there is no request entity that is read. However, there is a response object that is returned. This object wraps a JAXB object that contains the entity information. Adding the @Produces annotation on the resource method with a media type of `application/xml` indicates that the resource method always returns an XML representation with a media type of `application/xml`.

   Clients that have an Accept HTTP request header value compatible with the `application/xml` media type invoke the method correctly.

   Clients that do not have an Accept HTTP header value compatible with the `application/xml` media type automatically receive a `406 Not Acceptable` response status which indicates that the server cannot produce an acceptable response.

   The following example identifies the resource methods that read the request entity or return a response entity:

```
/*
 * Book.java
 * This class represents individual books. The @Produces annotation specifies a media type of application/xml.
 */
@Path("/bookstore/books/{bookID}")
public class Book {
  @GET
  @Produces("application/xml")
  public javax.ws.rs.core.Response retrieveSpecificBookInformation(@PathParam("bookID") String theBookID,
   @Context javax.ws.rs.core.HttpHeaders headers) {
   /* ... */
   return
    Response.ok(/* JAXB object to represent response body entity */).expires(/* Expires response header value*/).header("CustomHeaderName", "CustomHeaderValue").build();
   }
   @PUT
   public String updateBookInformation(@PathParam("bookID") String theBookID, String theRequestEntity,
    @javax.ws.rs.HeaderParam("Content-Length") String contentLengthHeader) { /* ... */ }

   @DELETE
   public void removeBook(@PathParam("bookID") String theBookID) { /* ... */ }
}
```

2. Identify the resource methods that need to consume the request information.

   In the following snippet, the PUT method on the book resource accepts the request entity content if a media type of `text/plain` is sent, as defined in the @Consumes annotation. This method returns content with a `text/plain` representation as specified in the @Produces annotations.

   If a client does not send a message with a Content-Type value of `text/plain`, then the PUT resource method is not invoked. If `Content-Type: application/xml` is sent in the HTTP request headers, the `updateBookInformation` Java method is not be called.

   The DELETE method neither reads a request entity nor returns a response entity; therefore, it does not require either an @Consumes or an @Produces annotation.

   The following example identifies the resource methods that consume the request information:

```
/*
 * Book.java
 * This class represents represent individual books with custom headers.
 */
@Path("/bookstore/books/{bookID}")
public class Book {
  @GET
  @Produces("application/xml")
  public javax.ws.rs.core.Response retrieveSpecificBookInformation(@PathParam("bookID") String theBookID, @Context javax.ws.rs.core.HttpHeaders headers) {
```

```
    /* ... */
    return Response.ok(/* JAXB object to represent response body entity */).expires(/* Expires response header value).header("CustomHeaderName", "CustomHeaderValue").build();
  }
  @PUT
  @Consumes("text/plain")
  @Produces("text/plain")
  public String updateBookInformation(@PathParam("bookID") String theBookID, String theRequestEntity, @javax.ws.rs.HeaderParam("Content-Length") String contentLengthHeader) {
    /* ... */
    String responseEntity = /* a plain text representation */;
    return responseEntity;
  }

  @DELETE
  public void removeBook(@PathParam("bookID") String theBookID) { /* ... */ }
}
```

What to do next

See the JAX-RS specification for a list of all the standard media formats that are supported for representations.

Advanced users might consider defining custom mappings of Java types to representations or using content negotiation for clients to negotiate preferred resource representations. To learn more about these options, see the using custom defined entity formats information or the serving multiple content types with content negotiation information.

Defining parameters for request representations to resources in RESTful applications

Parameters are used to pass and add additional information to a request. You can use parameters as part of the URL or in the headers. Path parameters, matrix parameters, query parameters, header parameters, and cookie parameters are useful for passing in additional information to a request.

About this task

Multiple parameters types exist. Java API for RESTful Web Services (JAX-RS) enables easy access to all the types of parameters using annotated injected parameters.

You can use any basic Java primitive type including java.lang.String as parameters, as well as Java types with a constructor that uses a single String or a valueOf(String) static method. Additionally, you can use `List`, `SortedSet`, and `Set` interfaces where the generic type is one of the previously mentioned types, such as a Set when a parameter can have multiple values. If you need to parse requests, then use String as the parameter type to enable you to complete basic inspection and customization of error path responses.

JAX-RS provides the following annotations to use on resource method parameters to specify that the resource method can be invoked with correct parameter values.

javax.ws.rs.PathParam annotation

Path parameters are part of the URL. For example, the URL can include `/collection/{item}`, where `{item}` is a path parameter that identifies the item in the collection. Because path parameters are part of the URL, they are essential in identifying the request.

If parts of the URL are parameters, you can use a @javax.ws.rs.PathParam annotated parameter; for example:

```
@javax.ws.rs.Path("/bookstore/books/{bookId}")
public class BooksCollection {
    @javax.ws.rs.GET
    public String getSpecificBookInfo(@javax.ws.rs.PathParam("bookId") String theBookId) {
        /* theBookId would contain the next path segment after /bookstore/books/  */
    }
}
```

In this example, requests to `/bookstore/books/12345` assigns the value of `12345` to the `theBookId` variable.

javax.ws.rs.MatrixParam annotation

Matrix parameters are part of the URL. For example, if the URL includes the path segment, `/collection;itemID=itemIDValue`, the matrix parameter name is `itemID` and `itemIDValue` is the value.

You can read matrix parameters with a @javax.ws.rs.MatrixParam annotated parameter; for example:

```
@javax.ws.rs.Path("/bookstore/books")
public class BooksCollection {
    @javax.ws.rs.GET
    public String getBookCollectionInfo(@javax.ws.rs.MatrixParam("page") int page, @javax.ws.rs.MatrixParam("filter") String filter) {
        /* This statement uses the page and filter parameters. */
    }
}
```

In this example, requests to`/bookstore/books;page=25;filter=test` invoke the `getBookCollectionInfo` parameter so that the value for the `page` variable is set to `25` and the value for `filter` variable is set to `test`.

javax.ws.rs.QueryParam annotation

Query parameters are appended to the URL after a "?" with name-value pairs. For instance, if the URL is `http://example.com/collection?itemID=itemIDValue`, the query parameter name is `itemID` and `itemIDValue` is the value. Query parameters are often used when filtering or paging through HTTP GET requests.

You can read query parameters with a @javax.ws.rs.QueryParam annotated parameter; for example:

```
@javax.ws.rs.Path("/bookstore/books")
public class BooksCollection {
    @javax.ws.rs.GET
    public String getBookCollectionInfo(@javax.ws.rs.QueryParam("page") int page, @javax.ws.rs.QueryParam("filter") String filter) {
        /* This statement uses the page and filter parameters. */
    }
}
```

In this example, requests to`/bookstore/books;page=25;filter=test` invoke the `getBookCollectionInfo` parameter so that the value for the `page` variable is set to `25` and the value for `filter` variable is set to `test`.

javax.ws.rs.HeaderParam annotation

Header parameters are HTTP headers. While there are pre-defined HTTP headers, you can also use custom headers. Headers often contain control metadata information for the client, intermediary, or server.

If a HTTP request header must be read, use the @javax.ws.rs.HeaderParam annotation; for example:

```
@javax.ws.rs.Path("/bookstore/books/")
public class BooksCollection {
    @javax.ws.rs.GET
    public String getBookCollectionInfo(@javax.ws.rs.HeaderParam("Range") String rangeValue) {
        /* The rangeValue variable contains the value of the HTTP request header "Range" */
    }
}
```

In this example, requests to `/bookstore/books/` with a `Range` HTTP request header value of `bytes=0-499` invokes the method with `bytes=0-499` as the value for the `rangeValue` variable.

javax.ws.rs.CookieParam annotation

Cookie parameters are special HTTP headers. While cookies are associated with storing session identification or stateful data that is not accepted as RESTful, cookies can contain stateless information.

If an HTTP cookie is sent, such as `mycustomid=customvalue123`, you can retrieve the value of the `mycustomid` variable using the following example:

```
@javax.ws.rs.Path("/bookstore/books/")
public class BooksCollection {
    @javax.ws.rs.GET
```

```
    public String getBookCollectionInfo(@javax.ws.rs.CookieParam("mycustomid") String mycustomid) {
        /* The cookie value is passed to the mycustomid variable. */
    }
}
```

javax.ws.rs.FormParam annotation

Form parameters are used when submitting a HTML form from a browser with a media type of `application/x-www-form-urlencoded`. The form parameters and values are encoded in the request message body in the form like the following: `firstParameter=firstValue &secondParameter=secondValue`. The javax.ws.rs.FormParam annotation enables easy access to individual form parameter values.

If a form is submitted and the entity value is `firstName=Bob&lastName=Smith`, you can retrieve the values of the form parameters using the following example:

```
@javax.ws.rs.Path("/customer")
public class Custommer {
    @javax.ws.rs.POST
    public String postCustomerInfo(@javax.ws.rs.FormParam("firstName") String firstName, @javax.ws.rs.FormParam("lastName") String lastName) {
        /* firstName would be "Bob" and secondName would be "Smith" */
    }
}
```

Note: You can either use a single unannotated parameter to represent the message body or use multiple FormParam annotated parameters, but not both. Because the FormParam requires the request message body to be read and the message body is represented as a byte stream, the message body cannot be read again. The following code is not valid:

```
@javax.ws.rs.Path("/bookstore/books")
public class BooksCollection {
    @javax.ws.rs.POST
    public String postSpecificBookInfo(@javax.ws.rs.FormParam("bookId") String theBookId, String theRequestEntity) {
        /* This code is invalid.  Can only use FormParam or a request entity parameter like "String theRequestEntity" and not both */
    }
}
```

Choose one of the following ways to define variables to read parameters.

Procedure

- Add a parameter to the resource method by using an appropriate JAX-RS parameter annotation on the method to identify the type of parameter. You can read multiple types of parameters from a request; for example:

```
@javax.ws.rs.Path("/bookstore/books/")
public class BooksCollection {
    @javax.ws.rs.GET
    public String getBookCollectionInfo(@javax.ws.rs.QueryParam("page") int page, @javax.ws.rs.QueryParam("filter") String filter) {
        /* This statement uses the page and filter parameters. */
    }
}
```

  Issuing an HTTP GET request using a web browser or other HTTP client, such as `http://<host_name>:<port>/<context_root>/<servlet_path>/bookstore/books?page=10&filter=FilterValue`, invokes the getBookCollectionInfo() method with the page set to 10 and filter set to `FilterValue`.

- Add the parameter annotation on the fields, JavaBeans properties, and constructor arguments; for example:

```
@javax.ws.rs.Path("/bookstore/books/")
public class BooksCollection {
    @javax.ws.rs.QueryParam("page") int page;

    String filter;

    @javax.ws.rs.QueryParam("filter")
    public void setFilter(String filter) {
        this.filter = filter;
    }

    @javax.ws.rs.GET
    public String getBookCollectionInfo() {
        /* This statement uses the page and filter parameters. */
    }
}
```

Issuing an HTTP GET request using a web browser or other HTTP client, such as `http://<host_name>:<port>/<context_root>/<servlet_path>/bookstore/books?page=10&filter=FilterValue`, also invokes the getBookCollectionInfo() method with the page set to 10 and filter set to `FilterValue`.

Results

Your resource methods are defined so that they can be invoked with appropriate parameter values.

Example

Defining exception mappers for resource exceptions and errors

Java API for RESTful Web Services (JAX-RS) applications can produce exceptions and errors. The default behavior is to use the exception handling functionality of application container such as JavaServer Pages (JSP) error pages. However, you can customize the error handling and send specific responses back when an exception or error occurs.

About this task

JAX-RS resource methods, like any Java method, can throw checked and unchecked exceptions. By default, an unchecked runtime exception or error occurs in the container again. A checked exception is wrapped in a `ServletException` for resources running in the web container. Therefore, a developer can use error handling facilities such as JSP error pages to handle exceptions thrown from a JAX-RS application.

JAX-RS introduced the exception, `javax.ws.rs.WebApplicationException`. A developer can specify a specific error class name or `javax.ws.rs.core.Response` object when creating a `WebApplicationException`. When the `WebApplicationException` is thrown, the information included in the exception by way of a status class name or Response object is used to serialize a response.

If you cannot throw the exception, `WebApplicationException`, in your code and you cannot use the error handling facilities in the web container, but you want to use a custom error response, then you can create a customized JAX-RS `javax.ws.rs.ext.ExceptionMapper` class to map exceptions to HTTP error responses.

The following procedure illustrates how to write a custom `ExceptionMapper` class.

Procedure

1. Create a class that implements the `javax.ws.rs.ext.ExceptionMapper` class and annotate the class with the `javax.ws.rs.ext.Provider` annotation. This step assumes that your JAX-RS resource can throw the exception, `MyCustomException`, in its methods. The following example illustrates a simple `ExceptionMapper` class:

```
import javax.ws.rs.core.Response;
import javax.ws.rs.ext.ExceptionMapper;
import javax.ws.rs.ext.Provider;

@Provider
public class CustomExceptionMapper implements ExceptionMapper<MyCustomException> {

    public Response toResponse(MyCustomException exception) {
        return null;
    }

}
```

2. In the `toResponse(MyCustomException)` method, return a `Response` object that contains the customized error response. The following example illustrates a customized `ExceptionMapper.toResponse(MyCustomException)` method:

```
@Provider
public class CustomExceptionMapper implements ExceptionMapper<MyCustomException> {

    public Response toResponse(MyCustomException exception) {
        return Response.status(500).entity("Unfortunately, the application cannot
```

```
            process your request at this time.").type("text/plain").build();
    }

}
```

You can have additional code where you log an error, inspect the exception thrown, or use more complex logic.

3. Package the compiled custom `ExceptionMapper` class with your web application project. If you rely on the annotation scanning capabilities to find all of your JAX-RS classes in your web application, no additional steps are required. However, if you return all of the relevant JAX-RS resource classes and providers in a JAX-RS application subclass method, then you must also add the custom `ExceptionMapper` class to the returned set. The following example illustrates a preexisting `javax.ws.rs.core.Application` subclass:

```
import java.util.HashSet;
import java.util.Set;

import javax.ws.rs.core.Application;

public class MyApplication extends Application {

    @Override
    public Set<Class<?>> getClasses() {
        Set<Class<?>> classes = new HashSet<Class<?>>();
        classes.add(CustomExceptionMapper.class);
        /* add your additional JAX-RS classes here */
        return classes;
    }
}
```

When exceptions occur in your JAX-RS resource methods, you can customize the HTTP error response so that a user cannot see a stack trace or potentially confidential data. Use an `ExceptionMapper` or the exception handling functionality in the web container to give more helpful responses if the application is not behaving correctly.

Results

You have written a custom `ExceptionMapper` to handle exceptions in your JAX-RS web application.

Developing JAX-RS web applications

Getting started with IBM JAX-RS

JAX-RS is a collection of interfaces and Java annotations that simplifies development of server-side REST applications. By using JAX-RS technology, Representational State Transfer (REST) applications are easier to develop and easier to consume when compared to other types of distributed systems.

About this task

JAX-RS is a Java API for developing REST applications quickly. While JAX-RS provides a faster way of developing web applications than servlets, the primary goal of JAX-RS is to build RESTful services. JAX-RS 1.0 defines a server-side component API to build REST applications. The IBM implementation of JAX-RS provides an implementation of the JAX-RS (JSR 311) specification.

Use this Getting Started guide to help you quickly develop and deploy a simple JAX-RS web application.

This procedure illustrates developing a simple Hello World service that is packaged inside a web application archive (WAR) module.

Procedure

1. Create a Java class. This class is used to represent a type of resource.

```
package com.ibm.jaxrs.sample;

public class HelloWorldResource {

}
```

2. Annotate the Java class with a `javax.ws.rs.Path` annotation. The value of the annotation is the relative part of the URL after the application context. The application context is fully defined during deployment. In JAX-RS terminology, this class is known as a root resource.

```
package com.ibm.jaxrs.sample;

@javax.ws.rs.Path("/helloworld")
public class HelloWorldResource {

}
```

3. Create a Java method that returns a `Hello World!` response. It is intended for the method to be invoked when an HTTP request is received.

```
package com.ibm.jaxrs.sample;

@javax.ws.rs.Path("/helloworld")
public class HelloWorldResource {

    public String sayHelloWorld() {
        return "Hello World!";
    }
}
```

4. Add a `javax.ws.rs.GET` annotation to the Java method.

   Now, whenever an HTTP GET request is received by the application to the `/helloworld` path, the `sayHelloWorld` Java method is invoked. The response message body will contain `Hello World!` as its content.

```
package com.ibm.jaxrs.sample;

@javax.ws.rs.Path("/helloworld")
public class HelloWorldResource {

    @javax.ws.rs.GET
    public String sayHelloWorld() {
        return "Hello World!";
    }
}
```

   The resource implementation is now complete.

5. You must create the JAX-RS `javax.ws.rs.core.Application` configuration subclass. This subclass needs to return the set of Java classes that is relevant to the JAX-RS runtime environment.

```
package com.ibm.jaxrs.sample;

public class HelloWorldAppConfig extends javax.ws.rs.core.Application {
    public Set<Class<?>> getClasses() {
        Set<Class<?>> classes = new HashSet<Class<?>>();
        classes.add(com.ibm.jaxrs.sample.HelloWorldResource.class);
        return classes;
    }
}
```

6. Create the `web.xml` web module configuration file.

   The file tells the web container that the web module contains the IBM JAX-RS REST servlet. You must initialize the IBM JAX-RS Rest servlet with the application configuration class.

```
<?xml version="1.0" encoding="UTF-8"?>
<web-app id="WebApp_9" version="2.4" xmlns=http://java.sun.com/xml/ns/j2ee xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
         xsi:schemaLocation="http://java.sun.com/xml/ns/j2ee http://java.sun.com/xml/ns/j2ee/web-app_2_4.xsd">
    <servlet>
        <servlet-name>HelloWorldApp</servlet-name>
        <servlet-class>com.ibm.websphere.jaxrs.server.IBMRestServlet</servlet-class>
        <init-param>
            <param-name>javax.ws.rs.Application</param-name>
            <param-value>com.ibm.jaxrs.sample.HelloWorldAppConfig</param-value>
        </init-param>
        <load-on-startup>1</load-on-startup>
    </servlet>
    <servlet-mapping>
        <servlet-name>HelloWorldApp</servlet-name>
        <url-pattern>/rest/*</url-pattern>
    </servlet-mapping>
</web-app>
```

See the servlet mapping that is specified in the previous example. The pattern is used to help determine the final URL of the RESTful service.

7. Add the `j2ee.jar` file to the classpath.

   Get the `j2ee.jar` file from the `app_server_root/dev/JavaEE` directory and add the JAR file to the classpath. Compile the classes.

8. Assemble the web application.

   By using the **jar** command-line tool that is included with the JDK, run the following command:

```
jar cvf helloworld-jaxrs.war *
```

   This command creates a WAR file.

9. Deploy the application onto the application server.

   When deploying the application, you might be prompted to provide a value for the context root of the module. The context root is used to define the application context.

   When using the IBM JAX-RS servlet, the following URL defines the application context:

```
http://<your_hostname>:<your Web_container_port>/<context_root_of_Web_application>/servlet_mapping_pattern
```

   Root resource URLs that are specified by the `@javax.ws.rs.Path` values are relative to the application context root. Therefore, if the context root is defined as `myapplication` during deployment, the URL pattern is defined in the `web.xml` file as `/rest/*`, and the Java root resource class has a `@javax.ws.rs.Path` value of `/helloworld`. An example of the final URL is:

```
http://localhost:9080/myapplication/rest/helloworld
```

   Now, you can send a client request to the final URL by using a web browser or any other HTTP client.

Results

You have developed and deployed a JAX-RS web application on the application server.

Setting up a development environment for JAX-RS applications

The application server provides command-line tools to develop web services clients and implementations that are based on the Java API for RESTful Web Services (JAX-RS) specification. You must set up your development environment before you start developing web services.

Before you begin

Before you can set up a web services development environment within WebSphere Application Server, you must install WebSphere Application Server. For detailed information about installing the application server, read about installing your application server environment.

To develop JAX-RS applications, the JAX-RS libraries must be added to the class path definition. See the information for your assembly tools to understand how to include libraries on the class path for the JAX-RS application.

About this task

Set up a web services development environment by completing the following actions.

Procedure

1. Set up the environment.

   Run the **setupCmdLine** script from the `. /profile_root/<application_server>/bin` directory.

2. Configure the path. You can add the WebSphere and Java `bin` directories to your path by typing:

```
set PATH=%WAS_PATH%;%PATH%
```

Results

You have set up an environment so that you can develop RESTful web services.

What to do next

Develop your JAX-RS application and configure the `web.xml` file for the JAX-RS servlet.

Development and assembly tools

You can use an Integrated Development Environment to develop, assemble, and deploy Java Platform, Enterprise Edition (Java EE) modules for WebSphere Application Server.

The IBM Rational Application Developer for WebSphere Software product and the IBM WebSphere Application Server Developer Tools for Eclipse product are supported tools for integrated development environments.

This information center refers to the products as the *assembly tools*. However, you can use the products to do more than assemble modules. Use these tools in an integrated development environment to develop, assemble, and deploy Java EE modules.

The Rational Application Developer for WebSphere Software is a more extensive set of tools supporting enterprise development. This workbench has integrated support for WebSphere Application Server Version 6.1 and later. This workbench also supports both the OSGi and Java EE programming models, and contains wizards and visual editors to help you develop Web 2.0, Service Component Architecture (SCA), Java, and Java EE applications. This product contains code quality tools to help you analyze code and improve performance. This product integrates with Rational Team Concert to provide a team-based environment to help developers share information and work collaboratively. The Trial download for Rational Application Developer is available at `http://www.ibm.com/developerworks/downloads/r/rad/`.

IBM WebSphere Application Server Developer Tools for Eclipse is a lightweight set of tools for developing, assembling, and deploying Java EE applications to WebSphere Application Server Version 7.0 and 8.x. This workbench integrates with the application server to help you to quickly deploy and test applications. This product contains wizards and visual editors that support the Java EE programming model.

For documentation on the tools, see “Rational Application Developer documentation.” Topics on application assembly in this information center supplement that documentation.

Important: The assembly tools run on Windows and Linux Intel platforms. Users of WebSphere Application Server on all platforms must assemble their modules using an assembly tool installed on Windows or Linux Intel platforms. To install an assembly tool, follow instructions available with the tool.

Directory conventions

References in product information to *app_server_root*, *profile_root*, and other directories imply specific default directory locations. This article describes the conventions in use for WebSphere Application Server.

Default product locations - z/OS

app_server_root

Refers to the top directory for a WebSphere Application Server node.

The node may be of any type—application server, deployment manager, or unmanaged for example. Each node has its own *app_server_root*. Corresponding product variables are *was.install.root* and *WAS_HOME*.

The default varies based on node type. Common defaults are *configuration_root*/AppServer and *configuration_root*/DeploymentManager.

configuration_root
Refers to the mount point for the configuration file system (formerly, the configuration HFS) in WebSphere Application Server for z/OS.

The *configuration_root* contains the various *app_server_root* directories and certain symbolic links associated with them. Each different node type under the *configuration_root* requires its own cataloged procedures under z/OS.

The default is /wasv8config/*cell_name*/*node_name*.

plug-ins_root
Refers to the installation root directory for Web Server Plug-ins.

profile_root
Refers to the home directory for a particular instantiated WebSphere Application Server profile.

Corresponding product variables are *server.root* and *user.install.root.*

In general, this is the same as *app_server_root*/profiles/*profile_name*. On z/OS, this will always be *app_server_root*/profiles/default because only the profile name "default" is used in WebSphere Application Server for z/OS.

smpe_root
Refers to the root directory for product code installed with SMP/E or IBM Installation Manager.

The corresponding product variable is *smpe.install.root*.

The default is /usr/lpp/zWebSphere/V8R5.

Configuring JAX-RS web applications

Configuring JAX-RS applications using JAX-RS 1.1 methods

You can configure Java API for RESTful Web Services (JAX-RS) applications in multiple ways depending on your needs. To take advantage of the Java Platform, Enterprise Edition (Java EE) 6 functionality, you can use the annotation scanning capabilities. By using annotation scanning, you can omit a JAX-RS javax.ws.rs.core.Application subclass or have a minimally defined javax.ws.rs.core.Application subclass.

About this task

The JAX-RS 1.1 specification supports several new ways to configure a JAX-RS application. You can use the built-in annotation scanning to help automatically configure the application. You can optionally add javax.ws.rs.core.Application subclasses to your application and then add the URL patterns required using either the javax.ws.rs.ApplicationPath annotation or a web.xml servlet definition. When using the IBM JAX-RS implementation, you do not have to specify the servlet class implementation because it is automatically added to the configuration of the web module by the time the JAX-RS application is started.

When using a web.xml file, you must use a Java Servlet 3.0 web.xml file.

Procedure

- Configure the JAX-RS application with only one JAX-RS default application in the web.xml file. Use this method if you only need one JAX-RS application and all resource classes are located after a single URL pattern. You can also specify security constraints with this method, if needed.
  1. Add all of your JAX-RS resource and provider classes to the WEB-INF/classes or WEB-INF/lib directory for your web application. You do not need to add a javax.ws.rs.core.Application subclass to your web application.
  2. In your web.xml file, add a servlet definition with javax.ws.rs.core.Application as the servlet name. You do not need to add a servlet-class. You must add a servlet URL pattern to the web.xml file.

The application server runtime environment adds the specific IBM JAX-RS implementation to the configuration of the web module by the time the JAX-RS application is started; for example:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-app xmlns="http://java.sun.com/xml/ns/j2ee" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:schemaLocation="http://java.sun.com/xml/ns/j2ee
http://java.sun.com/xml/ns/j2ee/web-app_3_0.xsd"
 version="3.0">
 <servlet>
  <servlet-name>javax.ws.rs.core.Application</servlet-name>
 </servlet>
 <servlet-mapping>
  <servlet-name>javax.ws.rs.core.Application</servlet-name>
  <url-pattern>/rest/*</url-pattern>
 </servlet-mapping>
</web-app>
```

The JAX-RS resources are now available at a URL such as:

http://{*hostname*}:{*port*}/{context_root_of_Web_ module}/{*value_of_Web.xml_URL_pattern*}/{*value_of_@javax.ws.rs.Path*}

- Configure the JAX-RS application using the javax.ws.rs.core.Application subclass and the web.xml file. Use this method if you need multiple JAX-RS applications or require only specific resources in certain JAX-RS applications with specific URL patterns. You can also specify security constraints with this method, if needed.
  1. Create a javax.ws.rs.core.Application subclass. In your javax.ws.rs.core.Application subclass getClasses() or getSingletons() methods, return the relevant JAX-RS resources and providers. If you return empty sets in both the getClasses() and getSingletons() methods, all the JAX-RS resource and provider classes that are found in the application are added to the JAX-RS application subclass; for example:

```
package com.example;

public class MyApplication extends javax.ws.rs.core.Application {

}
```

     This example uses the default implementations of javax.ws.rs.core.Application subclass getClasses() and getSingletons() methods that return empty sets. Therefore, all relevant JAX-RS classes are assumed to be returned by the javax.ws.rs.core.Application subclass.
  2. Add the javax.ws.rs.core.Application subclass to your web application.
  3. Add a partial servlet definition in the web.xml file. The servlet name is the full name of the javax.ws.rs.core.Application subclass. Do not define the servlet-class. You must add a servlet URL pattern to the web.xml file. The application server runtime environment adds the specific IBM JAX-RS implementation to the configuration of the web module by the time the JAX-RS application is started; for example:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-app xmlns="http://java.sun.com/xml/ns/j2ee" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:schemaLocation="http://java.sun.com/xml/ns/j2ee
http://java.sun.com/xml/ns/j2ee/web-app_3_0.xsd"
 version="3.0">
 <servlet>
  <servlet-name>com.example.MyApplication</servlet-name>
 </servlet>
 <servlet-mapping>
  <servlet-name>com.example.MyApplication</servlet-name>
  <url-pattern>/rest/*</url-pattern>
 </servlet-mapping>
</web-app>
```

     The JAX-RS resources are now available at a URL such as:

http://{*hostname*}:{*port*}/{context_root_of_Web_ module}/{*value_of_Web.xml_URL_pattern_for_Application_subclass*}/{*value_of_@javax.ws.rs.Path*}

- Configure the JAX-RS application without a web.xml file. Use this method if you do not want to use a web.xml file. When you use this method, you cannot specify security constraints. To specify security constraints, you must use a web.xml file.

1. Create a javax.ws.rs.core.Application subclass. In your javax.ws.rs.core.Application subclass getClasses() or getSingletons() methods, return the relevant JAX-RS resources and providers. If you return empty sets in both the getClasses() and getSingletons() methods, all the JAX-RS resource and provider classes that are found in the application are added to the JAX-RS application subclass; for example:

```
package com.example;

public class MyApplication extends javax.ws.rs.core.Application {

}
```

   This example uses the default implementations of javax.ws.rs.core.Application subclass getClasses() and getSingletons() methods that return empty sets. Therefore, all relevant JAX-RS classes are assumed to be returned by the javax.ws.rs.core.Application subclass.
2. Add a javax.ws.rs.ApplicationPath annotation to the javax.ws.rs.core.Application subclass. The ApplicationPath annotation is supported with the JAX-RS 1.1 specification. The value of the ApplicationPath annotation is used as the servlet URL pattern which is equivalent to the servlet URL pattern in the web.xml file; for example:

```
package com.example;

@javax.ws.rs.ApplicationPath("rest")
public class MyApplication extends javax.ws.rs.core.Application {

}
```

3. Add the javax.ws.rs.core.Application subclass to your web application. When the application is started, the resources are available at the following URL:

```
http://{hostname}:{port}/{context_root_of_Web_ module}/{value_of_@javax.ws.rs.ApplicationPath}}/{value_of_@javax.ws.rs.Path}
```

Results

You have configured your JAX-RS application using JAX-RS 1.1 supported methods by taking advantage of annotation scanning to help automatically configure the application.

Configuring the web.xml file for JAX-RS servlets

The `web.xml` file contains information about the structure and external dependencies of web components in the module and describes how the components are used at run time. To enable the web container to run Java API for RESTful Web Services (JAX-RS) applications, you can configure the `web.xml` file to point directly to the IBM JAX-RS servlet. When using servlets, you can define a servlet path in the `web.xml` file that is appended to the base URL.

About this task

You can configure the `web.xml` file for your web application to enable the JAX-RS application code. You can specify an IBM specific JAX-RS servlet to use to run your JAX-RS code. The `web.xml` file provides configuration and deployment information for the web components that comprise a web application. Read about configuring the `web.xml` file for JAX-RS to learn more about this deployment descriptor file.

When using servlets, any servlet path that is defined in the `web.xml` is appended to the base URL. For example, if a root resource has a @javax.ws.rs.Path value of `myresource` and a servlet path of `myservletpath`, the final URL of the resource is `http://<your_hostname>:<your Web_container_port>/<context_root_of_Web_application>//myservletpath/myresource`.

Procedure

1. Open the `WEB-INF/web.xml` file.
2. Add the following servlet definition to the `WEB-INF/web.xml` file. In the following servlet, you must replace the *unique_servlet_name* with your unique servlet name. Also, replace the *Java_class_name* variable with the full Java package and class name of the javax.ws.rs.core.Application subclass.

```
<servlet>
     <servlet-name>unique_servlet_name</servlet-name>
     <servlet-class>com.ibm.websphere.jaxrs.server.IBMRestServlet</servlet-class>
     <init-param>
         <param-name>javax.ws.rs.Application</param-name>
         <param-value>Java_class_name </param-value>
     </init-param>
     <load-on-startup>1</load-on-startup>
</servlet>
```

3. (optional) If there are multiple JAX-RS application subclasses needed in the same web application, you must include an additional servlet initialization parameter, `requestProcessorAttribute`, in the servlet definition that you add to the `WEB-INF/web.xml` file. In the following servlet, you must replace the *unique_servlet_name* with your unique servlet name, the *Java_class_name* variable with the full Java package and class name of the javax.ws.rs.core.Application subclass, and the *unique_identifier* variable with a unique identifier.

```
<servlet>
     <servlet-name>unique_servlet_name_a</servlet-name>
     <servlet-class>com.ibm.websphere.jaxrs.server.IBMRestServlet</servlet-class>
     <init-param>
         <param-name>javax.ws.rs.Application</param-name>
         <param-value>Java_class_name_a </param-value>
     </init-param>
     <init-param>
         <param-name>requestProcessorAttribute</param-name>
         <param-value>unique_identifier_a</param-value>
     </init-param>
     <load-on-startup>1</load-on-startup>
</servlet>
<servlet>
     <servlet-name>unique_servlet_name_b</servlet-name>
     <servlet-class>com.ibm.websphere.jaxrs.server.IBMRestServlet</servlet-class>
     <init-param>
         <param-name>javax.ws.rs.Application</param-name>
         <param-value>Java_class_name_b</param-value>
     </init-param>
     <init-param>
         <param-name>requestProcessorAttribute</param-name>
         <param-value>unique_identifier_b </param-value>
     </init-param>
     <load-on-startup>1</load-on-startup>
</servlet>
```

4. Add servlet mappings in the `WEB-INF/web.xml` file for each servlet definition. The servlet path is appended to the context root of the web application.

```
<servlet-mapping>
     <servlet-name>servlet_name</servlet-name>
     <url-pattern>servlet_pattern_path</url-pattern>
</servlet-mapping>
```

   For example, if the *servlet_pattern_path* is `/restapi/*`, all valid requests start at the following URL:

```
http://<your_hostname>:<your Web_container_port>/<context_root_of_Web_application>/restapi/
```

Results

After editing the `WEB-INF/web.xml` file, the web application is configured for the JAX-RS application.

Example

The following example illustrates a `WEB-INF/web.xml` file that configures a servlet path for a JAX-RS application. The servlet path that is defined in the `web.xml` file is appended to the base URL.

```
<?xml version="1.0" encoding="UTF-8"?>
<web-app id="WebApp_9" version="2.4"
xmlns=http://java.sun.com/xml/ns/j2ee
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="http://java.sun.com/xml/ns/j2ee http://java.sun.com/xml/ns/j2ee/web-app_2_4.xsd">

<servlet>
     <servlet-name>RestApplication1</servlet-name>
     <servlet-class>com.ibm.websphere.jaxrs.server.IBMRestServlet</servlet-class>
     <init-param>
         <param-name>javax.ws.rs.Application</param-name>
         <param-value>com.ibm.rest.sample.app1.MyApplication</param-value>
     </init-param>
     <init-param>
         <param-name>requestProcessorAttribute</param-name>
```

```
        <param-value>restApplication1ProcessorID</param-value>
    </init-param>
    <load-on-startup>1</load-on-startup>
</servlet>

<servlet>
    <servlet-name>OtherRestApplicationServlet</servlet-name>
    <servlet-class>com.ibm.websphere.jaxrs.server.IBMRestServlet</servlet-class>
    <init-param>
        <param-name>javax.ws.rs.Application</param-name>
        <param-value>com.ibm.rest.other.sample.OtherApplication </param-value>
    </init-param>
    <init-param>
       <param-name>requestProcessorAttribute</param-name>
        <param-value>otherRestApplicationID </param-value>
    </init-param>
   <load-on-startup>1</load-on-startup>
</servlet>

<servlet-mapping>
    <servlet-name> RestApplication1</servlet-name>
    <url-pattern>/rest/api/*</url-pattern>
</servlet-mapping>

<servlet-mapping>
    <servlet-name>OtherRestApplicationServlet /servlet-name>
    <url-pattern>/other/*</url-pattern>
</servlet-mapping>
</web-app>
```

What to do next

Assemble the web application.

Configuring the web.xml file for JAX-RS filters

The web.xml file contains information about the structure and external dependencies of web components in the module and describes how the components are used at run time. To enable the web container to run Java API for RESTful Web Services (JAX-RS) applications, you can configure the web.xml file to define filters that indicate the possible URLs on which the filter can be invoked.

About this task

You can configure the web.xml file for your web application to enable the JAX-RS application code. You can specify an IBM specific JAX-RS filter to use to run your JAX-RS code. The web.xml file provides configuration and deployment information for the web components that comprise a web application. Read about configuring the web.xml file for JAX-RS to learn more about this deployment descriptor file.

When using servlets, any servlet path defined in the web.xml is appended to the base URL. Filters do not append a path to the resource base URL. Instead, filter URL mappings indicate the possible URLs on which the filter can be invoked. For instance, if a root resource has a @javax.ws.rs.Path value of `myresource`, the final URL of the resource is `http://`*`<your_hostname>`*`:`*`<your Web_container_port>`*`/`*`<context_root_of_Web_application>`*`/myresource`. The URL mapping pattern for the filter must match `myresource` for the root resource to be served correctly. For this example, you can use `/*` or `/myresource` for the URL pattern. When there are multiple resources in the application, the URL pattern for the filter must match all of the resources. The `/*` pattern is a common value for the filter.

If the incoming request URL does not match any JAX-RS resources in the JAX-RS application, the request is passed to the rest of the filter chain. Depending on the application, you might want to use the filter behavior so that requests are served by the JAX-RS application, or if there is no JAX-RS resource available, the request can proceed to an underlying web container artifact, such as a JavaServer Pages (JSP). If the web container has no matching artifact, then the web container is responsible for the error response.

Procedure

1. Open the WEB-INF/web.xml file.

2. Define your filter in the WEB-INF/web.xml file. Add the following filter definition to the WEB-INF/web.xml file. Replace the *unique_filter_name* with your unique filter name. Also replace the *Java_class_name* variable with the full Java package and class name of the JAX-RS application Java subclass.

```
<filter>
        <filter-name>unique_filter_name</filter-name>
        <filter-class>com.ibm.websphere.jaxrs.server.IBMRestFilter</filter-class>
        <init-param>
                <param-name>javax.ws.rs.Application</param-name>
                <param-value>Java_class_name</param-value>
        </init-param>
 </filter>
```

3. (optional) If there are multiple JAX-RS application subclasses needed in the same web application, you must include an additional filter initialization parameter, `requestProcessorAttribute`, in the filter definition that you add to the WEB-INF/web.xml file. In the following filter, replace the *unique_filter_name* with your unique filter name; replace the *Java_class_name* variable with the full Java package and the class name of the JAX-RS application Java subclass; replace the *unique_identifier* variable with a unique identifier.

```
<filter>
   <filter-name>unique_filter_name_a</filter-name>
   <filter-class>com.ibm.websphere.jaxrs.server.IBMRestFilter</filter-class>
   <init-param>
       <param-name>javax.ws.rs.Application</param-name>
       <param-value>Java_class_name_a</param-value>
   </init-param>

   <init-param>
       <param-name>requestProcessorAttribute</param-name>
       <param-value>unique_identifier_a</param-value>
   </init-param>
</filter>

<filter>
   <filter-name>unique_filter_name_b</filter-name>
   <filter-class>com.ibm.websphere.jaxrs.server.IBMRestFilter</filter-class>
   <init-param>
       <param-name>javax.ws.rs.Application</param-name>
       <param-value>Java_class_name_b</param-value>
   </init-param>

   <init-param>
       <param-name>requestProcessorAttribute</param-name>
       <param-value>unique_identifier_b</param-value>
   </init-param>
</filter
```

4. Add filter mappings in the WEB-INF/web.xml file for each filter definition.

   The URL pattern specified in the filter mapping defines to the container the valid URL patterns for invoking the `IBMRestFilter` filter. If an incoming request URL is compatible with the URL pattern, the `IBMRestFilter` is invoked. If the request URL does not match, the filter is not invoked. The request URLs always start at the context root for the filter. See the following example filter mappings:

```
<filter-mapping>
    <filter-name>filter_name</filter-name>
    <url-pattern>/*</url-pattern>
</filter-mapping>
```

   For example, suppose you have the following two resources:

```
@javax.ws.rs.Path("myresource")
public class MyResource {

}
```

```
@javax.ws.rs.Path("myresource2")
public class MyResource2 {

}
```

   You can reach the resources using the following URL:

`http://<your_hostname>:<your Web_container_port>/<context_root_of_Web_application>/myresource`

`http://<your_hostname>:<your Web_container_port>/<context_root_of_Web_application>/myresource2`

   If you apply the following filter mapping:

```
<filter-mapping>
        <filter-name>filter_name</filter-name>
        <url-pattern>/myresource</url-pattern>
</filter-mapping>
```

you can use MyResource root resource by visiting the following URL:

```
http://<your_hostname>:<your Web_container_port>/<context_root_of_Web_application>/myresource
```

This URL invokes the `IBMRestFilter` filter and the URL can find the resource. Because the `/myresource` path matches with the URL pattern in the filter-mapping, the `IBMRestFilter` does get invoked and there is a root resource that has a matching @Path value.

However, suppose you visit the following URL:

```
http://<your_hostname>:<your Web_container_port>/<context_root_of_Web_application>/myresource2
```

the `IBMRestFilter` filter is not invoked because the URL pattern `/myresource` does not match `/myresource2`.

Results

After editing the WEB-INF/web.xml file to apply filters, the web application is configured for the JAX-RS application.

Example

The following example illustrates a WEB-INF/web.xml file that is configured to apply filters to a JAX-RS application. This example defines the `RestApplication1` filter. If an incoming request URL matches a resource in the RestApplication1 filter, the response is generated from RestApplication1 filter. If the incoming request URL does not match a resource in the RestApplication1 filter but matches a resource in OtherRestApplicationFilter, then the response is generated from the OtherRestApplicationFilter filter. If the incoming URL does not match either filter, then the request can be served from another web container artifact, such as a JSP.

```
<?xml version="1.0" encoding="UTF-8"?>
<web-app id="WebApp_9" version="2.4"
xmlns=http://java.sun.com/xml/ns/j2ee
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="http://java.sun.com/xml/ns/j2ee http://java.sun.com/xml/ns/j2ee/web-app_2_4.xsd">

     <filter>
        <filter-name>RestApplication1</filter-name>
        <filter-class>com.ibm.websphere.jaxrs.server.IBMRestFilter</filter-class>
        <init-param>
            <param-name>javax.ws.rs.Application</param-name>
            <param-value>com.ibm.rest.sample.app1.MyApplication</param-value>
        </init-param>
        <init-param>
            <param-name>requestProcessorAttribute</param-name>
            <param-value>restApplication1ProcessorID</param-value>
        </init-param>
    </filter>
     <filter>
        <filter-name>OtherRestApplicationServlet</filter-name>
        <filter-class>com.ibm.websphere.jaxrs.server.IBMRestFilter</filter-class>
        <init-param>
            <param-name>javax.ws.rs.Application</param-name>
            <param-value>com.ibm.rest.other.sample.OtherApplication</param-value>
        </init-param>
        <init-param>
            <param-name>requestProcessorAttribute</param-name>
            <param-value>otherRestApplicationID </param-value>
        </init-param>
    </filter>

    <filter-mapping>
        <filter-name>RestApplication1</filter-name>
        <url-pattern>/*</url-pattern>
    </filter-mapping>

    <filter-mapping>
        <filter-name>OtherRestApplicationServlet</filter-name>
        <url-pattern>/*</url-pattern>
    </filter-mapping>
</web-app>
```

What to do next

Assemble the web application.

Implementing clients using the Apache Wink REST client

You can use the Apache Wink REST client to send requests and process responses from RESTful services. You can use the client API in Java programs to communicate with web services.

About this task

By default, the Apache Wink client uses the java.net.HttpURLConnection class from the Java runtime environment for issuing requests and processing responses. The Apache Wink client can also use Apache HttpClient 4.0 as the underlying client transport.

You can also use JAX-RS entity providers to help serialize request entities or deserialize response entities. The standard JAX-RS providers used in the JAX-RS server-side services are provided with the client.

You can configure the Apache Wink REST client programmatically or by setting Java Virtual Machine (JVM) properties.

To implement an Apache Wink REST client, you must first create an org.apache.wink.client.ClientConfig object that is then used to construct an org.apache.wink.client.RestClient. You can change the configuration settings for the RestClient object programmatically, or you can use JVM properties to modify the default ClientConfig object values.

To configure the configuration settings for the RestClient object programmatically, invoke the public methods of the ClientConfig object.

Note: After a ClientConfig object is used to construct a RestClient object, the ClientConfig object can no longer be modified. Attempting to do so results in an org.apache.wink.client.ClientConfigException error message.

Alternatively, you can configure the configuration settings for the RestClient object using JVM properties to modify the default ClientConfig object values. Use the following JVM properties to modify the default ClientConfig object values:

wink.client.readTimeout

This property specifies how long the RestClient object waits (in milliseconds) for a response to requests before timing out. A value of zero (0) means that the client waits for an unlimited amount of time and will not timeout.

The default value is 60,000 milliseconds.

wink.client.connectTimeout

This property specifies how long the RestClient object waits (in milliseconds) before timing out when attempting to connect to the target resource. A value of zero (0) means that the client waits for an unlimited amount of time and will not timeout.

The default value is 60,000 milliseconds.

You can programmatically alter any values for the RestClient object that you specify using JVM properties. The programmatic values take precedence over any JVM property values.

Procedure

1. Create an org.apache.wink.client.ClientConfig object.

   The following code snippet illustrates how to create an org.apache.wink.client.ClientConfig object:

```
org.apache.wink.client.ClientConfig clientConfig = new org.apache.wink.client.ClientConfig();
```

.

If you use an Apache HTTP client as the underlying transport, create and use an org.apache.wink.client.ApacheHttpClientConfig object instead. You must also include the Apache HTTP client libraries in the classpath. The following code snippet illustrates how to create an org.apache.wink.client.ApacheHttpClientConfig object:

```
org.apache.wink.client.ClientConfig clientConfig = new org.apache.wink.client.ApacheHttpClientConfig();
```

2. (optional) Modify the default ClientConfig object values that you want to use for the RestClient object.
   - You can optionally modify the default configuration settings for the RestClient object programmatically. To specify the configuration settings for the RestClient object programmatically, invoke the public methods of the ClientConfig object; for example:

```
clientConfig.connectTimeout(30000);
clientConfig.readTimeout(30000);
```

   - If you are using the Thin Client for JAX-RS in a stand-alone unmanaged client runtime environment, you can optionally modify the configuration settings for the RestClient object using JVM properties. Set the custom JVM properties on the JVM under which the thin client is running.
   - If you are not using the Thin Client for JAX-RS as a stand-alone client runtime environment, but you are using the RestClient object in an application that is intended for installation on the application server, you can optionally modify the configuration settings for the RestClient object using JVM properties. Set the custom JVM properties using the administrative console for your REST client code that is running within an application that is installed on the application server. See the Java virtual machine custom properties information for details on using the administrative console to set these custom JVM properties.
3. (optional) If you use a custom entity provider, add the entity provider using the client configuration.

```
org.apache.wink.client.ClientConfig clientConfig = new org.apache.wink.client.ClientConfig();

javax.ws.rs.core.Application app = new javax.ws.rs.core.Application() {
       public Set<Class<?>> getClasses() {
           Set<Class<?>> classes = new HashSet<Class<?>>();
           classes.add(MyCustomEntityProvider.class);
           return classes;
       }
};
clientConfig.applications(app);
```

4. Create a org.apache.wink.client.RestClient object with the client configuration.

```
org.apache.wink.client.ClientConfig clientConfig = new org.apache.wink.client.ClientConfig();

javax.ws.rs.core.Application app = new javax.ws.rs.core.Application() {
       public Set<Class<?>> getClasses() {
           Set<Class<?>> classes = new HashSet<Class<?>>();
           classes.add(MyCustomEntityProvider.class);
           return classes;
       }
};
clientConfig.applications(app);

org.apache.wink.client.RestClient client = new org.apache.wink.client.RestClient(clientConfig);
```

5. Create a org.apache.wink.client.Resource object with a URI from the REST client.

```
org.apache.wink.client.ClientConfig clientConfig = new org.apache.wink.client.ClientConfig();

javax.ws.rs.core.Application app = new javax.ws.rs.core.Application() {
       public Set<Class<?>> getClasses() {
           Set<Class<?>> classes = new HashSet<Class<?>>();
           classes.add(MyCustomEntityProvider.class);
           return classes;
       }
};
clientConfig.applications(app);

org.apache.wink.client.RestClient client = new org.apache.wink.client.RestClient(clientConfig);

org.apache.wink.client.Resource resource = client.resource("http://www.example.com/rest/api/book/123");
```

6. You can add request headers to the pending request by calling methods on the Resource object.

   You can call a Java method such as post() with the request content as a parameter to send the request. In the following example, an HTTP POST request is made with a Content-Type header value of `text/plain` and an Accept header value of `*/*`.

```
org.apache.wink.client.ClientConfig clientConfig = new org.apache.wink.client.ClientConfig();

javax.ws.rs.core.Application app = new javax.ws.rs.core.Application() {
       public Set<Class<?>> getClasses() {
           Set<Class<?>> classes = new HashSet<Class<?>>();
           classes.add(MyCustomEntityProvider.class);
           return classes;
       }
};
clientConfig.applications(app);

org.apache.wink.client.RestClient client = new org.apache.wink.client.RestClient(clientConfig);

org.apache.wink.client.Resource resource = client.resource("http://www.example.com/rest/api/book/123");

ClientResponse response = resource.contentType("text/plain").accept("*/*").post("The request body as a string");
```

Instead of calling `resource.post("The request body as a string")` with a String object, you can use any other object that has a class with a valid javax.ws.rs.ext.MessageBodyWriter object such as a JAXB annotated class, a byte[], or a custom class that has a custom entity provider.

7. Process the response by using the status code, response headers, or the response message body.

```
org.apache.wink.client.ClientConfig clientConfig = new org.apache.wink.client.ClientConfig();

javax.ws.rs.core.Application app = new javax.ws.rs.core.Application() {
       public Set<Class<?>> getClasses() {
           Set<Class<?>> classes = new HashSet<Class<?>>();
           classes.add(MyCustomEntityProvider.class);
           return classes;
       }
};
clientConfig.applications(app);

org.apache.wink.client.RestClient client = new org.apache.wink.client.RestClient(clientConfig);

org.apache.wink.client.Resource resource = client.resource("http://www.example.com/rest/api/book/123");

ClientResponse response = resource.contentType("text/plain").accept("*/*").post("The request body as a string");

System.out.println("The response code is: " + response.getStatusCode());
System.out.println("The response message body is: " + response.getEntity(String.class));
```

Instead of calling the `response.getEntity(String.class)` object with String.class file, you can use any other class that has a valid javax.ws.rs.ext.MessageBodyReader object, such as a JAXB annotated class, a byte[], or a custom class that has a custom entity provider.

8. (optional) Configure the client to transmit basic authentication security tokens. To configure basic authentication for your client, you can choose to manage the appropriate HTTP headers yourself, or more simply, you can use the provided BasicAuthSecurityHandler handler class. The BasicAuthSecurityHandler class simplifies the enablement of basic authentication in the Wink client application. To learn more about using the security client handler to perform basic HTTP authentication, see the securing JAX-RS applications within the web container information.

Results

You have implemented a JAX-RS client using the Apache Wink REST client that can issue requests to a JAX-RS application.

Implementing a client using the unmanaged RESTful web services JAX-RS client

WebSphere Application Server provides a thin Java Platform, Standard Edition 6 (Java SE 6) RESTful web services client runtime to enable application developers to quickly and easily create JAX-RS client applications. The Thin Client for JAX-RS with WebSphere Application Server is a stand-alone Java SE 6 client environment that enables running unmanaged JAX-RS RESTful web services client applications in a non-WebSphere environment to invoke JAX-RS RESTful web services that are hosted by the application server.

Before you begin

Note: You can use the Thin Client for JAX-RS with WebSphere Application Server as a stand-alone client run time in a pure Java SE environment. The Thin Client for JAX-RS running within WebSphere Application Server or WebSphere Application Client environments is not supported. In this version of the application server, other Thin Client run times provided with the application server can also reside in the CLASSPATH and coexist with the Thin Client for JAX-RS.

Before you set up a JAX-RS unmanaged client execution environment, obtain the Thin Client for JAX-RS Java archive (JAR) file. To obtain the Thin Client for JAX-RS, install WebSphere Application Server Version 8.5 or the Application Client for WebSphere Application Server Version 8.5. The Thin Client for JAX-RS JAR file, `com.ibm.jaxrs.thinclient_8.5.0.jar`, is located in the *app_server_root*`\runtimes` directory.

Copy the Thin Client for JAX-RS `com.ibm.jaxrs.thinclient_8.5.0.jar` file to other machines to create a lightweight client environment that enables communications with the product. Copies of the Thin Client for JAX-RS are subject to the same terms and conditions of the license agreement for the WebSphere product where you obtained the Thin Client for JAX-RS. Refer to the license agreements for correct usage and other limitations.

The Thin Client for JAX-RS works with IBM Software Development Kits (SDKs) Version 6.0 and higher. The Thin Client for JAX-RS is also supported on non-IBM software development kits that are V6.0 and higher.

About this task

Set up a Thin Client for JAX-RS environment by completing the following steps.

Procedure

1. Configure the path. Enter the following command to add the Java `bin` directories to your path:

```
set PATH=<your_JDK_bin_directory>;%PATH%
```

2. Configure the class path. Add the Thin Client for JAX-RS JAR file to the classpath definition; for example:

```
set CLASSPATH=.;<your_jax-rs_thin_client_install_directory>\com.ibm.jaxrs.thinclient_8.5.0.jar;
<your_application_jars>;%CLASSPATH%
```

3. Enter the following command to run your client application:

```
%JAVA_HOME%/bin/java <your_client_application>
```

Results

You have set up an unmanaged JAX-RS client runtime environment to invoke RESTful web services that are hosted on a WebSphere Application Server.

Migrating a Feature Pack for Web 2.0 JAX-RS application to WebSphere Version 8

When packaging an application for the Feature Pack for Web 2.0, you must manually make the Java API for RESTful Web Services (JAX-RS) run time available on the application `CLASSPATH`. A common way of doing this is placing the JAX-RS runtime Java archive (JAR) files in the `WEB-INF/lib` directory of the web archive (WAR) module. In Version 8, the JAX-RS runtime environment is native to the application server. It is no longer necessary to manually add the path of the runtime libraries on the `CLASSPATH`. Migrating Web 2.0 applications to the native runtime environment simplifies packaging and deployment, and allows for future updates to take advantage of Java Platform, Enterprise Edition (Java EE) integration features.

Before you begin

Identify Feature Pack for Web 2.0 JAX-RS applications to migrate to the native Version 8 JAX-RS runtime environment. Identify where the JAX-RS runtime JAR files have been made available to the application `CLASSPATH`. Two common methods are the `WEB-INF/lib` directory of the WAR module or by way of a shared library.

About this task

In WebSphere Version 8, the JAX-RS run time runs natively within the application server process. Unlike deploying JAX-RS applications with the Web 2.0 Feature Pack installed on WebSphere Version 7 or earlier, it is no longer necessary to package the JAX-RS runtime JAR files as an external library for the application.

To migrate Web 2.0 applications to the Version 8 runtime environment, simply remove the external JAX-RS runtime libraries. For example, if the runtime JAR files were placed in the `WEB-INF/lib` directory of the WAR module, delete them from that directory before redeploying the application. No other changes are necessary. All other application configurations, such as `web.xml` configuration, are still valid in WebSphere Version 8.

Once the external JAX-RS runtime library is removed, the native runtime environment runs the JAX-RS application. There are advantages to this over Web 2.0 deployment. Application packaging and deployment are simplified since it is no longer necessary to add external libraries on the application `CLASSPATH`. Additionally, new Java EE integration features can be taken advantage of in future updates to the application. Examples are Enterprise JavaBeans (EJB) in a WAR and Java Contexts and Dependency Injection (JCDI) support.

Procedure

1. Remove external JAX-RS runtime libraries from the Feature Pack for Web 2.0 application.
2. Redeploy the application.

Results

You have migrated a Web 2.0 Feature Pack JAX-RS application to the native WebSphere Version 8 JAX-RS runtime environment.

Disabling the JAX-RS runtime environment

There are cases where you must disable the Java API for RESTful Web Services (JAX-RS) runtime environment. When disabling the JAX-RS runtime environment, JAX-RS features are not available, including base JAX-RS runtime capabilities, Enterprise JavaBeans (EJB) runtime integration, Java Contexts and Dependency Injection (JCDI) runtime integration, and Servlet 3.0 web container integration.

About this task

By disabling the JAX-RS runtime environment, any JAX-RS related processing of the application, including processing of classes with scanned JAX-RS annotations, EJB metadata, and JCDI bean enablement, is no longer performed. The JAX-RS runtime environment is not used to process requests and responses to and from the web container.

Note: Disabling the JAX-RS runtime environment does not disable Servlet 3.0 based annotation scanning for JAX-RS annotations such as `javax.ws.rs.Path`. To disable annotation scanning, set the `metadata-complete` attribute. If annotation scanning is disabled, it is disabled for all other components outside of JAX-RS.

The explicit plug points to the IBM JAX-RS runtime environment are the `com.ibm.websphere.jaxrs.server.IBMRestServlet` servlet class and the `com.ibm.websphere.jaxrs.server.IBMRestFilter` filter class. If you specify these classes as your servlet-class or servlet-filter in the web module's `web.xml` file, the IBM JAX-RS runtime environment is used to process requests to that servlet.

To disable the JAX-RS runtime environment from doing so, replace those classes with any other servlet or filter class that can handle expected requests to the servlet, or remove the servlet entirely from the `web.xml` file.

Note: Replacing the `IBMRestServlet` class with another might modify existing behavior in the application. Removing the servlet entirely results in requests not being processed.

Even if not explicitly using the `com.ibm.websphere.jaxrs.server.IBMRestServlet` or `com.ibm.websphere.jaxrs.server.IBMRestFilter` classes, the JAX-RS integration runtime environment may still process the application. For example, if the `web.xml` file of a web module is Servlet 3.0 based, and appropriate conditions are met according to the JSR-311 specification, the JAX-RS integration runtime environment processes scanned classes with JAX-RS annotations and may inject a servlet that can handle requests to the JAX-RS resources in the application.

To disable this functionality, and other functionality such as EJB and JCDI integration, set the `com.ibm.websphere.jaxrs.server.DisableIBMJAXRSEngine` custom Java virtual machine (JVM) property on the application server with a value of `true`.

Procedure

1. Remove references to `IBMRestServlet` and `IBMRestFilter` from the `web.xml` file. The following example illustrates a sample `web.xml` file from an application that uses the IBM JAX-RS runtime environment:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-app xmlns="http://java.sun.com/xml/ns/j2ee" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://java.sun.com/xml/ns/j2ee http://java.sun.com/xml/ns/j2ee/web-app_3_0.xsd"
    version="3.0">
    <servlet>
        <servlet-name>MyRestApplication1</servlet-name>
        <servlet-class>com.ibm.websphere.jaxrs.server.IBMRestServlet</servlet-class>
        <init-param>
            <param-name>javax.ws.rs.Application</param-name>
            <param-value>com.ibm.websphere.jaxrs.example.Application1</param-value>
        </init-param>
        <init-param>
            <param-name>requestProcessorAttribute</param-name>
            <param-value>MyRestApplication1RequestProcessorAttribute</param-value>
        </init-param>
        <load-on-startup>1</load-on-startup>
    </servlet>
    <servlet>
        <servlet-name>MyNonJAXRSApplication</servlet-name>
        <servlet-class>com.ibm.websphere.example.NonJAXRSServlet</servlet-class>
        <load-on-startup>1</load-on-startup>
    </servlet>
    <filter>
        <filter-name>MyRestApplication2</filter-name>
        <filter-class>com.ibm.websphere.jaxrs.server.IBMRestFilter</filter-class>
        <init-param>
            <param-name>javax.ws.rs.Application</param-name>
            <param-value>com.ibm.websphere.jaxrs.example.Application2</param-value>
        </init-param>
        <init-param>
            <param-name>requestProcessorAttribute</param-name>
            <param-value>MyRestApplication2RequestProcessorAttribute</param-value>
        </init-param>
    </filter>
    <servlet-mapping>
        <servlet-name>MyRestApplication1</servlet-name>
        <url-pattern>/jaxrsapp1/*</url-pattern>
    </servlet-mapping>
    <servlet-mapping>
        <servlet-name>MyNonJAXRSApplication</servlet-name>
```

```
        <url-pattern>/nonjaxrsapp/*</url-pattern>
    </servlet-mapping>
    <filter-mapping>
        <filter-name>MyRestApplication2</servlet-name>
        <url-pattern>/jaxrsapp2/*</url-pattern>
    </filter-mapping>
<web-app>
```

The following example illustrates how the `web.xml` file looks after removing the references to the `IBMRestServlet` and `IBMRestFilter` classes:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-app xmlns="http://java.sun.com/xml/ns/j2ee" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://java.sun.com/xml/ns/j2ee http://java.sun.com/xml/ns/j2ee/web-app_3_0.xsd"
    version="3.0">
    <servlet>
        <servlet-name>MyNonJAXRSApplication</servlet-name>
        <servlet-class>com.ibm.websphere.example.NonJAXRSServlet</servlet-class>
        <load-on-startup>1</load-on-startup>
    </servlet>
    <servlet-mapping>
        <servlet-name>MyNonJAXRSApplication</servlet-name>
        <url-pattern>/nonjaxrsapp/*</url-pattern>
    </servlet-mapping>
</web-app>
```

2. Set the `com.ibm.websphere.jaxrs.server.DisableIBMJAXRSEngine` custom JVM property on the application server with a value of `true`.
3. Restart the application server for the custom JVM property to take effect.

Results

You have disabled the JAX-RS runtime environment from processing your application.

Assembling JAX-RS web applications

After you develop the Java class files for your Java API for RESTful Web Services (JAX-RS) web application and edit the web.xml file to enable the JAX-RS servlet, you must assemble the application.

Before you begin

Identify the assembly tool to use to assemble your application. The web application is assembled into a web application archive (WAR) package. You can assemble the WAR package into an enterprise archive (EAR) package if required.

Before assembling the web application, ensure that you have customized the web.xml file to enable the JAX-RS servlet or filter configuration. To learn more, see the information about configuring the web.xml file for the JAX-RS application.

About this task

You must add the JAX-RS libraries to the web application in the WEB-INF/lib directory before you assemble the web application.

By packaging your JAX-RS application classes into the WEB-INF/classes directory of your WAR package and editing the web.xml file, you can use the built-in JAX-RS runtime environment.

Procedure

Create the WAR package using assembly tools.

1. Package your compiled JAX-RS Java classes into the `WEB-INF/classes` directory of your WAR package.
2. Package the web.xml file for your web application in the `WEB-INF/` directory into the WAR package.

Results

A WAR package is created that contains the web application. If needed, you can add the WAR package to an EAR package. The application server can deploy either the WAR or EAR packages.

What to do next

Deploy the web application.

Chapter 34. Developing web services - Security (WS-Security)

The Web Services Security specification defines core facilities for protecting the integrity and confidentiality of a message, and provides mechanisms for associating security-related claims with a message.

Developing applications that use Web Services Security

The Web Services Security specification provides a flexible framework for building secure web services to implement message content integrity and confidentiality. The Web Services Security service programming model supports this flexible framework by providing extension points to integrate new token formats, and methods to obtains keys needed for message protection. The application server programming model provides Web Services Security programming application programming interfaces (WSS API) for securing SOAP messages.

Configuring HTTP basic authentication for JAX-RPC web services programmatically

You can configure HTTP basic authentication for Java API for XML-based RPC (JAX-RPC) web services by programmatically modifying HTTP properties.

Before you begin

This task is one of three ways that you can configure HTTP basic authentication. You can also configure HTTP basic authentication with an assembly tool or with the administrative console.

If you programmatically configure HTTP basic authentication, the properties are configured in the Stub or Call instance. If you choose to configure HTTP basic authentication with the administrative console or an assembly tool, the Web Services Security binding information is modified. The values that are set programmatically take precedence over the values defined in the binding.

About this task

The HTTP basic authentication that is discussed in this topic is orthogonal to WS-Security and is distinct from basic authentication that WS-Security supports. WS-Security supports basic authentication token, not HTTP basic authentication.

Configure HTTP basic authentication programmatically with the following steps.

Procedure

Set the properties in the Stub or Call instance for a Web service or a web service client. You can set properties with the following constant names:

```
javax.xml.rpc.Call.USERNAME_PROPERTY
javax.xml.rpc.Call.PASSWORD_PROPERTY
javax.xml.rpc.Stub.USERNAME_PROPERTY
javax.xml.rpc.Stub.PASSWORD_PROPERTY
```

Example

The following code enables you to configure basic authentication programmatically:

```
Properties prop = new Properties();
InitialContext ctx = new InitialContext(prop);
Service service = (Service)ctx.lookup("java:comp/env/service/StockQuoteService");
QName portQname = new QName("http://httpchannel.test.wsfvt.ws.ibm.com", "StockQuoteHttp");
StockQuote sq = (StockQuote)service.getPort(portQname, StockQuote.class);
((javax.xml.rpc.Stub) sq)._setProperty(javax.xml.rpc.Stub.USERNAME_PROPERTY, "myUser");
((javax.xml.rpc.Stub) sq)._setProperty(javax.xml.rpc.Stub.PASSWORD_PROPERTY, "myPwd");
```

Developing message-level security for JAX-WS web services

JAX-WS applications can be secured with Web Services Security in one of two ways. The application can be secured using policy sets, or through the use of the Web Services Security API (WSS API). The WSS API can only be used to secure a JAX-WS client application. The Web Services Security service programming interface (WSS SPI) provides additional programming interfaces for securing web services.

Web Services Security API programming model

The application server programming model provides Web Services Security programming application programming interfaces (WSS API) for securing SOAP messages.

The API programming model is an interface-based programming model that is based on Web Services Security Version 1.1 standards, but the design also includes support for Web Services Security Version 1.0 for securing SOAP messages. The WSS API programming model implementation is a simplified version, which is based on an early draft proposal of JSR-183, which is the JSR for defining Java API binding for Web Services Security. By design, because the application code is programmed to the interface, any application code that is programmed with the open source implementation should be able to run on the WebSphere Application Server with minimal changes or no changes at all.

The configuration model for web services has also been redesigned from a deployment descriptor model to a policy set model. Web Services Security can be enabled by either using a policy set that is configured by using the administrative console, or by using the WSS API for configuration. The functions provided by the policy set configurations are the same as the functions supported by the WSS API for the Web Services Security run time. However, the security policy that is defined using policy sets has a higher priority over the WSS API. When the WSS API and the policy set are both used in the application, the default behavior is for the security policy from the policy set to be enforced and the WSS API to be ignored. To use the WSS API in the application, you must make sure that there is no policy set attached to the application or to the application resources, or make sure there is no security policy in the attached policy set.

You can still use your existing JAX-RPC applications with Web Services Security; however, those applications cannot take advantage of the Web Services Security Version 1.1 functions, such as configuring the security policy using a policy set, OM filter performance improvements, WSS API, Web Services Secure Conversation (WS-SecureConversation), Kerberos token and the associated SHA-1 key for message protection and identity propagation, and Web Services Trust (WS-Trust) features.

In order to take advantage of the Web Services Security Version 1.1 functions, you must rewrite an existing JAX-RPC application as a JAX-WS application, manually re-configure the security constraints to a policy set, and perform code migration of the DOM-based SPIs to the OM-based SPIs.

For example, when using the JAX-WS programming model, the improved design of the pluggable token framework allows the same security implementation to be used for both the API and policy sets. The framework uses the JAAS Login Module and JAAS Callback Handler for token creation and token validation.

The following diagrams illustrate differences between the programming models.

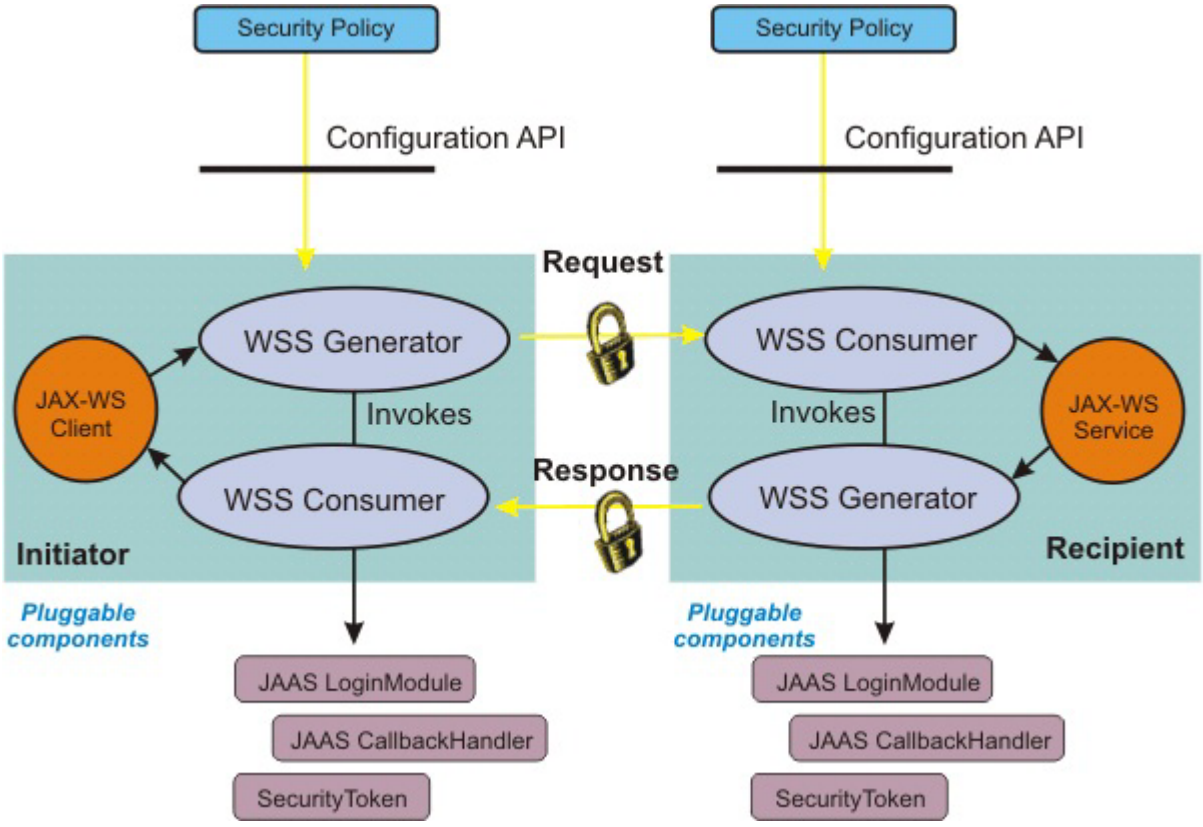

Figure 5. Pluggable token architecture using the JAX-WS programming model

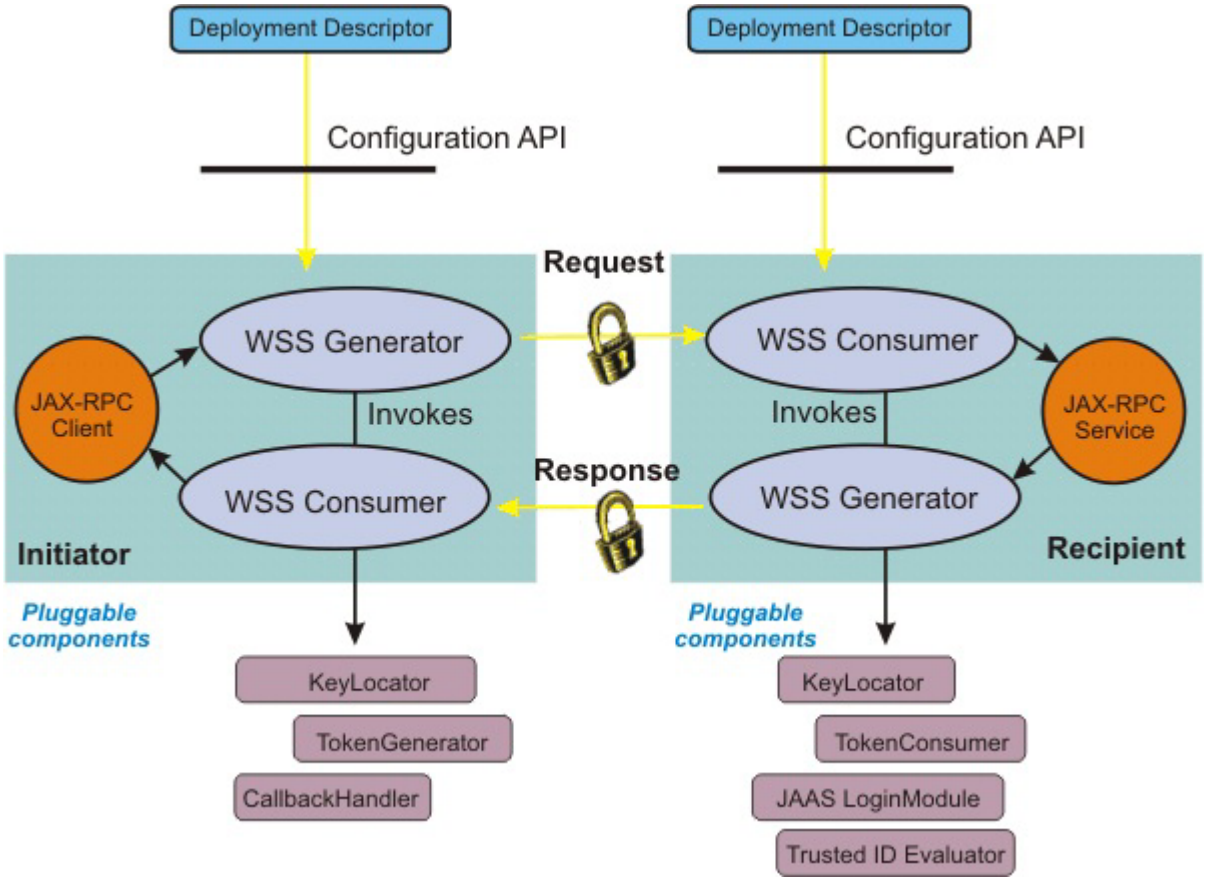

Figure 6. Pluggable token architecture using the JAX-RPC programming model

What is supported when using the WSS APIs

The WSS API can only be used on the client. You can use the Java SE 6 client, the J2EE Application client, or a server client (a service provider acting as client) using the API to secure SOAP message with message-level security.

You should have Web Services Security (WSS) knowledge to use the WSS APIs. Before using the WSS API, keep in mind that the WSS API:

- Are Java-based interfaces.
- Are implemented by using a factory model (WSSFactory).
- Supports the WS-Security Version 1.0 and 1.1 standards, which include the Username and X.509 token profiles, Versions 1.0 and 1.1.
- Are very XML centric.
- Include an object-oriented design which simplifies the APIs.
- Are task oriented and allow common usage scenarios, such as: signing the body and encrypting the SOAP message body content.
- Are flexible and extensible, and they let you to extend the token type support.
- Are based on the provider framework and allow the use of different data models to be used, such as: AXIOM or DOM.
- Provides application programmer with better control and flexibility in applying WSS in their applications.

The default values for the WSS API are predefined and are part of the Web Services Security run time. Default values are provided for:

- The duration of the timestamp
- The signing algorithm, canonicalization algorithm, digest method, transform algorithm, security token reference method and signed parts such as the SOAP body, Web Services Addressing headers and the time stamp.
- The key encryption algorithm, data encryption algorithm, security token reference method, and encrypted parts such as the SOAP body content.

The signature validation has similar default values as the signature (signing information). Similarly, decryption has similar default values as encryption.

What is not supported when using the WSS APIs

The WSS API provided with the application server does not support the following function:

- The application programming model is JAX-WS, meaning JAX-RPC (JSR-109) applications are not supported.
- The WSS API is available in the synchronous message exchange of the JAX-WS client application. However, the WSS API are not supported for the asynchronous client.
- WSS API support is available only for the requester and not for the provider.
- The identity assertion semantic programming model is not supported in the WSS API because identity assertion is not part of the Web Services Security Version 1.0 standard. However, you can use the WSS API to add Identity Assertion semantic in the token processing.

WS-Trust and WS-SecureConversation scenarios

There are several ways to secure the WS-Trust SOAP messages:

- Using the bootstrap policy defined in the policy set.
- Using the WSS API, which supports WS-SecureConversation.
- Enabling dynamic policy for the provider so that the client can retrieve the provider-side policy at run time.

An application would use the WSS API to acquire a security context token for programmatic API-based secure conversation. The WebSphere Application Server trust service provides an application the ability to request a security token for access to a service. The scope and focus of the trust service is only for a WebSphere Application Server Security Context Token (SCT) for WS-SecureConversation.

The WS-SecureConversation and WS-Trust scenarios focus on the inter-operability functions, such as the configuration and runtime interaction of various components. You would use the WSS API to secure the bootstrap RST and RSTR to acquire the security context token from the trust service. After acquiring the security context token, a Derived Key Token is created by using the WSS API. Then the Derived Key Token can be used for signature and encryption.

There are two conditions when using the WSS API to secure the SOAP message with Web Services Security:

- Generation of the secure SOAP message, which is in the request generator application code.
- Consuming of the secured SOAP message, which is in the response consumer application code.

In both cases, a Java exception class com.ibm.websphere.wssecurity.wssapi.WSSException is provided if an error is encountered.

Web services client security context

When the JAX-WS client invokes web services, the current security context that is constructed by the security handler is stored in the RequestContext object. By default, the security context in the JAX-WS

web services client runtime environment is reconstructed for the next web services request invocation. You can preserve the security context for subsequent web services invocations. An example of this is a scenario where the security policy requires the client to send a username security token with the user name and password. When the client sends the first request to invoke the service, you are prompted to enter the required user name and password. The user name and password is saved in a Username SecurityToken token in a Subject in the security context. To avoid being prompted to enter the same user name and password again in subsequent request invocations, you can preserve the security context. There are two methods to preserve the security context: 1) configure the client run time to automatically preserve the client security context for subsequent request invocations; or 2) preserve the security context manually.

To configure the JAX-WS client run time environment to automatically preserve the security context, set the Java system property `com.ibm.websphere.wssecurity.context.management` to `true`. When this system property is true, the JAX-WS client run time copies the security context constructed by the security handler to the RequestContext automatically, and the context is used for subsequent request invocations.

To manually preserve the security context, use the following sample code:

```
// First request
Service svc = Service.create(...);
svc.addPort(...);
Dispatch<String> dispatch = svc.createDispatch(...);
Map<String, Object> requestContext = dispatch.getRequestContext();
String response = dispatch.invoke(body.toString());

Object securityContext = requestContext.get(com.ibm.wsspi.websvcs.Constants.WEBSPHERE_SECURITY_CONTEXT);

// Subsequent request

Dispatch<String> dispatch = svc.createDispatch(...);
Map<String, Object> requestContext = dispatch.getRequestContext();
Object securityContext = requestContext.put(com.ibm.wsspi.websvcs.Constants.WEBSPHERE_SECURITY_CONTEXT, securityContext);
```

Service Programming Interfaces (SPI)

The Web Services Security service programming interface (WSS SPI) provides programming interfaces for securing Web Services Security.

The Web Services Security specification provides a flexible framework for building secure web services to implement message content integrity and confidentiality. The specification does not define specific token formats, but instead associates separate profile documents that define various security token formats and semantics for using those tokens. The Web Services Security service programming model supports the flexible framework by providing extension points to integrate with new token formats, and with methods to obtains keys needed for message protection. Web Services Security uses this programming model to implement support for the standard X.509 token profile, the Username token profile, and the Kerberos token profiles. The programming model is also used to implement support for the LTPA security token, and for new security token types.

The Web Service Security run time token generation and token consuming Service Programming Interfaces (SPI) have been redesigned so that the same security token interface and JAAS Login Module implementation can be used for both the WSS API and the SPI. The WSS SPI for the service provider extends the security token types and provides keys and deriving keys for signing, signature verification, encryption and decryption.

The Web Services Security service programming model provides mechanisms to process custom security tokens, to use custom token in signing and encryption, and to retrieve encryption and signing keys. The Web Services Security service programming interfaces for the JAX-RPC run time, and for the JAX-WS run time, are similar, but not identical.

JAX-RPC run time

The plug-in programming interfaces for the JAX-RPC run time consist of the TokenGenerator, KeyLocator, and JAAS CallbackHandler for outbound message processing, and the TokenConsumer, KeyLocator, and JAAS LoginModule for inbound message processing.

Token Generator, KeyLocator, and Callback Handler
The TokenGenerator class is responsible for formatting the security token to the XML element. This class calls the CallbackHandler class that is specified in the TokenGeneratorConfig object, which obtains the security token input data, and then stores the resulting security token in the Subject object private credentials.

Token Consumer, KeyLocator and JAAS LoginModule
The KeyLocator class is responsible for obtaining the required key for signing and encrypting SOAP message elements from a key store that is specified by the KeyStoreConfig and the KeyLocatorConfig configuration. The TokenConsumer class extracts the token data from the XML security token representation, and stores it in the JAAS Subject using a JAAS LoginModule. The specified KeyLocator class is invoked to find the required key for verifying the digital signature and decrypting the SOAP message elements.

JAX-WS run time

The plug-in programming interfaces for the JAX-WS run time are based on the JAAS programming model for both inbound and outbound SOAP message processing. The JAAS LoginModule and CallbackHandler are responsible for processing the security tokens in SOAP messages. The Login Module and Callback Handler both retrieve and generate tokens, and store the SecurityToken objects in the run time. They replace the functionality of the TokenGenerator, TokenConsumer, and KeyLocator interfaces.

Due to the differences in the programming models, any WebSphere Application Server or custom SPI implementation from the Web Services Security Version 6.1 run time is not supported to run on the Web Services Security run time with the Version 6.1 Feature Pack for Web Services, or the Version 7.0 and later Web Services Security runtime. However, the Web Services Security Version 6.1 run time is supported simultaneously with the Version 6.1 Feature Pack for Web Services, meaning the Version 6.1 SPI implementations are still supported through the original run time. Before using the new Web Services Security run time, a code migration is required to reprogram the Version 6.1 DOM-based SPIs to the AXIOM-based SPIs in the Feature Pack for Web Services, before the SPI can be used.

Developing SAML applications

Use the SAML library application programming interface (API), the SAMLTokenFactory, to configure token parameters, create a SAML token, and bind the created token to a service request. The SAML trust client API provides helper functions that send WS-Trust SOAP requests to the specified external Security Token Service (STS).

About this task

The SAMLTokenFactory API creates SAML tokens through various method signatures. The API also instantiates runtime configuration objects related to the SAML token requester, as well as the recipient.

The WS-Trust Client API for SAML includes the WSSTrustClient class, the WSSTrustClientValidateResult class, and other configuration utility classes.

The following topics provide more information about developing SAML applications using the APIs.

WS-Trust client API:

The WS-Trust client application programming interface (API) includes the WSSTrustClient class, the WSSTrustClientValidateResult class, and other configuration utility classes. The WSSTrustClient class

provides helper functions that send WS-Trust SOAP requests to the specified external Security Token Service (STS) so that the STS can issue or validate one or more SAML assertions and other types of security tokens.

Overview

WebSphere Application Server includes WS-Trust client function, implemented through the WSSTrustClient class, that sends WS-Trust SOAP requests to a specified external Security Token Service (STS). Using the trust requests, the STS can issue one or more SAML assertions or other types of security tokens. The WSSTrustClient class supports the OASIS WS-Trust Version 1.3 specification, and also the WS-Trust Version 1.2 specification. In addition, the SOAP Version 1.1 and SOAP Version 1.2 specifications are supported by the function.

The sample code which follows demonstrates how a web services client uses the WSSTrustClient API to request a SAML bearer token. In the explanatory text which precedes the code sample, the term **SAML token** is used interchangeably with the term **SAML assertion**.

The WSSTrustClient class

You can copy the sample code into an assembly tool application, such as Rational Application Developer, and start using the code after completing the configuration steps. Use the WSSTrustClient class, together with other SAML APIs, to build useful SAML functions. Refer to the SAML API Javadoc for more information.

The WSSTrustClient class is an abstract class and has two concrete implementations: a WS-Trust Version 1.3 implementation and a WS-Trust v1.2 implementation. On line 50 of the code sample, the SAMLWSTrustClientExample web services client code invokes the WSSTrustClient.getInstance(ProviderConfig) method to retrieve the WS-Trust v1.3 implementation. The getInstance() method takes a single ProviderConfig object, which specifies configuration data that are relevant to the SAML token issuer. A ProviderConfig object is also instantiated in the sample code on line 32. The client code sends WS-Trust Version 1.3 request messages to a target STS endpoint. In the sample, the endpoint is https://MyCompany/Trust/13/UsernameMixed. To use the sample code, replace this example STS endpoint with the specific STS endpoint you plan to use.

Note: Starting with WebSphere Application Server Release 8, you can use the `com.ibm.websphere.wssecurity.wssapi.token.SAMLToken` class in Web Services Security (WSS) application programming interface (API). When there is no concern of confusion we use the term `SAMLToken` instead of using its complete package name. You can use WSS API to request SAMLToken processing from an external Security Token Service (STS), to propagate SAMLTokens in SOAP request messages, and to use a symmetric or asymmetric key identified by SAMLTokens to protect SOAP messages.

The WSS API SAML support complements the `com.ibm.websphere.wssecurity.wssapi.token.SAMLTokenFactory` and `com.ibm.websphere.wssecurity.wssapi.trust.WSSTrustClient` interfaces. SAMLTokens that are generated using the `com.ibm.websphere.wssecurity.wssapi.WSSFactory newSecurityToken()` method can be processed by the `SAMLTokenFactory` and `WSSTrustClient` programming interfaces. Conversely, SAMLTokens that are generated by `SAMLTokenFactory` or returned by `WSSTrustClient` can be used in WSS API. Deciding which API to use in your application depends on your specific needs. WSS API SAML support is self contained in the sense that it provides functionality equivalent to that of the `SAMLTokenFactory` and `WSSTrustClient` interfaces as far as web services client applications are concerned. The `SAMLTokenFactory` interface has additional functions to validate SAMLTokens and to create the JAAS Subject that represents authenticated SAMLTokens. This validation is useful for the Web services provider side. When you develop applications to consume SAMLTokens, the `SAMLTokenFactory` programming interface is more suitable for you.

Example: Web services client code that uses the WSSTrustClient class

```
1.  package sample;
2.
3.   import com.ibm.websphere.wssecurity.wssapi.WSSException;
4.   import com.ibm.websphere.wssecurity.wssapi.token.SecurityToken;
5.   import com.ibm.websphere.wssecurity.wssapi.trust.WSSTrustClient;
6.   import com.ibm.websphere.wssecurity.wssapi.token.SAMLToken;
7.   import com.ibm.websphere.wssecurity.wssapi.XMLStructure;
8.
9.
10.  import com.ibm.wsspi.wssecurity.core.token.config.RequesterConfiguration;
11.  import com.ibm.wsspi.wssecurity.core.token.config.WSSConstants.Namespace;
12.  import com.ibm.wsspi.wssecurity.core.token.config.WSSConstants.TokenType;
13.  import com.ibm.wsspi.wssecurity.core.token.config.WSSConstants.WST13;
14.  import com.ibm.wsspi.wssecurity.trust.config.ProviderConfig;
15.  import com.ibm.wsspi.wssecurity.trust.config.RequesterConfig;
16.  import com.ibm.wsspi.wssecurity.wssapi.OMStructure;
17.
18.  import org.apache.axiom.om.OMElement;
19.  import org.apache.axis2.util.XMLPrettyPrinter;
20.
21.  import java.util.List;
22.  import java.io.ByteArrayOutputStream;
23.  import java.io.InputStream;
24.  import java.io.BufferedReader;
25.  import java.io.InputStreamReader;
26.  import java.io.IOException;
27.
28.  public class WSSTrustClientExample {
29.
30.    public static void main(String[] args) {
31.          try {
32.          ProviderConfig providerConfig = WSSTrustClient.newProviderConfig(Namespace.WST13, https://MyCompany.com/Trust/13/UsernameMixed );
33.
34.          showProviderConfigDefaultValue(providerConfig);
35.
36.          providerConfig.setPolicySetName("Username WSHTTPS default");
37.          providerConfig.setBindingName("SamlTCSample");
38.          providerConfig.setBindingScope("domain");
39.
40.
41.          RequesterConfig requesterConfig = WSSTrustClient.newRequesterConfig(Namespace.WST13);
42.
43.          showRequestConfigDefaultValue(requesterConfig);
44.
45.          requesterConfig.put(RequesterConfiguration.RSTT.APPLIESTO_ADDRESS, "https://user.MyCompany:9443/WSSampleSei/EchoService12");
46.          requesterConfig.put(RequesterConfiguration.RSTT.TOKENTYPE, TokenType.SAML11);
47.          requesterConfig.put(RequesterConfiguration.RSTT.KEYTYPE, WST13.KEYTYPE_BEARER);
48.          requesterConfig.setSOAPNamespace(Namespace.SOAP12);
49.
50.          WSSTrustClient client = WSSTrustClient.getInstance(providerConfig);
51.          List<SecurityToken> securityTokens = client.issue(providerConfig, requesterConfig);
52.
53.          // Process SAML token

WSSTrustClient class support for policy sets and bindings

The WS-Trust client function supports both application-specific bindings and general bindings for use with the trust client policy set and binding documents. In addition, general bindings and default bindings are supported if the application is running in the application server environment. General bindings are supported in the thin client environment, but default bindings are not.

Managing the policy set and bindings for the WS-Trust client API is similar to managing a policy set and bindings for a web services client. However, differences exist that are unique to the WS-Trust client. One difference is that the WS-Trust client does not use policy set attachments. Instead, the policy set name and binding name are specified in a ProviderConfig object, as shown in line 36 and line 37 of the sample code.

When the WS-Trust client looks for bindings, the way the client manages the search scope differs from the web services client. If you do not specify the wstrustClientBindingScope property for the trust client binding, the system first searches the application for an application-specific binding with the binding name that you specified. If a binding is found, it is used for the trust client request. If no application-specific binding is found, the system searches the available general bindings for a binding with the name that you specified. If a general binding is found, it is used for the trust client request. If no bindings with the specific name are found, then default bindings are used in a server environment. Default bindings are only used in a server environment. If the binding scope is specified, only that scope is used for the binding search.

Line 38 of the sample code, `providerConfig.setBindingScope("domain")`, indicates that the example uses general bindings. You can also set the binding scope to `application` to indicate that the sample code uses application-specific bindings. The example uses the general binding named **SamlTCSample**. Both application-specific and general bindings are supported in the application server and the thin client environment. For more information about configuring the SamlTCSample bindings when the application is installed on the application server, read about configuring policy sets and bindings to communicate with STS.

The showProviderConfigDefaultValue(providerConfig) code on line 34 of the sample code shows the default settings. The sample code includes a utility method that prints out the contents of providerConfig.

Line 51 of the sample code, List<SecurityToken> securityTokens = client.issue(providerConfig, requesterConfig), sends an issue WS-Trust request. The second parameter on this line specifies the RequesterConfig object, and this parameter determines the content of the issue request. The code on line 41, RequesterConfig requesterConfig = WSSTrustClient.newRequesterConfig(Namespace.WST13), instantiates a RequesterConfig object that is used to construct the trust request using the WS-Trust Version 1.3 namespace. A utility function is shown on line 43: showRequestConfigDefaultValue(requesterConfig). This function displays the default settings for the RequesterConfig object. The code between lines 45 and 48 initializes the RequesterConfig to request a Version 1.1 SAML bearer token. This token is used to access the service endpoint using the SOAP 1.2 namespace. In the example, the service endpoint is https://user.MyCompany.com:9443/WSSampleSei/EchoService12.

JVM arguments support

Before executing the sample code, you must set up several Java Virtual Machine (JVM) arguments. The sample code implements the Username WSHTTPS default policy set, which has two requirements: 1) a Username token is sent to the STS; and 2) messages are protected using Secure Sockets Layer (SSL). To set up the environment to meet these requirements, first configure the `ssl.client.props` file to define a truststore. For step-by-step instructions, read about running an unmanaged web services JAX-WS client.

To meet the second requirement regarding SSL message protection, obtain a copy of the STS SSL X.509 certificate and inset it into the truststore. To do this, follow the steps in the topic, Using the retrieveSigners command in SSL, to enable server-to-server trust. Alternately, you can accept the STS certificate when

you send the first trust request to the STS if the com.ibm.ssl.enableSignerExchangePrompt property in the profile_home/properties/ssl.client.props file is set to true. For more information about this option, read about changing the signer auto-exchange prompt at the client.

In addition, you must specify the client JAAS configuration file so that the client runtime environment can locate the Username token LoginModule JAAS login configuration. Specify the parameter using this code: -Djava.security.auth.login.config="%WAS_HOME%\properties\wsjaas_client.conf. You must also include the thin client jar, for example com.ibm.jaxws.thinclient_8.0.0.jar, in the classpath. For more information, read about running an unmanaged web services JAX-WS client application.

Sample code execution

A prerequisite to executing the sample code is to set up an external STS endpoint to issue a SAML 1.1 bearer token for the specified web services as defined by the RequesterConfiguration.RSTT.APPLIESTO_ADDRESS property.

Executing the sample code generates a WS-Trust issue request message, as shown in the example:

```
177.  <?xml version="1.0" encoding="UTF-8"?><soapenv:Envelope xmlns:soapenv="http://www.w3.org/2003/05/soap-envelope">
178.      <soapenv:Header>
179.          <wsa:To xmlns:wsa="http://www.w3.org/2005/08/addressing">https://user.MyCompany.com/Trust/13/UsernameMixed</wsa:To>
180.          <wsa:MessageID xmlns:wsa="http://www.w3.org/2005/08/addressing">urn:uuid:4951B6775950CAC92A1252458259166</wsa:MessageID>
181.          <wsa:Action xmlns:wsa="http://www.w3.org/2005/08/addressing">http://docs.oasis-open.org/ws-sx/ws-trust/200512/RST/Issue</wsa:Action>
182.      </soapenv:Header>
183.      <soapenv:Body>
184.          <wst:RequestSecurityToken xmlns:wst="http://docs.oasis-open.org/ws-sx/ws-trust/200512">
185.              <wst:TokenType>http://docs.oasis-open.org/wss/oasis-wss-saml-token-profile-1.1#SAMLV1.1</wst:TokenType>
186.              <wst:RequestType>http://docs.oasis-open.org/ws-sx/ws-trust/200512/Issue</wst:RequestType>
187.              <wst:KeyType>http://docs.oasis-open.org/ws-sx/ws-trust/200512/Bearer</wst:KeyType>
188.              <wsp:AppliesTo xmlns:wsp="http://schemas.xmlsoap.org/ws/2004/09/policy">
189.                  <wsa:EndpointReference xmlns:wsa="http://www.w3.org/2005/08/addressing">
190.                      <wsa:Address>https://user.MyCompany.com:9443/WSSampleSei/EchoService12</wsa:Address>
191.                  </wsa:EndpointReference>
192.              </wsp:AppliesTo>
193.          </wst:RequestSecurityToken>
194.      </soapenv:Body>
195.  </soapenv:Envelope>
```

To view the WS-Trust request message, you must enable a client-side trace. Set the following JVM properties:

- -DtraceSettingsFile=MyTraceSettings.properties
- -Djava.util.logging.manager=com.ibm.ws.bootstrap.WsLogManager
- -Djava.util.logging.configureByServer=true

For more information about these properties, read about enabling trace on client and stand-alone applications. In addition to setting the JVM properties, you must also specify the trace setting, com.ibm.ws.wssecurity.*=all=enabled, in the MyTraceSettings.properties file. Look for Trust Client outgoing request: in the trace log file.

SAML token return

The code on line 51 of the sample code, List<SecurityToken> securityTokens = client.issue(providerConfig, requesterConfig), returns a SAML token if the WS-Trust issue request is processed successfully. The code between lines 54 and 64 processes the returned SAML token. The utility function shown on line 58, showSAMLToken((SAMLToken)token), displays the content of the received SAML token. The showSAMLToken() routine shows the SAML token as an XML document. An example of this XML document is provided in line 196 to line 233 of the sample code.

```

SAML token library APIs:

The SAML token library application programming interfaces (APIs) provide methods you can use to create, validate, parse, and extract SAML tokens.

Overview

The library implementation for SAML Version 1.1 and SAML Version 2.0 provides three types of subject confirmation: holder-of-key (HoK), bearer, and sender-vouches. You can use the SAML token library APIs to create, validate, and extract the attributes of a SAML HoK or bearer token. SAML token propagation from web services SOAP messages is also discussed. Sample code is provided to demonstrate the use of the APIs.

WebSphere Application Server with SAML provides default policy sets to support the bearer and HoK subject confirmation.

These sections discuss creating a SAML token using the SAML token library APIs:

1. “Configuration of token creation parameters” on page 1476
2. “SAML token factory instance creation” on page 1477
3. “SAML token creation” on page 1477
4. “Sample code” on page 1478

The SAMLTokenFactory API is the primary SAML token library programming interface. SAMLTokenFactory supports creating, parsing, and validating both SAML 1.1 and SAML 2.0 tokens. Using the SAMLTokenFactory API, you can create ProviderConfid, RequesterConfig, and ConsumerConfig configuration objects to define the required SAML token characteristics. Read the API documentation for more details.

You can perform additional operations on a SAML token after it is created, including:

- “SAML token validation” on page 1477
- “SAML token identity mapped to a subject” on page 1477
- “Parse assertion elements” on page 1478
- “SAML token attributes extraction” on page 1478

Note: Starting with WebSphere Application Server Release 8, you can use the `com.ibm.websphere.wssecurity.wssapi.token.SAMLToken` class in Web Services Security (WSS) application programming interface (API). When there is no concern of confusion we use the term `SAMLToken` instead of using its complete package name. You can use WSS API to request

SAMLToken processing from an external Security Token Service (STS), to propagate SAMLTokens in SOAP request messages, and to use a symmetric or asymmetric key identified by SAMLTokens to protect SOAP messages.

The WSS API SAML support complements the `com.ibm.websphere.wssecurity.wssapi.token.SAMLTokenFactory` and `com.ibm.websphere.wssecurity.wssapi.trust.WSSTrustClient` interfaces. SAMLTokens that are generated using the `com.ibm.websphere.wssecurity.wssapi.WSSFactory newSecurityToken()` method can be processed by the `SAMLTokenFactory` and `WSSTrustClient` programming interfaces. Conversely, SAMLTokens that are generated by `SAMLTokenFactory` or returned by `WSSTrustClient` can be used in WSS API. Deciding which API to use in your application depends on your specific needs. WSS API SAML support is self contained in the sense that it provides functionality equivalent to that of the `SAMLTokenFactory` and `WSSTrustClient` interfaces as far as web services client applications are concerned. The `SAMLTokenFactory` interface has additional functions to validate SAMLTokens and to create the JAAS Subject that represents authenticated SAMLTokens. This validation is useful for the Web services provider side. When you develop applications to consume SAMLTokens, the `SAMLTokenFactory` programming interface is more suitable for you.

Configuration of token creation parameters

When you configure the token creation parameters, the configuration information relates to either the requesting entity, the issuing entity, or the receiving entity. In this example, configuration information is defined for the requesting and the issuing entities. For each type of supported subject confirmation, the SAML token library provides pre-configured attributes for the requesting entity. These attributes are used during the creation of the self-issued SAML token by the WebSphere runtime environment. A self-issued SAML token is one that is generated locally, instead of one that is requested from a Security Token Service (STS). If you need to customize the attributes for a default parameter, use the RequesterConfig parameter. For more information, read about the RequesterConfig parameter in the SAMLTokenFactory API topic.

First, set up the requestor configuration information:

```
// Setup the requester's configuration information (parameters needed
// to create the token specified as configuration properties).
// in this case we are using the configuration information to create a
// SAML token that contains a symmetric holder of key subject
// confirmation.
RequesterConfig requesterData =
     samlFactory.newSymmetricHolderOfKeyTokenGenerateConfig();
```

Next, set the recipient public key alias and optionally, the authentication method:

```
// Set recipient's public key alias
// (in this example we use SOAPRecipient), so the provider can encrypt secret
// key for the receiving end.
requesterData.setKeyAliasForAppliesTo("SOAPRecipient");

// Set the authentication method that took place. This is an optional
// parameter.
reqData.setAuthenticationMethod("Password");
```

Then set the issuer configuration attributes:

```
// Set issuer information by instantiating a default ProviderConfig.
// See javadocs for the SAMLTokenFactory class on the details of the
// default values and how to modify them.
ProviderConfig samlIssuerCfg =
  samlFactory.newDefaultProviderConfig("WebSphereSelfIssuer");
```

SAML token factory instance creation

Use the SAMLTokenFactory class, specifying the SAML token type, either Version 1.1 or Version 2.0. Set additional parameters for creating the SAML token.

Use the SAMLTokenFactory class with the SAML token type:

```
// Instantiate a token factory based on the version level of the token
// to use. In this example we use the SAML v1.1 token factory.
SAMLTokenFactory samlFactory =
SAMLTokenFactory.getInstance(SAMLTokenFactory.WssSamlV11Token11);
```

Set additional parameters in the CredentialConfig object using the caller subject or the runAsSubject:

```
// Retrieve the caller subject or the runAsSubject (depending on your
// scenario) then use the Subject to get a CredentialConfig object
// using the SAML token library.
// This invocation requires the
// wssapi.SAMLTokenFactory.newCredentialConfig" Java Security
// permission.
CredentialConfig cred = samlFactory.newCredentialConfig(runAsSubject);
```

SAML token creation

Create the SAML token using the token factory:

```
// Now create the SAML token. This invocation requires the
// "wssapi.SAMLTokenFactory.newSAMLToken" Java Security permission.
SecurityToken samlToken =
                samlFactory.newSAMLToken(cred, reqData, samlIssuerCfg);
```

SAML token validation

An entity that receives a SAML token, such as a business service, can use the SAML token library API to validate the token before using it. For example, the service needs to validate the token before extracting the SAML attributes from the requester. An existing SAML assertion document can be validated using the configuration data from the consumer.

The following API code validates the token:

```
ConsumerConfig consumerConfig = samlFactory.newConsumerConfig();
 XMLStructure xml =
 try {
    SAMLToken token = samlFactory.newSAMLToken( consumerConfig, XMLStructure xml );
    // token successfully validated
 } catch(WSSException e){
  // token failed validation
 }
```

SAML token identity mapped to a subject

A SAML token can be used to create a subject. The name identifier in the SAML token is mapped to a user in the user registry to obtain the principal name for the subject.

```
Subject subject;
SAMLToken aSAMLToken = ...;
  try {
        subject = samlFactory.newSubject(aSAMLToken);
  } catch(WSSException e) {
  }
```

Parse assertion elements

The recipient of a SAML token can parse and extract assertion elements from the SAML token using the SAMLToken APIs, which are included in the SAML token library API. For example, the token creation time can be extracted using this code:

```
Date dateCreated = samlToken.getSamlCreated();
```

Extract the name of the token issuer and the confirmation method as follows:

```
String confirmationMethpo = samlToken.getConfirmationMethod();
String issuerName = samlToken.getSAMLIssuerName();
```

If the extracted subject confirmation method is returned as holder-of-key confirmation, then you can use the following API to retrieve the bytes for the key material:

```
byte[] hokBytes = samlToken.getHolderOfKeyBytes();
```

For more information about all the SAML APIs, read the API documentation for the SAMLToken interface.

SAML token attributes extraction

Extract SAML attributes from the initiating entity (service requester) using the SAMLToken API, as shown in the following code snippets.

```
// Get all attributes
List<SAMLAttribute> allAttributes =
             ((SAMLToken) samlToken).getSAMLAttributes();

// Iterate over the attribute and process accordingly
Iterator<SAMLAttribute> iter = allAttributes.iterator();
while (iter.hasNext())
{
    SAMLAttribute anAttribute = iter.next();

    // Handle attributes
    String attributeName = anAttribute.getName();
    String[] attributeValues = anAttribute.getStringAttributeValue();

}
```

Sample code

The sample code demonstrates how to use the SAML token library APIs to accomplish some of the operations previously described. A JVM property that points to the location of the SAML properties file is a prerequisite for running this code. The SAML properties file, `SAMLIssuerConfig.properties`, must contain configuration attributes related to the issuer (provider) of the SAML token.

The default location of the SAMLIssuerConfig.properties file for the cell level is: *app_server_root*/profiles/*$PROFILE*/config/cells/*$CELLNAME*/sts.

For the server level, the default location is: *app_server_root*/profiles/*$PROFILE*/config/cells/*$CELLNAME*/nodes/*$NODENAME*/servers/*$SERVERNAME*.

```

Creating a SAML bearer token using the API:

Use the SAML library API to create a SAML bearer token.

About this task

This library allows you to create a SAML bearer token. You can use the SAML library API to create required SAML configuration objects, then use those configuration objects to generate a bearer SAML token.

Procedure

1. Create a SAMLTokenFactory instance using the SAML token version as a parameter.
   a. Use the following line of code to import the method:

```
import com.ibm.websphere.wssecurity.wssapi.token.SAMLTokenFactory;
```

b. Use one of these lines of code to create the instance, depending on the token version.
   - Add the following line of code to create a SAMLTokenFactory instance for a version 1.1 SAML token:

```
SAMLTokenFactory samlFactory = SAMLTokenFactory.getInstance(SAMLTokenFactory.WssSamlV11Token11);
```

   - Add the following line of code to create a SAMLTokenFactory instance for a version 2.0 SAML token:

```
SAMLTokenFactory samlFactory = SAMLTokenFactory.getInstance(SAMLTokenFactory.WssSamlV11Token20);
```

2. After you create the instance, the SAMLTokenFactory is used to create a RequesterConfig instance, which determines how the token will be generated, according the authentication requirements of the requester. Use this line of code to create the RequesterConfig instance for the bearer token:

```
RequesterConfig reqData = samlFactory.newBearerTokenGenerateConfig();
```

   The default RequestConfig instance is sufficient to generate a simple bearer token, but additional assertions can be included in the SAML token by customizing the RequesterConfig instance. For example, to include password authentication information in the token, use setAuthenticationMethod:

```
reqData.setAuthenticationMethod("password");
```

   To disable signing in a SAML assertion, use the setAssertionSignatureRequired method, for example:

```
reqData.setAssertionSignatureRequired(false);
```

   For more information, read about the SAML bearer assertion.

3. Use the SAMLTokenFactory to create a ProviderConfig instance, which describes the token issuer. The ProviderConfig instance specifies the SAML issuer name, as well as keystore and truststore information, which identifies the key for SAML encryption and signing. The ProviderConfig instance is created using property values from a property file. The property file specifies the default value of the ProviderConfig object. In a Java client environment, this property file is defined by a JVM system property, com.ibm.webservices.wssecurity.platform.SAMLIssuerConfigDataPath.

   In the WebSphere Application Server runtime environment, the property file name is SAMLIssuerConfig.properties. The file can be located either under the server level configuration directory, or the cell level directory, in that order of precedence. An example of the server level path follows:

```
app_server_root/profiles/$PROFILE/config/cells/$CELLNAME/nodes/$NODENAME/servers/$SERVERNAME/SAMLIssuerConfig.properties
```

   An example of the cell level path follows:

```
app_server_root/profiles/$PROFILE/config/cells/$CELLNAME/sts/SAMLIssuerConfig.properties
```

   The JVM system property, com.ibm.webservices.wssecurity.platform.SAMLIssuerConfigDataPath, is ignored if the property is defined in server runtime environment. For a detailed description of all the properties, read about configuration of a SAML token during token creation.

   Use the following line of code to create a default ProviderConfig instance:

```
ProviderConfig samlIssuerCfg = samlFactory.newDefaultProviderConfig("any issuer name");
```

   The issuer name is optional. If the issuer name is specified, the Issuer name appears in the SAML assertion. If the issuer name is not specified, a default issuer name property from the SAMLIssuerConfig.properties is used as the issuer name.

4. Optional: When creating a new SAML token, the SAMLTokenFactory uses either a JAAS subject or a CredentialConfig instance to populate the new SAML token. To use a JAAS subject to populate the token, use the com.ibm.websphere.security.auth.WSSubject getCallerSubject() API or the getRunAsSubject() API to obtain a JAAS subject that represents the requesting client, or the identity of the execution thread.

   When you use the JAAS subject to create a new SAML token, the SAMLTokenFactory searches for a SAMLToken object in the subject PrivateCredentials list. If a SAMLToken object exists, the NameId or NameIdentifier are copied to the new SAML token. The SAMLTokenFactory also copies the SAML attributes and AuthenticationMethod from the existing SAML token to the new SAML token. The new

SAML token includes a new issuer name, new signing certificate, confirmation method, new KeyInfo for the holder-of-key confirmation method, and new NotBefore and NotOnAfter conditions. These token settings are determined by the configuration parameters in the ProviderConfig and RequesterConfig objects.

If there is no SAMLToken object in the subject, only the WSPrincipal principal name is copied from the subject to the new SAML token. No other attributes in the subject are copied into the new SAML token. Similarly, the issuer name, signing certificate, confirmation method, KeyInfo for the holder-of-key, and NotBefore and NotOnOrAfter conditions are determined by configuration parameters in ProviderConfig and RequesterConfig objects.

Alternately, you can use the RunAsSubject method on the execution thread to create the SAML token. When using this method, do not pass the JAAS subject or the CredentialConfig object to the SAMLTokenFactory to create the SAML token. Instead, the content of the existing SAML token is copied to the new SAML token, as described previously.

Another method of creating a SAML token is to use a CredentialConfig object to populate the SAML NameId and Attributes programmatically. Use this method in the following circumstances:

- Custom SAML attributes must be included in the new SAML token.
- The SAML token is created manually instead of using the SAMLTokenFactory to populate the SAML token from a JAAS subject automatically.
- There is no existing SAML token in the subject.
- There is no JAAS subject available.

To create a CredentialConfig object without using the JAAS subject, use this line of code:

```
CredentialConfig cred = samlFactory.newCredentialConfig ();
```

There is no initial value provided for this CredentialConfig object, so you must use setter methods to populate the CredentialConfig object.

To populate the SAML NameIdentifier or NameID, use the following line of code:

```
cred.setRequesterNameID("any name");
```

The value of the *any name* variable is used as the principal name in the SAML token. The name appears in the assertion as the NameIdentifier in a SAML Version 1.1 token, or NameId in the SAML Version 2.0 token. For example, if the value of *any name* is `Alice`, the following assertion is generated in a SAML Version 1.1 token:

```
<saml:NameIdentifier>Alice</saml:NameIdentifier>
```

The following assertion is generated in a SAML Version 2.0 token:

```
<saml2:NameID>Alice</saml2:NameID>
```

To include SAML attributes in the <AttributeStatement> portion of an assertion, use this code:

```
SAMLAttribute samlAttribute = new SAMLAttribute("email" /* Name*/, new String[] {"joe@websphere"}
/*Attribute Values*/, null, "IBM WebSphere namespace" /* namespace*/, "email" /* format*/, "joe" /*friendly name */);
ArrayList<SAMLAttribute> al = new ArrayList<SAMLAttribute>();
al.add(samlAttribute)
sattribute = new SAMLAttribute("Membership", new String[] {"Super users", "Gold membership"}, null, null /* format*/, null, null );
al.add(samlAttribute );
cred.setSAMLAttributes(al);
```

This sample code generates the following <Attribute> assertions:

```
<saml:Attribute AttributeName="email" NameFormat="email" AttributeNamespace="IBM WebSphere namespace">
<saml:AttributeValue>joe@websphere</saml:AttributeValue>
</saml:Attribute>
<saml:Attribute AttributeName="Membership">
<saml:AttributeValue>Super users</saml:AttributeValue><saml:AttributeValue>Gold membership</saml:AttributeValue>
</saml:Attribute>
```

5. Generate a SAML bearer token using this line of code:

```
SAMLToken samlToken = samlFactory.newSAMLToken(cred, reqData, samlIssuerCfg);
```

This method requires the Java security permission wssapi.SAMLTokenFactory.newSAMLToken.

Complete code samples using lines of code from the previous steps are included in the Example section.

Example

Use this sample code to create a SAML version 1.1 bearer token from the subject:

```
SAMLTokenFactory samlFactory = SAMLTokenFactory.getInstance(SAMLTokenFactory.WssSamlV11Token11)

RequesterConfig reqData = samlFactory.newBearerTokenGenerateConfig();

ProviderConfig samlIssuerCfg = samlFactory.newDefaultProviderConfig("WebSphere Server");

Subject subject =  com.ibm.websphere.security.auth.WSSubject.getRunAsSubject();

SAMLToken samlToken = samlFactory.newSAMLToken(subject, reqData, samlIssuerCfg);
```

Use this sample code to create a SAML version 1.1 bearer token without using the subject:

```
SAMLTokenFactory samlFactory = SAMLTokenFactory.getInstance(SAMLTokenFactory.WssSamlV11Token11);

RequesterConfig reqData = samlFactory.newBearerTokenGenerateConfig();
reqData.setAuthenticationMethod("Password"); //Authentication method for Assertion

ProviderConfig samlIssuerCfg = samlFactory.newDefaultProviderConfig(Self issuer);

CredentialConfig cred = samlFactory.newCredentialConfig ();
cred.setRequesterNameID("Alice");   // SAML NameIdentifier
//SAML attributes:
SAMLAttribute attribute = new SAMLAttribute
   ("email" /* Name*/, new String[] {"joe@websphere"}
   /*Attribute Values in String*/,null
   /*Attribute Values in XML */, "WebSphere" /* Namespace*/, "email" /* format*/, "joe" /*Friendly_name */);
ArrayList<SAMLAttribute> al = new ArrayList<SAMLAttribute>();
al.add(attribute);
attribute = new SAMLAttribute("Membership", new String[] {"Super users", "My team"}, null, null, null, null  );
al.add(attribute);
cred.setSAMLAttributes(al);

SAMLToken samlToken = samlFactory.newSAMLToken(cred, reqData, samlIssuerCfg);
```

Creating a SAML holder-of-key token using the API:

The SAML holder-of-key token extends the security token public interface in WebSphere Application Server, and can be used as a protection token. WebSphere Application Server provides a SAML library API for SAML holder-of-key token creation.

About this task

SAML token creation requires three parameters:

- com.ibm.wsspi.wssecurity.saml.config.RequesterConfig
- com.ibm.wsspi.wssecurity.saml.config.ProviderConfig
- com.ibm.wsspi.wssecurity.saml.config.CredentialConfig

Follow the steps to create an instance for each of the parameters and then create a SAML holder-of-key token. As an alternative to CredentialConfig, you can also use javax.security.auth.Subject. For more information, read the API documentation.

Procedure

1. Create a com.ibm.websphere.wssecurity.wssapi.token.SAMLTokenFactory instance using the SAML token version as a parameter. The supported SAMLToken versions are http://docs.oasis-open.org/wss/oasis-wss-saml-token-profile-1.1#SAMLV1.1 and http://docs.oasis-open.org/wss/oasis-wss-saml-token-profile-1.1#SAMLV2.0. The SAMLTokenFactory instance is a singleton and therefore is thread-safe. Use one of these lines of code to create the instance, depending on the token version.
   - Use the following line of code to create a com.ibm.websphere.wssecurity.wssapi.token.SAMLTokenFactory instance for a version 1.1 SAML token:

```
SAMLTokenFactory samlFactory = SAMLTokenFactory.getInstance(SAMLTokenFactory.WssSamlV11Token11);
```

- Use the following line of code to create a com.ibm.websphere.wssecurity.wssapi.token.SAMLTokenFactory instance for a version 2.0 SAML token:

```
SAMLTokenFactory samlFactory = SAMLTokenFactory.getInstance(SAMLTokenFactory.WssSamlV11Token20);
```

2. The SAMLTokenFactory instance is used to create a RequesterConfig instance, which determines how the token is generated, according the authentication requirements of the requester. Use one of these lines of code to create the RequesterConfig instance, depending on whether you want the token to use a secret key (symmetric key) or a public key:
   - Use the following line of code to create a default RequesterConfig for the SAML holder-of-key token using a secret key (symmetric key), which is included in the SubjectConfirmation:

```
RequesterConfig reqData = samlFactory. newSymmetricHolderOfKeyTokenGenerateConfig ();
```

     You must also set the key alias for the target service so the provider can encrypt the secret key for the service:

```
reqData.setKeyAliasForAppliesTo("Soap Recipient");
```

   - Use the following line of code to create a default RequesterConfig for the SAML holder-of-key token using a public key, which is included in the SubjectConfirmation:

```
RequesterConfig reqData = samlFactory. newAsymmetricHolderOfKeyTokenGenerateConfig ();
```

     You must also set the key alias for the requester so the provider can extract the public key from the requester, and include the key in the SubjectConfirmation:

```
reqData.setKeyAliasForRequester("SOAP Initiator");
```

   The default RequestConfig instance is sufficient to generate a simple holder-of-key token, but additional assertions can be included in the SAML token by customizing the RequesterConfig instance. For example, to include password authentication information in the token, use setAuthenticationMethod:

```
reqData.setAuthenticationMethod("password");
```

3. Use the SAMLTokenFactory to create a ProviderConfig instance, which describes the token issuer. The ProviderConfig instance specifies the SAML issuer name, as well as keystore and truststore information, which identifies the key for SAML encryption and signing. The ProviderConfig instance is created using property values from a property file. The property file specifies the default value of the ProviderConfig object. In a Java client environment, this property file is defined by a JVM system property, com.ibm.webservices.wssecurity.platform.SAMLIssuerConfigDataPath.

   In the WebSphere Application Server runtime environment, the property file name is SAMLIssuerConfig.properties. The file can be located either under the server level configuration directory, or the cell level directory, in that order of precedence. An example of the server level path follows:

```
app_server_root/profiles/$PROFILE/config/cells/$CELLNAME/nodes/$NODENAME/servers/$SERVERNAME/SAMLIssuerConfig.properties
```

   An example of the cell level path follows:

```
app_server_root/profiles/$PROFILE/config/cells/$CELLNAME/sts/SAMLIssuerConfig.properties
```

   The JVM system property, com.ibm.webservices.wssecurity.platform.SAMLIssuerConfigDataPath, is ignored if the property is defined in server runtime environment. For a detailed description of all the properties, read about configuration of a SAML token during token creation.

   Use the following line of code to create a default ProviderConfig instance:

```
ProviderConfig samlIssuerCfg = samlFactory.newDefaultProviderConfig("any issuer name");
```

   The issuer name is optional. If the issuer name is specified, the Issuer name appears in the SAML assertion. If the issuer name is not specified, a default issuer name property from the SAMLIssuerConfig.properties is used as the issuer name.

4. Optional: When creating a new SAML token, the SAMLTokenFactory uses either a JAAS subject or a CredentialConfig instance to populate the new SAML token. To use a JAAS subject to populate the

token, use the com.ibm.websphere.security.auth.WSSubject getCallerSubject() API or the getRunAsSubject() API to obtain a JAAS subject that represents the requesting client, or the identity of the execution thread.

When you use the JAAS subject to create a new SAML token, the SAMLTokenFactory searches for a SAMLToken object in the subject PrivateCredentials list. If a SAMLToken object exists, the NameId or NameIdentifier are copied to the new SAML token. The SAMLTokenFactory also copies the SAML attributes and AuthenticationMethod from the existing SAML token to the new SAML token. The new SAML token includes a new issuer name, new signing certificate, confirmation method, new KeyInfo for the holder-of-key confirmation method, and new NotBefore and NotOnAfter conditions. These token settings are determined by the configuration parameters in the ProviderConfig and RequesterConfig objects.

If there is no SAMLToken object in the subject, only the WSPrincipal principal name is copied from the subject to the new SAML token. No other attributes in the subject are copied into the new SAML token. Similarly, the issuer name, signing certificate, confirmation method, KeyInfo for the holder-of-key, and NotBefore and NotOnOrAfter conditions are determined by configuration parameters in ProviderConfig and RequesterConfig objects.

Alternately, you can use the RunAsSubject method on the execution thread to create the SAML token. When using this method, do not pass the JAAS subject or the CredentialConfig object to the SAMLTokenFactory to create the SAML token. Instead, the content of the existing SAML token is copied to the new SAML token, as described previously.

Another method of creating a SAML token is to use a CredentialConfig object to populate the SAML NameId and Attributes programmatically. Use this method in the following circumstances:

- Custom SAML attributes must be included in the new SAML token.
- The SAML token is created manually instead of using the SAMLTokenFactory to populate the SAML token from a JAAS subject automatically.
- There is no existing SAML token in the subject.
- There is no JAAS subject available.

To create a CredentialConfig object without using the JAAS subject, use this line of code:

```
CredentialConfig cred = samlFactory.newCredentialConfig ();
```

There is no initial value provided for this CredentialConfig object, so you must use setter methods to populate the CredentialConfig object.

To populate the SAML NameIdentifier or NameID, use the following line of code:

```
cred.setRequesterNameID("any name");
```

The value of the *any name* variable is used as the principal name in the SAML token. The name appears in the assertion as the NameIdentifier in a SAML Version 1.1 token, or NameId in the SAML Version 2.0 token. For example, if the value of *any name* is `Alice`, the following assertion is generated in a SAML Version 1.1 token:

```
<saml:NameIdentifier>Alice</saml:NameIdentifier>
```

The following assertion is generated in a SAML Version 2.0 token:

```
<saml2:NameID>Alice</saml2:NameID>
```

To include SAML attributes in the <AttributeStatement> portion of an assertion, use this code:

```
SAMLAttribute samlAttribute = new SAMLAttribute("email" /* Name*/, new String[] {"joe@websphere"}
/*Attribute Values*/, null, "IBM WebSphere namespace" /* namespace*/, "email" /* format*/, "joe" /*friendly name */);
ArrayList<SAMLAttribute> al = new ArrayList<SAMLAttribute>();
al.add(samlAttribute)
sattribute = new SAMLAttribute("Membership", new String[] {"Super users", "Gold membership"}, null, null /* format*/, null, null );
al.add(samlAttribute );
cred.setSAMLAttributes(al);
```

This sample code generates the following <Attribute> assertions:

```
<saml:Attribute AttributeName="email" NameFormat="email" AttributeNamespace="IBM WebSphere namespace">
<saml:AttributeValue>joe@websphere</saml:AttributeValue>
</saml:Attribute>
<saml:Attribute AttributeName="Membership">
<saml:AttributeValue>Super users</saml:AttributeValue><saml:AttributeValue>Gold membership</saml:AttributeValue>
</saml:Attribute>
```

5. Generate a SAML holder-of-key token using this line of code:

```
SAMLToken samlToken = samlFactory.newSAMLToken(cred, reqData, samlIssuerCfg);
```

This method requires the Java security permission wssapi.SAMLTokenFactory.newSAMLToken. Complete code samples using lines of code from the previous steps are included in the Example section.

Example

Use this sample code to create a SAML version 1.1 holder-of-key token using a secret key (symmetric key) from the subject.

```
import com.ibm.wsspi.wssecurity.saml.config.RequesterConfig;
import com.ibm.wsspi.wssecurity.saml.config.ProviderConfig;
import com.ibm.wsspi.wssecurity.saml.config.CredentialConfoig ;
import com.ibm.websphere.wssecurity.wssapi.token.SAMLTokenFactory

SAMLTokenFactory samlFactory =  SAMLTokenFactory.getInstance(SAMLTokenFactory.WssSamlV11Token11);

RequesterConfig reqData  =  samlFactory.newSymmetricHolderOfKeyTokenGenerateConfig();

//Map "AppliesTo" to key alias, so library knows how to encrypt the Symmetric Key
reqData.setKeyAliasForAppliesTo("SOAPRecipient");

ProviderConfig samlIssuerCfg = samlFactory.newDefaultProviderConfig(IsserUri);

Subject subject =  com.ibm.websphere.security.auth.WSSubject.getRunAsSubject();

SAMLToken samlToken = samlFactory.newSAMLToken(subject, reqData, samlIssuerCfg);
```

Use this sample code to create a SAML version 2.0 holder-of-key token using a public key from the subject:

```
//User expression on how SAML should be created, default provided
RequesterConfig reqData =  samlFactory.newAsymmetricHolderOfKeyTokenGenerateConfig();

//Choose a public key to be included in SAML
reqData.setKeyAliasForRequester("SOAPInitiator");

//Get issuer key store so can sign or encrypt assertion, issuer name
ProviderConfig samlIssuerCfg = samlFactory.newDefaultProviderConfig("any_issuer");

//Get JAAS Subject so the factory can populate principal and attributes to SAML
Subject subject =  com.ibm.websphere.security.auth.WSSubject.getRunAsSubject();

SAMLToken samlToken = samlFactory.newSAMLToken(subject, reqData, samlIssuerCfg);
```

Use this sample code to create a SAML version 2.0 holder-of-key token using a secret key (symmetric key):

```
SAMLTokenFactory samlFactory =  SAMLTokenFactory.getInstance (SAMLTokenFactory.WssSamlV20Token11);

RequesterConfig reqData = samlFactory. newSymmetricHolderOfKeyTokenGenerateConfig ();
//Map "AppliesTo" to key alias so library knows how to encrypt the Symmetric Key
reqData.setKeyAliasForAppliesTo("SOAPRecipient");

ProviderConfig samlIssuerCfg = samlFactory.newDefaultProviderConfig(null);

CredentialConfig cred = samlFactory.newCredentialConfig ();
cred.setRequesterNameID("any_name");

SAMLToken samlToken =  samlFactory.newSAMLToken(subject, reqData, samlIssuerCfg);
```

Creating a SAML sender-vouches token using the API:

Use the SAML library API to create a SAML sender-vouches token, which includes the sender-vouches confirmation method. The sender-vouches confirmation method is used when a server needs to propagate the client identity or behavior of the client.

About this task

When SAML function is installed on a WebSphere server, a SAML library API is provided. Use the library to create a SAML sender-vouches token. You can use the SAML library API to create required SAML configuration objects. Then, use those configuration objects to generate a SAML sender-vouches token.

Procedure

1. Create a SAMLTokenFactory instance using the SAML token version as a parameter.
   a. Use the following line of code to import the method:

```
import com.ibm.websphere.wssecurity.wssapi.token.SAMLTokenFactory;
```

   b. Use one of these lines of code to create the instance, depending on the token version.
      - Add the following line of code to create a SAMLTokenFactory instance for a version 1.1 SAML token:

```
SAMLTokenFactory samlFactory = SAMLTokenFactory.getInstance(SAMLTokenFactory.WssSamlV11Token11);
```

      - Add the following line of code to create a SAMLTokenFactory instance for a version 2.0 SAML token:

```
SAMLTokenFactory samlFactory = SAMLTokenFactory.getInstance(SAMLTokenFactory.WssSamlV11Token20);
```

2. After you create the instance, the SAMLTokenFactory is used to create a RequesterConfig instance, which determines how the token will be generated, according the authentication requirements of the requester. Use this line of code to create the RequesterConfig instance for the sender-vouches token:

```
RequesterConfig reqData = samlFactory.newSenderVouchesTokenGenerateConfig();
```

   The default RequestConfig instance is sufficient to generate a simple sender-vouches token, but additional assertions can be included in the SAML token by customizing the RequesterConfig instance. For example, to include password authentication information in the token, use the method, setAuthenticationMethod:

```
reqData.setAuthenticationMethod("password");
```

   The trust validation for a sender-vouches assertion is the responsibility of the sender, not the issuer, so the Enveloped-Signature element is not required in the assertion. To remove the Enveloped-Signature element from the SAML assertion, use the setAssertionSignatureRequired method; for example:

```
reqData.setAssertionSignatureRequired(false);
```

3. Use the SAMLTokenFactory API to create a ProviderConfig instance, which describes the token issuer. The ProviderConfig instance specifies the SAML issuer name, as well as keystore and truststore information, which identifies the key for SAML encryption and signing. The ProviderConfig instance is created using property values from a property file. The property file specifies the default value of the ProviderConfig object. In a Java client environment, this property file is defined by a JVM system property, com.ibm.webservices.wssecurity.platform.SAMLIssuerConfigDataPath.

   In the WebSphere Application Server runtime environment, the property file name is SAMLIssuerConfig.properties. The file can be located either under the server level configuration directory, or the cell level directory, in that order of precedence. See the following example of the server-level path:

```
app_server_root/profiles/$PROFILE/config/cells/$CELLNAME/nodes/$NODENAME/servers/$SERVERNAME/SAMLIssuerConfig.properties
```

   See the following example of the cell-level path:

```
app_server_root/profiles/$PROFILE/config/cells/$CELLNAME/sts/SAMLIssuerConfig.properties
```

   The JVM system property, com.ibm.webservices.wssecurity.platform.SAMLIssuerConfigDataPath, is ignored if the property is defined in server runtime environment. For a detailed description of all the properties, read about configuration of a SAML token during token creation.

   Use the following line of code to create a default ProviderConfig instance:

```
ProviderConfig samlIssuerCfg = samlFactory.newDefaultProviderConfig("any issuer name");
```

The issuer name is optional. If the issuer name is specified, the Issuer name appears in the SAML assertion. If the issuer name is not specified, a default issuer name property from the SAMLIssuerConfig.properties is used as the issuer name.

4. Optional: When creating a new SAML token, the SAMLTokenFactory uses either a Java Authentication and Authorization Service (JAAS) subject or a CredentialConfig instance to populate the new SAML token. To use a JAAS subject to populate the token, use the com.ibm.websphere.security.auth.WSSubject getCallerSubject() API or the getRunAsSubject() API to obtain a JAAS subject that represents the requesting client, or the identity of the execution thread.
   - When you use the JAAS subject to create a new SAML token, the SAMLTokenFactory API searches for a SAMLToken object in the subject PrivateCredentials list. If a SAMLToken object exists, the NameId or NameIdentifier objects are copied to the new SAML token. The SAMLTokenFactory also copies the SAML attributes and AuthenticationMethod method from the existing SAML token to the new SAML token. The new SAML token includes a new issuer name, new signing certificate, confirmation method, new KeyInfo for the holder-of-key confirmation method, and new NotBefore and NotOnAfter conditions. These token settings are determined by the configuration parameters in the ProviderConfig and RequesterConfig objects.

     If there is no SAMLToken object in the subject, only the WSPrincipal principal name is copied from the subject to the new SAML token. No other attributes in the subject are copied into the new SAML token. Similarly, the issuer name, signing certificate, confirmation method, KeyInfo for the holder-of-key, and NotBefore and NotOnOrAfter conditions are determined by configuration parameters in ProviderConfig and RequesterConfig objects.

     Alternately, you can use the RunAsSubject method on the execution thread to create the SAML token. When using this method, do not pass the JAAS subject or the CredentialConfig object to the SAMLTokenFactory to create the SAML token. Instead, the content of the existing SAML token is copied to the new SAML token, as described previously.
   - Another method of creating a SAML token is to use a CredentialConfig object to populate the SAML NameId and Attributes programmatically. Use this method in the following circumstances:
     – Custom SAML attributes must be included in the new SAML token.
     – The SAML token is created manually instead of using the SAMLTokenFactory to populate the SAML token from a JAAS subject automatically.
     – There is no existing SAML token in the subject.
     – There is no JAAS subject available.

   a. To create a CredentialConfig object without using the JAAS subject, use this line of code:

```
CredentialConfig cred = samlFactory.newCredentialConfig ();
```

      There is no initial value provided for this CredentialConfig object, so you must use setter methods to populate the CredentialConfig object.

   b. To populate the SAML NameIdentifier or NameID, use the following line of code:

```
cred.setRequesterNameID("any name");
```

      The value of the parameter passed to the setRequesterNameID() method is used as the principal name in the SAML token. The name appears in the assertion as the NameIdentifier in a SAML Version 1.1 token, or NameId in the SAML Version 2.0 token. For example, if the value of the parameter passed to the setRequesterNameID() method is `Alice`, the following assertion is generated in a SAML Version 1.1 token:

```
<saml:NameIdentifier>Alice</saml:NameIdentifier>
```

      The following assertion is generated in a SAML Version 2.0 token:

```
<saml2:NameID>Alice</saml2:NameID>
```

   c. To include SAML attributes in the <AttributeStatement> portion of an assertion, use this code:

```
SAMLAttribute samlAttribute = new SAMLAttribute("email" /* Name*/, new String[] {"joe@websphere"}
/*Attribute Values*/, null, "IBM WebSphere namespace" /* namespace*/, "email" /* format*/, "joe" /*friendly name */);
ArrayList<SAMLAttribute> al = new ArrayList<SAMLAttribute>();
al.add(samlAttribute)
sattribute = new SAMLAttribute("Membership", new String[] {"Super users", "Gold membership"}, null, null /* format*/, null, null );
al.add(samlAttribute );
cred.setSAMLAttributes(al);
```

This sample code generates the following <Attribute> assertions:

```
<saml:Attribute AttributeName="email" NameFormat="email" AttributeNamespace="IBM WebSphere namespace">
<saml:AttributeValue>joe@websphere</saml:AttributeValue>
</saml:Attribute>
<saml:Attribute AttributeName="Membership">
<saml:AttributeValue>Super users</saml:AttributeValue><saml:AttributeValue>Gold membership</saml:AttributeValue>
</saml:Attribute>
```

5. Generate a SAML sender-vouches token using this line of code:

```
SAMLToken samlToken = samlFactory.newSAMLToken(cred, reqData, samlIssuerCfg);
```

This method requires the Java security permission wssapi.SAMLTokenFactory.newSAMLToken.

Complete code samples using lines of code from the previous steps are included in the Example section.

Example

Use this sample code to create a SAML version 1.1 sender-vouches token from the subject:

```
SAMLTokenFactory samlFactory = SAMLTokenFactory.getInstance(SAMLTokenFactory.WssSamlV11Token11)

RequesterConfig reqData = samlFactory.newSenderVouchesTokenGenerateConfig();

ProviderConfig samlIssuerCfg = samlFactory.newDefaultProviderConfig("WebSphere Server");

Subject subject =  com.ibm.websphere.security.auth.WSSubject.getRunAsSubject();

SAMLToken samlToken = samlFactory.newSAMLToken(subject, reqData, samlIssuerCfg);
```

Use this sample code to create a SAML version 1.1 sender-vouches token without using the subject:

```
SAMLTokenFactory samlFactory = SAMLTokenFactory.getInstance(SAMLTokenFactory.WssSamlV11Token11);

RequesterConfig reqData = samlFactory.newSenderVouchesTokenGenerateConfig();
reqData.setAuthenticationMethod("Password"); //Authentication method for Assertion

ProviderConfig samlIssuerCfg = samlFactory.newDefaultProviderConfig(Self issuer);

CredentialConfig cred = samlFactory.newCredentialConfig ();
cred.setRequesterNameID("Alice");   // SAML NameIdentifier
//SAML attributes:
SAMLAttribute attribute = new SAMLAttribute
   ("email" /* Name*/, new String[] {"joe@websphere"}
   /*Attribute Values in String*/,null
   /*Attribute Values in XML */, "WebSphere" /* Namespace*/, "email" /* format*/, "joe" /*Friendly_name */);
ArrayList<SAMLAttribute> al = new ArrayList<SAMLAttribute>();
al.add(attribute);
attribute = new SAMLAttribute("Membership", new String[] {"Super users", "My team"}, null, null, null, null  );
al.add(attribute);
cred.setSAMLAttributes(al);

SAMLToken samlToken = samlFactory.newSAMLToken(cred, reqData, samlIssuerCfg);
```

Propagation of SAML tokens using the API:

The SAML propagation function is useful for applications that interact across multiple servers. The propagation feature communicates token information from the originating server downstream to other servers.

You can propagate SAML tokens using administrative commands, or programmatically using the SAML application programming interface (API). Propagation through administrative commands is discussed in the topics Propagating SAML tokens and SAML token propagation methods.

Programmatic propagation of SAML tokens is achieved through a combination of explicit programming and use of the Web Services Security runtime environment. For example, you can extract the SAMLToken from the org.apache.axis2.jaxws.BindingProvider object. The token is then used for outbound calls. In this

example, since WebSphere security is not required, programmatically propagating the SAML token allows you to exploit SAML security at the application level. Furthermore, the SAML token can be communicated downstream using any protocol.

Use the following sample code to extract the SAMLToken on the client side after the first request is completed.

Create a Dispatch object and invoke the request:

```
javax.xml.ws.Dispatch dispatch = ...;
dispatch.invoke();
```

Obtain a response context and extract the SAMLToken:

```
Map<String, Object> responseContext = dispatch.getResponseContext();
   SAMLToken samlToken =
       (SAMLToken ) responseContext.get(com.ibm.wsspi.wssecurity.saml.config.SamlConstants.
    SAMLTOKEN_OUT_MESSAGECONTEXT);
```

The following sample code shows how to reuse a SAMLToken for subsequent web services requests.

The web services client program creates a dispatch instance to invoke a service:

```
javax.xml.ws.Dispatch dispatch = ...;
```

The web services client then uses this code to pass a SAMLToken to the Web Services Security handler:

```
Map<String, Object> requestContext = dispatch.getRequestContext();
     requestContext.put(com.ibm.wsspi.wssecurity.saml.config.SamlConstants.
     SAMLTOKEN_IN_MESSAGECONTEXT, samlToken);
```

The web services provider (receiver) can use the following code to extract a SAMLToken from an incoming web services request.

Extract a SAMLToken from the requestContext:

```
Subject subject = (Subject) context.get(com.ibm.wsspi.wssecurity.core.Constants.WSSECURITY_TOKEN_WSSSUBJECT);
 SAMLToken samlToken = null;
     try
     {
      samlToken = (SAMLToken) AccessController.doPrivileged(
        new java.security.PrivilegedExceptionAction() {
         public Object run() throws
             java.lang.Exception
         {
          final java.util.Iterator authIterator =
                subject.getPrivateCredentials(SAMLToken.class)
                .iterator();
          if ( authIterator.hasNext() ) {
           final SAMLToken token = (SAMLToken)
                  authIterator.next();

           return token;
          }
          return null;
         }
        });
 } catch (Exception ex) {
  // Error handling
```

Extract the SAML attributes:

```
List<SAMLAttribute> allAttributes;
allAttributes = ((SAMLToken) samlToken).getSAMLAttributes();
```

The web services client runtime environment can cache the SAML token. On subsequent client requests within the application, the security runtime environment retrieves the SAML token from the cache for use with the target.

Web services client token cache for SAML:

When a SAML token is initially requested, the web services runtime environment automatically caches the SAMLToken. As a result of this automatic client token caching function, subsequent web services requests can use the SAMLToken from the previous request.

The web services client token cache for SAML enables web services clients to reuse SAML tokens when accessing business services. Reusing valid SAML tokens reduces traffic to the Security Token Service (STS) and also reduces the performance impact of sending WS-Trust request messages. There are several requirements for a token to be considered valid and therefore available for caching and reuse.

In order for a SAML token to be reused, the expiration time of the token must be equivalent to, or greater than, the current time. A cache cushion is added to the current time when comparing the token expiration time with the current time so that the token does not expire immediately after it is sent.

In addition, a token is valid only if it is sent again to the same business service. The SAML function in WebSphere Application Server does not verify the AudienceRestriction condition for the SAML token. Therefore, a practical way to ensure that the SAML token is reused for the right audience is to reuse the token only for the same web service that originally used the token. If an assertion contains the OneTimeUse assertion, the SAML token is not cached.

To take advantage of the SAMLToken cache, the application and SAMLToken must meet the following requirements:

- The SAMLToken must have a relatively long expiration time, with at least 5 minutes remaining in the token lifetime after the first request is completed. The WS-Security runtime environment validates the cached SAMLToken expiration time against a predefined cache cushion. The cached token is valid only if the remaining token lifetime is greater than the cushion value. The default cushion value is 5 minutes. This value can be configured using the custom property, cacheCushion. To override the default cache cushion, edit the CallbackHandler custom property for the SAMLToken generator. Add the cacheCushion property and set the cache cushion value in milliseconds. If the cached SAMLToken lifetime is within the cache cushion limit, a new SAMLToken is requested. For example, you can change the cache cushion to 3 minutes or 180000 milliseconds.

Custom property name	Value
cacheCushion	180000

- The SAML token cannot contain the OneTimeUse assertion.
- If the SAML token is encrypted, make sure that the STS communicates the token expiration time outside the encrypted token, and that the SAML token does not include the OneTimeUse assertion.

When you do not want to reuse the same SAMLToken for subsequent requests, you can disable the client side SAMLToken cache with the cacheToken custom property. To disable the client side SAMLToken cache, modify the custom property in the CallbackHandler for the SAMLToken generator. Add the cacheToken property and set the value to `false`.

Custom property name	Value
cacheToken	false

Securing web services applications using the WSS APIs at the message level

Standards and profiles address how to provide protection for messages that are exchanged in a web service environment. Web Services Security is a message-level standard that is based on securing SOAP messages through XML digital signature, confidentiality through XML encryption, and credential propagation through security tokens.

Before you begin

To secure web services, you must consider a broad set of security requirements, including authentication, authorization, privacy, trust, integrity, confidentiality, secure communications channels, delegation, and auditing across a spectrum of application and business topologies. One of the key requirements for the security model in today's business environment is the ability to interoperate between formerly incompatible security technologies in heterogeneous environments. The complete Web Services Security protocol stack and technology roadmap is described in the web services roadmap.

About this task

The Organization for the Advancement of Structured Information Standards (OASIS) Web Services Security: SOAP Message Security Version 1.1 specification is the basic messaging transport for all web services. SOAP 1.2 adds extensions to the existing SOAP 1.1 extensions so that you can build secure web services. Attachments can be added to SOAP messages by using Message Transmission Optimization Mechanism (MTOM) and XML-binary Optimized Packaging (XOP) instead of the SOAP with Attachments (SWA) profile.

The OASIS Web Services Security (WS-Security) Version 1.1 specification is the building block that is used in conjunction with other web service and application-specific protocols to accommodate a wide variety of security models. Web Services Security for WebSphere Application Server is based on specific standards that are included in the OASIS Web Services Security Version 1.1 specification and profiles.

The Version 1.1 specification defines additional facilities for protecting the integrity and confidentiality of a message. The Version 1.1 specification also provides the mechanisms for associating security-related claims with the message. The Web Services Security Version 1.1 standards that are supported by WebSphere Application Server include the signature confirmation, encrypted header elements, the Username Token Profile and the X.509 Token Profile. The Username Token Profile and the X.509 Token Profile have been updated as Version 1.1 profiles. For the X.509 Certificate Token Profile, one new type of security token reference is the Thumbprint reference, which is specified in the binding.

XML Schema, Part 1 and Part 2 are specifications that explain how schemas are organized in XML documents. The two WS-Security Version 1.0 schemas have been updated to the Version 1.1 specifications plus a new Version 1.1 schema has been added. Note that the Version 1.1 schema does not replace the Version 1.0 schema but instead builds upon it by defining an additional set of capabilities within a Version 1.1 namespace.

You can use the following methods to configure Web Services Security and to define policy types to secure the SOAP messages:

- **Use the administrative console to configure policy sets.**

  This method uses the bootstrap policy that is defined in the policy set. You can use policy sets, or assertions about how services are defined, to simplify your security configuration for web services. You can use the administrative console to create, modify, and delete custom policy sets. A set of default policy sets are available.

  For example, you can define the bootstrap policy in the policy set to secure the Web Services Trust (WS-Trust) SOAP messages.

  You can also use the administrative console to perform policy set management tasks and to secure web services using encryption, signing information, and security tokens.

  The following steps high-level steps describe how to configure WebSphere Application Server to use WS-Security and to secure the SOAP messages using the administrative console. The generator and consumer tasks that are discussed in the following steps use WS-Security Versions 1.0 and 1.1.

  – Create and configure the application policy sets or the system policy sets for trust service.

  – Define the policy types to be used to secure the SOAP messages when creating and configuring the policy sets.

- Configure the policy set binding. Select either the symmetric or asymmetric binding assertion to describe the token type and the algorithm to be used for message protection.
- Assemble your Web Services Security-enabled application by using an assembly tool.

- **Use the Web Services Security APIs (WSS API) to configure the SOAP message context (only for the client)**

  WebSphere Application Server uses a new API programming model. In addition to the existing JAX-RPC programming model, a new programming model, Java API for XML Web Services (JAX-WS), has been added. The JAX-WS programming standard aligns with the document-centric messaging model and replaces the remote procedure call programming model defined by the Java API for XML-based RPC (JAX-RPC) specification.

  For example, an application could create system policy sets and then use the WebSphere Application Server WSS API to acquire the security context token for programmatic API-based Web Services Secure Conversation (WS-SecureConversation).

  You can also use the administrative console to perform the encryption, signing, and token configuration tasks that the WSS APIs perform to secure web services.

  The following high-level steps describe how to configure WebSphere Application Server to use WS-Security and to secure the SOAP messages using the WSS APIs. The generator and consumer tasks that are discussed in the following steps use WS-Security Versions 1.0 and 1.1.

  - Use the WSSSignature API to configure the signing information for the request generator (client side) binding.

    Different message parts can be specified in the message protection for a request on the generator side. The default required parts are BODY, ADDRESSING_HEADERS and TIMESTAMP.

    The WSSSignature API also specifies the different algorithm methods to be used with the signature for message protection. The default signature method is RSA_SHA1. The default canonicalization method is EXC_C14N.
  - Use the WSSSignPart API if you want to change the digest method and the transform method.

    The default signed parts are WSSSignature.BODY, WSSSignature.ADDRESSING_HEADERS and WSSSignature.TIMESTAMP.

    The WSSSignPart API also specifies the different algorithm methods to be used if you added or changed the signed parts. The default digest method is SHA1. The default transform method is TRANSFORM_EXC_C14N. For example, use the WSSSignPart API if you want to generate the signature for the SOAP message using the SHA256 digest method instead of the default value of SHA1.
  - Use the WSSEncryption API to configure the encryption information on the request generator side.

    The encryption information on the generator side is used for encrypting an outgoing SOAP message for the request generator (client side) bindings. The default targets of encryption are BODY_CONTENT and SIGNATURE.

    The WSSEncryption API also specifies the different algorithm methods to be used to protect message confidentiality. The default data encryption method is AES128. The default key encryption method is KW_RSA_OAEP.
  - Use the WSSEncryptPart API if you want to set the transform method only.

    For example, if you want to change the data encryption method from the default value of AES128 to TRIPLE_DES.

    No algorithm methods are required for encrypted parts.
  - Use the WSS API to configure the token on the generator side.

    The requirements for the security token depend on the token type. The JAAS Login Module and the JAAS CallbackHandler are responsible for creating the security token on the generator side. Different stand-alone tokens can be sent in request and response. The default token is the X509Token. The other token that can be used for signing is the DerivedKeyToken, which is used only with Web Services Secure Conversation (WS-SecureConversation).
  - Use the WSSVerification API to verify the signature for the response consumer (client side) binding.

Different message parts can be specified in the message protection for a response on the consumer side. The required targets for verification are BODY, ADDRESSING_HEADERS and TIMESTAMP.

The WSSVerification API also specifies the different algorithm methods to be used for verifying the signature and for message protection. The default signature method is RSA_SHA1. The default canonicalization method is EXC_C14N.

– Use the WSSVerifyPart API to change the digest method and the transform method. The required verify parts are WSSVerification.BODY, WSSVerification.ADDRESSING_HEADERS and WSSVerification.TIMESTAMP.

  The WSSVerifyPart API also specifies the different algorithm methods to be used if you added or changed the verification parts. The default digest method is SHA1. The default transform method is TRANSFORM_EXC_C14N.

– Use the WSSDecryption API to configure the decryption information for the response consumer (client side) binding.

  The decryption information on the consumer side is used for decrypting an incoming SOAP message. The targets of decryption are BODY_CONTENT and SIGNATURE. The default key encryption method is KW_RSA_OAEP.

  No algorithm methods are required for decryption.

– Use the WSSDecryptPart API if you want to set the transform method only.

  For example, if you want to change the data encryption method from the default value of AES128 to TRIPLE_DES.

  No algorithm methods are required for decrypted parts.

– Use the WSS API to configure the token on the consumer side.

  The requirements for the security token depend on the token type. The JAAS Login Module and the JAAS CallbackHandler are responsible for validating (authenticating) the security token on the consumer side. Different stand-alone tokens can be sent in request or response.

  The WSS API adds the information for the candidate token that is used for decryption. The default token is X509Token.

- **Use the wsadmin administrative scripting tool to configure policy sets.**

  This method allows you to create, manage, and delete policy sets from the command-line or to create scripts to automate your tasks. You can use the wsadmin tool and the PolicySetManagement command group to manage default policy sets, create custom policy sets, configure policies, and manage attachments and bindings. For more information, use the policy set scripting topics in the information center.

To secure web services with WebSphere Application Server, you must configure the generator and the consumer security constraints. You must specify several different configurations. Although there is no specific sequence to specify these different configurations, some configurations reference other configurations. For example, decryption configurations reference encryption configurations.

Results

After completing these high-level steps for WebSphere Application Server, you have secured web services by configuring policy sets and by using the WSS API to configure encryption and decryption, the signature and signature verification information, and the consumer and generator tokens.

Securing messages at the request generator using WSS APIs:

You can secure SOAP messages by configuring signing information, encryption, and generator tokens to protect message integrity, confidentiality, and authenticity, respectively. This request (client-side) generator configuration defines the Web Services Security requirements for the outgoing SOAP message request.

Before you begin

To secure web services with WebSphere Application Server, you must configure the generator and the consumer security constraints. Therefore, in addition to securing messages at the request generator level, you must also secure messages at the response consumer level.

About this task

The request (client-side) generator configuration requirements involve generating a SOAP message request that uses a digital signature, incorporates encryption, and attaches security tokens.

To secure web service applications, you must specify several different configurations. Although there is no specific sequence to specify these different configurations, some configurations reference other configurations. For example, decryption configurations reference encryption configurations.

You can use the following interfaces to configure Web Services Security and to define policy types to secure the SOAP messages:

- Use the administrative console to configure policy sets.
- Use the Web Services Security APIs (WSS API) to configure the SOAP message context (only for the client)

The following high-level steps use the WSS APIs:

Procedure

- Configure generator signing to protect message integrity.
- Configure encryption to protect message confidentiality.
- Attach generator tokens to protect message authenticity.
- Propagate self-issued SAML bearer tokens using WSS APIs.
- Propagate self-issued SAML sender-vouches tokens with message protection using WSS APIs.
- Propagate self-issued SAML sender-vouches tokens with transport protection using WSS APIs.
- “Sending self-issued SAML holder-of-key tokens with symmetric key using WSS APIs” on page 1598.
- “Sending self-issued SAML holder-of-key tokens with asymmetric key using WSS APIs” on page 1600.

Results

After completing these procedures, you have secured messages at the request generator level.

What to do next

Next, if not already configured, secure messages with signature verification, decryption, and consumer tokens at the response consumer (client-side) level.

Configuring encryption to protect message confidentiality using the WSS APIs:

You can configure encryption information for the client-side request generator (sender) bindings. Encryption information is used to specify how the generators (senders) encrypt outgoing SOAP messages. To configure encryption, specify which message parts to encrypt and specify which algorithm methods and security tokens are to be used for encryption.

Before you begin

Confidentiality refers to encryption while integrity refers to digital signing. Confidentiality reduces the risk of someone understanding the message flowing across the Internet. With confidentiality specifications, the message is encrypted before it is sent and decrypted when it is received at the correct target. Prior to

configuring encryption, familiarize yourself with XML encryption.

About this task

For encryption, you must specify the following:

- Which parts of the message are to be encrypted.
- Which encryption algorithms to specify.

To configure encryption and encrypted parts on the client side, use the WSSEncryption and WSSEncryptPart APIs, or configure policy sets using the administrative console.

WebSphere Application Server provides default values for bindings. However, an administrator must modify the defaults for a production environment.

WebSphere Application Server uses encryption information for the default generator to encrypt parts of the SOAP message. The WSSEncryption API configures the following required parts as encrypted parts.

Table 149. Required encrypted parts. Use encrypted parts to increase the confidentiality of SOAP messages.

Encryption parts	Description
Keywords	Keywords are used to add the encrypted parts to the SOAP message.
XPath expression	An XPath expression is used to add the encrypted parts to the SOAP message.
WSSEncryptPart object	This object adds the encrypted parts to the SOAP message.
WSSSignature object	This object adds the signature component as an encrypted part.
Header	This part adds the header in the SOAP header, specified by QName, as an encryption part.
Security token object	This object adds the security token as an encryption part.

Web Services Security API (WSS API) supports symmetric encryption, by using a shared key, only when Web Services Secure Conversation (WS-SecureConversation) is used.

The WSS APIs allow the use of either keywords or an XPath expression to specify the parts of the message that are to be encrypted. WebSphere Application Server supports the use of the following keywords:

Table 150. Supported encryption keywords. Use keywords to specify encrypted parts.

Keyword	References
BODY_CONTENT	The keyword for the contents of the SOAP message body as an encryption target.
SIGNATURE	The keyword for the signature component as an encryption target.

If configuring using the WSS APIs, the WSSEncryption and WSSEncryptPart APIs complete these high-level steps:

Procedure

1. Use the WSSEncryption API to configure encryption. The WSSEncryption API performs these tasks by default:
   a. Generates the callback handler.
   b. Generates the generator security token object.
   c. Adds the security token reference type.
   d. Adds the signature component.
   e. Adds the WSSEncryptPart object.
   f. Adds the parts to be encrypted. Adds the default parts as targets of encryption by using keywords and XPath expressions.
   g. Adds the header in the SOAP message, specified by QName.

h. Sets the default data encryption method.
i. Specifies whether the key is to be encrypted using a Boolean value.
j. Sets the default key encryption method.
k. Selects a part reference.
l. Sets the MTOM optimization Boolean value.

2. Use the WSSEncryptPart API to configure encrypted parts or add a transform method. The WSSEncryptPart API performs these tasks by default:
   a. Sets the encrypted parts specified by using keywords or an XPath expression.
   b. Sets the encrypted parts specified by an XPath expression.
   c. Sets the signature component object, WSSSignature.
   d. Sets the header in the SOAP message, specified by QName.
   e. Sets the generator security token.
   f. Adds the transform method, if needed.
3. Change from the default values for algorithm or message parts, as needed. For example: you could change one or more of the following items:
   - Change the data encryption algorithm from the default value of AES 128.
   - Change the key encryption algorithm from the default value of KW_RSA_OAEP.
   - Specify to not encrypt the key (false).
   - Change the security token type from default of X.509 token.
   - Change the security token reference type from the default value of SecurityToken.REF_STR.
   - Only use BODY_CONTENT as an encryption part and not use SIGNATURE also.
   - Turn MTOM optimization on (true).

Results

The encryption information is configured for the generator binding.

Example

The following is an example of the WSSEncryption API:

```
WSSFactory factory = WSSFactory.getInstance();
WSSGenerationContext gencont = factory.newWSSGenerationContext();

X509GenerateCallbackHandler callbackhandler = generateCallbackHandler();
SecurityToken token = factory.newSecurityToken(X509Token.class, callbackHandler);
WSSEncryption enc = factory.newWSSEncryption(token);

gencont.add(enc);
```

What to do next

You must configure similar decryption information for the client-side response consumer (receiver) bindings, if you have not already configured the information.

Next, review the WSSEncryption API process.

Encrypting the SOAP message using the WSSEncryption API:

You can secure the SOAP messages, without using policy sets for configuration, by using the Web Services Security APIs (WSS API). To configure the client for request encryption on the generator side, use the WSSEncryption API to encrypt the SOAP message. The WSSEncryption API specifies which request SOAP message parts to encrypt when configuring the client.

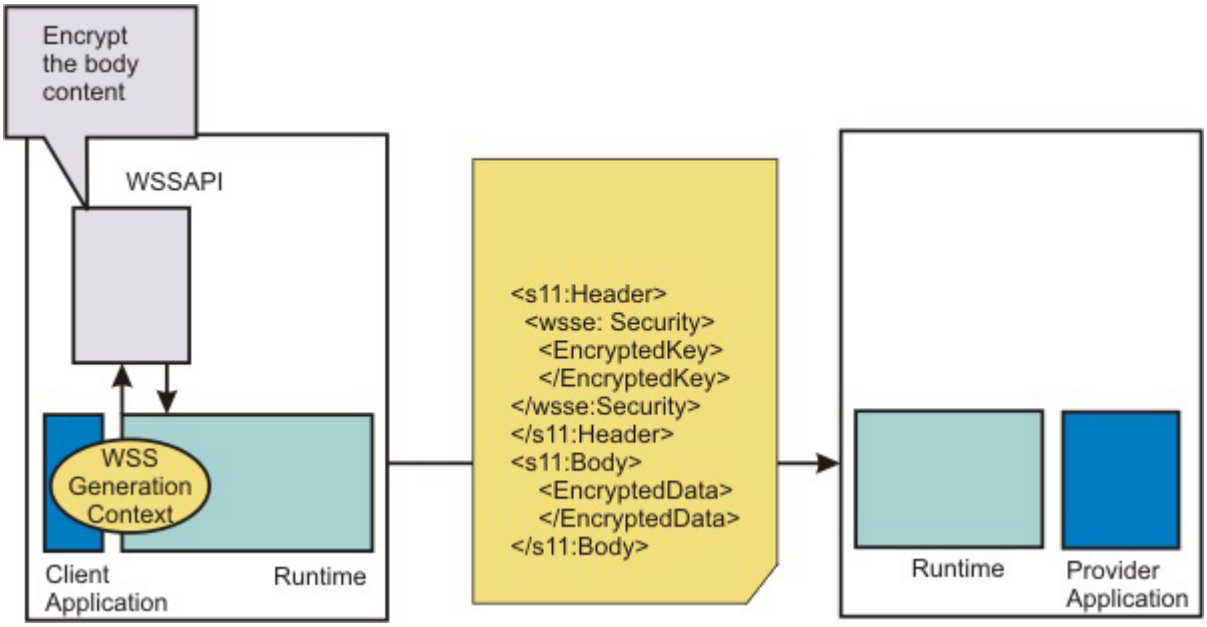
Before you begin

You can use the WSS API or use policy sets on the administrative console to enable encryption and add generator security tokens in the SOAP message. To secure SOAP messages, use the WSS APIs to complete the following encryption tasks, as needed:

- Configure encryption and choose the encryption methods using the WSSEncryption API.
- Configure the encrypted parts, as needed, using the WSSEncryptPart API.

About this task

The encryption information on the generator side is used for encrypting an outgoing SOAP message for the request generator (client side) bindings. The client generator configuration must match the configuration for the provider consumer.



Confidentiality settings require that confidentiality constraints be applied to generated messages. These constraints include specifying which message parts within the generated message must be encrypted, and which message parts to attach encrypted Nonce and timestamp elements to.

The following encryption parts can be configured:

Table 151. Encryption parts. Use the encryption parts to enable encryption in messages.

Encryption parts	Description
part	Adds the WSSEncryptPart object as a target of the encryption part.
keyword	Adds the encryption parts using keywords. WebSphere Application Server supports the following keywords: • BODY_CONTENT • SIGNATURE
xpath	Adds the encryption part using an XPath expression.
signature	Adds the WSSignature component as a target of the encrypted part.
header	Adds the SOAP header, specified by QName, as a target of the encrypted part.
securityToken	Adds the SecurityToken object as a target of the encrypted part.

For encryption, certain default behaviors occur. The simplest way to use the WSSEncryption API is to use the default behavior (see the example code).

WSSEncryption provides defaults for the key encryption algorithm, the data encryption algorithm, the security token reference method, and the encryption parts such as the SOAP body content and the signature. The encryption default behaviors include:

Table 152. Encryption decisions. Use encryption default behavior to secure the message body content and signature.

Encryption decisions	Default behavior
Which SOAP message parts to encrypt using keywords	Sets the encryption parts that you can add using keywords. The default encryption parts are the BODY_CONTENT and SIGNATURE. WebSphere Application Server supports using these keywords: • WSSEncryption.BODY_CONTENT • WSSEncryption.SIGNATURE
Which data encryption method to choose (algorithm)	Sets the data encryption method. Both data and key encryption methods can be specified. The default data encryption algorithm method is AES 128. WebSphere Application Server supports these data encryption methods: • WSSEncryption.AES128: http://www.w3.org/2001/04/xmlenc#aes128-cbc • WSSEncryption.AES192: http://www.w3.org/2001/04/xmlenc#aes192-cbc • WSSEncryption.AES256: http://www.w3.org/2001/04/xmlenc#aes256-cbc • WSSEncryption.TRIPLE_DES: http://www.w3.org.2001/04/xmlenc#tripledes-cbc
Whether to encrypt the key (isEncrypt)	Specifies whether to encrypt the key. The values are `true` or `false`. The default value is to encrypt the key (`true`).
Which key encryption method to choose (algorithm)	Sets the key encryption method. Both data and key encryption methods can be specified. The default key encryption algorithm method is key wrap RSA OAEP. WebSphere Application Server supports these key encryption methods: • WSSEncryption.KW_AES128: http://www.w3.org/2001/04/xmlenc#kw-aes128 • WSSEncryption.KW_AES192: http://www.w3.org/2001/04/xmlenc#kw-aes192 • WSSEncryption.KW_AES256: http://www.w3.org/2001/04/xmlenc#kw-aes256 • WSSEncryption.KW_RSA_OAEP: http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p • WSSEncryption.KW_RSA15: http://www.w3.org/2001/04/xmlenc#rsa-1_5 • WSSEncryption.KW_TRIPLE_DES: http://www.w3.org/2001/04/xmlenc#kw-tripledes
Which security token to specify (securityToken)	Sets the SecurityToken. The default security token type is the X509Token. WebSphere Application Server provides the following pre-configured consumer token types: • Derived key token • X.509 tokens
Which token reference to use (refType)	Sets the type of the security token reference. The default token reference is SecurityToken.REF_KEYID. WebSphere Application Server supports the following token reference types: • SecurityToken.REF_KEYID • SecurityToken.REF_STR • SecurityToken.REF_EMBEDDED • SecurityToken.REF_THUMBPRINT
Whether to use MTOM (mtomOptimize)	Sets Message Transmission Optimization Mechanism (MTOM) optimization for the encrypted part.

Procedure

1. To encrypt the SOAP message using the WSSEncryption API, first ensure that the application server is installed.
2. The WSS API process for encryption performs these process steps:
   a. Uses WSSFactory.getInstance() to get the WSS API implementation instance
   b. Creates the WSSGenerationContext instance from the WSSFactory instance.
   c. Creates the SecurityToken from WSSFactory used for encryption.
   d. Creates WSSEncryption from the WSSFactory instance using the SecurityToken. The default behavior of WSSEncryption is to encrypt the body content and the signature.
   e. Adds a new part to be encrypted in WSSEncryption if the existing part is not appropriate. After addEncryptPart(), addEncryptHeader(), or addEncryptPartByXPath() is called, the default part is cleared.
   f. Calls the encryptKey(false) if the key is not to be encrypted.
   g. Sets the data encryption method if the default method is not appropriate.

h. Sets the key encryption method if the default method is not appropriate.
i. Sets the token reference if the default token reference is not appropriate.
j. Adds WSSEncryption to WSSConsumingContext.
k. Calls WSSGenerationContext.process() with the SOAPMessageContext.

Results

If there is an error condition during encryption, a WSSException is provided. If successful, the API calls the WSSGenerationContext.process(), the WS-Security header is generated, and the SOAP message is now secured using Web Services Security.

Example

The following example provides sample code using methods that are defined in WSSEncryption:

```
// Get the message context
   Object msgcontext = getMessageContext();

// Generate the WSSFactory instance (step: a)
WSSFactory factory = WSSFactory.getInstance();

// Generate the WSSGenerationContext instance (step: b)
WSSGenerationContext gencont = factory.newWSSGenerationContext();

// Generate the callback handler
X509GenerateCallbackHandler callbackHandler = new
        X509GenerateCallbackHandler(
     "",
     "enc-sender.jceks",
     "jceks",
     "storepass".toCharArray(),
     "bob",
     null,
     "CN=Bob, O=IBM, C=US",
     null);

// Generate the security token used for encryption (step: c)
SecurityToken token = factory.newSecurityToken(X509Token.class , callbackHandler);

// Generate WSSEncryption instance (step: d)
WSSEncryption enc = factory.newWSSEncryption(token);

// Set the part to be encrypted (step: e)
// DEFAULT: WSSEncryption.BODY_CONTENT and WSSEncryption.SIGNATURE

// Set the part specified by the keyword (step: e)
   enc.addEncryptPart(WSSEncryption.BODY_CONTENT);

// Set the part in the SOAP Header specified by QName (step: e)
   enc.addEncryptHeader(new QName("http://www.w3.org/2005/08/addressing",
                                  "MessageID"));

// Set the part specified by WSSSignature (step: e)
   SecurityToken sigToken = getSecurityToken();
      WSSSignature sig = factory.newWSSSignature(sigToken);
   enc.addEncryptPart(sig);

// Set the part specified by SecurityToken (step: e)
   UNTGenerateCallbackHandler untCallbackHandler =
          new UNTGenerateCallbackHandler("Chris", "sirhC");
      SecurityToken unt = factory.newSecurityToken(UsernameToken.class,
                                                   untCallbackHandler);
   enc.addEncryptPart(unt, false);

// sSt the part specified by XPath expression (step: e)
   StringBuffer sb = new StringBuffer();
      sb.append("/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/'
         and local-name()='Envelope']");
      sb.append("/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/'
         and local-name()='Body']");
      sb.append("/*[namespace-uri()='http://xmlsoap.org/Ping'
         and local-name()='Ping']");
      sb.append("/*[namespace-uri()='http://xmlsoap.org/Ping'
         and local-name()='Text']");
   enc.addEncryptPartByXPath(sb.toString());

// Set whether the key is encrypted (step: f)
// DEFAULT: true
   enc.encryptKey(true);

// Set the data encryption method (step: g)
```

```
// DEFAULT: WSSEncryption.AES128
   enc.setEncryptionMethod(WSSEncryption.TRIPLE_DES);

// Set the key encryption method (step: h)
// DEFAULT: WSSEncryption.KW_RSA_OAEP
   enc.setEncryptionMethod(WSSEncryption.KW_RSA15);

// Set the token reference (step: i)
// DEFAULT: SecurityToken.REF_KEYID
  enc.setTokenReference(SecurityToken.REF_STR);

// Add the WSSEncryption to the WSSGenerationContext (step: j)
  gencont.add(enc);

// Process the WS-Security header (step: k)
gencont.process(msgcontext);
```

Note: The X509GenerationCallbackHandler does not need the key password because the public key is used for encryption. You do not need a password to obtain the public key from the Java keystore.

What to do next

If you have not previously specified which encryption methods to choose, use the WSS API or configure the policy sets using the administrative console to choose the data and key encryption algorithm methods.

Choosing encryption methods for generator bindings:

To configure the client for request encryption for the generator binding, you must specify which encryption methods to use when the client encrypts the SOAP messages.

Before you begin

Prior to completing these steps, read the XML encryption information to become familiar with encrypting and decrypting SOAP messages.

To specify which algorithm methods are to be used when the client encrypts the SOAP messages, complete the following tasks:

- Use the WSSEncryption API to configure the data encryption algorithm and the key encryption algorithm methods.
- Use the WSSEncryptPart API to configure a transform algorithm method, if needed. The default is no transform algorithm.

About this task

Some of the encryption-related definitions are based on the XML-Encryption specification. The following information defines some data encryption-related terms:

Data encryption method algorithm

Data encryption algorithms specify the algorithm uniform resource identifier (URI) of the data encryption method. This algorithm encrypts and decrypts data in fixed size, multiple octet blocks.

By default, the Java Cryptography Extension (JCE) is shipped with restricted or limited strength ciphers. To use 192-bit and 256-bit Advanced Encryption Standard (AES) encryption algorithms, you must apply unlimited jurisdiction policy files.

For the AES256-cbc and the AES192-cbc algorithms, you must download the unrestricted Java™ Cryptography Extension (JCE) policy files from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.

Key encryption method algorithm

Key encryption algorithms specify the algorithm uniform resource identifier (URI) of the method to encrypt the key that is used to encrypt data. The algorithm represents public key encryption algorithms that are specified for encrypting and decrypting keys.

By default, the RSA-OAEP algorithm uses the SHA1 message digest algorithm to compute a message digest as part of the encryption operation. Optionally, you can use the SHA256 or SHA512 message digest algorithm by specifying a key encryption algorithm property.

The property name is: com.ibm.wsspi.wssecurity.enc.rsaoaep.DigestMethod. The property value is one of the following URIs of the digest method:

- http://www.w3.org/2001/04/xmlenc#sha256
- http://www.w3.org/2001/04/xmlenc#sha512

By default, the RSA-OAEP algorithm uses a null string for the optional encoding octet string for the OAEPParams. You can provide an explicit encoding octet string by specifying a key encryption algorithm property. For the property name, you can specify `com.ibm.wsspi.wssecurity.enc.rsaoaep.OAEPparams`. The property value is the base 64-encoded value of the octet string.

Important: You can set these digest method and OAEPParams properties on the generator side only. On the consumer side, these properties are read from the incoming SOAP message.

For the KW-AES256 and the KW-AES192 key encryption algorithms, you must download the unrestricted JCE policy files from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.

Important: Your country of origin might have restrictions on the import, possession, use, or re-export to another country, of encryption software. Before downloading or using the unrestricted policy files, you must check the laws of your country, its regulations, and its policies concerning the import, possession, use, and re-export of encryption software, to determine if it is permitted.

Table 153. Encryption usage types. The encryption usage types describe encryptions methods.

Usage types	Description
Data encryption	Specifies the algorithm URI that is used for both encrypting and decrypting data. Encrypts and decrypts data in fixed size, multiple octet blocks.
Key encryption	Specifies the algorithm URI that is used for encrypting and decrypting the encryption key.

Data encryption

WebSphere Application Server supports the following pre-configured data encryption algorithms:

Table 154. Data encryption algorithms. These pre-configuring encryption algorithms are supported by WebSphere Application Server.

Data encryption name	Algorithm URI
WSSEncryption.AES128 (the default value)	A URI of data encryption algorithm, AES 128: http://www.w3.org/2001/04/xmlenc#aes128-cbc
WSSEncryption.AES192	A URI of data encryption algorithm, AES 192: http://www.w3.org/2001/04/xmlenc#aes192-cbc
WSSEncryption.AES256	A URI of data encryption algorithm, AES 256: http://www.w3.org/2001/04/xmlenc#aes256-cbc
WSSEncryption.TRIPLE_DES	A URI of data encryption algorithm, 3DES: http://www.w3.org.2001/04/xmlenc#tripledes-cbc

Key encryption

WebSphere Application Server supports the following pre-configured key encryption algorithms:

Table 155. Key encryption algorithms. These pre-configured encryption algorithms are supported by WebSphere Application Server.

Key encryption name	Algorithm URI
WSSEncryption.KW_AES128	A URI of key encryption algorithm, key wrap AES 128: http://www.w3.org/2001/04/xmlenc#kw-aes128

Table 155. Key encryption algorithms (continued). These pre-configured encryption algorithms are supported by WebSphere Application Server.

Key encryption name	Algorithm URI
WSSEncryption.KW_AES192	A URI of key encryption algorithm, key wrap AES 192: http://www.w3.org/2001/04/xmlenc#kw-aes192 **Restriction:** Do not use the 192-bit key encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP).
WSSEncryption.KW_AES256	A URI of key encryption algorithm, key wrap AES 256: http://www.w3.org/2001/04/xmlenc#kw-aes256
WSSEncryption.KW_RSA_OAEP (the default value)	A URI of key encryption algorithm, key wrap RSA OAEP: http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p
WSSEncryption.KW_RSA15	A URI of key encryption algorithm, key wrap RSA 1.5: http://www.w3.org/2001/04/xmlenc#rsa-1_5
WSSEncryption.KW_TRIPLE_DES	http://www.w3.org/2001/04/xmlenc#kw-tripledes

To configure the encryption and encrypted part algorithm methods, use the WSSEncryption API, or configure policy sets using the administrative console.

Note: Policy sets do not support symmetric key encryption. If you are using the WSS API for symmetric key encryption, you will not be able to interoperate with web services endpoints that use policy sets.

The WSS API process completes the following high-level steps to specify which encryption methods to use when configuring the client for request encryption:

Procedure

1. Using the WSSEncryption API, adds the required data encryption algorithm. The data encryption algorithm is used for encrypting or decrypting parts of a SOAP message. Data encryption algorithms specify the algorithm uniform resource identifier (URI) of the data encryption method.

   The client generator configuration must match the configuration for the provider consumer.

   The default data encryption algorithm is AES 128. The data encryption name is AES128, and the URI of the data encryption algorithm, is http://www.w3.org/2001/04/xmlenc#aes128-cbc. WebSphere Application Server supports the following pre-configured data encryption algorithms:

   - AES 128: http://www.w3.org/2001/04/xmlenc#aes128-cbc

     The AES 128 algorithm is the default data algorithm method.
   - AES 192: http://www.w3.org/2001/04/xmlenc#aes192-cbc

     Do not use the 192-bit key encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP).

     To use this AES 192-cbc algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.
   - AES 256: http://www.w3.org/2001/04/xmlenc#aes256-cbc

     To use this AES 256-cbc algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.
   - TRIPLEDES: http://www.w3.org/2001/04/xmlenc#tripledes-cbc
2. As needed, changes the WSSEncryption API method to specify another data encryption algorithm. For example, you might add the following code to change from the default AES 128 algorithm to the Triple DES algorithm:

```
// Default data encryption algorithm: AES128
WSSEncryption enc = factory.newWSSEncryption(x509t);
   enc.setEncryptionMethod(EncryptionMethod.TRIPLEDES_CBC);
gencont.add(enc);
```

3. Using the WSSEncryption API, adds the required key encryption algorithm. The key encryption algorithm is used for encrypting the key that is used for encrypting the message parts within the SOAP

message. If the encryption key, which is the key that is used for encrypting the message parts, is not encrypted, then the decryption API selects `false` to match the encryption key.

The client generator configuration must match the configuration for the provider consumer.

The default key encryption algorithm value is key wrap RSA OAP. The key encryption name is KW_RSA_OAEP, and the URI of the key encryption algorithm is http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p. WebSphere Application Server supports the following pre-configured key encryption algorithms:

- KW AES128: http://www.w3.org/2001/04/xmlenc#kw-aes128
- KW AES192: http://www.w3.org/2001/04/xmlenc#kw-aes192

  To use this key wrap AES 192 algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.

  Do not use the 192-bit key encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP).KW AES 256: http://www.w3.org/2001/04/xmlenc#kw-aes256

  To use this key wrap AES 256-cbc algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.
- KW RSA OAEP: http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p.

  The KW RSA OAEP algorithm is the default key algorithm method.

  When running with Software Development Kit (SDK) Version 1.4, the list of supported key transport algorithms does not include this algorithm. This algorithm appears in the list of supported key transport algorithms when running with SDK Version 1.5. See more information at http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p
- KW RSA15: http://www.w3.org/2001/04/xmlenc#rsa-1_5
- KW TRIPLE DES: http://www.w3.org/2001/04/xmlenc#kw-tripledes

Note: For Web Services Secure Conversation, the WSSEncryption API might specify addition key-related information, such as the:
- algorithmName
- keyLength

Results

If there is an error condition, a WSSException is provided. If successful, the API calls the WSSGenerationContext.process(), the WS-Security header is generated, and the SOAP message is now secured using Web Services Security.

Example

The following example provides sample WSS API code using WSSEncryption.setEncryptionMethod() and WSSEncryption.setKeyEncryptionMethod().

```
// Get the message context
   Object msgcontext = getMessageContext();

// Generate the WSSFactory instance
   WSSFactory factory = WSSFactory.getInstance();

// Generate the WSSGenerationContext instance
   WSSGenerationContext gencont = factory.newWSSGenerationContext();

// Generate callback handler
   X509GenerateCallbackHandler callbackHandler = new
       X509GenerateCallbackHandler(
                                  "",
                                  "enc-sender.jceks",
                                  "jceks",
                                  "storepass".toCharArray(),
                                  "bob",
```

```
                                    null,
                                    "CN=Bob, O=IBM, C=US",
                                    null);

// Generate the security token used for encryption
   SecurityToken token = factory.newSecurityToken(X509Token.class , callbackHandler);

// Generate WSSEncryption instance
   WSSEncryption enc = factory.newWSSEncryption(token);

// Set the data encryption method
// DEFAULT: WSSEncryption.AES128
      enc.setEncryptionMethod(WSSEncryption.TRIPLE_DES);

// Set the key encryption method
// DEFAULT: WSSEncryption.KW_RSA_OAEP
      enc.setEncryptionMethod(WSSEncryption.KW_RSA15);

// Add the WSSEncryption to the WSSGenerationContext
   gencont.add(enc);

// Generate the WS-Security header
gencont.process(msgcontext);
```

What to do next

Next, if you want to add a transform algorithm, review the WSSEncryptPart API process task.

Encryption methods:

For request generator binding settings, the encryption methods include specifying the data and key encryption algorithms to use to encrypt the SOAP message. The WSS API for encryption (WSSEncryption) specifies the algorithm name and the matching algorithm uniform resource identifier (URI) for the data and key encryption methods. If the data and key encryption algorithms are specified, only elements that are encrypted with those algorithms are accepted.

Data encryption algorithms

The data encryption algorithm is used to encrypt parts of the SOAP message, including the body and the signature. Data encryption algorithms specify the algorithm uniform resource identifier (URI) for each type of data encryption algorithms.

The following pre-configured data encryption algorithms are supported:

Table 156. Data encryption algorithms. The algorithms are used to encrypt SOAP messages.

Data encryption algorithm name	Algorithm URI
WSSEncryption.AES128 (the default value)	A URI of data encryption algorithm, AES 128: http://www.w3.org/2001/04/xmlenc#aes128-cbc
WSSEncryption.AES192	A URI of data encryption algorithm, AES 192: http://www.w3.org/2001/04/xmlenc#aes192-cbc
WSSEncryption.AES256	A URI of data encryption algorithm, AES 256: http://www.w3.org/2001/04/xmlenc#aes256-cbc
WSSEncryption.TRIPLE_DES	A URI of data encryption algorithm, TRIPLE DES: http://www.w3.org/2001/04/xmlenc#tripledes-cbc

By default, the Java Cryptography Extension (JCE) is shipped with restricted or limited strength ciphers. To use 192-bit and 256-bit Advanced Encryption Standard (AES) encryption algorithms, you must apply unlimited jurisdiction policy files.

Important: Your country of origin might have restrictions on the import, possession, use, or re-export to another country, of encryption software. Before downloading or using the unrestricted policy files, you must check the laws of your country, its regulations, and its policies concerning the import, possession, use, and re-export of encryption software, to determine if it is permitted.

For the AES256-cbc and the AES192-CBC algorithms, you must download the unrestricted Java™ Cryptography Extension (JCE) policy files from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.

The data encryption algorithm configured for encryption for the generator side must match the data encryption algorithm that is configured for decryption for the consumer side.

Key encryption algorithms

This algorithm is used to encrypt and decrypt keys. This key information is used to specify the configuration that is needed to generate the key for digital signature and encryption. The signing information and encryption information configurations can share the key information. The key information on the consumer side is used for specifying the information about the key that is used for validating the digital signature in the received message or for decrypting the encrypted parts of the message. The request generator is configured for the client.

Note: Policy sets do not support symmetric key encryption. If you are using the WSS API for symmetric key encryption, you will not be able to interoperate with web services endpoints using the policy sets.

Key encryption algorithms specify the algorithm uniform resource identifier (URI) of the key encryption method. The following pre-configured key encryption algorithms are supported:

Table 157. Supported pre-configured key encryption algorithms. The algorithms are used to encrypt and decrypt keys.

WSS API	URI
WSSEncryption.KW_AES128	A URI of key encryption algorithm, key wrap AES 128: http://www.w3.org/2001/04/xmlenc#kw-aes128
WSSEncryption.KW_AES192	A URI of key encryption algorithm, key wrap AES 192: http://www.w3.org/2001/04/xmlenc#kw-aes192 **Restriction:** Do not use the 192-bit key encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP).
WSSEncryption.KW_AES256	A URI of key encryption algorithm, key wrap AES 256: http://www.w3.org/2001/04/xmlenc#kw-aes256
WSSEncryption.KW_RSA_OAEP (the default value)	A URI of key encryption algorithm, key wrap RSA OAEP: http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p
WSSEncryption.KW_RSA15	A URI of key encryption algorithm, key wrap RSA 1.5: http://www.w3.org/2001/04/xmlenc#rsa-1_5
WSSEncryption.KW_TRIPLE_DES	A URI of key encryption algorithm, key wrap TRIPLE DES: http://www.w3.org/2001/04/xmlenc#kw-tripledes

For Secure Conversation, additional key-related information must be specified, such as:

- algorithmName
- keyLength

By default, the RSA-OAEP algorithm uses the SHA1 message digest algorithm to compute a message digest as part of the encryption operation. Optionally, you can use the SHA256 or SHA512 message digest algorithm by specifying a key encryption algorithm property. The property name is: `com.ibm.wsspi.wssecurity.enc.rsaoaep.DigestMethod`. The property value is one of the following URIs of the digest method:

- http://www.w3.org/2001/04/xmlenc#sha256
- http://www.w3.org/2001/04/xmlenc#sha512

By default, the RSA-OAEP algorithm uses a null string for the optional encoding octet string for the OAEPParams. You can provide an explicit encoding octet string by specifying a key encryption algorithm property. For the property name, you can specify `com.ibm.wsspi.wssecurity.enc.rsaoaep.OAEPparams`. The property value is the base 64-encoded value of the octet string.

Important: You can set these digest method and OAEPParams properties on the generator side only. On the consumer side, these properties are read from the incoming SOAP message.

For the KW-AES256 and the KW-AES192 key encryption algorithms, you must download the unrestricted JCE policy files from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.

The key encryption algorithm for the generator must match the key decryption algorithm that is configured for the consumer.

This example provides sample code for encryption to use the Triple DES for the data encryption method and to use RSA1.5 for the key encryption method:

```
// get the message context
Object msgcontext = getMessageContext();

// generate WSSFactory instance
WSSFactory factory = WSSFactory.getInstance();

// generate WSSGenerationContext instance
WSSGenerationContext gencont = factory.newWSSGenerationContext();

// generate callback handler
X509GenerateCallbackHandler callbackHandler = new X509GenerateCallbackHandler(
  "",
  "enc-sender.jceks",
  "jceks",
  "storepass".toCharArray(),
  "bob",
  null,
  "CN=Bob, O=IBM, C=US",
  null);

// generate the security token used to the encryption
SecurityToken token = factory.newSecurityToken(X509Token.class,
     callbackHandler);

// generate WSSEncryption instance to encrypt the SOAP body content
WSSEncryption enc = factory.newWSSEncryption(token);
enc.addEncryptPart(WSSEncryption.BODY_CONTENT);

// set the data encryption method
// DEFAULT: WSSEncryption.AES128
enc.setEncryptionMethod(WSSEncryption.TRIPLE_DES);

// set the key encryption method
// DEFAULT: WSSEncryption.KW_RSA_OAEP
enc.setEncryptionMethod(WSSEncryption.KW_RSA15);

// add the WSSEncryption to the WSSGenerationContext
gencont.add(enc);

// generate the WS-Security header
gencont.process(msgcontext);
```

Adding encrypted parts using the WSSEncryptPart API:

You can secure the SOAP messages, without using policy sets for configuration, by using the Web Services Security APIs (WSS API). To configure encrypted parts for the request generator (client side) bindings, use the WSSEncryptPart API to define and add to the listing of elements in the encrypted part. WSSEncryptPart is an interface that is part of the com.ibm.websphere.wssecurity.wssapi.encryption package.

Before you begin

You can use the WSS APIs or configure policy sets using the administrative console to enable the encrypted parts. To secure SOAP messages, use the WSS APIs to complete the following encryption tasks, as needed:

- Configure encryption and choose the encryption methods using the WSSEncryption API.
- Configure the encrypted parts using the WSSEncryptpart API, as needed.

About this task

Confidentiality settings require that confidentiality constraints be applied to generated messages. These constraints include specifying which message parts within the generated message must be encrypted, and which message parts to attach encrypted elements to. The encryption information on the generator side is used for encrypting an outgoing SOAP message. The request generator is configured for the client.

The WSSEncryptPart API specifies information related to encrypted parts and sets the encrypted parts that have been added for message confidentiality protection. Use the WSSEncryptPart to set the transform method and to specify the part to which the transform method is to be applied. Sets the transform method only if using SOAP with Attachments. The WSSEncryptPart is usually not needed except, in some case for tasks such as setting the transform method.

The encrypted parts and related information displayed in the following table are used to protect the confidentiality of messages.

Table 158. Encrypted parts. Use encrypted parts to secure messages.

Encrypted parts	Description
part	Adds the WSSEncryptPart object as a target of the encryption part.
keyword	Adds the encrypted parts using keywords. The default encryption parts that you can add using keywords are the BODY_CONTENT and SIGNATURE. WebSphere Application Server supports using these keywords: • BODY_CONTENT • SIGNATURE
xpath	Adds the encrypted part by using an XPath expression.
signature	Adds the WSSSignature component as a target of the encrypted part. WSSSignature is applicable only if the SOAP message contains a signature element.
header	Adds the SOAP header, specified by QName, as a target of the encrypted part.
securityToken	Adds the SecurityToken object as a target of the encrypted part.

For encrypted parts, certain default behaviors occur. The simplest way to use the WSSEncryptPart API is to use the default behavior. The WSSEncryptPart API provides defaults for specifying the transform algorithm, setting objects as targets, specifying the encrypted parts, such as: the SOAP body content and the signature.

The encryption default behaviors include:

Table 159. Encrypted part decisions. Several encrypted message parts are set by default.

Encrypted part decisions	Default behavior
Which SOAP message parts to encrypt using keywords	Specifies which keywords to use for the encrypted parts. WebSphere Application Server sets the following SOAP message parts by default for encryption: • WSSEncryption.BODY_CONTENT • WSSEncryption.SIGNATURE
Which transform method to add	WebSphere Application Server does not specify any transform method by default. Specify a transform method only if using SOAP with Attachments.

Procedure

1. To encrypt the SOAP message parts using the WSSEncryptPart API, first ensure that the application server is installed.
2. The WSS API process using WSSEncryptPart follows these process steps:
   a. Uses WSSFactory.getInstance() to get the WSS API implementation instance.
   b. Creates the WSSGenerationContext instance from the WSSFactory instance.
   c. Creates the SecurityToken from WSSFactory to configure the encryption.
   d. Creates WSSEncryption from the WSSFactory instance using SecurityToken.
   e. Creates WSSEncryptPart from WSSFactory.

f. Adds the parts to be encrypted and to be applied with the transform in WSSEncryptPart. WebSphere Application Server sets these encrypted parts by default for WSSEncryptPart: the BODY_CONTENT and SIGNATURE. After you add other encrypted parts, the default values are no longer valid. For example, if you call addEncryptPart(securityToken, false), only the security token is encrypted, and not the signature and body content. So if you want to encrypt the security token, the signature, and the body content, you must call addEncryptPart(securityToken, false), addEncryptPart(WSSEncryption.SIGNATURE), and addEncryptPart(WSSEncrypyion.BODY_CONTENT).

g. Sets the transform method.

h. Adds WSSEncryptPart to WSSEncryption.

i. Adds WSSEncryption to WSSGenerationContext.

j. Calls WSSGenerationContext.process() with the SOAPMessageContext.

Results

If there is an error condition during encryption of the message parts, a WSSException is provided. If successful, the API calls the WSSGenerationContext.process(), the WS-Security header is generated, and the SOAP message is now secured using Web Services Security.

What to do next

After enabling encrypted parts for the request generator (client side) binding, you must specify the same parts to be decrypted for the response consumer (client side) bindings. Next, to configure decryption and decrypted parts, use the WSS APIs or configure policy sets using the administrative console.

Configuring generator signing information to protect message integrity using the WSS APIs:

You can configure the signing information to protect message integrity for the request (client side) generator binding. Signing information includes the signature and the signed parts. To keep the integrity of the message, digital signatures are typically applied.

Before you begin

In addition to using a digital signature and configuring the signing information, the following tasks should also be performed:

- Verify the signing information.
- Incorporate encryption.
- Attach security tokens.

About this task

Integrity refers to digital signature while confidentiality refers to encryption. Integrity is provided by applying a digital signature to a SOAP message. To configure the signing information to protect message integrity, you must first digitally sign and then verify the signature for the SOAP messages. Integrity decreases the risk of data modification when you transmit data across a network.

Also, message integrity is provided by digitally signing the body, time stamp, and WS-Addressing headers using the signature algorithm methods. The WSS APIs specify which algorithm is to be used to sign the certificate. The signature algorithms specify the Uniform Resource Identifiers (URI) of the signature method. WebSphere Application Server supports several pre-configured request signing algorithm methods.

You can use the following interfaces to configure Web Services Security and to protect SOAP message integrity:

- Use the administrative console to configure policy sets for the signing information.
- Use the Web Services Security APIs (WSS API) to configure the SOAP message context (only for the client).

Perform the following signing tasks, using the WSS APIs, to configure the signing information and to protect message integrity for the generator binding.

Procedure

- Configure the signing information using the WSSSignature API. Configure the signing information for the generator binding using the WSSSignature API. Signing information is used to sign parts of a message including the SOAP body, the time stamp, and the WS-Addressing headers. Both signing and encryption can be applied to the same message parts, such as the SOAP body.
- Add or change signed parts using the WSSSignPart API.
- Configure the client for request signing methods using the WSSSignature or WSSSignPart APIs. To configure the client for request signing, choose the signing methods. The request signing methods include the signature, the canonicalization, the digest, and the transform methods. Use the WSSSignature API to configure the signature and canonicalization methods. Use the WSSSignPart API to configure the digest and transform methods.

Results

The WSS APIs also specify the security token for the generator (client) binding and set the type of token reference to protect message authenticity. By completing the steps in these tasks, you have configured generator signing to protect the integrity of the SOAP message.

What to do next

Next, verify the consumer signing information by using the WSS APIs or by configuring policy sets using the administrative console.

Configuring signing information using the WSS APIs:

You can configure the signing information for the client-side request generator (sender) bindings. Signing information is used to sign and validate parts of a message including the SOAP body, the timestamp information, and the Username token. To configure the client for request signing, specify which message parts to digitally sign when configuring the client.

Before you begin

WebSphere Application Server uses XML digital signature with existing algorithms such as RSA, HMAC, and SHA1. XML signature defines many methods for describing key information and enables the definition of a new method. Prior to completing these steps, familiarize yourself with XML digital signature for signing and verifying digital signatures for digital content.

About this task

By including XML signature in SOAP messages, the following issues are realized: message integrity and authentication. *Integrity* refers to digital signature whereas confidentiality refers to encryption. Integrity decreases the risk of data modification while the data is transmitted across the Internet. WebSphere Application Server uses the signing information for the default generator to sign parts of the message, such as the body, time stamp, and Username token.

For the signing information, you must specify the following:

- Which parts of the message are to be signed.
- The key information that is referenced by the key information for the signing keys.

- The signing algorithms.

WebSphere Application Server provides default values for bindings. However, an administrator must modify the defaults for a production environment.

The WSSSignature API configures the following parts as signature parts:

Table 160. Pre-configured signature parts. Use the signing information to validate parts of a message.

Part	Description
Security token object	This object authenticates the client. If this option is specified, then the message is signed. You can digitally sign the message using a security token if a login configuration authentication method is selected.
WSSTimestamp object	This object adds a time stamp to a message. The time stamp determines if the message is valid based on the time that the message is sent and then received.
WSSSignature Part object	This object adds the signature parts to a message.
SOAP header and the QName as a target	This signature part adds the header, specified by QName, as a verification part.

The WSS APIs allow the use of keywords or an XPath expression to specify which parts of the message are to be signed. WebSphere Application Server supports the use of the following keywords:

Table 161. Supported signature keywords. Key information is used to specify which parts of a message are signed.

Keyword	References
ADDRESSING_HEADERS	The Web Services Addressing (WS-Addressing) headers.
BODY	The SOAP message body. The body is the user data portion of the message.
TIMESTAMP	The creation and expiration timestamp information.

The Web Services Security API (WSS API) are used to configure the signing information for the request generator (client side) section of the bindings file. To configure the signing information on the client side, use the WSS APIs or configure policy sets for signing using the administrative console.

If configuring using the WSS APIs, the WSSSignature and WSSSignPart APIs complete the following steps to specify which message parts to digitally sign when configuring the client for request generator signing:

Procedure

1. The WSSSignature API adds the required parts of the SOAP message to digitally sign. Either a keyword or an XPath expression can be used to specify the required encryption parts.
2. The WSSSignature API sets the signature method algorithm. The default signature method is RSA_SHA1. WebSphere Application Server supports the following pre-configured algorithms:
   - RSA SHA1: http://www.w3.org/2000/09/xmldsig#rsa-sha1
   - HMAC SHA1http://www.w3.org/2000/09/xmldsig#hmac-sha1

   WebSphere Application Server does not support the following algorithm for DSA-SHA1: http://www.w3.org/2000/09/xmldsig#dsa-sha1. You cannot use the DSA-SHA1 algorithm if you want to be compliant with the Basic Security Profile (BSP).

   Any ds:SignatureMethod/@Algorithm element in a signature is based on a symmetric key and must have a value of RSA-SHA1 or HMAC-SHA1.

   The algorithm that is specified for the request generator configuration must match the algorithm that is specified for the request consumer configuration.
3. The WSSSignature API sets the canonicalization method. The default signature method is EXC_C14N. WebSphere Application Server supports the following pre-configured algorithms:
   - The URI of the exclusive canonicalization algorithm, EXC_C14N: http://www.w3.org/2001/10/xml-exc-c14n#.
   - The URI of the inclusive canonicalization algorithm, C14N: http://www.w3.org/2001/10/xml-c14n#.

The canonicalization algorithm that you specify for the generator must match the algorithm for the consumer.

4. The WSSSignature API adds a security token. The API adds information about the security token that is to be used for the signature, such as:
   - The class for security token.
   - The callback handler
   - The name of the JAAS login configuration.
5. The WSSSignature API sets the type of security token and sets the type of token reference. WebSphere Application Server supports the following pre-configured token references:
   - SecurityToken.REF_STR

     Represents the security token reference as a token reference type.
   - SecurityToken.REF_KEYID

     Represents the key identifier reference as a token reference type.
   - SecurityToken.REF_EMBEDDED

     Represents the embedded reference as a token reference type.
   - SecurityToken.REF_THUMBPRINT

     Represents the thumbprint reference as a token reference type.
6. If SecurityToken.REF_KEYID is set as the type of token reference, the WSSSignature API sets the key information signature type and configures the key information that is referenced by the key information references. WebSphere Application Server supports the following:
   - Specifying that the KeyInfo element is not signed.
   - Specifying that the entire <KeyInfo> element is signed.
   - Specifying that the child elements <Keyinfochildelements> of the <KeyInfo> element are signed.

   If you do not specify one of the previous signature types, WebSphere Application Server specifies that the entire <KeyInfo> element is signed, by default.

   If you select Keyinfo or Keyinfochildelements and you select http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform as the transform algorithm in a subsequent step, WebSphere Application Server also signs the referenced token.

   The key information signature type for the generator must match the signature type for the consumer.
7. The WSSSignature API specifies whether to require signature confirmation. The OASIS Web Services Security (WS-Security) Version 1.1 specification defines the use of signature confirmation. If you are using WS-Security Version 1.0, this function is not available.

   The signature confirmation value is stored in order to validate the signature confirmation with it after the receiving message is returned. This method is called if the response message is expected to attach the signature confirmation into the SOAP message.
8. The WSSSignPart API specifies the part reference. The part reference specifies which parts of the message to digitally sign.

   The part reference refers to the message part that is digitally signed. The part attribute refers to the name of the <Integrity> element when the <PartReference> element is specified for the signature. You can specify multiple <PartReference> elements within the <SigningInfo> element. The <PartReference> element has two child elements when it is specified for the signature verification: <DigestTransform> and <Transform>.
9. The WSSSignPart API specifies the digest method algorithm. The digest method algorithm specified within the <DigestMethod> element is used in the <SigningInfo> element.

   WebSphere Application Server supports the following pre-configured digest algorithms:
   - http://www.w3.org/2000/09/xmldsig#sha1
   - http://www.w3.org/2001/04/xmlenc#sha256
   - http://www.w3.org/2001/04/xmlenc#sha512

10. The WSSSignPart API specifies the transform algorithm. The transform algorithm is that is specified within the <Transform> element and specifies the transform algorithm for the signature. WebSphere Application Server supports the following pre-configured transform algorithms:
    - http://www.w3.org/2001/10/xml-exc-c14n#
    - http://www.w3.org/TR/1999/REC-xpath-19991116

      Do not use this transform algorithm if you want to be compliant with the Basic Security Profile (BSP). Instead use http://www.w3.org/2002/06/xmldsig-filter2 to ensure compliance.
    - http://www.w3.org/2002/06/xmldsig-filter2
    - http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform
    - http://www.w3.org/2002/07/decrypt#XML
    - http://www.w3.org/2000/09/xmldsig#enveloped-signature

    The transform algorithm that you select for the generator must match the transform algorithm that you select for the consumer.

    Important: If both of the following conditions are true, WebSphere Application Server signs the referenced token:
    - You previously selected the Keyinfo or the Keyinfochildelements option
    - You select http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform as the transform algorithm.
11. If you configure the client and server signing information correctly, but receive a `Soap body not signed` error when running the client, you might need to configure the actor. Configure policy sets using the administrative console to configure the same actor strings for the web service on the server, which processes the request and sends the response back.

    The actor information on both the client and server must refer to the same exact string. When the actor fields on the client and server match, the request or response is acted upon instead of being forwarded downstream. The actor might be different when you have web services acting as a gateway to other web services. However, in all other cases, make sure that the actor information matches on the client and server. When web services are acting as a gateway and they do not have the same actor configured as the request passing through the gateway, web services do not process the message from a client. Instead, these web services send the request downstream. The downstream process that contains the correct actor string processes the request. The same situation occurs for the response. Therefore, it is important that you verify that the appropriate client and server actor fields are synchronized.

Results

After the WSSSignature and WSSSignPart APIs complete these steps, the signing information is configured for the generator sections of the bindings files.

Example

The following example shows WSS API sample code to configure the signature, to generate the callback handler, and to specify the X.509 token type as the security token:

```
WSSFactory factory = WSSFactory.getInstance();
// Instantiate a generation context
WSSGenerationContext gencont = factory.newWSSGenerationContext();

// Generate the callback handler and specify the X.509 token
   X509GenerateCallbackHandler callbackhandler = generateCallbackHandler();
   SecurityToken token = factory.newSecurityToken(X509Token.class,
                                                  callbackHandler);

// Set the signature information
WSSSignature sig = factory.newWSSSignature(token);
// Add the header using QName
   sig.addSignHeader(new QName("http://www.w3.org/2005/08/addressing", "To"));
   sig.addSignHeader(new QName("http://www.w3.org/2005/08/addressing", "MessageID"));
```

```
   sig.addSignHeader(new QName("http://www.w3.org/2005/08/addressing", "Action"));
// Apply the signature
   gencont.add(sig);

// Secure the message
gencont.process(msgctx);
```

What to do next

You must configure similar signature information for the client-side request consumer (receiver) bindings by completing the following verification tasks:

- Verify the signature
- Choose the signature algorithm methods.
- Change or add signed parts, as needed.

If signature verification is already configured, configure the encryption and decryption information, or configure the consumer and generator tokens.

Configuring signing information using the WSSSignature API:

You can secure the SOAP messages, without using policy sets for configuration, by using the Web Services Security APIs (WSS API). To configure the signing information for the generator binding sections for the client-side request, use the WSSSignature API. The WSSSignature API is part of the com.ibm.websphere.wssecurity.wssapi.signature package.

Before you begin

Either you can use the WSS API or you can configure the policy sets by using the administrative console to enable the signing information. To secure SOAP messages, you must complete the following signing tasks:

- Configure the signing information.
- Choose the signing methods.
- Add or change signed parts, as needed.

About this task

WebSphere Application Server uses the signing information for the default generator to sign parts of the message, and uses XML digital signature with existing algorithms such as RSA-SHA1 and HMAC-SHA1.

XML signature defines many methods for describing key information and enables the definition of a new method. XML canonicalization (C14N) is often needed when you use XML signature. Information can be represented in various ways within serialized XML documents. The C14N process is used to canonicalize XML information. Select an appropriate C14N algorithm because the information that is canonicalized depends on this algorithm.

The signing information specifies the integrity constraints that are applied to generated messages. The constraints include specifying which message parts within the generated message must be digitally signed, and the message parts to attach digitally signed Nonce and timestamp elements to. The following signature and related signature part information are configured:

Table 162. Signature parts information. Use the signature parts to secure messages.

signature parts	Description
keyword	Adds a signature part using keywords. Use the following keywords for the signature parts: • ADDRESSING_HEADERS • BODY • TIMESTAMP The WS-Addressing headers are not encrypted but can be signed.
xpath	Adds a signature part by using an XPath expression.
part	Adds a WSSSignPart object as a target of the signature part.
timestamp	Adds a WSSTimestamp object as a target of the signature part. When specified, the timestamp information also specifies when the message is generated and when it expires.
header	Adds the header, specified by QName, as a target of the signature part.
securityToken	Adds a SecurityToken object as a target of the signature part.

For signing information, certain default behaviors occur. The simplest way to use the WSSSignature API is to use the default behavior (see the example code). The default values are defined by the WSS API for the signing method, the canonicalization method, the security token references, and the signature parts.

Table 163. Signature default behaviors. Several signature behaviors are configured by default.

Signature decisions	Default behavior
Which keywords to use	Sets the keywords. WebSphere Application Server supports the following keywords by default: • ADDRESSING_HEADERS • BODY • TIMESTAMP
Which signature method to use	Sets the signature algorithm. The default signature method is RSA SHA1. WebSphere Application Server supports the following pre-configured signature methods: • WSSSignature.RSA_SHA1: http://www.w3.org/2000/09/xmldsig#rsa-sha1 • WSSSignature.HMAC_SHA1: http://www.w3.org/2000/09/xmldsig#hmac-sha1 The DSA-SHA1 digital signature method (http://www.w3.org/2000/09/xmldsig#dsa-sha1) is not supported.
Which canonicalization method to use	Sets the canonicalization algorithm. The default canonicalization method is EXC C14N. WebSphere Application Server supports the following pre-configured canonicalization methods: • WSSSignature.EXC_C14N; http://www.w3.org/2001/10/xml-exc-c14n# • WSSSignature.C14N: http://www.w3.org/2001/10/xml-c14n#
Whether signature confirmation is required	Sets whether to require signature confirmation. The default value is **false**. Signature confirmation is defined in the OASIS Web Services Security Version 1.1 specification. If required, the value of your signature confirmation is stored in order to use it to validate the signature confirmation after receiving back the message that generated the signature confirmation in the response message. This method is for the requestor side.
Which security token to use	Sets the SecurityToken. The token type specifies which type of token to use for signing and validating messages. The X.509 token is the default token type. WebSphere Application Server provides the following pre-configured consumer token types: • Derived Key Token • X509 tokens You can also create custom token types, as needed.
Which token reference to set	Sets the refType. SecurityToken.REF_STR is the default value for the type of token reference. WebSphere Application Server supports these pre-configured token references types: • SecurityToken.REF_STR • SecurityToken.REF_KEYID • SecurityToken.REF_EMBEDDED • SecurityToken.REF_THUMBPRINT

If WSSSignature.requireSignatureConfirmation() is called, then the WSSSignature API expects that the response message will include the signature confirmation.

Procedure

1. To configure the signing information in a SOAP message by using the WSS API, first ensure that the application server is installed.
2. Use the WSSSignature API to sign the message parts and specify the algorithms in a SOAP message. The WSS API process for signature follows these process steps:
   a. Uses WSSFactory.getInstance() to get the WSS API implementation instance.
   b. Creates the WSSGenerationContext instance from the WSSFactory instance. WSSGenerationContext must be called in a JAX-WS client application.
   c. Creates the SecurityToken from WSSFactory to configure the key for signing.
   d. Creates WSSSignature from the WSSFactory instance using the SecurityToken. The default behavior of WSSSignature is to sign these signature parts: BODY, ADDRESSING_HEADERS, and TIMESTAMP.
   e. Adds the part to be signed, if the default part is not appropriate. If the digest method or transform method is changed, creates WSSSignPart and add it to WSSSignature.
   f. Creates WSSSignaturePart to WSSSignature. Calls the requiredSignatureConfirmation() method, if the signature confirmation is to be applied.
   g. Sets the canonicalization method, if the default is not appropriate.
   h. Sets the signature method, if the default is not appropriate.
   i. Sets the token reference, if the default is not appropriate.
   j. Adds WSSSignature to WSSGenerationContext.
   k. Calls WSSGenerationContext.process() with the SOAPMessageContext.

Results

You have completed the steps to configure the signature for the generator section of the bindings. If there is an error condition when signing the message parts, a WSSException is provided. If successful, the WSSGenerationContext.process() is called, and Web Services Security is applied to the SOAP message.

Example

The following example provides sample code that uses methods that are defined in the WSSignature API.

```
// Get the message context
   Object msgcontext = getMessageContext();

// Generate the com.ibm.websphere.wssecurity.wssapi.WSSFactory instance  (step: a)
   WSSFactory factory = com.ibm.websphere.wssecurity.wssapi.WSSFactory.getInstance();

// Generate the WSSGenerationContext instance  (step: b)
   WSSGenerationContext gencont = factory.newWSSGenerationContext();

// Generate the callback handler
   X509GenerateCallbackHandler callbackHandler = new
       X509GenerateCallbackHandler(
       "",
       "dsig-sender.ks",
       "jks",
       "client".toCharArray(),
       "soaprequester",
       "client".toCharArray(),
       "CN=SOAPRequester, OU=TRL, O=IBM, ST=Kanagawa, C=JP", null);

// Generate the security token to be used for the signature  (step: c)
   SecurityToken token = factory.newSecurityToken(X509Token.class,
        callbackHandler);

// Generate the WSSSignature instance (step: d)
   WSSSignature sig = factory.newWSSSignature(token);

// Set the part to be signed  (step: e)
// DEFAULT: WSSSignature.BODY, WSSSignature.ADDRESSING_HEADERS,
//          and WSSSignature.TIMESTAMP.

// Set the part in the SOAP Header specified by QName  (step: e)
      sig.addSignHeader(new
                        QName("http://www.w3.org/2005/08/addressing",
```

```
                        "MessageID"));

// Set the part specified by the keyword  (step: e)
      sig.addSignPart(WSSSignature.BODY);

// Set the part specified by SecurityToken  (step: e)
   UNTGenerateCallbackHandler untCallbackHandler = new
      UNTGenerateCallbackHandler("Chris", "sirhC");
      SecurityToken unt = factory.newSecurityToken(UsernameToken.class,
         untCallbackHandler);
      sig.addSignPart(unt);

// Set the part specified by WSSSignPart  (step: e)
   WSSSignPart sigPart = factory.newWSSSignPart();
      sigPart.setSignPart(WSSSignature.TIMESTAMP);
      sigPart.setDigestMethod(WSSSignPart.SHA256);
      sig.addSignPart(sigPart);

// Set the part specified by WSSTimestamp  (step: e)
   WSSTimestamp timestamp = factory.newWSSTimestamp();
      sig.addSignPart(timestamp);

// Set the part specified by XPath expression  (step: e)
   StringBuffer sb = new StringBuffer();
      sb.append("/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/'
         and local-name()='Envelope']");
      sb.append("/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/'
         and local-name()='Body']");
      sb.append("/*[namespace-uri()='http://xmlsoap.org/Ping'
         and local-name()='Ping']");
      sb.append("/*[namespace-uri()='http://xmlsoap.org/Ping'
         and local-name()='Text']");
      sig.addSignPartByXPath(sb.toString());

// Set to apply the signature confirmation  (step: f)
      sig.requireSignatureConfirmation();

// Set the canonicalization method  (step: g)
// DEFAULT: WSSSignature.EXC_C14N
      sig.setCanonicalizationMethod(WSSSignature.C14N);

// Set the signature method  (step: h)
// DEFAULT: WSSSignature.RSA_SHA1
      sig.setSignatureMethod(WSSSignature.HMAC_SHA1);

// Set the token reference  (step: i)
// DEFAULT: SecurityToken.REF_STR
      sig.setTokenReference(SecurityToken.REF_KEYID);

// Add the WSSSignature to WSSGenerationContext  (step: j)
   gencont.add(sig);

// Generate the WS-Security header  (step: k)
gencont.process(msgctx);
```

Note: The X509GenerationCallbackHandler needs the key password because the private key is used for signing.

What to do next

Next, chose the algorithm methods if you want a method that is different from the default values. If the algorithm methods do not need to be changed, next use the WSSVerification API to verify the signature and specify the algorithm methods in the consumer section of the binding. Note that the WSSVerification API is only supported on the response consumer (client side).

Adding signed parts using the WSSSignPart API:

You can secure the SOAP messages, without using policy sets for configuration, by using the Web Services Security APIs (WSS API). To configure parts to be signed for the request generator (client side) bindings, use the WSSSignPart API to protect the integrity of messages and to configure the digest and transform algorithm methods. The WSSSignPart API is part of the com.ibm.websphere.wssecurity.wssapi.signature package.

Before you begin

Either you can use the WSS API or you can configure the policy sets by using the administrative console to configure the signing information. To secure SOAP messages using the signing information, you must complete one of the following tasks:

- Configure the signature information
- Configure signed parts, as needed.

About this task

WebSphere Application Server uses the signing information for the default generator to sign parts of the message, and uses XML digital signature with existing digest and transform algorithms (for example, SHA1 or TRANSFORM_EXC_C14N).

The signing information specifies the integrity constraints that are applied to generated messages. The signed parts are used to protect the integrity of messages. You can specify the signed parts to add for message integrity protection.

The following table shows the required signed parts when the digital signature security constraint (integrity) is defined:

Table 164. Signed parts information. Use the signed parts to secure messages.

Signed parts	Description
keyword	Adds signed parts using keywords. WebSphere Application Server supports the following keywords for signed parts: • BODY • ADDRESSING_HEADERS • TIMESTAMP The WS-Addressing headers are not encrypted but can be signed.
xpath	Adds the required signed parts by using an XPath expression.
header	Adds the header, specified by QName, as a signed part.
timestamp	Adds a WSSTimestamp object as a signed part. If specified, the timestamp information specifies when the message is generated and when it expires.

Different message parts can be specified in the message protection for request on the generator side. WSSSignPart allows for adding a transform algorithm, setting a digest method, setting objects as targets, specifying whether an element, and the signed parts, such as: the SOAP body, the WS-Addressing header, and timestamp information.

For signing information, certain default behaviors occur. The simplest way to use the WSSSignPart API is to use the default behavior (see the example code). The signed parts default behaviors include:

Table 165. Default behavior of signed parts. Several signed part characteristics are configured by default.

Signature decisions	Default behavior
Which SOAP message parts to sign	WebSphere Application Server supports the following SOAP message parts to be signed and used for message protection: • WSSSignature.BODY • WSSSignature.ADDRESSING_HEADERS • WSSSignature.TIMESTAMP
Which digest method to use	Sets the digest algorithm method. The digest method algorithm that is specified within the <DigestMethod> element is used in the <SigningInfo> element. WebSphere Application Server supports the following pre-configured digest methods: • WSSSignPart.SHA1 (the default value): http://www.w3.org/2000/09/xmldsig#sha1 • WSSSignPart.SHA256: http://www.w3.org/2001/04/xmlenc#sha256 • WSSSignPart.SHA512: http://www.w3.org/2001/04/xmlenc#sha512

Table 165. Default behavior of signed parts (continued). Several signed part characteristics are configured by default.

Signature decisions	Default behavior
Which transform algorithms to use	Adds the transform method. The transform algorithm is specified within the <Transform> element and specifies the transform algorithm for the signature. WebSphere Application Server supports the following pre-configured transform algorithms: • WSSSignPart.TRANSFORM_EXC_C14N (the default value): http://www.w3.org/2001/10/xml-exc-c14n# • WSSSignPart.TRANSFORM_XPATH2_FILTER: http://www.w3.org/2002/06/xmldsig-filter2 Use this transform method to ensure compliance with the Basic Security Profile (BSP). • WSSSignPart.TRANSFORM_STRT10: http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform • WSSSignPart.TRANSFORM_ENVELOPED_SIGNATURE: http://www.w3.org/2000/09/xmldsig#enveloped-signature

Procedure

1. To enable Web Services Security by using the WSS API (WSSSignPart), first ensure that the application server is installed.
2. Use the WSSSignPart API to sign the message parts and specify the algorithms in a SOAP message. The WSS API process for signed parts follows these process steps:
   a. Uses WSSFactory.getInstance() to get the WSS API implementation instance.
   b. Creates the WSSGenerationContext instance from the WSSFactory instance.
   c. Creates the SecurityToken from WSSFactory to configure the key for signing.
   d. Creates WSSSignature from the WSSFactory instance using the SecurityToken.
   e. Creates WSSSignPart from the WSSFactory instance.
   f. Sets the part to be signed and the digest method or transform method specified by step g or step h if the default is not appropriate.
   g. Sets the digest method if the default is not appropriate.
   h. Sets the transform method if the default is not appropriate.
   i. Adds WSSSignPart to WSSSignature. After any WSSSignPart is set to WSSSignature, the default parts to be signed, which are specified in WSSSignature, are ignored.
   j. Adds WSSSignature to WSSGenerationContext.
   k. Calls WSSGenerationContext.process() with the SOAPMessageContext.

Results

You have completed the steps to configure the signed parts for the generator section of the bindings files. If there is an error condition, a WSSException is provided. If successful, the WSSGenerationContext.process() is called, and Web Services Security is applied to the SOAP message.

Example

The following example provides sample code that uses all of methods that are defined in the WSSSignPart API:

```
// Get the message context
   Object msgcontext = getMessageContext();

// Generate the WSSFactory instance  (step: a)
   WSSFactory factory = WSSFactory.getInstance();

// Generate WSSGenerationContext instance  (step: b)
   WSSGenerationContext gencont = factory.newWSSGenerationContext();

// Generate callback handler
   X509GenerateCallbackHandler callbackHandler = new
      X509GenerateCallbackHandler
      "",
```

```
      "dsig-sender.ks",
      "jks",
      "client".toCharArray(),
      "soaprequester",
      "client".toCharArray(),
      "CN=SOAPRequester, OU=TRL, O=IBM, ST=Kanagawa, C=JP", null);

// Generate the security token used to the signature  (step: c)
   SecurityToken token = factory.newSecurityToken(X509Token.class, callbackHandler);

// Generate WSSSignature instance (step: d)
   WSSSignature sig = factory.newWSSSignature(token);

// Set the part specified by WSSSignPart  (step: e)
   WSSSignPart sigPart = factory.newWSSSignPart();

// Set the part specified by WSSSignPart  (step: f)
   sigPart.setSignPart(WSSSignature.BODY);

// Set the digest method specified by WSSSignPart  (step: g)
   sigPart.setDigestMethod(WSSSignPart.SHA256);

// Set the transform method specified by WSSSignPart  (step: h)
   sigPart.setTransformMethod(WSSSignPart.TRANSFORM_STRT10);

// Add the part specified by WSSSignPart  (step: i)
   sig.addSignPart(sigPart);

// Add the WSSSignature to the WSSGenerationContext  (step: j)
   gencont.add(sig);

// Generate the WS-Security header  (step: k)
gencont.process(msgcontext);
```

Note: The X509GenerationCallbackHandler needs the key password because the private key is used for signing.

What to do next

Use the WSSVerifyPart API or configure policy sets using the administrative console to verify the signed parts on the consumer side.

Configuring request signing methods for the client:

Use the WSSSignature and WSSSignPart APIs to choose the signing methods. The request signing methods include the signature, canonicalization, digest, and transform methods.

Before you begin

First, you must have specified which parts of the message sent by the client must be digitally signed using the WSS APIs or configuring policy sets using the administrative console.

About this task

The following table describes the purpose of this information. Some of these definitions are based on the XML-Signature specification, which is located at the following website http://www.w3.org/TR/xmldsig-core.

Table 166. Signing methods. Use the signing methods to secure messages.

Name of method	Description
Canonicalization algorithm	Canonicalizes the <SignedInfo> element before the information is digested as part of the signature operation.
Signature algorithm	Calculates the signature value of the canonicalized <SignedInfo> element. The algorithm selected for the client request sender configuration must match the algorithm selected in the server request receiver configuration.
Transform method	Transforms the parts to be signed before the information is digested as part of the signature operation.
Digest method	Calculates the digest value of the transformed parts. The algorithm selected for the client request sender configuration must match the algorithms selected in the server request receiver configuration.

You can use the WSS APIs or configure policy sets using the administrative console to configure the signing algorithm methods. If using the WSS APIs, use the WSSSignature and WSSSignPart APIs to specify which message parts to digitally sign when configuring the client for request signing.

The WSSSignature and WSSSignPart APIs complete the following steps to configure the signature and signed part algorithm methods:

Procedure

1. For the generator binding, the WSSSignature API specifies the signature method. WebSphere Application Server supports the following pre-configured signature methods:
   - WSSSignature.RSA_SHA1 (the default value): http://www.w3.org/2000/09/xmldsig#rsa-sha1
   - WSSSignature.HMAC_SHA1: http://www.w3.org/2000/09/xmldsig#hmac-sha1

   For the WSS APIs, WebSphere Application Server does not support the DSA-SHA1 digital signature method, http://www.w3.org/2000/09/xmldsig#dsa-sha1.
2. For the generator binding, the WSSSignature API specifies the canonicalization method. WebSphere Application Server supports the following pre-configured canonicalization algorithms:
   - WSSSignature.EXC_C14N (the default value): The exclusive canonicalization algorithm, http://www.w3.org/2001/10/xml-exc-c14n#
   - WSSSignature.C14N: The inclusive canonicalization algorithm, http://www.w3.org/2001/10/xml-c14n#
3. For the generator binding, the WSSSignPart API specifies the digest method. WebSphere Application Server supports the following pre-configured digest methods:
   - WSSSignPart.SHA1 (the default value): http://www.w3.org/2000/09/xmldsig#sha1
   - WSSSignPart.SHA256: http://www.w3.org/2001/04/xmlenc#sha256
   - WSSSignPart.SHA512: http://www.w3.org/2001/04/xmlenc#sha512
4. For the generator binding, the WSSSignPart API specifies the transform method. WebSphere Application Server supports the following pre-configured transform algorithms:
   - WSSSignPart.TRANSFORM_EXC_C14N (the default value): http://www.w3.org/2001/10/xml-exc-c14n#
   - WSSSignPart.TRANSFORM_XPATH2_FILTER: http://www.w3.org/2002/06/xmldsig-filter2
   - WSSSignPart.TRANSFORM_STRT10: http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform
   - WSSSignPart.TRANSFORM_ENVELOPED_SIGNATURE: http://www.w3.org/2000/09/xmldsig#enveloped-signature

   For the WSS APIs, WebSphere Application Server does not support the following transform algorithms:
   - http://www.w3.org/TR/1999/REC-xpath-19991116
   - http://www.w3.org/2002/07/decrypt#XML

Results

Using the WSS APIs, you have specified which algorithm methods are used to digitally sign a message when the client sends a message to a server.

Example

The following example is sample code for specifying the signature information, HMAC_SHA1 as signature method, C14N as a canonicalizaion method, SHA256 as a digest method, and EXC_C14N and TRANSFORM_STRT10 as the transform methods:

```
//get the message context
Object msgcontext = getMessageContext();

//generate WSSFactory instance
WSSFactory factory = WSSFactory.getInstance();
```

```
//generate WSSGenerationContext instance
WSSGenerationContext gencont = factory.newWSSGenerationContext();

//generate callback handler
X509GenerateCallbackHandler callbackHandler = new X509GenerateCallbackHandler(
  "",
  "dsig-sender.ks",
  "jks",
  "client".toCharArray(),
  "soaprequester",
  "client".toCharArray(),
  "CN=SOAPRequester, OU=TRL, O=IBM, ST=Kanagawa, C=JP",
  null);

//generate the security token used to the signature
SecurityToken token = factory.newSecurityToken(X509Token.class, callbackHandler);

//generate WSSSignature instance
WSSSignature sig = factory.newWSSSignature(token);

//set the canonicalization method
// DEFAULT: WSSSignature.EXC_C14N
sig.setCanonicalizationMethod(WSSSignature.C14N);

//set the signature method
// DEFAULT: WSSSignature.RSA_SHA1
sig.setSignatureMethod(WSSSignature.HMAC_SHA1);

//set the part specified by WSSSignPart
WSSSignPart sigPart = factory.newWSSSignPart();

//set the digest method
 // DEFAULT: WSSSignPart.SHA1
sigPart.setDigestMethod(WSSSignPart.SHA256);

//add the transform method
// DEFAULT: WSSSignPart.TRANSFORM_EXC_C14N
sigPart.addTransformMethod(WSSSignPart.TRANSFORM_EXC_C14N);
sigPart.addTransformMethod(WSSSignPart.TRANSFORM_STRT10);

 // add the WSSSignPart to the WSSSignature
 sig.addSignPart(sigPart);

//add the WSSSignature to the WSSGenerationContext
gencont.add(sig);

//generate the WS-Security header
gencont.process(msgcontext);
```

What to do next

After you configure the client to digitally sign the message and to choose the algorithm methods, you must configure the server to verify the digital signature for request signing and to choose the algorithm methods.

Configure policy sets using the administrative console to configure the signature verification information and methods on the server.

Digital signing methods using the WSSSignature API:

You can configure the signing information for the generator binding using the WSS API. To configure the client for request signing, choose the digital signing methods. The algorithm methods include the signing and canonicalization methods.

You must configure generator signing information to protect message integrity by digitally signing SOAP messages. Integrity refers to digital signature while confidentiality refers to encryption. Integrity decreases the risk of data modification when you transmit data across a network.

After you have specified which message parts to digitally sign, you must specify which method is used to digitally sign the message.

Methods

Methods that are used for the signing information include the:

Signature method
Sets the signature algorithm method.

Canonicalization method
Sets the canonicalization algorithm method.

Signature algorithms

The signature algorithms specify the algorithm that is used to sign the certificate. The signature algorithms specify the Uniform Resource Identifiers (URI) of the signature method. WebSphere Application Server supports the following pre-configured algorithms:

Table 167. Signature algorithms. The algorithms include the signing methods.

Algorithm	Description
WSSSignature.HMAC_SHA1	A URI of the signature algorithm, HMAC: http://www.w3.org/2000/09/xmldsig#hmac-sha1
WSSSignature.RSA_SHA1 (the default value)	A URI of the signature algorithm, RSA: http://www.w3.org/2000/09/xmldsig#rsa-sha1

For the WSS APIs, WebSphere Application Server does not support the DSA-SHA1 algorithm, http://www.w3.org/2000/09/xmldsig#dsa-sha1

The signing algorithm that is specified for the request generator configuration must match the algorithm that is specified for the request consumer configuration.

Canonicalization algorithms

The canonicalization algorithms specify the Uniform Resource Identifiers (URI) of the canonicalization method. WebSphere Application Server supports the following pre-configured algorithms:

Table 168. Signature canonicalization algorithms. The algorithms include the canonicalization methods.

Algorithm	Description
WSSSignature.EXC_C14N (the default value)	A URI of the exclusive canonicalization algorithm EXC_C14N: http://www.w3.org/2001/10/xml-exc-c14n#
WSSSignature.C14N	A URI of the inclusive canonicalization algorithm, C14N: http://www.w3.org/2001/10/xml-c14n#

The canonicalization algorithm that is specified for the request generator configuration must match the algorithm that is specified for the request consumer configuration.

The following example provides sample WSS API code that specifies the HMAC_SHA1 as a signature method and C14n as a canonicalization method:

```
//generate WSSFactory instance
WSSFactory factory = WSSFactory.getInstance();

//generate WSSGenerationContext instance
WSSGenerationContext gencont = factory.newWSSGenerationContext();

//generate callback handler
X509GenerateCallbackHandler callbackHandler = new
    X509GenerateCallbackHandler(
  "",
  "dsig-sender.ks",
  "jks",
  "client".toCharArray(),
  "soaprequester",
  "client".toCharArray(),
  "CN=SOAPRequester, OU=TRL, O=IBM, ST=Kanagawa, C=JP",
  null);

//generate the security token used to the signature
SecurityToken token = factory.newSecurityToken(X509Token.class,
     callbackHandler);

//generate WSSSignature instance
```

```
WSSSignature sig = factory.newWSSSignature(token);

//set the canonicalization method
// DEFAULT: WSSSignature.EXC_C14N
sig.setCanonicalizationMethod(WSSSignature.C14N);

//set the signature method
// DEFAULT: WSSSignature.RSA_SHA1
sig.setSignatureMethod(WSSSignature.HMAC_SHA1);

//add the WSSSignature to the WSSGenerationContext
gencont.add(sig);

//generate the WS-Security header
gencont.process(msgcontext);
```

Signed parts methods using the WSSSignPart API:

You can configure the signed parts information for the generator binding using the WSS API. The algorithms include the digest and transform methods.

You can protect message integrity by configuring signed parts and key information. Integrity refers to digital signature while confidentiality refers to encryption. Integrity decreases the risk of data modification when you transmit data across a network.

Methods

Methods that are used for the signed parts include the:

Digest method
Sets the digest algorithm method.

Transform algorithm
Sets the transform algorithm method.

Digest algorithms

The digest method algorithm specified within the element is used in the element. WebSphere Application Server supports the following pre-configured algorithms:

Table 169. Signed parts digest methods. The methods are used for the signed parts.

Digest method	Description
WSSSignPart.SHA1 (the default value)	A URI of the digest algorithm, SHA1: http://www.w3.org/2000/09/xmldsig#sha1
WSSSignPart.SHA256	A URI of the digest algorithm, SHA256: http://www.w3.org/2001/04/xmlenc#sha256
WSSSignPart.SHA512	A URI of the digest algorithm, SHA256: http://www.w3.org/2001/04/xmlenc#sha512

Transform algorithms

The transform method algorithm specified within the element is used in the element. WebSphere Application Server supports the following pre-configured algorithms:

Table 170. Signed parts transform methods. The methods are used for the signed parts.

Digest method	Description
WSSSignPart.TRANSFORM_ENVELOPED_SIGNATURE	A URI of the transform algorithm, enveloped signature: http://www.w3.org/2000/09/xmldsig#enveloped-signature
WSSSignPart.TRANSFORM_STRT10	A URI of the transform algorithm, STR-Transform: http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform
WSSSignPart.TRANSFORM_EXC_C14N (the default value)	A URI of the transform algorithm, Exc-C14N: http://www.w3.org/2001/10/xml-exc-c14n#

Table 170. Signed parts transform methods (continued). The methods are used for the signed parts.

Digest method	Description
WSSSignPart.TRANSFORM_XPATH2_FILTER	A URI of the transform algorithm, XPath2 filter: http://www.w3.org/2002/06/xmldsig-filter2

The transform algorithm is specified within the <Transform> element and specifies the transform algorithm for the signed part.

For the WSS APIs, WebSphere Application Server does not support the following transform algorithms:

- http://www.w3.org/TR/1999/REC-xpath-19991116
- http://www.w3.org/2002/07/decrypt#XML

The following example provides sample WSS API code for specifying the signature and signed parts, setting the signing key and adding the STR-Transform transform algorithm as signed parts:

```
//get the message context
Object msgcontext = getMessageContext();

//generate WSSFactory instance
WSSFactory factory = WSSFactory.getInstance();

//generate WSSGenerationContext instance
WSSGenerationContext gencont = factory.newWSSGenerationContext();

//generate callback handler
X509GenerateCallbackHandler callbackHandler = new
      X509GenerateCallbackHandler(
  "",
  "dsig-sender.ks",
  "jks",
  "client".toCharArray(),
  "soaprequester",
  "client".toCharArray(),
  "CN=SOAPRequester, OU=TRL, O=IBM, ST=Kanagawa, C=JP",
  null);

//generate the security token used to the signature
SecurityToken token = factory.newSecurityToken(X509Token.class,
     callbackHandler);

//generate WSSSignature instance
WSSSignature sig = factory.newWSSSignature(token);

//set the part specified by WSSSignPart
WSSSignPart sigPart = factory.newWSSSignPart();

//set the part specified by WSSSignPart
sigPart.setSignPart(WSSSignature.BODY);

//set the digest method specified by WSSSignPart
sigPart.setDigestMethod(WSSSignPart.SHA256);

//set the transform method specified by WSSSignPart
sigPart.addTransform(WSSSignPart.TRANSFORM_STRT10);

//set the part specified by WSSSignPart
sig.addSignPart(sigPart);

//add the WSSSignature to the WSSGenerationContext
gencont.add(sig);

//generate the WS-Security header
gencont.process(msgcontext);
```

Attaching the generator token using WSS APIs to protect message authenticity:

When you specify the token generator, the information is used on the generator side to generate the security token.

Before you begin

The token processing and pluggable token architecture in the Web Services Security run time reuses the same security token interface and Java Authentication and Authorization Service (JAAS) Login Module

from the Web Services Security APIs (WSS API). The same implementation of token creation and validation can be used in both the WSS API and the WSS SPI in the Web Services Security run time.

Restriction: The `com.ibm.wsspi.wssecurity.token.TokenGeneratorComponent` interface is not used with JAX-WS web services. If you are using JAX-RPC web services, this interface is still valid.

Note that the key name (KeyName) element is not supported in the application server because there is no KeyName policy assertion defined in the current OASIS Web Services Security draft specification.

About this task

The JAAS callback handler (CallbackHandler) and the JAAS login module (LoginModule) are responsible for creating the security token on the generator side and validating (authenticating) the security token on the consumer side.

For example, on the generator side, the Username token is created by the JAAS LoginModule and using the JAAS CallbackHandler to pass the authentication data. The JAAS LoginModule creates the Username SecurityToken object and passes it to the Web Services Security run time.

Then, on the consumer side, the Username Token XML format is passed to the JAAS LoginModule for validation or authentication and the JAAS CallbackHandler is used to pass authentication data from the Web Services Security run time to the LoginModule. After the token is authenticated, a Username SecurityToken object is created and passed it to the Web Services Security run time.

Note: WebSphere Application Server does not support a stackable login module with the WebSphere Application Server default login module implementation, meaning adding the login module before or after the WebSphere Application Server login module implementation. If you want to stack the login module implementations, you must develop the required login modules because there is no default implementation.

The com.ibm.websphere.wssecurity.wssapi.token package provided by WebSphere Application Server includes support for these classes:

- Security token (SecurityTokenImpl)
- Binary security token (BinarySecurityTokenImpl)

In addition, WebSphere Application Server provides the following pre-configured sub-interfaces for security tokens:

- Derived key token
- Security context token (SCT)
- Username token
- LTPA token propagation
- LTPA token
- X509PKCS7 token
- X509PKIPath token
- X509v3 token
- Kerberos v5 token

The Username token, the X.509 tokens, and the LTPA tokens are used by default for message authenticity. The derived key token and the X.509 tokens are used by default for signing and encryption.

The WSS API and WSS SPI are only supported on the client. To specify the security token type on the generator side, you can also configure policy sets using the administrative console. You can also use the WSS APIs or policy sets for matching consumer security tokens.

The default Login Module and Callback implementations are designed to be used as a pair, meaning both a generator and a consumer part. To use the default implementations, select the appropriate generator and consumer security token in a pair. For example, select `system.wss.generate.x509` in the token generator and `system.wss.consume.x509` in the token consumer when the X.509 token is required.

To configure the generator-side security token, use the appropriate pre-configured token generator interface from the WSS APIs to complete the following token configuration process steps:

Procedure

1. Generate the wssFactory instance.
2. Generate the wssGenerationContext instance.

   The WSSGenerationContext interface stores the components for generating Web Services Security (WS-Security), such as the signing and encryption information, the security token, and the time stamp. When the generate() method is called, all of these components are generated.
3. Create the generator-side components, such as the WSSSignature and the WSSEncryption objects.
4. Specify a JAAS configuration by specifying the name of the JAAS login configuration. The Java Authentication and Authorization Service (JAAS) configuration specifies the name of the JAAS configuration. The JAAS configuration specifies how the token logs in on the consumer side. Do not remove the predefined system or application login configurations. However, within these configurations, you can add module class names and specify the order in which WebSphere Application Server loads each module.
5. Specifiy a token generator class name. The token generator class name specifies the required information to generate the SecurityToken. The Username token, the X.509 tokens, and the LTPA tokens are used by default for message authenticity.
6. Specifiy the settings for the callback handler by specifying a callback handler class name and also specifies the callback handler keys. This class name is the name of the callback handler implementation class that is used for the plug-in to the security token framework.

   The callback handler implementation obtains the required security token and passes it to the token generator. The token generator inserts the security token in the Web Services Security header within the SOAP message. Also, the token generator is a plug-in point for the pluggable security token framework. Service providers can provide their own implementation, but the implementation must use the WSSGenerationContext interface.

   WebSphere Application Server provides the following default callback handler implementations for the generator side:

   com.ibm.websphere.wssecurity.callbackhandler.PropertyCallback
   This class is a callback for handling the name-value pair in elements in the Web Services Security (WS-Security) configuration XMI files.

   com.ibm.websphere.wssecurity.callbackhandler.UNTGUIPromptCallbackHandler
   This class is a callback handler for the Username token with the GUI prompt on the generator side. This instance is used to set the WSSGenerationContext object to generate a Username token.

   com.ibm.websphere.wssecurity.callbackhandler.UNTGenerateCallbackHandler
   This class is a callback handler for the Username token on the generator side. This instance is used to set into WSSGenerationContext object to attach a Username token. Use this implementation for a Java Platform, Enterprise Edition (Java EE) application client only.

   com.ibm.websphere.wssecurity.callbackhandler.X509GenerateCallbackHandler
   This class is a callback handler that is used to generate the X.509 certificate that is inserted in the Web Services Security header within the SOAP message as a binary security token on the generator side. This instance is used to generate the WSSSignature and WSSEncryption objects, set the objects into the WSSGenerationContext object to generate the X.509 binary

security tokens. A keystore and a key definition are required for this callback handler. If you use this implementation, a key store password, path, and type must be provided on the generator side.

com.ibm.websphere.wssecurity.callbackhandler.LTPAGenerateCallbackHandler
This class is a callback handler for the Lightweight Third Party Authentication (LTPA) tokens on the generator side. This instance is used to generate WSSSignature object and WSSEncryption object to generate a LTPA token.

This callback handler is used to validate the LTPA security token inserted in the Web Services Security header within the SOAP message as a binary security token. However, if the user name and password are specified, WebSphere Application Server authenticates the user name and password to obtain the LTPA security token rather than obtaining it from the Run As Subject. Use this callback handler only when the web service is acting as a client on the application server. It is recommended that you do not use this callback handler on a Java EE application client. If you use this implementation, a basic authentication user ID and password must have been provided on the generator side.

com.ibm.websphere.wssecurity.callbackhandler.KRBTokenConsumeCallbackHandler
This class is a callback handler for the Kerberos v5 token on the generator side. This instance is used to set the WSSGenerationContext object to generate the Kerberos v5 AP-REQ as a binary security token. The instance is also used to generate the WSSSignature and WSSEncryption objects to use the Kerberos session key or derived key in the SOAP message signature and encryption.

7. If a X.509 token is specified, additional token information is also specified.

Table 171. Information for X.509 token. Use the X.509 token for signing and encryption.

Token Information	Description
storeRef	The reference name of the keystore.
storePath	The keystore file path from which the keystore is loaded, if needed. It is recommended that you use the `${USER_INSTALL_ROOT}` in the path name as this variable expands to the WebSphere Application Server path on your machine. This path is required when you use the X.509 tokens callback handler implementations.
storePassword	The password that is used to check the integrity of the keystore, or the keystore password that is used to unlock the keystore and to access the keystore file. The keystore and its configuration are used for some of the default callback handler implementations that are provided by WebSphere Application Server.
storeType	The keystore type of keystore that is used for the key locator. This selection indicates the format that is used by the keystore file. The following values are available for selection: **JKS** Use this option if the keystore uses the Java Keystore (JKS) format. **JCEKS** Use this option if the Java Cryptography Extension is configured in the software development kit (SDK). The default IBM JCE is configured in WebSphere Application Server. This option provides stronger protection for stored private keys by using Triple DES encryption. **JCERACFKS** Use JCERACFKS if the certificates are stored in a SAF key ring (z/OS only). **PKCS11KS (PKCS11)** Use this format if your keystore uses the PKCS#11 file format. Keystores using this format might contain RSA keys on cryptographic hardware or might encrypt keys that use cryptographic hardware to ensure protection. **PKCS12KS (PKCS12)** Use this option if your keystore uses the PKCS#12 file format.
alias	The key alias name. The key alias is used by the key locator to find the key within the keystore file.
keyPassword	The key password that is used for recovering the key. This password is needed to access the key object within the keystore file.
keyName	The name of the key. For digital signatures, the key name is used by the request generator or response consumer signing information to determine which key is used to digitally sign the message. For encryption, the key name is used to determine the key used for encryption. The key name must be a fully qualified, distinguished name (DN). For example, `CN=Bob,O=IBM,C=US`.
certStores	A list of certificate stores. A collection certificate store includes a list of untrusted, intermediary certificates and certificate revocation lists (CRLs). This step configures a collection certificate store and certificate revocation lists for the generator bindings.

Table 171. Information for X.509 token (continued). Use the X.509 token for signing and encryption.

Token Information	Description
identityAssertion	Specifies whether identity assertion is used. Selects this item if identity assertion is defined. This option indicates that only the identity of the initial sender is required and inserted into the Web Services Security header within the SOAP message. For an X.509 token generator, the application server sends the original signer certification only.
requestorCertificate	Specifies whether the certificate of the requestor is used.

The following can be specified for a X.509 token:

a. Without any keystore.

b. With a trust anchor. A trust anchor specifies a list of keystore configurations that contain trusted root certificates. These configurations are used to validate the certificate path of incoming X.509-formatted security tokens. For example, when you select the trust anchor or the certificate store of a trusted certificate, you must configure the trust anchor and the certificate store before setting the certificate path.

c. With a keystore that is used for the key locator.

First, you must have created the keystore file, by using a key tool utility, for example. The keystore is used to retrieve the X.509 certificate. This entry specifies the password that is used to access the keystore file. Keystore objects within trust anchors contain trusted root certificates that are used by the CertPath API to validate the trustworthiness of a certificate chain.

d. With keystore that is used for the key locator and the trust anchor.

e. With a map that includes key-value pairs. For example, you might specify the value type name and the value type Uniform Resource Identifier (URI). The value type specifies the namespace URI of the value type for the generated token, and represents the token type of this class:

ValueType: http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509v3

Specifies an X.509 certificate token.

ValueType: http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509PKIPathv1

Specifies X.509 certificates in a public key infrastructure (PKI) path. This callback handler is used to create X.509 certificates encoded with the PkiPath format. The certificate is inserted in the Web Services Security header within the SOAP message as a binary security token. A keystore is required for this callback handler. A CRL is not supported by the callback handler; therefore, the collection certificate store is not required or used. If you use this implementation, you must provide a key store password, path, and type on this panel.

ValueType: http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#PKCS7

Specifies a list of X.509 certificates and certificate revocation lists in a PKCS#7 format. This callback handler is used to create X.509 certificates encoded with the PKCS#7 format. The certificate is inserted in the Web Services Security header in the SOAP message as a binary security token. A keystore is required for this callback handler. You can specify a certificate revocation list (CRL) in the collection certificate store. The CRL is encoded with the X.509 certificate in the PKCS#7 format. If you use this implementation, you must provide a key store password, path, and type.

For some tokens, WebSphere Application Server provides a predefined local name for the value type. When you specify the following local name, you do not need to specify a value type URI:

ValueType: http://www.ibm.com/websphere/appserver/tokentype/5.0.2

For an LTPA token, you can use `LTPA` for the value type local name. This local name causes `http://www.ibm.com/websphere/appserver/tokentype/5.0.2` to be specified for the value type Uniform Resource Identifier (URI).

ValueType: http://www.ibm.com/websphere/appserver/tokentype/5.0.2
For LTPA token propagation, you can use `LTPA_PROPAGATION` for the value type local name. This local name causes `http://www.ibm.com/websphere/appserver/tokentype` to be specified for the value type Uniform Resource Identifier (URI).

8. If the Username token is specified as the token generator class name, the following token information can be specified:
   a. Whether to use IdentityAssertion option. This option is selected if identity assertion is defined. This option indicates that only the identity of the initial sender is required and inserted into the Web Services Security header within the SOAP message. For example, WebSphere Application Server sends only the user name of the original caller for a Username token generator.
   b. Whether to use RunAsSubject identity option. This option is used if an identity assertion is defined and you want to use the Run As identity instead of the initial caller identity for identity assertion in a downstream call. This option is valid only if you have configured the Username token as the token generator.
   c. Whether to use sendRealm.
   d. Whether to specify the nonce.

      This option indicates whether a Nonce is included for the token generator. Nonce is a unique, cryptographic number that is embedded in a message to help stop repeat, unauthorized attacks of Username tokens. Nonce is valid only when the generated token type is a Username token, and it is available only for the request generator binding.
   e. Specifies the keyword of the time stamp. This option indicates whether to verify a time stamp in the Username token. The time stamp is valid only when the incorporated token type is a Username token.
   f. Specifies a map that includes key-value pairs. For example, you might specify the value type name and the value type Uniform Resource Identifier (URI). The value type specifies the namespace URI of the value type for the generated token, and represents the token type of this class:

      URI value type: http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-username-token-profile-1.0#UsernameToken
      Specifies a Username token.
9. If the Kerberos v5 token is specified as the token generator class name, the following token information can be specified:

Token Information	Description	Default Value
name	Kerberos client principal name	
password	Kerberos client password	
realm	Kerberos realm associated with the Kerberos client	Default realm name in Kerberos configuration file. Specify null to use the default value.
targetService	Kerberos service name associated with the target web services.	
targetHost	Kerberos realm name associated with the Kerberos service name.	
tokenValueType	Kerberos token value type in QName defined by Oasis Kerberos Token Profile v1.1 specification.	http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ
targetRealm	Kerberos realm name associated with the Kerberos service name.	Default realm name in the Kerberos configuration file
prompt	A boolean value to enable the login prompt.	false

Token Information	Description	Default Value
supportTokenRequireSHA1	A boolean value to require a SHA1 key that is used in subsequent request messages when the Kerberos token is used as a supporting token.	false SHA1 key is consumed only if the supporting Kerberos token is protected. If set to true, the SHA1 key is always consumed.
alwaysAPREQ	A boolean value to indicate that the client should always send the Kerberos AP_REQ token in the request messages.	false The SHA1 key is used instead in the subsequent messages. If set to true, the Kerberos AP_REQ token is always used.
requireDKT	A boolean value to require a derived key for message protection.	false
clabel	The client label for the derived key.	WS-SecureConversation Specify null to use the default value.
slabel	The service label for the derived key.	WS-SecureConversation Specify null to use the default value.
keylen	The length of the derived key.	16 Specify zero to use the default value
noncelen	The length of the nonce.	16 Specify zero to use the default value
encComponent	An instance of WSSEncryption.	Set encComponent and sigComponent to null to initialize this first for either the encryption or signature component. Then, use the initialized component only in the callback handler constructor for the second component.
sigComponent	An instance of WSSSignature.	Set encComponent and sigComponent to null to initialize this first for either the encryption or signature component. Then, use the initialized component only in the callback handler constructor for the second component.

Additional token value types are defined in the OASIS Kerberos Token Profile v1.1 specification. Specify the token value type as the local name. It is not necessary to specify the value type URI for the Kerberos v5 token.

- http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#Kerberosv5_AP_REQ
- http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#Kerberosv5_AP_REQ1510
- http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ1510
- http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#Kerberosv5_AP_REQ4120
- http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ4120

10. If Secure Conversation is used for message protection, the following information must be specified:

Information	Description
bootstrapWSSGenerationContext	The bootstrap configuration used to secure the RequestSecurityToken (RST) token.
bootstrapWSSConmingContext	The bootstrap configuration used for consuming a secured RequestSecurityTokenResponse (RSTR).
ENDPOINT_URL	The service end point URL.
EncryptionAlgorithm	This determines the key size.
cLabel	The client label used when creating the derived key.
sLabel	The server label used when creating the derived key.

11. Set the components into the wssGenerationContext object.
12. Invoke the wssGenerationContext.process() method.

Results

Using the Web Services Security API (WSS API) process, you can configured the token generator.

What to do next

Next, you must specify a similar token consumer configuration.

Configuring generator security tokens using the WSS API:

You can secure the SOAP messages, without using policy sets, by using the Web Services Security APIs. To configure the token on the generator side, use the Web Services Security APIs (WSS API). The generator security tokens are part of the `com.ibm.websphere.wssecurity.wssapi.token` interface package.

Before you begin

The pluggable token framework in WebSphere Application Server has been redesigned so that the same framework from the WSS API can be reused. The same implementation of creating and validating security token can be used both for the Web Services Security runtime and for the WSS API application code. The redesigned framework also simplifies the SPI programming model and will make it easier to add security token types.

You can use the WSS API or you can configure the tokens by using the administrative console. To configure tokens, you must complete the following token tasks:

- Configure the generator tokens.
- Configure the consumer tokens.

About this task

The JAAS CallbackHandler and JAAS LoginModule are responsible for creating the security token on the generator side.

On the generator side, the token is created by using the JAAS LoginModule and by using JAAS CallbackHandler to pass authentication data. Then, the JAAS LoginModule creates the securityToken object, such as the UsernameToken, and passes it to the Web Services Security run time.

On the consumer side, the XML format is passed to the JAAS LoginModule for validation or authentication. then the JAAS CallbackHandler is used to pass authentication data from the Web Services Security runtime to the LoginModule. After the token is authenticated, a security token object is created, and the token is passed it to the Web Services Security runtime.

When using the WSS API for generator token creation, certain default behaviors occur. The simplest way to use the WSS API is to use the default behavior (see the example code). The WSS API provide default values for the token type, the token value, and the JAAS confirmation name. The default token behaviors include:

Table 172. Token decisions and default behaviors. Several token characteristics are configured by default.

Generator token decisions	Default behavior
Which token type to use	The token type specifies which type of token to use for message integrity, message confidentiality, or message authenticity. WebSphere Application Server provides the following pre-configured generator token types for message integrity and message confidentiality: • Derived key token • X509 tokens You can also create custom token types, as needed. WebSphere Application Server also provides the following pre-configured generator token types for the message authenticity: • Username token • LTPA tokens • X509 tokens You can also create custom token types, as needed.
What JAAS login configuration name to specify	The JAAS login configuration name specifies which JAAS login configuration name to use.
Which configuration type to use	The JAAS login module specifies the configuration type. Only the pre-configured generator configuration types can be used for generator token types.

The SecurityToken class (com.ibm.websphere.wssecurity.wssapi.token.SecurityToken) is the generic token class and represents the security token that has methods to get the identity, the XML format, and the cryptographic keys. Using the SecurityToken class, you can apply both the signature and encryption to the SOAP message. However, to apply both, you must have two SecurityToken objects, one for the signature and one for encryption, respectively.

The following tokens types are subclasses of the generic security token class:

Table 173. Subclasses of the SecurityToken. Use the subclasses to represent the security token.

Token type	JAAS login configuration name
Username token	system.wss.generate.unt
Security context token	system.wss.generate.sct
Derived key token	system.wss.generate.dkt

The following tokens types are subclasses of the binary security token class:

Table 174. Subclasses of the BinarySecurityToken. Use the subclasses to represent the binary security token.

Token type	JAAS login configuration name
LTPA token	system.wss.generate.ltpa
LTPA propagation token	system.wss.generate.ltpaProp
X.509 token	system.wss.generate.x509
X.509 PKI Path token	system.wss.generate.pkiPath
X.509 PKCS7 token	system.wss.generate.pkcs7

Note:

- For each JAAS login token generator configuration name, there is a respective token consumer configuration name. For example, for the Username token, the respective token consumer configuration name is system.wss.consume.unt.

- The LTPA and LTPA propagation tokens are only available to a requester that is running as a server-based client. The LTPA and LTPA propagation tokens are not supported for the Java SE 6 or Java EE application client.

Procedure

1. To configure the securityToken package, `com.ibm.websphere.wssecurity.wssapi.token`, first ensure that the application server is installed.
2. Use the Web Services Security token generator process to configure the tokens. For each token type, the process is similar to the following process that demonstrates the UsernameToken token generator process:
   a. Use WSSFactory.getInstance() to get the WSS API implementation instance.
   b. Create the WSSGenerationContext instance from the WSSFactory instance.
   c. Create a JAAS CallbackHandler. The authentication data, such as the user name and password are specified as part of the CallbackHandler. For example, the following code specifies Chris as the user name and sirhC as the password: UNTGenerationCallbackHandler("Chris", "sirhC");
   d. Call any JAAS CallbackHandler parameters and review the token class information for which parameters are required or optional. For example, for the UsernameToken, the following parameters can be configured also:

      Nonce
      Indicates whether a nonce is included in the user name token for the token generator. Nonce is a unique, cryptographic number that is embedded in a message to help stop repeat, unauthorized attacks of user name tokens. The nonce value is valid only when the generated token type is a UsernameToken and only when it applies to the request generator binding.

      Created timestamp
      Indicates whether to insert a time stamp into the UsernameToken. The timestamp value is valid only when the generated token type is a UsernameToken and only when it applies to the request generator binding.

   e. Create the SecurityToken from WSSFactory.

      By default, the UsernameToken API specifies the ValueType as: "http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-username-token-profile-1.0#UsernameToken"

      By default, the UsernameToken API provides the QName of this class and specifies the NamespaceURI as http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-secext-1.0.xsd and also specifies the LocalPart as UsernameToken.
   f. Optional: Specify the JAAS login module configuration name. On the generator side, the configuration type is always `generate` (for example, `system.wss.generate.unt`).
   g. Add the SecurityToken to the WSSGenerationContext.
   h. Call WSSGenerationContext.process() and generate the WS-Security header.

Results

If there is an error condition, a WSSException is provided. If successful, the WSSGenerationContext process() is called, and the security token for the generator binding is attached.

Example

The following example code shows how to use WSS APIs to create a Username security token, attach the Username token to the SOAP message, and configure the Username token in the generator binding.

```
// import the packages
import javax.xml.ws.BindingProvider;
import com.ibm.websphere.wssecurity.wssapi.*;
import com.ibm.websphere.wssecurity.callbackhandler.*;
...
   // obtain the binding provider
```

```
   BindingProvider bp = ... ;

   // get the request context
   Map<String, Object> reqContext = bp.getRequestContext();

   // generate WSSFactory instance
   WSSFactory factory = WSSFactory.getInstance();

   // generate WSSGenerationContext instance
   WSSGenerationContext gencont = factory.newWSSGenerationContext();

   // generate callback handler
   UNTGenerateCallbackHandler untCallbackHandler =
   new UNTGenerateCallbackHandler("Chris", "sirhC");

   // generate the username token
   SecurityToken unt = factory.newSecurityToken(UsernameToken.class, untCallbackHandler);

   // add the SecurityToken to the WSSGenerationContext
   gencont.add(unt);

   // generate the WS-Security header
   gencont.process(reqContext);
```

The following example code shows how to modify the preceding Username token sample to create an LTPAv2 token from the runAs identity on the current thread. The two lines of code that instantiate the callback handler and create the security token are replaced with the following two lines of code:

```
// generate callback handler
LTPAGenerateCallbackHandler ltpaCallbackHandler = new LTPAGenerateCallbackHandler(null, null);

// generate the LTPAv2 token
SecurityToken ltpa = wssfactory.newSecurityToken(LTPAv2Token.class, ltpaCallbackHandler);
```

The instantiation of the LTPAGenerateCallbackHandler object with (null, null) indicates that the LTPA token should be generated from the current runAs identity. If the callback handler is instantiated with basicAuth information, ("userName", "password"), a new LTPA token is created using the specified basicAuth information.

The following example shows how to use secure conversation with the WSS APIs to configure the generator tokens, as well as the consumer tokens. In this example, the SecurityContextToken token is created using the WS-SecureConversation draft namespace: `http://schemas.xmlsoap.org/ws/2005/02/sc/sct`. To use the WS-SecureConversation version 1.3 namespace, `http://docs.oasis-open.org/ws-sx/ws-secureconversation/200512/sct`, specify SecurityContextToken13.class instead of SecurityContextToken.class.

```
// import the packages
import javax.xml.ws.BindingProvider;
import com.ibm.websphere.wssecurity.wssapi.*;
import com.ibm.websphere.wssecurity.callbackhandler.*;
...
   // obtain the binding provider
   BindingProvider bp = ... ;

   // get the request context
   Map<String, Object> reqContext = bp.getRequestContext();

   // generate WSSFactory instance
   WSSFactory wssFactory = WSSFactory.getInstance();

   WSSGenerationContext bootstrapGenCon = wssFactory.newWSSGenerationContext();

   // Create a Timestamp
   ...
   // Add Timestamp
   ...

   // Sign the SOAP Body, WS-Addressing headers, and Timestamp
   X509GenerateCallbackHandler btspReqSigCbHandler = new X509GenerateCallbackHandler(...);
   SecurityToken btspReqSigToken = wssFactory.newSecurityToken(X509Token.class,
                                                               btspReqSigCbHandler);
   WSSSignature bootstrapReqSig = wssFactory.newWSSSignature(btspReqSigToken);
   bootstrapReqSig.setCanonicalizationMethod(WSSSignature.EXC_C14N);

   // Add Sign Parts
   ...
   bootstrapGenCon.add(bootstrapReqSig);

   // Encrypt the SOAP Body and the Signature
   X509GenerateCallbackHandler btspReqEncCbHandler = new X509GenerateCallbackHandler(...);
   SecurityToken btspReqEncToken = wssFactory.newSecurityToken(X509Token.class,
```

```
                                                        btspReqEncCbHandler);
WSSEncryption bootstrapReqEnc = wssFactory.newWSSEncryption(btspReqEncToken);
bootstrapReqEnc.setEncryptionMethod(WSSEncryption.AES128);
bootstrapReqEnc.setKeyEncryptionMethod(WSSEncryption.KW_RSA15);

// Add Encryption parts
...
bootstrapGenCon.add(bootstrapReqEnc);
WSSConsumingContext bootstrapConCon = wssFactory.newWSSConsumingContext();
X509ConsumeCallbackHandler btspRspVfyCbHandler = new X509ConsumeCallbackHandler(....);
WSSVerification bootstrapRspVfy = wssFactory.newWSSVerification(X509Token.class,
                                                          btspRspVfyCbHandler);
bootstrapRspVfy.addAllowedCanonicalizationMethod(WSSVerification.EXC_C14N);

// Add Verify parts
...
bootstrapConCon.add(bootstrapRspVfy);
X509ConsumeCallbackHandler btspRspDecCbHandler = new X509ConsumeCallbackHandler(...);
WSSDecryption bootstrapRspDec = wssFactory.newWSSDecryption(X509Token.class,
                                                        btspRspDecCbHandler);
bootstrapRspDec.addAllowedEncryptionMethod(WSSDecryption.AES128);
bootstrapRspDec.addAllowedKeyEncryptionMethod(WSSDecryption.KW_RSA15);

// Add Decryption parts
...
bootstrapConCon.add(bootstrapRspDec);
SCTGenerateCallbackHandler sctgch = new SCTGenerateCallbackHandler(bootstrapGenCon,
                                                                   bootstrapConCon,
                                                                   ENDPOINT_URL,
                                                                   WSSEncryption.AES128);
SecurityToken[] scts = wssFactory.newSecurityTokens(new Class[]{SecurityContextToken.class},
                                                    sctgch);
SecurityContextToken sct = (SecurityContextToken)scts[0];

// Use the SCT to generate DKTs for Secure Conversation
// Signature algorithm and client and service labels
DerivedKeyToken dktSig = sct.getDerivedKeyToken(WSSSignature.HMAC_SHA1,
                                                "WS-SecureConversation",
                                                "WS-SecureConversation");

// Encryption algorithm and client and service labels
DerivedKeyToken dktEnc = sct.getDerivedKeyToken(WSSEncryption.AES128,
                                                "WS-SecureConversation",
                                                "WS-SecureConversation");

// Create the application generation context for the request message
WSSGenerationContext applicationGenCon = wssFactory.newWSSGenerationContext();

// Create and add Timestamp
...

// Add the derived key token and Sign the SOAP Body and WS-Addressing headers
WSSSignature appReqSig = wssFactory.newWSSSignature(dktSig);
appReqSig.setSignatureMethod(WSSSignature.HMAC_SHA1);
appReqSig.setCanonicalizationMethod(WSSSignature.EXC_C14N);
...
applicationGenCon.add(appReqSig);

// Add the derived key token and Encrypt the SOAP Body and the Signature
WSSEncryption appReqEnc = wssFactory.newWSSEncryption(dktEnc);
appReqEnc.setEncryptionMethod(WSSEncryption.AES128);
appReqEnc.setTokenReference(SecurityToken.REF_STR);
appReqEnc.encryptKey(false);
...
applicationGenCon.add(appReqEnc);

// Create the application consuming context for the response message
WSSConsumingContext applicationConCon = wssFactory.newWSSConsumingContext();

//client and service labels and decryption algorithm
SCTConsumeCallbackHandler sctCbHandler = new SCTConsumeCallbackHandler("WS-SecureConversation",
                                                                       "WS-SecureConversation",
                                                                       WSSDecryption.AES128);

// Derive the token from SCT and use it to Decrypt the SOAP Body and the Signature
WSSDecryption appRspDec = wssFactory.newWSSDecryption(SecurityContextToken.class,
                                                      sctCbHandler);
appRspDec.addAllowedEncryptionMethod(WSSDecryption.AES128);
appRspDec.encryptKey(false);
...
applicationConCon.add(appRspDec);

// Derive the token from SCT and use it to Verify the
// signature on the SOAP Body, WS-Addressing headers, and Timestamp
WSSVerification appRspVfy = wssFactory.newWSSVerification(SecurityContextToken.class,
                                                    sctCbHandler);
...
```

```
applicationConCon.add(appRspVfy);
...
applicationGenCon.process(reqContext);
applicationConCon.process(reqContext);
```

What to do next

For each token type, configure the token using the WSS APIs or using the administrative console. Next, specify the similar consumer tokens if you have not done so.

If both the generator and consumer tokens are configured, continue securing SOAP messages either by signing the SOAP message or by encrypting the message, as needed. You can use either the WSS APIs or the administrative console to secure the SOAP messages.

Securing messages at the request generator using WSS APIs:

You can secure SOAP messages by configuring signing information, encryption, and generator tokens to protect message integrity, confidentiality, and authenticity, respectively. This request (client-side) generator configuration defines the Web Services Security requirements for the outgoing SOAP message request.

Before you begin

To secure web services with WebSphere Application Server, you must configure the generator and the consumer security constraints. Therefore, in addition to securing messages at the request generator level, you must also secure messages at the response consumer level.

About this task

The request (client-side) generator configuration requirements involve generating a SOAP message request that uses a digital signature, incorporates encryption, and attaches security tokens.

To secure web service applications, you must specify several different configurations. Although there is no specific sequence to specify these different configurations, some configurations reference other configurations. For example, decryption configurations reference encryption configurations.

You can use the following interfaces to configure Web Services Security and to define policy types to secure the SOAP messages:

- Use the administrative console to configure policy sets.
- Use the Web Services Security APIs (WSS API) to configure the SOAP message context (only for the client)

The following high-level steps use the WSS APIs:

Procedure

- Configure generator signing to protect message integrity.
- Configure encryption to protect message confidentiality.
- Attach generator tokens to protect message authenticity.
- Propagate self-issued SAML bearer tokens using WSS APIs.
- Propagate self-issued SAML sender-vouches tokens with message protection using WSS APIs.
- Propagate self-issued SAML sender-vouches tokens with transport protection using WSS APIs.
- “Sending self-issued SAML holder-of-key tokens with symmetric key using WSS APIs” on page 1598.
- “Sending self-issued SAML holder-of-key tokens with asymmetric key using WSS APIs” on page 1600.

Results

After completing these procedures, you have secured messages at the request generator level.

What to do next

Next, if not already configured, secure messages with signature verification, decryption, and consumer tokens at the response consumer (client-side) level.

Configuring encryption to protect message confidentiality using the WSS APIs:

You can configure encryption information for the client-side request generator (sender) bindings. Encryption information is used to specify how the generators (senders) encrypt outgoing SOAP messages. To configure encryption, specify which message parts to encrypt and specify which algorithm methods and security tokens are to be used for encryption.

Before you begin

Confidentiality refers to encryption while integrity refers to digital signing. Confidentiality reduces the risk of someone understanding the message flowing across the Internet. With confidentiality specifications, the message is encrypted before it is sent and decrypted when it is received at the correct target. Prior to configuring encryption, familiarize yourself with XML encryption.

About this task

For encryption, you must specify the following:

- Which parts of the message are to be encrypted.
- Which encryption algorithms to specify.

To configure encryption and encrypted parts on the client side, use the WSSEncryption and WSSEncryptPart APIs, or configure policy sets using the administrative console.

WebSphere Application Server provides default values for bindings. However, an administrator must modify the defaults for a production environment.

WebSphere Application Server uses encryption information for the default generator to encrypt parts of the SOAP message. The WSSEncryption API configures the following required parts as encrypted parts.

Table 175. Required encrypted parts. Use encrypted parts to increase the confidentiality of SOAP messages.

Encryption parts	Description
Keywords	Keywords are used to add the encrypted parts to the SOAP message.
XPath expression	An XPath expression is used to add the encrypted parts to the SOAP message.
WSSEncryptPart object	This object adds the encrypted parts to the SOAP message.
WSSSignature object	This object adds the signature component as an encrypted part.
Header	This part adds the header in the SOAP header, specified by QName, as an encryption part.
Security token object	This object adds the security token as an encryption part.

Web Services Security API (WSS API) supports symmetric encryption, by using a shared key, only when Web Services Secure Conversation (WS-SecureConversation) is used.

The WSS APIs allow the use of either keywords or an XPath expression to specify the parts of the message that are to be encrypted. WebSphere Application Server supports the use of the following keywords:

Table 176. Supported encryption keywords. Use keywords to specify encrypted parts.

Keyword	References
BODY_CONTENT	The keyword for the contents of the SOAP message body as an encryption target.
SIGNATURE	The keyword for the signature component as an encryption target.

If configuring using the WSS APIs, the WSSEncryption and WSSEncryptPart APIs complete these high-level steps:

Procedure

1. Use the WSSEncryption API to configure encryption. The WSSEncryption API performs these tasks by default:
   a. Generates the callback handler.
   b. Generates the generator security token object.
   c. Adds the security token reference type.
   d. Adds the signature component.
   e. Adds the WSSEncryptPart object.
   f. Adds the parts to be encrypted. Adds the default parts as targets of encryption by using keywords and XPath expressions.
   g. Adds the header in the SOAP message, specified by QName.
   h. Sets the default data encryption method.
   i. Specifies whether the key is to be encrypted using a Boolean value.
   j. Sets the default key encryption method.
   k. Selects a part reference.
   l. Sets the MTOM optimization Boolean value.
2. Use the WSSEncryptPart API to configure encrypted parts or add a transform method. The WSSEncryptPart API performs these tasks by default:
   a. Sets the encrypted parts specified by using keywords or an XPath expression.
   b. Sets the encrypted parts specified by an XPath expression.
   c. Sets the signature component object, WSSSignature.
   d. Sets the header in the SOAP message, specified by QName.
   e. Sets the generator security token.
   f. Adds the transform method, if needed.
3. Change from the default values for algorithm or message parts, as needed. For example: you could change one or more of the following items:
   - Change the data encryption algorithm from the default value of AES 128.
   - Change the key encryption algorithm from the default value of KW_RSA_OAEP.
   - Specify to not encrypt the key (false).
   - Change the security token type from default of X.509 token.
   - Change the security token reference type from the default value of SecurityToken.REF_STR.
   - Only use BODY_CONTENT as an encryption part and not use SIGNATURE also.
   - Turn MTOM optimization on (true).

Results

The encryption information is configured for the generator binding.

Example

The following is an example of the WSSEncryption API:

```
WSSFactory factory = WSSFactory.getInstance();
WSSGenerationContext gencont = factory.newWSSGenerationContext();

X509GenerateCallbackHandler callbackhandler = generateCallbackHandler();
SecurityToken token = factory.newSecurityToken(X509Token.class, callbackHandler);
WSSEncryption enc = factory.newWSSEncryption(token);

gencont.add(enc);
```

What to do next

You must configure similar decryption information for the client-side response consumer (receiver) bindings, if you have not already configured the information.

Next, review the WSSEncryption API process.

Encrypting the SOAP message using the WSSEncryption API:

You can secure the SOAP messages, without using policy sets for configuration, by using the Web Services Security APIs (WSS API). To configure the client for request encryption on the generator side, use the WSSEncryption API to encrypt the SOAP message. The WSSEncryption API specifies which request SOAP message parts to encrypt when configuring the client.

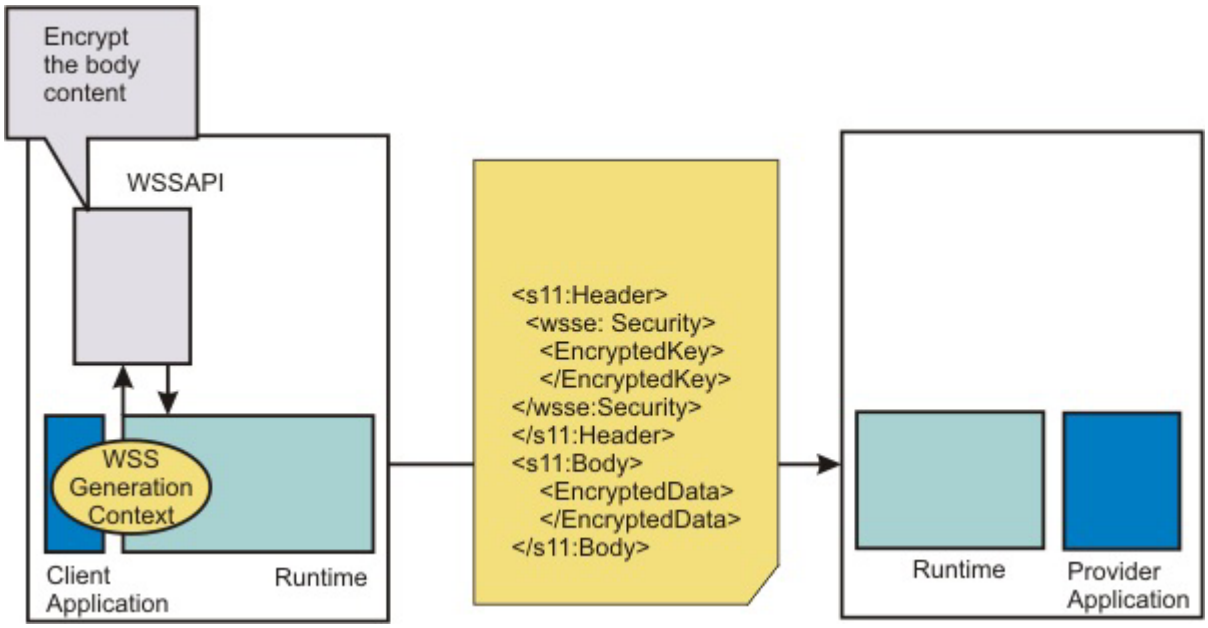
Before you begin

You can use the WSS API or use policy sets on the administrative console to enable encryption and add generator security tokens in the SOAP message. To secure SOAP messages, use the WSS APIs to complete the following encryption tasks, as needed:

- Configure encryption and choose the encryption methods using the WSSEncryption API.
- Configure the encrypted parts, as needed, using the WSSEncryptPart API.

About this task

The encryption information on the generator side is used for encrypting an outgoing SOAP message for the request generator (client side) bindings. The client generator configuration must match the configuration for the provider consumer.



Confidentiality settings require that confidentiality constraints be applied to generated messages. These constraints include specifying which message parts within the generated message must be encrypted, and which message parts to attach encrypted Nonce and timestamp elements to.

The following encryption parts can be configured:

Table 177. Encryption parts. Use the encryption parts to enable encryption in messages.

Encryption parts	Description
part	Adds the WSSEncryptPart object as a target of the encryption part.
keyword	Adds the encryption parts using keywords. WebSphere Application Server supports the following keywords: • BODY_CONTENT • SIGNATURE
xpath	Adds the encryption part using an XPath expression.
signature	Adds the WSSignature component as a target of the encrypted part.
header	Adds the SOAP header, specified by QName, as a target of the encrypted part.
securityToken	Adds the SecurityToken object as a target of the encrypted part.

For encryption, certain default behaviors occur. The simplest way to use the WSSEncryption API is to use the default behavior (see the example code).

WSSEncryption provides defaults for the key encryption algorithm, the data encryption algorithm, the security token reference method, and the encryption parts such as the SOAP body content and the signature. The encryption default behaviors include:

Table 178. Encryption decisions. Use encryption default behavior to secure the message body content and signature.

Encryption decisions	Default behavior
Which SOAP message parts to encrypt using keywords	Sets the encryption parts that you can add using keywords. The default encryption parts are the BODY_CONTENT and SIGNATURE. WebSphere Application Server supports using these keywords: • WSSEncryption.BODY_CONTENT • WSSEncryption.SIGNATURE

Table 178. Encryption decisions (continued). Use encryption default behavior to secure the message body content and signature.

Encryption decisions	Default behavior
Which data encryption method to choose (algorithm)	Sets the data encryption method. Both data and key encryption methods can be specified. The default data encryption algorithm method is AES 128. WebSphere Application Server supports these data encryption methods: • WSSEncryption.AES128: http://www.w3.org/2001/04/xmlenc#aes128-cbc • WSSEncryption.AES192: http://www.w3.org/2001/04/xmlenc#aes192-cbc • WSSEncryption.AES256: http://www.w3.org/2001/04/xmlenc#aes256-cbc • WSSEncryption.TRIPLE_DES: http://www.w3.org.2001/04/xmlenc#tripledes-cbc
Whether to encrypt the key (isEncrypt)	Specifies whether to encrypt the key. The values are `true` or `false`. The default value is to encrypt the key (`true`).
Which key encryption method to choose (algorithm)	Sets the key encryption method. Both data and key encryption methods can be specified. The default key encryption algorithm method is key wrap RSA OAEP. WebSphere Application Server supports these key encryption methods: • WSSEncryption.KW_AES128: http://www.w3.org/2001/04/xmlenc#kw-aes128 • WSSEncryption.KW_AES192: http://www.w3.org/2001/04/xmlenc#kw-aes192 • WSSEncryption.KW_AES256: http://www.w3.org/2001/04/xmlenc#kw-aes256 • WSSEncryption.KW_RSA_OAEP: http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p • WSSEncryption.KW_RSA15: http://www.w3.org/2001/04/xmlenc#rsa-1_5 • WSSEncryption.KW_TRIPLE_DES: http://www.w3.org/2001/04/xmlenc#kw-tripledes
Which security token to specify (securityToken)	Sets the SecurityToken. The default security token type is the X509Token. WebSphere Application Server provides the following pre-configured consumer token types: • Derived key token • X.509 tokens
Which token reference to use (refType)	Sets the type of the security token reference. The default token reference is SecurityToken.REF_KEYID. WebSphere Application Server supports the following token reference types: • SecurityToken.REF_KEYID • SecurityToken.REF_STR • SecurityToken.REF_EMBEDDED • SecurityToken.REF_THUMBPRINT
Whether to use MTOM (mtomOptimize)	Sets Message Transmission Optimization Mechanism (MTOM) optimization for the encrypted part.

Procedure

1. To encrypt the SOAP message using the WSSEncryption API, first ensure that the application server is installed.
2. The WSS API process for encryption performs these process steps:
   a. Uses WSSFactory.getInstance() to get the WSS API implementation instance
   b. Creates the WSSGenerationContext instance from the WSSFactory instance.
   c. Creates the SecurityToken from WSSFactory used for encryption.
   d. Creates WSSEncryption from the WSSFactory instance using the SecurityToken. The default behavior of WSSEncryption is to encrypt the body content and the signature.
   e. Adds a new part to be encrypted in WSSEncryption if the existing part is not appropriate. After addEncryptPart(), addEncryptHeader(), or addEncryptPartByXPath() is called, the default part is cleared.
   f. Calls the encryptKey(false) if the key is not to be encrypted.
   g. Sets the data encryption method if the default method is not appropriate.
   h. Sets the key encryption method if the default method is not appropriate.
   i. Sets the token reference if the default token reference is not appropriate.
   j. Adds WSSEncryption to WSSConsumingContext.
   k. Calls WSSGenerationContext.process() with the SOAPMessageContext.

Results

If there is an error condition during encryption, a WSSException is provided. If successful, the API calls the WSSGenerationContext.process(), the WS-Security header is generated, and the SOAP message is now secured using Web Services Security.

Example

The following example provides sample code using methods that are defined in WSSEncryption:

```
// Get the message context
   Object msgcontext = getMessageContext();

// Generate the WSSFactory instance (step: a)
WSSFactory factory = WSSFactory.getInstance();

// Generate the WSSGenerationContext instance (step: b)
WSSGenerationContext gencont = factory.newWSSGenerationContext();

// Generate the callback handler
X509GenerateCallbackHandler callbackHandler = new
         X509GenerateCallbackHandler(
     "",
     "enc-sender.jceks",
     "jceks",
     "storepass".toCharArray(),
     "bob",
     null,
     "CN=Bob, O=IBM, C=US",
     null);

// Generate the security token used for encryption (step: c)
SecurityToken token = factory.newSecurityToken(X509Token.class , callbackHandler);

// Generate WSSEncryption instance (step: d)
WSSEncryption enc = factory.newWSSEncryption(token);

// Set the part to be encrypted (step: e)
// DEFAULT: WSSEncryption.BODY_CONTENT and WSSEncryption.SIGNATURE

// Set the part specified by the keyword (step: e)
   enc.addEncryptPart(WSSEncryption.BODY_CONTENT);

// Set the part in the SOAP Header specified by QName (step: e)
   enc.addEncryptHeader(new QName("http://www.w3.org/2005/08/addressing",
                                  "MessageID"));

// Set the part specified by WSSSignature (step: e)
   SecurityToken sigToken = getSecurityToken();
      WSSSignature sig = factory.newWSSSignature(sigToken);
   enc.addEncryptPart(sig);

// Set the part specified by SecurityToken (step: e)
   UNTGenerateCallbackHandler untCallbackHandler =
          new UNTGenerateCallbackHandler("Chris", "sirhC");
      SecurityToken unt = factory.newSecurityToken(UsernameToken.class,
                                                   untCallbackHandler);
   enc.addEncryptPart(unt, false);

// sSt the part specified by XPath expression (step: e)
   StringBuffer sb = new StringBuffer();
      sb.append("/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/'
         and local-name()='Envelope']");
      sb.append("/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/'
         and local-name()='Body']");
      sb.append("/*[namespace-uri()='http://xmlsoap.org/Ping'
         and local-name()='Ping']");
      sb.append("/*[namespace-uri()='http://xmlsoap.org/Ping'
         and local-name()='Text']");
   enc.addEncryptPartByXPath(sb.toString());

// Set whether the key is encrypted (step: f)
// DEFAULT: true
   enc.encryptKey(true);

// Set the data encryption method (step: g)
// DEFAULT: WSSEncryption.AES128
   enc.setEncryptionMethod(WSSEncryption.TRIPLE_DES);

// Set the key encryption method (step: h)
// DEFAULT: WSSEncryption.KW_RSA_OAEP
   enc.setEncryptionMethod(WSSEncryption.KW_RSA15);

// Set the token reference (step: i)
// DEFAULT: SecurityToken.REF_KEYID
```

```
  enc.setTokenReference(SecurityToken.REF_STR);

// Add the WSSEncryption to the WSSGenerationContext (step: j)
  gencont.add(enc);

// Process the WS-Security header (step: k)
gencont.process(msgcontext);
```

Note: The X509GenerationCallbackHandler does not need the key password because the public key is used for encryption. You do not need a password to obtain the public key from the Java keystore.

What to do next

If you have not previously specified which encryption methods to choose, use the WSS API or configure the policy sets using the administrative console to choose the data and key encryption algorithm methods.

Choosing encryption methods for generator bindings:

To configure the client for request encryption for the generator binding, you must specify which encryption methods to use when the client encrypts the SOAP messages.

Before you begin

Prior to completing these steps, read the XML encryption information to become familiar with encrypting and decrypting SOAP messages.

To specify which algorithm methods are to be used when the client encrypts the SOAP messages, complete the following tasks:

- Use the WSSEncryption API to configure the data encryption algorithm and the key encryption algorithm methods.
- Use the WSSEncryptPart API to configure a transform algorithm method, if needed. The default is no transform algorithm.

About this task

Some of the encryption-related definitions are based on the XML-Encryption specification. The following information defines some data encryption-related terms:

Data encryption method algorithm

Data encryption algorithms specify the algorithm uniform resource identifier (URI) of the data encryption method. This algorithm encrypts and decrypts data in fixed size, multiple octet blocks.

By default, the Java Cryptography Extension (JCE) is shipped with restricted or limited strength ciphers. To use 192-bit and 256-bit Advanced Encryption Standard (AES) encryption algorithms, you must apply unlimited jurisdiction policy files.

For the AES256-cbc and the AES192-cbc algorithms, you must download the unrestricted Java™ Cryptography Extension (JCE) policy files from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.

Key encryption method algorithm

Key encryption algorithms specify the algorithm uniform resource identifier (URI) of the method to encrypt the key that is used to encrypt data. The algorithm represents public key encryption algorithms that are specified for encrypting and decrypting keys.

By default, the RSA-OAEP algorithm uses the SHA1 message digest algorithm to compute a message digest as part of the encryption operation. Optionally, you can use the SHA256 or SHA512 message digest algorithm by specifying a key encryption algorithm property.

The property name is: com.ibm.wsspi.wssecurity.enc.rsaoaep.DigestMethod. The property value is one of the following URIs of the digest method:

- http://www.w3.org/2001/04/xmlenc#sha256
- http://www.w3.org/2001/04/xmlenc#sha512

By default, the RSA-OAEP algorithm uses a null string for the optional encoding octet string for the OAEPParams. You can provide an explicit encoding octet string by specifying a key encryption algorithm property. For the property name, you can specify `com.ibm.wsspi.wssecurity.enc.rsaoaep.OAEPparams`. The property value is the base 64-encoded value of the octet string.

Important: You can set these digest method and OAEPParams properties on the generator side only. On the consumer side, these properties are read from the incoming SOAP message.

For the KW-AES256 and the KW-AES192 key encryption algorithms, you must download the unrestricted JCE policy files from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.

Important: Your country of origin might have restrictions on the import, possession, use, or re-export to another country, of encryption software. Before downloading or using the unrestricted policy files, you must check the laws of your country, its regulations, and its policies concerning the import, possession, use, and re-export of encryption software, to determine if it is permitted.

Table 179. Encryption usage types. The encryption usage types describe encryptions methods.

Usage types	Description
Data encryption	Specifies the algorithm URI that is used for both encrypting and decrypting data. Encrypts and decrypts data in fixed size, multiple octet blocks.
Key encryption	Specifies the algorithm URI that is used for encrypting and decrypting the encryption key.

Data encryption

WebSphere Application Server supports the following pre-configured data encryption algorithms:

Table 180. Data encryption algorithms. These pre-configuring encryption algorithms are supported by WebSphere Application Server.

Data encryption name	Algorithm URI
WSSEncryption.AES128 (the default value)	A URI of data encryption algorithm, AES 128: http://www.w3.org/2001/04/xmlenc#aes128-cbc
WSSEncryption.AES192	A URI of data encryption algorithm, AES 192: http://www.w3.org/2001/04/xmlenc#aes192-cbc
WSSEncryption.AES256	A URI of data encryption algorithm, AES 256: http://www.w3.org/2001/04/xmlenc#aes256-cbc
WSSEncryption.TRIPLE_DES	A URI of data encryption algorithm, 3DES: http://www.w3.org.2001/04/xmlenc#tripledes-cbc

Key encryption

WebSphere Application Server supports the following pre-configured key encryption algorithms:

Table 181. Key encryption algorithms. These pre-configured encryption algorithms are supported by WebSphere Application Server.

Key encryption name	Algorithm URI
WSSEncryption.KW_AES128	A URI of key encryption algorithm, key wrap AES 128: http://www.w3.org/2001/04/xmlenc#kw-aes128
WSSEncryption.KW_AES192	A URI of key encryption algorithm, key wrap AES 192: http://www.w3.org/2001/04/xmlenc#kw-aes192 **Restriction:** Do not use the 192-bit key encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP).
WSSEncryption.KW_AES256	A URI of key encryption algorithm, key wrap AES 256: http://www.w3.org/2001/04/xmlenc#kw-aes256

Table 181. Key encryption algorithms (continued). These pre-configured encryption algorithms are supported by WebSphere Application Server.

Key encryption name	Algorithm URI
WSSEncryption.KW_RSA_OAEP (the default value)	A URI of key encryption algorithm, key wrap RSA OAEP: http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p
WSSEncryption.KW_RSA15	A URI of key encryption algorithm, key wrap RSA 1.5: http://www.w3.org/2001/04/xmlenc#rsa-1_5
WSSEncryption.KW_TRIPLE_DES	http://www.w3.org/2001/04/xmlenc#kw-tripledes

To configure the encryption and encrypted part algorithm methods, use the WSSEncryption API, or configure policy sets using the administrative console.

Note: Policy sets do not support symmetric key encryption. If you are using the WSS API for symmetric key encryption, you will not be able to interoperate with web services endpoints that use policy sets.

The WSS API process completes the following high-level steps to specify which encryption methods to use when configuring the client for request encryption:

Procedure

1. Using the WSSEncryption API, adds the required data encryption algorithm. The data encryption algorithm is used for encrypting or decrypting parts of a SOAP message. Data encryption algorithms specify the algorithm uniform resource identifier (URI) of the data encryption method.

   The client generator configuration must match the configuration for the provider consumer.

   The default data encryption algorithm is AES 128. The data encryption name is AES128, and the URI of the data encryption algorithm, is http://www.w3.org/2001/04/xmlenc#aes128-cbc. WebSphere Application Server supports the following pre-configured data encryption algorithms:

   - AES 128: http://www.w3.org/2001/04/xmlenc#aes128-cbc

     The AES 128 algorithm is the default data algorithm method.
   - AES 192: http://www.w3.org/2001/04/xmlenc#aes192-cbc

     Do not use the 192-bit key encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP).

     To use this AES 192-cbc algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.
   - AES 256: http://www.w3.org/2001/04/xmlenc#aes256-cbc

     To use this AES 256-cbc algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.
   - TRIPLEDES: http://www.w3.org/2001/04/xmlenc#tripledes-cbc
2. As needed, changes the WSSEncryption API method to specify another data encryption algorithm. For example, you might add the following code to change from the default AES 128 algorithm to the Triple DES algorithm:

```
// Default data encryption algorithm: AES128
WSSEncryption enc = factory.newWSSEncryption(x509t);
   enc.setEncryptionMethod(EncryptionMethod.TRIPLEDES_CBC);
gencont.add(enc);
```

3. Using the WSSEncryption API, adds the required key encryption algorithm. The key encryption algorithm is used for encrypting the key that is used for encrypting the message parts within the SOAP message. If the encryption key, which is the key that is used for encrypting the message parts, is not encrypted, then the decryption API selects `false` to match the encryption key.

   The client generator configuration must match the configuration for the provider consumer.

The default key encryption algorithm value is key wrap RSA OAP. The key encryption name is KW_RSA_OAEP, and the URI of the key encryption algorithm is http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p. WebSphere Application Server supports the following pre-configured key encryption algorithms:

- KW AES128: http://www.w3.org/2001/04/xmlenc#kw-aes128
- KW AES192: http://www.w3.org/2001/04/xmlenc#kw-aes192

  To use this key wrap AES 192 algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.

  Do not use the 192-bit key encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP).KW AES 256: http://www.w3.org/2001/04/xmlenc#kw-aes256

  To use this key wrap AES 256-cbc algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.
- KW RSA OAEP: http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p.

  The KW RSA OAEP algorithm is the default key algorithm method.

  When running with Software Development Kit (SDK) Version 1.4, the list of supported key transport algorithms does not include this algorithm. This algorithm appears in the list of supported key transport algorithms when running with SDK Version 1.5. See more information at http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p
- KW RSA15: http://www.w3.org/2001/04/xmlenc#rsa-1_5
- KW TRIPLE DES: http://www.w3.org/2001/04/xmlenc#kw-tripledes

Note: For Web Services Secure Conversation, the WSSEncryption API might specify addition key-related information, such as the:
- algorithmName
- keyLength

Results

If there is an error condition, a WSSException is provided. If successful, the API calls the WSSGenerationContext.process(), the WS-Security header is generated, and the SOAP message is now secured using Web Services Security.

Example

The following example provides sample WSS API code using WSSEncryption.setEncryptionMethod() and WSSEncryption.setKeyEncryptionMethod().

```
// Get the message context
   Object msgcontext = getMessageContext();

// Generate the WSSFactory instance
   WSSFactory factory = WSSFactory.getInstance();

// Generate the WSSGenerationContext instance
   WSSGenerationContext gencont = factory.newWSSGenerationContext();

// Generate callback handler
   X509GenerateCallbackHandler callbackHandler = new
       X509GenerateCallbackHandler(
                                   "",
                                   "enc-sender.jceks",
                                   "jceks",
                                   "storepass".toCharArray(),
                                   "bob",
                                   null,
                                   "CN=Bob, O=IBM, C=US",
                                   null);

// Generate the security token used for encryption
   SecurityToken token = factory.newSecurityToken(X509Token.class , callbackHandler);
```

```
// Generate WSSEncryption instance
   WSSEncryption enc = factory.newWSSEncryption(token);

// Set the data encryption method
// DEFAULT: WSSEncryption.AES128
      enc.setEncryptionMethod(WSSEncryption.TRIPLE_DES);

// Set the key encryption method
// DEFAULT: WSSEncryption.KW_RSA_OAEP
      enc.setEncryptionMethod(WSSEncryption.KW_RSA15);

// Add the WSSEncryption to the WSSGenerationContext
   gencont.add(enc);

// Generate the WS-Security header
gencont.process(msgcontext);
```

What to do next

Next, if you want to add a transform algorithm, review the WSSEncryptPart API process task.

Encryption methods:

For request generator binding settings, the encryption methods include specifying the data and key encryption algorithms to use to encrypt the SOAP message. The WSS API for encryption (WSSEncryption) specifies the algorithm name and the matching algorithm uniform resource identifier (URI) for the data and key encryption methods. If the data and key encryption algorithms are specified, only elements that are encrypted with those algorithms are accepted.

Data encryption algorithms

The data encryption algorithm is used to encrypt parts of the SOAP message, including the body and the signature. Data encryption algorithms specify the algorithm uniform resource identifier (URI) for each type of data encryption algorithms.

The following pre-configured data encryption algorithms are supported:

Table 182. Data encryption algorithms. The algorithms are used to encrypt SOAP messages.

Data encryption algorithm name	Algorithm URI
WSSEncryption.AES128 (the default value)	A URI of data encryption algorithm, AES 128: http://www.w3.org/2001/04/xmlenc#aes128-cbc
WSSEncryption.AES192	A URI of data encryption algorithm, AES 192: http://www.w3.org/2001/04/xmlenc#aes192-cbc
WSSEncryption.AES256	A URI of data encryption algorithm, AES 256: http://www.w3.org/2001/04/xmlenc#aes256-cbc
WSSEncryption.TRIPLE_DES	A URI of data encryption algorithm, TRIPLE DES: http://www.w3.org/2001/04/xmlenc#tripledes-cbc

By default, the Java Cryptography Extension (JCE) is shipped with restricted or limited strength ciphers. To use 192-bit and 256-bit Advanced Encryption Standard (AES) encryption algorithms, you must apply unlimited jurisdiction policy files.

Important: Your country of origin might have restrictions on the import, possession, use, or re-export to another country, of encryption software. Before downloading or using the unrestricted policy files, you must check the laws of your country, its regulations, and its policies concerning the import, possession, use, and re-export of encryption software, to determine if it is permitted.

For the AES256-cbc and the AES192-CBC algorithms, you must download the unrestricted Java™ Cryptography Extension (JCE) policy files from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.

The data encryption algorithm configured for encryption for the generator side must match the data encryption algorithm that is configured for decryption for the consumer side.

Key encryption algorithms

This algorithm is used to encrypt and decrypt keys. This key information is used to specify the configuration that is needed to generate the key for digital signature and encryption. The signing information and encryption information configurations can share the key information. The key information on the consumer side is used for specifying the information about the key that is used for validating the digital signature in the received message or for decrypting the encrypted parts of the message. The request generator is configured for the client.

Note: Policy sets do not support symmetric key encryption. If you are using the WSS API for symmetric key encryption, you will not be able to interoperate with web services endpoints using the policy sets.

Key encryption algorithms specify the algorithm uniform resource identifier (URI) of the key encryption method. The following pre-configured key encryption algorithms are supported:

Table 183. Supported pre-configured key encryption algorithms. The algorithms are used to encrypt and decrypt keys.

WSS API	URI
WSSEncryption.KW_AES128	A URI of key encryption algorithm, key wrap AES 128: http://www.w3.org/2001/04/xmlenc#kw-aes128
WSSEncryption.KW_AES192	A URI of key encryption algorithm, key wrap AES 192: http://www.w3.org/2001/04/xmlenc#kw-aes192 **Restriction:** Do not use the 192-bit key encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP).
WSSEncryption.KW_AES256	A URI of key encryption algorithm, key wrap AES 256: http://www.w3.org/2001/04/xmlenc#kw-aes256
WSSEncryption.KW_RSA_OAEP (the default value)	A URI of key encryption algorithm, key wrap RSA OAEP: http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p
WSSEncryption.KW_RSA15	A URI of key encryption algorithm, key wrap RSA 1.5: http://www.w3.org/2001/04/xmlenc#rsa-1_5
WSSEncryption.KW_TRIPLE_DES	A URI of key encryption algorithm, key wrap TRIPLE DES: http://www.w3.org/2001/04/xmlenc#kw-tripledes

For Secure Conversation, additional key-related information must be specified, such as:

- algorithmName
- keyLength

By default, the RSA-OAEP algorithm uses the SHA1 message digest algorithm to compute a message digest as part of the encryption operation. Optionally, you can use the SHA256 or SHA512 message digest algorithm by specifying a key encryption algorithm property. The property name is: `com.ibm.wsspi.wssecurity.enc.rsaoaep.DigestMethod`. The property value is one of the following URIs of the digest method:

- http://www.w3.org/2001/04/xmlenc#sha256
- http://www.w3.org/2001/04/xmlenc#sha512

By default, the RSA-OAEP algorithm uses a null string for the optional encoding octet string for the OAEPParams. You can provide an explicit encoding octet string by specifying a key encryption algorithm property. For the property name, you can specify `com.ibm.wsspi.wssecurity.enc.rsaoaep.OAEPparams`. The property value is the base 64-encoded value of the octet string.

Important: You can set these digest method and OAEPParams properties on the generator side only. On the consumer side, these properties are read from the incoming SOAP message.

For the KW-AES256 and the KW-AES192 key encryption algorithms, you must download the unrestricted JCE policy files from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.

The key encryption algorithm for the generator must match the key decryption algorithm that is configured for the consumer.

This example provides sample code for encryption to use the Triple DES for the data encryption method and to use RSA1.5 for the key encryption method:

```
// get the message context
Object msgcontext = getMessageContext();

// generate WSSFactory instance
WSSFactory factory = WSSFactory.getInstance();

// generate WSSGenerationContext instance
WSSGenerationContext gencont = factory.newWSSGenerationContext();

// generate callback handler
X509GenerateCallbackHandler callbackHandler = new X509GenerateCallbackHandler(
  "",
  "enc-sender.jceks",
  "jceks",
  "storepass".toCharArray(),
  "bob",
  null,
  "CN=Bob, O=IBM, C=US",
  null);

// generate the security token used to the encryption
SecurityToken token = factory.newSecurityToken(X509Token.class,
     callbackHandler);

// generate WSSEncryption instance to encrypt the SOAP body content
WSSEncryption enc = factory.newWSSEncryption(token);
enc.addEncryptPart(WSSEncryption.BODY_CONTENT);

// set the data encryption method
// DEFAULT: WSSEncryption.AES128
enc.setEncryptionMethod(WSSEncryption.TRIPLE_DES);

// set the key encryption method
// DEFAULT: WSSEncryption.KW_RSA_OAEP
enc.setEncryptionMethod(WSSEncryption.KW_RSA15);

// add the WSSEncryption to the WSSGenerationContext
gencont.add(enc);

// generate the WS-Security header
gencont.process(msgcontext);
```

Adding encrypted parts using the WSSEncryptPart API:

You can secure the SOAP messages, without using policy sets for configuration, by using the Web Services Security APIs (WSS API). To configure encrypted parts for the request generator (client side) bindings, use the WSSEncryptPart API to define and add to the listing of elements in the encrypted part. WSSEncryptPart is an interface that is part of the com.ibm.websphere.wssecurity.wssapi.encryption package.

Before you begin

You can use the WSS APIs or configure policy sets using the administrative console to enable the encrypted parts. To secure SOAP messages, use the WSS APIs to complete the following encryption tasks, as needed:

- Configure encryption and choose the encryption methods using the WSSEncryption API.
- Configure the encrypted parts using the WSSEncryptpart API, as needed.

About this task

Confidentiality settings require that confidentiality constraints be applied to generated messages. These constraints include specifying which message parts within the generated message must be encrypted, and

which message parts to attach encrypted elements to. The encryption information on the generator side is used for encrypting an outgoing SOAP message. The request generator is configured for the client.

The WSSEncryptPart API specifies information related to encrypted parts and sets the encrypted parts that have been added for message confidentiality protection. Use the WSSEncryptPart to set the transform method and to specify the part to which the transform method is to be applied. Sets the transform method only if using SOAP with Attachments. The WSSEncryptPart is usually not needed except, in some case for tasks such as setting the transform method.

The encrypted parts and related information displayed in the following table are used to protect the confidentiality of messages.

Table 184. Encrypted parts. Use encrypted parts to secure messages.

Encrypted parts	Description
part	Adds the WSSEncryptPart object as a target of the encryption part.
keyword	Adds the encrypted parts using keywords. The default encryption parts that you can add using keywords are the BODY_CONTENT and SIGNATURE. WebSphere Application Server supports using these keywords: • BODY_CONTENT • SIGNATURE
xpath	Adds the encrypted part by using an XPath expression.
signature	Adds the WSSSignature component as a target of the encrypted part. WSSSignature is applicable only if the SOAP message contains a signature element.
header	Adds the SOAP header, specified by QName, as a target of the encrypted part.
securityToken	Adds the SecurityToken object as a target of the encrypted part.

For encrypted parts, certain default behaviors occur. The simplest way to use the WSSEncryptPart API is to use the default behavior. The WSSEncryptPart API provides defaults for specifying the transform algorithm, setting objects as targets, specifying the encrypted parts, such as: the SOAP body content and the signature.

The encryption default behaviors include:

Table 185. Encrypted part decisions. Several encrypted message parts are set by default.

Encrypted part decisions	Default behavior
Which SOAP message parts to encrypt using keywords	Specifies which keywords to use for the encrypted parts. WebSphere Application Server sets the following SOAP message parts by default for encryption: • WSSEncryption.BODY_CONTENT • WSSEncryption.SIGNATURE
Which transform method to add	WebSphere Application Server does not specify any transform method by default. Specify a transform method only if using SOAP with Attachments.

Procedure

1. To encrypt the SOAP message parts using the WSSEncryptPart API, first ensure that the application server is installed.
2. The WSS API process using WSSEncryptPart follows these process steps:
   a. Uses WSSFactory.getInstance() to get the WSS API implementation instance.
   b. Creates the WSSGenerationContext instance from the WSSFactory instance.
   c. Creates the SecurityToken from WSSFactory to configure the encryption.
   d. Creates WSSEncryption from the WSSFactory instance using SecurityToken.
   e. Creates WSSEncryptPart from WSSFactory.
   f. Adds the parts to be encrypted and to be applied with the transform in WSSEncryptPart. WebSphere Application Server sets these encrypted parts by default for WSSEncryptPart: the BODY_CONTENT and SIGNATURE. After you add other encrypted parts, the default values are no

longer valid. For example, if you call addEncryptPart(securityToken, false), only the security token is encrypted, and not the signature and body content. So if you want to encrypt the security token, the signature, and the body content, you must call addEncryptPart(securityToken, false), addEncryptPart(WSSEncryption.SIGNATURE), and addEncryptPart(WSSEncrypyion.BODY_CONTENT).

g. Sets the transform method.
h. Adds WSSEncryptPart to WSSEncryption.
i. Adds WSSEncryption to WSSGenerationContext.
j. Calls WSSGenerationContext.process() with the SOAPMessageContext.

Results

If there is an error condition during encryption of the message parts, a WSSException is provided. If successful, the API calls the WSSGenerationContext.process(), the WS-Security header is generated, and the SOAP message is now secured using Web Services Security.

What to do next

After enabling encrypted parts for the request generator (client side) binding, you must specify the same parts to be decrypted for the response consumer (client side) bindings. Next, to configure decryption and decrypted parts, use the WSS APIs or configure policy sets using the administrative console.

Configuring generator signing information to protect message integrity using the WSS APIs:

You can configure the signing information to protect message integrity for the request (client side) generator binding. Signing information includes the signature and the signed parts. To keep the integrity of the message, digital signatures are typically applied.

Before you begin

In addition to using a digital signature and configuring the signing information, the following tasks should also be performed:

- Verify the signing information.
- Incorporate encryption.
- Attach security tokens.

About this task

Integrity refers to digital signature while confidentiality refers to encryption. Integrity is provided by applying a digital signature to a SOAP message. To configure the signing information to protect message integrity, you must first digitally sign and then verify the signature for the SOAP messages. Integrity decreases the risk of data modification when you transmit data across a network.

Also, message integrity is provided by digitally signing the body, time stamp, and WS-Addressing headers using the signature algorithm methods. The WSS APIs specify which algorithm is to be used to sign the certificate. The signature algorithms specify the Uniform Resource Identifiers (URI) of the signature method. WebSphere Application Server supports several pre-configured request signing algorithm methods.

You can use the following interfaces to configure Web Services Security and to protect SOAP message integrity:

- Use the administrative console to configure policy sets for the signing information.
- Use the Web Services Security APIs (WSS API) to configure the SOAP message context (only for the client).

Perform the following signing tasks, using the WSS APIs, to configure the signing information and to protect message integrity for the generator binding.

Procedure

- Configure the signing information using the WSSSignature API. Configure the signing information for the generator binding using the WSSSignature API. Signing information is used to sign parts of a message including the SOAP body, the time stamp, and the WS-Addressing headers. Both signing and encryption can be applied to the same message parts, such as the SOAP body.
- Add or change signed parts using the WSSSignPart API.
- Configure the client for request signing methods using the WSSSignature or WSSSignPart APIs. To configure the client for request signing, choose the signing methods. The request signing methods include the signature, the canonicalization, the digest, and the transform methods. Use the WSSSignature API to configure the signature and canonicalization methods. Use the WSSSignPart API to configure the digest and transform methods.

Results

The WSS APIs also specify the security token for the generator (client) binding and set the type of token reference to protect message authenticity. By completing the steps in these tasks, you have configured generator signing to protect the integrity of the SOAP message.

What to do next

Next, verify the consumer signing information by using the WSS APIs or by configuring policy sets using the administrative console.

Configuring signing information using the WSS APIs:

You can configure the signing information for the client-side request generator (sender) bindings. Signing information is used to sign and validate parts of a message including the SOAP body, the timestamp information, and the Username token. To configure the client for request signing, specify which message parts to digitally sign when configuring the client.

Before you begin

WebSphere Application Server uses XML digital signature with existing algorithms such as RSA, HMAC, and SHA1. XML signature defines many methods for describing key information and enables the definition of a new method. Prior to completing these steps, familiarize yourself with XML digital signature for signing and verifying digital signatures for digital content.

About this task

By including XML signature in SOAP messages, the following issues are realized: message integrity and authentication. *Integrity* refers to digital signature whereas confidentiality refers to encryption. Integrity decreases the risk of data modification while the data is transmitted across the Internet. WebSphere Application Server uses the signing information for the default generator to sign parts of the message, such as the body, time stamp, and Username token.

For the signing information, you must specify the following:

- Which parts of the message are to be signed.
- The key information that is referenced by the key information for the signing keys.
- The signing algorithms.

WebSphere Application Server provides default values for bindings. However, an administrator must modify the defaults for a production environment.

The WSSSignature API configures the following parts as signature parts:

Table 186. Pre-configured signature parts. Use the signing information to validate parts of a message.

Part	Description
Security token object	This object authenticates the client. If this option is specified, then the message is signed. You can digitally sign the message using a security token if a login configuration authentication method is selected.
WSSTimestamp object	This object adds a time stamp to a message. The time stamp determines if the message is valid based on the time that the message is sent and then received.
WSSSignature Part object	This object adds the signature parts to a message.
SOAP header and the QName as a target	This signature part adds the header, specified by QName, as a verification part.

The WSS APIs allow the use of keywords or an XPath expression to specify which parts of the message are to be signed. WebSphere Application Server supports the use of the following keywords:

Table 187. Supported signature keywords. Key information is used to specify which parts of a message are signed.

Keyword	References
ADDRESSING_HEADERS	The Web Services Addressing (WS-Addressing) headers.
BODY	The SOAP message body. The body is the user data portion of the message.
TIMESTAMP	The creation and expiration timestamp information.

The Web Services Security API (WSS API) are used to configure the signing information for the request generator (client side) section of the bindings file. To configure the signing information on the client side, use the WSS APIs or configure policy sets for signing using the administrative console.

If configuring using the WSS APIs, the WSSSignature and WSSSignPart APIs complete the following steps to specify which message parts to digitally sign when configuring the client for request generator signing:

Procedure

1. The WSSSignature API adds the required parts of the SOAP message to digitally sign. Either a keyword or an XPath expression can be used to specify the required encryption parts.
2. The WSSSignature API sets the signature method algorithm. The default signature method is RSA_SHA1. WebSphere Application Server supports the following pre-configured algorithms:
   - RSA SHA1: http://www.w3.org/2000/09/xmldsig#rsa-sha1
   - HMAC SHA1http://www.w3.org/2000/09/xmldsig#hmac-sha1

   WebSphere Application Server does not support the following algorithm for DSA-SHA1: http://www.w3.org/2000/09/xmldsig#dsa-sha1. You cannot use the DSA-SHA1 algorithm if you want to be compliant with the Basic Security Profile (BSP).

   Any ds:SignatureMethod/@Algorithm element in a signature is based on a symmetric key and must have a value of RSA-SHA1 or HMAC-SHA1.

   The algorithm that is specified for the request generator configuration must match the algorithm that is specified for the request consumer configuration.
3. The WSSSignature API sets the canonicalization method. The default signature method is EXC_C14N. WebSphere Application Server supports the following pre-configured algorithms:
   - The URI of the exclusive canonicalization algorithm, EXC_C14N: http://www.w3.org/2001/10/xml-exc-c14n#.
   - The URI of the inclusive canonicalization algorithm, C14N: http://www.w3.org/2001/10/xml-c14n#.

   The canonicalization algorithm that you specify for the generator must match the algorithm for the consumer.
4. The WSSSignature API adds a security token. The API adds information about the security token that is to be used for the signature, such as:
   - The class for security token.

- The callback handler
- The name of the JAAS login configuration.

5. The WSSSignature API sets the type of security token and sets the type of token reference. WebSphere Application Server supports the following pre-configured token references:
   - SecurityToken.REF_STR

     Represents the security token reference as a token reference type.
   - SecurityToken.REF_KEYID

     Represents the key identifier reference as a token reference type.
   - SecurityToken.REF_EMBEDDED

     Represents the embedded reference as a token reference type.
   - SecurityToken.REF_THUMBPRINT

     Represents the thumbprint reference as a token reference type.
6. If SecurityToken.REF_KEYID is set as the type of token reference, the WSSSignature API sets the key information signature type and configures the key information that is referenced by the key information references. WebSphere Application Server supports the following:
   - Specifying that the KeyInfo element is not signed.
   - Specifying that the entire <KeyInfo> element is signed.
   - Specifying that the child elements <Keyinfochildelements> of the <KeyInfo> element are signed.

   If you do not specify one of the previous signature types, WebSphere Application Server specifies that the entire <KeyInfo> element is signed, by default.

   If you select Keyinfo or Keyinfochildelements and you select http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform as the transform algorithm in a subsequent step, WebSphere Application Server also signs the referenced token.

   The key information signature type for the generator must match the signature type for the consumer.
7. The WSSSignature API specifies whether to require signature confirmation. The OASIS Web Services Security (WS-Security) Version 1.1 specification defines the use of signature confirmation. If you are using WS-Security Version 1.0, this function is not available.

   The signature confirmation value is stored in order to validate the signature confirmation with it after the receiving message is returned. This method is called if the response message is expected to attach the signature confirmation into the SOAP message.
8. The WSSSignPart API specifies the part reference. The part reference specifies which parts of the message to digitally sign.

   The part reference refers to the message part that is digitally signed. The part attribute refers to the name of the <Integrity> element when the <PartReference> element is specified for the signature. You can specify multiple <PartReference> elements within the <SigningInfo> element. The <PartReference> element has two child elements when it is specified for the signature verification: <DigestTransform> and <Transform>.
9. The WSSSignPart API specifies the digest method algorithm. The digest method algorithm specified within the <DigestMethod> element is used in the <SigningInfo> element.

   WebSphere Application Server supports the following pre-configured digest algorithms:
   - http://www.w3.org/2000/09/xmldsig#sha1
   - http://www.w3.org/2001/04/xmlenc#sha256
   - http://www.w3.org/2001/04/xmlenc#sha512
10. The WSSSignPart API specifies the transform algorithm. The transform algorithm is that is specified within the <Transform> element and specifies the transform algorithm for the signature. WebSphere Application Server supports the following pre-configured transform algorithms:
    - http://www.w3.org/2001/10/xml-exc-c14n#
    - http://www.w3.org/TR/1999/REC-xpath-19991116

Do not use this transform algorithm if you want to be compliant with the Basic Security Profile (BSP). Instead use http://www.w3.org/2002/06/xmldsig-filter2 to ensure compliance.

- http://www.w3.org/2002/06/xmldsig-filter2
- http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform
- http://www.w3.org/2002/07/decrypt#XML
- http://www.w3.org/2000/09/xmldsig#enveloped-signature

The transform algorithm that you select for the generator must match the transform algorithm that you select for the consumer.

Important: If both of the following conditions are true, WebSphere Application Server signs the referenced token:

- You previously selected the Keyinfo or the Keyinfochildelements option
- You select http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform as the transform algorithm.

11. If you configure the client and server signing information correctly, but receive a `Soap body not signed` error when running the client, you might need to configure the actor. Configure policy sets using the administrative console to configure the same actor strings for the web service on the server, which processes the request and sends the response back.

    The actor information on both the client and server must refer to the same exact string. When the actor fields on the client and server match, the request or response is acted upon instead of being forwarded downstream. The actor might be different when you have web services acting as a gateway to other web services. However, in all other cases, make sure that the actor information matches on the client and server. When web services are acting as a gateway and they do not have the same actor configured as the request passing through the gateway, web services do not process the message from a client. Instead, these web services send the request downstream. The downstream process that contains the correct actor string processes the request. The same situation occurs for the response. Therefore, it is important that you verify that the appropriate client and server actor fields are synchronized.

Results

After the WSSSignature and WSSSignPart APIs complete these steps, the signing information is configured for the generator sections of the bindings files.

Example

The following example shows WSS API sample code to configure the signature, to generate the callback handler, and to specify the X.509 token type as the security token:

```
WSSFactory factory = WSSFactory.getInstance();
// Instantiate a generation context
WSSGenerationContext gencont = factory.newWSSGenerationContext();

// Generate the callback handler and specify the X.509 token
   X509GenerateCallbackHandler callbackhandler = generateCallbackHandler();
   SecurityToken token = factory.newSecurityToken(X509Token.class,
                                                  callbackHandler);

// Set the signature information
WSSSignature sig = factory.newWSSSignature(token);
// Add the header using QName
   sig.addSignHeader(new QName("http://www.w3.org/2005/08/addressing", "To"));
   sig.addSignHeader(new QName("http://www.w3.org/2005/08/addressing", "MessageID"));
   sig.addSignHeader(new QName("http://www.w3.org/2005/08/addressing", "Action"));
// Apply the signature
   gencont.add(sig);

// Secure the message
gencont.process(msgctx);
```

What to do next

You must configure similar signature information for the client-side request consumer (receiver) bindings by completing the following verification tasks:

- Verify the signature
- Choose the signature algorithm methods.
- Change or add signed parts, as needed.

If signature verification is already configured, configure the encryption and decryption information, or configure the consumer and generator tokens.

Configuring signing information using the WSSSignature API:

You can secure the SOAP messages, without using policy sets for configuration, by using the Web Services Security APIs (WSS API). To configure the signing information for the generator binding sections for the client-side request, use the WSSSignature API. The WSSSignature API is part of the com.ibm.websphere.wssecurity.wssapi.signature package.

Before you begin

Either you can use the WSS API or you can configure the policy sets by using the administrative console to enable the signing information. To secure SOAP messages, you must complete the following signing tasks:

- Configure the signing information.
- Choose the signing methods.
- Add or change signed parts, as needed.

About this task

WebSphere Application Server uses the signing information for the default generator to sign parts of the message, and uses XML digital signature with existing algorithms such as RSA-SHA1 and HMAC-SHA1.

XML signature defines many methods for describing key information and enables the definition of a new method. XML canonicalization (C14N) is often needed when you use XML signature. Information can be represented in various ways within serialized XML documents. The C14N process is used to canonicalize XML information. Select an appropriate C14N algorithm because the information that is canonicalized depends on this algorithm.

The signing information specifies the integrity constraints that are applied to generated messages. The constraints include specifying which message parts within the generated message must be digitally signed, and the message parts to attach digitally signed Nonce and timestamp elements to. The following signature and related signature part information are configured:

Table 188. Signature parts information. Use the signature parts to secure messages.

signature parts	Description
keyword	Adds a signature part using keywords. Use the following keywords for the signature parts: • ADDRESSING_HEADERS • BODY • TIMESTAMP The WS-Addressing headers are not encrypted but can be signed.
xpath	Adds a signature part by using an XPath expression.
part	Adds a WSSSignPart object as a target of the signature part.
timestamp	Adds a WSSTimestamp object as a target of the signature part. When specified, the timestamp information also specifies when the message is generated and when it expires.

Table 188. Signature parts information (continued). Use the signature parts to secure messages.

signature parts	Description
header	Adds the header, specified by QName, as a target of the signature part.
securityToken	Adds a SecurityToken object as a target of the signature part.

For signing information, certain default behaviors occur. The simplest way to use the WSSSignature API is to use the default behavior (see the example code). The default values are defined by the WSS API for the signing method, the canonicalization method, the security token references, and the signature parts.

Table 189. Signature default behaviors. Several signature behaviors are configured by default.

Signature decisions	Default behavior
Which keywords to use	Sets the keywords. WebSphere Application Server supports the following keywords by default: • ADDRESSING_HEADERS • BODY • TIMESTAMP
Which signature method to use	Sets the signature algorithm. The default signature method is RSA SHA1. WebSphere Application Server supports the following pre-configured signature methods: • WSSSignature.RSA_SHA1: http://www.w3.org/2000/09/xmldsig#rsa-sha1 • WSSSignature.HMAC_SHA1: http://www.w3.org/2000/09/xmldsig#hmac-sha1 The DSA-SHA1 digital signature method (http://www.w3.org/2000/09/xmldsig#dsa-sha1) is not supported.
Which canonicalization method to use	Sets the canonicalization algorithm. The default canonicalization method is EXC C14N. WebSphere Application Server supports the following pre-configured canonicalization methods: • WSSSignature.EXC_C14N; http://www.w3.org/2001/10/xml-exc-c14n# • WSSSignature.C14N: http://www.w3.org/2001/10/xml-c14n#
Whether signature confirmation is required	Sets whether to require signature confirmation. The default value is **false**. Signature confirmation is defined in the OASIS Web Services Security Version 1.1 specification. If required, the value of your signature confirmation is stored in order to use it to validate the signature confirmation after receiving back the message that generated the signature confirmation in the response message. This method is for the requestor side.
Which security token to use	Sets the SecurityToken. The token type specifies which type of token to use for signing and validating messages. The X.509 token is the default token type. WebSphere Application Server provides the following pre-configured consumer token types: • Derived Key Token • X509 tokens You can also create custom token types, as needed.
Which token reference to set	Sets the refType. SecurityToken.REF_STR is the default value for the type of token reference. WebSphere Application Server supports these pre-configured token references types: • SecurityToken.REF_STR • SecurityToken.REF_KEYID • SecurityToken.REF_EMBEDDED • SecurityToken.REF_THUMBPRINT

If WSSSignature.requireSignatureConfirmation() is called, then the WSSSignature API expects that the response message will include the signature confirmation.

Procedure

1. To configure the signing information in a SOAP message by using the WSS API, first ensure that the application server is installed.
2. Use the WSSSignature API to sign the message parts and specify the algorithms in a SOAP message. The WSS API process for signature follows these process steps:
   a. Uses WSSFactory.getInstance() to get the WSS API implementation instance.
   b. Creates the WSSGenerationContext instance from the WSSFactory instance. WSSGenerationContext must be called in a JAX-WS client application.
   c. Creates the SecurityToken from WSSFactory to configure the key for signing.

d. Creates WSSSignature from the WSSFactory instance using the SecurityToken. The default behavior of WSSSignature is to sign these signature parts: BODY, ADDRESSING_HEADERS, and TIMESTAMP.
e. Adds the part to be signed, if the default part is not appropriate. If the digest method or transform method is changed, creates WSSSignPart and add it to WSSSignature.
f. Creates WSSSignaturePart to WSSSignature. Calls the requiredSignatureConfirmation() method, if the signature confirmation is to be applied.
g. Sets the canonicalization method, if the default is not appropriate.
h. Sets the signature method, if the default is not appropriate.
i. Sets the token reference, if the default is not appropriate.
j. Adds WSSSignature to WSSGenerationContext.
k. Calls WSSGenerationContext.process() with the SOAPMessageContext.

Results

You have completed the steps to configure the signature for the generator section of the bindings. If there is an error condition when signing the message parts, a WSSException is provided. If successful, the WSSGenerationContext.process() is called, and Web Services Security is applied to the SOAP message.

Example

The following example provides sample code that uses methods that are defined in the WSSignature API.

```
// Get the message context
   Object msgcontext = getMessageContext();

// Generate the com.ibm.websphere.wssecurity.wssapi.WSSFactory instance  (step: a)
   WSSFactory factory = com.ibm.websphere.wssecurity.wssapi.WSSFactory.getInstance();

// Generate the WSSGenerationContext instance  (step: b)
   WSSGenerationContext gencont = factory.newWSSGenerationContext();

// Generate the callback handler
   X509GenerateCallbackHandler callbackHandler = new
       X509GenerateCallbackHandler(
       "",
       "dsig-sender.ks",
       "jks",
       "client".toCharArray(),
       "soaprequester",
       "client".toCharArray(),
       "CN=SOAPRequester, OU=TRL, O=IBM, ST=Kanagawa, C=JP", null);

// Generate the security token to be used for the signature  (step: c)
   SecurityToken token = factory.newSecurityToken(X509Token.class,
        callbackHandler);

// Generate the WSSSignature instance (step: d)
   WSSSignature sig = factory.newWSSSignature(token);

// Set the part to be signed  (step: e)
// DEFAULT: WSSSignature.BODY, WSSSignature.ADDRESSING_HEADERS,
//          and WSSSignature.TIMESTAMP.

// Set the part in the SOAP Header specified by QName  (step: e)
      sig.addSignHeader(new
                        QName("http://www.w3.org/2005/08/addressing",
                        "MessageID"));

// Set the part specified by the keyword  (step: e)
      sig.addSignPart(WSSSignature.BODY);

// Set the part specified by SecurityToken  (step: e)
   UNTGenerateCallbackHandler untCallbackHandler = new
      UNTGenerateCallbackHandler("Chris", "sirhC");
      SecurityToken unt = factory.newSecurityToken(UsernameToken.class,
         untCallbackHandler);
      sig.addSignPart(unt);

// Set the part specified by WSSSignPart  (step: e)
   WSSSignPart sigPart = factory.newWSSSignPart();
      sigPart.setSignPart(WSSSignature.TIMESTAMP);
      sigPart.setDigestMethod(WSSSignPart.SHA256);
      sig.addSignPart(sigPart);
```

```
// Set the part specified by WSSTimestamp  (step: e)
   WSSTimestamp timestamp = factory.newWSSTimestamp();
      sig.addSignPart(timestamp);

// Set the part specified by XPath expression  (step: e)
   StringBuffer sb = new StringBuffer();
      sb.append("/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/'
         and local-name()='Envelope']");
      sb.append("/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/'
         and local-name()='Body']");
      sb.append("/*[namespace-uri()='http://xmlsoap.org/Ping'
         and local-name()='Ping']");
      sb.append("/*[namespace-uri()='http://xmlsoap.org/Ping'
         and local-name()='Text']");
      sig.addSignPartByXPath(sb.toString());

// Set to apply the signature confirmation  (step: f)
      sig.requireSignatureConfirmation();

// Set the canonicalization method  (step: g)
// DEFAULT: WSSSignature.EXC_C14N
      sig.setCanonicalizationMethod(WSSSignature.C14N);

// Set the signature method  (step: h)
// DEFAULT: WSSSignature.RSA_SHA1
      sig.setSignatureMethod(WSSSignature.HMAC_SHA1);

// Set the token reference  (step: i)
// DEFAULT: SecurityToken.REF_STR
      sig.setTokenReference(SecurityToken.REF_KEYID);

// Add the WSSSignature to WSSGenerationContext  (step: j)
   gencont.add(sig);

// Generate the WS-Security header  (step: k)
gencont.process(msgctx);
```

Note: The X509GenerationCallbackHandler needs the key password because the private key is used for signing.

What to do next

Next, chose the algorithm methods if you want a method that is different from the default values. If the algorithm methods do not need to be changed, next use the WSSVerification API to verify the signature and specify the algorithm methods in the consumer section of the binding. Note that the WSSVerification API is only supported on the response consumer (client side).

Adding signed parts using the WSSSignPart API:

You can secure the SOAP messages, without using policy sets for configuration, by using the Web Services Security APIs (WSS API). To configure parts to be signed for the request generator (client side) bindings, use the WSSSignPart API to protect the integrity of messages and to configure the digest and transform algorithm methods. The WSSSignPart API is part of the com.ibm.websphere.wssecurity.wssapi.signature package.

Before you begin

Either you can use the WSS API or you can configure the policy sets by using the administrative console to configure the signing information. To secure SOAP messages using the signing information, you must complete one of the following tasks:

- Configure the signature information
- Configure signed parts, as needed.

About this task

WebSphere Application Server uses the signing information for the default generator to sign parts of the message, and uses XML digital signature with existing digest and transform algorithms (for example, SHA1 or TRANSFORM_EXC_C14N).

The signing information specifies the integrity constraints that are applied to generated messages. The signed parts are used to protect the integrity of messages. You can specify the signed parts to add for message integrity protection.

The following table shows the required signed parts when the digital signature security constraint (integrity) is defined:

Table 190. Signed parts information. Use the signed parts to secure messages.

Signed parts	Description
keyword	Adds signed parts using keywords. WebSphere Application Server supports the following keywords for signed parts: • BODY • ADDRESSING_HEADERS • TIMESTAMP The WS-Addressing headers are not encrypted but can be signed.
xpath	Adds the required signed parts by using an XPath expression.
header	Adds the header, specified by QName, as a signed part.
timestamp	Adds a WSSTimestamp object as a signed part. If specified, the timestamp information specifies when the message is generated and when it expires.

Different message parts can be specified in the message protection for request on the generator side. WSSSignPart allows for adding a transform algorithm, setting a digest method, setting objects as targets, specifying whether an element, and the signed parts, such as: the SOAP body, the WS-Addressing header, and timestamp information.

For signing information, certain default behaviors occur. The simplest way to use the WSSSignPart API is to use the default behavior (see the example code). The signed parts default behaviors include:

Table 191. Default behavior of signed parts. Several signed part characteristics are configured by default.

Signature decisions	Default behavior
Which SOAP message parts to sign	WebSphere Application Server supports the following SOAP message parts to be signed and used for message protection: • WSSSignature.BODY • WSSSignature.ADDRESSING_HEADERS • WSSSignature.TIMESTAMP
Which digest method to use	Sets the digest algorithm method. The digest method algorithm that is specified within the <DigestMethod> element is used in the <SigningInfo> element. WebSphere Application Server supports the following pre-configured digest methods: • WSSSignPart.SHA1 (the default value): http://www.w3.org/2000/09/xmldsig#sha1 • WSSSignPart.SHA256: http://www.w3.org/2001/04/xmlenc#sha256 • WSSSignPart.SHA512: http://www.w3.org/2001/04/xmlenc#sha512
Which transform algorithms to use	Adds the transform method. The transform algorithm is specified within the <Transform> element and specifies the transform algorithm for the signature. WebSphere Application Server supports the following pre-configured transform algorithms: • WSSSignPart.TRANSFORM_EXC_C14N (the default value): http://www.w3.org/2001/10/xml-exc-c14n# • WSSSignPart.TRANSFORM_XPATH2_FILTER: http://www.w3.org/2002/06/xmldsig-filter2 Use this transform method to ensure compliance with the Basic Security Profile (BSP). • WSSSignPart.TRANSFORM_STRT10: http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform • WSSSignPart.TRANSFORM_ENVELOPED_SIGNATURE: http://www.w3.org/2000/09/xmldsig#enveloped-signature

Procedure

1. To enable Web Services Security by using the WSS API (WSSSignPart), first ensure that the application server is installed.

2. Use the WSSSignPart API to sign the message parts and specify the algorithms in a SOAP message. The WSS API process for signed parts follows these process steps:
   a. Uses WSSFactory.getInstance() to get the WSS API implementation instance.
   b. Creates the WSSGenerationContext instance from the WSSFactory instance.
   c. Creates the SecurityToken from WSSFactory to configure the key for signing.
   d. Creates WSSSignature from the WSSFactory instance using the SecurityToken.
   e. Creates WSSSignPart from the WSSFactory instance.
   f. Sets the part to be signed and the digest method or transform method specified by step g or step h if the default is not appropriate.
   g. Sets the digest method if the default is not appropriate.
   h. Sets the transform method if the default is not appropriate.
   i. Adds WSSSignPart to WSSSignature. After any WSSSignPart is set to WSSSignature, the default parts to be signed, which are specified in WSSSignature, are ignored.
   j. Adds WSSSignature to WSSGenerationContext.
   k. Calls WSSGenerationContext.process() with the SOAPMessageContext.

Results

You have completed the steps to configure the signed parts for the generator section of the bindings files. If there is an error condition, a WSSException is provided. If successful, the WSSGenerationContext.process() is called, and Web Services Security is applied to the SOAP message.

Example

The following example provides sample code that uses all of methods that are defined in the WSSSignPart API:

```
// Get the message context
   Object msgcontext = getMessageContext();

// Generate the WSSFactory instance  (step: a)
   WSSFactory factory = WSSFactory.getInstance();

// Generate WSSGenerationContext instance  (step: b)
   WSSGenerationContext gencont = factory.newWSSGenerationContext();

// Generate callback handler
   X509GenerateCallbackHandler callbackHandler = new
      X509GenerateCallbackHandler
      "",
      "dsig-sender.ks",
      "jks",
      "client".toCharArray(),
      "soaprequester",
      "client".toCharArray(),
      "CN=SOAPRequester, OU=TRL, O=IBM, ST=Kanagawa, C=JP", null);

// Generate the security token used to the signature  (step: c)
   SecurityToken token = factory.newSecurityToken(X509Token.class, callbackHandler);

// Generate WSSSignature instance (step: d)
   WSSSignature sig = factory.newWSSSignature(token);

// Set the part specified by WSSSignPart  (step: e)
   WSSSignPart sigPart = factory.newWSSSignPart();

// Set the part specified by WSSSignPart  (step: f)
   sigPart.setSignPart(WSSSignature.BODY);

// Set the digest method specified by WSSSignPart  (step: g)
   sigPart.setDigestMethod(WSSSignPart.SHA256);

// Set the transform method specified by WSSSignPart  (step: h)
   sigPart.setTransformMethod(WSSSignPart.TRANSFORM_STRT10);

// Add the part specified by WSSSignPart  (step: i)
   sig.addSignPart(sigPart);

// Add the WSSSignature to the WSSGenerationContext  (step: j)
```

```
   gencont.add(sig);

// Generate the WS-Security header  (step: k)
gencont.process(msgcontext);
```

Note: The X509GenerationCallbackHandler needs the key password because the private key is used for signing.

What to do next

Use the WSSVerifyPart API or configure policy sets using the administrative console to verify the signed parts on the consumer side.

Configuring request signing methods for the client:

Use the WSSSignature and WSSSignPart APIs to choose the signing methods. The request signing methods include the signature, canonicalization, digest, and transform methods.

Before you begin

First, you must have specified which parts of the message sent by the client must be digitally signed using the WSS APIs or configuring policy sets using the administrative console.

About this task

The following table describes the purpose of this information. Some of these definitions are based on the XML-Signature specification, which is located at the following website http://www.w3.org/TR/xmldsig-core.

Table 192. Signing methods. Use the signing methods to secure messages.

Name of method	Description
Canonicalization algorithm	Canonicalizes the <SignedInfo> element before the information is digested as part of the signature operation.
Signature algorithm	Calculates the signature value of the canonicalized <SignedInfo> element. The algorithm selected for the client request sender configuration must match the algorithm selected in the server request receiver configuration.
Transform method	Transforms the parts to be signed before the information is digested as part of the signature operation.
Digest method	Calculates the digest value of the transformed parts. The algorithm selected for the client request sender configuration must match the algorithms selected in the server request receiver configuration.

You can use the WSS APIs or configure policy sets using the administrative console to configure the signing algorithm methods. If using the WSS APIs, use the WSSSignature and WSSSignPart APIs to specify which message parts to digitally sign when configuring the client for request signing.

The WSSSignature and WSSSignPart APIs complete the following steps to configure the signature and signed part algorithm methods:

Procedure

1. For the generator binding, the WSSSignature API specifies the signature method. WebSphere Application Server supports the following pre-configured signature methods:
   - WSSSignature.RSA_SHA1 (the default value): http://www.w3.org/2000/09/xmldsig#rsa-sha1
   - WSSSignature.HMAC_SHA1: http://www.w3.org/2000/09/xmldsig#hmac-sha1

   For the WSS APIs, WebSphere Application Server does not support the DSA-SHA1 digital signature method, http://www.w3.org/2000/09/xmldsig#dsa-sha1.
2. For the generator binding, the WSSSignature API specifies the canonicalization method. WebSphere Application Server supports the following pre-configured canonicalization algorithms:

- WSSSignature.EXC_C14N (the default value): The exclusive canonicalization algorithm, http://www.w3.org/2001/10/xml-exc-c14n#
- WSSSignature.C14N: The inclusive canonicalization algorithm, http://www.w3.org/2001/10/xml-c14n#

3. For the generator binding, the WSSSignPart API specifies the digest method. WebSphere Application Server supports the following pre-configured digest methods:
   - WSSSignPart.SHA1 (the default value): http://www.w3.org/2000/09/xmldsig#sha1
   - WSSSignPart.SHA256: http://www.w3.org/2001/04/xmlenc#sha256
   - WSSSignPart.SHA512: http://www.w3.org/2001/04/xmlenc#sha512
4. For the generator binding, the WSSSignPart API specifies the transform method. WebSphere Application Server supports the following pre-configured transform algorithms:
   - WSSSignPart.TRANSFORM_EXC_C14N (the default value): http://www.w3.org/2001/10/xml-exc-c14n#
   - WSSSignPart.TRANSFORM_XPATH2_FILTER: http://www.w3.org/2002/06/xmldsig-filter2
   - WSSSignPart.TRANSFORM_STRT10: http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform
   - WSSSignPart.TRANSFORM_ENVELOPED_SIGNATURE: http://www.w3.org/2000/09/xmldsig#enveloped-signature

   For the WSS APIs, WebSphere Application Server does not support the following transform algorithms:
   - http://www.w3.org/TR/1999/REC-xpath-19991116
   - http://www.w3.org/2002/07/decrypt#XML

Results

Using the WSS APIs, you have specified which algorithm methods are used to digitally sign a message when the client sends a message to a server.

Example

The following example is sample code for specifying the signature information, HMAC_SHA1 as signature method, C14N as a canonicalizaion method, SHA256 as a digest method, and EXC_C14N and TRANSFORM_STRT10 as the transform methods:

```
//get the message context
Object msgcontext = getMessageContext();

//generate WSSFactory instance
WSSFactory factory = WSSFactory.getInstance();

//generate WSSGenerationContext instance
WSSGenerationContext gencont = factory.newWSSGenerationContext();

//generate callback handler
X509GenerateCallbackHandler callbackHandler = new X509GenerateCallbackHandler(
  "",
  "dsig-sender.ks",
  "jks",
  "client".toCharArray(),
  "soaprequester",
  "client".toCharArray(),
  "CN=SOAPRequester, OU=TRL, O=IBM, ST=Kanagawa, C=JP",
  null);

//generate the security token used to the signature
SecurityToken token = factory.newSecurityToken(X509Token.class, callbackHandler);

//generate WSSSignature instance
WSSSignature sig = factory.newWSSSignature(token);

//set the canonicalization method
// DEFAULT: WSSSignature.EXC_C14N
sig.setCanonicalizationMethod(WSSSignature.C14N);

//set the signature method
// DEFAULT: WSSSignature.RSA_SHA1
sig.setSignatureMethod(WSSSignature.HMAC_SHA1);
```

```
//set the part specified by WSSSignPart
WSSSignPart sigPart = factory.newWSSSignPart();

//set the digest method
 // DEFAULT: WSSSignPart.SHA1
sigPart.setDigestMethod(WSSSignPart.SHA256);

//add the transform method
// DEFAULT: WSSSignPart.TRANSFORM_EXC_C14N
sigPart.addTransformMethod(WSSSignPart.TRANSFORM_EXC_C14N);
sigPart.addTransformMethod(WSSSignPart.TRANSFORM_STRT10);

 // add the WSSSignPart to the WSSSignature
 sig.addSignPart(sigPart);

//add the WSSSignature to the WSSGenerationContext
gencont.add(sig);

//generate the WS-Security header
gencont.process(msgcontext);
```

What to do next

After you configure the client to digitally sign the message and to choose the algorithm methods, you must configure the server to verify the digital signature for request signing and to choose the algorithm methods.

Configure policy sets using the administrative console to configure the signature verification information and methods on the server.

Digital signing methods using the WSSSignature API:

You can configure the signing information for the generator binding using the WSS API. To configure the client for request signing, choose the digital signing methods. The algorithm methods include the signing and canonicalization methods.

You must configure generator signing information to protect message integrity by digitally signing SOAP messages. Integrity refers to digital signature while confidentiality refers to encryption. Integrity decreases the risk of data modification when you transmit data across a network.

After you have specified which message parts to digitally sign, you must specify which method is used to digitally sign the message.

Methods

Methods that are used for the signing information include the:

Signature method
Sets the signature algorithm method.

Canonicalization method
Sets the canonicalization algorithm method.

Signature algorithms

The signature algorithms specify the algorithm that is used to sign the certificate. The signature algorithms specify the Uniform Resource Identifiers (URI) of the signature method. WebSphere Application Server supports the following pre-configured algorithms:

Table 193. Signature algorithms. The algorithms include the signing methods.

Algorithm	Description
WSSSignature.HMAC_SHA1	A URI of the signature algorithm, HMAC: http://www.w3.org/2000/09/xmldsig#hmac-sha1
WSSSignature.RSA_SHA1 (the default value)	A URI of the signature algorithm, RSA: http://www.w3.org/2000/09/xmldsig#rsa-sha1

For the WSS APIs, WebSphere Application Server does not support the DSA-SHA1 algorithm, http://www.w3.org/2000/09/xmldsig#dsa-sha1

The signing algorithm that is specified for the request generator configuration must match the algorithm that is specified for the request consumer configuration.

Canonicalization algorithms

The canonicalization algorithms specify the Uniform Resource Identifiers (URI) of the canonicalization method. WebSphere Application Server supports the following pre-configured algorithms:

Table 194. Signature canonicalization algorithms. The algorithms include the canonicalization methods.

Algorithm	Description
WSSSignature.EXC_C14N (the default value)	A URI of the exclusive canonicalization algorithm EXC_C14N: http://www.w3.org/2001/10/xml-exc-c14n#
WSSSignature.C14N	A URI of the inclusive canonicalization algorithm, C14N: http://www.w3.org/2001/10/xml-c14n#

The canonicalization algorithm that is specified for the request generator configuration must match the algorithm that is specified for the request consumer configuration.

The following example provides sample WSS API code that specifies the HMAC_SHA1 as a signature method and C14n as a canonicalization method:

```
//generate WSSFactory instance
WSSFactory factory = WSSFactory.getInstance();

//generate WSSGenerationContext instance
WSSGenerationContext gencont = factory.newWSSGenerationContext();

//generate callback handler
X509GenerateCallbackHandler callbackHandler = new
     X509GenerateCallbackHandler(
  "",
  "dsig-sender.ks",
  "jks",
  "client".toCharArray(),
  "soaprequester",
  "client".toCharArray(),
  "CN=SOAPRequester, OU=TRL, O=IBM, ST=Kanagawa, C=JP",
  null);

//generate the security token used to the signature
SecurityToken token = factory.newSecurityToken(X509Token.class,
     callbackHandler);

//generate WSSSignature instance
WSSSignature sig = factory.newWSSSignature(token);

//set the canonicalization method
// DEFAULT: WSSSignature.EXC_C14N
sig.setCanonicalizationMethod(WSSSignature.C14N);

//set the signature method
// DEFAULT: WSSSignature.RSA_SHA1
sig.setSignatureMethod(WSSSignature.HMAC_SHA1);

//add the WSSSignature to the WSSGenerationContext
gencont.add(sig);

//generate the WS-Security header
gencont.process(msgcontext);
```

Signed parts methods using the WSSSignPart API:

You can configure the signed parts information for the generator binding using the WSS API. The algorithms include the digest and transform methods.

You can protect message integrity by configuring signed parts and key information. Integrity refers to digital signature while confidentiality refers to encryption. Integrity decreases the risk of data modification when you transmit data across a network.

Methods

Methods that are used for the signed parts include the:

Digest method
Sets the digest algorithm method.

Transform algorithm
Sets the transform algorithm method.

Digest algorithms

The digest method algorithm specified within the element is used in the element. WebSphere Application Server supports the following pre-configured algorithms:

Table 195. Signed parts digest methods. The methods are used for the signed parts.

Digest method	Description
WSSSignPart.SHA1 (the default value)	A URI of the digest algorithm, SHA1: http://www.w3.org/2000/09/xmldsig#sha1
WSSSignPart.SHA256	A URI of the digest algorithm, SHA256: http://www.w3.org/2001/04/xmlenc#sha256
WSSSignPart.SHA512	A URI of the digest algorithm, SHA256: http://www.w3.org/2001/04/xmlenc#sha512

Transform algorithms

The transform method algorithm specified within the element is used in the element. WebSphere Application Server supports the following pre-configured algorithms:

Table 196. Signed parts transform methods. The methods are used for the signed parts.

Digest method	Description
WSSSignPart.TRANSFORM_ENVELOPED_SIGNATURE	A URI of the transform algorithm, enveloped signature: http://www.w3.org/2000/09/xmldsig#enveloped-signature
WSSSignPart.TRANSFORM_STRT10	A URI of the transform algorithm, STR-Transform: http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform
WSSSignPart.TRANSFORM_EXC_C14N (the default value)	A URI of the transform algorithm, Exc-C14N: http://www.w3.org/2001/10/xml-exc-c14n#
WSSSignPart.TRANSFORM_XPATH2_FILTER	A URI of the transform algorithm, XPath2 filter: http://www.w3.org/2002/06/xmldsig-filter2

The transform algorithm is specified within the <Transform> element and specifies the transform algorithm for the signed part.

For the WSS APIs, WebSphere Application Server does not support the following transform algorithms:

- http://www.w3.org/TR/1999/REC-xpath-19991116
- http://www.w3.org/2002/07/decrypt#XML

The following example provides sample WSS API code for specifying the signature and signed parts, setting the signing key and adding the STR-Transform transform algorithm as signed parts:

```
//get the message context
Object msgcontext = getMessageContext();

//generate WSSFactory instance
WSSFactory factory = WSSFactory.getInstance();

//generate WSSGenerationContext instance
WSSGenerationContext gencont = factory.newWSSGenerationContext();

//generate callback handler
X509GenerateCallbackHandler callbackHandler = new
      X509GenerateCallbackHandler(
```

```
    "",
    "dsig-sender.ks",
    "jks",
    "client".toCharArray(),
    "soaprequester",
    "client".toCharArray(),
    "CN=SOAPRequester, OU=TRL, O=IBM, ST=Kanagawa, C=JP",
    null);

  //generate the security token used to the signature
  SecurityToken token = factory.newSecurityToken(X509Token.class,
       callbackHandler);

  //generate WSSSignature instance
  WSSSignature sig = factory.newWSSSignature(token);

  //set the part specified by WSSSignPart
  WSSSignPart sigPart = factory.newWSSSignPart();

  //set the part specified by WSSSignPart
  sigPart.setSignPart(WSSSignature.BODY);

  //set the digest method specified by WSSSignPart
  sigPart.setDigestMethod(WSSSignPart.SHA256);

  //set the transform method specified by WSSSignPart
  sigPart.addTransform(WSSSignPart.TRANSFORM_STRT10);

  //set the part specified by WSSSignPart
  sig.addSignPart(sigPart);

  //add the WSSSignature to the WSSGenerationContext
  gencont.add(sig);

  //generate the WS-Security header
  gencont.process(msgcontext);
```

Attaching the generator token using WSS APIs to protect message authenticity:

When you specify the token generator, the information is used on the generator side to generate the security token.

Before you begin

The token processing and pluggable token architecture in the Web Services Security run time reuses the same security token interface and Java Authentication and Authorization Service (JAAS) Login Module from the Web Services Security APIs (WSS API). The same implementation of token creation and validation can be used in both the WSS API and the WSS SPI in the Web Services Security run time.

Restriction: The `com.ibm.wsspi.wssecurity.token.TokenGeneratorComponent` interface is not used with JAX-WS web services. If you are using JAX-RPC web services, this interface is still valid.

Note that the key name (KeyName) element is not supported in the application server because there is no KeyName policy assertion defined in the current OASIS Web Services Security draft specification.

About this task

The JAAS callback handler (CallbackHandler) and the JAAS login module (LoginModule) are responsible for creating the security token on the generator side and validating (authenticating) the security token on the consumer side.

For example, on the generator side, the Username token is created by the JAAS LoginModule and using the JAAS CallbackHandler to pass the authentication data. The JAAS LoginModule creates the Username SecurityToken object and passes it to the Web Services Security run time.

Then, on the consumer side, the Username Token XML format is passed to the JAAS LoginModule for validation or authentication and the JAAS CallbackHandler is used to pass authentication data from the Web Services Security run time to the LoginModule. After the token is authenticated, a Username SecurityToken object is created and passed it to the Web Services Security run time.

Note: WebSphere Application Server does not support a stackable login module with the WebSphere Application Server default login module implementation, meaning adding the login module before or after the WebSphere Application Server login module implementation. If you want to stack the login module implementations, you must develop the required login modules because there is no default implementation.

The com.ibm.websphere.wssecurity.wssapi.token package provided by WebSphere Application Server includes support for these classes:

- Security token (SecurityTokenImpl)
- Binary security token (BinarySecurityTokenImpl)

In addition, WebSphere Application Server provides the following pre-configured sub-interfaces for security tokens:

- Derived key token
- Security context token (SCT)
- Username token
- LTPA token propagation
- LTPA token
- X509PKCS7 token
- X509PKIPath token
- X509v3 token
- Kerberos v5 token

The Username token, the X.509 tokens, and the LTPA tokens are used by default for message authenticity. The derived key token and the X.509 tokens are used by default for signing and encryption.

The WSS API and WSS SPI are only supported on the client. To specify the security token type on the generator side, you can also configure policy sets using the administrative console. You can also use the WSS APIs or policy sets for matching consumer security tokens.

The default Login Module and Callback implementations are designed to be used as a pair, meaning both a generator and a consumer part. To use the default implementations, select the appropriate generator and consumer security token in a pair. For example, select `system.wss.generate.x509` in the token generator and `system.wss.consume.x509` in the token consumer when the X.509 token is required.

To configure the generator-side security token, use the appropriate pre-configured token generator interface from the WSS APIs to complete the following token configuration process steps:

Procedure

1. Generate the wssFactory instance.
2. Generate the wssGenerationContext instance.

   The WSSGenerationContext interface stores the components for generating Web Services Security (WS-Security), such as the signing and encryption information, the security token, and the time stamp. When the generate() method is called, all of these components are generated.
3. Create the generator-side components, such as the WSSSignature and the WSSEncryption objects.
4. Specify a JAAS configuration by specifying the name of the JAAS login configuration. The Java Authentication and Authorization Service (JAAS) configuration specifies the name of the JAAS configuration. The JAAS configuration specifies how the token logs in on the consumer side. Do not remove the predefined system or application login configurations. However, within these configurations, you can add module class names and specify the order in which WebSphere Application Server loads each module.

5. Specifiy a token generator class name. The token generator class name specifies the required information to generate the SecurityToken. The Username token, the X.509 tokens, and the LTPA tokens are used by default for message authenticity.
6. Specifiy the settings for the callback handler by specifying a callback handler class name and also specifies the callback handler keys. This class name is the name of the callback handler implementation class that is used for the plug-in to the security token framework.

   The callback handler implementation obtains the required security token and passes it to the token generator. The token generator inserts the security token in the Web Services Security header within the SOAP message. Also, the token generator is a plug-in point for the pluggable security token framework. Service providers can provide their own implementation, but the implementation must use the WSSGenerationContext interface.

   WebSphere Application Server provides the following default callback handler implementations for the generator side:

   com.ibm.websphere.wssecurity.callbackhandler.PropertyCallback
   This class is a callback for handling the name-value pair in elements in the Web Services Security (WS-Security) configuration XMI files.

   com.ibm.websphere.wssecurity.callbackhandler.UNTGUIPromptCallbackHandler
   This class is a callback handler for the Username token with the GUI prompt on the generator side. This instance is used to set the WSSGenerationContext object to generate a Username token.

   com.ibm.websphere.wssecurity.callbackhandler.UNTGenerateCallbackHandler
   This class is a callback handler for the Username token on the generator side. This instance is used to set into WSSGenerationContext object to attach a Username token. Use this implementation for a Java Platform, Enterprise Edition (Java EE) application client only.

   com.ibm.websphere.wssecurity.callbackhandler.X509GenerateCallbackHandler
   This class is a callback handler that is used to generate the X.509 certificate that is inserted in the Web Services Security header within the SOAP message as a binary security token on the generator side. This instance is used to generate the WSSSignature and WSSEncryption objects, set the objects into the WSSGenerationContext object to generate the X.509 binary security tokens. A keystore and a key definition are required for this callback handler. If you use this implementation, a key store password, path, and type must be provided on the generator side.

   com.ibm.websphere.wssecurity.callbackhandler.LTPAGenerateCallbackHandler
   This class is a callback handler for the Lightweight Third Party Authentication (LTPA) tokens on the generator side. This instance is used to generate WSSSignature object and WSSEncryption object to generate a LTPA token.

   This callback handler is used to validate the LTPA security token inserted in the Web Services Security header within the SOAP message as a binary security token. However, if the user name and password are specified, WebSphere Application Server authenticates the user name and password to obtain the LTPA security token rather than obtaining it from the Run As Subject. Use this callback handler only when the web service is acting as a client on the application server. It is recommended that you do not use this callback handler on a Java EE application client. If you use this implementation, a basic authentication user ID and password must have been provided on the generator side.

   com.ibm.websphere.wssecurity.callbackhandler.KRBTokenConsumeCallbackHandler
   This class is a callback handler for the Kerberos v5 token on the generator side. This instance is used to set the WSSGenerationContext object to generate the Kerberos v5 AP-REQ as a binary security token. The instance is also used to generate the WSSSignature and WSSEncryption objects to use the Kerberos session key or derived key in the SOAP message signature and encryption.
7. If a X.509 token is specified, additional token information is also specified.

Table 197. Information for X.509 token. Use the X.509 token for signing and encryption.

Token Information	Description
storeRef	The reference name of the keystore.
storePath	The keystore file path from which the keystore is loaded, if needed. It is recommended that you use the `${USER_INSTALL_ROOT}` in the path name as this variable expands to the WebSphere Application Server path on your machine. This path is required when you use the X.509 tokens callback handler implementations.
storePassword	The password that is used to check the integrity of the keystore, or the keystore password that is used to unlock the keystore and to access the keystore file. The keystore and its configuration are used for some of the default callback handler implementations that are provided by WebSphere Application Server.
storeType	The keystore type of keystore that is used for the key locator. This selection indicates the format that is used by the keystore file. The following values are available for selection: **JKS** Use this option if the keystore uses the Java Keystore (JKS) format. **JCEKS** Use this option if the Java Cryptography Extension is configured in the software development kit (SDK). The default IBM JCE is configured in WebSphere Application Server. This option provides stronger protection for stored private keys by using Triple DES encryption. **JCERACFKS** Use JCERACFKS if the certificates are stored in a SAF key ring (z/OS only). **PKCS11KS (PKCS11)** Use this format if your keystore uses the PKCS#11 file format. Keystores using this format might contain RSA keys on cryptographic hardware or might encrypt keys that use cryptographic hardware to ensure protection. **PKCS12KS (PKCS12)** Use this option if your keystore uses the PKCS#12 file format.
alias	The key alias name. The key alias is used by the key locator to find the key within the keystore file.
keyPassword	The key password that is used for recovering the key. This password is needed to access the key object within the keystore file.
keyName	The name of the key. For digital signatures, the key name is used by the request generator or response consumer signing information to determine which key is used to digitally sign the message. For encryption, the key name is used to determine the key used for encryption. The key name must be a fully qualified, distinguished name (DN). For example, `CN=Bob,O=IBM,C=US`.
certStores	A list of certificate stores. A collection certificate store includes a list of untrusted, intermediary certificates and certificate revocation lists (CRLs). This step configures a collection certificate store and certificate revocation lists for the generator bindings.
identityAssertion	Specifies whether identity assertion is used. Selects this item if identity assertion is defined. This option indicates that only the identity of the initial sender is required and inserted into the Web Services Security header within the SOAP message. For an X.509 token generator, the application server sends the original signer certification only.
requestorCertificate	Specifies whether the certificate of the requestor is used.

The following can be specified for a X.509 token:

a. Without any keystore.

b. With a trust anchor. A trust anchor specifies a list of keystore configurations that contain trusted root certificates. These configurations are used to validate the certificate path of incoming X.509-formatted security tokens. For example, when you select the trust anchor or the certificate store of a trusted certificate, you must configure the trust anchor and the certificate store before setting the certificate path.

c. With a keystore that is used for the key locator.

First, you must have created the keystore file, by using a key tool utility, for example. The keystore is used to retrieve the X.509 certificate. This entry specifies the password that is used to access the keystore file. Keystore objects within trust anchors contain trusted root certificates that are used by the CertPath API to validate the trustworthiness of a certificate chain.

d. With keystore that is used for the key locator and the trust anchor.

e. With a map that includes key-value pairs. For example, you might specify the value type name and the value type Uniform Resource Identifier (URI). The value type specifies the namespace URI of the value type for the generated token, and represents the token type of this class:

ValueType: http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509v3

Specifies an X.509 certificate token.

ValueType: http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509PKIPathv1

Specifies X.509 certificates in a public key infrastructure (PKI) path. This callback handler is used to create X.509 certificates encoded with the PkiPath format. The certificate is inserted in the Web Services Security header within the SOAP message as a binary security token. A keystore is required for this callback handler. A CRL is not supported by the callback handler; therefore, the collection certificate store is not required or used. If you use this implementation, you must provide a key store password, path, and type on this panel.

ValueType: http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#PKCS7

Specifies a list of X.509 certificates and certificate revocation lists in a PKCS#7 format. This callback handler is used to create X.509 certificates encoded with the PKCS#7 format. The certificate is inserted in the Web Services Security header in the SOAP message as a binary security token. A keystore is required for this callback handler. You can specify a certificate revocation list (CRL) in the collection certificate store. The CRL is encoded with the X.509 certificate in the PKCS#7 format. If you use this implementation, you must provide a key store password, path, and type.

For some tokens, WebSphere Application Server provides a predefined local name for the value type. When you specify the following local name, you do not need to specify a value type URI:

ValueType: http://www.ibm.com/websphere/appserver/tokentype/5.0.2

For an LTPA token, you can use `LTPA` for the value type local name. This local name causes `http://www.ibm.com/websphere/appserver/tokentype/5.0.2` to be specified for the value type Uniform Resource Identifier (URI).

ValueType: http://www.ibm.com/websphere/appserver/tokentype/5.0.2

For LTPA token propagation, you can use `LTPA_PROPAGATION` for the value type local name. This local name causes `http://www.ibm.com/websphere/appserver/tokentype` to be specified for the value type Uniform Resource Identifier (URI).

8. If the Username token is specified as the token generator class name, the following token information can be specified:
   a. Whether to use IdentityAssertion option. This option is selected if identity assertion is defined. This option indicates that only the identity of the initial sender is required and inserted into the Web Services Security header within the SOAP message. For example, WebSphere Application Server sends only the user name of the original caller for a Username token generator.
   b. Whether to use RunAsSubject identity option. This option is used if an identity assertion is defined and you want to use the Run As identity instead of the initial caller identity for identity assertion in a downstream call. This option is valid only if you have configured the Username token as the token generator.
   c. Whether to use sendRealm.
   d. Whether to specify the nonce.

      This option indicates whether a Nonce is included for the token generator. Nonce is a unique, cryptographic number that is embedded in a message to help stop repeat, unauthorized attacks of Username tokens. Nonce is valid only when the generated token type is a Username token, and it is available only for the request generator binding.
   e. Specifies the keyword of the time stamp. This option indicates whether to verify a time stamp in the Username token. The time stamp is valid only when the incorporated token type is a Username token.
   f. Specifies a map that includes key-value pairs. For example, you might specify the value type name and the value type Uniform Resource Identifier (URI). The value type specifies the namespace URI of the value type for the generated token, and represents the token type of this class:

URI value type: http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-username-token-profile-1.0#UsernameToken

Specifies a Username token.

9. If the Kerberos v5 token is specified as the token generator class name, the following token information can be specified:

Token Information	Description	Default Value
name	Kerberos client principal name	
password	Kerberos client password	
realm	Kerberos realm associated with the Kerberos client	Default realm name in Kerberos configuration file. Specify null to use the default value.
targetService	Kerberos service name associated with the target web services.	
targetHost	Kerberos realm name associated with the Kerberos service name.	
tokenValueType	Kerberos token value type in QName defined by Oasis Kerberos Token Profile v1.1 specification.	http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ
targetRealm	Kerberos realm name associated with the Kerberos service name.	Default realm name in the Kerberos configuration file
prompt	A boolean value to enable the login prompt.	false
supportTokenRequireSHA1	A boolean value to require a SHA1 key that is used in subsequent request messages when the Kerberos token is used as a supporting token.	false SHA1 key is consumed only if the supporting Kerberos token is protected. If set to true, the SHA1 key is always consumed.
alwaysAPREQ	A boolean value to indicate that the client should always send the Kerberos AP_REQ token in the request messages.	false The SHA1 key is used instead in the subsequent messages. If set to true, the Kerberos AP_REQ token is always used.
requireDKT	A boolean value to require a derived key for message protection.	false
clabel	The client label for the derived key.	WS-SecureConversation Specify null to use the default value.
slabel	The service label for the derived key.	WS-SecureConversation Specify null to use the default value.
keylen	The length of the derived key.	16 Specify zero to use the default value
noncelen	The length of the nonce.	16 Specify zero to use the default value

Token Information	Description	Default Value
encComponent	An instance of WSSEncryption.	Set encComponent and sigComponent to null to initialize this first for either the encryption or signature component. Then, use the initialized component only in the callback handler constructor for the second component.
sigComponent	An instance of WSSSignature.	Set encComponent and sigComponent to null to initialize this first for either the encryption or signature component. Then, use the initialized component only in the callback handler constructor for the second component.

Additional token value types are defined in the OASIS Kerberos Token Profile v1.1 specification. Specify the token value type as the local name. It is not necessary to specify the value type URI for the Kerberos v5 token.

- http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#Kerberosv5_AP_REQ
- http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#Kerberosv5_AP_REQ1510
- http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ1510
- http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#Kerberosv5_AP_REQ4120
- http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ4120

10. If Secure Conversation is used for message protection, the following information must be specified:

Information	Description
bootstrapWSSGenerationContext	The bootstrap configuration used to secure the RequestSecurityToken (RST) token.
bootstrapWSSConmingContext	The bootstrap configuration used for consuming a secured RequestSecurityTokenResponse (RSTR).
ENDPOINT_URL	The service end point URL.
EncryptionAlgorithm	This determines the key size.
cLabel	The client label used when creating the derived key.
sLabel	The server label used when creating the derived key.

11. Set the components into the wssGenerationContext object.
12. Invoke the wssGenerationContext.process() method.

Results

Using the Web Services Security API (WSS API) process, you can configured the token generator.

What to do next

Next, you must specify a similar token consumer configuration.

Configuring generator security tokens using the WSS API:

You can secure the SOAP messages, without using policy sets, by using the Web Services Security APIs. To configure the token on the generator side, use the Web Services Security APIs (WSS API). The generator security tokens are part of the `com.ibm.websphere.wssecurity.wssapi.token` interface package.

Before you begin

The pluggable token framework in WebSphere Application Server has been redesigned so that the same framework from the WSS API can be reused. The same implementation of creating and validating security token can be used both for the Web Services Security runtime and for the WSS API application code. The redesigned framework also simplifies the SPI programming model and will make it easier to add security token types.

You can use the WSS API or you can configure the tokens by using the administrative console. To configure tokens, you must complete the following token tasks:

- Configure the generator tokens.
- Configure the consumer tokens.

About this task

The JAAS CallbackHandler and JAAS LoginModule are responsible for creating the security token on the generator side.

On the generator side, the token is created by using the JAAS LoginModule and by using JAAS CallbackHandler to pass authentication data. Then, the JAAS LoginModule creates the securityToken object, such as the UsernameToken, and passes it to the Web Services Security run time.

On the consumer side, the XML format is passed to the JAAS LoginModule for validation or authentication. then the JAAS CallbackHandler is used to pass authentication data from the Web Services Security runtime to the LoginModule. After the token is authenticated, a security token object is created, and the token is passed it to the Web Services Security runtime.

When using the WSS API for generator token creation, certain default behaviors occur. The simplest way to use the WSS API is to use the default behavior (see the example code). The WSS API provide default values for the token type, the token value, and the JAAS confirmation name. The default token behaviors include:

Table 198. Token decisions and default behaviors. Several token characteristics are configured by default.

Generator token decisions	Default behavior
Which token type to use	The token type specifies which type of token to use for message integrity, message confidentiality, or message authenticity. WebSphere Application Server provides the following pre-configured generator token types for message integrity and message confidentiality: • Derived key token • X509 tokens You can also create custom token types, as needed. WebSphere Application Server also provides the following pre-configured generator token types for the message authenticity: • Username token • LTPA tokens • X509 tokens You can also create custom token types, as needed.
What JAAS login configuration name to specify	The JAAS login configuration name specifies which JAAS login configuration name to use.
Which configuration type to use	The JAAS login module specifies the configuration type. Only the pre-configured generator configuration types can be used for generator token types.

The SecurityToken class (com.ibm.websphere.wssecurity.wssapi.token.SecurityToken) is the generic token class and represents the security token that has methods to get the identity, the XML format, and the cryptographic keys. Using the SecurityToken class, you can apply both the signature and encryption to the SOAP message. However, to apply both, you must have two SecurityToken objects, one for the signature and one for encryption, respectively.

The following tokens types are subclasses of the generic security token class:

Table 199. Subclasses of the SecurityToken. Use the subclasses to represent the security token.

Token type	JAAS login configuration name
Username token	system.wss.generate.unt
Security context token	system.wss.generate.sct
Derived key token	system.wss.generate.dkt

The following tokens types are subclasses of the binary security token class:

Table 200. Subclasses of the BinarySecurityToken. Use the subclasses to represent the binary security token.

Token type	JAAS login configuration name
LTPA token	system.wss.generate.ltpa
LTPA propagation token	system.wss.generate.ltpaProp
X.509 token	system.wss.generate.x509
X.509 PKI Path token	system.wss.generate.pkiPath
X.509 PKCS7 token	system.wss.generate.pkcs7

Note:

- For each JAAS login token generator configuration name, there is a respective token consumer configuration name. For example, for the Username token, the respective token consumer configuration name is system.wss.consume.unt.
- The LTPA and LTPA propagation tokens are only available to a requester that is running as a server-based client. The LTPA and LTPA propagation tokens are not supported for the Java SE 6 or Java EE application client.

Procedure

1. To configure the securityToken package, `com.ibm.websphere.wssecurity.wssapi.token`, first ensure that the application server is installed.
2. Use the Web Services Security token generator process to configure the tokens. For each token type, the process is similar to the following process that demonstrates the UsernameToken token generator process:
   a. Use WSSFactory.getInstance() to get the WSS API implementation instance.
   b. Create the WSSGenerationContext instance from the WSSFactory instance.
   c. Create a JAAS CallbackHandler. The authentication data, such as the user name and password are specified as part of the CallbackHandler. For example, the following code specifies Chris as the user name and sirhC as the password: UNTGenerationCallbackHandler("Chris", "sirhC");
   d. Call any JAAS CallbackHandler parameters and review the token class information for which parameters are required or optional. For example, for the UsernameToken, the following parameters can be configured also:

      Nonce

      Indicates whether a nonce is included in the user name token for the token generator. Nonce is a unique, cryptographic number that is embedded in a message to help stop repeat, unauthorized attacks of user name tokens. The nonce value is valid only when the generated token type is a UsernameToken and only when it applies to the request generator binding.

Created timestamp

Indicates whether to insert a time stamp into the UsernameToken. The timestamp value is valid only when the generated token type is a UsernameToken and only when it applies to the request generator binding.

e. Create the SecurityToken from WSSFactory.

   By default, the UsernameToken API specifies the ValueType as: "http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-username-token-profile-1.0#UsernameToken"

   By default, the UsernameToken API provides the QName of this class and specifies the NamespaceURI as http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-secext-1.0.xsd and also specifies the LocalPart as UsernameToken.

f. Optional: Specify the JAAS login module configuration name. On the generator side, the configuration type is always `generate` (for example, `system.wss.generate.unt`).

g. Add the SecurityToken to the WSSGenerationContext.

h. Call WSSGenerationContext.process() and generate the WS-Security header.

Results

If there is an error condition, a WSSException is provided. If successful, the WSSGenerationContext process() is called, and the security token for the generator binding is attached.

Example

The following example code shows how to use WSS APIs to create a Username security token, attach the Username token to the SOAP message, and configure the Username token in the generator binding.

```
// import the packages
import javax.xml.ws.BindingProvider;
import com.ibm.websphere.wssecurity.wssapi.*;
import com.ibm.websphere.wssecurity.callbackhandler.*;
...
   // obtain the binding provider
   BindingProvider bp = ... ;

   // get the request context
   Map<String, Object> reqContext = bp.getRequestContext();

   // generate WSSFactory instance
   WSSFactory factory = WSSFactory.getInstance();

   // generate WSSGenerationContext instance
   WSSGenerationContext gencont = factory.newWSSGenerationContext();

   // generate callback handler
   UNTGenerateCallbackHandler untCallbackHandler =
   new UNTGenerateCallbackHandler("Chris", "sirhC");

   // generate the username token
   SecurityToken unt = factory.newSecurityToken(UsernameToken.class, untCallbackHandler);

   // add the SecurityToken to the WSSGenerationContext
   gencont.add(unt);

   // generate the WS-Security header
   gencont.process(reqContext);
```

The following example code shows how to modify the preceding Username token sample to create an LTPAv2 token from the runAs identity on the current thread. The two lines of code that instantiate the callback handler and create the security token are replaced with the following two lines of code:

```
// generate callback handler
LTPAGenerateCallbackHandler ltpaCallbackHandler = new LTPAGenerateCallbackHandler(null, null);

// generate the LTPAv2 token
SecurityToken ltpa = wssfactory.newSecurityToken(LTPAv2Token.class, ltpaCallbackHandler);
```

The instantiation of the LTPAGenerateCallbackHandler object with (null, null) indicates that the LTPA token should be generated from the current runAs identity. If the callback handler is instantiated with basicAuth information, ("userName", "password"), a new LTPA token is created using the specified basicAuth information.

The following example shows how to use secure conversation with the WSS APIs to configure the generator tokens, as well as the consumer tokens. In this example, the SecurityContextToken token is created using the WS-SecureConversation draft namespace: `http://schemas.xmlsoap.org/ws/2005/02/sc/sct`. To use the WS-SecureConversation version 1.3 namespace, `http://docs.oasis-open.org/ws-sx/ws-secureconversation/200512/sct`, specify SecurityContextToken13.class instead of SecurityContextToken.class.

```
// import the packages
import javax.xml.ws.BindingProvider;
import com.ibm.websphere.wssecurity.wssapi.*;
import com.ibm.websphere.wssecurity.callbackhandler.*;
...
   // obtain the binding provider
   BindingProvider bp = ... ;

   // get the request context
   Map<String, Object> reqContext = bp.getRequestContext();

   // generate WSSFactory instance
   WSSFactory wssFactory = WSSFactory.getInstance();

   WSSGenerationContext bootstrapGenCon = wssFactory.newWSSGenerationContext();

   // Create a Timestamp
   ...
   // Add Timestamp
   ...

   // Sign the SOAP Body, WS-Addressing headers, and Timestamp
   X509GenerateCallbackHandler btspReqSigCbHandler = new X509GenerateCallbackHandler(...);
   SecurityToken btspReqSigToken = wssFactory.newSecurityToken(X509Token.class,
                                                               btspReqSigCbHandler);
   WSSSignature bootstrapReqSig = wssFactory.newWSSSignature(btspReqSigToken);
   bootstrapReqSig.setCanonicalizationMethod(WSSSignature.EXC_C14N);

   // Add Sign Parts
   ...
   bootstrapGenCon.add(bootstrapReqSig);

   // Encrypt the SOAP Body and the Signature
   X509GenerateCallbackHandler btspReqEncCbHandler = new X509GenerateCallbackHandler(...);
   SecurityToken btspReqEncToken = wssFactory.newSecurityToken(X509Token.class,
                                                               btspReqEncCbHandler);
   WSSEncryption bootstrapReqEnc = wssFactory.newWSSEncryption(btspReqEncToken);
   bootstrapReqEnc.setEncryptionMethod(WSSEncryption.AES128);
   bootstrapReqEnc.setKeyEncryptionMethod(WSSEncryption.KW_RSA15);

   // Add Encryption parts
   ...
   bootstrapGenCon.add(bootstrapReqEnc);
   WSSConsumingContext bootstrapConCon = wssFactory.newWSSConsumingContext();
   X509ConsumeCallbackHandler btspRspVfyCbHandler = new X509ConsumeCallbackHandler(....);
   WSSVerification bootstrapRspVfy = wssFactory.newWSSVerification(X509Token.class,
                                                                   btspRspVfyCbHandler);
   bootstrapRspVfy.addAllowedCanonicalizationMethod(WSSVerification.EXC_C14N);

   // Add Verify parts
   ...
   bootstrapConCon.add(bootstrapRspVfy);
   X509ConsumeCallbackHandler btspRspDecCbHandler = new X509ConsumeCallbackHandler(...);
   WSSDecryption bootstrapRspDec = wssFactory.newWSSDecryption(X509Token.class,
                                                               btspRspDecCbHandler);
   bootstrapRspDec.addAllowedEncryptionMethod(WSSDecryption.AES128);
   bootstrapRspDec.addAllowedKeyEncryptionMethod(WSSDecryption.KW_RSA15);

   // Add Decryption parts
   ...
   bootstrapConCon.add(bootstrapRspDec);
   SCTGenerateCallbackHandler sctgch = new SCTGenerateCallbackHandler(bootstrapGenCon,
                                                                      bootstrapConCon,
                                                                      ENDPOINT_URL,
                                                                      WSSEncryption.AES128);
   SecurityToken[] scts = wssFactory.newSecurityTokens(new Class[]{SecurityContextToken.class},
                                                       sctgch);
   SecurityContextToken sct = (SecurityContextToken)scts[0];

   // Use the SCT to generate DKTs for Secure Conversation
   // Signature algorithm and client and service labels
   DerivedKeyToken dktSig = sct.getDerivedKeyToken(WSSSignature.HMAC_SHA1,
                                                   "WS-SecureConversation",
                                                   "WS-SecureConversation");

   // Encryption algorithm and client and service labels
   DerivedKeyToken dktEnc = sct.getDerivedKeyToken(WSSEncryption.AES128,
                                                   "WS-SecureConversation",
                                                   "WS-SecureConversation");
```

```
// Create the application generation context for the request message
WSSGenerationContext applicationGenCon = wssFactory.newWSSGenerationContext();

// Create and add Timestamp
...

// Add the derived key token and Sign the SOAP Body and WS-Addressing headers
WSSSignature appReqSig = wssFactory.newWSSSignature(dktSig);
appReqSig.setSignatureMethod(WSSSignature.HMAC_SHA1);
appReqSig.setCanonicalizationMethod(WSSSignature.EXC_C14N);
...
applicationGenCon.add(appReqSig);

// Add the derived key token and Encrypt the SOAP Body and the Signature
WSSEncryption appReqEnc = wssFactory.newWSSEncryption(dktEnc);
appReqEnc.setEncryptionMethod(WSSEncryption.AES128);
appReqEnc.setTokenReference(SecurityToken.REF_STR);
appReqEnc.encryptKey(false);
...
applicationGenCon.add(appReqEnc);

// Create the application consuming context for the response message
WSSConsumingContext applicationConCon = wssFactory.newWSSConsumingContext();

//client and service labels and decryption algorithm
SCTConsumeCallbackHandler sctCbHandler = new SCTConsumeCallbackHandler("WS-SecureConversation",
                                                                       "WS-SecureConversation",
                                                                       WSSDecryption.AES128);

// Derive the token from SCT and use it to Decrypt the SOAP Body and the Signature
WSSDecryption appRspDec = wssFactory.newWSSDecryption(SecurityContextToken.class,
                                                      sctCbHandler);
appRspDec.addAllowedEncryptionMethod(WSSDecryption.AES128);
appRspDec.encryptKey(false);
...
applicationConCon.add(appRspDec);

// Derive the token from SCT and use it to Verify the
// signature on the SOAP Body, WS-Addressing headers, and Timestamp
WSSVerification appRspVfy = wssFactory.newWSSVerification(SecurityContextToken.class,
                                                          sctCbHandler);
...
applicationConCon.add(appRspVfy);
...
applicationGenCon.process(reqContext);
applicationConCon.process(reqContext);
```

What to do next

For each token type, configure the token using the WSS APIs or using the administrative console. Next, specify the similar consumer tokens if you have not done so.

If both the generator and consumer tokens are configured, continue securing SOAP messages either by signing the SOAP message or by encrypting the message, as needed. You can use either the WSS APIs or the administrative console to secure the SOAP messages.

Sending self-issued SAML bearer tokens using WSS APIs:

You can create self-issued SAML tokens with the bearer subject confirmation method and then send these tokens with Web services request messages using the Java API for XML-Based Web Services (JAX-WS) programming model and Web Services Security APIs (WSS API).

Before you begin

This task assumes that you are familiar with the JAX-WS programming model, the WSS API interfaces, SAML concepts, and the use of policy sets to configure and administer web services settings.

About this task

You can build your web services client to use SAML tokens with the bearer subject confirmation method in SOAP request messages using the Web Services Security programming interfaces. Using the programming interfaces in a web services client to specify the use of SAML tokens with bearer subject confirmation is an alternative approach to using policy sets and binding configurations.

You can create a self-issued SAML token and then send the SAML token in web services request messages from a web services client. The web services application client used in this task is a modified version of the client code that is contained in the JaxWSServicesSamples sample application that is available for download. Code snippets from the sample are described in the procedure section, and a complete, ready-to-use web services client sample is provided in the Example section.

Procedure

1. Identify and obtain the web services client that you want to use to invoke a web services provider.

   Use this client to insert SAML tokens in SOAP request messages programmatically using WSS APIs.

   The web services client used in this procedure is a modified version of the client code that is contained in the JaxWSServicesSamples web services sample application.

   To obtain and modify the sample web services client to add the Web Services Security API to pass SAML tokens in SOAP request messages programmatically using WSS APIs, complete the following steps:

   a. Download the JaxWSServicesSamples sample application. The JaxWSServicesSamples sample is not installed by default.

   b. Obtain the JaxWSServicesSamples client code.

      For example purposes, this procedure uses a modified version of the Echo thin client sample that is included in the JaxWSServicesSamples sample. The web services Echo thin client sample file, `SampleClient.java`, is located in the `src\SampleClientSei\src\com\ibm\was\wssample\sei\cli` directory. The sample class file is included in the `WSSampleClientSei.jar` file.

      The `JaxWSServicesSamples.ear` enterprise application and supporting Java archives (JAR) files are located in the `installableApps` directory within the JaxWSServicesSamples sample application.

   c. Deploy the `JaxWSServicesSamples.ear` file onto the application server. After you deploy the `JaxWSServicesSamples.ear` file, you are ready to test the sample web services client code against the sample application.

   Instead of using the web services client sample, you can choose to add the code snippets to pass SAML tokens in SOAP request messages programmatically using WSS APIs in your own web services client application. The example in this procedure uses a JAX-WS Web services thin client; however, you can also use a managed client.

2. Attach the SAML20 Bearer WSHTTPS default policy set to the web services provider. This policy set is used to protect messages using HTTPS transport. Read about configuring client and provider bindings for the SAML Bearer token for details on how to attach the SAML20 Bearer WSHTTPS default policy set to the Web services provider. The example in this procedure uses self-issued SAML tokens. When you configure the provider bindings, the truststore configuration and certificate must match the signing key of the self-issued token.

3. Assign the SAML Bearer Provider sample default general bindings to the sample web services provider. Read about configuring client and provider bindings for the SAML bearer token for details on assigning the SAML Bearer Provider sample default general bindings to your web services application.

4. Create the self-issued SAML token. The following code snippet illustrates creating the SAML token:

```
// Create the SAML token.
HashMap<Object, Object> map = new HashMap<Object, Object>();
map.put(SamlConstants.CONFIRMATION_METHOD, "Bearer");
map.put(SamlConstants.TOKEN_TYPE, WSSConstants.SAML.SAML20_VALUE_TYPE);
map.put(SamlConstants.SAML_NAME_IDENTIFIER, "Alice");
map.put(SamlConstants.SIGNATURE_REQUIRED, "true");
SAMLGenerateCallbackHandler callbackHandler = new SAMLGenerateCallbackHandler(map);
SecurityToken samlToken = factory.newSecurityToken(SAMLToken.class, callbackHandler, "system.wss.generate.saml");

System.out.println("SAMLToken id = " + samlToken.getId());
```

   a. Use the CallService() method to specify the Web services security configuration parameters that are required to invoke a target Web services provider using a self-issued SAML token.

      The CallService() method sets the configuration parameters that are required by the Web Services Security runtime environment via the `com.ibm.websphere.wssecurity.wssapi.WSSGenerationContext` custom property to generate a self-issued SAMLToken.

Read about configuring a SAML token during token creation for more information about how you can specify configuration properties to control how the token is configured.

b. Add the Thin Client for JAX-WS JAR file to the class path. Add the *app_server_root*/runtimes/com.ibm.jaxws.thinclient_8.5.0.jar file to the class path. See the testing web services-enabled clients information for more information about adding this JAR file to the class path.

c. Use the WSSFactory newSecurityToken method to specify how to create the SAML token.

Specify the following method to create the SAML token:

```
WSSFactory  newSecurityToken(SAMLToken.class, callbackHandler, "system.wss.generate.saml")
```

Creating a SAML token requires the Java security permission wssapi.SAMLTokenFactory.newSAMLToken. Use the PolicyTool to add the following policy statement to the Java security policy file or the application client was.policy file:

```
permission java.security.SecurityPermission "wssapi.SAMLTokenFactory.newSAMLToken
```

The `SAMLToken.class` parameter specifies the type of security token to create.

The `callbackHandler` object contains parameters that define the characteristics of the SAMLToken that you are creating. This object points to a SAMLGenerateCallbackHandler object that specifies the configuration parameters described in the following table:

Table 201. SAMLGenerateCallbackHandler properties. This table describes the configuration parameters for the SAMLGenerateCallbackHandler object using the bearer subject confirmation method.

Property	Description	Required
SamlConstants.CONFIRMATION_METHOD	Specifies to use the `Bearer` confirmation method.	Yes
SamlConstants.TOKEN_TYPE	Uses the constant value, `WSSConstants.SAML.SAML20_VALUE_TYPE`, to specify a SAML 2.0 token type. When a web services client has policy set attachments, this property is not used by Web Services Security runtime environment. In this scenario, specify the token value type by the valueType attribute of the tokenGenerator binding configuration. The example in this procedure uses a SAML 2.0 token; however, you can also use the `WSSConstants.SAML.SAML11_VALUE_TYPE` value.	Yes
SamlConstants.SAML_NAME_IDENTIFIER	Specifies a user identity such as `myname` as the NameID value in the SAML token. If you do not define this parameter when using the Thin Client for JAX-WS, the NameID value does not contain useful information. If you are using a web services managed client, such a Java Platform, Enterprise Edition (Java EE) application making a web services request invocation, the Web Services Security runtime environment tries to extract user security information from the security context. Similarly, if you do not define this parameter for a managed web services client, the NameID value contains an UNAUTHENTICATED name identifier. This property is not used if your web services client has policy set attachments. Read about sending SAML tokens to learn more about sending the SAML token identity and attributes.	No
SamlConstants.SIGNATURE_REQUIRED	Specifies whether the issuer is required to digitally sign the SAML token. A `true` value specifies that issuer is required to digitally sign the SAML token. This value is the default.	No

The `system.wss.generate.saml` parameter specifies the Java Authentication and Authorization Service (JAAS) login module that is used to create the SAML token. You must specify a JVM property to define a JAAS configuration file that contains the required JAAS login configuration; for example:

```
-Djava.security.auth.login.config=profile_root/properties/wsjaas_client.conf
```

Alternatively, you can specify a JAAS login configuration file by setting a Java system property in the sample client code; for example:

```
System.setProperty("java.security.auth.login.config", "profile_root/properties/wsjaas_client.conf ");
```

d. Obtain the token identifier of the created SAML token.

Use the following statement as a simple test for the SAML token that you created:

```
System.out.println("SAMLToken id = " + samlToken.getId())
```

5. Add the SAML token to the SOAP security header of a Web services request messages.
   a. Initialize the web services client and configure the SOAPAction properties. The following code snippet illustrates these actions:

```
// Initialize web services client
EchoService12PortProxy echo = new EchoService12PortProxy();
echo._getDescriptor().setEndpoint(endpointURL);

// Configure SOAPAction properties
BindingProvider bp = (BindingProvider) (echo._getDescriptor().getProxy());
Map<String, Object> requestContext = bp.getRequestContext();
requestContext.put(BindingProvider.ENDPOINT_ADDRESS_PROPERTY, endpointURL);
requestContext.put(BindingProvider.SOAPACTION_USE_PROPERTY, Boolean.TRUE);
requestContext.put(BindingProvider.SOAPACTION_URI_PROPERTY, "echoOperation");
```

   b. Initialize the WSSGenerationContext. The following code illustrates the use of the WSSGenerationContext interface to initialize a generation context and enable you to insert the `SAMLToken` into the web services request message:

```
// Initialize WSSGenerationContext
WSSGenerationContext gencont = factory.newWSSGenerationContext();
gencont.add(samlToken);
```

      Specifically, the `gencont.add(samlToken)` method call specifies to put the SAML token into a request message. Use the PolicyTool to add the following policy statement to the Java security policy file or the application client was.policy file:

```
 "permission javax.security.auth.AuthPermission "modifyPrivateCredentials"
```

   c. Add the timestamp element in the SOAP messages security header. The SAML20 Bearer WSHTTPS default policy set requires web services requests and response messages to carry a timestamp element in SOAP messages Security header. In the following code snippet, the `factory.newWSSTimestamp()` method call generates the timestamp, and the `gencont.add(timestamp)` method call specifies the timestamp to put into a request message:

```
// Add a timestamp to the request message.
WSSTimestamp timestamp = factory.newWSSTimestamp();
gencont.add(timestamp);

gencont.process(requestContext);
```

   d. Attach WSSGenerationContext object to the web services RequestContext object. The WSSGenerationContext object now contains all the security information that is required to format a request message. The `gencont.process(requestContext)` method call attaches the WSSGenerationContext object to the web services RequestContext object to enable the Web Services Security runtime environment to format the required SOAP security header; for example:

```
// Attaches WSSGenerationContext object to the web services RequestContext object.
gencont.process(requestContext);
```

   e. Specify SSL transport level message protection using JVM properties.

      The SAML20 Bearer WSHTTPS default policy set requires transport-level message protection using SSL. Specify SSL transport-level message protection using the following JVM property:

```
-Dcom.ibm.SSL.ConfigURL=file:profile_root\properties\ssl.client.props
```

      Alternatively, you can define the SSL configuration file using a Java system property in the sample client code; for example:

```
System.setProperty("com.ibm.SSL.ConfigURL", "file:profile_root/properties/ssl.client.props");
```

Results

You have created a self-issued SAML token with the bearer subject confirmation method and then sent this token with web services request messages using the JAX-WS programming model and WSS APIs.

Example

The following code sample is a web services client application that demonstrates how to create a self-issued SAML token and send that SAML token in web services request messages. If your usage

scenario requires SAML tokens, but does not require your application to pass the SAML tokens using web services messages, you only need to use the first part of the following sample code, up through the `// Initialize web services client` section.

```
/**
 * The following source code is sample code created by IBM Corporation.
 * This sample code is provided to you solely for the purpose of assisting you in the
 * use of the technology.  The code is provided 'AS IS', without warranty or condition of
 * any kind.  IBM shall not be liable for any damages arising out of your use of the
 * sample code, even if IBM has been advised of the possibility of such damages.

      // Initialize WSSGenerationContext
      WSSGenerationContext gencont = factory.newWSSGenerationContext();
      // Initialize SAML issuer configuration via custom properties
      HashMap<Object, Object> customProps = new HashMap<Object,Object>();

      customProps.put(SamlConstants.ISSUER_URI_PROP, "example.com");
      customProps.put(SamlConstants.TTL_PROP, "3600000");
      customProps.put(SamlConstants.KS_PATH_PROP, "keystores/saml-provider.jceks");
      customProps.put(SamlConstants.KS_TYPE_PROP, "JCEKS");
      customProps.put(SamlConstants.KS_PW_PROP, "{xor}LCswLTovPiws");
      customProps.put(SamlConstants.KEY_ALIAS_PROP, "samlissuer");
      customProps.put(SamlConstants.KEY_NAME_PROP, "CN=SAMLIssuer, O=EXAMPLE");
      customProps.put(SamlConstants.KEY_PW_PROP, "{xor}NDomLz4sLA==");
      customProps.put(SamlConstants.TS_PATH_PROP, "keystores/saml-provider.jceks");
      customProps.put(SamlConstants.TS_TYPE_PROP, "JCEKS");
      customProps.put(SamlConstants.TS_PW_PROP, "{xor}LCswLTovPiws");
      gencont.add(customProps); //Add custom properties
```

```
      // Create SAMLToken
      HashMap<Object, Object> map = new HashMap<Object, Object>();
      map.put(SamlConstants.CONFIRMATION_METHOD, "Bearer");
      map.put(SamlConstants.TOKEN_TYPE, WSSConstants.SAML.SAML20_VALUE_TYPE);
      map.put(SamlConstants.SAML_NAME_IDENTIFIER, "Alice");
      map.put(SamlConstants.SIGNATURE_REQUIRED, "true");
      SAMLGenerateCallbackHandler callbackHandler = new SAMLGenerateCallbackHandler(map);

      SecurityToken samlToken = factory.newSecurityToken(SAMLToken.class, callbackHandler, "system.wss.generate.saml");

      System.out.println("SAMLToken id = " + samlToken.getId());

      // Initialize web services client
      EchoService12PortProxy echo = new EchoService12PortProxy();
      echo._getDescriptor().setEndpoint(endpointURL);

      // Configure SOAPAction properties
      BindingProvider bp = (BindingProvider) (echo._getDescriptor().getProxy());
      Map<String, Object> requestContext = bp.getRequestContext();
      requestContext.put(BindingProvider.ENDPOINT_ADDRESS_PROPERTY, endpointURL);
      requestContext.put(BindingProvider.SOAPACTION_USE_PROPERTY, Boolean.TRUE);
      requestContext.put(BindingProvider.SOAPACTION_URI_PROPERTY, "echoOperation");

      gencont.add(samlToken);

      // Add timestamp
      WSSTimestamp timestamp = factory.newWSSTimestamp();
      gencont.add(timestamp);

      gencont.process(requestContext);

      // Build the input object
      EchoStringInput echoParm =
        new com.ibm.was.wssample.sei.echo.ObjectFactory().createEchoStringInput();
      echoParm.setEchoInput(input);
      System.out.println(">> CLIENT: SEI Echo to " + endpointURL);

      // Prepare to consume timestamp in response message.
      WSSConsumingContext concont = factory.newWSSConsumingContext();
      concont.add(WSSConsumingContext.TIMESTAMP);
      concont.process(requestContext);

      // Call the service
      response = echo.echoOperation(echoParm).getEchoResponse();

      System.out.println(">> CLIENT: SEI Echo invocation complete.");
      System.out.println(">> CLIENT: SEI Echo response is: " + response);
    } catch (Exception e) {
      System.out.println(">> CLIENT: ERROR: SEI Echo EXCEPTION.");
      e.printStackTrace();
    }
  }
}
```

When this web services client application sample runs correctly, you receive messages like the following messages:

```
SAMLToken id = _191EBC44865015D9AB1270745072344
Retrieving document at 'file:profile_root/.../wsdl/'.
>> CLIENT: SEI Echo to https://localhost:9443/WSSampleSei/EchoService12
>> CLIENT: SEI Echo invocation complete.
>> CLIENT: SEI Echo response is: SOAP12==>>HELLO
```

Inserting SAML attributes using WSS APIs:

You can insert custom attributes into self-issued SAML tokens by using the Java API for XML-Based Web Services (JAX-WS) programming model and Web Services Security APIs (WSS APIs).

Before you begin

This task assumes that you are familiar with the JAX-WS programming model, the WSS API interfaces, SAML concepts, and the use of policy sets to configure and administer web services settings. Complete the following actions before you begin this task:

- Read about propagating self-issued SAML bearer tokens by using WSS APIs.
- Read about propagating self-issued SAML sender-vouches tokens by using WSS APIs with message level protection.

- Read about propagating self-issued SAML sender-vouches tokens by using WSS APIs with SSL transport protection.
- Read about propagating self-issued SAML holder-of-key tokens with symmetric key by using WSS APIs.
- Read about propagating self-issued SAML holder-of-key tokens with asymmetric key by using WSS APIs.

About this task

This task shows example code that inserts custom attributes into self-issued SAML security tokens. This particular example uses the bearer subject confirmation method. You can add attributes to any SAML security tokens, and the same code can be used with other subject confirmation methods.

Procedure

Insert custom attributes when creating SAML security tokens; for example:

```
import com.ibm.websphere.wssecurity.wssapi.token.SecurityToken;
import com.ibm.websphere.wssecurity.callbackhandler.SAMLGenerateCallbackHandler;
import com.ibm.websphere.wssecurity.wssapi.token.SAMLToken;
import com.ibm.wsspi.wssecurity.core.token.config.WSSConstants;
import com.ibm.wsspi.wssecurity.saml.config.SamlConstants;
import com.ibm.wsspi.wssecurity.saml.data.SAMLAttribute;

WSSFactory factory = WSSFactory.getInstance();
HashMap<Object, Object> map = new HashMap<Object, Object>();
map.put(SamlConstants.CONFIRMATION_METHOD, "Bearer");
map.put(SamlConstants.Token_REQUEST, "issue");
map.put(SamlConstants.TOKEN_TYPE, WSSConstants.SAML.SAML20_VALUE_TYPE);
map.put(SamlConstants.SAML_NAME_IDENTIFIER, "Alice");
map.put(SamlConstants.SIGNATURE_REQUIRED, "true");
ArrayList<SAMLAttribute> al = new ArrayList<SAMLAttribute>();
String groups[] = {"IBMer", "Texan"};
SAMLAttribute sattribute = new SAMLAttribute("Membership", groups, null,null, null, null);
al.add(sattribute);
String gender[] = {"Female"};
sattribute = new SAMLAttribute("Gender", gender, null,null, null, null);
al.add(sattribute);
map.put(SamlConstants.SAML_ATTRIBUTES, al);
SAMLGenerateCallbackHandler callbackHandler = new SAMLGenerateCallbackHandler(map);
SecurityToken samlToken = factory.newSecurityToken(SAMLToken.class, callbackHandler,
                                                   "system.wss.generate.saml");
```

Results

You have inserted custom attributes to a SAML security token.

Example

The following example shows the custom attributes in the SAML Assertion:

```
<saml2:Assertion xmlns:saml2="urn:oasis:names:tc:SAML:2.0:assertion"
                 Version="2.0"
                      ID="_E62A1CA3C2F21D9A9B1287772824570"
                      IssueInstant="2010-10-22T18:40:24.531Z">
    <saml2:Issuer>example.com</saml2:Issuer>
    <ds:Signature xmlns:ds="http://www.w3.org/2000/09/xmldsig#">
    ...
    </ds:Signature>
    <saml2:Subject>
        <saml2:NameID>Alice</saml2:NameID>
        <saml2:SubjectConfirmation Method="urn:oasis:names:tc:SAML:2.0:cm:bearer"></saml2:SubjectConfirmation>
    </saml2:Subject>
    <saml2:Conditions NotBefore="2010-10-22T18:40:24.531Z"
                   NotOnOrAfter="2010-10-22T19:40:24.531Z">
    </saml2:Conditions>
    <saml2:AttributeStatement>
        <saml2:Attribute Name="Membership">
            <saml2:AttributeValue>IBMer</saml2:AttributeValue>
            <saml2:AttributeValue>Texan</saml2:AttributeValue>
        </saml2:Attribute>
```

```
        <saml2:Attribute Name="Gender">
            <saml2:AttributeValue>Female</saml2:AttributeValue>
        </saml2:Attribute>
    </saml2:AttributeStatement>
</saml2:Assertion>
```

What to do next

Merge the code with the example code listed in the “Propagating self-issued SAML bearer tokens by using WSS APIs” topic to generate SAML security tokens. You can see SAML attributes in the SAML Assertions.

Sending self-issued SAML sender-vouches tokens using WSS APIs with message level protection:

You can create self-issued SAML tokens with the sender-vouches subject confirmation method and then use the Java API for XML-Based Web Services (JAX-WS) programming model and Web Services Security APIs (WSS APIs) to send these tokens with web services request messages with message level protection.

Before you begin

This task assumes that you are familiar with the JAX-WS programming model, the WSS API interfaces, SAML concepts, and the use of policy sets to configure and administer web services settings.

About this task

You can protect SOAP request messages and SAML tokens by using the Web Services Security programming interface to satisfy the sender-vouches subject confirmation method validation requirements with message level protection. Using the programming interfaces in web services client is an alternative approach to using policy set and binding configuration.

You can create a self-issued SAML token and then send the SAML token in web services request messages from a web services client. The web services application client used in this task is a modified version of the client code that is contained in the JaxWSServicesSamples sample application that is available for download. Code snippets from the sample are described in the procedure section, and a complete, ready-to-use web services client sample is provided in the Example section.

This product does not provide a default policy set that requires SAML tokens with sender-vouches subject confirmation method. Read about configuring client and provider bindings for the SAML sender-vouches token to learn more about how to create a Web Services Security policy to require SAML tokens with sender-vouches subject confirmation and how to create a custom binding configuration. You must attach the policy and binding to the web services provider. The code sample described in this task assumes that the web services provider policy requires that both the SAML tokens and the message bodies are digitally signed by using an X.509 security token.

Procedure

1. Identify and obtain the web services client that you want to use to invoke a web services provider.

   Use this client to insert SAML tokens in SOAP request messages programmatically using WSS APIs.

   The web services client used in this procedure is a modified version of the client code that is contained in the JaxWSServicesSamples web services sample application.

   To obtain and modify the sample web services client to add the Web Services Security API to pass SAML sender-vouches tokens in SOAP request messages programmatically using WSS APIs, complete the following steps:

   a. Download the JaxWSServicesSamples sample application. The JaxWSServicesSamples sample is not installed by default.
   b. Obtain the JaxWSServicesSamples client code.

For example purposes, this procedure uses a modified version of the Echo thin client sample that is included in the JaxWSServicesSamples sample. The web services Echo thin client sample file, `SampleClient.java`, is located in the `src\SampleClientSei\src\com\ibm\was\wssample\sei\cli` directory. The sample class file is included in the `WSSampleClientSei.jar` file.

The `JaxWSServicesSamples.ear` enterprise application and supporting Java archives (JAR) files are located in the `installableApps` directory within the JaxWSServicesSamples sample application.

c. Deploy the `JaxWSServicesSamples.ear` file onto the application server. After you deploy the `JaxWSServicesSamples.ear` file, you are ready to test the sample web services client code against the sample application.

Instead of using the web services client sample, you can choose to add the code snippets to pass SAML tokens in SOAP request messages programmatically using WSS APIs in your own web services client application. The example in this procedure uses a JAX-WS Web services thin client; however, you can also use a managed client.

2. Use the CallService() method to specify the Web services security configuration parameters that are required to invoke a target Web services provider using a self-issued SAML token.

   The CallService() method sets configuration parameters that are required by the Web Services Security runtime environment via the `com.ibm.websphere.wssecurity.wssapi.WSSGenerationContext` custom property to generate a self-issued SAMLToken.

   The following code snippet illustrates using the CallService() method to set the `SamlConstants.SAML_SELF_ISSUER_CONFIG` system property:

```
public static void main(String[] args) {
  SampleSamlSVClient sample = new SampleSamlSVClient();
  sample.CallService();
}

/**
 * CallService Parms were already read. Now call the service proxy classes
 *
 */
void CallService() {
  String response = "ERROR!:";
  try {
    System.setProperty("java.security.auth.login.config", "profile_root/properties/wsjaas.conf");
```

   Read about configuring a SAML token during token creation for more information about how you can specify configuration properties to control how the token is configured.

3. Add the Thin Client for JAX-WS JAR file to the class path. Add *app_server_root*/runtimes/com.ibm.jaxws.thinclient_8.5.0.jar file to the class path. See the testing web services-enabled clients information for more information about adding this JAR file to the class path.

4. Create the self-issued SAML token. The following code snippet illustrates creating the SAML token:

```
// Create SAMLToken
HashMap<Object, Object> map = new HashMap<Object, Object>();
map.put(SamlConstants.CONFIRMATION_METHOD, "sender-vouches");
map.put(SamlConstants.TOKEN_TYPE, WSSConstants.SAML.SAML20_VALUE_TYPE);
map.put(SamlConstants.SAML_NAME_IDENTIFIER, "Alice");
map.put(SamlConstants.SIGNATURE_REQUIRED, "true");
SAMLGenerateCallbackHandler callbackHandler = new SAMLGenerateCallbackHandler(map);
SecurityToken samlToken = factory.newSecurityToken(SAMLToken.class, callbackHandler, "system.wss.generate.saml");
System.out.println("SAMLToken id = " + samlToken.getId());
```

   a. Use the WSSFactory newSecurityToken method to specify how to create the SAML token.

      Specify the following method to create the SAML token:

```
WSSFactory  newSecurityToken(SAMLToken.class, callbackHandler, "system.wss.generate.saml")
```

      Creating a SAML token requires the Java security permission wssapi.SAMLTokenFactory.newSAMLToken. Add the following policy statement to the Java security policy file or the application client was.policy file:

```
permission java.security.SecurityPermission "wssapi.SAMLTokenFactory.newSAMLToken
```

      The `SAMLToken.class` parameter specifies the type of security token to create.

      The `callbackHandler` object contains parameters that define the characteristics of the SAMLToken that you are creating. This object points to a SAMLGenerateCallbackHandler object that specifies the following configuration parameters described in the following table:

Table 202. SAMLGenerateCallbackHandler properties. This table describes the configuration parameters for the SAMLGenerateCallbackHandler object using the sender-vouches confirmation method.

Property	Description	Required
SamlConstants.CONFIRMATION_METHOD	Specifies to use the `sender-vouches` confirmation method.	Yes
SamlConstants.TOKEN_TYPE	Uses the constant value, `WSSConstants.SAML.SAML20_VALUE_TYPE` to specify a SAML 2.0 token type. When a web services client has policy set attachments, this property is not used by Web Services Security runtime environment. In this scenario, specify the token value type by the valueType attribute of the tokenGenerator binding configuration. The example in this procedure uses a SAML 2.0 token; however, you can also use the `WSSConstants.SAML.SAML11_VALUE_TYPE` value.	Yes
SamlConstants.SAML_NAME_IDENTIFIER	Specifies a user identity such as `myname` as the NameID value in the SAMLToken. If you do not define this parameter when using the Thin Client for JAX-WS, the NameID value does not contain useful information. If you are using a web services managed client, such a Java Platform, Enterprise Edition (Java EE) application making a web services request invocation, the Web Services Security runtime environment tries to extract user security information from the security context. Similarly, if you do not define this parameter for a managed web services client, the NameID value contains an UNAUTHENTICATED name identifier. This property is not used if your web services client has policy set attachments. Read about sending SAML tokens to learn more about sending the SAML token identity and attributes.	No
SamlConstants.SIGNATURE_REQUIRED	Specifies whether the issuer is required to digitally sign the SAML token. A `true` value specifies that issuer is required to digitally sign the SAML token. This value is the default.	No

The `system.wss.generate.saml` parameter specifies to use a Java Authentication and Authorization Service (JAAS) login configuration and specifies the login module that is invoked to create the SAML token. You must specify a JVM property to define a JAAS configuration file that contains the required JAAS login configuration; for example:

```
Djava.security.auth.login.config=profile_root/properties/wsjaas.conf
```

Alternatively, you can specify a JAAS login configuration file using a Java system property in the sample client code; for example:

```
System.setProperty("java.security.auth.login.config", "profile_root/properties/wsjaas.conf");
```

b. Obtain the token identifier of the created SAML token.

Use the following statement as a simple test for the SAML token that you created:

```
System.out.println("SAMLToken id = " + samlToken.getId())
```

5. Add the SAML token to the SOAP security header of web services request messages.

a. Initialize the web services client and configure the SOAPAction properties. The following code example illustrates these actions:

```
// Initialize web services client
EchoService12PortProxy echo = new EchoService12PortProxy();
echo._getDescriptor().setEndpoint(endpointURL);

// Configure SOAPAction properties
BindingProvider bp = (BindingProvider) (echo._getDescriptor().getProxy());
Map<String, Object> requestContext = bp.getRequestContext();
requestContext.put(BindingProvider.ENDPOINT_ADDRESS_PROPERTY, endpointURL);
requestContext.put(BindingProvider.SOAPACTION_USE_PROPERTY, Boolean.TRUE);
requestContext.put(BindingProvider.SOAPACTION_URI_PROPERTY, "echoOperation");

// Initialize WSSGenerationContext
WSSGenerationContext gencont = factory.newWSSGenerationContext();
gencont.add(samlToken);
```

b. Initialize the WSSGenerationContext. The following code snippet illustrates the use of the gencont.object of the WSSGenerationContext type to initialize a generation context to enable you to insert the SAMLToken into a web services request message:

```
// Initialize WSSGenerationContext
WSSGenerationContext gencont = factory.newWSSGenerationContext();
gencont.add(samlToken);
```

Specifically, the gencont.add(samlToken) method call specifies to put the SAML token into a request message. This operation requires the client code to have the following Java 2 Security permission:

```
 "permission javax.security.auth.AuthPermission "modifyPrivateCredentials"
```

6. Add an X.509 token for message protection.

This sample code uses the dsig-sender.ks key file and the SOAPRequester sample key. You must not use the sample key in a production environment. The following code snippet illustrates adding an X.509 token for message protection:

```
// Add an X.509 Token for message protection
X509GenerateCallbackHandler x509callbackHandler = new X509GenerateCallbackHandler(
        null,
        "profile_root/etc/ws-security/samples/dsig-sender.ks",
        "JKS",
        "client".toCharArray(),
        "soaprequester",
        "client".toCharArray(),
        "CN=SOAPRequester, OU=TRL, O=IBM, ST=Kanagawa, C=JP", null);

SecurityToken x509 = factory.newSecurityToken(X509Token.class,
        x509callbackHandler, "system.wss.generate.x509");

WSSSignature sig = factory.newWSSSignature(x509);
sig.setSignatureMethod(WSSSignature.RSA_SHA1);

WSSSignPart sigPart = factory.newWSSSignPart();
sigPart.setSignPart(samlToken);
sigPart.addTransform(WSSSignPart.TRANSFORM_STRT10);
sig.addSignPart(sigPart);
sig.addSignPart(WSSSignature.BODY);
```

a. Create a WSSSignature object with the X509 token. The following line of code creates a WSSSignature object with the X509 token:

```
WSSSignature sig = factory.newWSSSignature(x509);
```

b. Add the signed part to use for message protection. The following line of code specifies to add WSSSignature.BODY as the signed part:

```
sig.addSignPart(WSSSignature.BODY);
```

c. Add the timestamp element in the SOAP messages security header. The SAML20 SenderVouches WSHTTPS and SAML11 SenderVouches WSHTTPS policy sets require web services requests and response messages to carry a timestamp element in the SOAP messages Security header. In the following code snippet, the factory.newWSSTimestamp() method call generates the timestamp, and the gencont.add(timestamp) method call adds the timestamp into the request message:

```
// Add Timestamp
WSSTimestamp timestamp = factory.newWSSTimestamp();
gencont.add(timestamp);
sig.addSignPart(WSSSignature.TIMESTAMP);

gencont.add(sig);

WSSConsumingContext concont = factory.newWSSConsumingContext();
```

d. Configure the verification of the digital signature in the response message.

A separate WSSSignPart is needed to specify the SecurityTokenReference transformation algorithm that is represented by the WSSSignPart.TRANSFORM_STRT10 attribute. A SAML Token cannot be digitally signed directly. This attribute enables the Web Services Security runtime environment to generate a SecurityTokenReference element to reference the SAMLToken and to digitally sign the SAMLToken using the SecurityTokenReference transformation. The following line of code specifies to use the WSSSignPart.TRANSFORM_STRT10 attribute:

```
WSSSignPart sigPart = factory.newWSSSignPart();
sigPart.setSignPart(samlToken);
sigPart.addTransform(WSSSignPart.TRANSFORM_STRT10);
```

e. Attach the WSSGenerationContext object to the web services RequestContext object. The WSSGenerationContext object now contains all the security information that is required to format a

request message. The `gencont.process(requestContext)` method call attaches the WSSGenerationContext object to the web services RequestContext object to enable the Web Services Security runtime environment to format the required SOAP security header; for example:

```
// Attaches the WSSGenerationContext object to the web services RequestContext object.
gencont.process(requestContext);
```

7. Use the X.509 token to validate the digital signature and the integrity of the response message. If the provider policy requires the response message to be digitally signed, you must initialize the X.509 token.
   a. A X509ConsumeCallbackHandler object is initialized with a truststore, dsig-receiver.ks, and a certificate path object to validate the provider digital signature. The following line of code is used to initialize the X509ConsumeCallbackHandler object:

```
X509ConsumeCallbackHandler callbackHandlerVer = new X509ConsumeCallbackHandler(
        "profile_root/etc/ws-security/samples/dsig-receiver.ks",
        "JKS",
        "server".toCharArray(),
        certList,
        java.security.Security.getProvider("IBMCertPath"));
```

   b. A WSSVerification object is created and the message body is added to the verification object so that the Web Services Security runtime environment validates the digital signature.

      The following line of code is used to initialize the WSSVerification object:

```
WSSVerification ver = factory.newWSSVerification(X509Token.class, callbackHandlerVer);
```

      The WSSConsumingContext object now contains all the security information that is required to format a request message. The `concont.process(requestContext)` method call attaches the WSSConsumingContext object to the response method; for example:

```
// Attaches the WSSConsumingContext object to the web services RequestContext object.
concont.process(requestContext);
```

Results

You have created a self-issued SAML token with the sender-vouches confirmation method and then sent this token with web services request messages using the JAX-WS programming model and WSS APIs.

Example

The following code sample is a complete, ready-to-use web services client application that demonstrates how to create a self-issued SAML sender-vouches token and send that SAML token in web services request messages. This sample code illustrates the procedure steps described previously.

```

      System.out.println(">> CLIENT: ERROR: SEI Echo EXCEPTION.");
      e.printStackTrace();
    }
  }
}
```

When this web services client application sample runs correctly, you receive messages like the following messages:

```
SAMLToken id = _6CDDF0DBF91C044D211271166233407
Retrieving document at 'file:profile_root/.../wsdl/'.
>> CLIENT: SEI Echo to http://localhost:9080/WSSampleSei/EchoService12
>> CLIENT: SEI Echo invocation complete.
>> CLIENT: SEI Echo response is: SOAP12==>>HELLO
```

Sending self-issued SAML sender-vouches tokens using WSS APIs with SSL transport protection:

You can create self-issued SAML tokens with the sender-vouches subject confirmation method and then use the Java API for XML-Based Web Services (JAX-WS) programming model and Web Services Security APIs (WSS APIs) to send these tokens with web services request messages with transport protection.

Before you begin

This task assumes that you are familiar with the JAX-WS programming model, the WSS API interfaces, SAML concepts, SSL transport protection, and the use of policy sets to configure and administer web services settings.

About this task

You can build your web services client to use SAML tokens with the sender-vouches subject confirmation method in SOAP request messages using the Web Services Security programming interfaces. Using the programming interfaces in a web services client to specify the use of SAML tokens with sender-vouches subject confirmation using message protection at the transport level is an alternative approach to using policy sets and binding configurations.

You can create a self-issued SAML token and then send the SAML token in web services request messages from a web services client. The web services client application used in this task is a modified version of the client code that is contained in the JaxWSServicesSamples sample application that is available for download. Code examples from the sample are described in the procedure section, and a complete, ready-to-use web services client sample is provided in the Example section.

Procedure

1. Identify and obtain the web services client that you want to use to invoke a web services provider.

   Use this client to insert SAML tokens in SOAP request messages programmatically using WSS APIs.

   The web services client used in this procedure is a modified version of the client code that is contained in the JaxWSServicesSamples web services sample application.

   To obtain and modify the sample web services client to use the Web Services Security API to pass SAML sender-vouches tokens in SOAP request messages programmatically using WSS APIs, complete the following steps:

   a. Download the JaxWSServicesSamples sample application. The JaxWSServicesSamples sample is not installed by default.
   b. Obtain the JaxWSServicesSamples client code.

      For example purposes, this procedure uses a modified version of the Echo thin client sample that is included in the JaxWSServicesSamples sample. The web services Echo thin client sample file, `SampleClient.java`, is located in the `src\SampleClientSei\src\com\ibm\was\wssample\sei\cli` directory. The sample class file is included in the `WSSampleClientSei.jar` file.

The `JaxWSServicesSamples.ear` enterprise application and supporting Java archives (JAR) files are located in the `installableApps` directory within the JaxWSServicesSamples sample application.

c. Deploy the `JaxWSServicesSamples.ear` file onto the application server. After you deploy the `JaxWSServicesSamples.ear` file, you are ready to test the sample web services client code against the sample application.

Instead of using the web services client sample, you can choose to add the code snippets to pass SAML tokens in SOAP request messages programmatically using WSS APIs in your own web services client application. The example in this procedure uses a JAX-WS Web services thin client; however, you can also use a managed client.

2. Create a copy of either the SAML20 Bearer WSHTTPS default policy set or the SAML11 Bearer WSHTTPS default policy set.

   Provide a name for the copy of the policy set; for example SAML20 SenderVouches WSHTTPS or SAML11 SenderVouches WSHTTPS to help you identify that this new policy set uses the sender-vouches confirmation method.

   No additional change is required to the new policy file because the subject confirmation method is specified in the binding configuration and not in the policy.

   The new policy file contains either SAMLToken20Bearer or the SAMLToken11Bearer as the policy identifiers. Change the identifier of the SAMLToken20Bearer policy to SAMLToken20SV or change the identifier of the SAMLToken11Bearer policy to SAMLToken11SV to specify a more descriptive name. Changing the identifier of the policy does not change the policy enforcement in any way; however, adding a descriptive identifier helps you to identify that these policy identifiers use the sender-vouches confirmation method.

   If you want to view the settings of these policies, use the administrative console to complete the following actions:

   a. Click **Services** > **Policy sets** > **Application policy sets** > ***policy_set_name***.

   b. Click the **WS-Security** policy in the policies table.

   c. Click the **Main policy** link or the **Bootstrap policy** link.

   d. Click **Request token policies** from the Policy Details section.

3. Attach the new SAML20 SenderVouches WSHTTPS or SAML11 SenderVouches WSHTTPS policy set to the web services provider application. Read about configuring client and provider bindings for the SAML sender-vouches token for details on attaching this policy set to your web services provider application.

4. Create a copy of the SAML Bearer Provider sample default general bindings.

   a. For the new copy of the default policy set, provide a name that includes sender-vouches, such as `SAML Sender-vouches provider binding`.

   b. Change the value of the confirmationMethod property to `sender-vouches` in the token consumer configuration for the intended SAML token version. Read about configuring client and provider bindings for the SAML sender-vouches token for details on modifying the sender-vouches bindings to satisfy the vouching requirement.

5. Assign the new provider binding to the JaxWSServicesSamples provider sample. Read about configuring client and provider bindings for the SAML sender-vouches for details on assigning the SAML sender-vouches provider sample, default general bindings to your web services provider application.

6. Enable the web services provider SSL configuration attribute, clientAuthentication, to require X.509 client certificate authentication.

   The clientAuthentication attribute determines whether SSL client authentication is required. To specify the clientAuthentication attribute, use the administrative console to complete the following actions:

   a. Click **Security** > **SSL certificates and key management** > **Manage endpoint security configurations** > **{Inbound | Outbound}** > ***SSL_configuration***.

   b. Click the **WC_defaulthost_secure** link.

   c. Under Related Items, click the **SSL_configurations** link.

d. Select the **NodeDefaultSSLSettings** resource.

e. Click **Quality of protection (QoP) settings** link.

f. Select **Required** from the menu to specify client authentication.

Read about creating a secure sockets layer configuration to learn more about configuring the clientAuthentication attribute.

7. In the web services client code, use the CallService() method to specify the properties file that contains configuration parameters required to generate a self-issued SAML token.

   The CallService() method specifies configuration parameters that are required by the Web Services Security runtime environment to generate a self-issued SAMLToken.

   The following code snippet illustrates using the CallService() method to specify Web services security configuration parameters:

```
public static void main(String[] args) {
  SampleSamlSVClient sample = new SampleSamlSVClient();
  sample.CallService();
 }

/**
 * CallService Parms were already read. Now call the service proxy classes
 *
 */
void CallService() {
  String response = "ERROR!:";
  try {
    System.setProperty("java.security.auth.login.config", "profile_root/properties/wsjaas_client.conf ");
    // Initialize WSSFactory object
    WSSFactory factory = WSSFactory.getInstance();

    // Initialize WSSGenerationContext
    WSSGenerationContext gencont = factory.newWSSGenerationContext();
    // Initialize SAML issuer configuration via custom properties
    HashMap <Object, Object> customProps = new HashMap<Object,Object>();

    customProps.put(SamlConstants.ISSUER_URI_PROP, "example.com");
    customProps.put(SamlConstants.TTL_PROP, "3600000");
    customProps.put(SamlConstants.KS_PATH_PROP, "keystores/saml-provider.jceks");
    customProps.put(SamlConstants.KS_TYPE_PROP, "JCEKS");
    customProps.put(SamlConstants.KS_PW_PROP, "{xor}LCswLTovPiws");
    customProps.put(SamlConstants.KEY_ALIAS_PROP, "samlissuer");
    customProps.put(SamlConstants.KEY_NAME_PROP, "CN=SAMLIssuer, O=EXAMPLE");
    customProps.put(SamlConstants.KEY_PW_PROP, "{xor}NDomLz4sLA==");
    customProps.put(SamlConstants.TS_PATH_PROP, "keystores/saml-provider.jceks");
    customProps.put(SamlConstants.TS_TYPE_PROP, "JCEKS");
    customProps.put(SamlConstants.TS_PW_PROP, "{xor}LCswLTovPiws");
    gencont.add(customProps); //Add custom properties
```

   Read about configuring a SAML token during token creation for more information about how you can specify configuration properties to control how the token is configured.

8. Add the Thin Client for JAX-WS JAR file to the classpath. Add *app_server_root*/runtimes/com.ibm.jaxws.thinclient_8.5.0.jar file to the classpath. See the testing web services-enabled clients information for more information about adding this JAR file to the classpath.

9. Create the self-issued SAML token. The following code snippet illustrates creating the SAML sender-vouches token:

```
// Create SAMLToken
HashMap<Object, Object> map = new HashMap<Object, Object>();
map.put(SamlConstants.CONFIRMATION_METHOD, "sender-vouches");
map.put(SamlConstants.TOKEN_TYPE, WSSConstants.SAML.SAML20_VALUE_TYPE);
map.put(SamlConstants.SAML_NAME_IDENTIFIER, "Alice");
map.put(SamlConstants.SIGNATURE_REQUIRED, "true");
SAMLGenerateCallbackHandler callbackHandler = new SAMLGenerateCallbackHandler(map);
SecurityToken samlToken = factory.newSecurityToken(SAMLToken.class, callbackHandler, "system.wss.generate.saml");
System.out.println("SAMLToken id = " + samlToken.getId());
```

   a. Use the WSSFactory newSecurityToken method to specify how to create the SAML token.

      Specify the following method to create the SAML token:

```
WSSFactory  newSecurityToken(SAMLToken.class, callbackHandler, "system.wss.generate.saml")
```

      Creating a SAML token requires the Java security permission wssapi.SAMLTokenFactory.newSAMLToken. Use the PolicyTool to add the following policy statement to the Java security policy file or the application client was.policy file:

```
permission java.security.SecurityPermission "wssapi.SAMLTokenFactory.newSAMLToken
```

      The `SAMLToken.class` parameter specifies the type of security token to create.

The `callbackHandler` object contains parameters that define the characteristics of the SAMLToken that you are creating. This object points to a SAMLGenerateCallbackHandler object that specifies the configuration parameters described in the following table:

Table 203. SAMLGenerateCallbackHandler properties. This table describes the configuration parameters for the SAMLGenerateCallbackHandler object using the sender-vouches confirmation method.

Property	Description	Required
SamlConstants.CONFIRMATION_METHOD	Specifies to use the `sender-vouches` confirmation method.	Yes
SamlConstants.TOKEN_TYPE	Uses the constant value, `WSSConstants.SAML.SAML20_VALUE_TYPE` to specify a SAML 2.0 token type. When a web services client has policy set attachments, this property is not used by Web Services Security runtime environment. In this scenario, specify the token value type by the valueType attribute of the tokenGenerator binding configuration. The example in this procedure uses a SAML 2.0 token; however, you can also use the `WSSConstants.SAML.SAML11_VALUE_TYPE` value.	Yes
SamlConstants.SAML_NAME_IDENTIFIER	Specifies a user identity such as `myname` as the NameID value in the SAMLToken. If you do not define this parameter when using the Thin Client for JAX-WS, the NameID value does not contain useful information. If you are using a web services managed client, such a Java Platform, Enterprise Edition (Java EE) application making a web services request invocation, the Web Services Security runtime environment tries to extract user security information from the security context. Similarly, if you do not define this parameter for a managed web services client, the NameID value contains an UNAUTHENTICATED name identifier. This property is not used if your web services client has policy set attachments. Read about sending SAML tokens to learn more about sending the SAML token identity and attributes.	No
SamlConstants.SIGNATURE_REQUIRED	Specifies whether the issuer is required to digitally sign the SAML token. A `true` value specifies that issuer is required to digitally sign the SAML token. This value is the default.	No

The `system.wss.generate.saml` parameter specifies the Java Authentication and Authorization Service (JAAS) login module that is used to create the SAML token. You must specify a JVM property to define a JAAS configuration file that contains the required JAAS login configuration; for example:

```
-Djava.security.auth.login.config=profile_root/properties/wsjaas_client.conf
```

Alternatively, you can specify a JAAS login configuration file by setting a Java system property in the sample client code; for example:

```
System.setProperty("java.security.auth.login.config", "profile_root/properties/wsjaas_client.conf ");
```

b. Obtain the token identifier of the created SAML token.

Use the following statement as a simple test for the SAML token that you created:

```
System.out.println("SAMLToken id = " + samlToken.getId())
```

Results

You have created a self-issued SAML token with the sender-vouches confirmation method with transport protection and then sent this token with web services request messages using the JAX-WS programming model and WSS APIs.

Example

The following code sample is a complete, ready-to-use web services client application that demonstrates how to create a self-issued SAML sender-vouches token and send that SAML token in web services request messages. This sample code illustrates the procedure steps described previously.

```
/**

      map.put(SamlConstants.SAML_NAME_IDENTIFIER, "Alice");
      map.put(SamlConstants.SIGNATURE_REQUIRED, "true");
      SAMLGenerateCallbackHandler callbackHandler = new SAMLGenerateCallbackHandler(map);
      SecurityToken samlToken = factory.newSecurityToken(SAMLToken.class, callbackHandler, "system.wss.generate.saml");

      System.out.println("SAMLToken id = " + samlToken.getId());

      // Initialize web services client
```

```
      EchoService12PortProxy echo = new EchoService12PortProxy();
      echo._getDescriptor().setEndpoint(endpointURL);

      // Configure SOAPAction properties
      BindingProvider bp = (BindingProvider) (echo._getDescriptor().getProxy());
      Map<String, Object> requestContext = bp.getRequestContext();
      requestContext.put(BindingProvider.ENDPOINT_ADDRESS_PROPERTY, endpointURL);
      requestContext.put(BindingProvider.SOAPACTION_USE_PROPERTY, Boolean.TRUE);
      requestContext.put(BindingProvider.SOAPACTION_URI_PROPERTY, "echoOperation");

      gencont.add(samlToken);

      // Add timestamp
      WSSTimestamp timestamp = factory.newWSSTimestamp();
      gencont.add(timestamp);

      gencont.process(requestContext);

      // Build the input object
      EchoStringInput echoParm =
          new com.ibm.was.wssample.sei.echo.ObjectFactory().createEchoStringInput();
      echoParm.setEchoInput(input);
      System.out.println(">> CLIENT: SEI Echo to " + endpointURL);

      // Prepare to consume timestamp in response message
      WSSConsumingContext concont = factory.newWSSConsumingContext();
      concont.add(WSSConsumingContext.TIMESTAMP);
      concont.process(requestContext);

      // Call the service
      response = echo.echoOperation(echoParm).getEchoResponse();

      System.out.println(">> CLIENT: SEI Echo invocation complete.");
      System.out.println(">> CLIENT: SEI Echo response is: " + response);
    } catch (Exception e) {
      System.out.println(">> CLIENT: ERROR: SEI Echo EXCEPTION.");
      e.printStackTrace();
    }
  }
}
```

When this web services client application sample runs correctly, you receive messages like the following messages:

```
SAMLToken id = _6CDDF0DBF91C044D211271166233407
Retrieving document at 'file:profile_root/.../wsdl/'.
>> CLIENT: SEI Echo to http://localhost:9443/WSSampleSei/EchoService12
>> CLIENT: SEI Echo invocation complete.
>> CLIENT: SEI Echo response is: SOAP12==>>HELLO
```

Sending self-issued SAML holder-of-key tokens with symmetric key using WSS APIs:

You can create self-issued SAML tokens with the holder-of-key subject confirmation method and then use the Java API for XML-Based Web Services (JAX-WS) programming model and Web Services Security APIs (WSS APIs) to send these tokens with web services request messages.

Before you begin

This task assumes that you are familiar with the JAX-WS programming model, the WSS API interfaces, SAML concepts, and the use of policy sets to configure and administer web services settings. Complete the following actions before you begin this task:

- Read about sending self-issued SAML bearer tokens by using WSS APIs.
- Read about sending self-issued SAML sender-vouches tokens by using WSS APIs with message level protection.

About this task

This task focuses on using the symmetric key that is embedded in SAML security tokens to generate a digital signature of selected SOAP message elements in order to satisfy holder-of-key subject confirmation method security requirements. The Web Services Security policy attached to the web services provider is that of the *SAML20 HoK Symmetric WSSecurity default* policy set that is shipped in WebSphere Application Server 7.0.0.7 and later releases.

Procedure

1. Create a SAML security token that contains holder-of-key subject confirmation method; for example:

```
WSSFactory factory = WSSFactory.getInstance();
// Initialize WSSGenerationContext
com.ibm.websphere.wssecurity.wssapi.WSSGenerationContext gencont = factory.newWSSGenerationContext();
// Initialize SAML issuer configuration via custom properties
HashMap<Object, Object> customProps = new HashMap<Object,Object>();

customProps.put(SamlConstants.ISSUER_URI_PROP, "example.com");
customProps.put(SamlConstants.TTL_PROP, "3600000");
customProps.put(SamlConstants.KS_PATH_PROP, "keystores/saml-provider.jceks");
customProps.put(SamlConstants.KS_TYPE_PROP, "JCEKS");
customProps.put(SamlConstants.KS_PW_PROP, "{xor}LCswLTovPiws");
customProps.put(SamlConstants.KEY_ALIAS_PROP, "samlissuer");
customProps.put(SamlConstants.KEY_NAME_PROP, "CN=SAMLIssuer, O=EXAMPLE");
customProps.put(SamlConstants.KEY_PW_PROP, "{xor}NDomLz4sLA==");
customProps.put(SamlConstants.TS_PATH_PROP, "keystores/saml-provider.jceks");
customProps.put(SamlConstants.TS_TYPE_PROP, "JCEKS");
customProps.put(SamlConstants.TS_PW_PROP, "{xor}LCswLTovPiws");
gencont.add(customProps); //Add custom properties
HashMap<Object, Object> map = new HashMap<Object, Object>();
map.put(SamlConstants.CONFIRMATION_METHOD, "holder-of-key");
map.put(SamlConstants.Token_REQUEST, "issue");
map.put(SamlConstants.TOKEN_TYPE, WSSConstants.SAML.SAML20_VALUE_TYPE);
map.put(SamlConstants.SAML_NAME_IDENTIFIER, "Alice");
map.put(SamlConstants.SIGNATURE_REQUIRED, "true");
map.put(SamlConstants.SERVICE_ALIAS, "soaprecipient");
map.put(SamlConstants.KEY_TYPE,
        "http://docs.oasis-open.org/ws-sx/ws-trust/200512/SymmetricKey");
map.put(SamlConstants.SAML_APPLIES_TO, "http://localhost:9080/your_Web_service");
map.put(RequesterConfiguration.RSTT.ENCRYPTIONALGORITHM,
        "http://www.w3.org/2001/04/xmlenc#aes256-cbc");
map.put(SamlConstants.KEY_SIZE, "256");
SAMLGenerateCallbackHandler callbackHandler = new
        SAMLGenerateCallbackHandler(map);
SAMLToken samlToken = (SAMLToken) factory.newSecurityToken(SAMLToken.class,
        callbackHandler, "system.wss.generate.saml");
```

   The embedded proof key in the SAML security token is encrypted for the target Web service. The public key of the target service that encrypts the proof key is specified by the `SamlConstants.SERVICE_ALIAS` property which specifies a public certificate in the trust file. The trust file location is specified by a `com.ibm.websphere.wssecurity.wssapi.WSSGenerationContext` custom property. In this example, you must import the Java Cryptography Extension (JCE) policy file because encryption uses 256 bit key size. For more information, read about using the unrestricted JCE policy files in the "Tuning Web Services Security applications" topic.

   If you prefer to use derived keys for digital signing and for encryption instead of using symmetric key directly, add the following name-value pair:

```
map.put(SamlConstants.REQUIRE_DKT, "true");
```

2. Use the `WSSGenerationContext` object to prepare for request message security header processing; for example:

```
gencon.add(samlToken); //this line of code can be omitted

WSSTimestamp timestamp = factory.newWSSTimestamp();
gencon.add(timestamp);

WSSSignature sig = factory.newWSSSignature(samlToken);

sig.setSignatureMethod(WSSSignature.HMAC_SHA1);
sig.setCanonicalizationMethod(WSSSignature.EXC_C14N);
sig.addSignPart(WSSSignature.BODY);
sig.addSignPart(WSSSignature.TIMESTAMP);
sig.addSignPart(WSSSignature.ADDRESSING_HEADERS);
sig.setTokenReference(SecurityToken.REF_KEYID);
//If the gencon.add(samlToken); line of code is omitted, or DerivedKey is used
//the above line of code must be replaced with
//sig.setTokenReference(SecurityToken.REF_STR);

gencon.add(sig);

WSSEncryption enc = factory.newWSSEncryption(samlToken);

enc.setEncryptionMethod(WSSEncryption.AES256);
enc.setTokenReference(SecurityToken.REF_KEYID);
//If the gencon.add(samlToken); line of code is omitted, or DerivedKey is used
//the above line of code must be replaced with
//enc.setTokenReference(SecurityToken.REF_STR);
```

```
enc.encryptKey(false);
enc.addEncryptPart(WSSEncryption.BODY_CONTENT);
enc.addEncryptPart(WSSEncryption.SIGNATURE);
gencon.add(enc);
```

3. Create the `WSSConsumingContext` object to prepare for response message, security header processing; for example:

```
WSSConsumingContext concont = factory.newWSSConsumingContext();

HashMap<Object, Object> map = new HashMap<Object, Object>();

SAMLConsumerCallbackHandler callbackHandler = new
        SAMLConsumerCallbackHandler(map);

WSSDecryption dec = factory.newWSSDecryption(SAMLToken.class, callbackHandler,
        "system.wss.consume.saml");
dec.addAllowedEncryptionMethod(WSSDecryption.AES256);
dec.encryptKey(false);
dec.addRequiredDecryptPart(WSSDecryption.BODY_CONTENT);

concont.add(dec);

callbackHandler = new SAMLConsumerCallbackHandler(map);
WSSVerification ver = factory.newWSSVerification(SAMLToken.class, callbackHandler,
        "system.wss.consume.saml");
ver.addAllowedSignatureMethod(WSSVerification.HMAC_SHA1);
ver.addRequiredVerifyPart(WSSVerification.BODY);
ver.addRequiredVerifyPart(WSSVerification.TIMESTAMP);

concont.add(ver);
```

4. Use the JDK `keytool` utility to generate the `saml-provider.jceks` and `recipient.jceks`files that are used to test the example code; for example:

```
keytool -genkey -alias samlissuer -keystore saml-provider.jceks -dname "CN=SAMLIssuer, O=ACME" -storepass issuerstorepass
 -keypass issuerkeypass -storetype jceks -validity 5000 -keyalg RSA -keysize 2048

keytool -genkey -alias soaprecipient -keystore recipient.jceks -dname "CN=SOAPRecipient, O=ACME" -storepass reciptstorepass
 -keypass reciptkeypass -storetype jceks -validity 5000 -keyalg RSA -keysize 2048

keytool -export -alias soaprecipient -file reciptpub.cer -keystore recipient.jceks -storepass reciptstorepass -storetype jceks

keytool -import -alias soaprecipient -file reciptpub.cer -keystore saml-provider.jceks -storepass issuerstorepass -storetype jceks
 -keypass issuerkeypass -noprompt
```

Results

You have learned key building blocks to create a web services client application to send a SAML security token in a SOAP message and to use the symmetric key that is embedded in SAML security in message level protection.

Sending self-issued SAML holder-of-key tokens with asymmetric key using WSS APIs:

You can create self-issued SAML tokens with the holder-of-key subject confirmation method and then use the Java API for XML-Based Web Services (JAX-WS) programming model and Web Services Security APIs (WSS APIs) to send these tokens with web services request messages.

Before you begin

This task assumes that you are familiar with the JAX-WS programming model, the WSS API interfaces, SAML concepts, and the use of policy sets to configure and administer web services settings. Complete the following actions before you begin this task:

- Read about sending self-issued SAML bearer tokens by using WSS APIs.
- Read about sending self-issued SAML sender-vouches tokens by using WSS APIs with message level protection.

About this task

This task focuses on using the asymmetric key that is identified by SAML security tokens to generate a digital signature of selected SOAP message elements in order to satisfy holder-of-key subject confirmation method security requirements. The X.509 certificate of the sender is embedded in the SAML security token. The sender signs selected parts of request message elements by using its corresponding private key and encrypts the request message by using the public key of the recipient. The recipient signs the selected elements of the response message by using the private key of the recipient, and encrypts selected elements of the response message by using the public key of the sender in SAML security tokens. The Web services security policy attached to the web services provider is provided for your reference.

Procedure

1. Create a SAML security token that contains the holder-of-key subject confirmation method; for example:

```
WSSFactory factory = WSSFactory.getInstance();
// Initialize WSSGenerationContext
com.ibm.websphere.wssecurity.wssapi.WSSGenerationContext gencont = factory.newWSSGenerationContext();
// Initialize SAML issuer configuration via custom properties
HashMap<Object, Object> customProps = new HashMap<Object,Object>();
customProps.put(SamlConstants.ISSUER_URI_PROP, "example.com");
customProps.put(SamlConstants.TTL_PROP, "3600000");
customProps.put(SamlConstants.KS_PATH_PROP, "keystores/saml-provider.jceks");
customProps.put(SamlConstants.KS_TYPE_PROP, "JCEKS");
customProps.put(SamlConstants.KS_PW_PROP, "{xor}LCswLTovPiws");
customProps.put(SamlConstants.KEY_ALIAS_PROP, "samlissuer");
customProps.put(SamlConstants.KEY_NAME_PROP, "CN=SAMLIssuer, O=EXAMPLE");
customProps.put(SamlConstants.KEY_PW_PROP, "{xor}NDomLz4sLA==");
customProps.put(SamlConstants.TS_PATH_PROP, "keystores/saml-provider.jceks");
customProps.put(SamlConstants.TS_TYPE_PROP, "JCEKS");
customProps.put(SamlConstants.TS_PW_PROP, "{xor}LCswLTovPiws");
gencont.add(customProps); //Add custom properties
HashMap<Object, Object> map = new HashMap<Object, Object>();
map.put(SamlConstants.CONFIRMATION_METHOD, "holder-of-key");
map.put(SamlConstants.Token_REQUEST, "issue");
map.put(SamlConstants.TOKEN_TYPE, WSSConstants.SAML.SAML20_VALUE_TYPE);
map.put(SamlConstants.SAML_NAME_IDENTIFIER, "Alice");
map.put(SamlConstants.SIGNATURE_REQUIRED, "true");
map.put(SamlConstants.KEY_TYPE,
        "http://docs.oasis-open.org/ws-sx/ws-trust/200512/PublicKey");
map.put(SamlConstants.SAML_APPLIES_TO, "http://localhost:9080/your_Web_service");
map.put(SamlConstants.KEY_ALIAS, "soapinitiator" );
map.put(SamlConstants.KEY_NAME, "CN=SOAPInitator, O=ACME");
map.put(SamlConstants.KEY_PASSWORD, "keypass");
map.put(SamlConstants.KEY_STORE_PATH, "keystores/initiator.jceks");
map.put(SamlConstants.KEY_STORE_PASSWORD, "storepass");
map.put(SamlConstants.KEY_STORE_TYPE, "jceks");
SAMLGenerateCallbackHandler callbackHandler = new SAMLGenerateCallbackHandler(map);
SAMLToken samlToken = (SAMLToken) factory.newSecurityToken(SAMLToken.class,
                      callbackHandler, "system.wss.generate.saml");
```

   The private key of the sender is specified by the `SamlConstants.KEY_ALIAS` property and is used to sign selected elements of the request message.

2. Use the `WSSGenerationContext` object to prepare for request message security header processing; for example:

```
gencon.add(samlToken); //this line of code can be omitted
WSSTimestamp timestamp = factory.newWSSTimestamp();
gencon.add(timestamp);
WSSSignature sig = factory.newWSSSignature(samlToken);
sig.setTokenReference(SecurityToken.REF_KEYID);
//If the gencon.add(samlToken); line of code is omitted,
//the above line of code must be replaced with
//sig.setTokenReference(SecurityToken.REF_STR);

sig.setSignatureMethod(WSSSignature.RSA_SHA1);
sig.setCanonicalizationMethod(WSSSignature.EXC_C14N);
sig.addSignPart(WSSSignature.BODY);
sig.addSignPart(WSSSignature.TIMESTAMP);
sig.addSignPart(WSSSignature.ADDRESSING_HEADERS);
gencon.add(sig);
```

```
X509GenerateCallbackHandler x509callbackHandler2 = new X509GenerateCallbackHandler(
        null,
        "keystores/initiator.jceks",
        "jceks",
        "storepass".toCharArray(),
        "soaprecipient",
        null,
        "", null);
SecurityToken st2 = factory.newSecurityToken(X509Token.class, x509callbackHandler2);
WSSEncryption enc = factory.newWSSEncryption(st2);
enc.addEncryptPart(WSSEncryption.BODY_CONTENT);
enc.addEncryptPart(WSSEncryption.SIGNATURE);
enc.setEncryptionMethod(WSSEncryption.AES256);
enc.setKeyEncryptionMethod(WSSEncryption.KW_RSA_OAEP);
gencon.add(enc);
```

In this example, encryption uses a 256 bit key size so you must import the Java Cryptography Extension (JCE) policy file. For more information, read about using the unrestricted JCE policy files in the “Tuning Web Services Security applications” topic.

3. Create the `WSSConsumingContext` object to prepare for response message security header processing; for example:

```
WSSConsumingContext concont = factory.newWSSConsumingContext();

HashMap<Object, Object> map = new HashMap<Object, Object>();

SAMLConsumerCallbackHandler callbackHandler = new SAMLConsumerCallbackHandler(map);
WSSDecryption dec = factory.newWSSDecryption(SAMLToken.class, callbackHandler,
                            "system.wss.consume.saml");
dec.addAllowedEncryptionMethod(WSSDecryption.AES256);
dec.addAllowedKeyEncryptionMethod(WSSDecryption.KW_RSA_OAEP);
dec.encryptKey(false);
dec.addRequiredDecryptPart(WSSDecryption.BODY_CONTENT);
concont.add(dec);
X509ConsumeCallbackHandler verHandler = new X509ConsumeCallbackHandler(null,
            "keystores/initiator.jceks",
            "jceks",
            "storepass".toCharArray(),
            "soaprecipient",
            null, null);
WSSVerification ver = factory.newWSSVerification(X509Token.class, verHandler);
ver.addRequiredVerifyPart(WSSVerification.BODY);
concont.add(ver);
```

4. Use the JDK **keytool** utility to generate the `saml-provider.jceks`, `initiator.jceks`, and `recipient.jceks`files that are used to test the example code; for example:

```
keytool -genkey -alias samlissuer -keystore saml-provider.jceks -dname "CN=SAMLIssuer, O=ACME" -storepass storepass -keypass keypass
 -storetype jceks -validity 5000 -keyalg RSA -keysize 2048

keytool -genkey -alias soaprecipient -keystore recipient.jceks -dname "CN=SOAPRecipient, O=ACME" -storepass storepass -keypass keypass
 -storetype jceks -validity 5000 -keyalg RSA -keysize 2048

keytool -genkey -alias soapinitiator -keystore initiator.jceks -dname "CN=SOAPInitator, O=ACME" -storepass storepass -keypass keypass
 -storetype jceks -validity 5000 -keyalg RSA -keysize 2048

keytool -export -alias samlissuer -file issuerpub.cer -keystore saml-provider.jceks -storepass storepass -storetype jceks
keytool -export -alias soaprecipient -file reciptpub.cer -keystore recipient.jceks -storepass storepass -storetype jceks
keytool -export -alias soapinitiator -file initatpub.cer -keystore initiator.jceks -storepass storepass -storetype jceks

keytool -import -alias samlissuer -file issuerpub.cer -keystore initiator.jceks -storepass storepass -storetype jceks -keypass keypass -noprompt
keytool -import -alias soaprecipient -file reciptpub.cer -keystore initiator.jceks -storepass storepass -storetype jceks -keypass keypass -noprompt

keytool -import -alias samlissuer -file issuerpub.cer -keystore recipient.jceks -storepass storepass -storetype jceks -keypass keypass -noprompt
keytool -import -alias soapinitiator -file initatpub.cer -keystore recipient.jceks -storepass storepass -storetype jceks -keypass keypass -noprompt

keytool -import -alias soapinitiator -file initatpub.cer -keystore saml-provider.jceks -storepass storepass -storetype jceks -keypass keypass -noprompt
```

Results

You have learned key building blocks to create a web services client application to send a SAML security token in a SOAP message and to use the asymmetric key that is embedded in SAML security in message level protection.

Example

The following example illustrates the web services provider Web services security policy:

```
<?xml version="1.0" encoding="UTF-8" standalone="yes"?>
<wsp:Policy xmlns:wsp="http://schemas.xmlsoap.org/ws/2004/09/policy"
  xmlns:wsu="http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-utility-1.0.xsd"
  xmlns:sp="http://docs.oasis-open.org/ws-sx/ws-securitypolicy/200512" xmlns:wsa="http://schemas.xmlsoap.org/ws/2004/08/addressing"
  xmlns:spe="http://www.ibm.com/xmlns/prod/websphere/200605/ws-securitypolicy-ext">
    <wsp:Policy wsu:Id="response:app_encparts">
        <sp:EncryptedElements>
            <sp:XPath>/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/'
             and local-name()='Envelope']/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/'
             and local-name()='Header']/*[namespace-uri()='http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-secext-1.0.xsd'
             and local-name()='Security']/*[namespace-uri()='http://www.w3.org/2000/09/xmldsig#' and local-name()='Signature']</sp:XPath>
            <sp:XPath>/*[namespace-uri()='http://www.w3.org/2003/05/soap-envelope'
             and local-name()='Envelope']/*[namespace-uri()='http://www.w3.org/2003/05/soap-envelope'
             and local-name()='Header']/*[namespace-uri()='http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-secext-1.0.xsd'
             and local-name()='Security']/*[namespace-uri()='http://www.w3.org/2000/09/xmldsig#' and local-name()='Signature']</sp:XPath>

</wsp:Policy>
```

Requesting SAML bearer tokens from an external STS using WSS APIs and transport level protection:

You can request SAML tokens with the bearer subject confirmation method from an external Security Token Service (STS). After obtaining the SAML bearer token, you can then send these tokens with web services request messages using the Java API for XML-Based Web Services (JAX-WS) programming model and Web Services Security APIs (WSS API).

Before you begin

This task assumes that you are familiar with the JAX-WS programming model, the WSS API interfaces, SAML concepts, and the use of policy sets to configure and administer web services settings.

About this task

You can request a SAML token with the bearer subject confirmation method from an external STS and then send the SAML token in web services request messages from a web services client using WSS APIs.

The web services application client used in this task is a modified version of the client code that is contained in the JaxWSServicesSamples sample application that is available for download. Code snippets from the sample are described in the procedure section, and a complete, ready-to-use web services client sample is provided in the Example section.

Procedure

1. Identify and obtain the web services client that you want to use to invoke a web services provider.

   Use this client to insert SAML tokens in SOAP request messages programmatically using WSS APIs.

   The web services client used in this procedure is a modified version of the client code that is contained in the JaxWSServicesSamples web services sample application.

   To obtain and modify the sample web services client to add the Web Services Security API to pass SAML tokens in SOAP request messages programmatically using WSS APIs, complete the following steps:

   a. Download the JaxWSServicesSamples sample application. The JaxWSServicesSamples sample is not installed by default.

   b. Obtain the JaxWSServicesSamples client code.

      For example purposes, this procedure uses a modified version of the Echo thin client sample that is included in the JaxWSServicesSamples sample. The web services Echo thin client sample file, `SampleClient.java`, is located in the `src\SampleClientSei\src\com\ibm\was\wssample\sei\cli` directory. The sample class file is included in the `WSSampleClientSei.jar` file.

      The `JaxWSServicesSamples.ear` enterprise application and supporting Java archives (JAR) files are located in the `installableApps` directory within the JaxWSServicesSamples sample application.

   c. Deploy the `JaxWSServicesSamples.ear` file onto the application server. After you deploy the `JaxWSServicesSamples.ear` file, you are ready to test the sample web services client code against the sample application.

   Instead of using the web services client sample, you can choose to add the code snippets to pass SAML tokens in SOAP request messages programmatically using WSS APIs in your own web services client application. The example in this procedure uses a JAX-WS web services thin client; however, you can also use a managed client.

2. Attach the SAML20 Bearer WSHTTPS default policy set to the web services provider. This policy set is used to protect messages using HTTPS transport. Read about configuring client and provider bindings for the SAML Bearer token for details on how to attach the SAML20 Bearer WSHTTPS default policy set to the web services provider.

3. Assign the SAML Bearer Provider sample default general bindings to the sample web services provider. Read about configuring client and provider bindings for the SAML bearer token for details on assigning the SAML Bearer Provider sample default general bindings to your web services application.

4. Verify that the trustStoreType, trustStorePassword and trustStorePath custom properties correspond to the trust store containing the STS signer certificate. Using the administrative console, complete the following steps:
   a. Click **Services** > **Policy sets** > **General provider policy set bindings** > **Saml Bearer Provider sample** > **WS-Security** > **Authentication and protection**.
   b. Click **gen_saml11token** in the Authentication tokens table.
   c. Click **Callback handler**.
   d. In the Custom Properties section, ensure that the trustStoreType, trustStorePassword and trustStorePath custom properties correspond to the trust store containing the STS signer certificate.
5. Request the SAML token from an external STS. The following code snippet illustrates how to request the SAML token and assumes that an external STS is configured to accept a UsernameToken, and to issue a SAML 2.0 token after validation:

```
//Request the SAML Token from external STS
WSSFactory factory = WSSFactory.getInstance();
String STS_URI  = "https://externalstsserverurl:port/TrustServerWST13/services/RequestSecurityToken";
String ENDPOINT_URL = "http://localhost:9080/WSSampleSei/EchoService";
WSSGenerationContext gencont1 = factory.newWSSGenerationContext();
WSSConsumingContext concont1 = factory.newWSSConsumingContext();
HashMap<Object, Object> cbackMap1 = new HashMap<Object, Object>();
cbackMap1.put(SamlConstants.STS_ADDRESS, STS_URI);
cbackMap1.put(SamlConstants.SAML_APPLIES_TO, ENDPOINT_URL);
cbackMap1.put(SamlConstants.TRUST_CLIENT_WSTRUST_NAMESPACE, "http://docs.oasis-open.org/ws-sx/ws-trust/200512");
cbackMap1.put(SamlConstants.TRUST_CLIENT_COLLECTION_REQUEST, "false");
cbackMap1.put(SamlConstants.TOKEN_TYPE, WSSConstants.SAML.SAML20_VALUE_TYPE);
cbackMap1.put(SamlConstants.CONFIRMATION_METHOD, "Bearer");

SAMLGenerateCallbackHandler cbHandler1 = new SAMLGenerateCallbackHandler(cbackMap1);

// Add UNT to trust request
UNTGenerateCallbackHandler utCallbackHandler = new UNTGenerateCallbackHandler("testuser", "testuserpwd");
SecurityToken ut = factory.newSecurityToken(UsernameToken.class, utCallbackHandler);

gencont1.add(ut);

cbHandler1.setWSSConsumingContextForTrustClient(concont1);
cbHandler1.setWSSGenerationContextForTrustClient(gencont1);
SecurityToken samlToken = factory.newSecurityToken(SAMLToken.class, cbHandler1, "system.wss.generate.saml");

System.out.println("SAMLToken id = " + samlToken.getId());
```

   a. Add the Thin Client for JAX-WS JAR file to the class path. Add the *app_server_root*/runtimes/com.ibm.jaxws.thinclient_8.5.0.jar file to the class path. See the testing web services-enabled clients information for more information about adding this JAR file to the class path.
   b. Use the WSSFactory newSecurityToken method to request a SAML token from an external STS.

      Specify the following method to request the SAML token:

```
WSSFactory  newSecurityToken(SAMLToken.class, callbackHandler, "system.wss.generate.saml")
```

      Requesting a SAML token requires the Java security permission wssapi.SAMLTokenFactory.newSAMLToken. Use the Policy Tool to add the following policy statement to the Java security policy file or the application client was.policy file:

```
permission java.security.SecurityPermission "wssapi.SAMLTokenFactory.newSAMLToken"
```

      The `SAMLToken.class` parameter specifies the type of security token to create.

      The `callbackHandler` object contains parameters that define the characteristics of the SAML token that you are requesting and other parameters required to reach the STS and obtain the SAML token. The SAMLGenerateCallbackHandler object specifies the configuration parameters described in the following table:

Table 204. SAMLGenerateCallbackHandler properties. This table describes the configuration parameters for the SAMLGenerateCallbackHandler object using the bearer subject confirmation method.

Property	Description	Required
SamlConstants.CONFIRMATION_METHOD	Specifies to use the `Bearer` confirmation method.	Yes

Table 204. SAMLGenerateCallbackHandler properties (continued). This table describes the configuration parameters for the SAMLGenerateCallbackHandler object using the bearer subject confirmation method.

Property	Description	Required
SamlConstants.TOKEN_TYPE	Specifies the token type. When a web services client has policy set attachments, this property is not used by Web Services Security runtime environment. Specify the token value type by using the `valueType` attribute of the tokenGenerator binding configuration. The example in this procedure uses a SAML 2.0 token; however, you can also use the `WSSConstants.SAML.SAML11_VALUE_TYPE` value.	Yes
SamlConstants.STS_ADDRESS	Specifies the Security Token Service address. For the example used in this task topic, the value of this property is set to `https` to specify to use SSL to protect the SAML Token request. You must set the -Dcom.ibm.SSL.ConfigURL property to enable the use of SSL to protect the SAML token request with the STS.	Yes
SamlConstants.SAML_APPLIES_TO	Specifies the target STS address for where you want to use the SAML token.	No
SamlConstants.TRUST_CLIENT_COLLECTION_REQUEST	Specifies whether to request from the STS a single token that is enclosed in a RequestSecurityToken (RST) element or multiple tokens in a collection of RST elements that are enclosed in a single RequestSecurityTokenCollection (RSTC) element. The default behavior is to request a single token that is enclosed in a RequestSecurityToken (RST) element from the STS. Specifying a `true` value for this property indicates to request multiple tokens in a collection of RST elements that are enclosed in a single RequestSecurityTokenCollection (RSTC) element from the STS.	No
SamlConstants.TRUST_CLIENT_WSTRUST_NAMESPACE	Specifies the WS-Trust namespace that is included in the WS-Trust request.	No

A WSSGenerationContext instance and a WSSConsumingContext instance are also set in the SAMLGenerateCallbackHandler object. The WSSGenerationContext instance must contain a UNTGenerateCallbackHandler object with the information to create the UsernameToken that you want to send to the STS.

The `system.wss.generate.saml` parameter specifies the Java Authentication and Authorization Service (JAAS) login module that is used to create the SAML token. You must specify a JVM property to define a JAAS configuration file that contains the required JAAS login configuration; for example:

```
-Djava.security.auth.login.config=profile_root/properties/wsjaas_client.conf
```

Alternatively, you can specify a JAAS login configuration file by setting a Java system property in the sample client code; for example:

```
System.setProperty("java.security.auth.login.config", "profile_root/properties/wsjaas_client.conf");
```

c. Obtain the token identifier of the created SAML token.

Use the following statement as a simple test for the SAML token that you created:

```
System.out.println("SAMLToken id = " + samlToken.getId())
```

6. Add the SAML token to the SOAP security header of a web services request messages.

a. Initialize the web services client and configure the SOAPAction properties. The following code snippet illustrates these actions:

```
// Initialize web services client
EchoService12PortProxy echo = new EchoService12PortProxy();
echo._getDescriptor().setEndpoint(endpointURL);
```

```
// Configure SOAPAction properties
BindingProvider bp = (BindingProvider) (echo._getDescriptor().getProxy());
Map<String, Object> requestContext = bp.getRequestContext();
requestContext.put(BindingProvider.ENDPOINT_ADDRESS_PROPERTY, endpointURL);
requestContext.put(BindingProvider.SOAPACTION_USE_PROPERTY, Boolean.TRUE);
requestContext.put(BindingProvider.SOAPACTION_URI_PROPERTY, "echoOperation");
```

b. Initialize the WSSGenerationContext. The following code illustrates the use of the WSSGenerationContext interface to initialize a generation context and enable you to insert the `SAMLToken` into the web services request message:

```
// Initialize WSSGenerationContext
WSSGenerationContext gencont = factory.newWSSGenerationContext();
gencont.add(samlToken);
```

Specifically, the `gencont.add(samlToken)` method call specifies to put the SAML token into a request message. Use the Policy Tool to add the following policy statement to the Java security policy file or the application client was.policy file:

```
permission javax.security.auth.AuthPermission "modifyPrivateCredentials"
```

c. Add the timestamp element in the SOAP messages security header. The SAML20 Bearer WSHTTPS default policy set requires web services requests and response messages to carry a timestamp element in SOAP messages Security header. In the following code snippet, the `factory.newWSSTimestamp()` method call generates the timestamp, and the `gencont.add(timestamp)` method call specifies the timestamp to put into a request message:

```
// Add a timestamp to the request message.
WSSTimestamp timestamp = factory.newWSSTimestamp();
gencont.add(timestamp);

gencont.process(requestContext);
```

d. Attach WSSGenerationContext object to the web services RequestContext object. The WSSGenerationContext object now contains all the security information that is required to format a request message. The `gencont.process(requestContext)` method call attaches the WSSGenerationContext object to the web services RequestContext object to enable the Web Services Security runtime environment to format the required SOAP security header; for example:

```
// Attaches WSSGenerationContext object to the web services RequestContext object.
gencont.process(requestContext);
```

e. Specify SSL transport level message protection using JVM properties.

The SAML20 Bearer WSHTTPS default policy set requires transport-level message protection using SSL. In addition, you can use this same property to enable protection of the SAML token request to the STS using SSL. Specify SSL transport-level message protection using the following JVM property:

```
-Dcom.ibm.SSL.ConfigURL=file:profile_root\properties\ssl.client.props
```

Alternatively, you can define the SSL configuration file using a Java system property in the sample client code; for example:

```
System.setProperty("com.ibm.SSL.ConfigURL", "file:profile_root/properties/ssl.client.props");
```

Results

You have requested a SAML token with the bearer subject confirmation method with transport level protection from an external STS. After obtaining the token, you sent the token with web services request messages using the JAX-WS programming model and WSS APIs.

If you want to request a SAML token with the bearer subject confirmation method with message level protection from an external STS, see the documentation for requesting SAML sender-vouches tokens from an external STS using WSS APIs and message level protection. To use message level protection for SAML tokens with the bearer subject confirmation method, in the step to request the SAML token from an external STS, specify a confirmation method of `Bearer` instead of `sender-vouches`; for example:

```
//Request the SAML Token from external STS
WSSFactory factory = WSSFactory.getInstance();
String STS_URI  = "https://externalstsserverurl:port/TrustServerWST13/services/RequestSecurityToken";
String ENDPOINT_URL = "http://localhost:9080/WSSampleSei/EchoService";
WSSGenerationContext gencont1 = factory.newWSSGenerationContext();
WSSConsumingContext concont1 = factory.newWSSConsumingContext();
HashMap<Object, Object> cbackMap1 = new HashMap<Object, Object>();
cbackMap1.put(SamlConstants.STS_ADDRESS, STS_URI);
```

```
cbackMap1.put(SamlConstants.SAML_APPLIES_TO, ENDPOINT_URL);
cbackMap1.put(SamlConstants.TRUST_CLIENT_WSTRUST_NAMESPACE, "http://docs.oasis-open.org/ws-sx/ws-trust/200512");
cbackMap1.put(SamlConstants.TRUST_CLIENT_COLLECTION_REQUEST, "false");
cbackMap1.put(SamlConstants.TOKEN_TYPE, WSSConstants.SAML.SAML11_VALUE_TYPE);
cbackMap1.put(SamlConstants.CONFIRMATION_METHOD, "Bearer");

SAMLGenerateCallbackHandler cbHandler1 = new SAMLGenerateCallbackHandler(cbackMap1);

// Add UNT to trust request
UNTGenerateCallbackHandler utCallbackHandler = new UNTGenerateCallbackHandler("testuser", "testuserpwd");
SecurityToken ut = factory.newSecurityToken(UsernameToken.class, utCallbackHandler);

gencont1.add(ut);

cbHandler1.setWSSConsumingContextForTrustClient(concont1);
cbHandler1.setWSSGenerationContextForTrustClient(gencont1);
SecurityToken samlToken = factory.newSecurityToken(SAMLToken.class, cbHandler1, "system.wss.generate.saml");

System.out.println("SAMLToken id = " + samlToken.getId());
```

Additionally, the step to configure the verification of the digital signature in the response message is optional in the case of the bearer token.

Example

The following code sample is a web services client application that demonstrates how to request a SAML token from an external STS and send that SAML token in web services request messages. If your usage scenario requires SAML tokens, but does not require your application to pass the SAML tokens using web services messages, you only need to use the first part of the following sample code, up through the `// Initialize web services client` section.

```
/**
 * The following source code is sample code created by IBM Corporation.
 * This sample code is provided to you solely for the purpose of assisting you in the
 * use of the technology.  The code is provided 'AS IS', without warranty or condition of
 * any kind.  IBM shall not be liable for any damages arising out of your use of the
 * sample code, even if IBM has been advised of the possibility of such damages.
 */

SAMLGenerateCallbackHandler cbHandler1 = new SAMLGenerateCallbackHandler(cbackMap1);

// Add UNT to trust request
UNTGenerateCallbackHandler utCallbackHandler = new UNTGenerateCallbackHandler("testuser", "testuserpwd");
SecurityToken ut = factory.newSecurityToken(UsernameToken.class, utCallbackHandler);

gencont1.add(ut);

cbHandler1.setWSSConsumingContextForTrustClient(concont1);
cbHandler1.setWSSGenerationContextForTrustClient(gencont1);
SecurityToken samlToken = factory.newSecurityToken(SAMLToken.class, cbHandler1, "system.wss.generate.saml");

System.out.println("SAMLToken id = " + samlToken.getId());

        // Initialize web services client
   EchoService12PortProxy echo = new EchoService12PortProxy();
   echo._getDescriptor().setEndpoint(endpointURL);

   // Configure SOAPAction properties
   BindingProvider bp = (BindingProvider) (echo._getDescriptor().getProxy());
   Map<String, Object> requestContext = bp.getRequestContext();
   requestContext.put(BindingProvider.ENDPOINT_ADDRESS_PROPERTY, endpointURL);
   requestContext.put(BindingProvider.SOAPACTION_USE_PROPERTY, Boolean.TRUE);
   requestContext.put(BindingProvider.SOAPACTION_URI_PROPERTY, "echoOperation");

   // Initialize WSSGenerationContext
   WSSGenerationContext gencont = factory.newWSSGenerationContext();
        gencont.add(samlToken);

        // Add timestamp
        WSSTimestamp timestamp = factory.newWSSTimestamp();
   gencont.add(timestamp);

        gencont.process(requestContext);

        // Build the input object
   EchoStringInput echoParm =
    new com.ibm.was.wssample.sei.echo.ObjectFactory().createEchoStringInput();
   echoParm.setEchoInput(input);
   System.out.println(">> CLIENT: SEI Echo to " + endpointURL);

   // Prepare to consume timestamp in response message.
   WSSConsumingContext concont = factory.newWSSConsumingContext();
       concont.add(WSSConsumingContext.TIMESTAMP);
       concont.process(requestContext);

   // Call the service
   response = echo.echoOperation(echoParm).getEchoResponse();

   System.out.println(">> CLIENT: SEI Echo invocation complete.");
   System.out.println(">> CLIENT: SEI Echo response is: " + response);
  } catch (Exception e) {
   System.out.println(">> CLIENT: ERROR: SEI Echo EXCEPTION.");
   e.printStackTrace();
  }
 }
}
```

When this web services client application sample runs correctly, you receive messages like the following messages:

```
SAMLToken id = _191EBC44865015D9AB1270745072344
Retrieving document at 'file:profile_root/.../wsdl/'.
>> CLIENT: SEI Echo to https://localhost:9443/WSSampleSei/EchoService12
>> CLIENT: SEI Echo invocation complete.
>> CLIENT: SEI Echo response is: SOAP12===>>HELLO
```

Requesting SAML sender-vouches tokens from an external STS using WSS APIs and message level protection:

You can request SAML tokens with the sender-vouches subject confirmation method from an external Security Token Service (STS). After obtaining the SAML sender-vouches token, you can then send these tokens with web services request messages using the Java API for XML-Based Web Services (JAX-WS) programming model and Web Services Security APIs (WSS API) with message level protection.

Before you begin

This task assumes that you are familiar with the JAX-WS programming model, the WSS API interfaces, SAML concepts, SSL transport protection, X.509 security token, and the use of policy sets to configure and administer web services settings.

About this task

You can request a SAML token with the sender-vouches subject confirmation method from an external STS and then send the SAML token in web services request messages from a web services client using WSS APIs with message level protection.

This product does not provide a default policy set that requires SAML tokens with sender-vouches subject confirmation method. Read about configuring client and provider bindings for the SAML sender-vouches token to learn more about how to create a Web Services Security policy to require SAML tokens with sender-vouches subject confirmation and how to create a custom binding configuration. You must attach the policy and binding to the web services provider. The code sample described in this task assumes that the web services provider policy requires that both the SAML tokens and the message bodies are digitally signed by using an X.509 security token.

The web services client application used in this task is a modified version of the client code that is contained in the JaxWSServicesSamples sample application that is available for download. Code examples from the sample are described in the procedure, and a complete, ready-to-use web services client sample is provided.

Procedure

1. Identify and obtain the web services client that you want to use to invoke a web services provider.

   Use this client to insert SAML tokens in SOAP request messages programmatically using WSS APIs.

   The web services client used in this procedure is a modified version of the client code that is contained in the JaxWSServicesSamples web services sample application.

   To obtain and modify the sample web services client to add the Web Services Security API to pass SAML sender-vouches tokens in SOAP request messages programmatically using WSS APIs, complete the following steps:

   a. Download the JaxWSServicesSamples sample application. The JaxWSServicesSamples sample is not installed by default.

   b. Obtain the JaxWSServicesSamples client code.

      For example purposes, this procedure uses a modified version of the Echo thin client sample that is included in the JaxWSServicesSamples sample. The web services Echo thin client sample file, `SampleClient.java`, is located in the `src\SampleClientSei\src\com\ibm\was\wssample\sei\cli` directory. The sample class file is included in the `WSSampleClientSei.jar` file.

The JaxWSServicesSamples.ear enterprise application and supporting Java archives (JAR) files are located in the installableApps directory within the JaxWSServicesSamples sample application.

c. Deploy the JaxWSServicesSamples.ear file onto the application server. After you deploy the JaxWSServicesSamples.ear file, you are ready to test the sample web services client code against the sample application.

Instead of using the web services client sample, you can choose to add the code snippets to pass SAML tokens in SOAP request messages programmatically using WSS APIs in your own web services client application. The example in this procedure uses a JAX-WS web services thin client; however, you can also use a managed client.

2. Specify to use SSL message-level message protection. Use the following JVM property to specify to use SSL to protect the SAML token request with the STS:

```
-Dcom.ibm.SSL.ConfigURL=file:profile_root\properties\ssl.client.props
```

Alternatively, you can define the SSL configuration file using a Java system property in the sample client code; for example:

```
System.setProperty("com.ibm.SSL.ConfigURL", "file:profile_root/properties/ssl.client.props");
```

3. Add the Thin Client for JAX-WS JAR file to the class path. Add the *app_server_root*/runtimes/com.ibm.jaxws.thinclient_8.5.0.jar file to the class path. See the testing web services-enabled clients information for more information about adding this JAR file to the class path.

4. Request the SAML token from an external STS. The following code snippet illustrates how to request the SAML sender-vouches token and assumes that an external STS is configured to accept a Username token, and to issue a SAML 2.0 token using sender-vouches after validation:

```
//Request the SAML Token from external STS
WSSFactory factory = WSSFactory.getInstance();
String STS_URI  = "https://externalstsserverurl:port/TrustServerWST13/services/RequestSecurityToken";
String ENDPOINT_URL = "http://localhost:9080/WSSampleSei/EchoService";
WSSGenerationContext gencont1 = factory.newWSSGenerationContext();
WSSConsumingContext concont1 = factory.newWSSConsumingContext();
HashMap<Object, Object> cbackMap1 = new HashMap<Object, Object>();
cbackMap1.put(SamlConstants.STS_ADDRESS, STS_URI);
cbackMap1.put(SamlConstants.SAML_APPLIES_TO, ENDPOINT_URL);
cbackMap1.put(SamlConstants.TRUST_CLIENT_WSTRUST_NAMESPACE, "http://docs.oasis-open.org/ws-sx/ws-trust/200512");
cbackMap1.put(SamlConstants.TRUST_CLIENT_COLLECTION_REQUEST, "false");
cbackMap1.put(SamlConstants.TOKEN_TYPE, WSSConstants.SAML.SAML11_VALUE_TYPE);
cbackMap1.put(SamlConstants.CONFIRMATION_METHOD, "sender-vouches");

SAMLGenerateCallbackHandler cbHandler1 = new SAMLGenerateCallbackHandler(cbackMap1);

// Add UNT to trust request
UNTGenerateCallbackHandler utCallbackHandler = new UNTGenerateCallbackHandler("testuser", "testuserpwd");
SecurityToken ut = factory.newSecurityToken(UsernameToken.class, utCallbackHandler);

gencont1.add(ut);

cbHandler1.setWSSConsumingContextForTrustClient(concont1);
cbHandler1.setWSSGenerationContextForTrustClient(gencont1);
SecurityToken samlToken = factory.newSecurityToken(SAMLToken.class, cbHandler1, "system.wss.generate.saml");

System.out.println("SAMLToken id = " + samlToken.getId());
```

a. Use the WSSFactory newSecurityToken method to specify how to request the SAML token from an external STS.

Specify the following method to create the SAML token:

```
WSSFactory  newSecurityToken(SAMLToken.class, callbackHandler, "system.wss.generate.saml")
```

Requesting a SAML token requires the Java security permission wssapi.SAMLTokenFactory.newSAMLToken. Use the Policy Tool to add the following policy statement to the Java security policy file or the application client was.policy file:

```
permission java.security.SecurityPermission "wssapi.SAMLTokenFactory.newSAMLToken"
```

The SAMLToken.class parameter specifies the type of security token to create.

The callbackHandler object contains parameters that define the characteristics of the SAMLToken that you are requesting and other parameters required to reach the STS and obtain the SAML token. The SAMLGenerateCallbackHandler object specifies the configuration parameters described in the following table:

Table 205. SAMLGenerateCallbackHandler properties. This table describes the configuration parameters for the SAMLGenerateCallbackHandler object using the sender-vouches confirmation method.

Property	Description	Required
SamlConstants.CONFIRMATION_METHOD	Specifies to use the `sender-vouches` confirmation method.	Yes
SamlConstants.TOKEN_TYPE	Specifies the token type. When a web services client has policy set attachments, this property is not used by the Web Services Security runtime environment. Specify the token value type by using the `valueType` attribute of the tokenGenerator binding configuration. The example in this procedure uses a SAML 1.1 token; however, you can also use the `WSSConstants.SAML.SAML20_VALUE_TYPE` value.	Yes
SamlConstants.STS_ADDRESS	Specifies the Security Token Service address. For the example used in this task topic, the value of this property is set to `https` to specify to use SSL to protect the SAML Token request. You must set the -Dcom.ibm.SSL.ConfigURL property to enable the use of SSL to protect the SAML token request with the STS.	Yes
SamlConstants.SAML_APPLIES_TO	Specifies the target STS address for where you want to use the SAML token.	No
SamlConstants.TRUST_CLIENT_COLLECTION_REQUEST	Specifies whether to request from the STS a single token that is enclosed in a RequestSecurityToken (RST) element or multiple tokens in a collection of RST elements that are enclosed in a single RequestSecurityTokenCollection (RSTC) element. The default behavior is to request a single token that is enclosed in a RequestSecurityToken (RST) element from the STS. Specifying a `true` value for this property indicates to request multiple tokens in a collection of RST elements that are enclosed in a single RequestSecurityTokenCollection (RSTC) element from the STS.	No
SamlConstants.TRUST_CLIENT_WSTRUST_NAMESPACE	Specifies the WS-Trust namespace that is included in the WS-Trust request. The default value is WSTrust 1.3.	No

A WSSGenerationContext instance and a WSSConsumingContext instance are also set in the SAMLGenerateCallbackHandler object. The WSSGenerationContext instance must contain a UNTGenerateCallbackHandler object with the information to create the UsernameToken that you want to send to the STS.

The `system.wss.generate.saml` parameter specifies the Java Authentication and Authorization Service (JAAS) login module that is used to create the SAML token. You must specify a JVM property to define a JAAS configuration file that contains the required JAAS login configuration; for example:

```
-Djava.security.auth.login.config=profile_root/properties/wsjaas_client.conf
```

Alternatively, you can specify a JAAS login configuration file by setting a Java system property in the sample client code; for example:

```
System.setProperty("java.security.auth.login.config", "profile_root/properties/wsjaas_client.conf");
```

b. Obtain the token identifier of the created SAML token.

Use the following statement as a simple test for the SAML token that you created:

```
System.out.println("SAMLToken id = " + samlToken.getId())
```

5. Add the SAML token to the SOAP security header of web services request messages.

a. Initialize the web services client and configure the SOAPAction properties. The following code example illustrates these actions:

```
// Initialize web services client
EchoService12PortProxy echo = new EchoService12PortProxy();
echo._getDescriptor().setEndpoint(endpointURL);

// Configure SOAPAction properties
BindingProvider bp = (BindingProvider) (echo._getDescriptor().getProxy());
Map<String, Object> requestContext = bp.getRequestContext();
requestContext.put(BindingProvider.ENDPOINT_ADDRESS_PROPERTY, endpointURL);
requestContext.put(BindingProvider.SOAPACTION_USE_PROPERTY, Boolean.TRUE);
requestContext.put(BindingProvider.SOAPACTION_URI_PROPERTY, "echoOperation");

// Initialize WSSGenerationContext
WSSGenerationContext gencont = factory.newWSSGenerationContext();
gencont.add(samlToken);
```

b. Initialize the WSSGenerationContext. The following code snippet illustrates the use of the gencont.object of the WSSGenerationContext type to initialize a generation context to enable you to insert the `SAMLToken` into a web services request message:

```
// Initialize WSSGenerationContext
WSSGenerationContext gencont = factory.newWSSGenerationContext();
gencont.add(samlToken);
```

Specifically, the `gencont.add(samlToken)` method call specifies to put the SAML token into a request message. This operation requires the client code to have the following Java 2 Security permission:

```
permission javax.security.auth.AuthPermission "modifyPrivateCredentials"
```

6. Add an X.509 token for message protection using the Web Services Security API.

   This sample code uses the dsig-sender.ks key file and the SOAPRequester sample key. You must not use the sample key in a production environment. The following code snippet illustrates adding an X.509 token for message protection:

```
// Add an X.509 Token for message protection
    X509GenerateCallbackHandler x509callbackHandler = new X509GenerateCallbackHandler(
         null,
         "profile_root/etc/ws-security/samples/dsig-sender.ks",
         "JKS",
         "client".toCharArray(),
         "soaprequester",
         "client".toCharArray(),
         "CN=SOAPRequester, OU=TRL, O=IBM, ST=Kanagawa, C=JP", null);

   SecurityToken x509 = factory.newSecurityToken(X509Token.class,
   x509callbackHandler, "system.wss.generate.x509");

   WSSSignature sig = factory.newWSSSignature(x509);
   sig.setSignatureMethod(WSSSignature.RSA_SHA1);

   WSSSignPart sigPart = factory.newWSSSignPart();
   sigPart.setSignPart(samlToken);
   sigPart.addTransform(WSSSignPart.TRANSFORM_STRT10);
   sig.addSignPart(sigPart);
   sig.addSignPart(WSSSignature.BODY);
```

a. Create a WSSSignature object with the X509 token. The following line of code creates a WSSSignature object with the X509 token:

```
WSSSignature sig = factory.newWSSSignature(x509);
```

b. Add the signed part to use for message protection. The following line of code specifies to add WSSSignature.BODY as the signed part:

```
sig.addSignPart(WSSSignature.BODY);
```

c. Add the timestamp element in the SOAP messages security header. The SAML20 SenderVouches WSHTTPS and SAML11 SenderVouches WSHTTPS policy sets require web services requests and response messages to carry a timestamp element in the SOAP messages Security header. In the following code snippet, the `factory.newWSSTimestamp()` method call generates the timestamp, and the `gencont.add(timestamp)` method call adds the timestamp into the request message:

```
// Add Timestamp
WSSTimestamp timestamp = factory.newWSSTimestamp();
   gencont.add(timestamp);
sig.addSignPart(WSSSignature.TIMESTAMP);

gencont.add(sig);

WSSConsumingContext concont = factory.newWSSConsumingContext();
```

d. Configure the SAML token signature using STR-Transform transform algorithm.

   A separate WSSSignPart is needed to specify the SecurityTokenReference transformation algorithm that is represented by the `WSSSignPart.TRANSFORM_STRT10` attribute. A SAML Token cannot be digitally signed directly. This attribute enables the Web Services Security runtime environment to generate a SecurityTokenReference element to reference the SAMLToken and to digitally sign the SAMLToken using the SecurityTokenReference transformation. The following line of code specifies to use the `WSSSignPart.TRANSFORM_STRT10` attribute:

```
WSSSignPart sigPart = factory.newWSSSignPart();
sigPart.setSignPart(samlToken);
sigPart.addTransform(WSSSignPart.TRANSFORM_STRT10);
```

e. Attach the WSSGenerationContext object to the web services RequestContext object. The WSSGenerationContext object now contains all the security information that is required to format a request message. The `gencont.process(requestContext)` method call attaches the WSSGenerationContext object to the web services RequestContext object to enable the Web Services Security runtime environment to format the required SOAP security header; for example:

```
// Attaches the WSSGenerationContext object to the web services RequestContext object.
gencont.process(requestContext);
```

7. Use the X.509 token to validate the digital signature and the integrity of the response message. If the provider policy requires the response message to be digitally signed, you must initialize the X.509 token.

   a. A X509ConsumeCallbackHandler object is initialized with a truststore, dsig-receiver.ks, and a certificate path object to validate the provider digital signature. The following line of code is used to initialize the X509ConsumeCallbackHandler object:

```
X509ConsumeCallbackHandler callbackHandlerVer = new X509ConsumeCallbackHandler(
 "profile_root/etc/ws-security/samples/dsig-receiver.ks",
          "JKS",
           "server".toCharArray(),
            certList,
                 java.security.Security.getProvider("IBMCertPath"));
```

   b. A WSSVerification object is created and the message body is added to the verification object so that the Web Services Security runtime environment validates the digital signature.

      The following line of code is used to initialize the WSSVerification object:

```
WSSVerification ver = factory.newWSSVerification(X509Token.class, callbackHandlerVer);
```

      The WSSConsumingContext object now contains all the security information that is required to format a request message. The `concont.process(requestContext)` method call attaches the WSSConsumingContext object to the response method; for example:

```
// Attaches the WSSConsumingContext object to the web services RequestContext object.
concont.process(requestContext);
```

Results

You have requested a SAML token with the sender-vouches confirmation method from an external STS. After obtaining the token, you sent the token with web services request messages using message level protection using the JAX-WS programming model and WSS APIs.

Example

The following code sample is a complete, ready-to-use web services client application that demonstrates how to request a SAML token from an external STS and send that SAML token in web services request messages with message level protection. This sample code illustrates the procedure steps described previously.

```

          "server".toCharArray(),
          certList,
          java.security.Security.getProvider("IBMCertPath"));

        WSSVerification ver = factory.newWSSVerification(X509Token.class, callbackHandlerVer);

        ver.addRequiredVerifyPart(WSSVerification.BODY);
        concont.add(ver);

        gencont.process(requestContext);
        concont.process(requestContext);

        // Build the input object
   EchoStringInput echoParm =
    new com.ibm.was.wssample.sei.echo.ObjectFactory().createEchoStringInput();
   echoParm.setEchoInput(input);
   System.out.println(">> CLIENT: SEI Echo to " + endpointURL);

   // Call the service
   response = echo.echoOperation(echoParm).getEchoResponse();

   System.out.println(">> CLIENT: SEI Echo invocation complete.");
   System.out.println(">> CLIENT: SEI Echo response is: " + response);
  } catch (Exception e) {
   System.out.println(">> CLIENT: ERROR: SEI Echo EXCEPTION.");
   e.printStackTrace();
  }
 }
}
```

When this web services client application sample runs correctly, you receive messages like the following messages:

```
SAMLToken id = _6CDDF0DBF91C044D211271166233407
Retrieving document at 'file:profile_root/.../wsdl/'.
>> CLIENT: SEI Echo to http://localhost:9443/WSSampleSei/EchoService12
>> CLIENT: SEI Echo invocation complete.
>> CLIENT: SEI Echo response is: SOAP12==>>HELLO
```

Requesting SAML sender-vouches tokens from an external STS using WSS APIs and transport level protection:

You can request SAML tokens with the sender-vouches subject confirmation method from an external Security Token Service (STS). After obtaining the SAML sender-vouches token, you can then send these tokens with web services request messages using the Java API for XML-Based Web Services (JAX-WS) programming model and Web Services Security APIs (WSS API) with transport level protection.

Before you begin

This task assumes that you are familiar with the JAX-WS programming model, the WSS API interfaces, SAML concepts, SSL transport protection, and the use of policy sets to configure and administer web services settings.

About this task

You can request a SAML token with the sender-vouches subject confirmation method from an external STS and then send the SAML token in web services request messages from a web services client using WSS APIs with transport level protection.

The web services client application used in this task is a modified version of the client code that is contained in the JaxWSServicesSamples sample application that is available for download. Code examples from the sample are described in the procedure, and a complete, ready-to-use web services client sample is provided.

Procedure

1. Identify and obtain the web services client that you want to use to invoke a web services provider. Use this client to insert SAML tokens in SOAP request messages programmatically using WSS APIs.

The web services client used in this procedure is a modified version of the client code that is contained in the JaxWSServicesSamples web services sample application.

To obtain and modify the sample web services client to add the Web Services Security API to pass SAML sender-vouches tokens in SOAP request messages programmatically using WSS APIs, complete the following steps:

a. Download the JaxWSServicesSamples sample application. The JaxWSServicesSamples sample is not installed by default.

b. Obtain the JaxWSServicesSamples client code.

   For example purposes, this procedure uses a modified version of the Echo thin client sample that is included in the JaxWSServicesSamples sample. The web services Echo thin client sample file, `SampleClient.java`, is located in the `src\SampleClientSei\src\com\ibm\was\wssample\sei\cli` directory. The sample class file is included in the `WSSampleClientSei.jar` file.

   The `JaxWSServicesSamples.ear` enterprise application and supporting Java archives (JAR) files are located in the `installableApps` directory within the JaxWSServicesSamples sample application.

c. Deploy the `JaxWSServicesSamples.ear` file onto the application server. After you deploy the `JaxWSServicesSamples.ear` file, you are ready to test the sample web services client code against the sample application.

Instead of using the web services client sample, you can choose to add the code snippets to pass SAML tokens in SOAP request messages programmatically using WSS APIs in your own web services client application. The example in this procedure uses a JAX-WS Web services thin client; however, you can also use a managed client.

2. Create a copy of either the SAML20 Bearer WSHTTPS default policy set or the SAML11 Bearer WSHTTPS default policy set.

   Provide a name for the copy of the policy set; for example SAML20 SenderVouches WSHTTPS or SAML11 SenderVouches WSHTTPS to help you identify that this new policy set uses the sender-vouches confirmation method.

   No additional change is required to the new policy file because the subject confirmation method is specified in the binding configuration and not in the policy.

   The new policy file contains either SAMLToken20Bearer or the SAMLToken11Bearer as the policy identifiers. Change the identifier of the SAMLToken20Bearer policy to SAMLToken20SV or change the identifier of the SAMLToken11Bearer policy to SAMLToken11SV to specify a more descriptive name. Changing the identifier of the policy does not change the policy enforcement in any way; however, adding a descriptive identifier helps you to identify that these policy identifiers use the sender-vouches confirmation method.

   If you want to view the settings of these policies, use the administrative console to complete the following actions:

   a. Click **Services** > **Policy sets** > **Application policy sets** > ***policy_set_name***.

   b. Click the **WS-Security** policy in the policies table.

   c. Click the **Main policy** link or the **Bootstrap policy** link.

   d. Click **Request token policies** from the Policy Details section.

3. Attach the new SAML20 SenderVouches WSHTTPS or SAML11 SenderVouches WSHTTPS policy set to the web services provider application. Read about configuring client and provider bindings for the SAML sender-vouches token for details on attaching this policy set to your web services provider application.

4. Create a copy of the SAML Bearer Provider sample default general bindings.

   a. For the new copy of the default policy set, provide a name that includes sender-vouches, such as `SAML Sender-vouches provider binding`.

   b. In the callback handler of your SAML11 or SAML20 token consumer, change the value of the confirmationMethod property to `sender-vouches` in the token consumer configuration for the intended SAML token version. Ensure that the custom properties trustStoreType, trustStorePassword and trustStorePath correspond to the trust store containing the STS signer

certificate. Read about configuring client and provider bindings for the SAML sender-vouches token for details on modifying the sender-vouches bindings to satisfy the vouching requirement.

5. Assign the new provider binding to the JaxWSServicesSamples provider sample. Read about configuring client and provider bindings for the SAML sender-vouches for details on assigning the SAML sender-vouches provider sample, default general bindings to your web services provider application.
6. Enable the web services provider SSL configuration attribute, clientAuthentication, to require X.509 client certificate authentication.

   The clientAuthentication attribute determines whether SSL client authentication is required. To specify the clientAuthentication attribute, use the administrative console to complete the following actions:

   a. Click **Security** > **SSL certificates and key management** > **Manage endpoint security configurations** > **{Inbound | Outbound}** > ***SSL_configuration***.
   b. Click the **WC_defaulthost_secure** link in the inbound topology.
   c. From Related Items, click the **SSL_configurations** link.
   d. Select the **NodeDefaultSSLSettings** resource.
   e. Click **Quality of protection (QoP) settings** link.
   f. Select **Required** from the menu to specify client authentication.

   Read about creating a secure sockets layer configuration to learn more about configuring the clientAuthentication attribute.
7. Specify to use SSL transport-level message protection. Use the following JVM property to specify to use SSL to protect the SAML token request with the STS:

```
-Dcom.ibm.SSL.ConfigURL=file:profile_root\properties\ssl.client.props
```

   Alternatively, you can define the SSL configuration file using a Java system property in the sample client code; for example:

```
System.setProperty("com.ibm.SSL.ConfigURL", "file:profile_root/properties/ssl.client.props");
```

8. Add the Thin Client for JAX-WS JAR file to the class path. Add the *app_server_root*/runtimes/com.ibm.jaxws.thinclient_8.5.0.jar file to the class path. See the testing web services-enabled clients information for more information about adding this JAR file to the class path.
9. Request the SAML token from an external STS. The following code snippet illustrates how to request the SAML sender-vouches token and assumes that an external STS is configured to accept a UsernameToken, and to issue a SAML 1.1 token using sender-vouches after validation:

```
//Request the SAML Token from external STS
WSSFactory factory = WSSFactory.getInstance();
String STS_URI  = "https://externalstsserverurl:port/TrustServerWST13/services/RequestSecurityToken";
String ENDPOINT_URL = "http://localhost:9080/WSSampleSei/EchoService";
WSSGenerationContext gencont1 = factory.newWSSGenerationContext();
WSSConsumingContext concont1 = factory.newWSSConsumingContext();
HashMap<Object, Object> cbackMap1 = new HashMap<Object, Object>();
cbackMap1.put(SamlConstants.STS_ADDRESS, STS_URI);
cbackMap1.put(SamlConstants.SAML_APPLIES_TO, ENDPOINT_URL);
cbackMap1.put(SamlConstants.TRUST_CLIENT_WSTRUST_NAMESPACE, "http://docs.oasis-open.org/ws-sx/ws-trust/200512");
cbackMap1.put(SamlConstants.TRUST_CLIENT_COLLECTION_REQUEST, "false");
cbackMap1.put(SamlConstants.TOKEN_TYPE, WSSConstants.SAML.SAML11_VALUE_TYPE);
cbackMap1.put(SamlConstants.CONFIRMATION_METHOD, "sender-vouches");

SAMLGenerateCallbackHandler cbHandler1 = new SAMLGenerateCallbackHandler(cbackMap1);

// Add UNT to trust request
UNTGenerateCallbackHandler utCallbackHandler = new UNTGenerateCallbackHandler("testuser", "testuserpwd");
SecurityToken ut = factory.newSecurityToken(UsernameToken.class, utCallbackHandler);

gencont1.add(ut);

cbHandler1.setWSSConsumingContextForTrustClient(concont1);
cbHandler1.setWSSGenerationContextForTrustClient(gencont1);
SecurityToken samlToken = factory.newSecurityToken(SAMLToken.class, cbHandler1, "system.wss.generate.saml");

System.out.println("SAMLToken id = " + samlToken.getId());
```

   a. Use the WSSFactory newSecurityToken method to specify how to request the SAML token from an external STS.

      Specify the following method to create the SAML token:

```
WSSFactory  newSecurityToken(SAMLToken.class, callbackHandler, "system.wss.generate.saml")
```

Requesting a SAML token requires the Java security permission wssapi.SAMLTokenFactory.newSAMLToken. Use the Policy Tool to add the following policy statement to the Java security policy file or the application client was.policy file:

```
permission java.security.SecurityPermission "wssapi.SAMLTokenFactory.newSAMLToken"
```

The `SAMLToken.class` parameter specifies the type of security token to create.

The `callbackHandler` object contains parameters that define the characteristics of the SAMLToken that you are requesting and other parameters required to reach the STS and obtain the SAML token. The SAMLGenerateCallbackHandler object specifies the configuration parameters described in the following table:

Table 206. SAMLGenerateCallbackHandler properties. This table describes the configuration parameters for the SAMLGenerateCallbackHandler object using the sender-vouches confirmation method.

Property	Description	Required
SamlConstants.CONFIRMATION_METHOD	Specifies to use the `sender-vouches` confirmation method.	Yes
SamlConstants.TOKEN_TYPE	Specifies the token type. When a web services client has policy set attachments, this property is not used by the Web Services Security runtime environment. Specify the token value type by using the `valueType` attribute of the tokenGenerator binding configuration. The example in this procedure uses a SAML 1.1 token; however, you can also use the `WSSConstants.SAML.SAML20_VALUE_TYPE` value.	Yes
SamlConstants.STS_ADDRESS	Specifies the Security Token Service address. For the example used in this task topic, the value of this property is set to `https` to specify to use SSL to protect the SAML Token request. You must set the -Dcom.ibm.SSL.ConfigURL property to enable the use of SSL to protect the SAML token request with the STS.	Yes
SamlConstants.SAML_APPLIES_TO	Specifies the target STS address for where you want to use the SAML token.	No
SamlConstants.TRUST_CLIENT_COLLECTION_REQUEST	Specifies whether to request from the STS a single token that is enclosed in a RequestSecurityToken (RST) element or multiple tokens in a collection of RST elements that are enclosed in a single RequestSecurityTokenCollection (RSTC) element. The default behavior is to request a single token that is enclosed in a RequestSecurityToken (RST) element from the STS. Specifying a `true` value for this property indicates to request multiple tokens in a collection of RST elements that are enclosed in a single RequestSecurityTokenCollection (RSTC) element from the STS.	No
SamlConstants.TRUST_CLIENT_WSTRUST_NAMESPACE	Specifies the WS-Trust namespace that is included in the WS-Trust request. The default value is WSTrust 1.3.	No

A WSSGenerationContext instance and a WSSConsumingContext instance are also set in the SAMLGenerateCallbackHandler object. The WSSGenerationContext instance must contain a UNTGenerateCallbackHandler object with the information to create the UsernameToken that you want to send to the STS.

The `system.wss.generate.saml` parameter specifies the Java Authentication and Authorization Service (JAAS) login module that is used to create the SAML token. You must specify a JVM property to define a JAAS configuration file that contains the required JAAS login configuration; for example:

```
-Djava.security.auth.login.config=profile_root/properties/wsjaas_client.conf
```

Alternatively, you can specify a JAAS login configuration file by setting a Java system property in the sample client code; for example:

```
System.setProperty("java.security.auth.login.config", "profile_root/properties/wsjaas_client.conf");
```

b. Obtain the token identifier of the created SAML token.

Use the following statement as a simple test for the SAML token that you created:

```
System.out.println("SAMLToken id = " + samlToken.getId())
```

Results

You have requested a SAML token with the sender-vouches confirmation method from an external STS. After obtaining the token, you sent the token with web services request messages using transport protection using the JAX-WS programming model and WSS APIs.

Example

The following code sample is a complete, ready-to-use web services client application that demonstrates how to request a SAML token from an external STS and send that SAML token in web services request messages with transport level protection. This sample code illustrates the procedure steps described previously.

```

         WSSTimestamp timestamp = factory.newWSSTimestamp();
   gencont.add(timestamp);

         gencont.process(requestContext);

         // Build the input object
   EchoStringInput echoParm =
    new com.ibm.was.wssample.sei.echo.ObjectFactory().createEchoStringInput();
   echoParm.setEchoInput(input);
   System.out.println(">> CLIENT: SEI Echo to " + endpointURL);

   // Prepare to consume timestamp in response message
   WSSConsumingContext concont = factory.newWSSConsumingContext();
       concont.add(WSSConsumingContext.TIMESTAMP);
       concont.process(requestContext);

   // Call the service
   response = echo.echoOperation(echoParm).getEchoResponse();

   System.out.println(">> CLIENT: SEI Echo invocation complete.");
   System.out.println(">> CLIENT: SEI Echo response is: " + response);
  } catch (Exception e) {
   System.out.println(">> CLIENT: ERROR: SEI Echo EXCEPTION.");
   e.printStackTrace();
     }
 }
}
```

When this web services client application sample runs correctly, you receive messages like the following messages:

```
SAMLToken id = _6CDDF0DBF91C044D211271166233407
Retrieving document at 'file:profile_root/.../wsdl/'.
>> CLIENT: SEI Echo to http://localhost:9443/WSSampleSei/EchoService12
>> CLIENT: SEI Echo invocation complete.
>> CLIENT: SEI Echo response is: SOAP12===>>HELLO
```

Requesting SAML holder-of-key tokens with symmetric key from external security token service using WSS APIs:

You can request an external security token service (STS) to issue SAML tokens with the holder-of-key subject confirmation method with symmetric key that is encrypted for a target service. Use the Java API for XML-Based Web Services (JAX-WS) programming model and Web Services Security APIs (WSS APIs) to complete this task.

Before you begin

This task assumes that you are familiar with the JAX-WS programming model, the WSS API interfaces, SAML concepts, and the use of policy sets to configure and administer web services settings. Complete the following actions before you begin this task:

- Read about propagating self-issued SAML holder-of-key tokens with symmetric key by using WSS APIs.
- Become familiar with using embedded key materials in SAML tokens for message protection by using WSS APIs. Your usage scenario requires requesting SAML tokens from an external STS instead of using self-issued SAML tokens.
- Read about requesting SAML sender-vouches tokens from an external STS to propagate by using WSS APIs with message level protection.
- Read about requesting SAML sender-vouches tokens from an external STS to propagate by using WSS APIs with transport level protection.
- Read about requesting SAML bearer tokens from an external STS to propagate by using WSS APIs with transport level protection.
- Be familiar with accessing an external STS by using WSS APIs.

About this task

This task shows example code to request SAML tokens from an external STS, with holder-of-key subject confirmation method and embedded symmetric key that is encrypted for the target service by using WSS APIs. This task focuses on sending a WS-Trust request message to an external STS to request SAML holder-of-key tokens with symmetric keys.

Procedure

1. Specify an STS from which to request a SAML security token that contains holder-of-key subject confirmation method; for example:

```
com.ibm.websphere.wssecurity.wssapi.WSSFactory factory =
    com.ibm.websphere.wssecurity.wssapi.WSSFactory.getInstance();
WSSGenerationContext gencont1 = factory.newWSSGenerationContext();
WSSConsumingContext concont1 = factory.newWSSConsumingContext();
HashMap<Object, Object> cbackMap1 = new HashMap<Object, Object>();
cbackMap1.put(SamlConstants.STS_ADDRESS, "https://www.example.com/sts");  //STS URL
cbackMap1.put(SamlConstants.SAML_APPLIES_TO, "http://myhost:9080/myService");  //Target Service
cbackMap1.put(IssuedTokenConfigConstants.TRUST_CLIENT_SOAP_VERSION, "1.1");
cbackMap1.put(IssuedTokenConfigConstants.TRUST_CLIENT_WSTRUST_NAMESPACE,
                  "http://docs.oasis-open.org/ws-sx/ws-trust/200512");
cbackMap1.put(IssuedTokenConfigConstants.TRUST_CLIENT_COLLECTION_REQUEST,
              "true");   //RST or RSTC
cbackMap1.put(SamlConstants.TOKEN_TYPE,
              "http://docs.oasis-open.org/wss/oasis-wss-saml-token-profile-1.1#SAMLV2.0");
cbackMap1.put(SamlConstants.CONFIRMATION_METHOD, "holder-of-key");
```

   To request a holder-of-key SAML security token from the STS, you must specify whether to embed a symmetric key or a public key by way of a `KeyType` element in a trust request. This example requires a symmetric key type as shown in the next step.

2. Specify the symmetric key to be embedded in SAML security tokens; for example:

```
cbackMap1.put(SamlConstants.KEY_TYPE,
             "http://docs.oasis-open.org/ws-sx/ws-trust/200512/SymmetricKey");

SAMLGenerateCallbackHandler cbHandler1 = new SAMLGenerateCallbackHandler(cbackMap1);
cbHandler1.setWSSConsumingContextForTrustClient(concont1);
cbHandler1.setWSSGenerationContextForTrustClient(gencont1);

SecurityToken samlToken = factory.newSecurityToken(SAMLToken.class,
                                                   cbHandler1, "system.wss.generate.saml");
```

The requested SAML token contains a symmetric key that is encrypted for the target service. The STS also returns the unencrypted symmetric key through the `WS-Trust RequestedProofToken` element. See the following example.

```
<wst:RequestedProofToken>
    <wst:BinarySecret
      xmlns:wsu="http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-utility-1.0.xsd"
      wsu:Id="_27325D34CE4BCC83141288966548620">n68rFQba+XTZLNBfEc4prg==</wst:BinarySecret>
</wst:RequestedProofToken>
```

The `RequestedProofToken` element is shown here for your information. The detailed processing is not exposed to WSS APIs users. The `RequestedProofToken` element and the symmetric key are handled by the Web Services Security runtime environment, or more precisely by the `SAMLGenerateLoginModule` that is specified in the `system.wss.geenrate.saml` JAAS login configuration.

Results

You have learned key building blocks for requesting SAML tokens with holder-of-key subject confirmation method and symmetric key from an external STS by using WSS APIs. To use the SAML token to sign request messages, review the example code in the “Propagating self-issued SAML holder-of-key tokens with symmetric key by using WSS APIs” topic.

Requesting SAML holder-of-key tokens with asymmetric key from External Security Token Service using WSS APIs:

You can request an external Security Token Service (STS) to issue SAML tokens with the holder-of-key subject confirmation method with a public key in an X.509 certificate with the Java API for XML-Based Web Services (JAX-WS) programming model and Web Services Security APIs (WSS APIs).

Before you begin

This task assumes that you are familiar with the JAX-WS programming model, the WSS API interfaces, SAML concepts, and the use of policy sets to configure and administer web services settings. Complete the following actions before you begin this task:

- Read about propagating self-issued SAML holder-of-key tokens with asymmetric key by using WSS APIs.
- Become familiar with using embedded key materials in SAML tokens for message protection by using WSS APIs. Your usage scenario requires requesting SAML tokens from an external STS instead of using self-issued SAML tokens.
- Read about requesting SAML sender-vouches tokens from an external STS to propagate by using WSS APIs with message level protection.
- Read about requesting SAML sender-vouches tokens from an external STS to propagate by using WSS APIs with transport level protection.
- Read about requesting SAML bearer tokens from an external STS, which you propagate by using WSS APIs with transport level protection.
- Become familiar with accessing an external STS by using WSS APIs.

About this task

This task shows example code to request SAML tokens with the holder-of-key subject confirmation method and the embedded public key in an X.509 certificate by using WSS APIs, from an external STS. This task focuses on sending an X.509 certificate to an external STS when requesting SAML holder-of-key tokens.

Procedure

1. Specify an STS from which to request a SAML security token that contains holder-of-key subject confirmation method; for example:

```
com.ibm.websphere.wssecurity.wssapi.WSSFactory factory =
    com.ibm.websphere.wssecurity.wssapi.WSSFactory.getInstance();
WSSGenerationContext gencont1 = factory.newWSSGenerationContext();
WSSConsumingContext concont1 = factory.newWSSConsumingContext();
HashMap<Object, Object> cbackMap1 = new HashMap<Object, Object>();
cbackMap1.put(SamlConstants.STS_ADDRESS, "https://www.example.com/sts");
cbackMap1.put(SamlConstants.SAML_APPLIES_TO, "http://myhost:9080/myService");
cbackMap1.put(IssuedTokenConfigConstants.TRUST_CLIENT_SOAP_VERSION, "1.1");
cbackMap1.put(IssuedTokenConfigConstants.TRUST_CLIENT_WSTRUST_NAMESPACE,
              "http://docs.oasis-open.org/ws-sx/ws-trust/200512");
cbackMap1.put(IssuedTokenConfigConstants.TRUST_CLIENT_COLLECTION_REQUEST,
              "true");   //RST or RSTC
cbackMap1.put(SamlConstants.TOKEN_TYPE,
              "http://docs.oasis-open.org/wss/oasis-wss-saml-token-profile-1.1#SAMLV2.0");
cbackMap1.put(SamlConstants.CONFIRMATION_METHOD, "holder-of-key");
```

For the holder-of-key subject confirmation method, you must specify whether a public key or a symmetric key is embedded in SAML tokens. This example specifies a public key type. It then specifies the location of a certificate that contains the public key, and the location of the corresponding private key for the sender to digitally sign elements of SOAP messages to satisfy the holder-of-key subject confirmation requirements.

2. Specify the location of an X.509 certificate to embed in SAML tokens and a corresponding private key for using to digitally sign message elements; for example:

```
cbackMap1.put(SamlConstants.KEY_TYPE,
              "http://docs.oasis-open.org/ws-sx/ws-trust/200512/PublicKey");
cbackMap1.put(SamlConstants.KEY_ALIAS, "soapinitiator" );
cbackMap1.put(SamlConstants.KEY_NAME, "CN=SOAPInitator, O=Example");
cbackMap1.put(SamlConstants.KEY_PASSWORD, "keypass");
cbackMap1.put(SamlConstants.KEY_STORE_PATH, "keystores/initiator.jceks");
cbackMap1.put(SamlConstants.KEY_STORE_PASSWORD, "storepass");
cbackMap1.put(SamlConstants.KEY_STORE_TYPE, "jceks");

SAMLGenerateCallbackHandler cbHandler1 = new SAMLGenerateCallbackHandler(cbackMap1);
cbHandler1.setWSSConsumingContextForTrustClient(concont1);
cbHandler1.setWSSGenerationContextForTrustClient(gencont1);

SecurityToken samlToken = factory.newSecurityToken(SAMLToken.class,
                                                   cbHandler1, "system.wss.generate.saml");
```

The specified X.509 certificate is sent in WS-Trust requests to the external STS in the `trust:UseKey` element. For more information read about SAML assertions defined in the SAML Token Profile standard. SSL is used to protect integrity and confidentiality of WS-Trust request and response messages in this example.

Results

You have learned key building blocks to request SAML tokens with the holder-of-key subject confirmation method and asymmetric key from an external STS using WSS APIs. To use the SAML token to sign request messages, become familiar with the example code in the "Propagating self-issued SAML holder-of-key tokens with asymmetric key by using WSS APIs" topic.

Sending a security token using WSSAPIs with a generic security token login module:

You can request an authentication token from an external *Security Token Service (STS)*, and then send the token with web service request messages using the Java API for XML-Based Web Services (JAX-WS) programming model and Web Services Security APIs (WSS API), with message or transport level protection.

Before you begin

This task assumes that you are familiar with the JAX-WS programming model, the WSS API interfaces, WebSphere web service security generic security token login modules, SSL transport protection, message level protection, and the use of policy sets to configure and administer web services settings.

About this task

The web service client application used in this task is a modified version of the client code that is contained in the JaxWSServicesSamples sample application that is available for download. Code examples from the sample are described in the procedure, and a complete, ready-to-use web service client sample is provided.

Complete the following steps to request a SAML Bearer authentication token from an external STS and send the token:

Procedure

1. Identify and obtain the web service client that you want to use to invoke a web service provider. Use this client to request and to insert authentication tokens in the SOAP request messages programmatically using WSS APIs. The web service client used in this procedure is a modified version of the client code that is contained in the JaxWSServicesSamples web service sample application.

   Complete the following steps to obtain and modify the sample web service client to add the Web Services Security API to pass a security token in the SOAP request message programmatically using WSS APIs:

   a. Download the JaxWSServicesSamples sample application. The JaxWSServicesSamples sample is not installed by default.

   b. Obtain the JaxWSServicesSamples client code. For the purpose of this example, the procedure uses a modified version of the Echo thin client sample that is included in the JaxWSServicesSamples sample. The web service Echo thin client sample file, `SampleClient.java`, is located in the `src\SampleClientSei\src\com\ibm\was\wssample\sei\cli` directory. The sample class file is included in the `WSSampleClientSei.jar` file.

      The `JaxWSServicesSamples.ear` enterprise application and supporting Java archives (JAR) files are located in the `installableApps` directory within the JaxWSServicesSamples sample application.

   c. Deploy the `JaxWSServicesSamples.ear` file onto the application server. After you deploy the `JaxWSServicesSamples.ear` file, you are ready to test the sample web service client code against the sample application.

      Instead of using the PolicySet for the protection of the web service client sample, you can choose to add the code snippets to pass authentication tokens in the SOAP request message programmatically using WSS APIs in your own web service client application. The example in this procedure uses a JAX-WS web service thin client; however, you can also use a managed client.

   d. Attach the SAML11 Bearer WSHTTPS default policy set to the web services provider. This policy set is used to protect messages using HTTPS transport. Read about configuring client and provider bindings for the SAML Bearer token for details on how to attach the SAML11 Bearer WSHTTPS default policy set to the web services provider.

   e. Assign the SAML Bearer Provider sample default general bindings to the sample web services provider. Read about configuring client and provider bindings for the SAML bearer token for details on assigning the SAML Bearer Provider sample default general bindings to your web services application.

   f. Verify that the trustStoreType, trustStorePassword and trustStorePath custom properties correspond to the trust store containing the STS signer certificate. Complete the following steps by using the administrative console:

      1) Click **Services** > **Policy sets** > **General provider policy set bindings** > **Saml Bearer Provider sample** > **WS-Security** > **Authentication and protection**.

      2) Click **con_saml11token** in the Authentication tokens table.

      3) Click **Callback handler**.

      4) In the Custom Properties section, ensure that the trustStoreType, trustStorePassword and trustStorePath custom properties correspond to the trust store containing the STS signer certificate.

2. If you are using SSL Transport-level protection to protect the web service request or the WS-Trust request, use the following Java virtual machine (JVM) property to set up the SSL configuration.

```
-Dcom.ibm.SSL.ConfigURL=file:<profile_root>\properties\ssl.client.props
```

   Alternatively, you can define the SSL configuration file using a Java system property in the sample client code:

```
System.setProperty("com.ibm.SSL.ConfigURL", "file:profile_root/properties/ssl.client.props");
```

3. Add the JAR file for the JAX-WS thin client to the class path: `app_server_root/runtimes/com.ibm.jaxws.thinclient_8.5.0.jar`. See the testing web service-enabled clients information for more information about adding this JAR file to the class path.
4. Request the authentication token from an external STS. The following code snippet illustrates how to request the authentication token to be used with WebSphere generic SecurityToken login module, and assumes that an external STS is configured to accept a Username token as authentication token, and to issue a SAML 1.1 token.

```
//Request SecurityToken from external STS:
WSSFactory factory = WSSFactory.getInstance();
//STS URL that issues the requested token
String STS_URI  = "https://externalstsserverurl:port/TrustServerWST13/services/RequestSecurityToken";
//Web services endpoint that receives the issued token
String ENDPOINT_URL = "http://localhost:9080/WSSampleSei/EchoService";

//Begin sample code 1 (Using WS-Trust Issue to request the token from
//the STS in which authentication token is send over WS-Security head):
HashMap<Object, Object> cbackMap1 = new HashMap<Object, Object>();
cbackMap1.put(IssuedTokenConfigConstants.STS_ADDRESS, STS_URI);
cbackMap1.put(IssuedTokenConfigConstants.APPLIES_TO, ENDPOINT_URL);
//The following property specifies that the ws-trust request should be
//compliance with WS-Trust 1.3 spec
cbackMap1.put(IssuedTokenConfigConstants.TRUST_CLIENT_WSTRUST_NAMESPACE,
"http://docs.oasis-open.org/ws-sx/ws-trust/200512");
cbackMap1.put(IssuedTokenConfigConstants.TRUST_CLIENT_COLLECTION_REQUEST, "false");
//This request is made with WS-TRust Issue only (without the use of
//WS-Trust Validate)
cbackMap1.put(IssuedTokenConfigConstants.USE_RUN_AS_SUBJECT, "false");

GenericIssuedTokenGenerateCallbackHandler cbHandler1 =
new GenericIssuedTokenGenerateCallbackHandler (cbackMap1);

//Create the context object for WS-Trust request:
WSSGenerationContext gencont1 = factory.newWSSGenerationContext();
WSSConsumingContext concont1 = factory.newWSSConsumingContext();
// Use UNT for trust request authentication
UNTGenerateCallbackHandler utCallbackHandler = new UNTGenerateCallbackHandler("testuser", "testuserpwd");
SecurityToken ut = factory.newSecurityToken(UsernameToken.class, utCallbackHandler);
gencont1.add(ut);
cbHandler1.setWSSConsumingContextForTrustClient(concont1);
cbHandler1.setWSSGenerationContextForTrustClient(gencont1);
//End of sample code 1.

//Begin sample code 2 (using WS-Trust Validate to request a token by
//exchanging a token in RunAs Subject).
//If web service client has RunAs Subject , for example an
//authenticated intermediate server acts as a client to invoke the
//downstream service, you can program the client to use the token from
//the RunAs subject to exchange with the STS by using WS-Trust validate.
//To do so, you replace sample code 1 with the following:
HashMap<Object, Object> cbackMap1 = new HashMap<Object, Object>();
cbackMap1.put(IssuedTokenConfigConstants.STS_ADDRESS, STS_URI);
cbackMap1.put(IssuedTokenConfigConstants.APPLIES_TO, ENDPOINT_URL);
//This request is made with WS-Trust 1.3
cbackMap1.put(IssuedTokenConfigConstants.TRUST_CLIENT_WSTRUST_NAMESPACE,
"http://docs.oasis-open.org/ws-sx/ws-trust/200512");
cbackMap1.put(IssuedTokenConfigConstants.TRUST_CLIENT_COLLECTION_REQUEST, "false");

//add the next line if you do not want to fallback to WS-Trust Issue if
//token exchange fails.
cbackMap1.put(IssuedTokenConfigConstants.USE_RUN_AS_SUBJECT_ONLY, "true");

//add the next line to specify the token type in the RunAs subject that
//will be used to exchange the requested token. For example, you use
//the LTPA token to exchange for a SAML token. If the exchanged token
//in the RunAs subject has the same value type as the requested token,
//setting IssuedTokenConfigConstants.USE_TOKEN is not required.
cbackMap1.put(IssuedTokenConfigConstants.USE_TOKEN, LTPAToken.ValueType);

GenericIssuedTokenGenerateCallbackHandler cbHandler1 =
    new GenericIssuedTokenGenerateCallbackHandler (cbackMap1);
//The following codes are added if Authentication token in ws-security
//head or Message level security protection is required. If there is no
//Message level protection or additional authentication token for
//WS-Trust Validate, do not create the context object shown below.
//Context object for WS-Trust request:
```

```
WSSGenerationContext gencont1 = factory.newWSSGenerationContext();
WSSConsumingContext concont1 = factory.newWSSConsumingContext();
// Use UNT for trust request authentication
UNTGenerateCallbackHandler utCallbackHandler =
    new UNTGenerateCallbackHandler("testuser", "testuserpwd");
SecurityToken ut = factory.newSecurityToken(UsernameToken.class, utCallbackHandler);
gencont1.add(ut);
cbHandler1.setWSSConsumingContextForTrustClient(concont1);
cbHandler1.setWSSGenerationContextForTrustClient(gencont1);

//End of sample code 2.

GenericSecurityToken token = (GenericSecurityToken) factory.newSecurityToken
(GenericSecurityToken.class, cbHandler1, "system.wss.generate.issuedToken");

//The following step to set ValueType is required..
//The parameter is always the QName of the requested token's valueType.
//QName for SAML1.1:
QName Saml11ValueType = new QName(WSSConstants.SAML.SAML11_VALUE_TYPE);
            token.setValueType(Saml11ValueType);

//This article includes QName definitions for  SAML11, SAML20, TAM
//token, and Pass ticket token.
//QName for SAML 2.0:
QName Saml20ValueType = new QName(WSSConstants.SAML.SAML20_VALUE_TYPE);
token.setValueType(Saml11ValueType);
//QName for TAM token:
QName TamValueType = new QName("http://ibm.com/2004/01/itfim/ivcred");
//QName for PassTicket token:
QName PassTicketValueType = new QName("http://docs.oasis-open.org/wss/
2004/01/oasis-200401-wss-username-token-profile-1.0#UsernameToken");

//You can use the Token interface to get the token ValueType QName for
//all other tokens. For example, a Username Token's QName is //UsernameToken.ValueType.
```

The `GenericIssuedTokenGenerateCallbackHandler` object contains parameters that define the characteristics of the security token that you are requesting, as well as other parameters required to reach the STS and to obtain the security token. The `GenericIssuedTokenGenerateCallbackHandler` object specifies the configuration parameters described in the following table:

Table 207. `GenericIssuedTokenGenerateCallbackHandler` properties. This table describes the configuration parameters for the `GenericIssuedTokenGenerateCallbackHandler` object, and specifies whether or not the property is required.

Property	Description	Required
`IssuedTokenConfigConstants.STS_ADDRESS`	Specifies the http address of the STS. When communication to the STS is protected with SSL, you must set the `-Dcom.ibm.SSL.ConfigURL` property. SSL connection to the STS is indicated with an `https://` address prefix.	Yes
`IssuedTokenConfigConstants.APPLIES_TO`	Specifies the target service address for where you want to use the token.	No
`IssuedTokenConfigConstants.TRUST_CLIENT_COLLECTION_REQUEST`	Specifies whether to request a single token from the STS that is enclosed in a `RequestSecurityToken (RST)` element or multiple tokens in a collection of RST elements that are enclosed in a single `RequestSecurityTokenCollection (RSTC)` element. The default behavior is to request a single token that is enclosed in a `RequestSecurityToken (RST)` element from the STS. Specifying a `true` value for this property indicates a request for multiple tokens in a collection of RST elements that are enclosed in a single `RequestSecurityTokenCollection (RSTC)` element from the STS. The default value is `false`.	No
`IssuedTokenConfigConstants.TRUST_CLIENT_WSTRUST_NAMESPACE`	Specifies the WS-Trust namespace that is included in the WS-Trust request. The default value is `WSTrust 1.3`.	No

Table 207. `GenericIssuedTokenGenerateCallbackHandler` properties (continued). This table describes the configuration parameters for the `GenericIssuedTokenGenerateCallbackHandler` object, and specifies whether or not the property is required.

Property	Description	Required
`IssuedTokenConfigConstants.USE_RUN_AS_SUBJECT`	Specify if you want WS-Security to use the token from the RunAs subject to exchange the requested token first by using WS-Trust Validate. If set to `false`, WS-Security will use WS-Trust Issue to request the token. The default value is `true`.	No
`IssuedTokenConfigConstants.USE_RUN_AS_SUBJECT_ONLY`	Specify if you do not want WS-Security to use WS-Trust Issue to the requested token if token exchange fails. The default value is `false`.	No
`IssuedTokenConfigConstants.USE_TOKEN`	Use this value to choose a token from the RunAs subject to exchange the requested token. The default value is the requested token's `ValueType`.	No

A `WSSGenerationContext` instance and a `WSSConsumingContext` instance are also set in the `GenericIssuedTokenGenerateCallbackHandler` object. In this example, the `WSSGenerationContext` instance contains a `UNTGenerateCallbackHandler` object with the information to create the `UsernameToken` that you want to send to the STS.

The `system.wss.generate.issuedToken` parameter specifies the Java Authentication and Authorization Service (JAAS) login module that is used to create the generic security token. You must specify a JVM property to define a JAAS configuration file that contains the required JAAS login configuration; for example:

```
-Djava.security.auth.login.config=profile_root/properties/wsjaas_client.conf
```

Alternatively, you can specify a JAAS login configuration file by setting a Java system property in the sample client code; for example:

```
System.setProperty("java.security.auth.login.config", "profile_root/properties/wsjaas_client.conf");
```

5. Add the requested authentication token from the STS to the SOAP security header of web services request messages.
   a. Initialize the web service client and configure the `SOAPAction` properties. The following code illustrates these actions:

```
// Initialize web service client
EchoService12PortProxy echo = new EchoService12PortProxy();
echo._getDescriptor().setEndpoint(endpointURL);

// Configure SOAPAction properties
BindingProvider bp = (BindingProvider) (echo._getDescriptor().getProxy());
Map<String, Object> requestContext = bp.getRequestContext();
requestContext.put(BindingProvider.ENDPOINT_ADDRESS_PROPERTY, endpointURL);
requestContext.put(BindingProvider.SOAPACTION_USE_PROPERTY, Boolean.TRUE);
requestContext.put(BindingProvider.SOAPACTION_URI_PROPERTY, "echoOperation");

// Initialize WSSGenerationContext
WSSGenerationContext gencont = factory.newWSSGenerationContext();
gencont.add(token);
```

   b. Initialize the `WSSGenerationContext` object. The following code illustrates using the `WSSFactory.newWSSGenerationContext` method to obtain a `WSSGenerationContext` object. The `WSSGenerationContext` object is then used to insert the token into a web service request message:

```
// Initialize WSSGenerationContext
WSSGenerationContext gencont = factory.newWSSGenerationContext();
gencont.add(token);
```

The `WSSGenerationContext.add` method requires the client code to have the following Java 2 Security permission:

```
permission javax.security.auth.AuthPermission "modifyPrivateCredentials"
```

6. Add an X.509 token for message protection (skip this step if the web service is protected with SSL Transport level protection only). The following sample code uses the `dsig-sender.ks` key file and the

SOAPRequester sample key. You must not use the sample key in a production environment. The following code illustrates adding an X.509 token for message protection:

```
//Add an X.509 Token for message protection
X509GenerateCallbackHandler x509callbackHandler = new X509GenerateCallbackHandler(
    null,
    "profile_root/etc/ws-security/samples/dsig-sender.ks",
    "JKS",
    "client".toCharArray(),
    "soaprequester",
    "client".toCharArray(),
    "CN=SOAPRequester, OU=TRL, O=IBM, ST=Kanagawa, C=JP", null);

SecurityToken x509 = factory.newSecurityToken(X509Token.class,
x509callbackHandler, "system.wss.generate.x509");

WSSSignature sig = factory.newWSSSignature(x509);
sig.setSignatureMethod(WSSSignature.RSA_SHA1);

WSSSignPart sigPart = factory.newWSSSignPart();
sigPart.setSignPart(token);
sigPart.addTransform(WSSSignPart.TRANSFORM_STRT10);
sig.addSignPart(sigPart);
sig.addSignPart(WSSSignature.BODY);
```

a. Create a WSSSignature object with the X.509 token. The following line of code creates a WSSSignature object with the X.509 token:

```
WSSSignature sig = factory.newWSSSignature(x509);
```

b. Add the signed part to use for message protection. The following line of code specifies to add WSSSignature.BODY as the signed part:

```
sig.addSignPart(WSSSignature.BODY);
```

c. Add the Timestamp element in the SOAP Security header. The SAML20 SenderVouches WSHTTPS and SAML11 SenderVouches WSHTTPS policy sets require web service requests and responses to contain a Timestamp element in the SOAP Security header. In the following code, the WSSFactory.newWSSTimestamp() method generates a Timestamp element, and the WSSGenerationContext.add(timestamp) method adds the Timestamp element to the request message:

```
// Add Timestamp element
WSSTimestamp timestamp = factory.newWSSTimestamp();
    gencont.add(timestamp);
sig.addSignPart(WSSSignature.TIMESTAMP);

gencont.add(sig);

WSSConsumingContext concont = factory.newWSSConsumingContext();
```

d. Skip this step if token signature is not required. If the requested security token needs to be signed with the *STR Dereference Transform* reference option, follow step 1. Otherwise, follow step 2. The *STR Dereference Transform* reference option is commonly known as *STR-Transform*.

Step 1: Some tokens, including SAML Tokens, cannot be digitally signed directly. You must sign the token using *STR-Transform*. In order for a token to be signed with *STR-Transform*, it must be referenced by a <wsse:SecurityTokenReference> element in the <wsse:Security> header block. To sign a security token with *STR-Transform*, a separate WSSSignPart is created to specify the SecurityTokenReference with a transformation algorithm that is represented by the WSSSignPart.TRANSFORM_STRT10 attribute. This attribute enables the WS-Security runtime environment to generate a SecurityTokenReference element to reference the token, and to digitally sign the token using the *STR Dereference* reference option. The following code illustrates the use of the WSSSignPart.TRANSFORM_STRT10 attribute:

```
WSSSignPart sigPart = factory.newWSSSignPart();
sigPart.setSignPart(token);
sigPart.addTransform(WSSSignPart.TRANSFORM_STRT10);
```

Step 2: If the requested signed token is not a SAML token, or *STR-Transform* is not used, use the following code instead:

```
sig.addSignPart(token);
```

e. Attach the WSSGenerationContext object to the web service RequestContext object. The WSSGenerationContext object now contains all of the security information required to format a request message. The WSSGenerationContext.process(requestContext) method attaches the

WSSGenerationContext object to the web service RequestContext object to enable the WS-Security runtime environment to format the required SOAP Security header; for example:

```
// Attaches the WSSGenerationContext object to the web service RequestContext object.
gencont.process(requestContext);
```

7. Use the X.509 token to validate the digital signature and the integrity of the response message if the provider policy requires the response message to be digitally signed. Skip this step if using SSL Transport level protection.
   a. An X509ConsumeCallbackHandler object is initialized with a trust store and a List of certificate path objects to validate the digital signature in a response message. The following code initializes the X509ConsumeCallbackHandler object with dsig-receiver.ks trust store and a certificate path object called certList:

```
ArrayList certList = new ArrayList();
java.security.cert.CertStore certStore = java.security.cert.CertStore.getDefaultType();
certList.add(certStore);

X509ConsumeCallbackHandler callbackHandlerVer = new
    X509ConsumeCallbackHandler("profile_root/etc/ws-security/samples/dsig-receiver.ks",
    "JKS",
    "server".toCharArray(),
    certList,
    java.security.Security.getProvider("IBMCertPath"));
```

   b. A WSSVerification object is created and the message body is added to the verification object so that the WS-Security runtime environment validates the digital signature. The following code is used to initialize the WSSVerification object:

```
WSSVerification ver = factory.newWSSVerification(X509Token.class, callbackHandlerVer);
```

The WSSConsumingContext object now contains all the security information that is required to format a request message. The WSSConsumingContext.process(requestContext) method attaches the WSSConsumingContext object to the response method; for example:

```
// Attaches the WSSConsumingContext object to the web service RequestContext object.
concont.process(requestContext);
```

Results

You have requested a security token from an external STS. After obtaining the token, you sent the token with web services request messages using message level protection using the JAX-WS programming model and WSS APIs.

Example

The following code example is a web service client application that demonstrates how to request a SAML Bearer token from an external STS and send that SAML token in a web service request message. If your usage scenario requires SAML tokens, but does not require your application to pass the SAML tokens using web service messages, you only need to use the first part of the following sample code, up through the // Initialize web service client section.

```

            concont.add(WSSConsumingContext.TIMESTAMP);
            concont.process(requestContext);

            // Call the service
            response = echo.echoOperation(echoParm).getEchoResponse();

            System.out.println(">> CLIENT: SEI Echo invocation complete.");
            System.out.println(">> CLIENT: SEI Echo response is: " + response);
        } catch (Exception e) {
            System.out.println(">> CLIENT: ERROR: SEI Echo EXCEPTION.");
            e.printStackTrace();
        }
    }
}
```

Securing messages at the response consumer using WSS APIs:

You can secure SOAP messages with signature verification, decryption, and consumer tokens to protect message integrity, confidentiality, and authenticity, respectively. The response consumer (client-side) configuration defines the Web Services Security requirements for the incoming SOAP response.

About this task

To secure web services with WebSphere Application Server, you must configure the generator and the consumer security constraints. You must specify several different configurations. Although there is no specific sequence to specify these different configurations, some configurations reference other configurations. For example, decryption configurations reference encryption configurations.

The response consumer (client-side) configuration requirements involve verifying that the integrity parts are signed and that the signature is verified, verifying that the required confidential parts are encrypted and that the parts are decrypted; and validating the security tokens.

You can use the following methods to configure Web Services Security and to define policy types to secure the SOAP messages:

- Use the administrative console to configure policy sets.
- Use the Web Services Security APIs (WSS API) to configure the SOAP message context (only for the client)

The following high-level steps use the WSS APIs:

Procedure

- Verify consumer signing information to protect message integrity.
- Configure decryption to protect message confidentiality.
- Validate consumer tokens to protect message authenticity.

Results

After completing these procedures, you have secured messages at the response consumer level.

What to do next

Next, if not already configured, secure messages with signing information, encryption, and generator tokens at the response (client-side) generator level.

Configuring decryption methods to protect message confidentiality using the WSS APIs:

You can configure decryption method information for the response consumer (client side) section of the binding file. Decryption information is used to specify how the consumers (receivers) decrypt incoming

SOAP messages. To configure decryption, specify which message parts to decrypt and specify which algorithm methods and security tokens are to be used for decryption.

Before you begin

Confidentiality refers to encryption while integrity refers to digital signing. Confidentiality reduces the risk of someone understanding the message flowing across the Internet. With confidentiality specifications, the message is encrypted before it is sent and decrypted when it is received at the correct target. Prior to configuring decryption, familiarize yourself with XML encryption.

About this task

For decryption, you must specify the following:

- Which parts of the message are to be decrypted.
- Which decryption algorithms to specify.

To configure decryption and decrypted parts on the client side, use the WSSDecryption and WSSDecryptPart APIs, or configure policy sets using the administrative console.

WebSphere Application Server provides default values for bindings. However, an administrator must modify the defaults for a production environment.

WebSphere Application Server uses decryption information for the default consumer to decrypt parts of the SOAP message. The WSSDecryption API configures the following required parts as decrypted parts.

Table 208. Required decrypted parts. Use the decryption information to specify how incoming messages are decrypted.

Decryption parts	Description
Keywords	Keywords are used to add the decrypted parts to the SOAP message.
XPath expression	XPath expressions are used to add the decrypted parts to the SOAP message.
WSSDencryptPart object	This object adds the decrypted parts to the SOAP message.
WSSVerification object	This object adds the signature verification component as a decrypted part.
Header	This part adds the header in the SOAP header, specified by QName, as a decrypted part.
Security token object	This object adds the security token as a decrypted part.

Web Services Security API (WSS API) supports symmetric encryption, by using a shared key, only when Web Services Secure Conversation (WS-SecureConversation) is used.

The WSS APIs allow the use of either keywords or an XPath expression to specify the parts of the SOAP message that are to be decrypted. WebSphere Application Server supports the use of the following keywords:

Table 209. Supported decryption keywords. Use the keywords to decrypt incoming messages.

Keyword	References
BODY_CONTENT	The keyword for the body contents of the SOAP message body as a decryption target.
SIGNATURE	The keyword for the signature element as a decryption target.
USERNAME_TOKEN,	The keyword for the Username token element as a decryption target.

If configuring using the WSS APIs, the WSSDecryption and WSSDecryptPart APIs complete these high-level steps:

Procedure

1. Use the WSSDecryption API to configure encryption. The WSSDecryption API performs these tasks by default:

a. Generates the callback handler.
b. Generates the consumer security token object.
c. Adds the security token reference type.
d. Adds the WSSEncryptPart object.
e. Adds the parts to be encrypted. Adds the default parts for decryption by using keywords and XPath expressions.
f. Adds the verification component.
g. Adds the header in the SOAP message, specified by QName.
h. Sets the default data encryption method.
i. Specifies whether the key is to be decrypted using a Boolean value. Calls this method when the shared key is encrypted.
j. Sets the default key encryption method.

2. Use the WSSEncryptPart API to configure encrypted parts or add a transform method. The WSSEncryptPart API performs these tasks by default:
   a. Sets the encrypted parts specified by using keywords or an XPath expression.
   b. Sets the encrypted parts specified by an XPath expression.
   c. Sets the signature component object, WSSSignature.
   d. Sets the header in the SOAP message, specified by QName.
   e. Sets the generator security token.
   f. Adds the transform method, if needed.
3. Change from the default values for algorithm or message parts, as needed. For example: you could change one or more of the following items:
   - Add USERNAME_TOKEN as a target of decryption.
   - Change the data encryption algorithm from the default value of AES 128.
   - Change the key encryption algorithm from the default value of KW_RSA_OAEP.
   - Specify to not encrypt the encryption key (false).
   - Change the security token type from the default value of X.509 token.
   - Only use BODY_CONTENT as an encryption part and not use SIGNATURE also.

Results

The decryption information is configured for the consumer binding.

Example

The following is an example of the WSSDecryption API:

```
WSSFactory factory = WSSFactory.getInstance();
WSSConsumingContext concont = factory.newWSSConsumingContext();
    X509ConsumeCallbackHandler callbackhandler = generateCallbackHandler();
// see X509ConsumeCallbackHandler
    WSSDecryption dec = factory.newWSSDecryption(X509Token.class,
        callbackhandler);

 concont.add(dec);
```

What to do next

You must configure similar encryption information for the client-side request generator (sender) bindings, if you have not already configured the information.

Next, review the WSSDecryption API process.

Decrypting SOAP messages using the WSSDecryption API:

You can secure the SOAP messages, without using policy sets for configuration, by using the Web Services Security APIs (WSS API). To configure the client for decryption on the response (client) consumer side, use the WSSDecryption API to decrypt the SOAP messages. The WSSDecryption API specifies which request SOAP message parts to decrypt when configuring the client.

Before you begin

You can use the WSS API or use policy sets on the administrative console to enable decryption and add consumer security tokens in the SOAP message. To secure SOAP messages, you must have completed the following decryption tasks:

- Encrypted the SOAP message.
- Chosen the decryption method.

About this task

The decryption information on the consumer side is used for decrypting an incoming SOAP message for the response consumer (client side) bindings. The client consumer configuration must match the configuration for the provider generator.

Confidentiality settings require that confidentiality constraints be applied to generated messages.

The following decryption parts can be configured:

Table 210. Decryption parts. Use the decryption parts to secure messages.

Decryption parts	Description
part	Adds the WSSDecryptPart object as a target of the decryption part.
keyword	Adds the decryption part using keywords. WebSphere Application Server supports the following keywords: • BODY_CONTENT • SIGNATURE • USERNAME_TOKEN
xpath	Adds the decryption part using an XPath expression.
verification	Adds the WSSVerification instance as a target of the decryption part.
header	Adds the SOAP header, specified by QName, as a target of the decryption part.

For decryption, certain default behaviors occur. The simplest way to use the WSS API for decryption is to use the default behavior (see the example code). WSSDecryption provides defaults for the key encryption algorithm, the data encryption algorithm, and the decryption parts such as the SOAP body content and the signature. The decryption default behaviors include:

Table 211. Decryption decisions. Several decryption part characteristics are configured by default.

Decryption decisions	Default behavior
Which parts to decrypt	The default decryption parts are the BODY_CONTENT and SIGNATURE. WebSphere Application Server supports using these keywords: • WSSDecryption.BODY_CONTENT • WSSDecryption.SIGNATURE • WSSDecryption.USERNAME_TOKEN After you specify which message parts to decrypt, you must specify which method to use when decrypting the consumer request message. For example, if both signature and body content are applied for encryption, then the SOAP message parts that are decrypted include the same parts.
Whether to encrypt the key (isEncrypt)	The default value is to encrypt the key (`true`).

Table 211. Decryption decisions (continued). Several decryption part characteristics are configured by default.

Decryption decisions	Default behavior
Which data decryption algorithm to choose (method)	The default data decryption algorithm method is AES128. WebSphere Application Server supports these data encryption methods: • WSSDecryption.AES128: http://www.w3.org/2001/04/xmlenc#aes128-cbc • WSSDecryption.AES192: http://www.w3.org/2001/04/xmlenc#aes192-cbc • WSSDecryption.AES256: http://www.w3.org/2001/04/xmlenc#aes256-cbc • WSSDecryption.TRIPLE_DES: http://www.w3.org/2001/04/xmlenc#tripledes-cbc
Which key decryption method to choose (algorithm)	The default key decryption algorithm method is key wrap RSA OAEP. WebSphere Application Server supports these key encryption methods: • WSSDecryption.KW_AES128: http://www.w3.org/2001/04/xmlenc#kw-aes128 • WSSDecryption.KW_AES192: http://www.w3.org/2001/04/xmlenc#kw-aes192 • WSSDecryption.KW_AES256: http://www.w3.org/2001/04/xmlenc#kw-aes256 • WSSDecryption.KW_RSA_OAEP: http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p • WSSDecryption.KW_RSA15: http://www.w3.org/2001/04/xmlenc#rsa-1_5 • WSSDecryption.KW_TRIPLE_DES: http://www.w3.org/2001/04/xmlenc#kw-tripledes
Which security token to specify	The default security token type is the X509 token. WebSphere Application Server provides the following pre-configured consumer token types: • Derived key token • X509 tokens

Procedure

1. To decrypt the SOAP message using the WSSDecryption API, first ensure that the application server is installed.
2. The WSS API process for decryption performs these process steps:
   a. Uses WSSFactory.getInstance() to get the WSS API implementation instance.
   b. Creates the WSSConsumingContext instance from the WSSFactory instance. The WSSConsumingContext must always be called in a JAX-WS client application.
   c. Creates the callback handler for the consumer side.
   d. Creates WSSDecryption with the class for the security token and the callback handler from the WSSFactory instance. The default behavior of WSSDecryption is to assume that the body content and the signature are encrypted.
   e. Adds the parts to be decrypted, if the default is not appropriate.
   f. Adds the candidates of the data encryption methods to use for decryption.
   g. Adds the candidates of the key encryption methods to use for decryption.
   h. Adds the candidates of the security token to use for decryption.
   i. Calls WSSDecryption.encryptKey(false) if the application does not want the key to be encrypted in the incoming message.
   j. Adds WSSDecryption to WSSConsumingContext.
   k. Calls WSSConsumingContext.process() with the SOAPMessageContext

Results

If there is an error condition during decryption, a WSSException is provided. If successful, the WSSConsumingContext.process() is called, and Web Services Security is applied to the SOAP message.

Example

The following example provides sample code for decrypting the SOAP message body content:

```
// Get the message context
   Object msgcontext = getMessageContext();

// Generate the WSSFactory instance (step: a)
   WSSFactory factory = WSSFactory.getInstance();
```

```
// Generate the WSSConsumingContext instance (step: b)
   WSSConsumingContext gencont = factory.newWSSConsumingContext();

// Generate the callback handler (step: c)
   X509ConsumeCallbackHandler callbackHandler = new
       X509ConsumeCallbackHandler(
                                  "",
                                  "enc-sender.jceks",
                                  "jceks",
                                  "storepass".toCharArray(),
                                  "alice",
                                  "keypass".toCharArray(),
 "CN=Alice, O=IBM, C=US");

// Generate the WSSDecryption instance (step: d)
   WSSDecryption dec = factory.newWSSDecryption(X509Token.class,
                                               callbackHandler);

// Set the part to be encrypted (step: e)
// DEFAULT: WSSEncryption.BODY_CONTENT and WSSEncryption.SIGNATURE

// Set the part to be encrypted (step: e)
// DEFAULT: WSSEncryption.BODY_CONTENT and WSSEncryption.SIGNATURE

// Set the part specified by the keyword (step: e)
      dec.addRequiredDecryptPart(WSSDecryption.BODY_CONTENT);

// Set the part in the SOAP Header specified by QName (step: e)
    dec.addRequiredDecryptHeader(new
       QName("http://www.w3.org/2005/08/addressing",
       "MessageID"));

// Set the part specified by WSSVerification  (step: e)
   X509ConsumeCallbackHandler verifyCallbackHandler =
      getCallbackHandler();
   WSSVerification ver = factory.newWSSVerification(X509Token.class,
                                                    verifyCallbackHandler);
      dec.addRequiredDecryptPart(ver);

// Set the part specified by XPath expression (step: e)
      StringBuffer sb = new StringBuffer();
         sb.append("/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/'
            and local-name()='Envelope']");
         sb.append("/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/'
            and local-name()='Body']");
         sb.append("/*[namespace-uri()='http://xmlsoap.org/Ping'
            and local-name()='Ping']");
         sb.append("/*[namespace-uri()='http://xmlsoap.org/Ping'
            and local-name()='Text']");
      dec.addRequiredDecryptPartByXPath(sb.toString());

// Set the part in the SOAP header to be decrypted specified by QName (step: e)
      dec.addRequiredDecryptHeader(new
          QName("http://www.w3.org/2005/08/addressing",
          "MessageID"));

// Set the candidates for the data encryption method (step: f)
// DEFAULT : WSSDecryption.AES128
      dec.addAllowedEncryptionMethod(WSSDecryption.AES128);
      dec.addAllowedEncryptionMethod(WSSDecryption.AES192);

// Set the candidates for the key encryption method (step: g)
// DEFAULT : WSSDecryption.KW_RSA_OAEP
      dec.addAllowedKeyEncryptionMethod(WSSDecryption.KW_TRIPLE_DES);

// Set the candidate security token to used for the decryption (step: h)
   X509ConsumeCallbackHandler callbackHandler2 = getCallbackHandler2();
      dec.addToken(X509Token.class, callbackHandler2);

// Set whether or not the key should be encrypted in the incoming SOAP message (step: i)
// DEFAULT: true
      dec.encryptKey(true);

// Add the WSSDecryption to the WSSConsumingContext (step: j)
   concont.add(dec);

// Validate the WS-Security header (step: k)
concont.process(msgcontext);
```

What to do next

Next, use the WSSDecryptPart API or configure the policy sets using the administrative console to add decrypted parts for the consumer message.

Choosing decryption methods for the consumer binding:

To configure the client for response decryption for the consumer binding, specify which data and transform algorithm methods to use when the client decrypts the SOAP messages.

Before you begin

Prior to completing these steps, read the XML encryption information to become familiar with encrypting and decrypting SOAP messages.

To complete decryption configuration to secure SOAP messages, you must complete the following tasks:

- Configure decryption of the SOAP message parts
- Specify the decryption methods.

You can configure the decryption methods using the WSSDecryption and WSSDecryptPart APIs. Or you can also configure policy sets using the administrative console to configure the decryption methods.

About this task

Some of the encryption-related definitions are based on the XML-Encryption specification. The following information defines some data encryption-related terms:

Data encryption method algorithm

Data encryption algorithms specify the algorithm uniform resource identifier (URI) of the data encryption method. This algorithm encrypts and decrypts data in fixed size, multiple octet blocks.

By default, the Java Cryptography Extension (JCE) is shipped with restricted or limited strength ciphers. To use 192-bit and 256-bit Advanced Encryption Standard (AES) encryption algorithms, you must apply unlimited jurisdiction policy files.

For the AES256-cbc and the AES192-cbc algorithms, you must download the unrestricted Java™ Cryptography Extension (JCE) policy files from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.

Key encryption method algorithm

Key encryption algorithms specify the algorithm uniform resource identifier (URI) of the key encryption method. The algorithm represents public key encryption algorithms that are specified for encrypting and decrypting keys.

By default, the RSA_OAEP algorithm uses the SHA1 message digest algorithm to compute a message digest as part of the encryption operation. Optionally, you can use the SHA256 or SHA512 message digest algorithm by specifying a key encryption algorithm property. The property name is: `com.ibm.wsspi.wssecurity.enc.rsaoaep.DigestMethod`. The property value is one of the following URIs of the digest method:

- http://www.w3.org/2001/04/xmlenc#sha256
- http://www.w3.org/2001/04/xmlenc#sha512

By default, the RSA_OAEP algorithm uses a null string for the optional encoding octet string for the OAEPParams. You can provide an explicit encoding octet string by specifying a key encryption algorithm property. For the property name, you can specify `com.ibm.wsspi.wssecurity.enc.rsaoaep.OAEPparams`. The property value is the base 64-encoded value of the octet string.

Important: You can set these digest method and OAEPParams properties on the generator side only. On the consumer side, these properties are read from the incoming SOAP message.

For the KW_AES256 and the KW_AES192 key encryption algorithms, you must download the unrestricted JCE policy files from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.

Important: Your country of origin might have restrictions on the import, possession, use, or re-export to another country, of encryption software. Before downloading or using the unrestricted policy files, you must check the laws of your country, its regulations, and its policies concerning the import, possession, use, and re-export of encryption software, to determine if it is permitted.

To complete the decryption configuration, you must specify the algorithm uniform resource identifier (URI) and its usage type. If the URI is used for multiple usage types, then you must define the URI to each usage type. WebSphere Application Server supports the following decryption usage types:

Table 212. Decryption usage types. These decryption types are supported by WebSphere Application Server.

Usage types	Description
Data encryption	Specifies the algorithm URI that is used for both encrypting and decrypting data. Encrypts and decrypts data in fixed size, multiple octet blocks.
Key encryption	Specifies the algorithm URI that is used for encrypting and decrypting the encryption key.

To configure the decryption and decrypted part algorithms, use the WSSDecryption and WSSDecryptPart APIs, or configure policy sets using the administrative console.

Note: Policy sets do not support symmetric key encryption. If you are using the WSS API for symmetric key encryption, you will not be able to interoperate with web services endpoints that use policy sets.

If you are using the WSS APIs, the WSSDecryption and WSSDecryptPart APIs specify which algorithm methods are used when the client decrypts the SOAP messages.

- Use the WSSDecryption API to configure the data encryption algorithm and the key encryption algorithm methods.
- Use the WSSDecryptPart API to configure a transform algorithm method.

The WSS API process completes the following high-level steps to specify which decryption and decrypted part algorithm methods to use when configuring the client for response decryption:

Procedure

1. Using the WSSDecryption API, adds the required data encryption algorithm. The data encryption algorithm is used for encrypting or decrypting parts of a SOAP message. Data decryption algorithms specify the algorithm uniform resource identifier (URI) of the data encryption method.

   The default data encryption algorithm is AES 128. The data encryption name is AES128, and the URI of the data encryption algorithm, is http://www.w3.org/2001/04/xmlenc#aes128-cbc. WebSphere Application Server supports the following pre-configured data decryption algorithms:

   - AES128: http://www.w3.org/2001/04/xmlenc#aes128-cbc

     The AES 128 algorithm is the default data algorithm method.
   - AES256: http://www.w3.org/2001/04/xmlenc#aes256-cbc

     To use this AES 256-cbc algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.
   - AES192: http://www.w3.org/2001/04/xmlenc#aes192-cbc

     Do not use the 192-bit key encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP).

     To use this AES 192-cbc algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.
   - TRIPLE_DES: http://www.w3.org/2001/04/xmlenc#tripledes-cbc

2. As needed, changes the WSSEncryption API method to specify another data encryption algorithm. For example, you might add the following code to change from the default AES 128 algorithm to the Triple DES algorithm:

```
dec.addAllowedKeyEncryptionMethod(WSSDecryption.TRIPLE_DES);
```

3. Using the WSSDecryption API, adds the required key encryption algorithm. The key encryption algorithm is used for encrypting the key that is used for encrypting the message parts within the SOAP message. If no key for encrypting the data is needed, then you must specify WSSDecryption.encryptKey(false).

   The key encryption algorithm that you select for the consumer side must match the key encryption method that you select for the generator side.

   The default key encryption algorithm value is key wrap RSA_OAEP. The key encryption name is KW_RSA_OAEP, and the URI of the key encryption algorithm is http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p. WebSphere Application Server supports the following pre-configured key encryption algorithms:

   - KW_AES128: http://www.w3.org/2001/04/xmlenc#kw-aes128
   - KW_AES192: http://www.w3.org/2001/04/xmlenc#kw-aes192

     To use this key wrap AES 192 algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.

     Restriction: Do not use the 192-bit key encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP).
   - KW_AES256: http://www.w3.org/2001/04/xmlenc#kw-aes256

     To use this key wrap AES 256-cbc algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.
   - KW_RSA_OAEP: http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p.

     The KW_RSA_OAEP algorithm is the default key algorithm method.

     When running with Software Development Kit (SDK) Version 1.4, the list of supported key transport algorithms does not include this algorithm. This algorithm appears in the list of supported key transport algorithms when running with SDK Version 1.5. See more information at http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p
   - KW_RSA_15: http://www.w3.org/2001/04/xmlenc#rsa-1_5
   - KW_TRIPLE_DES: http://www.w3.org/2001/04/xmlenc#kw-tripledes

   Note: For Web Services Secure Conversation, the WSSEncryption API might specify addition key-related information, such as the:
   - algorithmName
   - keyLength

4. As needed, uses the WSSDecryption API method to change to other key encryption algorithms. For example, you might add the following code to change from the default key encryption algorithm KW_RSA_OAEP to the TRIPLE_DES algorithm:

```
dec.addAllowedKeyEncryptionMethod(WSSDecryption.KW_TRIPLE_DES);
```

5. Using the WSSDecryptPart API, adds a transform algorithm, as needed. There is no default transform algorithm. However, WebSphere Application Server provides a pre-configured decrypted part, `WSSDecryptPart.TRANSFORM_ATTACHMENT_CIPHERTEXT`, that can be added.

Results

If there is an error condition, a WSSException is provided. If successful, the API calls the `WSSConsumerContext.process()` method, the WS-Security header is validated, and the SOAP message is now secured using Web Services Security.

Example

The following example provides sample WSS API code for decrypting the body content as well as changing the data encryption and key encryption algorithms from the default values:

```
// Get the message context
   Object msgcontext = getMessageContext();

// Generate the WSSFactory instance
   WSSFactory factory = WSSFactory.getInstance();

// Generate the WSSConsumingContext instance
   WSSConsumingContext gencont = factory.newWSSConsumingContext();

// Generate the callback handler
   X509ConsumeCallbackHandler callbackHandler = new
      X509ConsumeCallbackHandler(
                                 "",
                                 "enc-sender.jceks",
                                 "jceks",
                                 "storepass".toCharArray(),
                                 "alice",
                                 "keypass".toCharArray(),
                                 "CN=Alice, O=IBM, C=US");

// Generate WSSDecryption instance
   WSSDecryption dec = factory.newWSSDecryption(X509Token.class,
                                                callbackHandler);

// Set the candidates for the data encryption method
// DEFAULT : WSSDecryption.AES128
   dec.addAllowedEncryptionMethod(WSSDecryption.AES128);
   dec.addAllowedEncryptionMethod(WSSDecryption.AES192);

// Set the candidates for the key encryption method
// DEFAULT : WSSDecryption.KW_RSA_OAEP
   dec.addAllowedKeyEncryptionMethod(WSSDecryption.KW_TRIPLE_DES);

// Add the WSSDecryption to WSSConsumingContext
   concont.add(dec);

// Validate the WS-Security header
concont.process(msgcontext);
```

Adding decrypted parts using the WSSDecryptPart API:

You can secure the SOAP messages, without using policy sets for configuration, by using the Web Services Security APIs (WSS API). To configure decrypted parts for the response consumer (client side) bindings, use the WSSDecryptPart API to define and add to the listing of elements in the decrypted part. WSSDecryptPart is an interface that is part of the com.ibm.websphere.wssecurity.wssapi.decryption package.

Before you begin

You can use either the WSS APIs or configure the policy sets using the administrative console to configure and add new encrypted parts. To secure SOAP messages using the WSSDecryptPart APIs, you must configure the decrypted parts for the response consumer bindings.

About this task

Confidentiality settings require that confidentiality constraints be applied to generated messages. These constraints include specifying which message parts within the generated message must be encrypted and decrypted, and which message parts to attach encrypted elements to.

The WSSDecryptPart API specifies information related to decryption and sets the decrypted parts that have been added for message confidentiality protection. Use the WSSDecryptPart to set the transform method and to specify the part to which the transform method is to be applied. Sets the transform method only if using SOAP with Attachments. The WSSDecryptPart is usually not needed except, in some case for tasks such as setting the transform method.

The decrypted parts displayed in the following table are used to protect the confidentiality of messages.

Table 213. Decrypted Parts. Use the decrypted parts to secure messages.

Decrypted parts	Description
keyword	Sets the decrypted part using keywords. The default decrypted parts that you can add using keywords are the BODY_CONTENT and SIGNATURE. WebSphere Application Server supports the following keywords: • BODY_CONTENT • SIGNATURE • USERNAME_TOKEN
xpath	Sets the decrypted part by using an XPath expression.
verification	Sets the WSSVerification component as a decrypted part. The WSSVerification part is applicable only if the SOAP message contains a signature element.
header	Sets the header, specified by QName, as a decrypted part.

For decrypted parts, certain default behaviors occur. The simplest way to use the WSSDecryptPart API is to use the default behavior (see the example code).

WSSDecryptPart provides defaults for setting the transform algorithm, adding a transform method, setting objects as targets, whether an element, and the encrypted parts, such as: the SOAP body content and the signature.

Table 214. Decrypted part decisions. Several characteristics of decrypted parts are configured by default.

Decryption decisions	Default behavior
Which SOAP message parts to decrypt using keywords	Specifies which keywords to use for the decrypted parts. WebSphere Application Server sets the following SOAP message parts by default for decryption: • WSSDecryption.BODY_CONTENT • WSSDecryption.SIGNATURE
Which transform algorithm to use (algorithm)	WebSphere Application Server does not specify any transform algorithm by default. Specify a transform method only if using SOAP with Attachments.

Procedure

1. To decrypt the SOAP message parts using the WSSDecryptPart API, first ensure that the application server is installed.
2. The WSS API process using WSSDecryptPart follows these steps:
   a. Uses WSSFactory.getInstance() to get the WSS API implementation instance.
   b. Creates the WSSConsumingContext instance from the WSSFactory instance. Note that the WSSConsumingContext must always be called in a JAX-WS client application.
   c. Creates the SecurityToken from WSSFactory to configure decryption.
   d. Creates WSSDecryption from the WSSFactory instance using SecurityToken.
   e. Creates WSSDecryptPart from the WSSFactory instance. The default behavior of WSSDecryptPart is to assume that the body content and signature are encrypted.
   f. Adds the parts to be decrypted and to be applied with the transform in WSSDecryptPart. WebSphere Application Server sets these encrypted parts by default for WSSDecryptPart: the BODY_CONTENT and SIGNATURE. After you add other decrypted parts, the default values are no longer valid. For example, if you call addDecryptPart(securityToken, false), only the security token is encrypted, and not the signature and body content. So if you want to decrypt the security token, the signature, and the body content, you must call addDecryptPart(securityToken, false), addDecryptPart(WSSDecryption.SIGNATURE), and addDecryptPart(WSSDecryption.BODY_CONTENT).
   g. Sets the transform method.
   h. Adds WSSDecryptPart to WSSDecryption.
   i. Adds WSSDecryption to WSSConsumingContext.
   j. Calls WSSConsumingContext.process() with the SOAPMessageContext

Results

If there is an error condition when decrypting the message, a WSSException is provided. If successful, the API calls the WSSConsumingContext.process(), the WS-Security header is generated, and the SOAP message is now secured using Web Services Security.

What to do next

After enabling decrypted parts for the response consumer (client side) binding, specify the generator and consumer tokens, if the security tokens have not already been specified.

Decryption methods:

The decryption algorithms specify the data and key encryption algorithms that are used to decrypt the SOAP message. The WSS API for decryption (WSSDecryption) specifies the algorithm uniform resource identifier (URI) of the data and key encryption methods. The WSSDecryption interface is part of the `com.ibm.websphere.wssecurity.wssapi.decryption` package.

Data encryption algorithms

The data encryption algorithms are the algorithms that are used to encrypt and decrypt data. This algorithm type is used for encrypting data to encrypt and decrypt various parts of the message, including the body content and the signature.

Data decryption algorithms specify the algorithm uniform resource identifier (URI) of the data encryption method. WebSphere Application Server supports the following pre-configured data decryption algorithms:

Table 215. Supported pre-configured data decryption algorithms. The algorithms are used to decrypt SOAP messages.

WSS API	URI
WSSDecryption.AES128 (the default value)	A URI of data encryption algorithm, AES 128: http://www.w3.org/2001/04/xmlenc#aes128-cbc
WSSDecryption.AES192	A URI of data encryption algorithm, AES 192: http://www.w3.org/2001/04/xmlenc#aes192-cbc
WSSDecryption.AES256	A URI of data encryption algorithm, AES 256: http://www.w3.org/2001/04/xmlenc#aes256-cbc
WSSDecryption.TRIPLE_DES	A URI of data encryption algorithm, TRIPLE DES: http://www.w3.org/2001/04/xmlenc#tripledes-cbc

By default, the Java Cryptography Extension (JCE) is shipped with restricted or limited strength ciphers. To use 192-bit and 256-bit Advanced Encryption Standard (AES) encryption algorithms, you must apply unlimited jurisdiction policy files.

Important: Your country of origin might have restrictions on the import, possession, use, or re-export to another country, of encryption software. Before downloading or using the unrestricted policy files, you must check the laws of your country, its regulations, and its policies concerning the import, possession, use, and re-export of encryption software, to determine if it is permitted.

For the AES256-cbc and the AES192-cbc algorithms, you must download the unrestricted Java™ Cryptography Extension (JCE) policy files from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.

The data encryption algorithm must match the data decryption algorithm that is configured for the consumer.

Key encryption algorithms

The key encryption algorithms are the algorithms that are used to encrypt and decrypt keys.

This key information is used to specify the configuration that is needed to generate the key for digital signature and encryption. The signing information and encryption information configurations can share the key information. The key information on the consumer side is used for specifying the information about the key that is used for validating the digital signature in the received message or for decrypting the encrypted parts of the message. The request generator is configured for the client.

Key encryption algorithms specify the algorithm uniform resource identifier (URI) of the key encryption method. WebSphere Application Server supports the following pre-configured key encryption algorithms:

Table 216. Supported pre-configured key encryption algorithms. The algorithms are used to decrypt SOAP messages.

WSS API	URI
WSSDecryption.KW_AES128	A URI of key encryption algorithm, key wrap AES 128: http://www.w3.org/2001/04/xmlenc#kw-aes128
WSSDecryption.KW_AES192	A URI of key encryption algorithm, key wrap AES 192: http://www.w3.org/2001/04/xmlenc#kw-aes192 **Restriction:** Do not use the 192-bit key encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP).
WSSDecryption.KW_AES256	A URI of key encryption algorithm, key wrap AES 256: http://www.w3.org/2001/04/xmlenc#kw-aes256
WSSDecryption.KW_RSA_OAEP (the default value)	A URI of key encryption algorithm, key wrap RSA OAEP: http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p
WSSDecryption.KW_RSA15	A URI of key encryption algorithm, key wrap RSA 1.5: http://www.w3.org/2001/04/xmlenc#rsa-1_5
WSSDecryption.KW_TRIPLE_DES	A URI of data encryption algorithm, key wrap TRIPLE DES: http://www.w3.org/2001/04/xmlenc#kw-tripledes

By default, the RSA-OAEP algorithm uses the SHA1 message digest algorithm to compute a message digest as part of the encryption operation. Optionally, you can use the SHA256 or SHA512 message digest algorithm by specifying a key encryption algorithm property. The property name is: `com.ibm.wsspi.wssecurity.enc.rsaoaep.DigestMethod`. The property value is one of the following URIs of the digest method: `http://www.w3.org/2001/04/xmlenc#sha256` `http://www.w3.org/2001/04/xmlenc#sha512`

By default, the RSA-OAEP algorithm uses a null string for the optional encoding octet string for the OAEPParams. You can provide an explicit encoding octet string by specifying a key encryption algorithm property. For the property name, you can specify `com.ibm.wsspi.wssecurity.enc.rsaoaep.OAEPparams`. The property value is the base 64-encoded value of the octet string.

Important: You can set these digest method and OAEPParams properties on the generator side only. On the consumer side, these properties are read from the incoming SOAP message.

For the kw-aes256 and the kw-aes192 key encryption algorithms, you must download the unrestricted JCE policy files from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.

The key encryption algorithm for the generator and the consumer must match.

The following example provides a sample of the WSS API code for the default algorithms that are used for WebSphere Application Server decryption:

```
WSSFactory factory = WSSFactory.getInstance();
WSSConsumingContext concont = factory.newWSSConsumingContext();

// Required to attach username token into the message.
X509ConsumeCallbackHandler callbackHandler =
       new X509ConsumeCallbackHandler("",
                                      "enc-sender.jceks",
```

```
                                    "JCEKS",
                                    "storepass".toCharArray(),
                                    "alice",
                                    "keypass".toCharArray(),
                                    "CN=Alice, O=IBM, C=US");
// Set the decrypt component.
// Default encrypted part: Body-Content
// Default data encryption algorithm: AES128
// Default key encryption algorithm: KW-RSA-OAEP
WSSDecryption dec = factory.newWSSDecryption(X509Token.Type,
callbackHandler);
concont.add(dec);

// validate the WS-Security header.
concont.process(msgctx);
```

Verifying consumer signing information to protect message integrity using WSS APIs:

You can verify the signing information to protect message integrity for the response (client side) consumer binding. Signing information includes the signature and the signed parts for the generator side as well as signature verification and verify parts for the consumer side. To keep the integrity of the message, digital signatures are typically applied.

Before you begin

Ensure that the signature and signed parts information has been configured. The signature verification information must match what was configured on the generator side.

About this task

Integrity refers to digital signature while confidentiality refers to encryption. Integrity is provided by applying a digital signature to a SOAP message. To configure the signing information to protect message integrity, you must first digitally sign and then verify the signature for the SOAP messages. Integrity decreases the risk of data modification when you transmit data across a network.

Also, message integrity is provided by verifying the digitally signed body, time stamp, and WS-Addressing headers using the signature verification algorithm methods. The WSS APIs specify which algorithm is to be used to verify the certificate. The signature algorithms specify the Uniform Resource Identifiers (URI) of the signature verification method. WebSphere Application Server supports several pre-configured verification algorithm methods.

You can use the following interfaces to configure Web Services Security and to protect SOAP message integrity:

- Use the administrative console to configure policy sets for signature verification.
- Use the Web Services Security APIs (WSS API) to configure the SOAP message context (only for the client)

Perform the following verification tasks, using the WSS APIs, to configure the signing information and to protect message integrity for the consumer binding.

Procedure

- Configure the signing information using the WSSSignature API. Configure the signature verification information for the consumer binding using the WSSVerification API. Signature verification information is used to verify parts of a message including the SOAP body, the time stamp, and the WS-Addressing headers. Both verifying and decryption can be applied to the same message parts, such as the SOAP body.
- Add or change verify parts using the WSSVerifyPart API.

- Configure the client for request signing methods using the WSSVerification or WSSVerifyPart APIs. To configure the client for response verification, choose the verification methods. Use the WSSVerification API to configure the canonicalization and signature methods. Use the WSSVerifyPart API to configure the digest and transform methods.

Results

By completing the steps in these tasks, you have configured the consumer verification information to protect the integrity of messages.

Verifying signing information for the consumer binding using the WSS APIs:

You can configure the signing information for the client-side response consumer (receiver) bindings. Signing information is used to sign and validate parts of a message including the SOAP body, the timestamp information, and the Username token.

Before you begin

WebSphere Application Server uses XML digital signature with existing algorithms such as RSA, HMAC, and SHA1. XML signature defines many methods for describing key information and enables the definition of a new method. Prior to completing these steps, read the information about XML digital signature to become familiar with signing and verifying digital signatures for digital content.

By including XML signature in SOAP messages, the following issues are realized: message integrity and authentication. *Integrity* refers to digital signature whereas confidentiality refers to encryption. Integrity decreases the risk of data modification while the data is transmitted across the Internet.

Before you can verify the signature and SOAP message signed parts, you must have completed the following tasks:

- Configured the signature.
- Added signed parts, as needed.
- Chosen the signature and signed parts methods.

About this task

Use the Web Services Security APIs (WSS API) to configure the signing verification information for the response consumer (client side) section of the bindings file. Use the WSSVerification or WSSVerifyPart APIs to configure the client for request signature verification and to specify which digitally signed message parts to verify.

WebSphere Application Server uses the signing information on the consumer side to verify the integrity of the received SOAP message by validating that the message parts (such as the body, time stamp, and Username token) are signed.

On the client side, use the WSS APIs, or configure policy sets using the administrative console to specify which parts of the message are signed and to configure the key information that is referenced by the key information references. To verify the signature and signed parts, use the WSSVerification and WSSVerifyPart APIs.

WebSphere Application Server provides default values for bindings. However, an administrator must modify the defaults for a production environment.

The WSSVerification and WSSVerifyPart APIs complete the following steps to specify which digitally signed message parts to verify when configuring the client for response consumer signing:

Procedure

1. The WSSVerification API adds the required verify parts of the SOAP message.

   The part reference refers to the message part that is digitally signed. The part attribute refers to the name of the <Integrity> element when the <PartReference> element is specified for the signature. You can specify multiple <PartReference> elements within the <SigningInfo> element. The <PartReference> element has two child elements when it is specified for the signature: <DigestTransform> and <Transform>.

   The WSSVerification API configures the following parts as verification parts:

Verification part	Description
Security token	Adds information for the security token that is used for the signature verification.
SOAP header and the QName as a target	Adds the SOAP header, specified by QName, as a verification part.

   The WSS APIs allow the use of keywords or an XPath expression to specify which parts of the message are to be verified. WebSphere Application Server supports the use of the following keywords:

Keyword	References
WSSVerification.ADDRESSING_HEADERS	The Web Services Addressing (WS-Addressing) headers.
WSSVerification.BODY	The SOAP message body. The body is the user data portion of the message.
WSSVerification.TIMESTAMP	The creation and expiration timestamp information.

2. The WSSVerification API adds the required header to the SOAP message. The header, specified by QName, is a required verification header.
3. The WSSVerification API adds a security token. Adds information about the security token that is to be used for the signature verification, such as:
   - The class for security token.
   - The callback handler
   - The name of the JAAS login configuration.
4. The WSSVerification API adds the signature method algorithm. The signature method is the algorithm that is used to convert the canonicalized <SignedInfo> element in the binding file into the <SignatureValue> element. The algorithm that is specified for the consumer, which is the response consumer configuration, must match the algorithm specified for the request generator configuration. WebSphere Application Server supports the following pre-configured signature algorithms:
   - WSSVerification.RSA_SHA1:http://www.w3.org/2000/09/xmldsig#rsa-sha1
   - WSSVerification.HMAC_SHA1:http://www.w3.org/2000/09/xmldsig#hmac-sha1

   WebSphere Application Server does not support the following algorithm for DSA-SHA1: http://www.w3.org/2000/09/xmldsig#dsa-sha1. You cannot use the DSA-SHA1 algorithm if you want to be compliant with the Basic Security Profile (BSP).
5. The WSSVerification API adds a canonicalization method. The canonicalization method algorithm is used to canonicalize the <SignedInfo> element before it is incorporated as part of the digital signature operation. The canonicalization algorithm that you specify for the generator must match the algorithm for the consumer.

   WebSphere Application Server supports the following pre-configured canonicalization algorithms:
   - WSSVerification.EXC_C14N: http://www.w3.org/2001/10/xml-exc-c14n#
   - WSSVerification.C14N: http://www.w3.org/TR/xml-c14n
6. The WSSVerification API verifies whether a signature confirmation is required. The OASIS Web Services Security (WS-Security) Version 1.1 specification defines the use of signature confirmation. If you are using WS-Security Version 1.0, this function is not available.

The signature confirmation value is stored in order to validate the signature confirmation with it after the receiving message is returned. This method is called if the response message is expected to attach the signature confirmation into the SOAP message.

7. The WSSVerifyPart API adds a digest method. For each part reference in the signing information, the API specifies both a digest method algorithm and a transform algorithm.

   WebSphere Application Server supports the following pre-configured digest algorithms:

   - WSSVerifyPart.SHA1: http://www.w3.org/2000/09/xmldsig#sha1
   - WSSVerifyPart.SHA256: http://www.w3.org/2001/04/xmlenc#sha256
   - WSSVerifyPart.SHA512: http://www.w3.org/2001/04/xmlenc#sha512

8. The WSSVerifyPart API adds a transform method. For each part reference in the signing information, the API specifies both a digest method algorithm and a transform algorithm.

   WebSphere Application Server supports the following pre-configured transform algorithms:

   - WSSVerifyPart.TRANSFORM_EXC_C14N (the default value): http://www.w3.org/2001/10/xml-exc-c14n#
   - WSSVerifyPart.TRANSFORM_XPATH2_FILTER: http://www.w3.org/2002/06/xmldsig-filter2
   - WSSVerifyPart.TRANSFORM_STRT10: http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform
   - WSSVerifyPart.TRANSFORM_ENVELOPED_SIGNATURE: http://www.w3.org/2000/09/xmldsig#enveloped-signature

   For the WSS APIs, WebSphere Application Server does not support these algorithms:

   - http://www.w3.org/2002/07/decrypt#XML
   - http://www.w3.org/TR/1999/REC-xpath-19991116

   The transform algorithm for the consumer must match the transform algorithm for the generator.

Results

You have completed the steps to configure the signing information for the client-side response consumer sections of the bindings files.

Example

The following example shows WSS API sample code to verify the signature and to verify the X.509 token type as the security token:

```
WSSFactory factory = WSSFactory.getInstance();
WSSConsumingContext concont = factory.newWSSConsumingContext();
// Generate the X.509 Callback Handler on the consumer side
    X509ConsumeCallbackHandler callbackhandler = generateCallbackHandler();
    WSSVerification ver = factory.newWSSVerification(X509Token.class,
        callbackhandler);
concont.add(ver);
```

What to do next

If not already configured, specify a similar signing information configuration for the generator bindings.

Next, if already configured, configure the encryption and decryption information, or configure the consumer and generator tokens.

Verifying the signature using the WSSVerification API:

You can secure the SOAP messages, without using policy sets for configuration, by using the Web Services Security APIs (WSS API). To verify the signing information for the consumer binding sections for the client side request, use the WSSVerification API. You must also specify which algorithm methods and which signature parts of the SOAP message are to be verified. The WSSVerification API is part of the com.ibm.websphere.wssecurity.wssapi.verification package.

Before you begin

Use the WSS APIs, or configure the policy sets by using the administrative console to verify the signing information. To secure SOAP messages, you must complete the following signature tasks:

- Configure the signature information.
- Choose the algorithm methods for signature and signature verification.
- Verify the signature information.

About this task

WebSphere Application Server uses the signing information for the default generator to sign parts of the message, and uses XML digital signature with existing algorithms such as RSA-SHA1 and HMAC-SHA1.

XML signature defines many methods for describing key information and enables the definition of a new method. XML canonicalization (C14N) is often needed when you use XML signature. Information can be represented in various ways within serialized XML documents. The C14N process is used to canonicalize XML information. Select an appropriate C14N algorithm because the information that is canonicalized depends on this algorithm.

The following table shows the required and optional binding information when the digital signature security constraint (integrity) is defined.

Table 217. Signature verification parts. Use the signature verification parts to secure messages.

Verification parts	Description
keywords	Adds required signature parts as targets of verification by using keywords . Different message parts can be specified in the message protection for request on the generator side. Use the following keywords for the required signature verification parts: • ADDRESSING_HEADERS • BODY • TIMESTAMP The WS-Addressing headers are not encrypted but can be signed.
xpath	Adds verification parts by using an XPath expression.
part	Adds the WSSVerifyPart object as a verification part.
header	Adds the header, specified by QName, as a verification part.

For signature verification information, certain default behaviors occur. The simplest way to use the WSSVerification API is to use the default behavior.

The default values are defined by the WSS API for the digest method, the transform method, the security token, and the required verification parts.

Table 218. Signature verification default behaviors. Several characteristics of the signature verification parts are configured by default.

Signature verification decisions	Default behavior
Which signature method to use (algorithm)	Sets the signature algorithm method. Both the data encryption and the signature and the canonicalization can be specified. The default signature method is RSA SHA1. WebSphere Application Server supports the following pre-configured signature methods: • WSSVerification.RSA_SHA1: http://www.w3.org/2000/09/xmldsig#rsa-sha1 • WSSVerification.HMAC_SHA1: http://www.w3.org/2000/09/xmldsig#hmac-sha1 The DSA-SHA1 digital signature method (http://www.w3.org/2000/09/xmldsig#dsa-sha1) is not supported.
Which canonicalization method to use (algorithm)	Sets the canonicalization algorithm method. Both the data encryption and the signature and the canonicalization can be specified. The default signature method is EXC_C14N. WebSphere Application Server supports the following pre-configured canonicalization methods: • WSSVerification.EXC_C14N: http://www.w3.org/2001/10/xml-exc-c14n# • WSSVerification.C14N: http://www.w3.org/2001/10/xml-c14n#

Table 218. Signature verification default behaviors (continued). Several characteristics of the signature verification parts are configured by default.

Signature verification decisions	Default behavior
Whether signature confirmation is required	If the WSSSignature API specifies that signature confirmation is required, then the WSSVerification API verifies the signature confirmation value in the response message that has the signature confirmation value attached to it when received. Signature confirmation is defined in the OASIS Web Services Security Version 1.1 specification. The default signature confirmation is false.
Which security token to specify (securityToken)	Adds the securityToken object as a signature part. WebSphere Application Server sets the token information to use for verification. WebSphere Application Server supports the following pre-configured tokens for signing: • X.509 Token • Derived Key Token Information required for tokens include the class for the token, the callback handler information, and the name of the JAAS login module.

Procedure

1. To verify the signature in a SOAP message by using the WSSVerification API, first ensure that the application server is installed.
2. Use the WSSVerification API to set the message parts to be verified and to specify the algorithms in a SOAP message. The WSS API process for signature verification follows these process steps:
   a. Uses WSSFactory.getInstance() to get the WSS API implementation instance.
   b. Creates the WSSConsumingContext instance from the WSSFactory instance.
   c. Ensures that WSSConsumingContext is called in the JAX-WS Provider implementation class. Due to the nature of the JAX-WS programming model, a JAX-WS provider needs to be implemented and must call the WSSConsumingContext to verify the SOAP message signature.
   d. Creates WSSVerification from the WSSFactory instance.
   e. Adds the part to be verified. If the digest method or the transform method are changed, create WSSVerifyPart and set it into WSSVerification.
   f. Sets the candidates of the canonicalization method, if the default is not appropriate.
   g. Sets the candidates of the signature method, if the default is not appropriate.
   h. Sets the candidate security token, if the default is not appropriate.
   i. Calls the requireSignatureConfirmation(), if the signature confirmation is applied.
   j. Adds WSSVerification to WSSConsumingContext.
   k. Calls WSSConsumingContext.process() with the SOAP message context.

Results

You have completed the steps to verify the signature for the consumer section of the bindings. If there is an error condition, a WSSException is provided. If successful, the WSSConsumingContext.process() is called, and Web Services Security is applied to the SOAP message.

Example

The following example provides sample code that uses methods that are defined in the WSSVerification API:

```
// Get the message context
  Object msgcontext = getMessageContext();

// Generate the WSSFactory instance (step: a)
   WSSFactory factory = WSSFactory.getInstance();

// Generate the WSSConsumingContext instance (step: b)
   WSSConsumingContext concont = factory.newWSSConsumingContext();
```

```
// Generate the certificate list
  String certpath = "c:/WebSphere/AppServer/etc/ws-security/samples/intca2.cer";
// The location of the X509 certificate file
  X509Certificate x509cert = null;
     try {
      InputStream is = new FileInputStream(certpath);
      CertificateFactory cf = CertificateFactory.getInstance("X.509");
      x509cert = (X509Certificate)cf.generateCertificate(is);
       } catch(FileNotFoundException e1){
        throw new WSSException(e1);
       } catch (CertificateException e2) {
        throw new WSSException(e2);
       }
      Set<Object> eeCerts = new HashSet<Object>();
       eeCerts.add(x509cert);
// Create the certificate store
   java.util.List<CertStore> certList = new java.util.ArrayList<CertStore>();
   CollectionCertStoreParameters certparam = new CollectionCertStoreParameters(eeCerts);
   CertStore cert = null;
   try {
    cert = CertStore.getInstance("Collection", certparam, "IBMCertPath");
   } catch (NoSuchProviderException e1) {
    throw new WSSException(e1);
   } catch (InvalidAlgorithmParameterException e2) {
    throw new WSSException(e2);
   } catch (NoSuchAlgorithmException e3) {
    throw new WSSException (e3);
   }
   if(certList != null ){
    certList.add(cert);
   }
// Generate the callback handler
   X509ConsumeCallbackHandler callbackHandler = new X509ConsumeCallbackHandler(
     "dsig-receiver.ks",
     "jks",
     "server".toCharArray(),
     certList,
     java.security.Security.getProvider("IBMCertPath")
   );

// Generate the WSSVerification instance (step: d)
  WSSVerification ver = factory.newWSSVerification(X509Token.class, callbackHandler);

// Set the part to be verified (step: e)
// DEFAULT: WSSVerification.BODY, WSSSignature.ADDRESSING_HEADERS,
// and WSSSignature.TIMESTAMP.

// Set the part in the SOAP header to be specified by QName (step: e)
     ver.addRequiredVerifyHeader(new QName("http://www.w3.org/2005/08/addressing", "MessageID"));

// Set the part to be specified by the keyword (step: e)
     ver.addRequiredVerifyPart(WSSVerification.BODY);

// Set the part to be specified by WSSVerifyPart (step: e)
  WSSVerifyPart verPart = factory.newWSSVerifyPart();
     verPart.setRequiredVerifyPart(WSSVerification.BODY);
     verPart.addAllowedDigestMethod(WSSVerifyPart.SHA256);
     ver.addRequiredVerifyPart(verPart);

// Set the part specified by XPath expression (step: e)
  StringBuffer sb = new StringBuffer();
        sb.append("/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/'
            and local-name()='Envelope']");
        sb.append("/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/'
            and local-name()='Body']");
        sb.append("/*[namespace-uri()='http://xmlsoap.org/Ping'
            and local-name()='Ping']");
        sb.append("/*[namespace-uri()='http://xmlsoap.org/Ping'
            and local-name()='Text']");
     ver.addRequiredVerifyPartByXPath(sb.toString());

// Set one or more canonicalization method candidates for verification (step: f)
// DEFAULT : WSSVerification.EXC_C14N
    ver.addAllowedCanonicalizationMethod(WSSVerification.C14N);
    ver.addAllowedCanonicalizationMethod(WSSVerification.EXC_C14N);

// Set one or more signature method candidates for verification (step: g)
// DEFAULT : WSSVerification.RSA_SHA1
    ver.addAllowedSignatureMethod(WSSVerification.HMAC_SHA1);

// Set the candidate security token to used for the verification (step: h)
  X509ConsumeCallbackHandler callbackHandler2 = getCallbackHandler2();
     ver.addToken(X509Token.class, callbackHandler2);

// Set the flag to require the signature confirmation (step: i)
   ver.requireSignatureConfirmation();
```

```
// Add the WSSVerification to the WSSConsumingContext (step: j)
  concont.add(ver);

//Validate the WS-Security header (step: k)
concont.process(msgcontext);
```

What to do next

After verifying the signature and setting algorithm methods for the SOAP message, you can set either the digest method or the transform method. If you want to set these methods, use the WSSVerifyPart API, or configure policy sets using the administrative console.

Verifying signed parts using the WSSVerifyPart API:

To secure SOAP messages on the consumer side, use the Web Services Security APIs (WSS API) to configure the verify parts information for the consumer binding on the response consumer (client side). You can specify which algorithm methods and which parts of the SOAP message are to be verified. Use the WSSVerifyPart API to change the digest method or the transform method. The WSSVerifyPart API is part of the com.ibm.websphere.wssecurity.wssapi.verification package.

Before you begin

To secure SOAP messages using the signing verification information, you must complete one of the following tasks:

- Configure the signature verification information using the WSSVerification API.
- Configure verify parts using the WSSVerifyPart API, as needed.

The WSSVerifyPart is used for specify the transform or digest methods for the verification. Use the WSSVerifyPart API or configure policy sets using the administrative console.

About this task

WebSphere Application Server uses the signing information for the default consumer to verify the signed parts of the message. The WSSVerifyPart API is only supported on the response consumer (requester).

The following table shows the required verification parts when the digital signature security constraint (integrity) is defined:

Table 219. Verify parts information. Use the verify parts to secure messages with signing verification information.

Verify parts information	Description
keyword	Sets the verify parts using the following keywords: • BODY • ADDRESSING_HEADERS • TIMESTAMP The WS-Addressing headers are not decrypted but can be signed and verified.
xpath	Sets the verify parts using an XPath expression.
header	Sets the header, specified by QName, as a required verify part.

For signature verification, certain default behaviors occur. The simplest way to use the WSSVerification API is to use the default behavior (see the example code). The default values are defined by the WSS API for the signing algorithm and the canonicalization algorithm, and the verify parts.

Table 220. Verify parts default behaviors. Several characteristics of verify parts are configured by default.

Verify parts decisions	Default behavior
Which keywords to specify	The different SOAP message parts to be signed and used for message protection. WebSphere Application Server supports the following keywords: • WSSVerification.BODY • WSSVerification.ADDRESSING_HEADERS • WSSVerification.TIMESTAMP
Which transform method to use (algorithm)	Adds the transform method. The transform algorithm is specified within the <Transform> element and specifies the transform algorithm for the signature. The default transform method is TRANSFORM_EXC_C14N. WebSphere Application Server supports the following pre-configured transform algorithms: • WSSVerifyPart.TRANSFORM_EXC_C14N (the default value): http://www.w3.org/2001/10/xml-exc-c14n# • WSSVerifyPart.TRANSFORM_XPATH2_FILTER: http://www.w3.org/2002/06/xmldsig-filter2 Use this transform method to ensure compliance with the Basic Security Profile (BSP). • WSSVerifyPart.TRANSFORM_STRT10: http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform • WSSVerifyPart.TRANSFORM_ENVELOPED_SIGNATURE: http://www.w3.org/2000/09/xmldsig#enveloped-signature
Which digest method to use (algorithm)	Sets the digest algorithm method. The digest method algorithm that is specified within the <DigestMethod> element is used in the <SigningInfo> element. The default digest method is SHA1. WebSphere Application Server supports the following digest method algorithms: • WSSVerifyPart.SHA1: http://www.w3.org/2000/09/xmldsig#sha1 • WSSVerifyPart.SHA256: http://www.w3.org/2001/04/xmlenc#sha256 • WSSVerifyPart.SHA512: http://www.w3.org/2001/04/xmlenc#sha512

Procedure

1. To verify signed parts by using the WSSVerifyPart API, first ensure that the application server is installed.
2. Use the Web Services Security API to verify the verification in a SOAP message. The WSS API process for verifying the signature follows these process steps:
   a. Uses WSSFactory.getInstance() to get the WSS API implementation instance.
   b. Creates the WSSConsumingContext instance from the WSSFactory instance. Ensures that WSSConsumingContext is called in the JAX-WS Provider implementation class. Due to the nature of the JAX-WS programming model, a JAX-WS provider needs to be implemented and must call the WSSConsumingContext to verify the SOAP message signature.
   c. Creates the CallbackHandler to use for verification.
   d. Create the WSSVerification object from the WSSFactory instance.
   e. Creates WSSVerifyPart from the WSSFactory instance.
   f. Sets the part to be verified, if the default is not appropriate.
   g. Sets the candidates for the digest method, if the default is not appropriate.
   h. Sets the candidates for the transform method, if the default is not appropriate.
   i. Adds WSSVerifyPart to WSSVerification.
   j. Adds WSSVerification to WSSConsumingContext.
   k. Calls WSSConsumingContext.process() with the SOAPMessageContext.

Results

You have completed the steps to verify to verify the signed parts on the consumer side. If there is an error condition when verifying the signing information, a WSSException is provided. If successful, the WSSConsumingContext.process() is called, and Web Services Security is verified for the SOAP message.

Example

The following example provides sample code for the WSSVerification API process for verifying the signing information in a SOAP message:

```
// Get the message context
   Object msgcontext = getMessageContext();

// Generate the WSSFactory instance (step: a)
   WSSFactory factory = WSSFactory.getInstance();

// Generate the WSSConsumingContext instance (step: b)
   WSSConsumingContext concont = factory.newWSSConsumingContext();

// Generate the certificate list
   String certpath =
   "c:/WebSphere/AppServer/etc/ws-security/samples/intca2.cer";
// The location of the X509 certificate file
   X509Certificate x509cert = null;
      try {
          InputStream is = new FileInputStream(certpath);
          CertificateFactory cf = CertificateFactory.getInstance("X.509");
          x509cert = (X509Certificate)cf.generateCertificate(is);
      } catch(FileNotFoundException e1){
            throw new WSSException(e1);
      } catch (CertificateException e2) {
            throw new WSSException(e2);
      }

      Set<Object> eeCerts = new HashSet<Object>();
      eeCerts.add(x509cert);
// create certStore
      java.util.List<CertStore> certList = new
          java.util.ArrayList<CertStore>();
      CollectionCertStoreParameters certparam = new
          CollectionCertStoreParameters(eeCerts);
      CertStore cert = null;
      try {
         cert = CertStore.getInstance("Collection",
              certparam, "IBMCertPath");
      } catch (NoSuchProviderException e1) {
           throw new WSSException(e1);
      } catch (InvalidAlgorithmParameterException e2) {
           throw new WSSException(e2);
      } catch (NoSuchAlgorithmException e3) {
           throw new WSSException (e3);
      }
      if(certList != null ){
      certList.add(cert);
      }

// generate callback handler (step: c)
   X509ConsumeCallbackHandler callbackHandler = new
       X509ConsumeCallbackHandler(
                                "dsig-receiver.ks",
                                "jks",
                                "server".toCharArray(),
                                certList,
       java.security.Security.getProvider("IBMCertPath")
);

// Generate the WSSVerification instance (step: d)
   WSSVerification ver = factory.newWSSVerification(X509Token.class,
       callbackHandler);

// Set the part to be specified by WSSVerifyPart (step: e)
   WSSVerifyPart verPart = factory.newWSSVerifyPart();

// Set the part to be specified by the keyword (step: f)
   verPart.setRequiredVerifyPart(WSSVerification.BODY);

// Set the candidates for the digest method for verification (step: g)
// DEFAULT : WSSVerifyPart.SHA1
   verPart.addAllowedDigestMethod(WSSVerifyPart.SHA256);

// Set the candidates for the transform method for verification (step: h)
// DEFAULT : WSSVerifypart.TRANSFORM_EXC_C14N : String
   verPart.addAllowedTransform(WSSVerifyPart.TRANSFORM_STRT10);

// Set WSSVerifyPart to WSSVerification (step: i)
   ver.addRequiredVerifyPart(verPart);

// Add WSSVerification to WSSConsumingContext (step: j)
   concont.add(ver);

//Validate the WS-Security header (step: k)
concont.process(msgcontext);
```

What to do next

You have completed configuring the signed part to be verified.

Configuring response signature verification methods for the client:

Use the WSSVerification and WSSVerifyPart APIs to choose the signing verification methods. The request signing verification methods include the digest algorithm and the transport methods.

Before you begin

To complete configuration of the signature verification information to secure SOAP messages, you must perform the following algorithm tasks:

- Use the WSSVerification API to configure the canonicalization and signature methods.
- Use the WSSVerifyPart API to configure the digest and transform methods.

to configure the algorithm methods to use when configuring the client for request signing.

About this task

The following table describes the purpose of this information. Some of these definitions are based on the XML-Signature specification, which is located at the following website http://www.w3.org/TR/xmldsig-core.

Table 221. Signing verification methods. Use signing verification information to secure messages.

Name of method	Purpose
Digest algorithm	Applies to the data after transforms are applied, if specified, to yield the <DigestValue> element. Signing the <DigestValue> element binds the resource content to the signer key. The algorithm selected for the client request sender configuration must match the algorithm selected in the client request receiver configuration.
Transform algorithm	Applies to the <Transform> element.
Signature algorithm	Specifies the Uniform Resource Identifiers (URI) of the signature verification method.
Canonicalization algorithm	Specifies the Uniform Resource Identifiers (URI) of the canonicalization method.

After configuring the client to digitally sign the message, you must configure the client to verify the digital signature. You can use the WSS APIs or configure policy sets using the administrative console to verify the digital signature and to choose the verification and verify part algorithms. If using the WSS APIs to configure, use the WSSVerification and WSSVerifyPart APIs to specify which digitally signed message parts to verify and to specify which algorithm methods to use when configuring the client for request signing.

The WSSVerification and WSSVerifyPart APIs perform the following steps to configure the signature verification and verify parts algorithm methods:

Procedure

1. For the consumer binding, the WSSVerification API specifies the signature methods to allow for the signature verification. WebSphere Application Server supports the following pre-configured signature methods:
   - WSSVerification.RSA_SHA1 (the default value): http://www.w3.org/2000/09/xmldsig#rsa-sha1
   - WSSVerification.HMAC_SHA1: http://www.w3.org/2000/09/xmldsig#hmac-sha1

   The DSA-SHA1 digital signature method (http://www.w3.org/2000/09/xmldsig#dsa-sha1) is not supported.

2. For the consumer binding, the WSSVerification API specifies the canonicalization method to allow for the signature verification. WebSphere Application Server supports the following pre-configured canonicalization methods by default:
   - WSSVerification.EXC_C14N (the default value): http://www.w3.org/2001/10/xml-exc-c14n#
   - WSSVerification.C14N: http://www.w3.org/2001/10/xml-c14n#
3. For the consumer binding, the WSSVerifyPart API specifies the digest method, as needed. WebSphere Application Server supports the following digest method algorithms for signed parts verification:
   - WSSVerifyPart.SHA1 (the default value): http://www.w3.org/2000/09/xmldsig#sha1
   - WSSVerifyPart.SHA256: http://www.w3.org/2001/04/xmlenc#sha256
   - WSSVerifyPart.SHA512: http://www.w3.org/2001/04/xmlenc#sha512
4. For the consumer binding, the WSSVerifyPart API specifies the transform method. WebSphere Application Server supports the following transform algorithms for verify parts:
   - WSSVerifyPart.TRANSFORM_EXC_C14N (the default value): http://www.w3.org/2001/10/xml-exc-c14n#
   - WSSVerifyPart.TRANSFORM_XPATH2_FILTER: http://www.w3.org/2002/06/xmldsig-filter2
   - WSSVerifyPart.TRANSFORM_STRT10: http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform
   - WSSVerifyPart.TRANSFORM_ENVELOPED_SIGNATURE: http://www.w3.org/2000/09/xmldsig#enveloped-signature

   For the WSS APIs, WebSphere Application Server does not support these algorithms:
   - http://www.w3.org/2002/07/decrypt#XML
   - http://www.w3.org/TR/1999/REC-xpath-19991116

Results

You have specified which method to use when verifying a digital signature when the client sends a message.

Example

The following example provides sample WSS API code that specifies the verification information, the body as a part to be verified, the HMAC_SHA1 as a signature method, C14N and EXC_C14N as the candidates of canonicalization methods, TRANSFORM_STRT10 as a transform method, and SHA256 as a digest method.

```
// Get the message context
   Object msgcontext = getMessageContext();

// Generate the WSSFactory instance
   WSSFactory factory = WSSFactory.getInstance();

// Generate the WSSConsumingContext instance
   WSSConsumingContext concont = factory.newWSSConsumingContext();

// Generate the certificate list
   String certpath = "intca2.cer";
// The location of the X509 certificate file
      X509Certificate x509cert = null;

      }

// Generate the callback handler
   X509ConsumeCallbackHandler callbackHandler = new
      X509ConsumeCallbackHandler(
                                "dsig-receiver.ks",
                                "jks",
                                "server".toCharArray(),
                                certList,
                                java.security.Security.getProvider(
                                      "IBMCertPath")
                                );

// Generate the WSSVerification instance
   WSSVerification ver = factory.newWSSVerification(X509Token.class,
                                                    callbackHandler);

// Set one or more candidates of the signature method used for
//    verification (step. 1)
// DEFAULT : WSSVerification.RSA_SHA1
      ver.addAllowedSignatureMethod(WSSVerification.HMAC_SHA1);

// Set one or more candidates of the canonicalization method used for
//    verification (step. 2)
// DEFAULT : WSSVerification.EXC_C14N
      ver.addAllowedCanonicalizationMethod(WSSVerification.C14N);
      ver.addAllowedCanonicalizationMethod(WSSVerification.EXC_C14N);

// Set the part to be specified by WSSVerifyPart
   WSSVerifyPart verPart = factory.newWSSVerifyPart();

// Set the part to be specified by the keyword
      verPart.setRequiredVerifyPart(WSSVerification.BODY);

// Set the candidates of digest methods to use for verification (step. 3)
// DEFAULT : WSSVerifypart.TRANSFORM_EXC_C14N : String
      verPart.addAllowedTransform(WSSVerifyPart.TRANSFORM_STRT10);

// Set the candidates of digest methods to use for verification (step. 4)
// DEFAULT : WSSVerifyPart.SHA1
      verPart.addAllowedDigestMethod(WSSVerifyPart.SHA256);

// Set WSSVerifyPart to WSSVerification
      ver.addRequiredVerifyPart(verPart);

// Add the WSSVerification to the WSSConsumingContext
   concont.add(ver);

// Validate the WS-Security header
concont.process(msgcontext);
```

What to do next

You have completed configuring the signature verification algorithms. Next, configure the encryption or decryption algorithms, if not already configured. Or, configure the security token information, as needed.

Signature verification methods using the WSSVerification API:

You can verify the signing or signature information using the WSS API for the consumer binding. The signature and canonicalization algorithm methods are used for the generator binding. The WSSVerification API is provided in the com.ibm.websphere.wssecurity.wssapi.verification package.

To configure consumer signing information to protect message integrity, you must first digitally sign and then verify the signature for the SOAP messages. Integrity refers to digital signature while confidentiality refers to encryption. Integrity decreases the risk of data modification when you transmit data across a network.

Methods

Methods that are used for the signature verification include the:

Signature method
Sets the signature algorithm method.

Canonicalization method
Sets the canonicalization algorithm method.

The algorithm that is specified for the request generator configuration must match the algorithm that is specified for the response consumer configuration.

Signature algorithms

The signature algorithms specify the signature verification algorithm that is used to sign the certificate. The signature algorithms specify the Uniform Resource Identifiers (URI) of the signature verification method. WebSphere Application Server supports the following pre-configured algorithms:

Table 222. Signature verification algorithms. The algorithms include the signature methods.

Algorithm	Description
WSSVerification.HMAC_SHA1	A URI of the signature algorithm, HMAC: http://www.w3.org/2000/09/xmldsig#hmac-sha1
WSSVerification.RSA_SHA1 (the default value)	A URI of the signature algorithm, RSA: http://www.w3.org/2000/09/xmldsig#rsa-sha1

WebSphere Application Server does not support the algorithm for DSA-SHA1: http://www.w3.org/2000/09/xmldsig#dsa-sha1

Canonicalization algorithms

The canonicalization algorithms specify the Uniform Resource Identifiers (URI) of the canonicalization method. WebSphere Application Server supports the following pre-configured algorithms:

Table 223. Verification canonicalization algorithms. The algorithms include the canonicalization methods.

Algorithm	Description
WSSVerification.C14N	A URI of the inclusive canonicalization algorithm, C14N: http://www.w3.org/2001/10/xml-c14n#
WSSVerification.EXC_C14N (the default value)	A URI of the exclusive canonicalization algorithm EXC_C14N: http://www.w3.org/2001/10/xml-exc-c14n#

The following example provides sample WSS API code that specifies the X.509 token security token for signature verification:

```
WSSFactory factory = WSSFactory.getInstance();
WSSConsumingContext concont = factory.newWSSConsumingContext();

// X509ConsumeCallbackHandler
X509ConsumeCallbackHandler callbackHandler = new
   X509ConsumeCallbackHandler("dsig-receiver.ks",
                              "jks",
                              "server".toCharArray(),
                              certList,
   java.security.Security.getProvider("IBMCertPath")46 );

// Set the verification component
// DEFAULT verification parts: Body, WS-Addressing header, and Timestamp
// DEFAULT data encryption algorithm: RSA-SHA1
// DEFAULT digest algorithm: SHA1
// DEFAULT canonicalization algorithm: exc-c14n
WSSVerification ver = factory.newWSSVerification(X509Token.class,
                                                 callbackhandler);
concont.add(ver);

// Validate the WS-Security header
concont.validate(msgctx);
```

Choosing the verify parts methods using the WSSVerifyPart API:

You can configure the signing verification information for the consumer binding using the WSS API. The transform algorithm and digest methods are used for the consumer binding. Use the WSSVerifyPart API to configure the algorithm methods. The WSSVerifyPart API is provided in the com.ibm.websphere.wssecurity.wssapi.verification package.

To configure consumer verify parts information to protect message integrity, you must first digitally sign and then verify the signature and signed parts for the SOAP messages. Integrity refers to digital signature while confidentiality refers to encryption. Integrity decreases the risk of data modification when you transmit data across a network.

Methods

Methods that are used for the signing information include the:

Digest method
Sets the digest method.

Transform method
Sets the transform algorithm method.

Digest algorithms

The digest method algorithm is specified within the element is used in the <Digest> element. WebSphere Application Server supports the following pre-configured digest algorithms:

Table 224. Verify parts digest methods. Use the verify parts to protect message integrity.

Digest method	Description
WSSVerifyPart.SHA1 (the default value)	A URI of the digest algorithm, SHA1: http://www.w3.org/2000/09/xmldsig#sha1
WSSVerifyPart.SHA256	A URI of the digest algorithm, SHA256: http://www.w3.org/2001/04/xmlenc#sha256
WSSVerifyPart.SHA512	A URI of the digest algorithm, SHA256: http://www.w3.org/2001/04/xmlenc#sha512

Transform algorithms

The transform algorithm is specified within the <Transform> element and specifies the transform algorithm for the signed part. WebSphere Application Server supports the following pre-configured transform algorithms:

Table 225. Verify parts transform methods. Use the verify parts to protect message integrity.

Digest method	Description
WSSVerifyPart.TRANSFORM_ENVELOPED_SIGNATURE	A URI of the transform algorithm, enveloped signature: http://www.w3.org/2000/09/xmldsig#enveloped-signature
WSSVerifyPart.TRANSFORM_STRT10	A URI of the transform algorithm, STR-Transform: http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform
WSSVerifyPart.TRANSFORM_EXC_C14N (the default value)	A URI of the transform algorithm, Exc-C14N: http://www.w3.org/2001/10/xml-exc-c14n#
WSSVerifyPart.TRANSFORM_XPATH2_FILTER	A URI of the transform algorithm, XPath2 filter: http://www.w3.org/2002/06/xmldsig-filter2

For the WSS APIs, WebSphere Application Server does not support the following transform algorithms:

- http://www.w3.org/TR/1999/REC-xpath-19991116
- http://www.w3.org/2002/07/decrypt#XML

The following example provides sample WSS API code that verifies the body using SHA256 as the digest method and TRANSFORM_EXC_14N and TRANSFORM_STRT10 as the transform methods:

```
// get the message context
Object msgcontext = getMessageContext();

// generate WSSFactory instance
WSSFactory factory = WSSFactory.getInstance();

// generate WSSConsumingContext instance
WSSConsumingContext concont = factory.newWSSConsumingContext();

// generate the cert list
String certpath = "intca2.cer";// The location of the X509
   certificate file X509Certificate x509cert = null;
try {
 InputStream is = new FileInputStream(certpath);
 CertificateFactory cf = CertificateFactory.getInstance("X.509");
 x509cert = (X509Certificate)cf.generateCertificate(is);
} catch(FileNotFoundException e1){
 throw new WSSException(e1);
} catch (CertificateException e2) {
 throw new WSSException(e2);
}

Set<Object> eeCerts = new HashSet<Object>();
eeCerts.add(x509cert);
// create certStore
java.util.List<CertStore> certList = new java.util.ArrayList<CertStore>();
CollectionCertStoreParameters certparam = new
      CollectionCertStoreParameters(eeCerts);
CertStore cert = null;
try {
 cert = CertStore.getInstance("Collection", certparam, "IBMCertPath");
} catch (NoSuchProviderException e1) {
 throw new WSSException(e1);
} catch (InvalidAlgorithmParameterException e2) {
 throw new WSSException(e2);
} catch (NoSuchAlgorithmException e3) {
 throw new WSSException (e3);
}
if(certList != null ){
 certList.add(cert);
}

// generate callback handler
X509ConsumeCallbackHandler callbackHandler = new
      X509ConsumeCallbackHandler(
  "dsig-receiver.ks",
  "jks",
  "server".toCharArray(),
  certList,
  java.security.Security.getProvider("IBMCertPath")
);

//generate WSSVerification instance
WSSVerification ver = factory.newWSSVerification(X509Token.class,
     callbackHandler);

//set one or more candidates of the signature method used for the
 //verification (step. 1)
// DEFAULT : WSSVerification.RSA_SHA1
ver.addAllowedSignatureMethod(WSSVerification.HMAC_SHA1);

//set one or more candidates of the canonicalization method used
 //for the verification (step. 2)
// DEFAULT : WSSVerification.EXC_C14N
ver.addAllowedCanonicalizationMethod(WSSVerification.C14N);
ver.addAllowedCanonicalizationMethod(WSSVerification.EXC_C14N);

//set the part to be specified by WSSVerifyPart
WSSVerifyPart verPart = factory.newWSSVerifyPart();

//set the part to be specified by the keyword
verPart.setRequiredVerifyPart(WSSVerification.BODY);

//set the candidates of digest methods to use for verification (step. 3)
// DEFAULT : WSSVerifypart.TRANSFORM_EXC_C14N
verPart.addAllowedTransform(WSSVerifyPart.TRANSFORM_EXC_C14N);
verPart.addAllowedTransform(WSSVerifyPart.TRANSFORM_STRT10);

//set the candidates of digest methods to use for verification (step. 4)
// DEFAULT : WSSVerifyPart.SHA1
verPart.addAllowedDigestMethod(WSSVerifyPart.SHA256);

//set WSSVerifyPart to WSSVerification
ver.addRequiredVerifyPart(verPart);
```

```
//add the WSSVerification to the WSSConsumingContext
concont.add(ver);

//validate the WS-Security header
concont.process(msgcontext);
```

Validating the consumer token to protect message authenticity:

The token consumer information is used on the consumer side to incorporate and validate the security token. The Username token, X509 tokens, and LTPA tokens by default are used for message authenticity.

Before you begin

The token processing and pluggable token architecture in the Web Services Security run time reuses the same security token interface and Java Authentication and Authorization Service (JAAS) Login Module from the Web Services Security APIs (WSS API). The same implementation of token creation and validation can be used in both the WSS API and the WSS SPI in the Web Services Security run time.

Restriction: The `com.ibm.wsspi.wssecurity.token.TokenConsumingComponent` interface is not used with JAX-WS web services. If you are using JAX-RPC web services, this interface is still valid.

Note that the key name (KeyName) element is not supported because there is no KeyName policy assertion defined in the current OASIS Web Services Security draft specification.

About this task

The JAAS callback handler (CallbackHandler) and the JAAS login module (LoginModule) are responsible for creating the security token on the generator side and validating (authenticating) the security token on the consumer side.

For example, on the generator side, the Username token is created by the JAAS LoginModule and using the JAAS CallbackHandler to pass the authentication data. The JAAS LoginModule creates the Username SecurityToken object and passes it to the Web Services Security run time.

Then, on the consumer side, the Username Token XML format is passed to the JAAS LoginModule for validation or authentication and the JAAS CallbackHandler is used to pass authentication data from the Web Services Security run time to the LoginModule. After the token is authenticated, a Username SecurityToken object is created and passed it to the Web Services Security run time.

Note: WebSphere Application Server does not support a stackable login module with the WebSphere Application Server default login module implementation, meaning adding the login module before or after the WebSphere Application Server login module implementation. If you want to stack the login module implementations, you must develop the required login modules because there is no default implementation.

The com.ibm.websphere.wssecurity.wssapi.token package provided by WebSphere Application Server includes support for these classes:

- Security token (SecurityTokenImpl)
- Binary security token (BinarySecurityTokenImpl)

In addition, WebSphere Application Server provides the following pre-configured sub-interfaces for security tokens:

- Derived key token
- Security context token (SCT)
- Username token
- LTPA token propagation

- LTPA token
- X509PKCS7 token
- X509PKIPath token
- X509v3 token
- Kerberos v5 token

The Username token, the X.509 tokens, and the LTPA tokens are used by default for message authenticity. The derived key token and the X.509 tokens are used by default for signing and encryption.

The WSS API and WSS SPI are only supported on the client. To specify the security token type on the consumer side, you can also configure policy sets using the administrative console. You can also use the WSS APIs or policy sets for matching generator security tokens.

The default Login Module and Callback implementations are designed to be used as a pair, meaning both a generator and a consumer part. To use the default implementations, select the appropriate generator and consumer security token in a pair. For example, select `system.wss.generate.x509` in the token generator and `system.wss.consume.x509` in the token consumer when the X.509 token is required.

To configure the consumer-side security token, use the appropriate pre-configured token consumer interface from the WSS APIs to complete the following token configuration process steps:

Procedure

1. Generate the wssFactory instance.
2. Generate the wssConsumingContext instance.

   The WSSConsumingContext interface stores the components for consuming Web Services Security (WS-Security), such as verification, decryption, the security token, and the time stamp. When the validate() method is called, all of these components are validated.
3. Create the consumer-side components, such as the WSSVerification and the WSSDecryption objects.
4. Specify a JAAS configuration by specifying the name of the JAAS login configuration. The Java Authentication and Authorization Service (JAAS) configuration specifies the name of the JAAS configuration. The JAAS configuration specifies how the token logs in on the consumer side. Do not remove the predefined system or application login configurations. However, within these configurations, you can add module class names and specify the order in which WebSphere Application Server loads each module.
5. Specify a token consumer class name. The token consumer class name specifies the required information to validate the SecurityToken. The Username token, the X.509 tokens, and the LTPA tokens are used by default for message authenticity.
6. Specify the settings for the callback handler by specifying a callback handler class name and also specifies the callback handler keys. This class name is the name of the callback handler implementation class that is used for the plug-in to the security token framework.

   WebSphere Application Server provides the following default callback handler implementations for the consumer side:

   com.ibm.websphere.wssecurity.callbackhandler.PropertyCallback
   This class is a callback for handling the name-value pair in elements in the Web Services Security (WS-Security) configuration XMI files.

   ccom.ibm.websphere.wssecurity.callbackhandler.UNTConsumeCallbackHandler
   This class is a callback handler for the Username token on the consumer side. This instance is used to set into WSSConsumingContext object to validate a Username token. Use this implementation for a Java Platform, Enterprise Edition (Java EE) application client only.

   com.ibm.websphere.wssecurity.callbackhandler.X509ConsumeCallbackHandler
   This class is a callback handler that is used to validate the X.509 certificate that is inserted in

the Web Services Security header within the SOAP message as a binary security token on the consumer side. This instance is used to generate the WSSVerification object and WSSDecryption objects, set the objects into WSSConsumingContext object to validate the X.509 binary security tokens. A keystore and a key definition are required for this callback handler. If you use this implementation, a key store password, path, and type must have been provided on the generator side.

com.ibm.websphere.wssecurity.callbackhandler.LTPAConsumeCallbackHandler
This class is a callback handler for the Lightweight Third Party Authentication (LTPA) tokens on the consumer side. This instance is used to generate the WSSVerification and WSSDecryption objects to validate an LTPA token.

This callback handler is used to validate the LTPA security token inserted in the Web Services Security header within the SOAP message as a binary security token. However, if the user name and password are specified, WebSphere Application Server authenticates the user name and password to obtain the LTPA security token rather than obtaining it from the Run As Subject. Use this callback handler only when the web service is acting as a client on the application server. It is recommended that you do not use this callback handler on a Java EE application client. If you use this implementation, a basic authentication user ID and password must have been provided on the generator side.

com.ibm.websphere.wssecurity.callbackhandler.KRBTokenConsumeCallbackHandler
This class is a callback handler for the Kerberos v5 token on the consumer side. This instance is used to set the WSSConsumingContext object to consume the Kerberos v5 AP-REQ as a binary security token. The instance is also used to generate the WSSVerification and WSSDecryption objects to use the Kerberos session key or derived key in the SOAP message verification and decryption.

7. If a X.509 token is specified, additional token information is also specified.

Table 226. Information for the X.509 token. Use the X.509 token to authenticate messages.

Token Information	Description
keyStoreRef	The reference name of the keystore that is used for the key locator.
keyStorePath	The keystore file path from which the keystore is loaded, if needed. It is recommended that you use the `${USER_INSTALL_ROOT}` in the path name as this variable expands to the WebSphere Application Server path on your machine. This path is required when you use the X.509 tokens callback handler implementations.
keyStorePassword	The password that is used to check the integrity of the keystore, or the keystore password that is used to unlock the keystore and to access the keystore file. The keystore and its configuration are used for some of the default callback handler implementations that are provided by WebSphere Application Server.
keyStoreType	The keystore type of keystore that is used for the key locator. This selection indicates the format that is used by the keystore file. The following values are available for selection: **JKS** Use this option if the keystore uses the Java Keystore (JKS) format. **JCEKS** Use this option if the Java Cryptography Extension is configured in the software development kit (SDK). The default IBM JCE is configured in WebSphere Application Server. This option provides stronger protection for stored private keys by using Triple DES encryption. **JCERACFKS** Use JCERACFKS if the certificates are stored in a SAF key ring (z/OS only). **PKCS11KS (PKCS11)** Use this format if your keystore uses the PKCS#11 file format. Keystores using this format might contain RSA keys on cryptographic hardware or might contain encrypt keys that use cryptographic hardware to ensure protection. **PKCS12KS (PKCS12)** Use this option if your keystore uses the PKCS#12 file format.
alias	The key alias name. The key alias is used by the key locator to find the key within the keystore file.
keyPassword	The key password that is used for recovering the key. This password is needed to access the key object within the keystore file.
keyName	The name of the key. For digital signatures, the key name is used by the request generator or response consumer signing information to determine which key is used to digitally sign the message. For encryption, the key name is used to determine the key used for encryption. The key name must be a fully qualified, distinguished name (DN). For example, `CN=Bob,O=IBM,C=US`.
trustAnchorPath	The file path from which the trust anchor is loaded.

Table 226. Information for the X.509 token (continued). Use the X.509 token to authenticate messages.

Token Information	Description
trustAnchorType	The type of trust anchor.
trustAnchorPassword	The password that is used to check the integrity of the trust anchor or the password used to unlock the keystore.
certStores	A list of certificate stores. A collection certificate store includes a list of untrusted, intermediary certificates and certificate revocation lists (CRLs). The collection certificate store is used to validate the certificate path of the incoming X.509-formatted security tokens.
provider	The security provider.

The following can be specified for a X.509 token:

a. Without any keystore.

b. With a trust anchor. A trust anchor specifies a list of keystore configurations that contain trusted root certificates. These configurations are used to validate the certificate path of incoming X.509-formatted security tokens. For example, when you select the trust anchor or the certificate store of a trusted certificate, you must configure the trust anchor and the certificate store before setting the certificate path.

c. With a keystore that is used for the key locator.

   First, you must have created the keystore file, by using a key tool utility, for example. The keystore is used to retrieve the X.509 certificate. This entry specifies the password that is used to access the keystore file. Keystore objects within trust anchors contain trusted root certificates that are used by the CertPath API to validate the trustworthiness of a certificate chain. The names of the trust anchor and the collection certificate store are created in the certificate path under your token consumer.

d. With a keystore that is used for the key locator and the trust anchor.

e. With a map that includes key-value pairs. For example, you might specify the value type name and the value type Uniform Resource Identifier (URI). The value type specifies the namespace URI of the value type for the consumer token, and represents the token type of this class:

   ValueType: http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509v3
   Specifies an X.509 certificate token.

   ValueType: http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509PKIPathv1
   Specifies X.509 certificates in a public key infrastructure (PKI) path. This callback handler is used to create X.509 certificates encoded with the PkiPath format. The certificate is inserted in the Web Services Security header within the SOAP message as a binary security token. A keystore is required for this callback handler. A CRL is not supported by the callback handler; therefore, the collection certificate store is not required or used. If you use this implementation, you must provide a key store password, path, and type on this panel.

   ValueType: http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#PKCS7
   Specifies a list of X.509 certificates and certificate revocation lists in a PKCS#7 format. This callback handler is used to create X.509 certificates encoded with the PKCS#7 format. The certificate is inserted in the Web Services Security header in the SOAP message as a binary security token. A keystore is required for this callback handler. You can specify a certificate revocation list (CRL) in the collection certificate store. The CRL is encoded with the X.509 certificate in the PKCS#7 format. If you use this implementation, you must provide a key store password, path, and type.

   For some tokens, WebSphere Application Server provides a predefined local name for the value type. When you specify the following local name, you do not need to specify a value type URI:

   ValueType: http://www.ibm.com/websphere/appserver/tokentype/5.0.2
   For an LTPA token, you can use `LTPA` for the value type local name. This local name

causes `http://www.ibm.com/websphere/appserver/tokentype/5.0.2` to be specified for the value type Uniform Resource Identifier (URI).

ValueType: http://www.ibm.com/websphere/appserver/tokentype/5.0.2
For LTPA token propagation, you can use `LTPA_PROPAGATION` for the value type local name. This local name causes`http://www.ibm.com/websphere/appserver/tokentype` to be specified for the value type Uniform Resource Identifier (URI).

8. If the Username token is specified as the token consumer class name, the following token information can be specified:
   a. Whether to specify the nonce.

      This option indicates whether a Nonce is included for the token consumer. Nonce is a unique, cryptographic number that is embedded in a message to help stop repeat, unauthorized attacks of Username tokens. Nonce is valid only when the validating token type is a Username token, and it is available only for the response consumer binding.
   b. Specifies the keyword of the time stamp. This option indicates whether to verify a time stamp in the Username token. The time stamp is valid only when the incorporated token type is a Username token.
   c. Specifies a map that includes key-value pairs. For example, you might specify the value type name and the value type Uniform Resource Identifier (URI). The value type specifies the namespace URI of the value type for the consumer token, and represents the token type of this class:

      URI value type: http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-username-token-profile-1.0#UsernameToken
      Specifies a Username token.
9. If a Kerberos v5 token is specified as the token generator class name, the following token information can be specified:

Token Information	Description	Default Value
tokenValueType	Kerberos token value type in QName defined by Oasis Kerberos Token Profile v1.1 specification.	http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ
requireDKT	A boolean value to require a derived key for message protection.	false
clabel	The client label for the derived key.	WS-SecureConversation Specify null to use the default value.
slabel	The service label for the derived key.	WS-SecureConversation Specify null to use the default value.
keylen	The length of the derived key.	16 Specify zero to use the default value
supportTokenRequireSHA1	A boolean value to require a SHA1 key that is used in subsequent request messages when the Kerberos token is used as a supporting token.	false SHA1 key is consumed only if the supporting Kerberos token is protected. If set to true, the SHA1 key is always consumed.

Token Information	Description	Default Value
decComponent	An instance of WSSDecryption .	Set decComponent and verComponent to null to initialize this first for either the decryption or verification component. Then, use the initialized component only in the callback handler constructor for the second component.
verComponent	An instance of WSSVerfication.	Set decComponent and verComponent to null to initialize this first for either the decryption or verification component. Then, use the initialized component only in the callback handler constructor for the second component.

Additional token value types are defined in the OASIS Kerberos Token Profile v1.1 specification. Specify the token value type as the local name. It is not necessary to specify the value type URI for the Kerberos v5 token.

- http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#Kerberosv5_AP_REQ1510
- http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ1510
- http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#Kerberosv5_AP_REQ4120
- http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ4120

10. If secure conversation is used for message protection, then the following information must be specified:

Information	Description
EncryptionAlgorithm	This determines the key size.
cLabel	The client label used when creating the derived key.
sLabel	The server label used when creating the derived key.

11. Set the components into the wssConsumingContext object.
12. Invoke the wssConsumingContext.process() method.

Results

Using the WSS APIs, you have configured the token consumer.

What to do next

You must specify a similar token generator configuration, if not already completed.

Configuring the consumer security tokens using the WSS API:

You can secure the SOAP messages, without using policy sets, by using the Web Services Security APIs. To configure the token on the consumer side, use the Web Services Security APIs (WSS API). The consumer security tokens are part of the com.ibm.websphere.wssecurity.wssapi.token interface package.

Before you begin

The pluggable token framework in WebSphere Application Server has been redesigned so that the same framework from the WSS API can be reused. The same implementation of creating and validating security token can be used both for the Web Services Security run time and for the WSS API application code. The redesigned framework also simplifies the SPI programming model and will make it easier to add security token types.

You can use the WSS API or you can configure the tokens by using the administrative console. To configure tokens, you must have completed the following token task: configure the generator tokens, as needed.

About this task

On the generator side, the JAAS CallbackHandler and JAAS LoginModule are responsible for creating the security token. The token is created by using the JAAS LoginModule and by using JAAS CallbackHandler to pass authentication data. Then, the JAAS LoginModule creates the securityToken object, such as the UsernameToken, and passes it to the Web Services Security run time.

On the consumer side, the XML format is passed to the JAAS LoginModule for validation or authentication. then the JAAS CallbackHandler is used to pass authentication data from the Web Services Security run time to the LoginModule. After the token is authenticated and a security token object is created, then the token is passed it to the Web Services Security run time.

When using the WSS API for consumer token validation, certain default behaviors occur. The simplest way to use the WSS API is to use the default JAAS login module and callback handler. The example uses the default for them so the example does not specify the JAAS login module name.

The simplest way to use the WSS API is to use the default behavior (see the example code). The WSS API provide defaults for the token type, the token value, and the JAAS configuration name. The default token behaviors include:

Table 227. Default token behaviors. Several token characteristics are configured by default.

Consumer token decisions	Default behavior
Which token type to use	The token type specifies which type of token to use for signing and validating messages. The X.509 token is the default token type. WebSphere Application Server provides the following pre-configured consumer token types: • Security context token • Derived key token • X509 tokens You can also create custom token types, as needed.
What JAAS login configuration name to specify	The JAAS login configuration name specifies which JAAS login configuration name to use.
Which configuration type to use	The JAAS login module configuration type. Only the pre-configured consumer configuration types can be used for consumer token types.

The SecurityToken class (com.ibm.websphere.wssecurity.wssapi.token.SecurityToken) is the generic token class and represents the security token that has methods to get the identity, XML format, and cryptographic keys. Using the SecurityToken class, you can apply both the signature and encryption to the SOAP message. However, to apply both, you must have two SecurityToken objects, one for the signature and one for encryption, respectively.

The following token types are subclasses of the generic security token class:

Table 228. Subclasses of the SecurityToken. Use the subclasses to represent the security token.

Token type	JAAS login configuration name
Security context token	system.wss.consume.sct
Derived key token	system.wss.consume.dkt

The following token types are subclasses of the binary security token class:

Table 229. Subclasses to the BinarySecurityToken. Use the subclasses to represent the binary security token.

Token type	JAAS login configuration name
X.509 token	system.wss.consume.x509
X.509 PKI Path token	system.wss.consume.pkiPath
X.509 PKCS7 token	system.wss.consume.pkcs7

Note:

- For each JAAS login token consumer configuration name, there is a respective token generator configuration name. For example, for the X509Token, the respective token generator configuration name is system.wss.generate.x509.
- The LTPA and LTPA propagation tokens are only available to a requester that is running as a server-based client. The LTPA and LTPA propagation tokens are not supported for the Java SE 6 or Java EE application client.

To validate the X509Token to the SOAP message on the consumer side, the <X509Token> element must be in the <wsse:Security> element.

Procedure

1. To validate the securityToken package, com.ibm.websphere.wssecurity.wssapi.token, first ensure that the application server is installed.
2. *If using the default values*, configures the tokens for the Web Services Security token consumer process. , for each token type, the process is similar to the following token consumer process:
   a. Uses WSSFactory.getInstance() to get the WSS API implementation instance.
   b. Creates the WSSConsumingContext instance from the WSSFactory instance. Note that the WSSConsumingContext must always be called in a JAX-WS client application.
   c. Creates a JAAS CallbackHandler with information that is required to validate the security token. Review the token class information for which parameters are required or optional. For example, for an X.509 token, you could configure the following:

Table 230. X.509 token options. Use the X.509 configuration options to control the behavior of the token.

Token Information	Description
keyStoreRef	Indicates the reference name of the keystore that is stored in the cryptographic card. It can be specified when the card is set to the hardware.
keyStorePath	Indicates the path of the keystore file. It is not necessary to specify the keyStorePath if the keyStoreRef is set.
keyStorePassword	Indicates the password of the keystore file.
keyStoreType	Indicates the type of keystore file.
alias	Indicates the alias of the key.
keyPassword	Indicates the password of the key.
keyName	Indicates the subject name of the key.

   d. Sets the callback handler into WSSDecryption, WSSVerification, or WSSConsumingContext.
   e. If the callback handler is set into the WSSDecryption or WSSVerification, adds either one into WSSConsumingContext.
   f. Calls WSSConsumingContext.process().

3. *If using other than the default values*, configures the tokens for the Web Services Security token consumer process. For each token type, the process is similar to the following token consumer process:
   a. If you do not use the default JAAS login module and callback handler, you need to prepare a custom one and register the name of JAAS login configuration using the administrative console in advance.
   b. Uses WSSFactory.getInstance() to get the WSS API implementation instance.
   c. Creates the WSSConsumingContext instance from the WSSFactory instance. Note that the WSSConsumingContext must always be called in a JAX-WS client application.
   d. Creates a callback handler with information that is required to validate the security token. Review the token class information for which parameters are required or optional. For example, for a X.509 token, you can configure the following:

Table 231. X.509 token options. Use the X.509 configuration options to control the behavior of the token.

Token Information	Description
keyStoreRef	Indicates the reference name of the keystore that is stored in the cryptographic card. It can be specified when the card is set to the hardware.
keyStorePath	Indicates the path of the keystore file. It is not necessary to specify the keyStorePath if the keyStoreRef is set.
keyStorePassword	Indicates the password of the keystore file.
keyStoreType	Indicates the type of keystore file.
alias	Indicates the alias of the key.
keyPassword	Indicates the password of the key.
keyName	Indicates the subject name of the key.

   e. Sets JAAS configuration name and callback handler into WSSDecryption or WSSVerification, or WSSConsumingContext.
   f. If JAAS configuration name and callback handler are set into the WSSDecryption or WSSVerification, adds either one into WSSConsumingContext.
   g. Calls WSSConsumingContext.process().

Results

If there is an error condition, a WSSException is provided. If successful, the WSSConsumingContext.process() is called, and the security token on the consumer side is validated (authenticated).

Example

The following sample code provides the WSS API example code for decryption using the default JAAS login module and callback handler:

```
// Get the message context
   Object msgcontext = getMessageContext();

// Generate the WSSFactory instance (step: a)
   WSSFactory factory = WSSFactory.getInstance();

// Generate the WSSConsumingContext instance (step: b)
   WSSConsumingContext gencont = factory.newWSSConsumingContext();

// Generate the callback handler (step: c)
   X509ConsumeCallbackHandler callbackHandler = new
        X509ConsumeCallbackHandler(
                                   "",
                                   "enc-sender.jceks",
                                   "jceks",
                                   "storepass".toCharArray(),
                                   "alice",
                                   "keypass".toCharArray(),
                                   "CN=Alice, O=IBM, C=US");

// Generate the WSSDecryption instance (step: d)
   WSSDecryption dec = factory.newWSSDecryption(X509Token.class,
```

```
                                        callbackHandler);

// Add WSSDecryption to WSSConsumingContext (step: e)
   concont.add(dec);

// Validate the WS-Security header (step: f)
concont.process(msgcontext);
```

What to do next

For each token type, configure the token using the WSS APIs or using the administrative console. Next, specify the similar generator tokens if you have not done so.

If both the generator and consumer tokens are configured, continue securing SOAP messages at the response consumer using the WSS APIs or configure the tokens using the administrative console.

If both the generator and consumer tokens are configured, continue securing SOAP messages either by verifying the signature or by decrypting the message, as needed. You can use either the WSS APIs or the administrative console to secure the SOAP messages.

Configuring Web Services Security using the WSS APIs:

The Web Services Security application programming interfaces (WSS API) provide support for securing SOAP message.

Before you begin

Web Service Security supports the following programming models:

- Programming API for securing SOAP message with Web Services Security (WSS API).

  The API programming model design has been redesigned. The new design is an interface-based programming model and is based on Web Services Security Version 1.1 standards but the design also includes support for Web Services Security Version 1.0 for securing the SOAP message. The WSS API programming model implementation is a simplified version, which is based on an early draft proposal of JSR-183, which is the JSR for defining Java API binding for Web Services Security. By design, because the application code is programmed to the interface, any application code that is programmed with the open source implementation should be able to run on the WebSphere Application Server with minimal changes or no changes at all.
- Service Programming Interfaces (SPI) for a service provider

  Similarly, the Web Services Security run time token generation and token consuming SPI have been redesign so that the same security token interface and JAAS Login Module implementation can be used for both the WSS API and the SPI. The WSS SPI for the service provider extend the security token types and provide keys and deriving keys for signing, signature verification, encryption and decryption.

Usage statement: You must use the IBM implementation of the WS-Security standards in the context of web services.

About this task

These programming models extend the following functions :

- Security token types and deriving keys for signing
- Signature and verification
- Encryption and decryption

The following figure demonstrates how to use the simplified WSS APIs to secure a SOAP message by using XML digital signature and XML encryption.

The configuration model for web services has also been redesigned from a deployment descriptor model to a policy set model. The configuration programming model is based on configuring policy sets using a security policy to specify security constraints.

The functions provided by the policy set configurations are the same as the functions supported by the WSS API for the Web Services Security run time. However, the security policy that is defined using policy sets has a higher priority over the WSS API. When the WSS API and the policy set are both used in the application, the default behavior is for the security policy from the policy set to be enforced and the WSS API to be ignored. To use the WSS API in the application, you must make sure that there is no policy set attached to the application or to the application resources, or make sure there is no security policy in the attached policy set.

Web Service Security can be enabled by either using a policy set that is configured by using the administrative console, or by using the WSS API for configuration.

Using the WSS API, complete the following high-level steps to secure the SOAP message:

Procedure

1. Use the WSSSignature API to configure the signing information for the request generator (client side) binding. Different message parts can be specified in the message protection for a request on the generator side. The default required parts are BODY, ADDRESSING_HEADERS, and TIMESTAMP.

   The WSSSignature API also specifies the different algorithm methods to be used with the signature for message protection. The default signature method is RSA_SHA1. The default canonicalization method is EXC_C14N.
2. Use the WSSSignPart API if you want to add or change the signed parts to be used for message protection. The default signed parts are WSSSignature.BODY, WSSSignature.ADDRESSING_HEADERS, and WSSSignature.TIMESTAMP.

   The WSSSignPart API also specifies the different algorithm methods to be used if you added or changed the signed parts. The default digest method is SHA1. The default transform method is TRANSFORM_EXC_C14N. For example, use the WSSSignPart API if you want to generate the signature for the SOAP message using the SHA256 digest method instead of the default value of SHA1.
3. Use the WSSEncryption API to configure the encryption information on the request generator side. The encryption information on the generator side is used for encrypting an outgoing SOAP message for the request generator (client side) bindings. The default targets of encryption are BODY_CONTENT and SIGNATURE

   The WSSEncryption API also specifies the different algorithm methods to be used to protect message confidentiality. The default data encryption method is AES128. The default key encryption method is KW_RSA_OAEP.
4. Use the WSSEncryptPart API if you want to add or change the encrypted parts to be used for message confidentiality. For example, if you want to change the data encryption method from the default value of AES128 to TRIPLE_DES.

   No algorithm methods are required for encrypted parts.
5. Use the WSS API to attach the token on the generator side. The requirements for the security token depend on the token type. The JAAS Login Module and the JAAS CallbackHandler are responsible for creating the security token on the generator side. Different stand-alone tokens can be sent in request or response. The default token is the X509Token. The other token that can be used for signing is the DerivedKeyToken, which is used only with Web Services Secure Conversation (WS-SecureConversation).
6. Use the WSSVerification API to verify the signature for the response consumer (client side) binding. Different message parts can be specified in the message protection for a response on the consumer side. The required targets for verification are BODY, ADDRESSING_HEADERS, and TIMESTAMP.

The WSSVerification API also specifies the different algorithm methods to be used for verifying the signature and for message protection. The default signature method is RSA_SHA1. The default canonicalization method is EXC_C14N.

7. Use the WSSVerifyPart API to add or change the verify signed parts to be used for message protection. The required verify parts are WSSVerification.BODY, WSSVerification.ADDRESSING_HEADERS, and WSSVerification.TIMESTAMP.

   The WSSVerifyPart API also specifies the different algorithm methods to be used if you added or changed the verification parts. The default digest method is SHA1. The default transform method is TRANSFORM_EXC_C14N.

8. Use the WSSDecryption API to configure the decryption information for the response consumer (client side) binding. The decryption information on the consumer side is used for decrypting an incoming SOAP message. The default targets of decryption are BODY_CONTENT and SIGNATURE. The default data encryption method is AES128. The default key encryption method is KW_RSA_OAEP.

   No algorithm methods are required for decryption.

9. Use the WSSDecryptPart API if you want to add or change the decrypted parts to be used for message confidentiality. For example, if you want to change the data encryption method from the default value of AES128 to TRIPLE_DES.

   No algorithm methods are required for decrypted parts.

10. Use the WSS API to configure the token on the consumer side. The requirements for the security token depend on the token type. The JAAS Login Module and the JAAS CallbackHandler are responsible for validating (authenticating) the security token on the consumer side. Different stand-alone tokens can be sent in request or response.

    The WSS API adds the information for the candidate token that is used for decryption. The default token is X509Token.

Results

What to do next

The Web Services Security run time token generation and token consuming Service Programming Interfaces (SPI) have been redesign so that the same Security Token interface and JAAS Login Module implementation can be used in both the WSS API and the SPI. See the SPI information for detail descriptions.

Web Services Security APIs:

The Web Services Security programming model provides application programming interfaces (WSS API) for securing the SOAP message. The WSS API model is based on Web Services Security Version 1.1 standards but also includes support for Web Services Security Version 1.0.

The Web Services Security APIs (WSS APIs) can generate and process the following SOAP-related bindings for XML security:

- XML signature and signature verification
- XML encryption and decryption

The token processing and pluggable token architecture in the Web Service Security run time has been redesign to reuse the same Security Token interface and the JAAS Login Module as those used for the WSS APIs.

The following table lists the WSS API interfaces that are provided with WebSphere Application Server and used to configure signing and encryption information in the SOAP bindings for the generator and consumer bindings.

Table 232. WSS API interfaces. Use the interfaces to configure security information in the bindings.

WSS API interfaces	Description
WSSDecryption	Package: com.ibm.websphere.wssecurity.wssapi.decryption This interface is responsible for specifying decryption. The default values for decryption include: • Targets: BODY_CONTENT, SIGNATURE • Data encryption method: AES128 • Key encryption method: KW_RSA_OAEP • Security token: X.509
WSSDecryptPart	Package: com.ibm.websphere.wssecurity.wssapi.decryption This interface is responsible for adding decrypted parts, as needed. If specified, the default values for decrypted parts include: • Security token: X.509 • Transform method: N/A (not applicable)
WSSEncryption	Package: com.ibm.websphere.wssecurity.wssapi.encryption This interface is responsible for the encryption component. The default values for encryption include: • Targets: BODY_CONTENT, SIGNATURE • Data encryption method: AES128 • Key encryption method: KW_RSA_OAEP • Security token: X.509 • refType: SecurityToken.REF_KEYID • mtomOptimize: false
WSSEncryptPart	Package: com.ibm.websphere.wssecurity.wssapi.encryption This interface is responsible for adding encrypted parts, as needed. If specified, the default values for encrypted parts include: • Transform method: N/A (not applicable)
WSSSignature	Package: com.ibm.websphere.wssecurity.wssapi.signature This interface is responsible for specifying the signature. The default values for signature include: • Targets: BODY, ADDRESSING_HEADERS, TIMESTAMP • Signature method: RSA_SHA1 • Canonicalization method: EXC_C14N • Security token: X.509 • Type of token reference: SecurityToken.REF_STR
WSSSignPart	Package: com.ibm.websphere.wssecurity.wssapi.signature This interface is responsible for adding signed parts, as needed. If specified, the default values for signed parts include: • Transform method : TRANSFORM_EXC_C14N • Digest method: SHA1
WSSVerification	Package: com.ibm.websphere.wssecurity.wssapi.verification This interface is responsible for specifying the signature verification. The default values for verification include: • Targets: BODY, ADDRESSING_HEADERS, TIMESTAMP • Signature method: RSA_SHA1 • Canonicalization method: EXC_C14N • Security token: X.509
WSSVerifyPart	Package: com.ibm.websphere.wssecurity.wssapi.verification This interface is responsible for adding verify parts, as needed. If specified, the default values for verify parts include: • Digest method: SHA1 • Transform method: TRANSFORM_EXC_C14N

Also see the information about pre-configured generator and consumer tokens.

Web Services Security configuration considerations when using the WSS API:

To secure Web Services Security for WebSphere Application Server, you can specify several different configurations using the Web Services Security APIs (WSS API). The Web Services Security specification provides a flexible way to secure web services messages using XML digital signature, XML encryption, and attaching security tokens. You can enable Web Services Security by either configuring a policy set or by using the Web Services Security APIs (WSS API). The implementation for WSS API has default values for which message parts are to be signed or encrypted. The default values for the WSS APIs help end users to enable Web Services Security quickly.

Different message parts can be specified in the message protection for request or response, and different stand-alone tokens can be sent in request or response. However, there is only one symmetric or one asymmetric binding assertion to describe the token type and the algorithm that is used for message protection.

Using the WSS API, you can override any default values. However, when you alter the protection parts, note that all the default protection parts are cleared. For example, if you specify that you want to encrypt the Username token instead of the default X.509 token, all the default values of the encrypting protection parts are cleared.

The following table shows an example of the relationships between each of the configurations:

Table 233. Request generator and response consumer configurations. Use the table to determine the mapping between the configurations and the default values.

Type of configuration	Configuration name	Configurations and default values
Request generator	Signing information	• Canonicalization method: WSSSignature.EXC_C14N • Signature method: WSSSignature.RSA_SHA1 • Digest method: WSSSignPart.SHA1 • Transform method: WSSSignPart.TRANSFORM_EXC_C14N • Signed part - Body: WSSSignature.BODY • Signed part - Addressing: WSSSignature.ADDRESSING_HEADERS • Signed part - Timestamp: WSSSignature.TIMESTAMP • Token reference: SecurityToken.REF_STR • Token - Value type: X509Token.ValueType • Token - JAAS login configuration name: system.wss.generate.x509
Response consumer	Signature verification information	• Canonicalization method: WSSVerification.EXC_C14N • Signature method: WSSVerification.RSA_SHA1 • Transform method: WSSVerifyPart.TRANSFORM_EXC_C14N • Signed part - Body: WSSVerification.BODY • Signed part - Addressing: WSSVerification.ADDRESSING_HEADERS • Signed part - Timestamp: WSSVerification.TIMESTAMP • Token - Value type: X509Token.ValueType • Token - JAAS login configuration name: system.wss.consume.x509
Request generator	Encryption information	• Encrypted key: true • Key encryption method: WSSEncryption.KW_RSA_OAEP • Data encryption method: WSSEncryption.AES128 • Encryption part: WSSEncryption.BODY_CONTENT • Token reference: SecurityToken.REF_KEYID • Token - Value type: X509Token.ValueType • Token - JAAS login configuration name: system.wss.generate.x509
Response consumer	Decryption information	• Encrypted key: true • Key decryption method: WSSDecryption.KW_RSA_OAEP • Data decryption method: WSSDecryption.AES128 • Decryption part: WSSDecryption.BODY_CONTENT • Token - Value type: 509Token.ValueType • Token - JAAS login configuration name: system.wss.consume.x509

Encrypted SOAP headers:

The encrypted header element provides a standard way of encrypting SOAP headers. As one of the extensions to the OASIS SOAP message security specification, the encrypted header element indicates that the responder has processed the request. Encrypting SOAP headers and parts help to provide more secure message-level security.

The EncryptedHeader or <wsse11:EncryptedHeader> element is a part of the updated Web Services Security Version 1.1 standard and enables interoperability with other vendors that support the Version 1.1 standards, such as Microsoft .NET and DataPower®.

Use the EncryptedHeader element for encrypting SOAP header blocks. The EncryptedHeader element allows Web Services Security to be compliant with the SOAP mustUnderstand processing guidelines and to prevent disclosure of information that is contained in attributes on a SOAP header block.

The <wsse11:EncryptedHeader> element must contain one <xenc:EncryptedData> element. Only one <xenc:EncryptedData> element per encrypted header element is permitted.

Encrypted data element

Normally, the programming model, such as JAX-WS, deserializes the SOAP message to a Java binding object before dispatching the call to the application code. However, if the SOAP message is encrypted, the deserialization fails because, before encryption, the original content is replaced with the EncryptedData XML element from the XML Encryption standard.

In certain cases, it might be desirable for the token that is included in the <wsse:Security> header to be encrypted for the recipient processing role.

Follow these guidelines when using the EncryptedData element:

- The EncryptedHeader element must contain one EncryptedData element.
- The <xenc:EncryptedData> element may be used to contain a security token and include it in the <wsse:Security> header.
- The <xenc:EncryptedData> must not include an XML ID for referencing the contained security token.
- All <xenc:EncryptedData> tokens must either have an embedded encryption key or must be referenced by a separate encryption key.
- If compliance with Basic Security Profile 1.1 is desired, the <xenc:EncryptedData> element must have an Id attribute.

Policy assertion for encrypted parts

The EncryptedParts policy assertion specifies which header is to be encrypted in the security policy. The following table describes the elements and attributes that can be used for EncryptedParts.

Table 234. Attributes and elements of the EncryptedParts element. Use encrypted parts to provide more secure message-level security.

Element or attribute	Description
/sp:EncryptedParts/sp:Header	Optional. Presence of this optional element indicates that a specific SOAP header (or set of such headers) must be protected. You can have multiple sp:Header elements within a single EncryptedParts element. Each header (or set of headers) must be encrypted, and this encryption will encrypt the elements by using Web Services Security Version 1.1 encrypted headers. As such, if WS-Secuirty 1.1 Encrypted Headers are not supported by a service, then the headers cannot be encrypted by using message-level security. If multiple SOAP headers with the same local name but different namespace names are to be encrypted, multiple sp:Header elements are required, either as part of a single sp:EncryptedParts assertion or as part of separate sp:EncryptedParts assertions.

Table 234. Attributes and elements of the EncryptedParts element (continued). Use encrypted parts to provide more secure message-level security.

Element or attribute	Description
/sp:EncryptedParts/sp:Header/@Name	Optional. This attribute indicates the local name of the SOAP header to be confidentiality protected. If this attribute is not specified, all SOAP headers whose namespace matches the Namespace attribute are to be protected.
/sp:EncryptedParts/sp:Header/@Namespace	Required. This attribute indicates the namespace of the SOAP headers to be confidentiality protected.

The following message example shows what the EncryptedHeader element looks like on a message where the EncryptedParts policy assertion for the encrypted header has been specified on the policy:

```
<S:Envelope xmlns:S="..." xmlns:wsse="..." xmlns:wsse11="..." xmlns:wsu="..."
   xmlns:xenc="..." xmlns:ds="...">
   <S:Header>
     <wsse:Security>
      <!-- Tokens etc. -->
       <xenc:EncryptedKey>
         <xenc:EncryptionMethod Algorithm="..."/>
           <ds:KeyInfo>
             ... ...
           </ds:KeyInfo>
          <xenc:CipherData>
            <xenc:CipherValue>...</xenc:CipherValue>
          </xenc:CipherData>
          <xenc:ReferenceList>
            <xenc:DataReference URI="#hdrID"/>
          </xenc:ReferenceList>
        </xenc:EncryptedKey>
     </wsse:Security>
     <wsse11:EncryptedHeader wsu:Id="hdrID">
       <xenc:EncryptedData Id="encDataID">
         <xenc:CipherData>
           <xenc:CipherValue>...</xenc:CipherValue>
         </xenc:CipherData>
         ...
       </xenc:EncryptedData>
     </wsse11:EncryptedHeader>
   </S:Header>
   <S:Body>
     ...
   </S:Body>
</S:Envelope>
```

To encrypt headers in the Web Services Security Version 1.0 specification format, specify the com.ibm.wsspi.wssecurity.encryptedHeader.generate.WSS1.0 property with a value of `true` on the <encryptionInfo> element in the binding. When this property is specified, the target header for encryption is replaced by an <EncryptedData> element, instead of an <EncryptedHeader> element that contains an <EncryptedData> element.

For Web Services Security Version 1.1 behavior that is equivalent to WebSphere Application Server versions prior to version 7.0, specify the com.ibm.wsspi.wssecurity.encryptedHeader.generate.WSS1.1.pre.V7 property with a value of `true` on the <encryptionInfo> element in the binding. When this property is specified, the <EncryptedHeader> element includes a wsu:Id parameter and the <EncryptedData> element omits the Id parameter. This property should only be used if compliance with Basic Security Profile 1.1 is not required.

For complete information about the EncryptedHeader element and the EncryptedData element, see the Web Services Security Version 1.1 specification.

Signature confirmation:

Web Services Security signature confirmation is an enhanced XML digital signature, and it is included in the Web Services Security standard. XML digital signature is used for signing elements of the SOAP envelope.

As one of the extensions to the OASIS SOAP message security specification, the signature confirmation element incorporates the elements that are needed within the response message in order to confirm the signature that is contained in a request message. XML digital signature and signature confirmation help to provide more secure message-level security.

Web Services Security Version 1.0 for SOAP message security did not provide any guidance on how to confirm mutual understanding of the request that prompted this response. The SignatureConfirmation or <wsse11:SignatureConfirmation> element has been added to the Web Services Security Version 1.1 specification. The <wsse11:SignatureConfirmation> element ensures that the signature is processed by the intended recipient and indicates that the responder has processed the signature in the request. The signature confirmation element is part of the updated Web Services Security standard and enables interoperability with other vendors that support the Version 1.1 standards, such as Microsoft .NET and DataPower.

Because of the stateless nature of web services and due to different message exchange patterns (MEPs), consider the following assumptions:

- Assume that session affinity is enabled if a cluster is enabled for the clients that are running in WebSphere Application Server. When session affinity is enabled, it implies that the response is sent back to the initiating client of the server.
- Assume WS-Addressing is enabled for asynchronous message exchange patterns. When WS-Addressing is enabled, it allows the run time to relate the response back to the request. An asynchronous response is sent back to the application of the initiating WebSphere Application Server.

Syntax

The SignatureConfirmation element indicates that the responder has processed the signature in the request. When this element is not present in a response, the initiator interprets that the responder is not compliant.

The format for the signature confirmation element is as follows:

```
<wsse11:SignatureConfirmation wsu:Id="..." Value="..." />
```

where:

wsu:Id
The identifier that is used when referencing this element in the <ds:SignedInfo> reference list of the signature of the associated response message. This attribute is required so that unambiguous references are made to this <wsse11:SignatureConfirmation> element.

Value This attribute is optional and contains the contents of a <ds:SignatureValue> that is copied from the associated request. If the request is unsigned, this attribute must not be present. If this attribute is specified without a value (empty), the initiator interprets this as incorrect behavior and processes it accordingly. When this attribute is not present, the initiator interprets this to mean that the response is based on a request that was not signed.

Configuration

To configure signature confirmation, configure the policy file using the administrative console, and select **Require signature confirmation**. To process Signature Confirmation correctly, the initiator of the request needs to preserve the signatures during request generator processing and later needs to retrieve the signatures for confirmation checks.

Response generation rules

Additional SOAP security elements for the SOAP responder are used to confirm that the response is in relationship to a particular request. The responder must include the contents of the <ds:SignatureValue> element of the request signature as the value of the @Value attribute of the <wsse11:SignatureConfirmation> element.

The following response generation rules apply when using the SignatureConfirmation policy assertion:

- If there are no signatures on the request, the response contains one SignatureConfirmation element, without a value. For MEPs where there are multiple requests (all without signatures) and one response, the response contains one SignatureConfirmation element without a value.
- If there are signatures on the request, the response contains a SignatureConfirmation element for each signature, with a value that matches the signature value on the request. For MEPs where there are multiple requests, with at least one containing a signature, and one response, the response contains a SignatureConfirmation element for each signature that is found on the requests, with a value that matches the signature value on the request.
- For MEPs where there is one request and multiple responses, each response contains the appropriate SignatureConfirmation elements as noted in the first and second bullets.
- If the SOAP request contains multiple signatures, the requester will find all of the signature confirmation elements contained in the response, and will check the values of the value fields of the signature confirmation elements against the values of the signatures in the original SOAP request.

Developing JAX-WS based web services client applications that retrieve security tokens

The security handlers are responsible for propagating security tokens. These security tokens are embedded in the SOAP security header and passed to downstream servers.

About this task

This information applies only to Java API for XML-based Web Services (JAX-WS) .

The security tokens are encapsulated in the implementation classes for the com.ibm.wsspi.wssecurity.auth.token.Token interface. You can retrieve the security token data from either a server application or a client application.

With a client application, the application serves as the request generator and the response consumer and runs as the Java Platform, Enterprise Edition (Java EE) client application. The consumer component for Web Services Security stores the security tokens that it receives in one of the properties of the MessageContext object for the current web services call. You can retrieve a set of token objects through the javax.xml.rpc.Stub interface of that web services call. You must know which security tokens to retrieve and their token IDs in case multiple security tokens are included in the SOAP security header. Complete the following steps to retrieve the security token data from a client application:

Procedure

1. Use the com.ibm.wsspi.wssecurity.token.tokenPropergation key string to obtain the Hashtable for the tokens through a property value in the javax.xml.ws.Stub interface. The following example shows how to obtain the Hashtable:

```
java.util.Hashtable t;

javax.xml.ws.Service serv = ...;
serv.addPort(...);
javax.xml.ws.Dispatch<Object> dispatch = svc.createDispatch(...);

Map<String, Object> requestContext = dispatch.getRequestContext();
requestContext.put(BindingProvider.ENDPOINT_ADDRESS_PROPERTY, ..);
requestContext.put(BindingProvider.SOAPACTION_USE_PROPERTY, ..);
```

```
requestContext.put(BindingProvider.SOAPACTION_URI_PROPERTY, ..);

String response = dispatch.invoke(body.toString());

Map<String, Object> responseContext = dispatch.getResponseContext();

t = (Hashtable) responseContext.get(
com.ibm.wsspi.wssecurity.Constants.WSSECURITY_TOKEN_PROPERGATION);
```

2. Search the targeting token objects in the Hashtable. Each token object in the Hashtable is set with its token ID as a key. You must have prior knowledge of the security token IDs to retrieve the security tokens. The following example shows how to retrieve a username token from the security header with a certain token ID value:

```
com.ibm.wsspi.wssecurity.auth.token.UsernameToken unt;
if (t != null) {
  unt = (com.ibm.wsspi.wssecuty.auth.token.UsernameToken)t.get("...");
}
```

Results

After completing these steps, you have retrieved the security tokens that are processed by the Web Services Security handler in a client application.

Developing JAX-WS based web services server applications that retrieve security tokens

With a server application, the application acts as the request consumer, and the response generator is deployed and runs in the Java Platform, Enterprise Edition (Java EE) container. The consumer component for Web Services Security stores the security tokens that it receives in the Java Authentication and Authorization Service (JAAS) Subject of the current thread. You can retrieve the security tokens from the JAAS Subject that is maintained as a local thread in the container.

About this task

This information applies only to Java API for XML-based Web Services (JAX-WS).

The security handlers are responsible for propagating security tokens. These security tokens are embedded in the SOAP security header and passed to downstream servers. The security tokens are encapsulated in the implementation classes for the com.ibm.wsspi.wssecurity.auth.token.Token interface. You can retrieve the security token data from either a server application or a client application.

Complete the following steps to retrieve the security token data from a server application:

Procedure

1. Obtain the JAAS Subject of the current thread using the WSSubject API. If you enable Java 2 Security on the Global security panel in the administrative console, access to the JAAS Subject is denied if the application code is not granted the javax.security.auth.AuthPermission("wssecurity.getCallerSubject") permission. The following code sample shows how to obtain the JAAS subject:

```
javax.security.auth.Subject subject;

try {
subject = com.ibm.websphere.security.auth.WSSubject.getCallerSubject();
} catch (com.ibm.websphere.security.WSSecurityException e) {
  ...
}
```

2. Obtain a set of private credentials from the Subject. For more information, see the application programming interface (API) com.ibm.websphere.security.auth.WSSubject class through the information center . To access this information within the information center, click **Reference >**

Developer > API Documentation > Application Programming Interfaces. In the Application Programming Interfaces article, click **com.ibm.websphere.security.auth > WSSubject**.

Attention: When Java 2 Security is enabled, you might need to use the AccessController class to avoid a security violation that is caused by operating the security objects in the Java EE container.

The following code sample shows how to set the AccessController class and obtain the private credentials:

```
Set s = (Set) AccessController.doPrivileged(new PrivilegedAction() {
   public Object run() {
   return subj.getPrivateCredentials();
   }
      });
```

3. Search the targeting token class in the private credentials. You can search the targeting token class by using the java.util.Iterator interface. The following example shows how to retrieve a username token with a certain token ID value in the security header. You can also use other method calls to retrieve security tokens. For more information, see the application programming interface (API) documents for the com.ibm.wsspi.wssecurity.auth.token.Token interface or custom token classes.

```
com.ibm.wsspi.wssecurity.auth.token.UsernameToken unt;
Iterator it = s.iterator();
while (it.hasNext()) {
  Object obj = it.next();
  if (obj != null &&
obj instanceOf com.ibm.wsspi.wssecurity.auth.token.UsernameToken) {
    unt =(com.ibm.wsspi.wssecurity.auth.token.UsernameToken) obj;
if (unt.getId().equals("...")) break;
else continue;
  }
}
```

Results

After completing these steps, you have retrieved the security tokens from the JAAS Subject in a server application.

Developing message-level security for JAX-RPC web services

IBM® WebSphere® Application Server supports the Java™ API for XML-Based Web Services (JAX-WS) programming model and the Java API for XML-based RPC (JAX-RPC) programming model.

Developing web services clients that retrieve tokens from the JAAS Subject in an application

The security handlers are responsible for propagating security tokens. These security tokens are embedded in the SOAP security header and passed to downstream servers.

About this task

This information applies only to Java API for XML-based RPC (JAX-RPC) Web services.

The security tokens are encapsulated in the implementation classes for the com.ibm.wsspi.wssecurity.auth.token.Token interface. You can retrieve the security token data from either a server application or a client application.

With a client application, the application serves as the request generator and the response consumer and runs as the Java Platform, Enterprise Edition (Java EE) client application. The consumer component for Web Services Security stores the security tokens that it receives in one of the properties of the MessageContext object for the current Web services call. You can retrieve a set of token objects through the javax.xml.rpc.Stub interface of that web services call. You must know which security tokens to retrieve and their token IDs in case multiple security tokens are included in the SOAP security header. Complete the following steps to retrieve the security token data from a client application:

Procedure

1. Use the com.ibm.wsspi.wssecurity.token.tokenPropergation key string to obtain the Hashtable for the tokens through a property value in the javax.xml.rpc.Stub interface. The following example shows how to obtain the Hashtable:

```
java.util.Hashtable t;
javax.xml.rpc.Service serv = ...;
MyWSPortType pt = (MyWSPortType)serv.getPort(MyWSPortType.class);
t = (Hashtable)((javax.xml.rpc.Stub)pt)._getProperty(
com.ibm.wsspi.wssecurity.Constants.WSSECURITY_TOKEN_PROPERGATION);
```

2. Search the targeting token objects in the Hashtable. Each token object in the Hashtable is set with its token ID as a key. You must have prior knowledge of the security token IDs to retrieve the security tokens. The following example shows how to retrieve a username token from the security header with a certain token ID value:

```
com.ibm.wsspi.wssecurity.auth.token.UsernameToken unt;
if (t != null) {
  unt = (com.ibm.wsspi.wssecuty.auth.token.UsernameToken)t.get("...");
}
```

Results

After completing these steps, you have retrieved the security tokens from the JAAS Subject in a client application

Developing web services applications that retrieve tokens from the JAAS Subject in a server application

With a server application, the application acts as the request consumer, and the response generator is deployed and runs in the Java Platform, Enterprise Edition (Java EE) container. The consumer component for Web Services Security stores the security tokens that it receives in the Java Authentication and Authorization Service (JAAS) Subject of the current thread. You can retrieve the security tokens from the JAAS Subject that is maintained as a local thread in the container.

About this task

The security handlers are responsible for propagating security tokens. These security tokens are embedded in the SOAP security header and passed to downstream servers. The security tokens are encapsulated in the implementation classes for the com.ibm.wsspi.wssecurity.auth.token.Token interface. You can retrieve the security token data from either a server application or a client application.

Complete the following steps to retrieve the security token data from a server application:

Procedure

1. Obtain the JAAS Subject of the current thread using the WSSubject utility class. If you enable Java 2 Security on the Global security panel in the administrative console, access to the JAAS Subject is denied if the application code is not granted the javax.security.auth.AuthPermission("wssecurity.getCallerAsSubject") permission. The following code sample shows how to obtain the JAAS subject:

```
javax.security.auth.Subject subj;
try {
subj = com.ibm.websphere.security.auth.WSSubject.getCallerSubject();
} catch (com.ibm.websphere.security.WSSecurityException e) {
  ...
}
```

2. Obtain a set of private credentials from the Subject. For more information, see the application programming interface (API) com.ibm.websphere.security.auth.WSSubject class through the information center . To access this information within the information center, click **Reference >**

Developer > API Documentation > Application Programming Interfaces. In the Application Programming Interfaces article, click **com.ibm.websphere.security.auth > WSSubject**.

Attention: When Java 2 Security is enabled, you might need to use the AccessController class to avoid a security violation that is caused by operating the security objects in the Java EE container.

The following code sample shows how to set the AccessController class and obtain the private credentials:

```
Set s = (Set) AccessController.doPrivileged(new PrivilegedAction() {
   public Object run() {
   return subj.getPrivateCredentials();
   }
      });
```

3. Search the targeting token class in the private credentials. You can search the targeting token class by using the java.util.Iterator interface. The following example shows how to retrieve a username token with a certain token ID value in the security header. You can also use other method calls to retrieve security tokens. For more information, see the application programming interface (API) documents for the com.ibm.wsspi.wssecurity.auth.token.Token interface or custom token classes.

```
com.ibm.wsspi.wssecurity.auth.token.UsernameToken unt;
Iterator it = s.iterator();
while (it.hasNext()) {
  Object obj = it.next();
  if (obj != null &&
obj instanceOf com.ibm.wsspi.wssecurity.auth.token.UsernameToken) {
    unt =(com.ibm.wsspi.wssecurity.auth.token.UsernameToken) obj;
if (unt.getId().equals("...")) break;
else continue;
  }
}
```

Results

After completing these steps, you have retrieved the security tokens from the JAAS Subject in a server application

Web Services Security service provider programming interfaces

Several Service Provider Interfaces (SPIs) are provided to extend the capability of the Web Services Security runtime.

About this task

Important: There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

The following list contains the SPIs that are available for WebSphere Application Server:

Procedure

- com.ibm.wsspi.wssecurity.config.KeyLocator is an abstract for obtaining the keys for digital signature and encryption. The following list contains the default implementations:
  1. com.ibm.wsspi.wssecurity.config.KeyStoreKeyLocator implements the Java key store.
  2. com.ibm.wsspi.wssecurity.config.WSIdKeyStoreMapKeyLocator povides a mapping of the authenticated identity to a key for encryption or, the implementation uses the default key that is specified.
  3. com.ibm.wsspi.wssecurity.config.CertInRequestKeyLocator Provides the capability of using the signer key for encryption in the response message. This implementation is typically used in the response sender configuration.

- com.ibm.wsspi.wssecurity.id.TrustedIDEvaluator is an interface that is used to evaluate the trust for identity assertion. The default implementation is com.ibm.wsspi.wssecurity.id.TrustedIDEvaluatorImpl, which enables you to define a list of trusted identities.
- The Java Authentication and Authorization Service (JAAS) CallbackHandler application programming interfaces (APIs) are used for token generation by the request sender. This interface can be extended to generate a custom token that can be inserted in the Web Services Security header. The following list contains the default implementations that are provided by WebSphere Application Server:
  1. com.ibm.wsspi.wssecurity.auth.callback.GUIPromptCallbackHandler presents a login prompt to gather the basic authentication data. Use this implementation in the client environment only.
  2. com.ibm.wsspi.wssecurity.auth.callback.StdinPromptCallbackHandler collects the basic authentication data in the standard in (stdin) prompt. Use this implementation in the client environment only.

     Restriction: If you have a multi-threaded client and multiple threads attempt to read from standard in at the same time, all the threads will not successfully obtain the user name and password information. Therefore, you cannot use the com.ibm.wsspi.wssecurity.auth.callback.StdinPromptCallbackHandler implementation with a multi-threaded client where multiple threads might attempt to obtain data from standard in concurrently.
  3. com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler reads the basic authentication data from the application binding file. This implementation might be used on the server side to generate a user name token.
  4. com.ibm.wsspi.wssecurity.auth.callback.LTPATokenCallbackHandler Generates a Lightweight Third Party Authentication (LTPA) token in the Web Services Security header as a binary security token. If basic authentication data is defined in the application binding file, it is used to perform a login, to extract the LTPA token from the WebSphere credentials, and to insert the token in the Web Services Security header. Otherwise, it will extract the LTPA security token from the invocation credentials (RunAs identity) and insert the token in the Web Services Security header.

What to do next

The JAAS LoginModule API is used for token validation on the request receiver side of the message. You can implement a custom LoginModule API to perform validation of the custom token on the request receiver of the message. After the token is verified and validated, the token is set as the caller and then run as the identity in the WebSphere Application Server runtime. The identity is used for authorization checks by the containers before a Java Platform, Enterprise Edition (Java EE) resource is invoked. The following list presents the default AuthMethod configurations provided by WebSphere Application Server:

BasicAuth
Validates a user name token.

Signature
Maps the distinguished name (DN) of a verified certificate to a Java Authentication and Authorization Service (JAAS) subject.

IDAssertion
Maps a trusted identity to a JAAS subject.

LTPA Validates an LTPA token that is received in the message and creates a JAAS subject.

Configuring Web Services Security during application assembly

If you configure Web Services Security with an assembly tool, the Web Services Security binding information is modified

Configuring HTTP outbound transport level security with an assembly tool

You can configure the HTTP outbound transport level security with an assembly tool.

Before you begin

You can configure HTTP outbound transport level security with assembly tools provided with WebSphere Application Server.

This task is one of several ways that you can configure the HTTP outbound transport level security for a web service acting as a client to another web service server. You can also configure the HTTP outbound transport level security with the administrative console or by using the Java properties. If you do not configure the HTTP outbound transport level security, the web services runtime defers to the Java Platform, Enterprise Edition (Java EE) security runtime in the WebSphere product for an effective Secure Sockets Layer (SSL) configuration. If there is no SSL configuration with the Java EE security runtime in the WebSphere product, the Java Secure Socket Extension (JSSE) system properties are used.

About this task

If you configure the HTTP outbound transport level security with assembly tool or with the administrative console, the Web Services Security binding information is modified. If you have not yet installed the web services application into WebSphere Application Server, you can configure the HTTP SSL configuration with an assembly tool. This task assumes that you have not deployed the web services application into the WebSphere product.

If you configure the HTTP outbound transport level security using the standard Java properties for JSSE, the properties are configured as system properties. The configuration that is specified in the binding takes precedence over the Java properties. However, the configurations that are specified by the Java EE security programming model, or are associated with the Dynamic selection, have a higher precedence.

To learn more, see the secure communications using Secure Sockets Layer information.

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer documentation.
3. Migrate the web application archive (WAR) files that are created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to the Rational Application Developer assembly tool. To migrate files, import your WAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer documentation.
4. Configure the HTTP outbound transport level security. Read about enabling web service endpoints in the Rational Application Developer documentation.

Results

You have configured the HTTP outbound transport level security for a web service acting as a client to another web service with an assembly tool.

Configuring HTTP basic authentication for JAX-RPC web services with an assembly tool

You can configure HTTP basic authentication for Java API for XML-based RPC (JAX-RPC) web services with an assembly tool.

Before you begin

You can configure HTTP basic authentication with assembly tools provided with WebSphere Application Server.

About this task

This task is one of three ways that you can configure HTTP basic authentication. You can also configure HTTP basic authentication with the administrative console or by modifying the HTTP properties programmatically.

If you choose to configure the HTTP basic authentication with an assembly tool or with the administrative console, the Web Services Security binding information is modified. You can use an assembly tool to configure HTTP basic authentication before you deploy or install the web services application into WebSphere Application Server. This task assumes that you have not deployed the web services application into the WebSphere product.

If you configure HTTP basic authentication programmatically, the properties are configured in the Stub or Call instance. The values set programmatically take precedence over the values defined in the binding.

The HTTP basic authentication that is discussed in this topic is orthogonal to WS-Security and is distinct from basic authentication that WS-Security supports. WS-Security supports basic authentication token, not HTTP basic authentication.

To configure HTTP basic authentication, use the WebSphere Application Server tools to modify the binding information.

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer documentation.
3. Migrate the web application archive (WAR) files that are created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to the Rational Application Developer assembly tool. To migrate files, import your WAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer documentation.
4. Configure the HTTP basic authentication in the Web Services Client Port Binding page for a web service or a web service client. The Web Services Client Port Binding page is available after double-clicking the client deployment descriptor file. Read about Web Services Client Port Bindings in the Rational Application Developer documentation.

Configuring XML digital signature for Version 5.x web services with an assembly tool

XML digital signature is one of the methods WebSphere® Application Server provides to secure your web services. It provides message integrity and authentication capabilities when used with SOAP messages.

Configuring trust anchors using an assembly tool

Use an assembly tool to configure trust anchors (that specify keystores which contain trusted root certificates to validate the signer certificate) or trust stores at the application level.

Before you begin

Important: There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

This document describes how to configure trust anchors or trust stores at the application level. It does not describe how to configure trust anchors at the server or cell level. Trust anchors defined at the application level have a higher precedence over trust anchors defined at the server or cell level. You can configure an application-level trust anchor using an assembly tool or the administrative console. This document describes how to configure the application-level trust anchor using an assembly tool.

About this task

A trust anchor specifies keystores that contain trusted root certificates, which validate the signer certificate. These keystores are used by the request receiver (as defined in the `ibm-webservices-bnd.xmi` file) and the response receiver (as defined in the `application-client.xml` file when web services are acting as client) to validate the signer certificate of the digital signature. The keystores are critical to the integrity of the digital signature validation. If they are tampered with, the result of the digital signature verification is doubtful and comprised. Therefore, it is recommended that you secure these keystores. The binding configuration specified for the request receiver in the `ibm-webservices-bnd.xmi` file must match the binding configuration for the response receiver in the `application-client.xml` file.

Complete the following steps to configure trust anchors using an assembly tool.

Procedure

1. Configure an assembly tool to work with a Java Platform, Enterprise Edition (Java EE) enterprise application. For more information, see the related information on Assembly Tools.
2. Create a web services-enabled Java EE enterprise application.
3. Configure the client-side response receiver, which is defined in the `ibm-webservicesclient-bnd.xmi` bindings extensions file.
   a. Use an assembly tool to import your Java EE application.
   b. Click **Window** > **Open Perspective** > **Other** > **J2EE**.
   c. Click **Application Client projects** > ***application_name*** > **appClientModule** > **META-INF**
   d. Right-click the `application-client.xml` file, select **Open with** > **Deployment Descriptor Editor**, and click the **WS Binding** tab. The Client Deployment Descriptor is displayed.
   e. Locate the Port qualified name binding section and either select an existing entry or click **Add**, to add a new port binding. The web services client port binding editor displays for the selected port.
   f. Locate the Trust anchor section and click **Add**. The Trust anchor window is displayed.
      1) Enter a unique name within the port binding for the **Trust anchor name**.
         The name is used to reference the trust anchor that is defined.
      2) Enter the keystore password, path, and keystore type.
         The supported keystore types are the Java Cryptography Extension (JCE) and Java Cryptography Extension Keystores (JCEKS) types.

      Click **Edit** to edit the selected trust anchor.

      Click **Remove** to remove the selected trust anchor.

When you start the application, the configuration is validated in the run time while the binding information is loading.

g. Save the changes.

4. Configure the server-side request receiver, which is defined in the `ibm-webservices-bnd.xmi` bindings extensions file.
   a. Click **Window** > **Open perspective** > **J2EE**.
   b. Select the web services enabled Enterprise JavaBeans (EJB) or web module.
   c. In the Package Explorer window, click the `META-INF` directory for an EJB module or the `WEB-INF` directory for a web module.
   d. Right-click the `webservices.xml` file, select **Open with** > **Web services editor**, and click the bindings tab. The web services bindings editor is displayed.
   e. Locate the web service description bindings section and either select an existing entry or click **Add** to add a new web services descriptor.
   f. Click **Binding configurations**. The web services binding configurations editor is displayed for the selected web services descriptor.
   g. Locate the Trust anchor section and click **Add**. The Trust anchor dialog box is displayed.
      1) Enter a unique name within the binding for the **Trust anchor name**.

         This unique name is used to reference the trust anchor defined.

      2) Enter the keystore password, path, and keystore type. The supported keystore types are `JCE` and `JCEKS`.

      Click **Edit** to edit the selected trust anchor.

      Click **Remove** to remove the selected trust anchor.

      When you start the application, the configuration is validated in the run time while the binding information is loading.

   h. Save the changes.

Results

This procedure defines trust anchors that can be used by the request receiver or the response receiver (if the web services is acting as client) to verify the signer certificate.

Example

The request receiver or the response receiver (if the web service is acting as a client) uses the defined trust anchor to verify the signer certificate. The trust anchor is referenced using the trust anchor name.

What to do next

To complete the signing information configuration process for request receiver, complete the following tasks:

1. “Configuring the server for request digital signature verification: Verifying the message parts” on page 1697
2. “Configuring the server for request digital signature verification: choosing the verification method” on page 1698

To complete the process for the response receiver, if the web services is acting as a client, complete the following tasks:

1. “Configuring the client for response digital signature verification: verifying the message parts” on page 1704
2. “Configuring the client for response digital signature verification: choosing the verification method” on page 1706

Configuring the client-side collection certificate store using an assembly tool

You can configure the client-side collection certificate store using the assembly tool.

About this task

Important: There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6 and later applications.

A collection certificate store is a collection of non-root, certificate authority (CA) certificates and certificate revocation lists (CRLs). This collection of CA certificates and CRLs are used to check the signature of a digitally signed SOAP message.

You can configure the collection certificate either by using an assembly tool or the WebSphere Application Server administrative console. Complete the following steps to configure the client-side collection certificate store using the assembly tool.

Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **Application Client projects** > ***application_name*** > **appClientModule** > **META-INF**.
4. Right-click the `application-client.xml` file, select **Open with** > **Deployment Descriptor Editor**, and click the **WS Binding** tab, which is located at the bottom of deployment descriptor editor within the assembly tool. The Client Deployment Descriptor is displayed.
5. Click the **Port binding** tab in deployment descriptor editor within the assembly tool. The web services client port binding window is displayed.
6. Select one of the port-qualified name binding entries.
7. Expand the **Security response receiver binding configuration** > **certificate store list** > **Collection certificate store** section.
8. Click **Add** to create a new collection certificate store, click **Edit** to edit an existing certificate store, or click **Remove** to delete an existing certificate store.
9. Enter a name in the **Name** field. This name is referenced in the Certificate store reference field in the Signing info dialog box.
10. Leave the Provider field as `IBMCertPath`.
11. Click **Add** to enter the path to your certificate store. For example, the path might be: `${USER_INSTALL_ROOT}/etc/ws-security/samples/intca2.cer`. If you have additional certificate store paths, click **Add** to add the paths.
12. Click **OK** when you finish adding paths.

Configuring the server-side collection certificate store using an assembly tool

A *collection certificate store* is a collection of non-root, certificate authority (CA) certificates and certificate revocation lists (CRLs). This collections of CA certificates and CRLs are used to check the signature of a digitally signed SOAP message. You can configure the server-side collection certificate store by using an assembly tool.

About this task

Important: There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

You can configure the collection certificate either by using an assembly tool or by using the WebSphere Application Server administrative console. Complete the following steps to configure the server-side collection certificate store using an assembly tool.

Procedure

1. Start an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **EJB projects** > ***application_name*** > **ejbModule** > **META-INF**.
4. Right-click the `webservices.xml` file, select **Open with** > **Web Services Editor**.
5. Click the Binding configurations tab in the web services editor within the assembly tool. The Web Service Binding Configuration window is displayed.
6. Select one of the web service description binding entries under the Port Component Binding section.
7. Expand the **Request receiver binding configuration details** > **Certificate store list** > **Collection certificate store** section.
8. Click **Add** to create a new collection certificate store, click **Edit** to edit an existing certificate store, or click **Remove** to delete an existing certification store.
9. Enter a name in the **Name** field. This name is referenced in the **Certificate store reference** field in the Signing info dialog.
10. Leave the **Provider** field as `IBMCertPath`.
11. Click **Add** to enter the path to your certificate store. For example, the path might be: `${USER_INSTALL_ROOT]/etc/ws-security/samples/intca2.cer`. If you have additional certificate store paths, click **Add** to add the paths.
12. Click **OK** when you finish adding paths.

Configuring key locators using an assembly tool

The following information provides instructions on how to configure key locators using an assembly tool.

About this task

Important: There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

You can configure key locators in various locations within the assembly tool. The following procedure provides instructions on how to configure key locators at any of these locations because the concept is the same.

Procedure

1. Start an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **Application Client projects** > ***application_name*** > **appClientModule** > **META-INF**.
4. Right-click the `application-client.xml` file, select **Open with** > **Deployment Descriptor Editor**, and click the **WS Binding** tab. The Client Deployment Descriptor is displayed.
5. Click the **WS Binding** tab in deployment descriptor editor within the assembly tool or the **Binding configurations** tab in the Web services editor within the assembly tool.
6. Expand one of the **Binding configuration** sections.
7. Expand the **Key locators** section.

8. Click **Add** to create a new key locator, click **Edit** to edit an existing key locator, or click **Remove** to delete an existing key locator.
9. Enter a key locator name. The name entered for the **Key locator name** is used to refer to the key locator from the Encryption information and Signing Information sections.
10. Enter a key locator class. The key locator class is the implementation of the `KeyLocator` interface. When using default implementations, select a class from the menu.
11. Determine whether to click **Use key store**. Select this option when you use the default implementations as they use key stores. If you click **Use key store**, complete the following steps:
    a. Enter a value in the key store storepass field. The key store storepass is the password used to access the key store.
    b. Enter a path name in the key store path field. The key store path is the location on the file system where the key store resides. Make sure that the location can be found wherever you deploy the application.
    c. Enter a type value in the key store type field. The valid types to enter are JKS and JCEKS. JKS is used when you are not using the Java Cryptography Extensions (JCE) policy. JCEKS is used when you are using JCE. Although the JCEKS type is more secure, it might decrease performance.
    d. Click **Add** to create an entry for a key in the key store.
        1) Enter a value in the Alias field.

           The key alias is a reference to this particular key from the Signing Information section.
        2) Enter a value in the Key pass field.

           The key pass is the password associated with the certificate which is created using the Java SE Development Kit 6 `keytool.exe` file.
        3) Enter a value in the Key name field.

           The key name refers to the alias of the certificate as found in the key store.
12. Click **Add** to create a custom property. The property can be used by custom key locator implementations. For example, you can use properties with the `WSIdKeyStoreMapKeyLocator` default implementation. The key locator implementation has the following property names:
    - *id_*, which maps to a credential user ID.
    - *mappedName_* , which maps to the key alias to use for this user name.
    - *default*, which maps to a key alias to use when a credential does not have an associated *id_* entry.

    A typical set of properties for this key locator might be: `id_1=user1`, `mappedName_1=key1`, `id_2=user2`, `mappedName_2=key2`, `default=key3`. If `user1` or `user2` authenticates, then the associated `key1` or `key2` is used, respectively. However, if none of the user properties authenticate or the user is not `user1` or `user2`, then `key3` is used.
    a. Enter a name in the Name field. The name entered is the property name.
    b. Enter a value in the Value field. This value entered is the property value.

Securing web services for Version 5.x applications using XML digital signature

XML digital signature is one of the methods WebSphere Application Server provides to secure your web services. It provides message integrity and authentication capabilities when used with SOAP messages.

Before you begin

Important: There is an important distinction between Version 5.*x* and Version 6.0.*x* and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

WebSphere Application Server provides several different methods to secure your web services; XML digital signature is one of these methods. You can secure your web services by using any of the following methods:

- XML digital signature
- XML encryption
- Basicauth authentication
- Identity assertion authentication
- Signature authentication
- Pluggable token

About this task

XML digital signature provides both message integrity and authentication capabilities when it is used with SOAP messages. A message receiver can verify that attackers or accidents have not altered parts of the message after the message was signed by a key. If a message has a digital certificate issued by a certificate authority (CA) and a signature in the message is validated successfully by a public key in the certificate, it is proof that the signer has the corresponding private key. To use XML digital signature to secure web services, complete the following steps:

Procedure

1. Define the security constraints or extensions. To configure the security constraints, you must use an assembly tool. For more information, see the related information on Assembly Tools.
   a. Configure the client to digitally sign a message request. To configure the client, complete the following steps to specify which parts of the SOAP message to digitally sign and define the method used to digitally sign the message. The client in these steps is the request sender.
      1) Specify the message parts by following the steps found in “Configuring the client for request signing: digitally signing message parts” on page 1693.
      2) Select the method used to digitally sign the request message. You can select the digital signature method by following the steps in “Configuring the client for request signing: choosing the digital signature method” on page 1695.
   b. Configure the server to verify the digital signature that is used in the message request. To configure the server, you must specify which parts of the SOAP message, sent by the request sender, contain digitally signed information and which method was used to digitally sign the message. The settings chosen for the request receiver, or the server in this step, must match the settings chosen for the request sender in the previous step.
      1) Define the message parts by following the steps found in “Configuring the server for request digital signature verification: Verifying the message parts” on page 1697.
      2) Select the same method used by the request sender to digitally sign the message. You can select the digital signature method by following the steps in “Configuring the server for request digital signature verification: choosing the verification method” on page 1698
   c. Configure the server to digitally sign a message response. To configure the server, complete the following steps to specify which parts of the SOAP message to digitally sign and define the method used to digitally sign the message. The sender in these steps is the response sender.
      1) Specify which message parts to digitally sign by following the steps found in “Configuring the server for response signing: digitally signing message parts” on page 1701.
      2) Select the method used to digitally sign the response message. You can select the digital signature method by following the steps in “Configuring the server for response signing: choosing the digital signature method” on page 1703
   d. Configure the client to verify the digital signature that is used in the message response. To configure the client, you must specify which parts of the SOAP message sent by the response sender contain digitally signed information and which method was used to digitally sign the

message. The settings chosen for the response receiver, or client in this step, must match the settings chosen for the response sender in the previous step.

1) Define the message parts by following the steps found in “Configuring the client for response digital signature verification: verifying the message parts” on page 1704
2) Select the same method used by the response sender to digitally sign the message. You can select the digital signature method by following the steps in “Configuring the client for response digital signature verification: choosing the verification method” on page 1706

2. Define the client security bindings. To configure the client security bindings, complete the steps in either of the following topics:
   - “Configuring the client security bindings using an assembly tool” on page 1708
   - Configuring the security bindings on a server acting as a client using the administrative console
3. Define the server security bindings. To configure the server security bindings, complete the steps in either of the following topics:
   - “Configuring the server security bindings using an assembly tool” on page 1711
   - Configuring the server security bindings using the administrative console

Results

After completing these steps, you have secured your web services using XML digital signature.

Configuring the client for request signing: digitally signing message parts

To configure the client for request signing, specify which message parts to digitally sign when configuring the client.

Before you begin

Important: There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

Prior to completing these steps, read either of the following topics to become familiar with the **Security Extensions** tab and the **Port Binding** tab in the Web Services Client Editor within an assembly tool.

- “Configuring the client security bindings using an assembly tool” on page 1708
- Configuring the security bindings on a server acting as a client using the administrative console

These two tabs are used to configure the Web Services Security extensions and the Web Services Security bindings, respectively.

About this task

Complete the following steps to specify which message parts to digitally sign when configuring the client for request signing:

Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Click **Window** > **Open perspective** > **Other** > **J2EE**.
3. Click **Application Client projects** > ***application_name*** > **appClientModule** > **META-INF**.
4. Right-click the `application-client.xml` file, select **Open with** > **Deployment Descriptor Editor**, and click the **WS Extension** tab. The Client Deployment Descriptor is displayed.
5. Expand **Request sender configuration** > **Integrity**. *Integrity* refers to digital signature while confidentiality refers to encryption. Integrity decreases the risk of data modification while the data is transmitted across the Internet.

6. Indicate which parts of the message to sign by clicking **Add** and selecting **body**, **timestamp**, or **SecurityToken**. The following list contains descriptions of the message parts

   body The body is the user data portion of the message.

   timestamp
   The time stamp determines if the message is valid based on the time that the message is sent and then received. If **timestamp** is selected, proceed to the next step and select **Add created time stamp** to add a time stamp to a message.

   SecurityToken
   The security token authenticates the client. If this option is selected, the message is signed.

   You can choose to digitally sign the message using a time stamp if **Add created time stamp** is selected and configured. You can digitally sign the message using a security token if a login configuration authentication method is selected.
7. Optional: Expand the **Add created time stamp** section and select this option if you want a time stamp added to the message. You can specify an expiration time for the time stamp, which helps defend against replay attacks. The lexical representation for duration is the [ISO 8601] extended format *PnYnMnDTnHnMnS*, where:
   - *nY* represents the number of years
   - *nM* represents the number of months
   - *nD* represents the number of days
   - *T* is the date and time separator
   - *nH* represents the number of hours
   - *nM* represents the number of minutes
   - *nS* represents the number of seconds. The number of seconds can include decimal digits to arbitrary precision.

   For example, to indicate a duration of 1 year, 2 months, 3 days, 10 hours, and 30 minutes, the format is: `P1Y2M3DT10H30M`. Typically, you configure a message time stamp for about 10 to 30 minutes, for example, 10 minutes is represented as: `P0Y0M0DT0H10M0S`. The *P* character precedes time and date values.

Results

Important: If you configure the client and server signing information correctly, but receive a `Soap body not signed` error when executing the client, you might need to configure the actor. You can configure the actor in the following locations on the client in the Web Services Client Editor within an assembly tool:

- Click **Security extensions** > **Client service configuration details** and indicate the actor information in the **Actor URI** field.
- Click **Security extensions** > **Request sender configuration** > **Details** and indicate the actor information in the **Actor** field.

You must configure the same actor strings for the web service on the server, which processes the request and sends the response back. Configure the actor in the following locations:

- Click **Security extensions** > **Server service configuration**.
- Click **Security extensions** > **Response sender service configuration details** > **Details** and indicate the actor information in the **Actor** field.

The actor information on both the client and server must refer to the same exact string. When the **Actor** fields on the client and server match, the request or response is acted upon instead of being forwarded downstream. The **Actor** fields might be different when you have web services acting as a gateway to other web services. However, in all other cases, make sure that the actor information matches on the client and server. When web services are acting as

a gateway and they do not have the same actor configured as the request passing through the gateway, web services do not process the message from a client. Instead, these web services send the request downstream. The downstream process that contains the correct actor string processes the request. The same situation occurs for the response. Therefore, it is important that you verify that the appropriate client and server **Actor** fields are synchronized.

What to do next

After you have specified which message parts to digitally sign, you must specify which method is used to digitally sign the message. See "Configuring the client for request signing: choosing the digital signature method" for more information.

Configuring the client for request signing: choosing the digital signature method

To configure the client for request signing, specify which message parts to digitally sign when configuring the client.

Before you begin

Important: There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

Prior to completing these steps, read either of the following topics to become familiar with the **Security extensions** tab and the **Port binding** tab in the web services client editor within an assembly tool:

- "Configuring the client security bindings using an assembly tool" on page 1708
- Configuring the server security bindings using the administrative console

These two tabs are used to configure the Web Services Security extensions and the Web Services Security bindings, respectively. You must specify which parts of the message sent by the client must be digitally signed. See "Configuring the client for request signing: digitally signing message parts" on page 1693 for more information.

About this task

Complete the following steps to specify which message parts to digitally sign when configuring the client for request signing:

Procedure

1. Launch an assembly tool. For more information, see the related information on assembly tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open perspective** > **Other** > **J2EE**.
3. Click **Application Client projects** > ***application_name*** > **appClientModule** > **META-INF**.
4. Right-click the `application-client.xml` file, select **Open with** > **Deployment Descriptor Editor**, and click the **WS Binding** tab. The Client Deployment Descriptor is displayed.
5. Expand **Security request sender binding configuration** > **Signing information**.
6. Select **Edit** to view the signing information and select a digital signature method from the **Signature method algorithm** field. The following table describes the purpose of this information. Some of these definitions are based on the XML-Signature specification, which is located at the following website http://www.w3.org/TR/xmldsig-core.

Table 235. Digital signature methods. The digital signature method information is stored in the client deployment descriptor.

Name	Purpose
Canonicalization method algorithm	Canonicalizes the <SignedInfo> element before the information is digested as part of the signature operation.
Digest method algorithm	Applies to the data after transforms are applied, if specified, to yield the <DigestValue> element. Signing the <DigestValue> element binds the resource content to the signer key. The algorithm selected for the client request sender configuration must match the algorithm selected in the server request receiver configuration.
Signature method algorithm	Converts the canonicalized <SignedInfo> element into the <SignatureValue> element. The algorithm selected for the client request sender configuration must match the algorithm selected in the server request receiver configuration.
Signing key name	Represents the key entry associated with the signing key locator. The key entry refers to an alias of the key, which is found in the key store and is used to sign the request.
Signing key locator	Represents a reference to a key locator implementation class that locates the correct hey store where the alias and the certificate exist.

7. Optional: Select **Show only FIPS Compliant Algorithms** if you only want the FIPS compliant algorithms to be shown in the **Digest method algorithm** and **Signature method algorithm** drop-down lists. Use this option if you expect this application to be run on a WebSphere Application Server that has set the **Use the United States Federal Information Processing Standard (FIPS) algorithms** option in the SSL certificate and key management panel of the WebSphere administrative console.

Results

Important: If you configure the client and server signing information correctly, but receive a `Soap body not signed` error when running the client, you might need to configure the actor. You can configure the actor in the following locations on the client in the web services client editor within an assembly tool:

- Click **Security extensions** > **Client service configuration details** and indicate the actor information in the **Actor URI** field.
- Click **Security extensions** > **Request sender configuration > Details** and indicate the actor information in the **Actor** field.

You must configure the same actor strings for the web service on the server, which processes the request and sends the response back. Configure the actor in the following locations in the web services editor within an assembly tool:

- Click **Security extensions** > **Server service configuration**.
- Click **Security extensions** > **Response sender service configuration details** > **Details** and indicate the actor information in the **Actor** field.

The actor information on both the client and server must refer to the same exact string. When the actor fields on the client and server match, the request or response is acted upon instead of being forwarded downstream. The **Actor** fields might be different when you have web services acting as a gateway to other web services. However, in all other cases, make sure that the actor information matches on the client and server. When web services are acting as a gateway and they do not have the same actor configured as the request passing through the gateway, web services do not process the message from a client. Instead, these web services send the request downstream. The downstream process that contains the correct actor string processes the request. The same situation occurs for the response. Therefore, it is important that you verify that the appropriate client and server actor fields are synchronized.

You have specified which method is used to digitally sign a message when the client sends a message to a server.

What to do next

After you configure the client to digitally sign the message, you must configure the server to verify the digital signature. See “Configuring the server for request digital signature verification: Verifying the message parts” for more information.

Configuring the server for request digital signature verification: Verifying the message parts

Configure the server for request digital signature verification by modifying the extensions to indicate which parts of the request to verify.

Before you begin

Important: There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

Prior to completing these steps, read either of the following topics to become familiar with the **Extensions** tab and the **Binding Configurations** tab in the web services editor within the assembly tools:

- “Configuring the server security bindings using an assembly tool” on page 1711
- Configuring the server security bindings using the administrative console

You can use these two tabs to configure the Web Services Security extensions and the Web Services Security bindings, respectively. Also, you must specify which parts of the message sent by the client must be digitally signed. See “Configuring the client for request signing: digitally signing message parts” on page 1693 to determine which message parts are digitally signed. The message parts specified for the client request sender must match the message parts specified for the server request receiver.

About this task

Complete the following steps to configure the server for request digital signature verification. The steps describe how to modify the extensions to indicate which parts of the request to verify.

Procedure

1. Launch an assembly tool. For more information, see the related information on assembly tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open perspective** > **Other** > **J2EE**.
3. Click **EJB Projects** > ***application_name*** > **ejbModule** > **META-INF**.
4. Right-click the `webservices.xml` file, and click **Open with** > **Web services editor**.
5. Click the Extensions tab in the web services editor.
6. Expand the **Request receiver service configuration details** > **Required integrity** section. Required integrity refers to the parts of the message that require digital signature verification. The purpose of digital signature verification is to make sure that the message parts have not been modified while transmitting across the Internet.
7. Indicate parts of the message to verify by clicking **Add**, and selecting one of the following three parts: **body**, **Timestamp**, or **SecurityToken**. You can determine which parts of the message to verify by looking at the web service request sender configuration in the client application. To view the web service request sender configuration information in the web services client editor, click the Security extensions tab and expand **Request sender configuration** > **Integrity**. The following includes a list and description of the message parts:

   Body This is the user data portion of the message.

Timestamp
The time stamp determines if the message is valid based on the time that the message is sent and then received. If **Timestamp** is selected, proceed to the next step to `Add Created Time Stamp` to the message.

SecurityToken
The security token authenticates the client. If **SecurityToken** is selected, the message is signed.

8. Optional: Expand the **Add received time stamp** section. The Add Received Time Stamp value indicates to validate the Add Created Time Stamp option configured by the client. You must select this option if you selected the Add Created Time Stamp on the client. The time stamp ensures message integrity by indicating the timeliness of the request. This option helps defend against replay attacks.

Results

Important: If you configure the client and server signing information correctly, but receive a `Soap body not signed` error when running the client, you might need to configure the actor. You can configure the actor in the following locations:

- Click **Security extensions** > **Client service configuration details** and indicate the actor information in the **Actor URI** field.
- Click **Security extensions** > **Request sender configuration** > **Details** and indicate the actor information in the **Actor** field.

You must configure the same actor strings for the web service on the server, which processes the request and sends the response back. Configure the actor in the following locations:

- Click **Security extensions** > **Server service configuration**.
- Click **Security extensions** > **Response sender service configuration details** > **Details** and indicate the actor information in the **Actor** field.

The actor information on both the client and server must refer to the same exact string. When the actor fields on the client and server match, the request or response is acted upon instead of being forwarded downstream. The actor fields might be different when you have web services acting as a gateway to other web services. However, in all other cases, make sure that the actor information matches on the client and server. When web services are acting as a gateway and they do not have the same actor configured as the request passing through the gateway, web services do not process the message from a client. Instead, these web services send the request downstream. The downstream process that contains the correct actor string processes the request. The same situation occurs for the response. Therefore, it is important that you verify that the appropriate client and server actor fields are synchronized.

You have specified which message parts are digitally signed and must be verified by the server when the client sends a message to a server.

What to do next

After you specify which message parts contain a digital signature that must be verified by the server, you must configure the server to recognize the digital signature method used to digitally sign the message. See “Configuring the server for request digital signature verification: choosing the verification method” for more information.

Configuring the server for request digital signature verification: choosing the verification method

To configure the server for request digital signature verification, use an assembly tool to modify the extensions and indicate which digital signature method the server will use during verification.

Before you begin

Important: There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

Prior to completing these steps, read either of the following topics to become familiar with the Extensions tab and the Binding Configurations tab in the Web Services Editor within the IBM assembly tools:

- "Configuring the server security bindings using an assembly tool" on page 1711
- Configuring the server security bindings using the administrative console

You can use these two tabs to configure the Web Services Security extensions and Web Services Security bindings, respectively. You must specify which message parts contain digital signature information that must be verified by the server. See "Configuring the server for request digital signature verification: Verifying the message parts" on page 1697. The message parts specified for the client request sender must match the message parts specified for the server request receiver. Likewise, the digital signature method chosen for the client must match the digital signature method used by the server.

About this task

Complete the following steps to configure the server for request digital signature verification. The steps describe how to modify the extensions to indicate which digital signature method the server will use during verification.

Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open perspective** > **Other** > **J2EE**.
3. Click **EJB Projects** > ***application_name*** > **ejbModule** > **META-INF**.
4. Right-click the `webservices.xml` file, and click **Open with** > **Web services editor**.
5. Click the **Binding Configurations** tab.
6. Expand the **Security request receiver binding configuration details** > **Signing information** section.
7. Click **Edit** to edit the signing information. The signing information dialog is displayed, select or enter the following information:
   - Canonicalization method algorithm
   - Digest method algorithm
   - Signature method algorithm
   - Use certificate path reference
   - Trust anchor reference
   - Certificate store reference
   - Trust any certificate

   For more conceptual information on digitally signing SOAP messages, see XML digital signature. The following table describes the purpose for each of these selections. Some of the following definitions are based on the XML-Signature specification, which is located at the following web address: http://www.w3.org/TR/xmldsig-core.

Table 236. Digital signature methods. The digital signature method is part of the binding configuration.

Name	Purpose
Canonicalization method algorithm	Canonicalizes the `<SignedInfo>` element before it is digested as part of the signature operation. The algorithm selected for the server request receiver configuration must match the algorithm selected in the client request sender configuration.

Table 236. Digital signature methods (continued). The digital signature method is part of the binding configuration.

Name	Purpose
Digest method algorithm	Applies to the data after transforms are applied, if specified, to yield the <DigestValue> element. The signing of the <DigestValue> element binds resource content to the signer key. The algorithm selected for the server request receiver configuration must match the algorithm selected in the client request sender configuration.
Signature method algorithm	Converts the canonicalized <SignedInfo> element into the <SignatureValue> element. The algorithm selected for the server request receiver configuration must match the algorithm selected in the client request sender configuration.
Use certificate path reference or **Trust any certificate**	Validates a certificate or signature sent with a message. When a message is signed, the public key used to sign it is sent with the message. This public key or certificate might not be validated at the receiving end. By selecting **User certificate path reference**, you must configure a trust anchor reference and a certificate store reference to validate the certificate sent with the message. By selecting **Trust any certificate**, the signature is validated by the certificate sent with the message without the certificate itself being validated.
Use certificate path reference: Trust anchor reference	Refers to a key store that contains trusted, self-signed certificates and certificate authority (CA) certificates. These certificates are trusted certificates that you can use with any applications in your deployment.
Use certificate path reference: Certificate store reference	Contains a collection of X.509 certificates. These certificates are not trusted for all applications in your deployment, but might be used as an intermediary to validate certificates for an application.

8. Optional: Select **Show only FIPS Compliant Algorithms** if you only want the FIPS compliant algorithms to be shown in the Signature method algorithm and Digest method algorithm dropdown lists. Use this option if you expect this application to be run on a WebSphere Application Server that has set the **Use the United States Federal Information Processing Standard (FIPS) algorithms** option in the SSL certificate and key management panel of the administrative console.

Results

Important: If you configure the client and server signing information correctly, but receive a `Soap body not signed` error when running the client, you might need to configure the actor. You can configure the actor in the following locations on the client:

- Click **Security extensions** > **Client service configuration details** and indicate the actor information in the Actor URI field.
- Click **Security extensions** > **Request sender configuration > Details** and indicate the actor information in the Actor field.

You must configure the same actor strings for the web service on the server, which processes the request and sends the response back. Configure the actor in the following locations:

- Click **Security extensions** > **Server service configuration**.
- Click **Security extensions** > **Response sender service configuration details** > **Details** and indicate the actor information in the Actor field.

The actor information on both the client and server must refer to the same exact string. When the actor fields on the client and server match, the request or response is acted upon instead of being forwarded downstream. The **actor** fields might be different when you have web services acting as a gateway to other web services. However, in all other cases, make sure that the actor information matches on the client and server. When web services are acting as a gateway and they do not have the same actor configured as the request passing through the gateway, web services do not process the message from a client. Instead, these web services send the request downstream. The downstream process that contains the correct actor string processes the request. The same situation occurs for the response. Therefore, it is important that you verify that the appropriate client and server actor fields are synchronized.

You have specified the method that the server uses to verify the digital signature in the message parts.

What to do next

After you configure the client for request signing and the server for request digital signature verification, you must configure the server and the client to handle the response. Next, specify the response signing for the server. See “Configuring the server for response signing: digitally signing message parts” for more information.

Configuring the server for response signing: digitally signing message parts

Use an assembly tool to specify which message parts to digitally sign when configuring the server for response signing.

Before you begin

Important: There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this topic supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

Prior to completing these steps, read either of the following topics to become familiar with the **Extensions** tab and the **Binding** configurations tab in the web services editor within the IBM assembly tools:

- “Configuring the server security bindings using an assembly tool” on page 1711
- Configuring the server security bindings using the administrative console

These two tabs are used to configure the Web Services Security extensions and the Web Services Security bindings, respectively.

About this task

Complete the following steps to specify which message parts to digitally sign when configuring the server for response signing:

Procedure

1. Launch an assembly tool. For more information, see the related information on assembly tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open perspective** > **Other** > **J2EE**.
3. Click **EJB Projects** > ***application _name*** > **ejbModule** > **META-INF**.
4. Right-click the `webservices.xml` file and click **Open with** > **Web services editor**.
5. Click the **Extensions** tab, which is located at the bottom of the Web Services Editor within the assembly tool.
6. Expand **Response sender service configuration details** > **Integrity**. Integrity refers to digital signature while confidentiality refers to encryption. Integrity decreases the risk of data modification while the data is transmitted across the Internet. For more information on digitally signing SOAP messages, see XML digital signature.
7. Indicate the parts of the message to sign by clicking **Add**, and selecting **Body**, **Timestamp**, or **SecurityToken**.

   The following list contains descriptions of the message parts:

   Body The body is the user data portion of the message.

   Timestamp
   The time stamp determines if the message is valid based on the time that the message is sent and then received. If this option if selected, proceed to the next step and click **Add Created Time Stamp**, which indicates that the time stamp is added to the message.

SecurityToken
The security token is used for authentication. If this option is selected, the authentication information is added to the message.

8. Optional: Expand the **Add created time stamp** section. Select this option if you want a time stamp added to the message. You can specify an expiration time for the time stamp, which helps defend against replay attacks. The lexical representation for duration is the ISO 8601 extended format, *PnYnMnDTnHnMnS*, where:
   - *nY* represents the number of years.
   - *nM* represents the number of months.
   - *nD* represents the number of days.
   - *T* is the date and time separator.
   - *nH* represents the number of hours.
   - *nM* represents the number of minutes.
   - *nS* represents the number of seconds. The number of seconds can include decimal digits to arbitrary precision.

   For example, to indicate a duration of 1 year, 2 months, 3 days, 10 hours, and 30 minutes, the format is: `P1Y2M3DT10H30M`. Typically, you configure a message time stamp for about 10 to 30 minutes. 10 minutes is represented as: `P0Y0M0DT0H10M0S`. The *P* character precedes time and date values.

Results

Important: If you configure the client and server signing information correctly, but receive a `Soap body not signed` error when running the client, you might need to configure the actor. You can configure the actor in the following locations:
- Click **Security extensions** > **Client service configuration details** and indicate the actor information in the **Actor URI** field.
- Click **Security extensions** > **Request sender configuration** > **Details** and indicate the actor information in the **Actor** field.

You must configure the same actor strings for the web service on the server, which processes the request and sends the response back. Configure the actor in the following locations:
- Click **Security extensions** > **Server service configuration**.
- Click **Security extensions** > **Response sender service configuration details** > **Details** and indicate the actor information in the **Actor** field.

The actor information on both the client and server must refer to the same exact string. When the actor fields on the client and server match, the request or response is acted upon instead of being forwarded downstream. The actor fields might be different when you have web services acting as a gateway to other web services. However, in all other cases, make sure that the actor information matches on the client and server. When web services are acting as a gateway and they do not have the same actor configured as the request passing through the gateway, web services do not process the message from a client. Instead, these web services send the request downstream. The downstream process that contains the correct actor string processes the request. The same situation occurs for the response. Therefore, it is important that you verify that the appropriate client and server actor fields are synchronized.

You have specified which message parts to digitally sign when the server sends a response to the client.

What to do next

After you specifying which message parts to digitally sign, you must specify which method is used to digitally sign the message. See “Configuring the server for response signing: choosing the digital signature method” on page 1703 for more information.

Configuring the server for response signing: choosing the digital signature method

Use an assembly tool to specify which digital signature method to use when configuring the server for response signing.

Before you begin

Important: There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

Prior to completing these steps, read either of the following topics to become familiar with the Extensions tab and the **Binding configurations** tab in the web services editor within the IBM assembly tools:

- "Configuring the server security bindings using an assembly tool" on page 1711
- Configuring the server security bindings using the administrative console

These two tabs are used to configure the Web Services Security extensions and the Web Services Security bindings, respectively.

About this task

Complete the following steps to specify which digital signature method to use when configuring the server for response signing:

Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **EJB Projects** > ***application _name*** > **ejbModule** > **META-INF**.
4. Right-click the `webservices.xml` file and click **Open with** > **Web services editor**.
5. Click the **Binding Configurations** tab.
6. Expand **Response sender binding configuration details** > **Signing information**.
7. Click **Edit** to choose a signing method. The signing info dialog is displayed and either select or enter the following information:
   - Canonicalization method algorithm
   - Digest method algorithm
   - Signature method algorithm
   - Signing key name
   - Signing key locator

   The following table describes the purpose of this information. Some of these definitions are based on the XML-Signature specification, which is located at the following address: http://www.w3.org/TR/xmldsig-core.

Table 237. Digital signature methods. Use the methods to configure the server for response signing.

Name	Purpose
Canonicalization method algorithm	Canonicalizes the <SignedInfo> element before the information is digested as part of the signature operation. Use the same algorithm on the client response receiver. The algorithm selected for the server response sender configuration must match the algorithm selected in the client response receiver configuration.

Table 237. Digital signature methods (continued). Use the methods to configure the server for response signing.

Name	Purpose
Digest method algorithm	Applies to the data after transforms are applied, if specified, to yield the <DigestValue> element. Signing the <DigestValue> element binds resource content to the signer key. The algorithm selected for the server response sender configuration must match the algorithm selected in the client response receiver configuration.
Signature method algorithm	Converts the canonicalized <SignedInfo> element into the <SignatureValue> element. The algorithm selected for the server response sender configuration must match the algorithm selected in the client response receiver configuration.
Signing key name	Represents the key entry associated with the signing key locator. The key entry refers to an alias of the key, which is found in the key store and is used to sign the request.
Signing key locator	Represents a reference to a key locator implementation class that locates the correct key store where the alias and certificate exists. For more information on configuring key locators, see the following file: • "Configuring key locators using an assembly tool" on page 1690

8. Optional: Select **Show only FIPS Compliant Algorithms** if you only want the FIPS compliant algorithms to be shown in the Signature method algorithm and Digest method algorithm dropdown lists. Use this option if you expect this application to be run on a WebSphere Application Server that has set the **Use the United States Federal Information Processing Standard (FIPS) algorithms** option in the SSL certificate and key management panel of the administrative console for WebSphere Application Server.

Results

You have specified which method is used to digitally sign a message when the server sends a message to a client.

What to do next

After you configure the server to digitally sign the response message, you must configure the client to verify the digital signature contained in the response message. See "Configuring the client for response digital signature verification: verifying the message parts" for more information.

Configuring the client for response digital signature verification: verifying the message parts

To configure the Web Services Security extensions and the Web Services Security bindings, use the **WS Extension** tab and the **WS Binding** tab in the Client Deployment Descriptor within an assembly tool.

Before you begin

Important: There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

Prior to completing these steps, read either of the following topics to becomes familiar with the **WS Extension** tab and the **WS Binding** tab in the Client Deployment Descriptor within the assembly tool:

- "Configuring the client security bindings using an assembly tool" on page 1708
- Configuring the security bindings on a server acting as a client using the administrative console

You can use these two tabs to configure the Web Services Security extensions and the Web Services Security bindings, respectively.

About this task

Complete the following steps to configure the client for response digital signature verification. The steps describe how to modify the extensions to indicate which parts of the response to verify.

Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open perspective** > **Other** > **J2EE**.
3. Click **Application Client projects** > ***application_name*** > **appClientModule** > **META-INF**.
4. Right-click the `application-client.xml` file and click **Open With** > **Deployment descriptor editor**.
5. Click the **WS extension** tab.
6. Expand the **Response receiver configuration** > **Required integrity** section. Required integrity refers to parts that require digital signature verification. Digital signature verification decreases the risk that the message parts have been modified while the message is transmitted across the Internet.
7. Indicate the parts of the message that must be verified. You can determine which parts of the message to verify by looking at the web service response sender configuration. Click **Add** and select one of the following parts:

   Body The body is the user data portion of the message.

   Timestamp
   The time stamp determines if the message is valid based on the time that the message is sent and then received. If the timestamp option is selected, proceed to the next step to add a received time stamp to the message.

   Securitytoken
   The security token authenticates the client. If the Securitytoken option is selected, the message is signed.
8. Optional: Expand the **Add received time stamp** section. Select **Add received time stamp** to add the received time stamp to the message.

Results

Important: If you configure the client and server signing information correctly, but receive a `Soap body not signed` error when running the client, you might need to configure the actor. You can configure the actor in the following locations on the client in the web services client editor within an assembly tool:

- Click **Security extensions** > **Client service configuration details** and indicate the actor information in the Actor URI field.
- Click **Security extensions** > **Request sender configuration** > **Details** and indicate the actor information in the Actor field.

You must configure the same actor strings for the web service on the server, which processes the request and sends the response back. Configure the actor in the following locations in the web services editor within an assembly tool:

- Click **Security extensions** > **Server service configuration**.
- Click **Security extensions** > **Response sender service configuration details** > **Details** and indicate the actor information in the Actor field.

The actor information on both the client and server must refer to the same exact string. When the actor fields on the client and server match, the request or response is acted upon instead of being forwarded downstream. The actor fields might be different when you have web services acting as a gateway to other web services. However, in all other cases, make sure

that the actor information matches on the client and server. When web services are acting as a gateway and they do not have the same actor configured as the request passing through the gateway, web services do not process the message from a client. Instead, these web services send the request downstream. The downstream process that contains the correct actor string processes the request. The same situation occurs for the response. Therefore, it is important that you verify that the appropriate client and server actor fields are synchronized.

You have specified which message parts are digitally signed and must be verified by the client when the server sends a response message to the client.

What to do next

After you specify which message parts contain a digital signature that must be verified by the client, you must configure the client to recognize the digital signature method used to digitally sign the message. See "Configuring the client for response digital signature verification: choosing the verification method" for more information.

Configuring the client for response digital signature verification: choosing the verification method

You can configure the Web Services Security extensions and Web Services Security bindings using the **WS extension** tab and the **WS binding** tab in the web services editor within an assembly tool.

Before you begin

Important: There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

Prior to completing these steps, read either of the following topics to become familiar with the **WS extension** tab and the **WS binding** tab in the web services editor within the IBM assembly tools:

- "Configuring the server security bindings using an assembly tool" on page 1711
- Configuring the server security bindings using the administrative console

You can use these two tabs to configure the Web Services Security extensions and Web Services Security bindings, respectively. Also, you must specify which message parts contain digital signature information that must be verified by the client. See "Configuring the client for response digital signature verification: verifying the message parts" on page 1704 to specify which message parts are digitally signed by the server and must be verified by the client. The message parts specified for the server response sender must match the message parts specified for the client response receiver. Likewise, the digital signature method chosen for the server must match the digital signature method used by the client.

About this task

Complete the following steps to configure the client for response digital signature verification. The steps describe how to modify the extensions to indicate which digital signature method the client will use during verification.

Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open perspective** > **Other** > **J2EE**.
3. Click **Application Client Projects** > ***application_name*** > **appClientModule** > **META-INF**.
4. Right-click the `application-client.xml` file, select **Open with** > **Deployment descriptor editor**.
5. Click the **WS Binding** tab.

6. Expand the **Security response receiver binding configuration** > **Signing information** section.
7. Click **Edit** to select a digital signature method. The signing info dialog displays and either select or enter the following information:
   - **Canonicalization method algorithm**
   - **Digest method algorithm**
   - **Signature method algorithm**
   - **Signing key name**
   - **Signing key locator**

   For more conceptual information on digitally signing SOAP messages, see XML digital signature. The following table describes the purpose for each of these selections. Some of the following definitions are based on the XML-Signature specification, which can be found at: http://www.w3.org/TR/xmldsig-core.

Table 238. Digital signature methods. Use the methods to configure the client for response digital signature verification.

Name	Purpose
Canonicalization method algorithm	The canonicalization method algorithm is used to canonicalize the `<SignedInfo>` element before it is digested as part of the signature operation.
Digest method algorithm	The digest method algorithm is the algorithm applied to the data after transforms are applied, if specified, to yield the `<DigestValue>`. The signing of the `<DigestValue>` binds resource content to the signer key. The algorithm selected for the client response receiver configuration must match the algorithm selected in the server response sender configuration.
Signature method algorithm	The signature method is the algorithm that is used to convert the canonicalized `<SignedInfo>` element into the `<SignatureValue>` element. The algorithm selected for the client response receiver configuration must match the algorithm selected in the server response sender configuration.
Use certificate path reference or **Trust any certificate**	When a message is signed, the public key used to sign it is transmitted with the message. To validate this public key at the receiving end, configure a certificate path reference. By selecting **User certificate path reference,** you must configure a trust anchor reference and certificate store reference to validate the certificate sent with the message. By selecting **Trust any certificate**, the signature is validated by the certificate sent with the message without the certificate itself being validated.
Use certificate path reference: Trust anchor reference	A trust anchor is a configuration that refers to a keystore that contains trusted, self-signed certificates and certificate authority (CA) certificates. These certificates are trusted certificates that you can use with any applications in your deployment.
Use certificate path reference: Certificate store reference	A certificate store is a configuration that has a collection of X.509 certificates. These certificates are not trusted for all applications in your deployment, but might be used as an intermediary to validate certificates for an application.

8. Optional: Select **Show only FIPS Compliant Algorithms** if you only want the FIPS compliant algorithms to be shown in the Signature method algorithm and Digest method algorithm dropdown lists. Use this option if you expect this application to be run on a WebSphere Application Server that has set the **Use the United States Federal Information Processing Standard (FIPS) algorithms** option in the SSL certificate and key management panel of the administrative console for WebSphere Application Server.

Results

Important: If you configure the client and server signing information correctly, but receive a `Soap body not signed` error when running the client, you might need to configure the actor. You can configure the actor in the following locations on the client in the web services client editor within an assembly tool:

- Click **Security extensions** > **Client service configuration details** and indicate the actor information in the Actor URI field.
- Click **Security extensions** > **Request sender configuration** > **Details** and indicate the actor information in the Actor field.

You must configure the same actor strings for the web service on the server, which processes the request and sends the response back. Configure the actor in the following locations in the web services editor within an assembly tool:

- Click **Security extensions** > **Server service configuration**.
- Click **Security extensions** > **Response sender service configuration details** > **Details** and indicate the actor information in the **Actor** field.

The actor information on both the client and server must refer to the same exact string. When the actor fields on the client and server match, the request or response is acted upon instead of being forwarded downstream. The actor fields might be different when you have web services acting as a gateway to other web services. However, in all other cases, make sure that the actor information matches on the client and server. When web services are acting as a gateway and they do not have the same actor configured as the request passing through the gateway, web services do not process the message from a client. Instead, these web services send the request downstream. The downstream process that contains the correct actor string processes the request. The same situation occurs for the response. Therefore, it is important that you verify that the appropriate client and server actor fields are synchronized.

You have specified which method the client uses to verify the digital signature in the message parts.

What to do next

After you configure the server for response signing and the client for request digital signature verification, verify that you have configured the client and the server to handle the message request.

Configuring the client security bindings using an assembly tool

Use the web services client editor within an assembly tool to include the binding information, that describes how to run the security specifications found in the extensions, in the client enterprise archive (EAR) file.

About this task

Important: There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

When configuring a client for Web Services Security, the bindings describe how to run the security specifications found in the extensions. Use the web services client editor within an assembly tool to include the binding information in the client enterprise archive (EAR) file.

You can configure the client-side bindings from a pure client accessing a web service or from a web service accessing a downstream web service. This document focuses on the pure client situation. However, the concepts, and in most cases the steps, also apply when a web service is configured to communicate downstream to another web service that has client bindings. Complete the following steps to edit the security bindings on a pure client (or server acting as a client) using an assembly tool:

Procedure

1. Import the web services client EAR file into an assembly tool. When you edit the client bindings on a server acting as a client, the same basic steps apply. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **Application Client Projects** > ***application_name*** > **appClientModule** > **META-INF**.

4. Right-click the `application-client.xml` file, select **Open with** > **Deployment descriptor editor**. The Client Deployment Descriptor is displayed.
5. Click the **WS Extension** tab and select the port QName bindings that you want to configure. The Web Services Security extensions are configured for outbound requests and inbound responses. You need to configure the following information for Web Services Security extensions. These topics are discussed in more detail in other sections of the documentation.

   Request sender configuration details

Key locators
"Configuring key locators using an assembly tool" on page 1690

What to do next

Important: When configuring the security request sender binding configuration, you must synchronize the information used to perform the specified security with the security request receiver binding configuration, which is configured in the server EAR file. These two configurations must be synchronized in all respects because there is no negotiation during run time to determine the requirements of the server.

For example, when configuring the encryption information in the security request sender binding Configuration, you must use the public key from the server for encryption. Therefore, the key locator that you choose must contain the public key from the server configuration. The server must contain the private key to decrypt the message. This example illustrates the important relationship between the client and server configuration. Additionally, when configuring the security response receiver binding configuration, the server must send the response using security information known by this client security response receiver binding configuration.

The following table shows the related configurations between the client and the server. The client request sender and the server request receiver are relative configurations that must be synchronized with each other. The server response sender and the client response receiver are related configurations that must be synchronized with each other. Note that the related configurations are end points for any request or response. One end point must communicate its actions with the other end point because run time requirements are not negotiated.

Table 239. Related configurations. The configurations must be synchronized with each other.

Client configuration	Server configuration
Request sender	Request receiver
Response receiver	Response sender

Configuring the server security bindings using an assembly tool

Use an assembly tool to edit bindings for a web service after these bindings are deployed on a server.

Before you begin

Important: There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

Prior to importing the web services enterprise archive (EAR) file into the assembly tool, make sure that you have already run the **WSDL2Java** command on your web service to enable your Java Platform, Enterprise Edition (Java EE) application. You must import the Web services EAR file into the assembly tool.

About this task

Create an Enterprise JavaBeans (EJB) file Java archive (JAR) file or a web application archive (WAR) file containing the security binding file (`ibm-webservices-bnd.xmi`) and the security extension file (`ibm-webservices-ext.xmi`). If this archive is acting as a client to a downstream service, you also need the client-side binding file (`ibm-webservicesclient-bnd.xmi`) and the client-side extension file (`ibm-webservicesclient-ext.xmi`). These files are generated using the **WSDL2Java** command. For more information, read about the **WSDL2Java** command for JAX-RPC applications. You can edit these files using the web services editor in the assembly tool.

When configuring server-side security for Web Services Security, the security extensions configuration specifies what security is performed, the security bindings configuration indicates how to perform what is specified in the security extensions configuration. You can use the defaults for some elements at the cell and server levels in the bindings configuration, including key locators, trust anchors, the collection certificate store, trusted ID evaluators, and login mappings and reference these elements from the WAR and JAR binding configurations.

Open the web services editor in an assembly tool to begin editing the server security extensions and bindings. The following steps can locate the server security extensions and bindings. Other tasks specify how to configure each section of the extensions and bindings in more detail.

Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java EE perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Configure the server for inbound requests and outbound responses security configuration. To configure the server for inbound requests and outbound responses, complete the following steps:
   a. Click **EJB Projects** > ***application_name*** > **ejbModule** > **META-INF**.
   b. Right-click the `webservices.xml` file and click **Open with** > **Web services editor**. The `webservices.xml` file represents the server-side (inbound) web services configuration. The `webservicesclient.xml` file represents the client-side (outbound) web services configuration.
4. In the web services editor (for the `webservices.xml` file and inbound requests and outbound responses web services configuration), there are several tabs at the bottom of the editor including Web Services,

Port Components, Handlers, Security Extensions, Bindings, and Binding Configurations. The security extensions are edited using the **Security Extensions** tab. The security bindings are edited using the Security Bindings tab.

a. Click the **WS Extensions** tab and select the port component binding to edit. The Web Services Security extensions are configured for inbound requests and outbound responses. You need to configure the following information for Web Services Security extensions. These topics are discussed in more detail in other topics in the documentation.

   Request receiver service configuration details

   Required integrity
   "Configuring the server for request digital signature verification: Verifying the message parts" on page 1697

   Required confidentiality
   "Configuring the server for request decryption: decrypting the message parts" on page 1717

   Login config

   BasicAuth
   "Configuring the server to handle basic authentication information" on page 1731

   ID assertion
   "Configuring the server to handle identity assertion authentication" on page 1736

   Signature
   "Configuring the server to support signature authentication" on page 1744

   LTPA "Configuring the server to handle LTPA token authentication information" on page 1752

   Add received time stamp
   "Configuring the server for request digital signature verification: Verifying the message parts" on page 1697

   Response sender service configuration details

   Details
   "Configuring the server for response signing: digitally signing message parts" on page 1701

   Integrity
   "Configuring the server for response signing: digitally signing message parts" on page 1701

   Confidentiality
   "Configuring the server for response encryption: encrypting the message parts" on page 1720

   Add created time stamp
   "Configuring the server for response signing: digitally signing message parts" on page 1701

b. Click the **Binding Configurations** tab and select the port component binding to edit. The Web Services Security bindings are configured for inbound requests and outbound responses. You need to configure the following information for Web Services Security bindings. These topics are discussed in more details in other topics in the documentation.

   Response receiver binding configuration details

   Signing Information
   "Configuring the server for request digital signature verification: choosing the verification method" on page 1698

   Encryption Information
   "Configuring the server for request decryption: choosing the decryption method" on page 1718

Trust Anchor
"Configuring trust anchors using an assembly tool" on page 1687

Trusted ID evaluator

Trusted ID evaluator reference

Response sender binding configuration details

Signing information
"Configuring the server for response signing: choosing the digital signature method" on page 1703

Encryption information
"Configuring the server for response encryption: choosing the encryption method" on page 1721

Key locators
"Configuring key locators using an assembly tool" on page 1690

What to do next

Configure the client for outbound requests and inbound responses security configuration by right-clicking the `webservicesclient.xml` file and clicking **Open With** > **Deployment descriptor editor**. For more information, see "Configuring the client security bindings using an assembly tool" on page 1708.

Configuring XML encryption for Version 5.x web services with an assembly tool

XML encryption is one method that WebSphere® Application Server provides to secure your web services. It enables you to encrypt an XML element, the content of an XML element, or arbitrary data such as an XML document.

Securing web services for Version 5.x applications using XML encryption

XML encryption is one method that WebSphere Application Server provides to secure your web services. It enables you to encrypt an XML element, the content of an XML element, or arbitrary data such as an XML document.

Before you begin

Important: There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

WebSphere Application Server provides several different methods to secure your web services. XML encryption is one of these methods. You can secure your web services using any of the following methods:

- XML digital signature
- XML encryption
- Basicauth authentication
- Identity assertion authentication
- Signature authentication
- Pluggable token

About this task

XML encryption enables you to encrypt an XML element, the content of an XML element, or arbitrary data such as an XML document. Like XML digital signature, a message is sent by the client as the request sender to the server as the request receiver. The response is sent by the server as the response sender to the client as the request receiver. Unlike XML digital signature, which verifies the authenticity of the sender, XML encryption scrambles the message content using a key, which can be unscrambled by a receiver that possesses the same key. You can use XML encryption in conjunction with XML digital signature to scramble the content while verifying the authenticity of the message sender.

To use XML encryption to secure web services, you must use an assembly tool. For more information, see the related information on Assembly Tools.

To securing web services for Version 5.*x* applications using XML encryption, complete the following steps:

Procedure

1. Specify the encryption settings for the request sender. The message parts and the encryption method settings chosen for the request sender on the client must match the message parts and the method settings chosen for the request receiver on the server. To specify the encryption settings for the request sender:
   a. “Configuring the client for request encryption: Encrypting the message parts” on page 1715.
   b. “Configuring the client for request encryption: choosing the encryption method” on page 1716.
2. Specify the encryption settings for the request receiver. The decryption settings chosen for the request receiver must match the encryption settings chosen for the request sender.

   To specify the decryption settings for the request receiver:
   a. “Configuring the server for request decryption: decrypting the message parts” on page 1717.
   b. “Configuring the server for request decryption: choosing the decryption method” on page 1718.
3. Specify the encryption settings for the response sender. The message parts and the encryption method settings chosen for the response sender on the server must match the message parts and the method settings chosen for the response receiver on the client. To specify the encryption settings for the response sender:
   a. “Configuring the server for response encryption: encrypting the message parts” on page 1720.
   b. “Configuring the server for response encryption: choosing the encryption method” on page 1721.
4. Specify the encryption settings for the response receiver.

Remember: The decryption settings chosen for the response receiver must match the encryption settings chosen for the response sender.

To specify the decryption settings for the response receiver, complete the following steps:

a. "Configuring the client for response decryption: decrypting the message parts" on page 1722.

b. "Configuring the client for response decryption: choosing a decryption method" on page 1723.

Results

After completing these steps, you have secured your web services using XML encryption.

Configuring the client for request encryption: Encrypting the message parts

To configure the client for request encryption, specify which message parts to encrypt when configuring the client.

Before you begin

Important: There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

Prior to completing these steps, read either of the following topics to familiarize yourself with the **WS Extensions** tab and the **WS Binding** tab in the Client Deployment Descriptor Editor within an assembly tool:

- "Configuring the client security bindings using an assembly tool" on page 1708
- Configuring the security bindings on a server acting as a client using the administrative console

These two tabs are used to configure the Web Services Security extensions and Web Services Security bindings, respectively.

About this task

Complete the following steps to specify which message parts to encrypt when configuring the client for request encryption:

Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **Application Client Projects** > ***application_name*** > **appClientModule** > **META-INF**.
4. Right-click the `application-client.xml` file, select **Open with** > **Deployment descriptor editor**.
5. Click the **WS extensions** tab, which is located at the bottom of Client Deployment Descriptor Editor within the assembly tool.
6. Expand **Request sender configuration** > **Confidentiality**. Confidentiality refers to encryption while integrity refers to digital signing. Confidentiality reduces the risk of someone understanding the message flowing across the Internet. With confidentiality specifications, the message is encrypted before it is sent and decrypted when it is received at the correct target. For more information on encrypting , see XML encryption.
7. Select the parts of the message that you want to encrypt by clicking **Add**. You can select one of the following parts:

   Bodycontent
   User data portion of the message

Usernametoken
Basic authentication information, if selected

What to do next

After you specify which message parts to encrypt, you must specify which method to use to encrypt the request message. See “Configuring the client for request encryption: choosing the encryption method” for more information.

Configuring the client for request encryption: choosing the encryption method

To configure the client for request encryption, specify which encryption method to use when configuring the client.

Before you begin

Important: There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

Prior to completing these steps, read either of the following topics to familiarize yourself with the **WS Extensions** tab and the **WS Binding** tab in the Client Deployment Descriptor editor within an assembly tool:

- “Configuring the client security bindings using an assembly tool” on page 1708
- Configuring the security bindings on a server acting as a client using the administrative console

These two tabs are used to configure the Web Services Security extensions and Web Services Security bindings, respectively.

About this task

Complete the following steps to specify which encryption method to use when configuring the client for request encryption:

Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **Application Client Projects** > ***application_name*** > **appClientModule** > **META-INF**.
4. Right-click the `application-client.xml` file, select **Open with** > **Deployment descriptor editor**.
5. Click the **WS binding** tab, which is located at the bottom of the Client Deployment Descriptor editor within the assembly tool.
6. Expand **Security request sender binding configuration** > **Encryption information**.
7. Select an encryption option and click **Edit** to view the encryption information or click **Add** to add another option. The following table describes the purpose of this information. Some of these definitions are based on the XML-Encryption specification, which is located at the following web address: http://www.w3.org/TR/xmlenc-core

   Encryption name
   Refers to the name of the encryption information entry.

   Data encryption method algorithm
   Encrypts and decrypts data in fixed size, multiple octet blocks.

Key encryption method algorithm
Represents public key encryption algorithms that are specified for encrypting and decrypting keys.

Encryption key name
Represents a Subject (**Owner** field of the certificate) from a public key certificate found by the encryption key locator, which is used by the key encryption method algorithm to encrypt the private key. The private key is used to encrypt the data.

The key chosen must be a public key of the target. Encryption must be done using the public key and decryption must be done by the target using the private key (the personal certificate of the target).

Encryption key locator
Represents a reference to a key locator implementation class that locates the correct key store where the alias and the certificate exist. For more information on configuring key locators, see "Configuring key locators using an assembly tool" on page 1690 and Configuring key locators using the administrative console.

8. Optional: Select **Show only FIPS Compliant Algorithms** if you only want the FIPS compliant algorithms to be shown in the **Data Encryption method algorithm** and **Key Encryption method algorithm** dropdown lists. Use this option if you expect this application to be run on a WebSphere Application Server that has set the **Use the United States Federal Information Processing Standard (FIPS) algorithms** option in the SSL certificate and key management panel of the WebSphere administrative console.

Results

For more information, see "Configuring key locators using an assembly tool" on page 1690 and Configuring key locators using the administrative console.

What to do next

You must specify which parts of the request message to encrypt. See "Configuring the client for request encryption: Encrypting the message parts" on page 1715 if you have not previously specified this information.

Configuring the server for request decryption: decrypting the message parts

Use the **WS Extensions** tab and the **WS Binding** configurations tab to specify which parts of the request message must be decrypted by the server.

Before you begin

Important: There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.x and later applications.

Complete this task to specify which parts of the request message must be decrypted by the server. You must know which parts of the request message the client encrypts because the server must decrypt the same message parts.

Prior to completing these steps, read either of the following topics to become familiar with the **WS Extensions** tab and the **WS Binding** configurations tab:

- "Configuring the server security bindings using an assembly tool" on page 1711
- Configuring the server security bindings using the administrative console

These two tabs are used to configure the Web Services Security extensions and Web Services Security bindings, respectively.

About this task

Complete the following steps to configure the request receiver extensions:

Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **EJB Projects** > ***application_name*** > **ejbModule** > **META_INF**.
4. Right-click the `webservices.xml` file, and click **Open with** > **Web services editor**.
5. Click the **Extensions** tab, which is located at the bottom of the web services editor within the assembly tool.
6. Expand the **Request receiver service configuration details** > **Required confidentiality** section.
7. Select the parts of the message to decrypt. The message parts selected for the request decryption on the server must match the message parts selected for the message encryption on the client. Click **Add** and select either of the following message parts:

   bodycontent
   The user data section of the message.

   usernametoken
   This token is the basic authentication information.

What to do next

After you specify which parts of the request message to decrypt, you must specify the method to use decrypt the message. See “Configuring the server for request decryption: choosing the decryption method” for more information.

Configuring the server for request decryption: choosing the decryption method

You can use an assembly tool and the administrative console to configure the Web Services Security extensions and Web Services Security bindings.

Before you begin

Important: There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

Prior to completing these steps, read either of the following topics to become familiar with the **WS Extensions** tab and the **WS Bindings** tab:

- “Configuring the server security bindings using an assembly tool” on page 1711
- Configuring the server security bindings using the administrative console

These two tabs are used to configure the Web Services Security extensions and Web Services Security bindings, respectively.

About this task

Complete this task to specify which decryption method is used by the server to decrypt the request message. You must know which decryption method the client uses because the server must use the same method.

Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **EJB Projects** > ***application_name*** > **ejbModule** > **META_INF**.
4. Right-click the `webservices.xml` file, select **Open with** > **Web services editor**.
5. Click the **Binding Configurations** tab, which is located at the bottom of the web services editor within the assembly tool.
6. Expand the **Request receiver binding configuration details** > **Encryption information** section.
7. Click **Edit** to view the encryption information. The following table describes the purpose for each of these selections. Some definitions are taken from the XML-Encryption specification , which is located at the following web address: http://www.w3.org/TR/xmlenc-core

   Encryption name
   Represents the name of this encryption information entry; an alias for the entry.

   Data encryption method algorithm
   Encrypts and decrypts data in fixed size, multiple octet blocks. This algorithm must be the same as the algorithm selected in the client request sender configuration.

   Key encryption method algorithm
   Represents algorithms specified for encrypting and decrypting keys. This algorithm must be the same as the algorithm selected in the client request sender configuration.

   Encryption key name
   Represents a Subject from a personal certificate, which is typically a distinguished name (DN) that is found by the encryption key locator. The subject is used by the key encryption method algorithm to decrypt the secret key, and the secret key is used to decrypt the data.

   The key chosen must be a private key in the key store configured by the key locator. The key requires the same Subject used by the client to encrypt the data. Encryption must be done using the public key and decryption by using the private key (personal certificate). To ensure that the client encrypts the data with the correct public or private key, you must extract the public key from the server key store and add it to the key store specified in the encryption configuration information for the client request sender.

   For example, the personal certificate of a server is `CN=Bob, O=IBM, C=US`. Therefore the server contains the public and private key pair. The client sending the request should encrypt the data using the public key for `CN=Bob, O=IBM, C=US`. The server decrypts the data using the private key for `CN=Bob, O=IBM, C=US`.

   Encryption key locator
   Represents a reference to a key locator implementation class that finds the correct keystore where the alias and the certificate exist. For more information on configuring key locators, go to the following sections: “Configuring key locators using an assembly tool” on page 1690 and Configuring key locators using the administrative console.
8. Optional: Select **Show only FIPS Compliant Algorithms** if you only want the FIPS compliant algorithms to be shown in the Data Encryption method algorithm and Key Encryption method algorithm dropdown lists. Use this option if you expect this application to be run on a WebSphere Application

Server that has set the **Use the United States Federal Information Processing Standard (FIPS) algorithms** option in the SSL certificate and key management panel of the administrative console for WebSphere Application Server.

Results

It is important to note that for decryption, the encryption key name chosen must refer to a personal certificate that can be located by the key locator of the server referenced in the encryption information. Enter the Subject of the personal certificate here, which is typically a Distinguished Name (DN). The Subject uses the default key locator to find the key. If a custom key locator is written, the encryption key name can be anything used by the key locator to find the correct encryption key. The encryption key locator references the implementation class that finds the correct key store where this alias and certificate exist. Refer to “Configuring key locators using an assembly tool” on page 1690 and Configuring key locators using the administrative console for more information.

What to do next

You must specify which parts of the request message to decrypt. See “Configuring the server for request decryption: decrypting the message parts” on page 1717 if you have not previously specified this information.

Configuring the server for response encryption: encrypting the message parts

You can specify which parts of the response message to encrypt when configuring the server for response encryption.

Before you begin

Important: There is an important distinction between Version 5.*x* and Version 6.0.*x* and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

Prior to completing these steps, read either of the following topics to become familiar with the **WS Extensions** tab and the **WS Bindings** tab in the Web services editor within an assembly tool:

- “Configuring the server security bindings using an assembly tool” on page 1711
- Configuring the server security bindings using the administrative console

These two tabs are used to configure the Web Services Security extensions and the Web Services Security bindings, respectively.

About this task

Complete the following steps to specify which parts of the response message to encrypt when configuring the server for response encryption:

Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window > Open Perspective > J2EE**.
3. Click **EJB Projects >** ***application_name*** **> ejbModule > META_INF**.
4. Right-click the `webservices.xml` file, select **Open with > Web services editor**.
5. Click the **Extensions** tab, which is located at the bottom of the Web Services Editor within the assembly tool.

6. Expand **Response sender service configuration details > Confidentiality**. Confidentiality refers to encryption while integrity refers to digital signing. Confidentiality reduces the risk of someone understanding the message flowing across the Internet. With confidentiality specifications, the response is encrypted before it is sent and decrypted when it is received at the correct target.
7. Select the parts of the response that you want to encrypt by clicking **Add** and selecting **Bodytoken** or **Usernametoken**. The following information describes the message parts:

   Bodycontent
   User data portion of the message.

   Usernametoken
   Basic authentication information, if selected.

   A user name token does not appear in the response so you do not need to select this option for the response. If you select this option, make sure that you also select it for the client response receiver. If you do not select this option, make sure that you do not select it for the client response receiver.

What to do next

After you specify which message parts to encrypt, you must specify which method to use message encryption. See the task for choosing the encryption method when configuring the server for response encryption.

Configuring the server for response encryption: choosing the encryption method

You can specify which method the server uses to encrypt the response message.

Before you begin

Important: There is an important distinction between Version 5.*x* and Version 6.0.*x* and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

Prior to completing these steps, read either of the following topics to become familiar with the **Extensions** tab and the **Binding configurations** tab in the web services editor within an assembly tool:

- "Configuring the server security bindings using an assembly tool" on page 1711
- Configuring the server security bindings using the administrative console

These two tabs are used to configure the Web Services Security extensions and Web Services Security bindings, respectively.

About this task

Complete the following steps to specify which method the server uses to encrypt the response message:

Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **EJB Projects** > ***application_name*** > **ejbModule** > **META_INF**.
4. Right-click the `webservices.xml` file, and click **Open with** > **Web services editor**.
5. Click the **Binding Configuration**s tab, which is located at the bottom of the Web Services Editor within the assembly tool.
6. Expand **Response sender binding configuration details** > **Encryption information**.

7. Click **Edit** to view the encryption information. The following table describes the purpose of this information. Some of these definitions are based on the XML-Encryption specification, which is located at the following web address: http://www.w3.org/TR/xmlenc-core

   Encryption name
   Refers to the name of the encryption information entry.

   Data encryption method algorithm
   Encrypts and decrypts data in fixed size, multiple octet blocks. The algorithm selected for the server response sender configuration must match the algorithm selected in the client response receiver configuration.

   Key encryption method algorithm
   Represents public key encryption algorithms that are specified for encrypting and decrypting keys. The algorithm selected for the server response sender configuration must match the algorithm selected in the client response receiver configuration.

   Encryption key name
   Represents a Subject from a public key certificate typically distinguished name (DN) that is found by the encryption key locator and used by the key encryption method algorithm to encrypt the private key. The private key is used to encrypt the data.

   The key name chosen in the server response sender encryption information must be the public key of the key configured in the client response receiver encryption information. Encryption by the response sender must be done using the public key and decryption must be done by the response receiver using the associated private key (the personal certificate of the response receiver).

   Encryption key locator
   The encryption key locator represents a reference to a key locator implementation class that finds the correct key store where the alias and the certificate exist. For more information, see the tasks for configuring key locators.
8. Select **Show only FIPS Compliant Algorithms** if you only want the FIPS compliant algorithms to be shown in the Data Encryption method algorithm and Key Encryption method algorithm drop-down lists. Use this option if you expect this application to be run on a WebSphere Application Server that has set the **Use the United States Federal Information Processing Standard (FIPS) algorithms** option in the SSL certificate and key management panel of the administrative console for WebSphere Application Server.

Results

The encryption key name chosen must refer to a public key of the response receiver. For the encryption key name, use the Subject of the public key certificate, typically a Distinguished Name (DN). The name chosen is used by the default key locator to find the key. If you write a custom key locator , the encryption key name might be anything that is used by the key locator to find the correct encryption key (a public key). The encryption key locator references the implementation class that finds the correct key store where the alias and certificate exist.

What to do next

You must specify which parts of the response message to encrypt. See the task for configuring the server for response encryption if you have not previously specified this information.

Configuring the client for response decryption: decrypting the message parts

To configure the client for response decryption, specify which response message parts to decrypt when configuring the client. The server response encryption and client response decryption configurations must match.

Before you begin

Important: There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

Prior to completing these steps, read either of the following topics to become familiar with the **WS Extensions** tab and the **WS Binding** tab in the Client Deployment Descriptor Editor within an assembly tool:

- "Configuring the client security bindings using an assembly tool" on page 1708
- Configuring the security bindings on a server acting as a client using the administrative console

These two tabs are used to configure the Web Services Security extensions and the Web Services Security bindings, respectively.

About this task

Complete the following steps to specify which response message parts to decrypt when configuring the client for response decryption. The server response encryption and client response decryption configurations must match.

Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **Application Client Projects** > ***application_name*** > **appClientModule** > **META-INF**.
4. Right-click the `application-client.xml` file, select **Open with** > **Deployment descriptor editor**.
5. Click the **WS Extensions** tab, which is located at the bottom of the deployment descriptor editor within the assembly tool.
6. Expand the **Response receiver configuration** > **Required confidentiality** section.
7. Select the parts of the message that you must decrypt by clicking **Add** and selecting either **Bodycontent** or **Usernametoken**. The following information describes these message parts:

   Bodycontent
   The user data portion of the message.

   Usernametoken
   The basic authentication information, if selected.

   The information selected in this step is encrypted by the server in the response sender.

   Important: A Username Token is typically not sent in the response. Thus, you usually do not need to select username token.

What to do next

After you specify which message parts to decrypt, you must specify which method to use when decrypting the response message. See "Configuring the client for response decryption: choosing a decryption method" for more information.

Configuring the client for response decryption: choosing a decryption method

To configure the client for response decryption, specify which decryption method to use when the client decrypts the response message. The server response encryption and client response decryption configurations must match.

Before you begin

Important: There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

Prior to completing these steps, read either of the following topics to become familiar with the **WS Extensions** tab and the **WS Bindings** tab in the Client Deployment Descriptor Editor within an assembly tool:

- "Configuring the client security bindings using an assembly tool" on page 1708
- Configuring the security bindings on a server acting as a client using the administrative console

These two tabs are used to configure the Web Services Security extensions and Web Services Security bindings, respectively.

About this task

Complete the following steps to specify which decryption method to use when the client decrypts the response message. The server response encryption and client response decryption configurations must match.

Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **Application Client Projects** > ***application_name*** > **appClientModule** > **META-INF**.
4. Right-click the `application-client.xml` file, select **Open with** > **Deployment descriptor editor**.
5. Click the **WS Binding** tab, which is located at the bottom of the deployment descriptor editor within the assembly tool.
6. Expand the **Security response receiver binding configuration** > **Encryption information** section. For more information on encrypting and decrypting SOAP messages, see XML encryption.
7. Click **Edit** to view the encryption information. The following table describes the purpose for this information. Some of these definitions are based on the XML-Encryption specification, which is located at the following web address: http://www.w3.org/TR/xmlenc-core

   Encryption name
   Refers to the alias that is used for the encryption information entry.

   Data encryption method algorithm
   Encrypts and decrypts data in fixed size, multiple octet blocks.

   Key encryption method algorithm
   Represents public key encryption algorithms specified for encrypting and decrypting keys.

   Encryption key name
   Represents a Subject from a personal certificate, which is typically a distinguished name (DN) that is found by the encryption key locator. The Subject is used by the key encryption method algorithm to decrypt the secret key. The secret key is used to decrypt the data.

   Important: The key chosen must be a private key of the client. Encryption must be done using the public key and decryption must be done by the private key (personal certificate). For example, the personal certificate of the client is: `CN=Alice, O=IBM, C=US`. Therefore, the client contains the public and private key pair. The target

server that sends the response encrypts the secret key by using the public key for `CN=Alice, O=IBM, C=US`. The client decrypts the secret key by using the private key for `CN=Alice, O=IBM, C=US`.

Encryption key locator
Represents a reference to a key locator implementation class that finds the correct key store where the alias and the certificate exist. For more information on configuring key locators, see "Configuring key locators using an assembly tool" on page 1690 and Configuring key locators using the administrative console.

8. Optional: Select **Show only FIPS Compliant Algorithms** if you only want the FIPS compliant algorithms to be shown in the Data Encryption method algorithm and Key Encryption method algorithm dropdown lists. Use this option if you expect this application to be run on a WebSphere Application Server that has set the **Use the United States Federal Information Processing Standard (FIPS) algorithms** option in the SSL certificate and key management panel of the administrative console for WebSphere Application Server.

Results

For decryption, the encryption key name chosen must refer to a personal certificate that can be located by the client key locator. The Subject (**owner** field of the certificate) of the personal certificate should be entered in the Encryption key name, this is typically a Distinguished Name (DN). The default key locator uses the Encryption key name to find the key within the keystore. If you write a custom key locator, the encryption key name can be anything used by the key locator to find the correct encryption key. The encryption key locator references the implementation class that locates the correct key store where this alias and certificate exists. For more information, see "Configuring key locators using an assembly tool" on page 1690 and Configuring key locators using the administrative console.

What to do next

You must specify which parts of the request message to decrypt. See the topic"Configuring the client for response decryption: decrypting the message parts" on page 1722 if you have not previously specified this information.

Configuring XML basic authentication for Version 5.x web services with an assembly tool

With the basic authentication (BasicAuth) authentication method, the request sender generates a BasicAuth security token using a callback handler. The request receiver retrieves the BasicAuth security token from the SOAP message and validates it using a Java™ Authentication and Authorization Service (JAAS) login module. Trust is established by using user name and password validation.

Securing web services for Version 5.x applications using basic authentication

With the basic authentication (BasicAuth) authentication method, the request sender generates a BasicAuth security token using a callback handler. The request receiver retrieves the BasicAuth security token from the SOAP message and validates it using a Java Authentication and Authorization Service (JAAS) login module. Trust is established by using user name and password validation.

About this task

Important: There is an important distinction between Version 5.*x* and Version 6.0.*x* and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

WebSphere Application Server provides several different methods to secure your web services. BasicAuth authentication is one of these methods. You might also secure your web services using any of the following methods:

- XML digital signature
- XML encryption
- BasicAuth authentication
- Identity assertion authentication
- Signature authentication
- Pluggable token

To use BasicAuth authentication to secure web services, complete the following tasks:

Procedure

1. Secure the client for BasicAuth authentication.
   a. Configure the client for basic authentication: specifying the method
   b. Configure the client for basic authentication: collecting the authentication information
2. Secure the server for BasicAuth authentication.
   a. Configure the server to handle basic authentication
   b. Configure the server to validate basic authentication information

Results

After completing these steps, you have secured your web services using BasicAuth authentication.

Configuring the client for basic authentication: specifying the method

Basic authentication (BasicAuth) refers to the user ID and password of a valid user in the registry of the target server. BasicAuth information can be collected in many ways, including through an administrative console prompt, a standard in (Stdin) prompt, or specified in the bindings that prevents user interaction.

Before you begin

Important: There is an important distinction between Version 5.*x* and Version 6.0.*x* and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

For more information on BasicAuth authentication, see: “BasicAuth authentication method” on page 1727.

About this task

Attention: WebSphere Application Server supports nonce (randomly generated token) with BasicAuth authentication. For more information, see Nonce.

Complete the following steps to specify BasicAuth as the authentication method:

Procedure

1. Launch an assembly tool. See more information on the assembly tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **Application Client Projects** > ***application_name*** > **appClientModule** > **META-INF**.
4. Right-click the `application-client.xml` file, select **Open with** > **Deployment descriptor editor**.

5. Click the **WS Extensions** tab, which is located at the bottom of the deployment descriptor editor within the assembly tool.
6. Expand the **Request sender configuration** > **Login configuration** section. The only valid login configuration choices for a pure client are **BasicAuth** and **Signature**.
7. Select **BasicAuth** to authenticate the client using a user ID and a password. This user ID and password must be specified in the target user registry. The other choice, Signature, attempts to authenticate the client using the certificate used to digitally sign the message.

What to do next

For more information on getting started with the web services client editor within the assembly tool, see either of the following topics:

- "Configuring the client security bindings using an assembly tool" on page 1708
- Configuring the security bindings on a server acting as a client using the administrative console

After you specify the BasicAuth authentication method, you must specify how to collect the authentication information. See "Configuring the client for basic authentication: collecting the authentication information" on page 1728.

BasicAuth authentication method:

When you use the BasicAuth authentication method, the security token that is generated is a <wsse:UsernameToken> element with <wsse:Username> and <wsse:Password> elements.

Important: There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6 and later applications.

WebSphere Application Server supports text passwords but not password digest because passwords are not stored and cannot be retrieved from the server. On the request sender side, a callback handler is invoked to generate the security token. On the request receiver side, a Java Authentication and Authorization Service (JAAS) login module is used to validate the security token. These two operations, token generation and token validation, are described in the following sections.

BasicAuth token generation

The request sender generates a BasicAuth security token using a callback handler. The security token returned by the callback handler is inserted in the SOAP message. The callback handler that is used is specified in the <LoginBinding> element of the bindings file, `ibm-webservicesclient-bnd.xmi`. The following callback handler implementations are provided with WebSphere Application Server and can be used with the BasicAuth authentication method:

- com.ibm.wsspi.wssecurity.auth.callback.GUIPromptCallbackHandler
- com.ibm.wsspi.wssecurity.auth.callback.StdinPromptCallbackHandler
- com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler

You can add your own callback handlers that implement the `javax.security.auth.callback.CallbackHandler` method.

BasicAuth token validation

The request receiver retrieves the BasicAuth security token from the SOAP message and validates it using a JAAS login module. The <wsse:Username> and <wsse:Password> elements in the security token are used to perform the validation. If the validation is successful, the login module returns a JAAS Subject. This Subject is set as the identity of the running thread. If the validation fails, the request is rejected with a SOAP fault exception.

The JAAS login configuration is specified in the <LoginMapping> element of the bindings file. Default bindings are specified in the `ws-security.xml` file. However, you can override these

bindings using the application-specific `ibm-webservices-bnd.xmi` file. The configuration information consists of a CallbackHandlerFactory and a ConfigName value. The CallbackHandlerFactory option specifies the name of a class that is used for creating the JAAS CallbackHandler object. WebSphere Application Server provides the com.ibm.wsspi.wssecurity.auth.callback.WSCallbackHandlerFactoryImpl CallbackHandlerFactory implementation. The ConfigName value specifies a JAAS configuration name entry. WebSphere Application Server searches the `security.xml` file for a matching configuration name entry. If a match is not found, it searches the `wsjaas.conf` file for a match. WebSphere Application Server provides the WSLogin default configuration entry, which is suitable for the BasicAuth authentication method.

Configuring the client for basic authentication: collecting the authentication information

The basic authentication (BasicAuth) method refers to the user ID and the password of a valid user in the registry of the target server. Collection of BasicAuth information can occur in many ways including through a user interface prompt, a standard in (Stdin) prompt, or specified in the bindings, which prevents user interaction.

About this task

Note: There is an important distinction between Version 5.*x* and Version 6.0.*x* and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

For more information on BasicAuth authentication, see “BasicAuth authentication method” on page 1727.

Complete this task to specify the authentication information needed for BasicAuth authentication:

Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **Application Client Projects** > ***application_name*** > **appClientModule** > **META-INF**.
4. Right-click the `application-client.xml` file, select **Open with** > **Deployment descriptor editor**.
5. Click the **WS Binding** tab, which is located at the bottom of deployment descriptor editor within the assembly tool.
6. Expand the **Security request sender binding configuration** > **Login binding** section.
7. Click **Edit** or **Enable** to view the login binding information. The login binding information displays and enter the following information:

   Authentication method
   Specifies the type of authentication. Select **BasicAuth** to use basic authentication.

   Token value type URI and Token value type local name
   When you select **BasicAuth**, you cannot edit the token value type URI and the local name values. Specifies values for custom authentication types. For BasicAuth authentication, leave these values blank.

   Callback handler
   Specifies the Java Authentication and Authorization Server (JAAS) callback handler implementation for collecting the BasicAuth information. You can use the following default implementations for the callback handler:

   com.ibm.wsspi.wssecurity.auth.callback.StdinPromptCallbackHandler
   This implementation is used for non-user interface console prompts.

Restriction: This implementation prompts for the user name and password and reads them into the configuration from standard in. If you have a multi-threaded client and multiple threads attempt to read from standard in at the same time, all the threads will not successfully obtain the user name and password information. Therefore, you cannot use the `com.ibm.wsspi.wssecurity.auth.callback.StdinPromptCallbackHandler` implementation with a multi-threaded client where multiple threads might attempt to obtain data from standard in concurrently.

com.ibm.wsspi.wssecurity.auth.callback.GUIPromptCallbackHandler
This implementation is used for user interface panel prompts.

com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler
This implementation is used when you plan to always enter the user ID and password in the BasicAuth user ID and password section that follows.

Basic Authentication user ID and Basic Authentication password
Specifies values for the BasicAuth user ID and password, regardless of the default callback handler indicated previously, these user ID and password values are used to authenticate to the server for the Web Services Security authentication. If you leave these values blank, use either the `GUIPromptCallbackHandler` or the `StdinPromptCallbackHandler` implementation, but only on a pure client. Always fill-in these values for any web service that acts as a client to another web service that you want to specify for BasicAuth for authentication downstream. If you want the client identity of the originator to flow downstream, configure the web service client to use either ID assertion or Lightweight Third Party Authentication (LTPA).

Property
Specifies properties with name and value pairs for custom callback handlers to use. For BasicAuth authentication, you do not need to enter any information. To enter a new property, click **Add** and enter the new property and value.

Results

Other basic authentication entries: There is a basic authentication entry in the Port Qualified Name Binding Details section. This entry is used for HTTP transport authentication, which might be required if the router servlet is protected.

Information specified in the Web Services Security basic authentication section overrides the basic authentication information specified in the Port Qualified Name Binding Details section for authorizing the web service.

For a server that acts as a client, do not specify a user interface or non-user interface prompt callback handler. To configure BasicAuth authentication from one web service to a downstream web service, select the `com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHander` implementation and explicitly specify the BasicAuth user ID and password. If you want the client identity of the originator to flow downstream, configure the web service client to use ID assertion.

What to do next

To use the BasicAuth authentication method, you must specify the method in the Login configuration section of the assembly tool . See “Configuring the client for basic authentication: specifying the method” on page 1726 if you have not previously specified this information.

Identity assertion authentication method:

When using the identity assertion (IDAssertion) authentication method, the security token generated is a <wsse:UsernameToken> element that contains a <wsse:Username> element.

Important: There is an important distinction between Version 5.*x* and Version 6.0.*x* applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* applications.

On the request sender side, a callback handler is invoked to generate the security token. On the request receiver side, the security token is validated. These two operations, token generation and token validation operations, are described in the following sections.

Identity assertion token validation:

The request receiver retrieves the IDAssertion security token from the SOAP message and validates it using a Java Authentication and Authorization Service (JAAS) login module. With identity assertion, special processing is required to establish trust before asserting the identity as the established identity of the running thread. This special processing is defined by the <IDAssertion> element in the deployment descriptor file, `ibm-webservices-ext.xmi`. If all the validation checks are successful, the asserted identity is set as the identity of the running thread. If the validation fails, the request is rejected with a SOAP fault exception.

The JAAS login configuration is specified in the<LoginMapping> element of the bindings file. Default bindings are specified in the `ws-security.xml` file. However, you can override these bindings using the application specific `ibm-webservices-bnd.xmi` file. The configuration information consists of CallbackHandlerFactory and a ConfigName. CallbackHandlerFactory specifies the name of a class that is used for creating the JAAS CallbackHandler object. WebSphere Application Server provides the `com.ibm.wsspi.wssecurity.auth.callback.WSCallbackHandlerFactoryImpl` CallbackHandlerFactory implementation. ConfigName specifies a JAAS configuration name entry.

WebSphere Application Server searches the `security.xml` file for a matching configuration name entry. If a match is not found it searches the `wsjaas.conf` file. WebSphere Application Server provides the system.wssecurity.IDAssertion default configuration entry, which is suitable for the identity assertion authentication method.

The <IDAssertion> element in the `ibm-webservices-ext.xmi` deployment descriptor file specifies the special processing required when using the identity assertion authentication method. The <IDAssertion> element is composed of two sub-elements: <IDType> and <TrustMode>.

The <IDType> element specifies the method for asserting the identity. The supported values for asserting the identity are:

- Username
- Distinguished name (DN)
- X.509 certificate

When <IDType> is *username*, a username token (for example, Bob) is provided. This user name is mapped to a user in the user registry and is the asserted identity after successful trust validation. When the <IDType> value is *DN*, a user name token containing a distinguished name is provided (for example, `cn=Bob Smith, o=ibm, c=us`). This DN is mapped to a user in the user registry and this user is the asserted identity after successful trust validation. When the <IDType> is *X509Certificate*, a binary security token containing an X509 certificate is provided and the SubjectDN value from the certificate (for example, `cn=Bob Smith, o=ibm, c=us`) is extracted. This SubjectDN value is mapped to a user in the user registry and this user is the asserted identity after successful trust validation.

The `<TrustMode>` element specifies how the trust authority, or asserting authority, provides trust information. The supported values are:

- Signature
- BasicAuth

- No value specified

When the <TrustMode> value is `Signature`, the signature is validated. Then, the signer (for example, `cn=IBM Authority, o=ibm, c=us`) is mapped to an identity in the user registry (for example, IBMAuthority). To ensure that the asserting authority is trusted, the mapped identity (for example, IBMAuthority) is validated against a list of trusted identities. When the <TrustMode> element is `BasicAuth`, there is a user name token with a user name and password, which is the user name and password of the asserting authority.

The user name and password are validated. If they are successfully validated, that user name (for example, IBMAuthority) is validated against a list of trusted identities. If a value is not specified for `<TrustMode>`, trust is presumed and additional trust validation is not performed. This type of identity assertion is called *presumed trust mode*. Use the presumed trust mode only in an environment where the trust is established using some other mechanism.

If all the validations described previously succeed, the asserted identity (for example, Bob) is set as the identity of the running thread. If any of the validations fail, the request is rejected with a SOAP fault exception.

Configuring the server to handle basic authentication information

Basic authentication (BasicAuth) refers to the user ID and the password of a valid user in the registry of the target server. After a request is received that contains basic authentication information, the server needs to log in to form a credential. The credential is used for authorization.

Before you begin

Important: There is an important distinction between Version 5.*x* and Version 6.0.*x* and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

About this task

Complete the following steps to configure the server to handle BasicAuth authentication information:

Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **EJB Projects** > ***application_name*** > **ejbModule** > **META-INF**.
4. Right-click the `webservices.xml` file, and click **Open with** > **Web services editor**.
5. Click the **Extensions** tab, which is located at the bottom of the web services editor within an assembly tool.
6. Expand the **Request receiver service configuration details** > **Login configuration** section. You can select the following options:
   - **BasicAuth**
   - **Signature**
   - **ID assertion**
   - **Lightweight Third Party Authentication (LTPA)**
7. Select **BasicAuth** to authenticate the client with a user ID and a password. The client must specify a valid user ID and password in the server user registry. If the user ID and the password supplied are not valid, an exception is provided, and the request ends without invoking the resource.

You can select multiple login configurations, which means that different types of security information might be received at the server. The order in which the login configurations are added decides the order in which they are processed when a request is received. Problems can occur if you have multiple login configurations added that have security tokens in common. For example, ID assertion contains a BasicAuth token. For ID assertion to work properly, list ID assertion ahead of BasicAuth in the processing list or the BasicAuth processing overrides the IDAssertion processing.

What to do next

After you specify how the server handles BasicAuth authentication information, you must specify how the server validates the authentication information. See the task for configuring the server to validate BasicAuth authentication if you have not previously specified this information.

Configuring the server to validate basic authentication information

Basic authentication (BasicAuth) refers to the user ID and the password of a valid user in the registry of the target server. You can specify how the server validates the BasicAuth information.

Before you begin

Important: There is an important distinction between Version 5.*x* and Version 6.0.*x* and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

After a request is received that contains basic authentication information, the server needs to log in to form a credential. The credential is used for authorization. If the user ID and the password supplied is invalid, an exception is thrown and the request ends without invoking the resource.

About this task

Complete the following steps to specify how the server validates the BasicAuth authentication information:

Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **EJB Projects** > ***application_name*** > **ejbModule** > **META-INF**.
4. Right-click the `webservices.xml` file, and click **Open with** > **Web services editor**.
5. Click the **Binding Configurations** tab, which is located at the bottom of the web services editor within an assembly tool.
6. Expand the **Request receiver binding configuration details** > **Login mapping** section.
7. Click **Edit** to view the login mapping information or click **Add** to add new login mapping information. The login mapping dialog is displayed. Select or enter the following information:

   Authentication method
   Specifies the type of authentication that occurs. Select **BasicAuth** to use basic authentication.

   Configuration name
   Specifies the Java Authentication and Authorization Service (JAAS) login configuration name. For the BasicAuth authentication method, enter `WSLogin` for the JAAS login Configuration name.

   Use token valid type
   Determines if you want to specify a custom token type. For the default authentication method selections, you do not need to specify this option.

Token value type URI and Token value type URI local name
When you select BasicAuth, you cannot edit the token value type URI and local name values. Specifies custom authentication types. For BasicAuth authentication leave these fields blank.

Callback handler factory class name
Creates a JAAS CallbackHandler implementation that understands the following callbacks:

- javax.security.auth.callback.NameCallback
- javax.security.auth.callback.PasswordCallback
- com.ibm.wsspi.wssecurity.auth.callback.BinaryTokenCallback
- com.ibm.wsspi.wssecurity.auth.callback.XMLTokenReceiverCallback
- com.ibm.wsspi.wssecurity.auth.callback.PropertyCallback

Callback handler factory property name and Callback handler factory property value
Specifies callback handler properties for custom callback handler factory implementations. You do not need to specify any properties for the default callback handler factory implementation. For BasicAuth, you do not need to enter any property values.

Login mapping property name and Login mapping property value
Specifies properties for a custom login mapping. For the default implementations including BasicAuth, leave these fields blank.

What to do next

You must specify how the server handles the BasicAuth authentication method. See the task for configuring the server to handle basic authentication if you have not previously specified this information.

Configuring identity assertion for Version 5.x web services with an assembly tool

With the identity assertion authentication method, the security token generates a <wsse:UsernameToken> element that contains a <wsse:Username> element. On the request sender side, a callback handler is invoked to generate the security token. On the request receiver side, the security token is validated. Trust is established through the use of a security token rather than through user name and password validation.

Securing web services for Version 5.x applications using identity assertion authentication

With the identity assertion authentication method, the security token generates a <wsse:UsernameToken> element that contains a <wsse:Username> element. On the request sender side, a callback handler is invoked to generate the security token. On the request receiver side, the security token is validated. Unlike BasicAuth authentication, trust is established through the use of a security token rather than through user name and password validation.

Before you begin

Important: There is an important distinction between Version 5.*x* and Version 6.0.*x* and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

WebSphere Application Server provides several different methods to secure your web services. Identity assertion authentication is one of these methods. You might also secure your web services using any of the following methods:

- XML digital signature
- XML encryption
- BasicAuth authentication

- Identity assertion authentication
- Signature authentication
- Pluggable token

About this task

To use identity assertion authentication to secure web services, complete the following tasks:

Procedure

1. Secure the client for identity assertion authentication.
   a. “Configuring the client for identity assertion: specifying the method”
   b. “Configuring the client for identity assertion: collecting the authentication method” on page 1735
2. Secure the server for identity assertion authentication.
   a. “Configuring the server to handle identity assertion authentication” on page 1736
   b. “Configuring the server to validate identity assertion authentication information” on page 1738

Results

After completing these steps, you have secured your web services by using identity assertion authentication.

Configuring the client for identity assertion: specifying the method

You can configure identity assertion authentication. The purpose of identity assertion is to assert the authenticated identity of the originating client from a web service to a downstream web service.

About this task

Important: There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

This task is used to configure identity assertion authentication. The purpose of identity assertion is to assert the authenticated identity of the originating client from a web service to a downstream web service. Do not attempt to configure identity assertion from a pure client. Identity assertion works only when you configure on the client-side of a web service acting as a client to a downstream web service.

In order for the downstream web service to accept the identity of the originating client (just the user name), you must supply a special trusted BasicAuth credential that the downstream web service trusts and can authenticate successfully. You must specify the user ID of the special BasicAuth credential in a trusted ID evaluator on the downstream web service configuration. See topics about trusted ID evaluators.

Complete the following steps to specify identity assertion as the authentication method:

Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **Application Client Projects** > ***application_name*** > **appClientModule** > **META-INF**.
4. Right-click the `application-client.xml` file, select **Open with** > **Deployment descriptor editor**.
5. Click the **WS Extension** tab, which is located at the bottom of the deployment descriptor editor within the assembly tool.
6. Expand the **Request sender configuration** > **Login configuration** section.

7. Select **IDAssertion** as the authentication method. For more conceptual information on identity assertion authentication, see Identity assertion in a SOAP message.
8. Expand the **IDAssertion** section.
9. For the ID type, select **Username**. This value works with all registry types and originating authentication methods.
10. For the trust mode, select either **BasicAuth** or **Signature**.
    - By selecting **BasicAuth**, you must include basic authentication information (user ID and password), which the downstream web service has specified in the trusted ID evaluator as a trusted user ID. See “Configuring the client for signature authentication: collecting the authentication information” on page 1742 to specify the user ID and password information.
    - By selecting **Signature** the certificate configured in the signature information section used to sign the data also is that is used as the trusted subject. The Signature is used to create a credential and user ID, which the certificate mapped to the downstream registry, is used in the trusted ID evaluator as a trusted user ID.

What to do next

See “Configuring the client security bindings using an assembly tool” on page 1708 for more information on the web services client editor within the assembly tool.

After you specify identity assertion as the authentication method used by the client, you must specify how to collect the authentication information. See “Configuring the client for identity assertion: collecting the authentication method” for more information.

Configuring the client for identity assertion: collecting the authentication method

You can configure identity assertion authentication. The purpose of identity assertion is to assert the authenticated identity of the originating client from a web service to a downstream web service.

About this task

Important: There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

This task is used to configure identity assertion authentication. The purpose of identity assertion is to assert the authenticated identity of the originating client from a web service to a downstream web service. Do not attempt to configure identity assertion from a pure client. Identity assertion works only when you configure on the client-side of a web service acting as a client to a downstream web service.

In order for the downstream web service to accept the identity of the originating client (just the user name), you must supply a special trusted BasicAuth credential that the downstream web service trusts and can authenticate successfully. You must specify the user ID of the special BasicAuth credential in a trusted ID evaluator on the downstream web service configuration. See the information on trusted ID evaluators.

Complete the following steps to specify how the client collects the authentication information:

Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **Application Client Projects** > ***application_name*** > **appClientModule** > **META-INF**.
4. Right-click the `application-client.xml` file, select **Open with** > **Deployment descriptor editor**.

5. Click the **WS Binding** tab, which is located at the bottom of the Deployment Descriptor Editor within an assembly tool.
6. Expand the **Security request sender binding configuration** > **Login binding** section.
7. Click **Edit** to view the login binding information and select **IDAssertion**. The login binding dialog is displayed. Select or enter the following information:

   Authentication method
   The authentication method specifies the type of authentication that occurs. Select **IDAssertion** to use identity assertion.

   Token value type URI and Token value type Local name
   When you select IDAssertion, you cannot edit the token value type Universal Resource Identifier (URI) and the local name. Specifies custom authentication types. For IDAssertion authentication, leave these values blank.

   Callback handler
   Specifies the Java Authentication and Authorization Service (JAAS) callback handler implementation for collecting the BasicAuth information. Specify the `com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler` implementation for IDAssertion.

   Basic authentication User ID and Basic authentication Password
   In this field, the trust mode entered in the extensions is BasicAuth. Specifies the trusted user ID and password in these fields. The user ID specified must be an ID that is trusted by the downstream web service. The web service trusts the user ID if it is entered as a trusted ID in a trusted ID evaluator in the downstream web service bindings. If the trust mode entered in the extensions is `Signature`, you do not need to specify any information in this field.

   Property name and Property value
   Specifies properties with name and value pairs, for use by custom callback handlers. For IDAssertion, you do not need to specify any information in this field.

What to do next

To use the identity assertion authentication method, you must specify the method in the Security extensions section of an assembly tool. See “Configuring the client for identity assertion: specifying the method” on page 1734 if you have not previously specified this information.

Configuring the server to handle identity assertion authentication

The purpose of identity assertion is to assert the authenticated identity of the originating client from a web service to a downstream web service. You can configure identity assertion authentication for the server. Do not attempt to configure identity assertion from a pure client.

About this task

Important: There is an important distinction between Version 5.*x* and Version 6.0.*x* and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

For the downstream web service to accept the identity of the originating client (user name only), you must supply a special trusted BasicAuth credential that the downstream web service trusts and can authenticate successfully. You must specify the user ID of the special BasicAuth credential in a trusted ID evaluator on the downstream web service configuration. For more information on trusted ID evaluators, see Trusted ID evaluator. The server side passes the special BasicAuth credential into the trusted ID evaluator, which returns `true` or `false` that this ID is trusted. After it is trusted, the user name of the client is mapped to the credential, which is used for authorization.

Complete the following steps to configure the server to handle identity assertion authentication information:

Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **EJB Projects** > ***application_name*** > **ejbModule** > **META-INF**.
4. Right-click the `webservices.xml` file, and click **Open with** > **Web services editor**.
5. Click the **Extensions** tab, which is located at the bottom of the web services editor within the assembly tool.
6. Expand the **Request receiver service configuration details** > **Login configuration** section. The options you can select are:
   - **BasicAuth**
   - **Signature**
   - **ID assertion**
   - **LTPA** (Lightweight Third Party Authentication)
7. Select **IDAssertion** to authenticate the client using the identity assertion data provided.

   The user ID of the client must be in the target user registry or repository, which is configured on the **Security** > **Global security** panel in the administrative console for WebSphere Application Server. You can select multiple login configurations, which means that different types of security information can be received at the server. The order in which the login configurations are added determines the processing order when a request is received. Problems can occur if you have multiple login configurations added that have common security tokens. For example, ID assertion contains a BasicAuth token, which is the trusted token. For ID assertion to work properly, you must list ID assertion ahead of BasicAuth in the list or BasicAuth processing overrides ID assertion processing.
8. Expand the **IDAssertion** section and select both the **ID Type** and the **Trust Mode**.
   a. For ID Type, the options are:
      - **Username**
      - **DN** (distinguished name)
      - **X509certificate**

      These choices are just preferences and are not guaranteed. Most of the time the Username option is used. You must choose the same ID Type as the client.
   b. For Trust Mode, the options are:
      - **BasicAuth**
      - **Signature**

      The Trust Mode refers to the information sent by the client as the trusted ID.
      1) If you select **BasicAuth**, the client sends basic authentication data (user ID and password). This BasicAuth data is authenticated to the configured user registry. When the authentication occurs successfully, the user ID must be part of the trusted ID evaluator trust list.
      2) If you select **Signature**, the client signing certificate is sent. This certificate must be mappable to the configured user registry. For **Local OS**, the common name (CN) of the distinguished name (DN) is mapped to a user ID in the registry. For **Lightweight Directory Access Protocol (LDAP)**, the DN is mapped to the registry for the ExactDN mode. If it is in the CertificateFilter mode, attributes are mapped accordingly. In addition, the user name from the credential generated must be in the Trusted ID Evaluator trust list.

What to do next

For more information on getting started with the Web Services Editor within an assembly tool, see “Configuring the server security bindings using an assembly tool” on page 1711.

After you specify how the server handles identity assertion authentication information, you must specify how the server validates the authentication information. See the task for configuring the server to validate identity assertion authentication information.

Configuring the server to validate identity assertion authentication information

The purpose of identity assertion is to assert the authenticated identity of the originating client from a web service to a downstream Web service.

About this task

Important: There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6 and later applications.

Use this task to configure identity assertion authentication. Do not attempt to configure identity assertion from a pure client.

For the downstream web service to accept the identity of the originating client (user name only), you must supply a special trusted BasicAuth credential that the downstream web service trusts and can authenticate successfully. You must specify the user ID of the special BasicAuth credential in a trusted ID evaluator on the downstream web service configuration. For more information on trusted ID evaluators, see the topic about the trusted ID evaluator. The server side passes the special BasicAuth credential into the trusted ID evaluator, which returns a `true` or `false` response that this ID is trusted. After it is trusted, the user name of the client is mapped to the credential, which is used for authorization.

Complete the following steps to validate the identity assertion authentication information:

Procedure

1. Launch an assembly tool. For more information, see the related information on assembly tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective > J2EE**.
3. Click **EJB Projects** > ***application_name*** > **ejbModule** > **META-INF**.
4. Right-click the `webservices.xml` file, and click **Open with** > **Web services editor**.
5. Click the Binding Configurations tab, which is located at the bottom of the web services editor within the assembly tool.
6. Expand the **Request receiver binding configuration details** > **Login mapping** section.
7. Click **Edit** to view the login mapping information. Click **Add** to add new login mapping information. The login mapping dialog is displayed. Select or enter the following information:

   Authentication method
   Specifies the type of authentication that occurs. Select **IDAssertion** to use basic authentication.

   Configuration name
   Specifies the Java Authentication and Authorization Service (JAAS) login configuration name. For the IDAssertion authentication method, enter `system.wssecurity.IDAssertion` for the Java Authentication and Authorization Service (JAAS) login configuration name.

Use token value type
Determines if you want to specify a custom token type. For the default authentication method selections, you do not need to specify this option.

Token value type URI and Token value type local name
When you select ID assertion, you cannot edit the token value type URI and local name values. Specifies custom authentication types. For the ID assertion authentication method, leave these values blank.

Callback handler factory class name
Ccreates a JAAS CallbackHandler implementation that understands the following callbacks:

- javax.security.auth.callback.NameCallback
- javax.security.auth.callback.PasswordCallback
- com.ibm.wsspi.wssecurity.auth.callback.BinaryTokenCallback
- com.ibm.wsspi.wssecurity.auth.callback.XMLTokenReceiverCallback
- com.ibm.wsspi.wssecurity.auth.callback.PropertyCallback

For any of the default authentication methods (BasicAuth, IDAssertion, and Signature), use the callback handler factory default implementation. Enter the following class name for any of the default Authentication methods including IDAssertion:

```
com.ibm.wsspi.wssecurity.auth.callback.WSCallbackHandlerFactoryImpl
```

This implementation creates the correct callback handler for the default implementations.

Callback handler factory property name and Callback handler factory property value
Specifies callback handler properties for custom callback handler factory implementations. The default callback handler factory implementation does not need any specified properties. For ID assertion, leave these values blank.

Login mapping property name and Login mapping property value
Specifies properties for a custom login mapping. For the default implementations including IDAssertion, leave these values blank.

8. Expand the **Trusted ID evaluator** section.
9. Click **Edit** to see a dialog that displays all the trusted ID evaluator information. The following table describes the purpose of this information.

Class name
Refers to the implementation of the trusted ID evaluator that you want to use. Enter the default implementation as

```
com.ibm.wsspi.wssecurity.id.TrustedIDEvaluatorImpl
```

If you want to implement your own trusted ID evaluator, you must implement the `com.ibm.wsspi.wssecurity.id.TrustedIDEvaluator` interface.

Property name
Represents the name of this configuration. Enter `BasicIDEvaluator`.

Property value
Defines the name and value pairs that can be used by the trusted ID evaluator implementation. For the default implementation, the trusted list is defined here. When a request comes in and the trusted ID is verified, the user ID, as it appears in the user registry, must be listed in this property. Specify the property as a name and value pair where the name is *trustedId_n*. *n* is an integer starting from 0 and the value is the user ID associated with that name. An example list with the trusted names include two properties.

For example: `trustedId_0 = user1, trustedId_1 = user2`. The previous example means that both `user1` and `user2` are trusted. `user1` and `user2` must be listed in the configured user registry

10. Expand the **Trusted ID evaluator reference** section.

11. Click **Enable** to add a new entry. The text you enter for the **Trusted ID evaluator reference** must be the same as the name entered previously in the **Trusted ID evaluator**. Make sure that the name matches exactly because the information is case sensitive. If an entry is already specified, you can change it by clicking **Edit**.

What to do next

You must specify how the server handles the identity assertion authentication method. See “Configuring the server to handle identity assertion authentication” on page 1736 if you have not previously specified this information.

Configuring signature authentication for Version 5.x web services with an assembly tool

With the signature authentication method, the request sender generates a signature security token using a callback handler. The security token returned by the callback handler is inserted in the SOAP message. The request receiver retrieves the Signature security token from the SOAP message and validates it using a Java™ Authentication and Authorization Service (JAAS) login module.

Securing web services for version 5.x applications using signature authentication

WebSphere Application Server provides several different methods to secure your web services. XML digital signature is one of these methods.

Before you begin

Important: There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6 and later applications.

You can secure your web services by using any of the following methods:

- XML digital signature
- XML encryption
- BasicAuth authentication
- Identity assertion authentication
- Signature authentication
- Pluggable token

About this task

With the signature authentication method, the request sender generates a signature security token using a callback handler. The security token returned by the callback handler is inserted in the SOAP message. The request receiver retrieves the Signature security token from the SOAP message and validates it using a Java Authentication and Authorization Service (JAAS) login module. To use signature authentication to secure Web services, complete the following tasks:

Procedure

1. Secure the client for signature authentication.
   a. “Configuring the client for signature authentication: specifying the method” on page 1741.
   b. “Configuring the client for signature authentication: collecting the authentication information” on page 1742.
2. Secure the server for signature authentication.
   a. “Configuring the server to support signature authentication” on page 1744.

b. “Configuring the server to validate signature authentication information” on page 1745.

Results

After completing these steps, you have secured your web services using signature authentication.

Configuring the client for signature authentication: specifying the method

Signature authentication, the use of an X.509 certificate to login on the target server, can be configured.

About this task

Important: There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

This task is used to configure signature authentication. A signature refers to the use of an X.509 certificate to login on the target server. For more information on signature authentication, see “Signature authentication method.”

Complete the following steps to specify signature as the authentication method:

Procedure

1. Launch an assembly tool. For more information, read about assembly tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **Application Client Projects** > ***application_name*** > **appClientModule** > **META-INF** .
4. Right-click the `application-client.xml` file, select **Open with** > **Deployment descriptor editor**.
5. Click the **WS Extension** tab, which is located at the bottom of the deployment descriptor editor within the assembly tool.
6. Expand the **Request sender configuration** > **Login configuration** section. The following login configuration options are valid for a managed client and Web services acting as a client are:

   BasicAuth
   Use this option for a managed client.

   Signature
   Use this option for a managed client.

   IDAssertion
   Use this option for web services acting as a client.
7. Select **Signature** to authenticate the client using the certificate used to digitally sign the request.

Results

For more information on getting started with the web services client editor within the assembly tool, see “Configuring the client security bindings using an assembly tool” on page 1708.

After you specify signature as the authentication method, you must specify how to collect the authentication information. See “Configuring the client for signature authentication: collecting the authentication information” on page 1742 for more information.

Signature authentication method:

Signature authentication refers to an X.509 certificate that is sent by the client to the server. The certificate is used to authenticate to the user registry that is configured at the server. When using the signature authentication method, the security token is generated with a ds:Signature and a wsse:BinarySecurityToken element.

Important: There is an important distinction between Version 5.*x* and Version 6.0.*x* and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

On the request sender side, a callback handler is invoked to generate the security token. On the request receiver side, a Java Authentication and Authorization Service (JAAS) login module is used to validate the security token. These two operations, token generation and token validation, are described in the following sections.

Signature token generation

The request sender generates a Signature security token using a callback handler. The security token returned by the callback handler is inserted in the SOAP message. The callback handler is specified in the <LoginBinding> element of the bindings file, `ibm-webservicesclient-bnd.xmi`. WebSphere Application Server provides the following callback handler implementation that can be used with the Signature authentication method:
com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler

You can add your own callback handlers that implement the javax.security.auth.callback.CallbackHandler implementation.

Security token validation

The request receiver retrieves the Signature security token from the SOAP message and validates it using a JAAS login module. The <ds:Signature> and <wsse:BinarySecurityToken> elements in the security token are used to perform the validation. If the validation is successful, the login module returns a Java Authentication and Authorization Service (JAAS) Subject. This Subject then is set as the identity of the running thread. If the validation fails, the request is rejected with a SOAP fault exception.

The JAAS login configuration is specified in the `<LoginMapping>` element of the bindings file. Default bindings are specified in the `ws-security.xml` file. However, you can override these bindings using the application-specific `ibm-webservices-bnd.xmi` file. The configuration information consists of a CallbackHandlerFactory and a ConfigName. The CallbackHandlerFactory specifies the name of a class that is used for creating the JAAS CallbackHandler object. WebSphere Application Server provides the com.ibm.wsspi.wssecurity.auth.callback.WSCallbackHandlerFactoryImp CallbackHandlerFactory implementation. The ConfigName specifies a JAAS configuration name entry. WebSphere Application Server searches in the `security.xml` file for a matching configuration name entry. If a match is not found, it searches the `wsjaas.conf` file. WebSphere Application Server provides the system.wssecurity.Signature default configuration entry, which is suitable for the signature authentication method.

Configuring the client for signature authentication: collecting the authentication information

Signature authentication refers to an X.509 certificate that is sent by the client to the server. The certificate is used to authenticate to the user registry that is configured at the server. The client collects the authentication information for signature authentication.

About this task

Important: There is an important distinction between Version 5.*x* and Version 6.0.*x* and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

You can configure signature authentication. A signature refers to the use of an X.509 certificate to login on the target server.

Complete the following steps to specify how the client collects the authentication information for signature authentication:

Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **Application Client Projects** > ***application_name*** > **appClientModule** > **META-INF**.
4. Right-click the `application-client.xml` file, select **Open with** > **Deployment descriptor editor**.
5. Click the WS Binding tab, which is located at the bottom of the deployment descriptor editor within the assembly tool.
6. Expand the **Security request sender binding configuration** > **Signing information** and click **Edit** to modify the signing key name and signing key locator. To create new signing information, click **Enable**. The certificate that is sent to log in at the server is the one configured in the Signing Information section. Review the key locator information to understand how the signing key name maps to a key within the key locator entry.

   The following list describes the purpose of this information. Some of these definitions are based on the XML-Signature specification, which is located at the following web address: http://www.w3.org/TR/xmldsig-core

   Canonicalization method algorithm
   Canonicalizes the <SignedInfo> element before it is digested as part of the signature operation.

   Digest mehod algorithm
   Represents the algorithm that is applied to the data after transforms are applied, if specified, to yield the <DigestValue> element. The signing of the <DigestValue> element binds the resource content to the signer key. The algorithm selected for the client request sender configuration must match the algorithm selected in the server request receiver configuration.

   Signature method algorithm
   Represents the algorithm that is used to convert the canonicalized <SignedInfo> element value into the <SignatureValue> value. The algorithm selected for the client request sender configuration must match the algorithm selected in the server request receiver configuration.

   Signing key name
   Represents the key entry that is associated with the signing key locator. The key entry refers to an alias of the key, which is used to sign the request.

   Signing key locator
   Represents a reference to a key locator implementation.
7. Expand the **Security request sender binding configuration** > **Login binding** section.
8. Click **Edit** to view the login binding information. Select or enter the following information:

   Authentication method
   Specifies the type of authentication that occurs. Select **Signature** to use signature authentication.

Token value type URI and Token value type URI local name
When you select **Signature**, you cannot edit token value type Uniform Resource Identifier (URI) and local name values. Specifies custom authentication types. For signature authentication, leave these fields blank.

Callback handler
Specifies the Java Authentication and Authorization Server (JAAS) callback handler implementation for collecting signature information. Enter the following callback handler for signature authentication:
`com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler`

This callback handler is used because the signature method does not require user interaction.

Basic authentication user ID and Basic authentication password
Leave the BasicAuth fields blank when signature authentication is used.

Property name and property value
This field enables you to enter properties and name and value pairs for use by custom callback handlers. For signature authentication, do not enter any information.

What to do next

Other customization entries: There is a basic authentication entry in the Port Qualified Name Binding Details section. This entry is used for HTTP transport authentication, which might be required if the router servlet is protected.

Information specified in the Web Services Security signature authentication section overrides the basic authentication information specified in the Port Qualified Name Binding Details section for authorizing the Web service.

To use the signature authentication method, you must specify the authentication method in the Login configuration section of an assembly tool.

Configuring the server to support signature authentication

Signature authentication refers to an X.509 certificate sent by the client to the server. The certificate is used to authenticate to the user registry configured at the server. After a request is received by the server that contains the certificate, the server needs to log in to form a credential. The credential is used for authorization. You can configure signature authentication at the server.

About this task

Important: There is an important distinction between Version 5.*x* and Version 6.0.*x* and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

If the certificate supplied cannot be mapped to an entry in the user registry, an exception is provided and the request ends without invoking the resource.

Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective by clicking **Window** > **Open perspective** > **Other** > **J2EE**.
3. Click **EJB Projects** > ***application_name*** > **ejbModule** > **META-INF**.
4. Right-click the `webservices.xml` file, and click **Open with** > **Web services editor**.
5. Click the **Extensions** tab, which is located at the bottom of the Web Services Editor within the assembly tool.

6. Expand the **Request receiver service configuration details** > **Login configuration** section. You can select from the following options:
   - BasicAuth
   - Signature
   - ID assertion
   - Lightweight Third Party Authentication (LTPA)
7. Select **Signature** to authenticate the client using an X509 certificate. The certificate that is sent from the client is the certificate that issued for signing the message. You must be able to map this certificate to the configured user registry. For Local operating system (OS) registries, the common name (cn) of the distinguished name (DN) is mapped to a user ID in the registry. For Lightweight Directory Access Protocol (LDAP), you can configure multiple mapping modes:
   - `EXACT_DN` is the default mode that directly maps the DN of the certificate to an entry in the LDAP server.
   - `CERTIFICATE_FILTER` is the mode that provides the LDAP advanced configuration with a place to specify a filter that maps specific attributes of the certificate to specific attributes of the LDAP server.

What to do next

For more information on getting started with the web services editor within the assembly tool, see "Configuring the server security bindings using an assembly tool" on page 1711.

After you specify how the server handles signature authentication information, you must specify how the server validates the authentication information. See the task for configuring the server to validate signature authentication.

Configuring the server to validate signature authentication information

Signature authentication refers to an X.509 certificate sent by the client to the server. The certificate is used to authenticate to the user registry configured at the server. After a request is received by the server that contains the certificate, the server needs to log in to form a credential. The credential is used for authorization. You can validate signature authentication at the server.

About this task

Important: There is an important distinction between Version 5.*x* and Version 6.0.*x* and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

If the certificate supplied cannot be mapped to an entry in the user registry, an exception is thrown and the request ends without invoking the resource.

Complete the following steps to configure the server to validate signature authentication:

Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective by clicking **Window** > **Open perspective** > **Other** > **J2EE**.
3. Click **EJB Projects** > ***application_name*** > **ejbModule** > **META-INF**.
4. Right-click the `webservices.xml` file, and click **Open with** > **Web services editor**.
5. Click the **Binding Configurations** tab, which is located at the bottom of the web services editor within the assembly tool.
6. Expand the **Request receiver binding configuration details** > **Login mapping** section.

7. Click **Edit** to view the login mapping information or click **Add** to add new login mapping information. The login mapping dialog is displayed and you select (or enter) the following information:

   Authentication method
   Specifies the type of authentication. Select **Signature** to use signature authentication.

   Configuration name
   Specifies the Java Authentication and Authorization Service (JAAS) login configuration name. For the signature authentication method, enter `system.wssecurity.Signature` for the JAAS login configuration name. This specification logs in with the `com.ibm.wsspi.wssecurity.auth.module.SignatureLoginModule` JAAS login module.

   Use token value type
   Determines if you want to specify a custom token type. For the default authentication method selections, you can leave this field blank.

   URI and local name
   When you select Signature method, you cannot edit the token value type URI and local name values. Specifies custom authentication types. For signature authentication, you can leave this field blank.

   Callback handler factory class name
   Creates a JAAS CallbackHandler implementation that understands the following callback handlers:

   - javax.security.auth.callback.NameCallback
   - javax.security.auth.callback.PasswordCallback
   - com.ibm.wsspi.wssecurity.auth.callback.BinaryTokenCallback
   - com.ibm.wsspi.wssecurity.auth.callback.XMLTokenReceiverCallback
   - com.ibm.wsspi.wssecurity.auth.callback.PropertyCallback

   For any of the default authentication methods (BasicAuth, IDAssertion, and Signature), use the callback handler factory default implementation. Enter the following class name for any of the default authentication methods including signature:

```
com.ibm.wsspi.wssecurity.auth.callback.WSCallbackHandlerFactoryImpl
```

   This implementation creates the correct callback handler for the default implementations.

   Callback handler factory property name and callback handler factory property value
   Specifies callback handler properties for custom callback handler factory implementations. You do not need to specify any properties for the default callback handler factory implementation. For signature, you can leave this field blank.

   Login mapping property name and login mapping property value
   Specifies properties for a custom login mapping to use. For the default implementations including signature, you can leave this field blank.

What to do next

Specify how the server handles the signature authentication method. See “Configuring the server to support signature authentication” on page 1744 if you have not previously specified this information.

Configuring pluggable tokens for Version 5.x web services with an assembly tool

WebSphere Application Server provides several different methods to secure your web services, including the pluggable token method. To use pluggable tokens to secure your web services, you must configure both the client request sender and the server request receiver.

Securing web services for version 5.x applications using a pluggable token

To use pluggable tokens to secure your web services, you must configure both the client request sender and the server request receiver. You can configure your pluggable tokens using the WebSphere Application Server administrative console.

About this task

Important: There is an important distinction between Version 5.*x* and Version 6.0.*x* and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

WebSphere Application Server provides several different methods to secure your web services. A pluggable token is one of these methods. You might secure your Web services by using any of the following methods:

- XML digital signature
- XML encryption
- Basicauth authentication
- Identity assertion authentication
- Signature authentication
- Pluggable token

Complete the following steps to secure your web services using a pluggable token:

Procedure

1. Generate a security token using the Java Authentication and Authorization Service (JAAS) CallbackHandler interface. The Web Services Security runtime uses the JAAS CallbackHandler interface as a plug-in to generate security tokens on the client side or when web services are acting as a client.
2. Configure your pluggable token. For more information, see the following tasks:
   - "Configuring pluggable tokens using an assembly tool"
   - Configuring pluggable tokens using the administrative console

Configuring pluggable tokens using an assembly tool

The following information describes how to configure a pluggable token using an assembly tool.

Before you begin

Important: There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

This document describes how to configure a pluggable token in the request sender (`ibm-webservicesclient-ext.xmi` and `ibm-webservicesclient-bnd.xmi` file) and request receiver (`ibm-webservices-ext.xmi` and `ibm-webservices-bnd.xmi` file).

The pluggable token is required for the request sender and request receiver because they are a pair. The request sender and the request receiver must match for the receiver to accept a request.

Prior to completing these steps, it is assumed that you have already created a web service that is based on the Java Platform, Enterprise Edition (Java EE) specification. See either of the following topics for an introduction of how to manage Web Services Security binding information for the server:

- “Configuring the server security bindings using an assembly tool” on page 1711
- Configuring the server security bindings using the administrative console

About this task

You must specify the security constraints in the `ibm-webservicesclient-ext.xmi` and the `ibm-webservices-ext.xmi` files for the required tokens using an IBM assembly tool.

Complete the following steps to configure the request sender using the `ibm-webservicesclient-ext.xmi` and `ibm-webservicesclient-bnd.xmi` files:

Procedure

1. Launch an assembly tool. For more information, read about assembly tools.
2. Switch to the Java EE perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **Application Client Projects** > ***application_name*** > **appClientModule** > **META-INF**.
4. Right-click the `application-client.xml` file, select **Open with** > **Deployment descriptor editor**.
5. Click the **WS Extension** tab. The web service client security extensions editor is displayed.
   a. Under Service References, select an existing service reference or click **Add** to create a new reference.
   b. Under Port Qname Bindings, select an existing port qualified name for the selected service reference or click **Add** to create a new port name binding.
   c. Under Request Sender Configuration: Login Configuration, select an exiting authentication method or type in a new one in the editable list box (Lightweight Third Party Authorization (LTPA) is a supported token generation when web services are acting as client).
   d. Click **File** > **Save** to save the changes.
6. Click the **Web services client binding** tab. The web services client binding editor is displayed.
   a. Under Port qualified name binding, select an existing entry or click **Add** to add a new port name binding. The web services client binding editor displays for the selected port.
   b. Under Login binding, click **Edit** or **Enable**. The Login Binding dialog box is displayed.
      1) In the Authentication Method field, enter the authentication method. The authentication method that you enter in this field must match the authentication method defined on the **Security Extension** tab for the same web service port. This field is mandatory.
      2) (Optional) Enter the token value type information in the URI and Local name fields. These fields are ignored for the BasicAuth, Signature, and IDAssertion authentication methods, but required for other authentication methods. The token value type information is inserted into the <wsse:BinarySecurityToken>@ValueType element for binary security token and is used as the namespace for the XML-based token.
      3) Enter an implementation of the Java Authentication and Authorization Service (JAAS) `javax.security.auth.callback.CallbackHandler` interface. This field is mandatory.
      4) Enter the basic authentication information in the **User ID** and **Password** fields. The basic authentication information is passed to the construct of the `CallbackHandler` implementation. The use of the basic authentication information depends on the implementation of `CallbackHandler`.
      5) In the Property field, add name and value pairs. These pairs are passed to the construct of the `CallbackHandler` implementation as `java.util.Map` values.
      6) Click **OK**.

      Click **Disable** under Login binding on the **Web services client port binding** tab to remove the authentication method login binding.
   c. Click **File** > **Save** to save the changes.

7. In the Package Explorer window, right-click the `webservices.xml` file and click **Open with** > **Web services editor**. The Web Services window displays.
   a. Click the **Security extensions** tab. The Web Service Security extensions editor is displayed.
      1) Under Web Services Description Extension, select an existing service reference or click **Add** to create a new extension.
      2) Under Port Component Binding, select an existing port qualified name for the selected service reference or click **Add** to create a new one.
      3) Under Request Receiver Service Configuration Details: Login Configuration, select an exiting authentication method or click **Add** and enter a new method in the **Add AuthMethod** field that displays. You can select multiple authentication methods for the request receiver. The security token of the incoming message is authenticated against the authentication methods in the order that they are specified in the list. Click **Remove** to remove the selected authentication method or methods.
   b. Click **File** > **Save** to save the changes.
   c. Click the **Bindings** tab. The web services bindings editor is displayed.
      1) Under web service description bindings, select an existing entry or click **Add** to add a new web services descriptor.
      2) Click the **Binding configurations** tab. The web services binding configurations editor is displayed for the selected web services descriptor.
      3) Under Request receiver binding configuration details: login mapping, click **Add** to create a new login mapping or click **Edit** to edit the selected login mapping. The Login mapping dialog is displayed.
         a) In the Authentication method field, enter the authentication method. The information entered in this field must match the authentication method defined on the **Security Extensions** tab for the same web service port. This field is mandatory.
         b) In the **Configuration name** field, enter a JAAS login configuration name. This field is mandatory. You must define the JAAS login configuration name in the WebSphere Application Server administrative console under **Security** > **Global security**. Under Authentication, click **Java Authentication and Authorization Service** > **Application logins**. For more information, read about configuring programmatic logins for Java Authentication and Authorization Service.
         c) (Optional) Select **Use Token value type** and enter the token value type information in the URI and Local name fields. This information is optional for BasicAuth, Signature and IDAssertion authentication methods, but required for any other authentication method. The token value type is used to validate the <wsse:BinarySecurityToken>@ValueType element for binary security tokens and to validate the namespace of the XML-based token.
         d) Under Callback Handler Factory, enter an implementation of the `com.ibm.wsspi.wssecurity.auth.callback.CallbackHandlerFactory` interface in the Class name field. This field is mandatory.
         e) Under Callback Handler Factory property, click **Add** and enter the name and value pairs for the Callback Handler Factory Property. These name and value pairs are passed as `java.util.Map` to the `com.ibm.wsspi.wssecurity.auth.callback.CallbackHandlerFactory.init()` method. The use of these name and value pairs is determined by the `CallbackHandlerFactory` implementation.
         f) Under Login Mapping Property, click **Add** and enter the name and value pairs for the Login mapping property. These name and value pairs are available to the JAAS Login Modules through the `com.ibm.wsspi.wssecurity.auth.callback.PropertyCallback` JAAS Callback interface. Click **Remove** to delete the selected login mapping.
         g) Click **OK**.
   d. Click **File** > **Save** to save the changes.

Results

The previous steps define how to configure the request sender to create security tokens in the SOAP message and to configure the request receiver to validate the security tokens found in the incoming SOAP message. WebSphere Application Server supports pluggable security tokens.

You can use the authentication method defined in the login bindings and login mappings to generate security tokens in the request sender and validate security tokens in the request receiver.

What to do next

After you configure pluggable tokens, you must configure both the client and the server to support pluggable tokens. See the following topics to configure the client and the server:

- Configuring the client for LTPA token authentication: Specifying LTPA token authentication
- Configuring the client for LTPA token authentication: Collecting the authentication information
- Configuring the server to handle LTPA token authentication
- Configuring the server to validate LTPA token authentication information

Configuring the client for LTPA token authentication: specifying LTPA token authentication

To configure Lightweight Third-Party Authentication (LTPA) token authentication, specify LTPA token authentication. Only configure the client for LTPA token authentication if the authentication mechanism configured in WebSphere Application Server is LTPA.

About this task

Important: There is an important distinction between Version 5.*x* and Version 6.0.*x* and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

Use this task to configure Lightweight Third-Party Authentication (LTPA) token authentication. Only configure the client for LTPA token authentication if the authentication mechanism configured in WebSphere Application Server is LTPA. When a client authenticates to a WebSphere Application Server, the credential created contains an LTPA token. When a web service calls a downstream web service, you can configure the first web service to send the LTPA token from the originating client. Do not attempt to configure LTPA from a pure client. LTPA works only when you configure the client-side of a web service acting as a client to a downstream web service. For the downstream web service to validate the LTPA token, the LTPA keys on both servers must be the same.

Complete the following steps to specify LTPA token as the authentication method:

Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **Application Client Projects** > ***application_name*** > **appClientModule** > **META-INF**.
4. Right-click the `application-client.xml` file, select **Open with** > **Deployment descriptor editor**.
5. Click the **Extensions** tab, which is located at the bottom of the deployment descriptor editor within the assembly tool.
6. Expand the **Request sender configuration** > **Login configuration** section.
7. Select **LTPA** as the authentication method. For more conceptual information on LTPA authentication, see “Lightweight Third Party Authentication” on page 1754.

What to do next

After you specify LTPA token as the authentication method, you must specify how to collect the LTPA token information. See “Configuring the client for LTPA token authentication: collecting the authentication method information” for more information.

Configuring the client for LTPA token authentication: collecting the authentication method information

To configure Lightweight Third-Party Authentication (LTPA) token authentication, collect the LTPA token authentication information. Do not configure the client for LTPA token authentication unless the authentication mechanism configured in WebSphere Application Server is LTPA.

About this task

Important: There is an important distinction between Version 5.*x* and Version 6.0.*x* and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

Use this task to configure Lightweight Third-Party Authentication (LTPA) token authentication. Do not configure the client for LTPA token authentication unless the authentication mechanism configured in WebSphere Application Server is LTPA. When a client authenticates to a WebSphere Application Server, the credential created contains an LTPA token. When a web service calls a downstream web service, you can configure the first web service to send the LTPA token from the originating client. Do not attempt to configure LTPA from a pure client. LTPA works only when you configure the client-side of a web service acting as a client to a downstream web service. In order for the downstream web service to validate the LTPA token, the LTPA keys on both servers must be the same.

Complete the following steps to specify how to collect the LTPA token authentication information:

Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **Application Client Projects** > ***application_name*** > **appClientModule** > **META-INF**.
4. Right-click the `application-client.xml` file, select **Open with** > **Deployment descriptor editor**.
5. Click the **WS Bindings** tab, which is located at the bottom of the deployment descriptor editor within the assembly tool.
6. Expand the **Security request sender binding configuration** > **Login binding** section.
7. Click **Edit** to view the login binding information and select **LTPA**. If LTPA is not already there, enter it as an option. The login binding dialog is displayed. Select or enter the following information:

   Authentication method
   Specifies the type of authentication that occurs. Select **LTPA** to use identity assertion.

   Token value type URI and token value type local name
   When you select **LTPA**, you must edit the token value type **URI** (Uniform Resource Identifier) and the **local name** fields. Specifies values for custom authentication types, which are authentication methods not mentioned in the specification. For the token value type **URI** field, enter the following string: `http://www.ibm.com/websphere/appserver/tokentype/5.0.2`. For the **local name** field, enter the following string: `LTPA`.

   Callback handler
   Specifies the Java Authentication and Authorization Service (JAAS) callback handler

implementation for collecting the LTPA information. Specify the `com.ibm.wsspi.wssecurity.auth.callback.LTPATokenCallbackHandler` implementation for LTPA.

Basic authentication user ID and basic authentication password
For LTPA, you can leave these fields empty. However, when you omit this information, the LTPA `CallbackHandler` implementation attempts to obtain the LTPA token from the invocation (RunAs) credential. If an invocation (RunAs) credential does not exist, then the LTPA token is not propagated.

Property name and property value
For LTPA, you can leave these fields blank.

What to do next

See "Configuring the client for LTPA token authentication: specifying LTPA token authentication" on page 1750 if you have not previously specified this information.

Configuring the server to handle LTPA token authentication information

Lightweight Third-Party Authentication (LTPA) is a type of authentication mechanism in WebSphere Application Server security that defines a particular token format. The purpose of the LTPA token authentication is to flow the LTPA token from the first web service, which authenticated the originating client, to the downstream web service. You can configure the server for LTPA token authentication.

About this task

Important: There is an important distinction between Version 5.*x* and Version 6.0.*x* and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

This task is used to configure LTPA. Do not attempt to configure LTPA from a pure client. After the downstream web service receives the LTPA token, it validates the token to verify that the token has not been modified and has not expired. For validation to be successful, the LTPA keys that are used by both the sending and receiving servers must be the same.

Complete the following steps to specify that LTPA is the authentication method. The authentication method indicated in these steps must match the authentication method that is specified for the client.

Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java Platform, Enterprise Edition (Java EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **EJB Projects** > ***application_name*** > **ejbModule** > **META-INF**.
4. Right-click the `webservices.xml` file, and click **Open with** > **Web services editor**.
5. Click the Extensions tab, which is located at the bottom of the web services editor within the assembly tool.
6. Expand the **Request receiver service configuration details** > **Login configuration** section. You can select from the following options:
   - **BasicAuth**
   - **Signature**
   - **ID assertion**
   - **LTPA**
7. Select **LTPA** to authenticate the client using the LTPA token received from the request.

What to do next

After you specify the authentication method, you must specify the information that the server must validate. See “Configuring the server to validate LTPA token authentication information” for more information.

Configuring the server to validate LTPA token authentication information

Lightweight Third-Party Authentication (LTPA) is a type of authentication mechanism in WebSphere Application Server security that defines a particular token format. The purpose of the LTPA token authentication is to flow the LTPA token from the first web service, which authenticated the originating client, to the downstream web service. You can configure the server to validate LTPA token authentication.

About this task

Important: There is an important distinction between Version 5.*x* and Version 6.0.*x* and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

This task is used to configure LTPA. Do not attempt to configure LTPA from a pure client. After the downstream web service receives the LTPA token, it validates the token to verify that the token has not been modified and has not expired. For validation to be successful, the LTPA keys used by both the sending and receiving servers must be the same.

Complete the following steps to specify how the server must validate the LTPA token authentication information:

Procedure

1. Launch an assembly tool. For more information, see the related information on Assembly Tools.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **EJB Projects** > ***application_name*** > **ejbModule** > **META-INF**.
4. Right-click the `webservices.xml` file, and click **Open with** > **Web services editor**.
5. Click the Binding Configurations tab, which is located at the bottom of the web services editor within the assembly tool.
6. Expand the **Request receiver binding configuration details** > **Login mapping** section.
7. Click **Edit** to view the login mapping information. The login mapping information is displayed. Select or enter the following information:

   Authentication method
   Specifies the type of authentication that occurs. Select `LTPA` to use LTPA token authentication.

   Configuration name
   Specifies the Java Authentication and Authorization Service (JAAS) login configuration name. For the LTPA authentication method, enter `WSLogin` for the JAAS login configuration name. This configuration understands how to validate an LTPA token.

   Use token value type
   Determines if you want to specify a custom token type. For LTPA authentication, you must select this option because LTPA is considered a custom type. LTPA is not in the Web Services Security Specification.

   Token value type URI and local name
   Specifies custom authentication types. If you select **Use Token value type** you must enter data into the Token value Type URI (Uniform Resource Identifier) and local name fields. For

the token value type URI field, enter the following string: `http://www.ibm.com/websphere/appserver/tokentype/5.0.2`. For the local name, enter the following string: `LTPA`

Callback handler factory class name
Creates a JAAS CallbackHandler implementation that understands the following callback handlers:

- javax.security.auth.callback.NameCallback
- javax.security.auth.callback.PasswordCallback
- com.ibm.wsspi.wssecurity.auth.callback.BinaryTokenCallback
- com.ibm.wsspi.wssecurity.auth.callback.XMLTokenReceiverCallback
- com.ibm.wsspi.wssecurity.auth.callback.PropertyCallback

For any of the default authentication methods (BasicAuth, IDAssertion, Signature, and LTPA), use the callback handler factory default implementation. Enter the following class name for any of the default authentication methods including LTPA:

```
com.ibm.wsspi.wssecurity.auth.callback.WSCallbackHandlerFactoryImpl
```

This implementation creates the correct callback handler for the default implementations.

Callback handler factory property
Specifies callback handler properties for custom callback handler factory implementations. Default callback handler factory implementation does not any property specifications. For LTPA, leave this field blank.

Login mapping property
Specifies properties for a custom login mapping. For default implementations including LTPA, leave this field blank.

What to do next

See the task for configuring the server to handle LTPA token authentication information if you have not previously specified this information.

Lightweight Third Party Authentication:

When you use the lightweight third party authentication (LTPA) method, the <wsse:BinarySecurityToken> security token is generated. On the request sender side, the security token is generated by invoking a callback handler. On the request receiver side, the security token is validated by a Java Authentication and Authorization Service (JAAS) login module.

Important: The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6 and later applications.

The following information describes token generation and token validation operations.

LTPA token generation
The request sender uses a callback handler to generate an LTPA security token. The callback handler returns a security token that is inserted in the SOAP message. Specify the appropriate callback handler in the <LoginBinding> element of the bindings file (`ibm-webservicesclient-bnd.xmi`). The following callback handler implementation can be used with the LTPA authentication method:

- `com.ibm.wsspi.wssecurity.auth.callback.LTPATokenCallbackHandler`

You can add your own callback handlers that implement the `javax.security.auth.callback.CallbackHandler` property.

When using the LTPA authentication method (or any authentication method other than BasicAuth, Signature or IDAssertion), the TokenValueType attribute of the <LoginBinding> element in the bindings file (`ibm-webservicesclient-bnd.xmi`) must be specified. The values to use for the LTPA TokenValueType attribute are:

- `uri="http://www.ibm.com/websphere/appserver/tokentype/5.0.2"`
- `localName="LTPA"`

LTPA token validation

The request receiver retrieves the LTPA security token from the SOAP message and validates the message using a JAAS login module. The <wsse:BinarySecurityToken> security token is used to perform the validation. If the validation is successful, the login module returns a JAAS Subject. Subsequently, this Subject is set as the identity of the running thread. If the validation fails, the request is rejected with a SOAP fault.

The appropriate JAAS login configuration to use is specified in the bindings file <LoginMapping> element. Default bindings specified in the `ws-security.xml` file, but these can be overridden using the application-specific `ibm-webservices-bnd.xmi` file. The configuration information consists of a CallbackHandlerFactory, a ConfigName and a TokenValueType attribute. The CallbackHandlerFactory specifies the name of a class to use to create the JAAS CallbackHandler object. A CallbackHandlerFactory implementation is provided (com.ibm.wsspi.wssecurity.auth.callback.WSCallbackHandlerFactoryImpl). The ConfigName attribute specifies a JAAS configuration name entry. The Web Services Security run time first searches the `security.xml` file for a matching entry and if a matching entry is not found, the run time searches the `wsjaas.conf` file. A default configuration entry suitable for the LTPA authentication method is provided (`WSLogin`). An appropriate TokenValueType element is located in the LTPA LoginMapping section of the default `ws-security.xml` file.

Chapter 35. Developing web services - Transaction support (WS-Transaction)

WS-Transaction is an interoperability standard that includes the WS-AtomicTransaction, WS-BusinessActivity, and WS-Coordination specifications. The Web Services Atomic Transaction (WS-AT) support in the application server provides transactional quality of service to the web services environment. Distributed web services applications, and the resources they use, can take part in distributed global transactions. With Web Services Business Activity (WS-BA) support in the application server, web services on different systems can coordinate activities that are more loosely coupled than atomic transactions. Such activities can be difficult or impossible to roll back atomically, and therefore require a compensation process if an error occurs. Web Services Coordination (WS-COOR) specifies a CoordinationContext and a Registration service with which participant web services can enlist to take part in the protocols that are offered by specific coordination types.

Creating an application that uses the Web Services Business Activity support

To create an application component that uses the business activity support, you must set **Run EJB methods under a Business Activity scope** in the deployment descriptor of the relevant application component, and if required, create and specify a compensation handler for the application to use if there is an error. You then build the component into the application and deploy the application onto a server that has the business activity support enabled. The application component can be either an enterprise bean or a web service that is implemented as an enterprise bean.

Before you begin

For information about editing deployment descriptors by using Rational Application Developer, refer to the Rational Application Developer information.

About this task

Complete this task for an application that runs on a business-activity-enabled sever to use the business activity support at run time, and to undertake work that might later be compensated by a compensation handler. If the application requires compensation when a business activity scope ends, the application passes the data that is required by the compensation process to a compensation handler indirectly, by using the business activity API. The data that is required by the compensation process can be in the form of either a serializable object or a Service Data Object (SDO).

Procedure

1. Design the application component that requires the business activity support. In particular, define the application component requirements for compensation and close activities. If the application component requires compensation, define the nature of the data in the serializable object or the SDO that the application component passes to the compensation handler.
2. Using the information from your application design, create the compensation handler for the application component, if required. This handler defines the close and compensation logic that runs upon completion of a business activity scope that has the handler added to it through an application component.
   a. Open your chosen WebSphere Application Server assembly tool.
   b. Create a new Java class that implements the appropriate interface, depending on the format of the data that is required by the compensation process:
      - For a serializable object, implement the com.ibm.websphere.wsba.serializable.CompensationHandler interface.
      - For an SDO, implement the com.ibm.websphere.wsba.CompensationHandler interface.

c. Implement the close and compensate methods on the new compensation handler object, to take appropriate actions depending on the serializable or SDO data that passes to the handler when it is invoked.

The compensation handler class is now ready for the application component to reference, and for assembly into an application.

3. Open the application component in the assembly tool.
4. Open the deployment descriptor for the application component in the deployment descriptor viewer.
5. Scroll to the **Compensation** section and select the **Run EJB methods under a Business Activity scope** check box.
6. In the **Compensation handler class** text field, type the fully qualified class name of the compensation handler class that you created earlier.
7. Save the deployment descriptor.
8. Build the application, including both the application component and the compensation handler. If the application is a web service, the application must be compliant with the Java Specification Request (JSR) 109 standard.
9. Deploy the application onto an application server that is business-activity-enabled.

Results

The application is now business-activity-enabled, and can use the business activity support at run time through the business activity API. The application component has a compensation handler associated with it, and can therefore call the setCompensationDataImmediate and setCompensationDataAtCommit methods at run time to add the compensation handler to the business activity scope. For more information about these methods, see the topics about the Business activity API. If the unit of work with which the business activity scope is associated fails, the compensation handler performs actions to compensate for the error.

What to do next

Ensure that the compensation handler class is on the application class path for the WebSphere Application Server runtime environment.

Business activity API

Use the business activity application programming interface (API) to create business activities and compensation handlers for an application component, and to log data that is required to compensate an activity if there is a failure in the overall business activity.

Overview

The business activity support provides a UserBusinessActivity API and two interfaces: a serializable.CompensationHandler interface and a CompensationHandler interface. Each interface has two exceptions: RetryCompensationHandlerException and CompensationHandlerFailedException. You can look up the UserBusinessActivity interface from the application server Java Naming and Directory Interface (JNDI) at `java:comp/websphere/UserBusinessActivity`. For example:

```
InitialContext ctx = new InitialContext();
UserBusinessActivity uba = (UserBusinessActivity) ctx.lookup("java:comp/websphere/UserBusinessActivity");
```

You can use the **`getId`** method to access the unique identifier for the business activity that is currently associated with the calling thread. The identifier is the same as the one that is generated for the business activity scope at run time and that is used for information, warning, and error messages. For example, the application can use the identifier in audit or diagnostic messages, and it is possible to correlate between application-generated and runtime-generated messages.

```
InitialContext initialContext = new InitialContext();
UserBusinessActivity uba = initialContext.lookup("java:comp/websphere/UserBusinessActivity");
...
String activityId = uba.getId();
if (activityId == null)
// No activity on the thread
else
// Output audit message including activity id
```

If an application component runs work that might require compensating upon failure in the business activity, you must provide a compensation handler class that is assembled as part of the deployed application. This Java class must implement one of the following interfaces:

- com.ibm.websphere.wsba.serializable.CompensationHandler, which takes a takes a parameter of a serializable object
- com.ibm.websphere.wsba.CompensationHandler, which takes a parameter of a Service Data Object (SDO)

Typically, applications that already have their data available in DataObject format will use the CompensationHandler interface, and applications that do not will use the serializable.CompensationHandler interface. Both interfaces support the close and compensate methods.

An application must register a compensation handler implementation that works with the type of compensation data (serializable object or SDO) that the application uses. If there is a mismatch between the type of data that the application component uses and the compensation handler implementation, there is an error.

During normal application processing, the application can make one or more invocations to the `setCompensationDataImmediate` or `setCompensationDataAtCommit` methods, passing in either a serializable object or an SDO that represents the current state of the work performed.

When the underlying unit of work (UOW) that the root business activity is associated with completes, all registered compensators are coordinated to complete. During completion, either the compensate or the close method is called on the compensation handler, passing in the most recent compensation data logged by the application component as a parameter. Your compensation handler implementation must be able to understand the data that is stored in either the serializable object or the SDO DataObject; when using this data, the compensation handler must be able to determine the nature of the work performed by the enterprise bean and compensate or close in an appropriate way, for example by undoing changes made to database rows if there is a failure in the business activity. You associate the compensation handler with an application component by using the assembly tooling, such as Rational Application Developer.

Active and inactive compensation handlers

You implement the serializable.CompensationHandler or CompensationHandler interface for any application component that executes code that might have to be compensated within a business activity scope. Compensation handler objects are registered implicitly with the business activity scope under which the application runs, whenever the application calls the UserBusinessActivity API to specify compensation data. Compensation handlers can be in one of two states, active or inactive, depending on any transactional UOW under which they are registered. A compensation handler that is registered within a transactional UOW might initially be inactive until the transaction commits, at which point the compensation handler becomes active (see the following section). A compensation handler that is registered outside a transactional UOW always becomes active immediately.

When a business activity completes, it drives only active compensation handlers. Any inactive compensation handlers that are associated with the business activity are discarded and never driven.

Logging compensation data

The business activity API specifies two methods that allow the application to log compensation data. This data is made available to the compensation handlers during their processing when the business activity completes. The application calls one of these methods, depending on whether it expects transactions to be part of the business activity.

setCompensationDataAtCommit()

Call the setCompensationDataAtCommit method when the application expects a global transaction on the thread.

- If a global transaction is present on the thread, the CompensationHandler object is initially inactive. If the global transaction fails, it rolls back any transactional work done within its transaction context in an atomic manner, and drives the business activity to compensate other completed UOWs. The compensation handler does not have to be involved. If the global transaction commits successfully, the compensation handler becomes active because if the overall business activity fails, the compensation handler is required to compensate the durable work that is completed by the global transaction. The setCompensationDataAtCommit method configures the CompensationHandler instance to undertake this compensation function.
- If a global transaction is not present when the setCompensationDataAtCommit method is called, the compensation handler becomes active immediately.

For example, for an SDO, and using the same business activity instance as in the previous example:

```
DataObject compensationData = doWorkWhichWouldNeedCompensating();
uba.setCompensationDataAtCommit(compensationData);
```

setCompensationDataImmediate()

Call the setCompensationDataImmediate method when the application does not expect a global transaction on the thread.

The setCompensationDataImmediate method makes a CompensationHandler instance active immediately, regardless of the current UOW context at the time that the method is invoked. The compensation handler is always able to participate during completion of the business activity.

The role of the setCompensationDataImmediate method is to compensate any non-transactional work, in other words, work that can be performed either inside or outside a global transaction, but that is not governed by the transaction. An example of this type of work is sending an email. The compensation handler must be active immediately so that if a failure occurs in a business activity, this non-transactional work is always compensated.

For example, for a serializable object, and using the same business activity instance as in the previous example:

```
Serializable compensationData = new MyCompensationData();
uba.setCompensationDataImmediate(compensationData);
```

Although these two compensation data logging methods, if called in the same enterprise bean, use the same compensation handler class, they create two separate instances of the compensation handler class at run time. Therefore, the actions of the methods are mutually exclusive; calling one of the methods does not overwrite any work carried out by the other method.

If a compensation handler instance is already added to the Business Activity by using one of these methods, and then the same method is called, passing in `null` as a parameter, that compensation handler instance is removed from the business activity, and is not driven to close or compensate during completion of the business activity.

As described previously, the business activity support adds a compensation handler instance to the business activity when a compensation data logging method is called for the first time by the enterprise bean that uses that business activity. At the same time, a snapshot of the enterprise application context is

taken and logged with the compensation data. When the business activity competes, all the compensation handlers that were added to the business activity are driven to compensate or close. The code that you create in the CompensationHandler or serializable.CompensationHandler class is guaranteed to run in the same enterprise application context that was captured in the earlier snapshot.

For details about the methods available in the business activity API, see the topic about additional APIs.

Chapter 36. Developing web services - Transports

Transport chains represent a network protocol stack that is used for I/O operations within an application server environment. Transport chains are part of the channel framework function that provides a common networking service for all components.

Configuring the SOAP over JMS transport for JAX-WS web services

SOAP over JMS protocol

The web services engine supports the use of an emerging industry standard SOAP over Java Message Service (JMS)-compliant messaging transport as an alternative to HTTP for communicating SOAP messages between clients and servers.

Note: This product supports an emerging industry standard SOAP over JMS protocol. The SOAP over JMS specification provides a standard set of interoperability guidelines for using a JMS-compliant transport with SOAP messages to enable interoperability between the implementations of different vendors. Using this standard, a mixture of client and server components from different vendors can interoperate when exchanging SOAP request and response messages over the JMS transport for both Java API for XML Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) web services. By using the JMS transport, your enterprise beans based web service clients and servers can communicate through JMS queues and topics instead of through HTTP connections.

IBM and other vendors have been working on the proposed SOAP over JMS specification since 2005. The specification has been submitted to W3C and a working group is established. The current member submission of this draft specification was jointly published in October, 2007. Refer to the SOAP over JMS specification for details of this industry standard.

This topic provides a summary of the emerging industry-standard SOAP over JMS protocol. Use this SOAP over JMS transport protocol if you need to provide implementations for the client or server components. Also, you need to make sure that the implementations are interoperable with the client and server components provided by the web services engine in WebSphere Application Server.

The client component is responsible for sending SOAP request messages and receiving SOAP response messages while adhering to the following protocol constraints:

- The client must use a `javax.jms.BytesMessage` object or a `javax.jms.TextMessage` object to transmit the SOAP request message to the server.
- The client must set the following properties on the JMS request message before sending the message to the destination queue or topic:
  - **`SOAPJMS_contentType`**: This property is similar to the Content-Type header found in an HTTP message and is used to describe the content type of the message. A text-only SOAP message, for example, a message with no attachments, has the following value set for this JMS message property:

```
text/xml; charset="UTF-8"
```

    For a SOAP message containing attachments, use the following code to set the SOAPJMS_contentType property on the JMS message:

```
multipart/related; type="text/xml"; start="<...content-id_of_first_ part...>"
```

    This example represents a multipart message, where the first part is of type `text/xml` and contains the SOAP envelope. The other parts of the multipart message contain various attachments. The HTTP 1.1 specification contains more information about the Content-Type header.

- **enableTransaction**: Set this optional property to `true` on an outbound JMS request message if you want the server component to process the web service request under the same transaction that was used to receive the message from the destination queue or topic. This property is an IBM extension to the SOAP over JMS specification.

  Note: For client components, only set this property to `true` for one-way or two-way asynchronous requests to avoid synchronization problems that can occur with two-way synchronous web service requests. If this property is not set or is set to the default value of `false`, the server suspends the transaction that was used to receive the request message from the destination queue or topic prior to invoking the web services engine to process the request.
- **SOAPJMS_requestURI**: You must set this property to the JMS endpoint URL associated with the request.
- **SOAPJMS_soapAction**: This optional property is set on an outbound JMS request message to indicate the soapAction value associated with the web services request. This property is similar to the SOAPAction HTTP header used when transporting web service requests over an HTTP transport. The value of the soapAction property is a URI identifying the intent of the SOAP request. If the SOAPJMS_soapAction property is specified, it is used by the server component to determine the target of the request. The SOAP specification places no restrictions on the format or specificity of the URI nor does the specification require that the URI is resolvable. Typically, this property is set to the soapAction value from the WSDL document.
- **SOAPJMS_targetService**: You must set this property on an outbound JMS request message, and the value must match the targetService property value that is found in the JMS endpoint URL for the request. This value is used by the server component to determine the port component to which the request is dispatched.
- **SOAPJMS_bindingVersion**: This property indicates the version number of the protocol used by the client and server. Set the value to `1.0`.

- If the request message represents a two-way request, meaning that a reply is expected, the client component must set the JMS message JMSReplyTo property to specify the queue that is used for the reply message. The JMS message `setJMSReplyTo` method is used to specify the queue. You can benefit from configuring a permanent reply queue on the client to prevent the client from having to create a temporary queue each time a web service request is made. Read about configuring a permanent reply queue for web services using SOAP over JMS to learn more about creating this special queue.
- If the SOAP request message represents a one-way request, meaning that a reply message is not expected, the client component must not set the JMS message JMSReplyTo property.
- The client component can assume that a reply message is a JMS BytesMessage object.
- The client component can assume that the reply message correlation ID matches the message ID of the original request message.

The server component is responsible for receiving the SOAP request messages and sending the SOAP response messages, while adhering to the following protocol constraints:

- The server component can expect to receive a JMS BytesMessage. If something other than a BytesMessage is received by the server component, then a fault with the subcode, `unsupportedJMSMessageFormat`, is returned to the client if a reply is expected.
- The server component can expect to receive a `javax.jms.BytesMessage` object or a `javax.jms.TextMessage` object. If something other than a BytesMessage or TextMessage is received by the server component, then a fault with the subcode, `unsupportedJMSMessageFormat`, is returned to the client if a reply is expected.
- The server component must process the SOAP request properly to produce an appropriate SOAP reply message.
- The server component must send a reply message back to the client only if the JMS request message's JMSReplyTo property is set. The JMS message `getJMSReplyTo` method is used to retrieve the JMSReplyTo property value from the JMS message. This property value indicates the reply destination.

- When sending a reply message, the server component must use the same message type as the request. If the request was received as a BytesMessage, the reply must be sent as a BytesMessage. Similarly, if the request was received as a TextMessage, the reply must be sent as a TextMessage.
- The server component must set the following properties in the JMS reply message before sending the message to the reply queue:
  - **SOAPJMS_contentType**: This property is used to describe the content type of the message. See the description for this property in the client responsibilities section in this topic.
  - **correlation ID**: Set the correlation ID property of the JMS reply message to the message ID of the original JMS request message. This correlation is done by calling the JMS message `setJMSCorrelationID` method.
  - **SOAPJMS_bindingVersion**: This property indicates the version number of the protocol used by the client and server. Set the value to `1.0`.

The following example displays the results from calling the JMS message `toString` method for a request message without attachments:

```
  JMSMessage class: jms_bytes
  JMSType:          null
  JMSDeliveryMode:  2
  JMSExpiration:    0
  JMSPriority:      4

```

JMS endpoint URL syntax

As part of an emerging industry-standard SOAP over JMS protocol, a Java Message Service (JMS) endpoint URL syntax has been defined. A JMS endpoint URL is used to access Java API for XML Web Services (JAX-WS) or Java API for XML-based RPC (JAX-RPC) web services with the JMS transport. This URL specifies the JMS destination and connection factory, as well as the port component name for the Web service request. This endpoint URL is similar to the HTTP endpoint URL, which specifies the host and port as well as the context root and port component name.

Note: This product supports an emerging industry standard SOAP over JMS protocol. The SOAP over JMS specification provides a standard set of interoperability guidelines for using a JMS-compliant transport with SOAP messages to enable interoperability between the implementations of different vendors. Using this standard, a mixture of client and server components from different vendors can interoperate when exchanging SOAP request and response messages over the JMS transport for both Java API for XML Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) web services. By using the JMS transport, your enterprise beans based web service clients and servers can communicate through JMS queues and topics instead of through HTTP connections.

IBM and other vendors have been working on the W3C SOAP over JMS specification since 2005. The specification has been submitted to W3C and a working group is established. The current member submission of this document was jointly published in October, 2007. The application server supports the current draft specification from W3C.

Note: A JMS endpoint URL has the following general form:

```
jms:jndi:<destination-jndi-name>?<property>=<value>&<property>=<value>&...
```

The URL consists of the `jms:` transport type, followed by the `jndi:` variant type, followed by the JNDI name of the destination queue or topic, followed by the query string containing a list of property and value pairs that are used to specify various JMS endpoint information. The `jndi:` variant means that JNDI is used to locate object names in the endpoint URL string.

The properties supported in the URL string are described in the following tables:

Table 240. Destination-related properties (required). Use these properties to specify destination-related properties for a JMS endpoint URL.

Property name	Description
jndiConnectionFactoryName	Specifies the JNDI name of the connection factory that is used by the client runtime to establish a connection to the JMS messaging engine.
targetService	Specifies the name of the port component to which the request is dispatched.

Table 241. JNDI-related properties (optional). Use these properties to specify JNDI-related properties for a JMS endpoint URL.

Property name	Description
jndiInitialContextFactory	Specifies the name of the initial context factory class to use. This value maps to the java.naming.factory.initial property.
jndiURL	Specifies the JNDI provider URL. This value maps to the java.naming.provider.url property.

Table 242. JMS-related properties (optional). Use these properties to specify JMS-related properties for a JMS endpoint URL.

Property name	Description
deliveryMode	Indicates whether the request message is persistent or not. The valid values are `PERSISTENT` and `NON_PERSISTENT`. The default value is `NON_PERSISTENT`.
timeToLive	Specifies the lifetime, in milliseconds, of the request message. A value of `0` indicates an infinite lifetime. If this parameter is not specified, then the JMS-defined default value is used.
priority	Specifies the JMS priority associated with the request message. Specify this value as a positive integer from 0, the lowest priority, to 9, the highest priority. If this parameter is not specified, then the JMS-defined default value is used.
replyToName	Specifies the JNDI name of the JMS destination to which the response message is sent. Using this optional property enables the client to use a previously defined, permanent queue rather than a temporary queue, for receiving replies.
messageType	Specifies the message type to use with the request message. A value of `BYTES` indicates the javax.jms.BytesMessage object is used. A value of `TEXT` indicates javax.jms.TextMessage object is used. The default value is `BYTES`.

The required properties jndiConnectionFactoryName and targetService must be in the JMS endpoint URL string. The remaining properties are optional.

If you set values for the deliveryMode, timeToLive, and priority properties on the JMS request, these values are propagated from the JMS request message to the corresponding JMS reply message.

See the SOAP over Java Message Service specification in the web services specifications and APIs documentation to learn more about this industry standard.

IBM proprietary SOAP over JMS protocol (deprecated)

You can use a SOAP over Java Message Service (JMS) transport as an alternative to HTTP for communicating SOAP messages between clients and servers. The web services engine supports the use of an IBM proprietary implementation as well as the industry standard implementation.

Note: In earlier versions of the application server, an IBM proprietary SOAP over JMS protocol was supported for Java API for XML-based RPC (JAX-RPC) applications. In WebSphere Application Server 7.0 and later, this proprietary SOAP over JMS protocol is now deprecated in favor of an emerging industry standard SOAP over JMS protocol. You can use the IBM proprietary SOAP over JMS protocol with your Java API for XML Web Services (JAX-WS) or JAX-RPC web services; however, take advantage of the emerging standard SOAP over JMS protocol. If your client application invokes enterprise beans-based web services that are supported by an earlier version of the WebSphere Application Server, you must continue to use the IBM proprietary SOAP over JMS protocol to access those web services.

You can use a SOAP over JMS transport if you need to provide implementations for the client or server components, and you need to make sure that the implementations are interoperable with the client and server components provided by the web services engine in the application server. The IBM proprietary SOAP over JMS protocol describes specific message exchange requirements for client and server components so they can exchange SOAP request and response messages through the use of the JMS APIs supported by the application server.

The client component is responsible for sending SOAP request messages and receiving SOAP response messages while adhering to the following protocol constraints:

- The client must use either a JMS TextMessage object, for example, javax.jms.TextMessage, or a BytesMessage object, for example, javax.jms.BytesMessage, to transmit the SOAP request message to the server. If the request message contains attachments, a BytesMessage object must be used. If the request message does not contain attachments, the client can use a TextMessage or a BytesMessage object. The application server client implementation uses only a BytesMessage object for the request message due to the potential need to transmit attachments.
- The client must set the following properties on the JMS request message before sending the message to the destination queue or topic:
  - contentType: This property is similar to the Content-Type header found in an HTTP message and is used to describe the content type of the message. A text-only SOAP message, for example, a message with no attachments, is written as follows:

```
text/xml; charset="UTF-8"
```

    The **contentType** property in a SOAP request message that contains attachments must be set as follows:

```
multipart/related; type="text/xml"; start="<...content-id of first part...>"
```

    This example represents a multi-part message, where the first part is of type `text/xml` that contains the SOAP message. The other parts of the multi-part message contain various attachments. The HTTP 1.1 specification contains more information about the Content-Type header.
  - enableTransaction: Set this optional property to `true` on the outgoing SOAP over JMS request message if the server component should process the web service request under the same transaction that was used to receive the message from the destination queue or topic. The client component should only set this property to `true` for a one-way request to avoid synchronization problems that can occur with a two-way web service request. If this property is not set or is set to the default value of `false`, then the server will suspend the transaction that was used to receive the request message from the destination queue or topic prior to invoking the web services engine to process the request.

    gotcha: The client component should only set this property to `true` for a one-way request. Setting this property to `true` for a two-way web server request is not supported because of synchronization problems.
  - endpointURL: This property must be set to the JMS endpoint URL associated with the request.
  - soapAction: This optional property is set on an outgoing SOAP over JMS request message to indicate the soapAction value associated with the web services request. This property is similar to the SOAPAction HTTP header used when transporting web service requests over an HTTP transport. The value of the soapAction property is a URI identifying the intent of the SOAP request. If the soapAction property is specified, it is used by the server component to determine the target of the request. The SOAP specification places no restrictions on the format or specificity of the URI or that it is resolvable. Typically, this property is set to the soapAction value from the WSDL document.
  - targetService: This property must be set to the targetService property value that is found in the JMS-style endpoint location URL for the request. This value is used by the server component to determine the port component in the target when dispatching the request.
  - transportVersion: This property indicates the version number of the protocol used by the client and server. Set the value to 1 (one).
- If the SOAP request message represents a two-way request, the client component must set the JMS message's replyTo property to specify the queue that is used for the reply message. The JMS message `setJMSReplyTo` method is used for this. It can be beneficial to configure a permanent **replyTo** queue on the client to prevent the client from having to set the JMS message's replyTo property each time a web service request is made.

- If the SOAP request message represents a one-way request, the client component must not set the JMS message's replyTo property.
- The client component must be prepared to handle a reply message that is a BytesMessage or a TextMessage object, regardless of the type of JMS message used to transmit the SOAP request. The application server component responds with the same type of JMS message that is received from the client, unless the response contains attachments and a BytesMessage object must be used.
- The client component can assume that the reply message correlation ID matches the original request message ID.

The server component is responsible for receiving the SOAP request messages and sending the SOAP response messages while adhering to the following protocol constraints:

- The server must be prepared to receive a TextMessage or a BytesMessage. If the request contains attachments, a ByteMessage must be used. The WebSphere product implementation of the server component responds in kind when sending the reply message back to the client, unless the response contains attachments and a BytesMessage is used.
- The server component must process the SOAP request properly to produce an appropriate SOAP reply message.
- The server component must send a reply message back to the client only if the JMS request message's replyTo property is set.
- The server component must set the following properties in the JMS reply message before sending the message to the replyTo queue:
  - contentType: See the description for this property in the client responsibilities section in this article.
  - Set the **correlation ID** of the JMS reply message to the message ID of the original JMS request message. This is done by calling the JMS message `setJMSCorrelationID` method.
  - transportVersion: This property indicates the version number of the protocol used by the client and server. Set the value to 1 (one).

The following example displays the results from calling the JMS message `toString` method for a request message without attachments:

```
JMSMessage class: jms_bytes
JMSType:          null
JMSDeliveryMode:  2
JMSExpiration:    0
JMSPriority:      4
JMSMessageID:     ID:d438eebf04cb124aa25c5821110a134f0000000000000001
JMSTimestamp:     1092110476167
JMSCorrelationID: null
JMSDestination:   topic://NewsGroupTopic?topicSpace=FvtTopicSpace
JMSReplyTo:       null
JMSRedelivered:   false
JMS_IBM_System_MessageID: 6B6765B36943A18C_11000001
transportVersion: 1
JMSXUserID:
targetService: NGConsumerJMS
JMSXAppID: Service Integration Bus
endpointURL: jms:/topic?destination=jms/NewsGroupTopic&connectionFactory;
  =jms/NewsGroupTCF&targetService;=NGConsumerJMS

contentType: text/xml; charset=utf-8
3c736f6170656e763a456e76656c6f706520786d6c6e733a736f6170656e763d22687474703a2f2f
736368656d61732e786d6c736f61702e6f72672f736f61702f656e76656c6f70652f2220786d6c6e
...
```

The following SOAP Version 1.1 example displays the payload from the previous message example:

```
<soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
 xmlns:soapenc="http://schemas.xmlsoap.org/soap/encoding/"
 xmlns:xsd="http://www.w3.org/2001/XMLSchema"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
<soapenv:Body soapenv:encodingStyle="http://schemas.xmlsoap.org/soap/encoding/">
<postMessage><ngName xsi:type="xsd:string">news.current.events</ngName>
```

```
<msg xsi:type="xsd:string">This is a sample news item.</msg>
</postMessage>
</soapenv:Body>
</soapenv:Envelope>
```

For SOAP Version 1.2, the `encodingStyle` parameter is not supported, so the example looks similar to the following:

```
<soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
 xmlns:soapenc="http://schemas.xmlsoap.org/soap/encoding/"
 xmlns:xsd="http://www.w3.org/2001/XMLSchema"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
<soapenv:Body>
<postMessage><ngName xsi:type="xsd:string">news.current.events</ngName>
<msg xsi:type="xsd:string">This is a sample news item.</msg>
</postMessage>
</soapenv:Body>
</soapenv:Envelope>
```

The following example displays the results from calling the JMS message `toString` method for a request message with attachments:

```
JMSMessage class: jms_bytes
JMSType:          null
JMSDeliveryMode:  1
JMSExpiration:    1092086312310
JMSPriority:      4
JMSMessageID:     ID:4bb64ed64e7d813d59ba5fec110a134f0000000000000001
JMSTimestamp:     1092086012310
JMSCorrelationID: null
JMSDestination:   queue://Logger_Q
JMSReplyTo:       queue://_Q_6B6765B36943A18C_00000385
JMSRedelivered:   false
JMS_IBM_System_MessageID: 6B6765B36943A18C_10000001
transportVersion: 1
JMSXUserID:
targetService: WSLoggerJMS
JMSXAppID: Service Integration Bus
endpointURL: jms:/queue?
destination=jms/Logger_Q&connectionFactory=jms/Logger_CF&targetService=WSLoggerJMS
contentType: multipart/related; type="text/xml";
start="<945414389.1092086011970.IBM.WEBSERVICES@myhost1>";

IBM proprietary JMS endpoint URL syntax (deprecated)

A Java Message Service (JMS) endpoint URL is used to access Java API for XML Web Services (JAX-WS) or Java API for XML-based RPC (JAX-RPC) web services with the JMS transport. This proprietary URL specifies the Java Message Service (JMS) destination and connection factory, as well as the port component name for the web service request. This endpoint URL is similar to the HTTP endpoint URL, which specifies the host and port as well as the context root and port component name.

Note: A JMS endpoint URL has the following general form:

`jms:/[queue|topic]?<property>=<value>&<property>=<value>&...`

> The URL consists of the `jms:` transport type, followed by either `/queue` or `/topic` to indicate the JMS destination type, followed by the query string containing a list of property and value pairs that are used to specify the JMS endpoint information.

The properties supported in the URL string are described in the following tables:

Table 243. Destination-related properties (required). Use these properties to specify destination-related properties for a JMS endpoint URL.

Property name	Description
destination	Specifies the Java Naming and Directory Interface (JNDI) name of the destination queue or topic.
connectionFactory	Specifies the JNDI name of the connection factory.
targetService	Specifies the name of the port component to which the request is dispatched.

Table 244. JNDI-related properties (optional). Use these properties to specify JNDI-related properties for a JMS endpoint URL.

Property name	Description
initialContextFactory	Specifies the name of the initial context factory to use which is mapped to the java.naming.factory.initial property.
jndiProviderURL	Specifies the JNDI provider URL, which is mapped to the java.naming.provider.url property.

Table 245. JMS-related properties (optional). Use these properties to specify JMS-related properties for a JMS endpoint URL.

Property name	Description
deliveryMode	Indicates whether the request message is persistent or not. The valid values are `1` for nonpersistent and `2` for persistent. The default value is `1`.
timeToLive	Specifies, in milliseconds, the lifetime of the JMS request message. The default value of `0` indicates an infinite lifetime. However, when you are using web services, this property is bounded by the value that is specified for the synchTimeout property. The setting for the synchTimeout property determines how long a client waits for a response from the server. This bounding prevents the JMS message from remaining active after the client has stopped waiting for a response from the server.
priority	Specifies the JMS priority associated with the request message. Valid values are between `0` to `9`. The default value is `4`. A value of `0` is the lowest priority and a value of `9` is the highest priority.
replyToDestination	Specifies the JNDI name of a queue to be used to receive reply messages. Using this optional property enables the client to use a permanent queue, rather than a temporary queue, for receiving replies.

If you set values for the deliveryMode, timeToLive, and priority properties on the JMS request, these values are propagated from the JMS request message to the corresponding JMS reply message.

The required properties, destination, connectionFactory, and targetService must be contained in the JMS endpoint URL string. The rest of the properties are optional.

You can set any of the properties on the client Stub object. The various properties can be specified by including them as part of the endpoint URL or you can set these properties programmatically by the client on the Stub object. Properties specified on the client Stub object take precedence over properties that are specified as part of a JMS endpoint URL string.

Invoking web service requests transactionally using SOAP over JMS transport

Use the `enableTransactionalOneWay` property to ensure that one-way and two-way asynchronous web service requests using the industry standard SOAP over JMS transport will be sent to the destination queue or topic transactionally.

About this task

When using JMS to transport Java API for XML Web Services (JAX-WS) or Java API for XML-based RPC (JAX-RPC) web service requests, the default behavior is for the SOAP message to be added to the destination queue or topic non-transactionally or outside of the client application's transaction. Adding the SOAP message to the destination queue or topic is done outside of the transaction to avoid synchronization problems that can occur with two-way synchronous web service requests. However, you can choose to enable one-way and two-way asynchronous requests to be processed as part of a transaction. You can use the `enableTransactionalOneWay` property to ensure that one-way and two-way asynchronous web service requests that use the JMS transport are sent to the destination queue or topic transactionally. When the client application invokes the web service request, the resulting SOAP request message is added to the destination queue or topic as part of the client application's transaction.

Use one of the following ways to enable the `enableTransactionalOneWay` property.

Procedure

- Set the `enableTransactionalOneWay` property programmatically. The value of the property is a Boolean.
  - For JAX-WS clients, set the property on the client JAX-WS `RequestContext` object. For example:

```
((BindingProvider) port).getRequestContext().put
(com.ibm.websphere.webservices.Constants.ENABLE_TRAN_ONEWAY,
new Boolean(true));
```

  - For JAX-RPC clients, set the property on the client JAX-RPC Stub or Call object. For example:

```
stub._setProperty(com.ibm.websphere.webservices.Constants.ENABLE_TRAN_ONEWAY,
new Boolean(true));
```

- For JAX-RPC clients, set the `enableTransactionalOneWay` property as a custom property in the `ibm-webservicesclient-bnd.xmi` deployment descriptor file by using the **wsadmin** command.

  For more information about the wsadmin tool options, see the options for the AdminApp object install, installInteractive, edit, editInteractive, update, and updateInteractive commands information..

  Use the `$AdminApp` object along with the `-WebServicesClientCustomProperty` option to set the value of the property within the client binding file, `ibm-webservicesclient-bnd.xmi`. The value of the custom property, `enableTransactionalOneWay`, is either `true` or `false`.
  - Using Jacl:

    ```
    $AdminApp edit MyApplication {-WebServicesClientCustomProperty {{MyEJBJar.jar MyEJB
    service/MyServiceRef MyPort enableTransactionalOneWay true}}}
    ```
  - Using Jython:

    ```
     AdminApp.edit('MyApplication', ['-WebServicesClientCustomProperty', [['MyEJBJar.jar',
    'MyEJB', 'service/MyServiceRef ', 'MyPort', 'enableTransactionalOneWay', 'true']]])
    ```

Results

You have a web services client application that is configured to invoke one-way and two-way asynchronous requests transactionally when using the JMS transport.

What to do next

After you have enabled the `enableTransactionalOneWay` property, run the client application.

Invoking one-way JAX-RPC web service requests transactionally using the JMS transport (deprecated)

Use the `enableTransactionalOneWay` property to ensure that one-way JAX-RPC web service requests using the IBM proprietary JMS transport will be sent to the destination queue or topic transactionally.

About this task

Note: Beginning with WebSphere Application Server 7.0, the IBM proprietary SOAP over JMS protocol is deprecated in favor of the emerging industry standard protocol. You can use the IBM proprietary SOAP over JMS protocol with your Java API for XML Web Services (JAX-WS) or JAX-RPC web services, however, you are encouraged to take advantage of the SOAP over JMS protocol standard. This task describes configuring a permanent replyTo queue when using the IBM proprietary SOAP over JMS transport. To learn more about the SOAP over JMS standard, see the using SOAP over JMS to transport web services documentation.

When using JMS to transport web service requests, the default behavior is for the SOAP message to be added to the destination queue or topic non-transactionally or outside of the client application's transaction. Adding the SOAP message to the destination queue or topic is done outside of the transaction to avoid synchronization problems that can occur with two-way web service requests. However, you can choose to enable one-way requests to be processed as part of the transaction. The `enableTransactionalOneWay` property can be used to ensure that one-way web service requests that use the JMS transport will be sent to the destination queue or topic transactionally. When the client application invokes the one-way web service request, the resulting SOAP request message is added to the destination queue or topic as part of the client application's transaction.

Use one of the following ways to enable the `enableTransactionalOneWay` property.

Procedure

- Set the `enableTransactionalOneWay` property programmatically on the client JAX-RPC Stub or Call object.

When using a static Stub to invoke the web service operation, set the `enableTransactionalOneWay` property on the Stub object before invoking the web service method. When using a Call object to invoke the web service operation, set the `enableTransactionalOneWay` property on the Call object before invoking the `invokeOneWay()` method.

```
Service service = /* Obtain the desired service */
MyStub stub = service.getPort();

/* Set enableTransactionalOneWay property on Stub */
stub._setProperty(com.ibm.websphere.webservices.Constants.ENABLE_TRAN_ONEWAY, new Boolean(true));

/* Invoke the one-way operation */
stub.myOneWayOperation("Parm1");
```

The value of the property is Boolean.

- Set the `enableTransactionalOneWay` property as a custom property in the `ibm-webservicesclient-bnd.xmi` deployment descriptor file by using the **wsadmin** command.

  For more information about the wsadmin tool options, see the options for the AdminApp object install, installInteractive, edit, editInteractive, update, and updateInteractive commands information.

  Use the `$AdminApp` object along with the `-WebServicesClientCustomProperty` option to set the value of the property within the client binding file, `ibm-webservicesclient-bnd.xmi`. The value of the custom property, `enableTransactionalOneWay`, is either `true` or `false`.
  - Using Jacl:

    ```
    $AdminApp edit MyApplication {-WebServicesClientCustomProperty {{MyEJBJar.jar MyEJB
    service/MyServiceRef MyPort enableTransactionalOneWay true}}}
    ```
  - Using Jython:

    ```
     AdminApp.edit('MyApplication', ['-WebServicesClientCustomProperty', [['MyEJBJar.jar',
    'MyEJB', 'service/MyServiceRef ', 'MyPort', 'enableTransactionalOneWay', 'true']]])
    ```

Results

You have a web service client application that is configured to invoke one-way requests transactionally while using the JMS transport.

What to do next

After you have enabled the `enableTransactionalOneWay` property, run the client application.

Configuring SOAP over JMS message types

You can configure your SOAP over Java Message Service (JMS) request or response messages to use either BytesMessage or TextMessage objects.

Before you begin

A web service must be implemented as an enterprise bean for accessibility through the JMS transport.

About this task

For your web services that use the emerging industry standard SOAP over JMS protocol, you can configure the SOAP over JMS requests and responses to specify whether the messages are transmitted within JMS BytesMessage (`javax.jms.BytesMessage`) or TextMessage (`javax.jms.TextMessage`) objects. The default message type is BytesMessage.

If the JMS message is a BytesMessage, the body of the JMS message is binary data.

If the JMS message is a TextMessage, the body of the JMS message is string data. For example, consider configuring text messages if you want to implement an audit or logging facility that requires JMS messages that are human readable.

When using SOAP over JMS as a transport for web services request and response messages, it is important to understand the following performance considerations when deciding whether to use BytesMessage or TextMessage objects:

- Memory usage -

  The payload within a TextMessage is string-based and because the individual characters are based on the UTF-16 character encoding, the payload within a TextMessage is likely to occupy twice as many bytes as an equivalent BytesMessage. For request and response messages with small payloads, this difference in memory usage between TextMessages and BytesMessages might not be important, but for large payloads, the difference in memory usage might become more important to consider for your business environment.

- Binary attachments -

  When a JMS TextMessage is used to transport request and response messages, any binary attachments that are included along with the SOAP message body must be base64-encoded because the underlying message payload is string-based. When binary attachments are base64-encoded, additional processing time and memory are required to perform the transformation on that data. As a result, it is possible that the base64-encoded binary attachment might be up to one-third larger than the original unencoded version of the attachment. In this case, if this larger encoded attachment part is then transported in a string-based message payload, the memory usage required to transport the binary attachment part might be almost three times the memory size of the original unencoded binary attachment within a BytesMessage.

Procedure

- Specify the JMS message type for JAX-WS applications.

  You can configure the JMS message type to specify `BYTES` or `TEXT` in the following ways when using JAX-WS applications. The JAX-WS Web services engine searches for the messageType property in the order of this list and uses the first setting that it finds.

  – Set the messageType property in the JMS endpoint location URL string; for example:

```
jms:jndi:jms/MyQueue&....&messageType=TEXT
```

    See the JMS endpoint URL syntax information for details on how to set this property using this method.

  – Set the com.ibm.websphere.webservices.transport.jms.messageType custom property in the JMS transport policy binding in the administrative console. See the JMS transport bindings information for details on how to set this property using the administrative console.

  – Set the com.ibm.websphere.webservices.transport.jms.messageType property programmatically on the RequestContext object of the JAX-WS BindingProvider.

  – Set the com.ibm.websphere.webservices.transport.jms.messageType global system property in the JVM process under which the application server is running. See the Java virtual machine custom properties information for details on how to set this property using this method.

- Specify the JMS message type for JAX-RPC applications.

  You can configure the JMS message type to specify `BYTES` or `TEXT` in the following ways when using JAX-RPC applications. The JAX-RPC Web services engine searches for the messageType property in the order of this list and uses the first setting that it finds.

  – Set the messageType property in the JMS endpoint location URL string; for example:

```
jms:jndi:jms/MyQueue&....&messageType=TEXT
```

    See the JMS endpoint URL syntax information for details on how to set this property using this method.

  – Set the com.ibm.websphere.webservices.transport.jms.messageType property programmatically on the Stub or Call object of the client application..

  – Set the com.ibm.websphere.webservices.transport.jms.messageType custom property in the client binding file, META-INF/ibm-webservicesclient-bnd.xmi.

– Set the com.ibm.websphere.webservices.transport.jms.messageType global system property in the JVM process under which the application server is running. See the Java virtual machine custom properties information for details on how to set this property using this method.

Results

You have configured a web service client to use either TextMessage or BytesMessage objects when using the SOAP over JMS protocol to transmit request and response messages.

Chapter 37. Developing web services - UDDI registry

The Universal Description, Discovery, and Integration (UDDI) specification defines a way to publish and discover information about web services. The UDDI specification defines a standard for the visibility, reusability, and manageability that are essential for a service-oriented architecture (SOA) registry service. The UDDI registry is a directory for web services that is implemented using the UDDI specification. It is a component of WebSphere® Application Server.

Web services are self-contained, modular applications that can be described, published, located, and invoked over a network. They implement a services oriented architecture (SOA), which supports the connecting or sharing of resources and data in a very flexible and standardized manner. Services are described and organized to support their dynamic, automated discovery and reuse.

Developing with the UDDI registry

You can access the UDDI registry in several ways; the UDDI registry user interface, application programming interfaces (APIs), or the Java API for XML Registries (JAXR).

About this task

You can access the UDDI registry programmatically by using several application programming interfaces (APIs).

You can also explore the UDDI registry by using the UDDI registry user interface (also referred to as the UDDI registry user console), which is a graphical interface.

You can access both UDDI (Version 2 only) and ebXML registries by using the Java API for XML Registries (JAXR). This Java client API is part of the Java EE specification.

Procedure

- "UDDI registry client programming"
- "Using the UDDI registry user interface" on page 1792
- "Using the JAXR provider for UDDI" on page 1798

UDDI registry client programming

The UDDI registry provides several application programming interfaces (APIs) that you can use to access the UDDI registry programmatically.

About this task

The UDDI Version 3 registry supports multiple versions of UDDI. It supports UDDI Version 1, Version 2, and Version 3.

For details of the Version 1 and Version 2 API, refer to the UDDI Version 2 Specifications.

For details of the UDDI Version 3.0.2 API, refer to the UDDI Version 3.0.2 Specification.

The UDDI registry information in this information center defines the support that the UDDI registry provides for the UDDI Version 3.0.2 specification and associated addenda.

The following UDDI Version 3 API sets are supported:
- The UDDI V3 Inquiry API
- The UDDI V3 Publish API
- The UDDI V3 Custody and Ownership Transfer API

- The UDDI V3 Security API

Restriction: In DB2 for zSeries® Version 7, the length of publish and inquiry strings are limited to 255 characters. If this limit is exceeded, error 10500 (E_Fatal) is returned. If you use a character set that uses multiple byte characters, it is easy to exceed this limit. Therefore, use care if you use this type of character set.

Procedure

1. Learn about the standard aspects of the UDDI APIs by using the following topics.
   - "UDDI registry Version 3 entity keys" on page 1784 explains UDDI entity keys, and the capability with UDDI Version 3 to save UDDI entities with publisher-assigned keys.
   - "Digital signatures and the UDDI registry" on page 1787 explains the support for digital signing of UDDI entities, and for validation of signatures.
2. Access the APIs programmatically. The recommended client API is the UDDI Version 3 Client, which allows access to the UDDI Version 3 APIs from Java client code.

   Other client APIs are provided for compatibility with previous versions of the UDDI registry:
   - The UDDI4J programming interface provides Java class libraries for accessing UDDI Version 1 and Version 2 APIs. These class libraries are both deprecated in this release, and are replaced by the UDDI Version 3 Client for Java.
   - The UDDI EJB Interface provides an Enterprise JavaBeans (EJB) interface to the UDDI Version 2 APIs. The UDDI EJB interface is deprecated in this release.

   Although the recommended programmatic access to the UDDI APIs is through the UDDI Version 3 Client for Java, it is also valid to use the UDDI APIs directly by using SOAP. To use the SOAP API, construct a properly-formed UDDI message in the body of a SOAP request, and send it by using HTTP POST to the appropriate SOAP endpoint for the UDDI service. The response is returned in the body of the HTTP reply.

   The UDDI registry samples include samples that demonstrate how to program directly to the SOAP API. The samples are written in Java code, but you can use other programming languages to create your SOAP client, provided that you still send requests that are compliant to the SOAP specification. Valid UDDI requests must conform to the UDDI schema, as detailed in the UDDI specification

   Support is also provided to use HTTP GET to return XML representations of UDDI entities: see "HTTP GET services for UDDI registry data structures" on page 1788 for details.

Inquiry API for the UDDI Version 3 registry

The Inquiry API provides four forms of query that follow broadly used conventions that match the needs of software that is traditionally used in registries.

The four forms of query are:
- The browse pattern
- The drilldown pattern
- The invocation pattern
- Inquiry API functions

Browse pattern for the UDDI registry

Software that is used to explore and examine data, especially hierarchical data, requires browse capabilities. The browse pattern characteristically involves starting with some broad information, performing a search, finding general result sets, then selecting more specific information for drill-down patterns.

The UDDI API specifications accommodate the browse pattern with the *find_xx* API calls. These calls form the search capabilities that the API provides. The calls are matched with summary return messages that return overview information about the registered information that is associated with the inquiry message type and the search criteria specified in the inquiry.

A typical browse sequence might involve finding whether there is any information registered for a business you know about. This sequence starts with a call to find_business, perhaps passing the first characters of the business name that you know. This action returns a businessList result. This result is overview information, including keys, names, and descriptions, that is derived from the registered businessEntity information, matching on the name fragment that you provide. If the business you are looking for is in this list, you can use the find_service API call to drill down into the corresponding businessService information, and look for specific technical models, such as purchasing or shipping. Similarly, if you know the technical *fingerprint*, that is, the tModel signature, of a particular software interface, and you want to see if the business you are looking for provides a web service that supports that interface, you can use the find_binding inquiry message.

Drilldown pattern for the UDDI registry

When you have a key for one of the four main data types that a UDDI registry manages, you can use that key to access the full registered details of a specific data instance. The UDDI data types are businessEntity, businessService, bindingTemplate, and tModel. You can access the full registered information for any of these structures by passing a relevant key type to one of the *get_xx* API calls.

Continuing the example from the previous section, one data item that is returned by all of the *find_x* return sets is key information. For the business you are interested in, the businessKey value that is returned in the contents of a businessList structure can be passed as an argument to the get_businessDetail message. The successful return to this message is a businessDetail message that contains the full registered information for the entity with the key value that is passed. This information will be a full businessEntity structure.

Invocation pattern for the UDDI registry

For an application to take advantage of a remote web service that is registered in the UDDI registry by other businesses or entities, you must prepare that application to use the information found in the registry for the specific service being invoked.

The *bindingTemplate* data that is obtained from the UDDI registry represents the specific details about an instance of a given interface type, including the location at which a program starts interacting with the service. The calling application or program caches this information and uses it to contact the service at the registered address whenever the calling application needs to communicate with the service instance.

In remote procedure technologies that were previously popular, tools automate the tasks that are associated with caching, or hard coding, location information. However, there are problems when a remote service moves and the callers do not know about the move. There are many reasons why a remote service might move, for example, a server upgrade, disaster recovery, service acquisition, or a change to the business name.

When a call fails using cached information previously obtained from a UDDI registry, the correct behavior is to query the UDDI registry for fresh bindingTemplate information. If the data that is returned is different from the cached information, the service invocation can automatically try the invocation again, using the fresh information. If the result of this retry is successful, the new information replaces the cached information.

By using this pattern with web services, a business that uses a UDDI registry can automate the recovery of a large number of partners without unneccessary communication and coordination costs. For example, if a business activates a disaster recovery site, most of the calls from partners fail when they try to invoke services at the failed site. By updating the UDDI information with the new address for the service, partners who use the invocation pattern automatically locate the new service information and recover without further administrative action.

Inquiry API functions in the UDDI registry:

You can use the Inquiry API set to locate and obtain details about entries in a UDDI registry.

The Inquiry API is split into a number of functions, where each function requires some mandatory and some optional arguments.

The find_*xx* API functions can accept an optional findQualifiers argument.

To access all API calls and arguments that are supported by the UDDI Version 3 registry programmatically, use the UDDI Version 3 Client for Java. To access the API functions graphically, you can use the UDDI user interface, but not all functions are available with this method.

The UDDI Version 3 registry supports the following Inquiry API calls:

find_binding
: Locates specific bindings in a registered businessService. Returns a bindingDetail message that contains zero or more bindingTemplate structures that match the criteria specified in the argument list.

find_business
: Locates information about one or more businesses. Returns a businessList message that matches the conditions specified in the arguments.

find_relatedBusinesses
: Locates information about businessEntity registrations that are related to a specific business entity whose key is passed in the inquiry. The related businesses feature is used to manage registration of business units and subsequently relate them based on organizational hierarchies or business partner relationships. Returns a relatedBusinessList message that contains results that match the conditions specified in the argument list.

find_service
: Locates specific services in a registered businessEntity. Returns a serviceList message that matches the conditions specified in the arguments.

find_tModel
: Locates a list of tModel entities that match a set of specified criteria. The response is a list of abbreviated information about registered tModel data that matches the specified criteria. The result is returned in a tModelList message.

get_bindingDetail
: Requests the runtime bindingTemplate information for the purpose of invoking a registered business API. Returns a bindingDetail message.

get_businessDetail
: Returns complete businessEntity information for one or more specified businessEntity registrations that match the specified businessKey values. Returns a businessDetail message.

get_opertionalInfo
: Gets full operational information pertaining to one or more entities in the registry. Returns an operationalInfos structure.

get_serviceDetail
: Requests full information about a known businessService structure. Returns a serviceDetail message.

get_tModelDetail
: Gets full details for a given set of registered tModel data. Returns a tModelDetail message.

For details of the query syntax, refer to the UDDI Version 3 API specification.

FindQualifier values for API functions in the UDDI registry:

The find_*xx* API functions (find_business, find_service, find_binding, find_tModel and find_relatedBusinesses) accept an optional findQualifiers argument, which can contain multiple findQualifier values.

The following list contains the findQualifier short names, a brief description, and the appropriate find function.

andAllKeys
Specifies that the identifierBag element uses AND behavior with keys, rather than OR behavior. This behavior is the default for the categoryBag and tModelBag elements. This value applies to the find_business, find_service, find_binding, and find_tModel functions. This value does not apply to the find_relatedBusinesses function.

approximateMatch
Specifies that wildcard search behavior is required. This is no longer the default behavior; the default behavior is specified by the exactMatch value. This value applies to the find_business, find_service, find_binding, find_tModel, and find_relatedBusiness functions.

binarySort
Specifies a faster sort by using a binary sort by name, as represented in Unicode codepoints. This value applies only to the find_business, find_service and find_tModel functions.

bindingSubset
This value is used only with a categoryBag element in the find_business or find_services functions.

caseInsensitiveMatch
Specifies that the matching behavior for name, keyValue, and keyName, where applicable, is not case-sensitive. By default, the matching behavior is case-sensitive. This value applies to the find_business, find_service, and find_tModel functions.

caseInsensitiveSort
Specifies that the sorting behavior for name, keyValue, and keyName, where applicable, is not case-sensitive. By default, the sorting behavior is case-sensitive.

caseSensitiveMatch
Specifies that the matching behavior for name, keyValue, and keyName, where applicable, is case-sensitive. This is the default behavior. This value applies to the find_business, find_service, find_binding, find_tModel, and find_relatedBusinesses functions.

caseSensitiveSort
Specifies that the sorting behavior for the result set is case-sensitive. This is the default behavior. This value applies to the find_business, find_service, and find_tModel functions.

combineCategoryBags
For a find_business function, specifies that the categoryBag entries for the full businessEntity element behave as though all categoryBag elements found at the businessEntity level and in all contained or referenced businessService elements and bindingTemplate elements are combined.

For a find_service function, specifies that the categoryBag entries for the full businessService element behave as though all categoryBag elements found at the businessService level and in all contained or referenced elements in the bindingTemplate elements are combined.

This value applies only to the find_business and find_service functions.

diacriticInsensitiveMatch
Specifies that the matching behavior for name, keyValue, and keyName, where applicable, is performed without regard to diacritics, for example accent marks. This is an optional value that applies to the find_business, find_service, find_binding, find_tModel, and find_relatedBusinesses functions.

diacriticSensitiveMatch
Specifies that the matching behavior for name, keyValue, and keyName, where applicable, is performed with regard to diacritics, for example accent marks. This is the default behavior. This value applies to the find_business, find_service, find_binding, find_tModel, and find_relatedBusinesses functions.

exactMatch
Specifies that only entries with names, keyValues, and keyNames, where applicable, that exactly match the name argument passed in, after normalization, are returned. The matching behavior is sensitive to case and diacritics, where applicable, and is the default behavior. This value applies to the find_business, find_service, find_binding, find_tModel, and find_relatedBusinesses functions.

signaturePresent
Specifies that the result set is restricted to either entities that contain an XML digital signature element, or entities that are contained in an entity that contains an XML digital signature element. This value applies to the find_business, find_service, find_binding, find_tModel, and find_relatedBusinesses functions.

orAllKeys
Specifies that the tModelBag and categoryBag elements use OR behavior with the keys in a bag, rather than AND behavior. It is not possible to use OR behavior with the categories and retain the default AND behavior of the tModel entities. For the find_business function, this is the default behavior for the identifierBag element. This value applies to the find_service, find_binding (for categoryBag and tModelBag) and find_tModel functions, where it is the default behavior for the identifierBag element and applies to the categoryBag element.

orLikeKeys
Specifies that when a categoryBag or identifierBag element contains multiple keyedReference elements, the elements use OR behavior with any keyedReference filters that come from the same namespace, that is, the filters have the same tModelKey value, rather than AND behavior. This value applies to the find_business, find_service, find_binding, and find_tModel functions.

serviceSubset
Specifies that the component of the search that involves categorization uses only the categoryBag elements from contained or referenced businessService elements in the registered data, and ignores any entries found in the categoryBag that are not direct descendent elements of registered businessEntity elements. This value applies only to the find_business function with the categoryBag element.

sortByNameAsc
Specifies that the result set that a find or get inquiry API returns is sorted on the name field in ascending order. This value takes precedence over sortByDateAsc and sortByDateDesc values, but if a sortByDate*Xxx* value is used without a sortByName*Xxx* value, the result set is sorted by date, regardless of the name field. This value applies to the find_business, find_service, find_tModel, and find_relatedBusinesses functions.

sortByNameDesc
Specifies that the result set that a find or get inquiry API returns is sorted on the name field in descending order. This value takes precedence over sortByDateAsc and sortByDateDesc values, but if a sortByDate*Xxx* value is used without a sortByName*Xxx* value, the result set is sorted by date, regardless of the name field. This value applies to the find_business, find_service, find_tModel, and find_relatedBusinesses functions.

sortByDateAsc
Specifies that the result set that a find or get inquiry API returns is sorted on the most recent date when each entity, or any entities that they contain, were last updated, in ascending chronological order, that is, the oldest entity is returned first. If this value is used with a sortByName*Xxx* value, the name-based sort takes precedence over the date-based sort, that is, the results are sorted by name, then within names by date, oldest to newest. This is the default behavior for the find_binding function. This value applies to the find_business, find_service, find_tModel, and find_relatedBusinesses functions.

sortByDateDesc
Specifies that the result set that a find or get inquiry API returns is sorted on the most recent date when each entity, or any entities that they contain, were last updated, in descending chronological order, that is, the most recently changed entity is returned first. If this value is used with a sortByName*Xxx* value, the name-based sort takes precedence over the date-based sort, that is, the results are sorted by name, then within names by date, newest to oldest. This value applies to the find_business, find_service, find_binding, find_tModel and find_relatedBusinesses functions.

suppressProjectedServices
Specifies that a find_service or find_business function must not return service projections. This value is enabled by default whenever the find_service function is used without a businessKey key. This value applies to the find_business and find_service functions.

For further details on the findQualifiers, refer to the UDDI Version 3 Specification documentation.

Publish API for the UDDI Version 3 registry

Use the UDDI Publish API to publish, delete, and update information that is contained in a UDDI registry. The messages that are defined in this section all behave synchronously.

To access all API calls and arguments that are supported by the UDDI Version 3 registry programmatically, use the UDDI Version 3 Client for Java. To access the API functions graphically, you can use the UDDI user interface, but not all functions are available with this method.

The UDDI Version 3 registry supports the following Publish API calls:

add_publisherAssertions
: Adds one or more publisherAssertions to the assertion collection of an individual publisher.

delete_binding
: Deletes one or more instances of bindingTemplate data from the UDDI registry.

delete_business
: Removes one or more business registrations and all direct contents from a UDDI registry.

delete_publisherAssertions
: Removes one or more publisherAssertion elements from an assertion collection of a publisher.

delete_service
: Removes one or more businessService elements from the UDDI registry and from its containing businessEntity parent.

delete_tModel
: Logically deletes one or more tModel structures. Logical deletion hides the deleted tModel entities from find_tModel result sets, but does not physically delete them, so they are returned on a get_registeredInfo request.

get_assertionStatusReport
: Provides administrative support to determine the status of current and outstanding publisher assertions that involve any of the business registrations that the individual publisher account manages. A publisher can use this message to see the status of assertions that they have made, and to see assertions that others have made that involve businessEntity structures that the calling publisher account controls.

get_publisherAssertions
: Obtains the full set of publisher assertions that are associated with an individual publisher account. Publisher assertions are used to control publicly visible business relationships.

get_registeredInfo
: Obtains an abbreviated list of all businessEntity and tModel data that are controlled by the individual that is associated with the credentials that are passed.

save_binding
: Saves or updates a complete bindingTemplate element. This message can be used to add or update one or more bindingTemplate elements as well as the container or contained relationship that each bindingTemplate has with one or more existing businessService elements.

save_business
: Saves or updates information about a complete businessEntity element. This API has the broadest scope of all the save_*xx* API calls in the publisher API, and can be used to make comprehensive changes to the published information for one or more businessEntity elements that an individual controls.

save_service
: Adds or updates one or more businessService elements that a specified businessEntity exposes.

save_tModel
: Adds or updates one or more registered tModel entities.

set_publisherAssertions
: Manages all the tracked relationship assertions that are associated with an individual publisher account.

For full details of the Publish API syntax, refer to the UDDI Version 3 API specification.

Custody and Ownership Transfer API for the UDDI Version 3 registry

Use the UDDI Custody and Ownership Transfer API to transfer custody or ownership of one or more entities that are contained in a UDDI Version 3 registry. The UDDI Version 3 registry supports only intra-node ownership transfer; it does not support inter-node custody transfer.

To access all API calls and arguments that are supported by the UDDI Version 3 registry programmatically, use the UDDI Version 3 Client for Java. To access the API functions graphically, you can use the UDDI user interface, but not all functions are available with this method.

The UDDI Version 3 registry supports the following Custody and Ownership Transfer API calls:

discard_transferToken
: Discards a transferToken that is obtained through the get_transferToken API.

get_transferToken
: Initiates the transfer of ownership of one or more businessEntity or tModel entities from one publisher to another. When the API is invoked, no transfer takes place. Instead, the relinquishing publisher uses this API to obtain permission from the custodial node, in the form of a transferToken, to undertake the transfer. The relinquishing publisher gives the transferToken to the recipient publisher, who must invoke the transfer_entities API to transfer the entities.

transfer_entities
: Performs the transfer of entities when called by the recipient publisher. The recipient publisher must specify an unexpired transferToken on the call.

For details of the query syntax, refer to the UDDI Version 3 API specification.

Security API for the UDDI Version 3 registry

The UDDI Version 3 registry has an independent Security API, unlike UDDI Version 1 and Version 2, where the Security API is part of the Publish API.

To access all API calls and arguments that are supported by the UDDI Version 3 registry programmatically, use the UDDI Version 3 Client for Java. To access the API functions graphically, you can use the UDDI user interface, but not all functions are available with this method.

The UDDI Version 3 registry supports the following Security API calls:

discard_authToken
: Informs a node that a previously obtained authentication token is no longer required and is no longer valid if it is used after this message is received. The token is discarded and the session is effectively ended.

get_authToken
: Requests an authentication token in the form of an authInfo element from a UDDI node.

For full details of the Security API syntax, refer to the UDDI Version 3 API specification.

UDDI registry Version 3 entity keys

The UDDI Version 3 specification expands the space available for keys. Entity keys can be any Universal Resource Identifier (URI) that follows the recommended UDDI scheme. Depending on registry policy, both the UDDI registry and the publisher of the entity can assign keys.

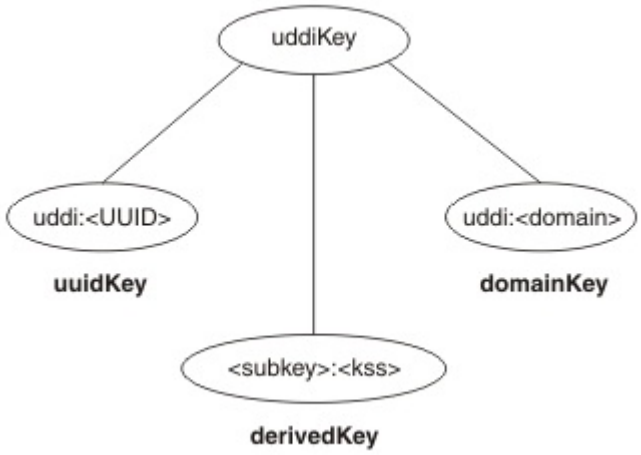
Entity keys are identifiers that are used to address entities in a UDDI registry. Each businessEntity, businessService, bindingTemplate, or tModel entity has a unique identifier that is generated or assigned when it is first published in the UDDI registry. In a particular registry, a key must be unique. For UDDI Version 1 and Version 2, the space is limited to a universal unique identifier (UUID). For UDDI Version 3, entity keys can be any URI that follows the recommended UDDI scheme.

For UDDI Version 3, depending on registry policy, not only can the UDDI registry assign keys, but also the publisher of the entity. These differences raise issues for maintaining key uniqueness and managing key space.

UDDI Scheme

The UDDI Version 3 registry implements the recommended UDDI scheme, as detailed in Section 4.4 of the UDDI Version 3 Specification. (http://uddi.org/pubs/uddi_v3.htm). This scheme defines the format of the keys, the valid characters, and the concept of key space.

In the UDDI Version 3 registry, a key is any URI and is limited to 255 characters. The following diagram shows the different types of keys in the UDDI key scheme:



All keys are composed of a set of tokens that are separated by colons (:). The first token for all keys that follow the UDDI scheme is uddi. There are three types of keys:

- The uuidKey keys contain two tokens, the mandatory uddi and a <UUID>. These keys ensure uniqueness through the UUID algorithm.
- The domainKey keys contain two tokens, the mandatory uddi and a domain name. These keys are for creating additional mutually exclusive key spaces.
- The derivedKey keys are composite keys that are based on a subkey, which is any uddiKey, and an additional token, kss, which is a key-specific string that differentiates keys. A publisher can assign the kss token, or the kss token can be calculated algorithmically (UUID).

Another concept that is included in the UDDI key scheme is a *key generator*. A key generator represents a key space. A publisher can save entities by using keys from a certain key space only if that publisher owns the key generator that represents the key space. This feature helps to secure unique keys. The key generator is a tModel entity, with a key that is in the form <subkey>:keygenerator. By owning this tModel entity, a publisher can assign keys in the form <subkey>:<kss>. The publisher can also publish new key generator tModel entities in the form <subkey>:<kss>:keygenerator.

Key uniqueness and registry root key space

You can configure instances of the UDDI registry as a root registry or as an affiliate registry.

Root registries define their own root key space by defining their own root key generator. This action defines the total key space that the registry manages. All keys that the registry generates are in this key space. If the policy allows, publishers can request subdivisions of this key space by publishing new key generator tModel entities in the form <rootkeygenerator>:<subdivisionIdentifier>:keygenerator. Publishers can then include publisher-supplied keys in subsequent publish requests that are in their allocated key space subdivision, <rootkeygenerator>:<subdivisionIdentifier>:<kss>.

To avoid key collisions, affiliate registries must establish their root key generator by first submitting a tModel:keygenerator request to the root registry they want to be an affiliate of, and then using this

subdivision of the key space of the root registry as their own root key generator. This process ensures that there are no collisions between keys that are generated or accepted by an affiliate registry, and other keys in the root registry key space.

To maintain key uniqueness, simple rules are applied. The registry generates new keys only in the key space that is defined by its own root key generator. The registry only accepts publisher-supplied keys that are in subdivisions of key space that the publisher owns, that is, as the result of a previous successful tModel tModel:keygenerator publish request.

Simple example for a private root registry:

```
with a Root keygenerator:

uddi:aPrivateRegistryKeySpaceIdentifier:keygenerator

generates Entity Keys of format:

uddi:aPrivateRegistryKeySpaceIdentifier:<uuid>

depending on Policy, accepts tModel:keygenerator requests from Publishers for
'top-level' subdivisions of format:

uddi:aPrivateRegistryKeySpaceIdentifier:aPublisherSubdivisionIdentifier:
keygenerator
```

Publishing tModel:keygenerator requests for subdivisions of key space

Depending on policy, a publisher can submit a request for a top-level subdivision of the key space in the root registry for its own use. The policy can specify whether the registry supports publisher-supplied keys and whether the user entitlements of particular publisher allow the publisher to submit requests for key space.

As well as top-level subdivisions of the key space in the root registry, a publisher can also create additional subdivisions of key space.

The following simple example is a continuation of the previous example and requests the subdivision `a`:

```
uddi:aPrivateRegistryKeySpaceIdentifier:aPublisherSubdivisionIdentifier:
a:keygenerator
```

For a request for a further subdivision to be successful, the publisher that requested, and owns, the tModel entity for the previous subdivision must make the request. In the previous example, this publisher is uddi:aPrivateRegistryKeySpaceIdentifier:aPublisherSubdivisionIdentifier:keygenerator).

Publishing with a publisher-supplied key

After a publisher successfully requests a subdivision of the key space in a root registry, that publisher must establish and maintain its own scheme to ensure that the keys that are generated for use as publisher-supplied keys in subsequent publish requests are unique in the subdivision.

Valid schemes need to generate keys that are unique derived keys in the allocated key space subdivision, for example by including a unique (incremented) numeric index.

The following simple example continues from the previous example. For a key space subdivision that results from the tModel:keygenerator request:

```
uddi:aPrivateRegistryKeySpaceIdentifier:aPublisherSubdivisionIdentifier:
a:keygenerator

valid keys are:

uddi:aPrivateRegistryKeySpaceIdentifier:aPublisherSubdivisionIdentifier:a:1

uddi:aPrivateRegistryKeySpaceIdentifier:aPublisherSubdivisionIdentifier:a:2
```

Digital signatures and the UDDI registry

In UDDI Version 3, publishers can digitally sign UDDI elements while they are publishing. The UDDI Version 3 schema supports the signing of businessEntity, businessServices, bindingTemplate, tModel, and publisherAssertion elements.

You can validate UDDI elements that are digitally signed to prove that they have not been modified or tampered with, and that their integrity is intact.

For full details about signing UDDI entities and verifying signatures, see *Appendix I: Support for XML Digital Signatures* in the UDDI Version 3.0.2. specification.

The UDDI registry does not validate signatures when signed elements are published. When the signed elements are retrieved, the retrieving client is responsible for validating the signature and providing a mechanism to ensure that the signer certificate is signed by a Certificate Authority (CA) that the client approves and trusts. If a signature is decrypted successfully by using the signer public key, it indicates that only the owner of the corresponding private key can have signed and published this element.

Signature generation

The attributes of an element are included in the generation of an element signature. Therefore, all entity keys must be available when the signature is generated. Publishers can generate publisher-assigned keys for all the keys of an element before signing. Alternatively, if publishers publish the element without keys, the registry node generates the required entity keys and then retrieves, signs, and republishes the signed element.

Signature validation

The signature element to validate is in the top-level element that a call to the getXXDetails method returns. The client is responsible for the validation. The client must have previously imported the X509.3 certificate of the publisher, and validated that certificate based on the CA it trusts. In this way, the client has access to the public validation key of the publisher that corresponds to the private signing key that the publisher used to sign the entity before publishing it.

You can use the UDDI Version 3 Client to construct Java API for XML-based RPC (JAX-RPC) objects and to invoke the UDDI Version 3 web service. As part of this client, you can use a helper class, com.ibm.uddi.v3.client.apilayer.xmldig.SignatureUtilities, to create and validate digital signatures on the UDDI Version 3 entities that support them. For details of application programming interfaces (APIs) in this helper class and the SignatureUtilitiesException exception, see the API information.

For UDDI, digital signatures are used to sign the data. They are not used to authenticate the SOAP message.

UDDI Version 3 Client

You can use the UDDI Version 3 Client for Java to access the UDDI Version 3 application programming interfaces (APIs) from Java client code.

The UDDI Version 3 Client for Java is a Java API for XML-based RPC (JAX-RPC) class library that provides an API that client programs can use to interact with a Version 3 UDDI registry. This class library can be used to construct UDDI JAX-RPC objects and to invoke the UDDI Version 3 web service.

This client also contains an XML digital signature utility class called SignatureUtilities, which is provided to construct and validate digital signatures on UDDI elements.

Multiple language encoding support

The UDDI Version 3 API supports both UTF-8 and UTF-16 encoding. Internally, UTF-16 characters are stored as UTF-8 characters. This behavior is not apparent to the user application.

Client JAR file

WebSphere Application Server provides the class library `uddiv3client.jar`, which contains the JAX-RPC UDDI Version 3 types and UDDI WebService invocation classes. This Java archive (JAR) file is in *app_server_root*/UDDIReg/clients.

The UDDI Version 3 client provides port types that map onto the UDDI Version 3 SOAP Inquiry, Publish, Custody Transfer, and Security APIs. These APIs are protected by access control mechanisms, for example role mappings. A client program that uses the UDDI Version 3 client gets the appropriate port type for the request that is issued, for example, the UDDI_Publication_PortType for a save_business request. If the role mappings are such that the request requires a WebSphere Application Server authenticated user ID, the client program passes the user ID and password by setting the relevant properties on the JAX-RPC stub for that port.

UDDI Version 3 Client samples

The following UDDI registry samples illustrate the use of the Version 3 Client. To access the samples, see the Samples for WebSphere Application Server and use the UDDI Registry link.

UDDIv3ClientBindingSample.java
An example of how to save and find binding templates.

UDDIv3ClientBusinessSample.java
An example of how to save and find business entities.

UDDIv3ClientServiceSample.java
An example of how to save and find business services.

UDDIv3ClientSignedBusinessSample.java
An example of how to sign and verify a business entity.

UDDIv3ClientTModelSample.java
An example of how to save and find TModel entities.

UDDIv3ClientSignedTModelSample.java
An example of how to sign and verify TModel entities.

These classes contain details on how to compile and run the samples.

HTTP GET services for UDDI registry data structures

The UDDI registry offers an HTTP GET service for access to the XML representations of the businessEntity, businessService, bindingTemplate, and tModel UDDI data structures. The Uniform Resource Locators (URLs) at which these structures are accessible use the entity key as a URL parameter. The XML element that is returned is a businessDetail, serviceDetail, bindingDetail or tModelDetail element, according to the type of entity key that is supplied.

XML for both UDDI Version 2 and Version 3 can be retrieved, each at different URLs. The URLs to send the HTTP GET requests to are in the following formats:

For UDDI Version 2:
http://*server*:*port*/uddisoap/get?*entityKey_type=v2_entityKey*

For UDDI Version 3:
http://*server*:*port*/uddiv3soap/get?*entityKey_type=v3 entityKey*

For example, if the server is myserver.com and the port is 9080, you can access the uddi-org:types tModel entity at the following URLs:

UDDI Version 2:
http://myserver.com:9080/uddisoap/get?tModelKey=uuid:c1acf26d-9672-4404-9d70-39b756e62ab4

UDDI Version 3:
http://myserver.com:9080/uddiv3soap/get?tModelKey=uddi:uddi.org:categorization:types

A number of UDDI node property and policy settings relate to the HTTP GET services:

- Version 3 HTTP GET for UDDI entities
  - Node supports HTTP GET
  - URL prefix for Version 3 GET servlet
  - Node generates discovery URLs
- Version 2 HTTP GET for discovery URLs
  - Prefix for generated discovery URLs
  - Node generates discovery URLs

UDDI registry SOAP service end points

UDDI Version 3 supports multiple versions of SOAP API services. Depending on the security settings for WebSphere Application Server and the user data constraint transport guarantee settings for the UDDI SOAP service, UDDI Version 3 supports different end points for different services.

The following list of default context root and Uniform Resource Locator (URL) values apply when WebSphere Application Server security is enabled and you and do not change the default supplied security settings. If you do not use the default security settings, the context root and URL values might differ.

In the following URLs, the variables have the following values:

- *host_name* is the name of the machine that is running the relevant profile.
- *http_port* is the internal HTTP port for the profile, for example 9080.
- *ssl_port* is the internal secure sockets layer (SSL) port for the profile, for example 9443.
- Version 1 and Version 2 SOAP API services

  Inquiry service
  Default (soap.war) context-root='/uddisoap' and url-pattern = 'inquiryAPI' or 'inquiryapi'.

  Default URL: http://*host_name*:*http_port*/uddisoap/inquiryapi

  Publish service
  Default (soap.war) context-root='/uddisoap' and url-pattern = 'publishAPI' or 'publishapi'.

  Default URL: https://*host_name*:*ssl_port*/uddisoap/publishapi or http://*host_name*:*http_port*/uddisoap/publishapi
- Version 3 SOAP API services

  Inquiry service
  Default (soap.war) context-root='/uddiv3soap' and url-pattern = '/services/UDDI_Inquiry_Port'

  Default URL: http://*host_name*:*http_port*/uddiv3soap/services/UDDI_Inquiry_Port

  Publish service
  Default (soap.war) context-root='/uddiv3soap' and url-pattern = '/services/UDDI_Publish_Port'

  Default URL: https://*host_name*:*ssl_port*/uddiv3soap/services/UDDI_Publish_Port or http://*host_name*:*http_port*/uddiv3soap/services/UDDI_Publish_Port

  Custody transfer service
  Default (soap.war) context-root='/uddiv3soap' and url-pattern = '/services/UDDI_Custody_Port'

Default URL: https://hostname:9443/uddiv3soap/services/UDDI_Custody_Port or
http://hostname:9080/uddiv3soap/services/UDDI_Custody_Port

Security service

Default (soap.war) context-root='/uddiv3soap' and url-pattern = '/services/UDDI_Security_Port'

Default URL: https://*host_name*:*ssl_port*/uddiv3soap/services/UDDI_Security_Port or
http://*host_name*:*http_port*/uddiv3soap/services/UDDI_Security_Port

An endpoint is available for using HTTP GET to return XML representations of UDDI entities. See the information about HTTP GET services for UDDI registry data structures.

If you configure the UDDI registry to use WebSphere Application Server security, and you do not change the default data confidentiality settings for the UDDI SOAP service, services with default end point URLs with HTTPS and a SSL port require that their data is transported confidentially. Requests that do not use HTTPS are rejected.

If you configure the UDDI registry to use WebSphere Application Server security and you change the data confidentiality setting for the UDDI SOAP service to NONE, or you disable WebSphere Application Server security, services with default end point URLs with HTTPS and a SSL port can also use HTTP and a HTTP port.

To understand how access to the SOAP APIs is protected, see the information about access control for UDDI registry interfaces.

UDDI4J programming interface (Deprecated)

The UDDI4J Version 2 APIs are deprecated in this version of WebSphere Application Server. The UDDI Version 3 Client for Java is the preferred API for accessing UDDI through Java code.

WebSphere Application Server provides UDDI4J classes in the com.ibm.uddi.jar file. This file contains classes that support Version 1 and Version 2 of the UDDI specification, providing compatability with earlier versions of WebSphere Application Server. The UDDI4J classes in this file are deprecated.

The UDDI4J methods map onto the UDDI Version 1 and Version 2 SOAP Inquiry and Publish APIs. These APIs are protected by access control mechanisms, for example role mappings. If the role mappings for these APIs are such that requests to these interfaces require a WebSphere Application Server authenticated user ID, a client program that uses UDDI4J must pass the user name and password, by setting the system properties http.basicAuthUserName and http.basicAuthPassword. A UDDI4J client program can also specify details for a proxy server, including a user name and password, by using the following system properties:

- http.proxyHost
- http.proxyPort
- http.proxyUserName
- http.proxyPassword

Using the UDDI EJB Interface (Deprecated)

Use the Enterprise JavaBeans (EJB) application programming interface (API) of the UDDI registry component to publish, find, and delete UDDI entries. However, the UDDI EJB interface is deprecated and supports UDDI version 2 API requests only.

Before you begin

Both WebSphere Application Server and the UDDI registry must be installed, and must both be running. You cannot use the EJB client from a machine that does not have WebSphere Application Server installed.

About this task

Note: The UDDI EJB interface is deprecated in WebSphere Application Server Version 6.0.

The client classes that are required for the EJB interface are contained in *app_server_root*/UDDIReg/clients/uddiejbclient.jar. For the Java documentation for these classes, see the information about additional APIs.

The EJB API is contained in two stateless session beans, one for the inquiry API (com.ibm.uddi.ejb.InquiryBean) and one for the publish API (com.ibm.uddi.ejb.PublishBean), whose public methods form an EJB interface for the UDDI registry. All the public methods on the InquiryBean class correspond to UDDI Version 2 inquiry API functions, and all the public methods on the PublishBean class correspond to UDDI Version 2 publish API functions. Not all UDDI Version 2 API functions are implemented, for example get_authToken, discard_authToken, and get_businessDetailExt.

In each interface, there are groups of overloaded methods that correspond to the operations in the UDDI 2.0 specification. There is a separate method for each major variation in function. For example, the single UDDI operation find_business is represented by ten variations of findBusiness methods, with different variations to find by arguments such as name or categoryBag.

The arguments for the EJB interface methods are Java objects in the com.ibm.uddi.datatypes package. Generally, there is a one-to-one correspondence between classes in this package and elements of the UDDI Version 2 XML schema. There are exceptions to this correspondence, for example, where UDDI XML elements can be represented by a single string. For more information, see the Java documentation for the package com.ibm.uddi.datatypes in the information about additional APIs.

The methods on the EJB InquiryBean class map to the EJB inquiry role, and those of the EJB PublishBean class map to the EJB publish role. The EJB inquiry and publish roles protect the EJB interface, as described in information about access control for UDDI registry interfaces. If the role mapping is such that a method requires a WebSphere Application Server authenticated user ID, a client program can supply the user ID and password, either when prompted by WebSphere Application Server, or by providing application code that logs in to the default realm using the user ID and password. Use the `sas.client.props` configuration file to determine how to specify the user ID and password when you configure security.

To use the EJB client, use the following steps.

Procedure

1. Set up your environment to communicate with WebSphere Application Server:

```
. app_server_root/bin/setupCmdLine.sh
```

   Notice that a single space character follows the period (.)

2. Ensure that your CLASSPATH includes the uddiejbclient.jar file (from the *app_server_root*/UDDIReg/clients directory), and the code for your client.
3. Compile your EJB client programs:

```
$JAVA_HOME/bin/javac -extdirs $WAS_EXT_DIRS:$JAVA_HOME/jre/lib/ext
-classpath $WAS_CLASSPATH:$CLASSPATH yourcode.java
```

4. Run the compiled programs:

```
$JAVA_HOME/bin/java -Djava.ext.dirs=$WAS_EXT_DIRS:$JAVA_HOME/jre/lib/ext
-Dwas.install.root=$WAS_HOME -Dserver.root=$WAS_HOME $CLIENTSAS $CLIENTSOAP
-cp $WAS_CLASSPATH:$WAS_HOME/UDDIReg/clients/uddiejbclient.jar:$CLASSPATH
<class name> <args>
```

   Ensure that your PATH statement starts with *app_server_root*/java/bin.

Using the UDDI registry user interface

The UDDI registry user interface (also referred to as the UDDI registry user console) is a graphical interface that you can use to issue inquiry requests and explore the UDDI registry.

Before you begin

If you require multiple language encoding, the UDDI user console supports only Universal Transformation Format (UTF)-8 encoding. For UTF-8 encoding support, configure the application server that hosts the UDDI registry for UCS transformation format. The UDDI user console does not support UTF-16 encoding.

About this task

The UDDI user console provides a graphical user interface to most of the UDDI Version 3 API. The user console does not support the full API set, but provides a way to issue inquiry requests and to familiarize yourself with general UDDI concepts. Explanatory text on the screens provides help. The following list describes areas that are not supported through the user console, and other known restrictions in the user console.

- You cannot specify maximum rows on find queries. You can set the “Single maximum rows” value for the registry by using the “Maximum inquiry result set size” general property on the administrative console.
- The identifier feature is not supported in the find business area or the find technical model (tModel) area.
- In the add business area, adding discovery URLs, identifiers or digital signatures is not supported.
- In the add technical model (tModel) area, adding identifiers or digital signatures is not supported.

The exact behavior of the user console depends on the following configurable factors:

- Whether WebSphere Application Server security is enabled.
- How the UDDI registry GUI role mappings are set. The UDDI registry supports two security roles for the user console:
  - GUI_Publish_User
  - GUI_Inquiry_User.
- How the UDDI registry GUI secure sockets layer (SSL) transport guarantee constraints are set. The UDDI registry supports the configuration of SSL settings, including two settings for the user console.

The following table summarizes the behavior of the UDDI registry user console.

Table 246. Behavior of the UDDI user console. The table lists the URLs used for the different UDDI registry settings, along with a description of the behavior associated with each setting.

WebSphere Application Server security status	URL used to access the UDDI user console	Behavior of the UDDI user console
Enabled	http://*host_name*:*http_port*/uddigui	Inquiry requests do not require authentication; they use the HTTP URL and are not secure. Publish requests require WebSphere Application Server authentication. When you access the publish pane, you are dynamically redirected to use HTTPS, and are prompted for a user ID and password. For a successful request, the authenticated user must be registered as a UDDI publisher. If the GUI_Inquiry_User role is mapped to all authenticated users, and the transport guarantee in the user data constraint section for that role is set to CONFIDENTIAL, all requests, including inquiry, require authentication and use of HTTPS.
	https://*host_name*:*ssl_port*/uddigui	Requests are secure; you are prompted to authenticate with a user ID and password. For a successful request, the authenticated user must be registered as a UDDI publisher.

Table 246. Behavior of the UDDI user console (continued). The table lists the URLs used for the different UDDI registry settings, along with a description of the behavior associated with each setting.

WebSphere Application Server security status	URL used to access the UDDI user console	Behavior of the UDDI user console
Disabled	http://*host_name*:*http_port*/uddigui	No requests, either publish or inquire, are authenticated and the data flow is not secure (non- SSL). Even though SSL transport-guarantee settings are defined, they are not enforced if security is disabled. All publish operations are performed using a user ID of UNAUTHENTICATED, or a value that can be configured by using the administrative console or the Java Management Extensions (JMX) management interface (this applies to new requests only).
	https://*host_name*:*ssl_port*/uddigui	No requests, either publish or inquire, are authenticated, but the data flow is secure because the SSL URL and port are used explicitly. All publish operations are performed using a user ID of UNAUTHENTICATED, or a value that can be configured by using the administrative console or the JMX management interface (this applies to new requests only).

The variables in the table have the following values:

- *host_name* is the name of the machine that is running the relevant profile.
- *http_port* is the internal HTTP port for the profile, for example 9080.
- *ssl_port* is the internal SSL port for the profile, for example 9443.

To display the UDDI registry user console, use the following procedure.

Procedure

1. Start the UDDI application, if it is not already running.
2. Open a browser window and ensure that cookies are enabled.
3. Access the UDDI registry user console through one of the following default URLs.
   - http://*host_name*:*http_port*/uddigui
   - https://*host_name*:*ssl_port*/uddigui
4. Optional: To change the appearance and operation of the UDDI registry user console, modify the appropriate `.css` stylesheet files. You can edit style class definitions in the stylesheet files, including font attributes, layout, and colors. The stylesheet files are in the following directory:

```
profile_root/installedApps/cell_name/
UDDIRegistry.node_name.server_name.ear/v3gui.war/theme
```

   After you change a stylesheet file, refresh the browser window for the changes to take effect.

Results

The user console displays the default frameset, which contains the following items:

- The header frame.
- The navigation frame, which shows find options.
- The details frame.

What to do next

You can now use the UDDI user console to find, edit, or publish UDDI information.

Finding an entity by using the UDDI registry user interface

You can use the UDDI registry user interface to find services, businesses, and technical models.

Before you begin

Ensure that the UDDI registry application is started and the UDDI registry user console is displayed.

About this task

To use the UDDI registry user interface (also referred to as the UDDI registry user console) to find services, businesses, and technical models, use the following procedure.

Procedure

1. In the UDDI registry console, activate the Find pane. Either click the **Find** tab, or click the **Find** link at the top of the page or on the Welcome page.
2. Optional: For a simple search without any find qualifiers, use the following steps:
   a. In the **Quick Find** section of the **Find** tab, select the kind of entity that you want to find; service, business, or technical model.
   b. In the **Starting with** field, enter the name of the entity. Use the percent (%) wildcard character to search for a partial name.
   c. Click **Find**.

   The results are displayed.
3. Optional: For advanced search, use the following steps:
   a. In the **Advanced Find** section of the **Find** tab, click the appropriate link for the kind of entity that you want to find; service, business, or technical model. The advanced search form is displayed in the frame.
   b. Enter your search criteria in the advanced search form, and select any find qualifiers that you require.

      You must enter at least one name to search for, by using the **Add Name** link. You can use this link to enter multiple names.

      You can also add multiple categorizations. To add a categorization, use the **Show category tree** link in the **Categorizations** section to display, a tree of categories (or taxonomies) that define the types of item to find according to various classification systems. Expand the tree to find the category that you want, click the category to add the information to the advanced search form, then use the **Add Categorization** link to include the category in the search.
   c. Click **Find *entities***.

   The results are displayed in the detail frame.

Publishing an entity by using the UDDI registry user interface

You can use the UDDI registry user interface to publish businesses and technical models.

Before you begin

Ensure that the UDDI registry application is started and the UDDI registry user console is displayed.

About this task

You can use the UDDI registry user interface (also referred to as the UDDI registry user console) to publish businesses and technical models.

To publish a service, publish a business, and then edit the entity to add a service to that business.

Procedure

1. In the UDDI registry console, activate the Publish pane. Either click the **Publish** tab, or click the **Publish** link at the top of the page or on the Welcome page.
2. Optional: To publish an entity by name only, use the Quick publish section and the following steps:
   a. In the **Quick Publish** section of the **Publish** tab, select the kind of entity that you want to publish; business or technical model.

b. In the **Name** field, enter the name of the entity.
c. Click **Publish**.

The details of the published entity are displayed.

3. Optional: To publish an entity with more information, use the following steps:
   a. In the **Advanced Publish** section of the **Publish** tab, click the appropriate link for the kind of entity you want to publish; business or technical model. The advanced publish form is displayed.
   a. Enter the details for the entity in the advanced publish form. You can enter multiple names, descriptions, contacts, or categorizations by using the relevant **Add** link.

      To add a categorization, use the **Show category tree** link in the **Categorizations** section to display a tree of categories (or taxonomies) that define the types of item to publish according to various classification systems. Expand the tree to find the category that you want, click the category to add the information to the advanced publish form, then click the **Add Categorization** link.
   b. Click **Publish *entity*** to publish the business or technical model to the UDDI registry.

Editing or deleting an entity by using the UDDI registry user interface

You can use the UDDI registry user interface to edit or delete the businesses and technical models that you own, for example, to add services to businesses.

Before you begin

Ensure that the UDDI registry application is started and the UDDI registry user console is displayed.

About this task

To use the UDDI registry user interface (also referred to as the UDDI registry user console) to edit or delete the businesses and technical models that you own, or add services to businesses, use the following steps.

Procedure

1. In the UDDI registry console, activate the Publish pane. Either click the **Publish** tab, or click the **Publish** link at the top of the page or on the Welcome page.
2. In the Registered Information section on the **Publish** tab, click **Show owned entities** to show the businesses and technical models that you registered in the UDDI registry.
3. Optional: To delete a business or a technical model, click **Delete** in the **Actions** column for that entity. When you delete a technical model, it is hidden, rather than physically deleted, as specified by the UDDI Version 3.0 specification. If you click **Shown owned entities**, the technical model is still displayed, but if you use the Find function, the technical model is not displayed. All other entities are deleted from the UDDI registry in the usual way.
4. Optional: To edit a business or technical model, click **Edit** in the **Actions** column for that entity, enter the required details, then click **Update *entity*** to save the changes in the UDDI registry.
5. Optional: To add a service to a business, click **Add service** in the **Actions** column for that business. Enter the details, then click **Add Service** to publish the service to the UDDI registry. The service details are displayed.

Creating business relationships by using the UDDI registry user interface

If your business has an association with another business in the UDDI registry, for example a preferred supplier, you can describe this association in the UDDI registry by creating a *business relationship*.

Before you begin

- The UDDI registry contains the following default relationship types:

Parent-child
A hierarchical relationship exists between the two business entities, which might represent, for example, a large organization and a subsidiary.

Peer-peer
The two business entities represent peer organizations, for example a company and its supplier.

Identity
The two business entities represent the same organization.

If you require a different relationship type, create a user-defined value set to represent the relationship type that you require, as described in the topic about user-defined value set support in the UDDI registry.

- Each business that is involved in the relationship must already exist in the UDDI registry.
- Ensure that the UDDI registry application is started and the UDDI registry user console is displayed.

About this task

Complete this task when you want to publicize an association between two businesses in the UDDI registry. For example, your organization, represented by a business entity in the UDDI registry, might have several departments, each one represented by a different business entity in the UDDI registry. You might want to declare these departments as being linked to the parent organization, by creating parent-child relationships between the appropriate business entities.

Procedure

1. Activate the **Publish** tab by clicking it, or by clicking the **Publish** link at the top of the page or on the Welcome page.
2. Under **Registered Information**, click **Show owned entities**. The entities that you own are displayed in the detail frame on the right.
3. In the section for the businesses that you own, find the business that you want to link from, and click the **Add relationship** link for that business. The Add Business Relationship pane is displayed. The business key for the business that you selected is already listed in the From section.
4. Click **Add** to add the second business, the business that you want to link to. The advanced find pane is displayed.
5. Find the second business, as described in the advanced find step of “Finding an entity by using the UDDI registry user interface” on page 1793.
6. Click **Select** to add the second business to the relationship. If you want to change the positions of the businesses, click **Swap**.
7. Select the type of relationship from the **Type** list.
8. If required, type a description in the **Usage** field.
9. Click **Add relationship** to create the relationship. If you own both businesses, no further action is required. The relationship is displayed as a *publisher assertion* in the list of entities that you own. The status of the assertion is complete.
10. If you do not own the second business, the status of the assertion is pending. The owner of the second business must create a relationship from their business to yours, for the relationship to be complete and visible to other parties. The relationship type must match the type that you chose earlier.

Results

The business relationship is published to the UDDI registry. The UDDI user interface only shows publisher assertions for entities that you own. To view other relationships, use the UDDI inquiry API provided.

What to do next

For more information about publisher assertions, refer to the UDDI specification.

To remove an assertion that you own, display your owned entities and click the **Delete** link for the relevant publisher assertion. If the business in the To field is owned by someone else, the status of the assertion becomes pending, and the relationship is no longer visible to other parties.

Example: Publishing a business, service, and technical model using the UDDI registry user interface

This example describes how to use the UDDI registry user interface to publish a used car business called Modern Cars to the UDDI registry, and how to publish a service and technical model for the business.

Before you begin, ensure that the UDDI registry application is started and the UDDI registry user console is displayed.

Adding the business

1. Click the **Publish** tab to activate the Publish pane.
2. Under **Advanced Publish**, click **Add a business**. The advanced publish form is displayed.
3. Type `Modern Cars` in the **Name** field for the business. Select the language of the business name from the list, then click **Add Name** to add the name to the business.
4. Type a description for the business, for example `Used cars for sale` in the **Description** field. Select the language of the description from the list, then click **Add Description** to add the description to the business. You can add multiple descriptions in a variety of languages as required.
5. In the **Contact** section, type your name as a contact for customers of the business. Select the language as before, and click **Add Contact**. The business contact form is displayed. Enter the details, using the **Add *entity*** links to add the information as you reach the end of each subsection. All the text fields in the form are cleared when you click an **Add *entity*** link. Click **Add Contact** to save the contact information into the Modern Cars business.
6. Use the **Categorizations** section to describe the Modern Cars business according to the NAICS 2002 categorization system:
   a. Click **Show category tree** to display the various categorization systems.
   b. Expand the **NAICS 2002** tree, then expand **Retail Trade [44]** > **Motor Vehicle and Parts Dealers [441]** > **Automobile Dealers [4411]** > **Used Car Dealers [44112]**. Click the **Used Car Dealers [441120]** category to add the category type, key name, and key value to the advanced publish form.
   c. Click **Add Categorization** to add the information to the business.
   d. Close the category tree by clicking **Close** .
7. Click **Publish Business** to publish the Modern Cars business to the UDDI registry. The details of the business are displayed.

Adding a service to the business

1. Click the **Publish** tab to activate the Publish pane.
2. Under **Registered Information**, click **Show owned entities** to display the Modern Cars business and any other entities that you own.
3. Click **Add service** in the **Actions** column of the Modern Cars business. The publish service page is displayed.
4. Add a name and description for the service, in the same way as for the business itself.
5. Click **Add a Service Binding** to display the service binding form.
   a. Enter an access point (the URL for the service on the network) and a description for the service binding.

b. Click **Add Technical Model Instance Information** to display a page where you can describe and publish a technical model instance for the service binding.
c. In the technical model information page, click **Add Technical Model**.
d. Search for the technical model that the instance uses, select the technical model from the results, then click **Add**.
e. Complete the other fields on the form and click **Add Technical Model Instance**.
f. Click **Add Binding** to save the information into the service.

Enter an access point (the URL for the service on the network) and a description for the service binding.

6. Add a categorization in the same way as for the business.
7. Click **Add Service** to publish the service to the UDDI registry.

Adding a technical model

1. In the **Advanced Publish** section, click **Add a technical model** to display the publish technical model form.
2. Add a name and description for the technical model, in the same way as for the business and the service.
3. Click **Add an Overview Document** to display the overview document form. The overview document describes the technical model.
   a. Type the location of the overview document in the **Overview URL** field.
   b. Click **Add Overview Document URL**.
   c. Add a description and click **Add Overview Document** to save the information in the technical model.
4. Add a categorization in the same way as for the business.
5. Click **Publish Technical Model** to publish the technical model to the UDDI registry.

Using the JAXR provider for UDDI

To get started with the Java API for XML Registries (JAXR) provider, you can use a sample program. You also need to consider class libraries, authentication and security, internal taxonomies, and logging and messages.

About this task

Note: From WebSphere Application Server Version 8.0, Java API for XML Registries (JAX-R) APIs are deprecated. The Java Platform, Enterprise Edition (Java EE) 6 platform began the deprecation process for JAX-R because it is based on Universal Description, Discovery and Integration (UDDI) 2 technology, which is no longer relevant. If your applications use JAX-R, then you might consider using UDDI 3.

Procedure

- To obtain the ConnectionFactory instance, create a connection to the registry, and save an organization in the registry, see the following sample program.

```
import java.net.PasswordAuthentication;
import java.util.ArrayList;
import java.util.Collection;
import java.util.HashSet;
import java.util.Properties;
import java.util.Set;

import javax.xml.registry.BulkResponse;
import javax.xml.registry.BusinessLifeCycleManager;
import javax.xml.registry.Connection;
import javax.xml.registry.ConnectionFactory;
import javax.xml.registry.JAXRException;
import javax.xml.registry.RegistryService;
```

```
import javax.xml.registry.infomodel.Key;
import javax.xml.registry.infomodel.Organization;

public class JAXRSample
{
    public static void main(String[] args) throws JAXRException
    {
        //Tell the ConnectionFactory to use the JAXR provider for UDDI
        System.setProperty("javax.xml.registry.ConnectionFactoryClass",
                           "com.ibm.xml.registry.uddi.ConnectionFactoryImpl");
        ConnectionFactory connectionFactory = ConnectionFactory.newInstance();

        //Set the URLs for the UDDI inquiry and publish APIs.
        //These must be the URLs of the UDDI version 2 APIs.
        Properties props = new Properties();
        props.setProperty("javax.xml.registry.queryManagerURL",
                          "http://localhost:9080/uddisoap/inquiryapi");
        props.setProperty("javax.xml.registry.lifeCycleManagerURL",
                          "http://localhost:9080/uddisoap/publishapi");
        connectionFactory.setProperties(props);

        //Create a Connection to the UDDI registry accessible at the above URLs.
        Connection connection = connectionFactory.createConnection();

        //Set the user ID and password used to access the UDDI registry.
        PasswordAuthentication pa = new PasswordAuthentication("Publisher1",
                        new char[] { 'p', 'a', 's', 's', 'w', 'o', 'r', 'd' });
        Set credentials = new HashSet();
        credentials.add(pa);
        connection.setCredentials(credentials);

        //Get the javax.xml.registry.BusinessLifeCycleManager interface,
        //which contains methods corresponding to UDDI publish API calls.
        RegistryService registryService = connection.getRegistryService();
        BusinessLifeCycleManager lifeCycleManager =
                                  registryService.getBusinessLifeCycleManager();

        //Create an Organization (UDDI businessEntity) with name
        //"Organization 1".
        Organization org =
                         lifeCycleManager.createOrganization("Organization 1");

        //Add the Organization to a Collection, ready to be saved in the UDDI
        //registry.
        Collection orgs = new ArrayList();
        orgs.add(org);

        //Save the Organization in the UDDI registry.
        BulkResponse bulkResponse = lifeCycleManager.saveOrganizations(orgs);

        //Obtain the Organization Key (the UDDI businessEntity
        //businessKey) from the response.
        if (bulkResponse.getExceptions() == null)
        {
        //1 Organization was saved, so 1 key will be returned in the
        //response collection
            Collection responses = bulkResponse.getCollection();
            Key organizationKey = (Key)responses.iterator().next();
            System.out.println("\nOrganization Key = " +
                                                    organizationKey.getId());
        }
    }
}
```

- Ensure that the class path is set.

  The class libraries of the JAXR provider for UDDI are in the com.ibm.uddi_1.0.0.jar file, in the *app_server_root*/plugins directory. When you use the JAXR API from a Java EE application running under WebSphere Application Server, all required classes are automatically on the class path. When you use the JAXR API from outside this environment, the following .jar files must be on the Java class path:

  – *app_server_root*/lib/bootstrap.jar
  – *app_server_root*/plugins/com.ibm.uddi_1.0.0.jar
  – *app_server_root*/plugins/com.ibm.ws.runtime_6.1.0

- To use the JAXR provider for UDDI, first you must specify the name of the ConnectionFactory implementation class. Set the javax.xml.registry.ConnectionFactoryClass system property to com.ibm.xml.registry.uddi.ConnectionFactoryImpl.

  If you do not set this system property, the value defaults to com.sun.xml.registry,common.ConnectionFactoryImpl, which cannot be found and causes a JAXRException exception when the ConnectionFactory.newInstance() method is called.

  The JAXR provider for UDDI does not support lookup of the ConnectionFactory using Java Naming and Directory Interface (JNDI).
- To specify connection-specific properties, set a java.util.Properties object on the JAXR ConnectionFactory before you obtain a connection.

  The full list of these properties is in the JAXR specification. The following table lists the three most important properties, and what values they take to use the JAXR provider for UDDI to access the UDDI registry.

Table 247. Connection-specific properties required to use the JAXR provider for UDDI to access the UDDI registry. The table lists the different properties along with a description for each one.

Property	Description
javax.xml.registry.queryManagerURL	The URL for the Inquiry API of the UDDI registry for UDDI Version 2. Typically, this property is in the form: `http://hostname:port/uddisoap/inquiryapi`. This property is required.
javax.xml.registry.lifeCycleManagerURL	The URL for the Publish API of the UDDI registry for UDDI Version 2. Typically, this property is in the form: `http://hostname:port/uddisoap/publishapi`. If you do not specify this property, it defaults to the value of the javax.xml.registry.queryManagerURL property. However, the UDDI registry typically has different URLs for the Inquiry and Publish APIs, so it is advisable to specify both properties.
javax.xml.registry.authenticationMethod	The method of authentication to use when authenticating with the registry. This can take one of two values, UDDI_GET_AUTHTOKEN and HTTP_BASIC. If you do not specify a value, the default value is UDDI_GET_AUTHTOKEN. See the following step for more information.

  The only required connection property is javax.xml.registry.queryManagerURL. However, it is advisable to set javax.xml.registry.lifeCycleManagerURL and understand the default value of javax.xml.registry.security.authenticationMethod. The other connection properties that are defined in the JAXR specification are optional, and their values are not specific to the UDDI registry. The JAXR provider for UDDI does not define any additional provider-specific properties.
- To determine which method the JAXR provider uses to authenticate with the UDDI registry, set the javax.xml.registry.authenticationMethod connection property.

  The javax.xml.registry.authenticationMethod connection property determines which method the JAXR provider uses to authenticate with the UDDI registry. Two values of this property are supported:

  – UDDI_GET_AUTHTOKEN

    The JAXR provider uses the UDDI V2 get_authToken API to authenticate with the registry. The JAXR provider makes the get_authToken call automatically when the connection credentials are set. The JAXR provider saves the UDDI V2 authToken that the call returns to use on subsequent UDDI publish API calls.

  – HTTP_BASIC

    The JAXR provider uses HTTP basic authentication to authenticate with the registry. WebSphere Application Server supports HTTP basic authentication when security is enabled. The JAXR provider does not make a get_authToken call. Instead, whenever there is a UDDI API call (both Inquiry and Publish), the user name and password are sent in the HTTP headers, using HTTP basic authentication. If the UDDI registry does not require HTTP basic authentication, the credentials are ignored.

  The JAXR provider for UDDI does not support the CLIENT_CERTIFICATE or MS_PASSPORT methods of authentication.

If you do not set this property, the default authentication method is UDDI_GET_AUTHTOKEN.

- To use Secure Sockets Layer (SSL) to encrypt HTTP traffic between the JAXR provider for UDDI and the UDDI registry, see “Using SSL with the UDDI JAXR provider” on page 1802.
- To supply a custom internal taxonomy, see “Creating a custom internal taxonomy for the JAXR provider” on page 1802.
- To switch on UDDI4J logging, set the org.uddi4j.logEnabled system property to `true`. The JAXR provider for UDDI uses UDDI4J Version 2 to communicate with the UDDI registry, and UDDI4J has its own logging.

Java API for XML Registries (JAXR) provider for UDDI

The Java API for XML Registries (JAXR) is a Java client API for accessing both UDDI (Version 2 only) and ebXML registries. It is part of the Java Platform, Enterprise Edition (Java EE) specification.

Note: From WebSphere Application Server Version 8.0, Java API for XML Registries (JAX-R) APIs are deprecated. The Java Platform, Enterprise Edition (Java EE) 6 platform began the deprecation process for JAX-R because it is based on Universal Description, Discovery and Integration (UDDI) 2 technology, which is no longer relevant. If your applications use JAX-R, then you might consider using UDDI 3.

The JAXR API comprises the Java EE packages javax.xml.registry and javax.xml.registry.infomodel. Java EE API documentation is at Web Services Reference.

The preferred UDDI Java client APIs are:

- UDDI4J Version 2, for UDDI Version 2
- UDDI Version 3 Client for Java, for UDDI Version 3

JAXR provider

The current JAXR specification (Version 1.0) defines a JAXR provider as an implementation of the JAXR API. Generally, a JAXR provider can be a JAXR provider for UDDI, a JAXR provider for ebXML, or a pluggable provider that supports both UDDI and ebXML. The JAXR provider for UDDI is a provider for UDDI only.

UDDI versions

A JAXR provider for UDDI accesses a UDDI registry that uses the UDDI Version 2 SOAP APIs only. The UDDI registry for UDDI Version 3 in this version of WebSphere Application Server supports the UDDI Version 1, 2 and 3 SOAP APIs. Therefore you can use the JAXR provider for UDDI to access this registry. You can also use the JAXR provider to access the UDDI registry for UDDI Version 2 in WebSphere Application Server Version 5.x.

To work with the UDDI Version 3 SOAP APIs, use the UDDI Version 3 Client for Java; you cannot use JAXR.

Capability level

The JAXR specification defines two capability profiles, capability level 0 and capability level 1. The JAXR API documentation categorizes each JAXR method as either level 0 or level 1. Generally, a JAXR provider for UDDI has capability level 0 and supports all level 0 methods, whereas a JAXR provider for ebXML has capability level 1 and supports all level 0 and level 1 methods. The JAXR provider for UDDI is a capability level 0 provider, and supports only level 0 methods.

Authentication and security

The javax.xml.registry.authenticationMethod connection property determines which method the JAXR provider uses to authenticate with the UDDI registry.

The JAXR provider uses UDDI Version 2 SOAP Inquiry and Publish APIs. These APIs are protected, as described in the topic about access control for UDDI registry interfaces.

You can use Secure Sockets Layer (SSL) to encrypt HTTP traffic between the JAXR provider for UDDI and the UDDI registry.

Using SSL with the UDDI JAXR provider

You can use Secure Sockets Layer (SSL) to encrypt HTTP traffic between the Java API for XML Registries (JAXR) provider for UDDI and the UDDI registry.

About this task

Note: From WebSphere Application Server Version 8.0, Java API for XML Registries (JAX-R) APIs are deprecated. The Java Platform, Enterprise Edition (Java EE) 6 platform began the deprecation process for JAX-R because it is based on Universal Description, Discovery and Integration (UDDI) 2 technology, which is no longer relevant. If your applications use JAX-R, then you might consider using UDDI 3.

To use SSL, set the JAXR client program as follows.

Procedure

1. For the javax.xml.registry.queryManagerURL and javax.xml.registry.lifeCycleManagerURL connection properties, specify a URL with the protocol https and the appropriate port to use SSL to access the UDDI registry. The default port of the UDDI registry for HTTPS is 9443. Often, only the lifeCycleManager URL, that is, the UDDI Publish API URL, requires SSL.
2. Add a new security provider to the java.security.Security object, according to the Java Secure Sockets Extension (JSSE) implementation that is used. If running under the JVM provided in WebSphere Application Server, the JSSE that is provided by IBM is on the classpath automatically. Use the following code to add the IBM security provider:

```
java.security.Security.addProvider(new com.ibm.jsse.JSSEProvider());
```

3. Set the javax.net.ssl.trustStore system property to the file name of the client trust store file. The client trust store file is a Java key store (.jks) file and must contain the server certificate of the UDDI registry. To manage key store files, you can use the iKeyman tool.
4. Set the javax.net.ssl.trustStorePassword system property. This property is the password used to open the client trust store file.
5. Optional: If you use a JVM version that is earlier than the version that is provided with WebSphere Application Server, you might need to set the java.protocol.handler.pkgs system property to com.ibm.net.ssl.internal.www.protocol.

What to do next

For more information about SSL and the iKeyman tool, see the topic about secure communications using SSL.

Creating a custom internal taxonomy for the JAXR provider

You can create a custom internal taxonomy and make it available to the Java API for XML Registries (JAXR) provider.

About this task

Note: From WebSphere Application Server Version 8.0, Java API for XML Registries (JAX-R) APIs are deprecated. The Java Platform, Enterprise Edition (Java EE) 6 platform began the deprecation process for JAX-R because it is based on Universal Description, Discovery and Integration (UDDI) 2 technology, which is no longer relevant. If your applications use JAX-R, then you might consider using UDDI 3.

The JAXR provider for UDDI supplies a number of internal taxonomies. You can also supply a custom internal taxonomy. To create a new custom internal taxonomy and make it available to the JAXR provider, use the following procedure.

Procedure

1. Create a text file that contains the taxonomy element data. You can use the `iso3166-2003-data.txt` file in `plugins/com.ibm.uddi_1.0.0` as an example. This file is the taxonomy data file for the supplied ISO 3166 taxonomy. The first few lines are:

```
iso3166#--#World#--
iso3166#AD#Andorra#--
iso3166#AE#United Arab Emirates#--
iso3166#AE-AJ#'Ajm?n#AE
iso3166#AE-AZ#Ab? Z?aby[Abu Dhabi]#AE
iso3166#AE-DU#Dubayy [Dubai]#AE
iso3166#AE-FU#Al Fujayrah#AE
iso3166#AE-RK#Ra's al Khaymah#AE
iso3166#AE-SH#Ash Sh?riqah [Sharjah]#AE
iso3166#AE-UQ#Umm al Qaywayn#AE
iso3166#AF#Afghanistan#--
iso3166#AF-BAL#Balkh#AF
iso3166#AF-BAM#B?m??n#AF
```

   Each line represents one element of the taxonomy, or one concept in the taxonomy concept tree. Each line has the following format:

```
<taxonomy ID>#<element value>#<element name>#<parent element value>
```

   The following table describes the tokens in the format.

Table 248. Tokens in the format of the taxonomy element data file. The table lists the different tokens along with a description for each one.

Token	Description
<taxonomy ID>	The taxonomy ID is the same for every element of a taxonomy.
<element value>	The concept value (UDDI keyValue).
<element name>	The concept name (UDDI keyName).
<parent element value>	The value of the parent element of the current element in the taxonomy tree. Except for the root element, for every element in the data file, there must be another line that defines a parent element. The root element is denoted by defining itself as its own parent. There must be only one root element, and no elements without parents.
#	The delimiter character. You can define this character for each taxonomy in the `taxonomyConfig.properties` file; the delimiter does not have to be the number sign (#).

2. Save a ClassificationScheme (UDDI tModel entity) in the UDDI registry to represent the new internal taxonomy. To do this, use the javax.xml.registry.BusinessLifeCycleManager.saveClassificationSchemes() method.
3. Add the new taxonomy to the `taxonomyConfig.properties` file
   a. Copy the supplied `taxonomyConfig.properties` file from the root of the `com.ibm.uddi_1.0.0.jar` file. The content of the supplied `taxonomyConfig.properties` file is:

```
naics-1997 = UUID:C0B9FE13-179F-413D-8A5B-5004DB8E5BB2, naics-1997-data.txt, #
naics-2002 = UUID:1FF729F2-1948-46CF-B660-31EC107F1663, naics-2002-data.txt, #
unspsc  = UUID:DB77450D-9FA8-45D4-A7BC-04411D14E384, unspsc-data.txt,     #
unspsc7_data = UUID:CD153257-086A-4237-B336-6BDCBDCC6634, unspsc7-data.txt,   #
iso3166-2003 = UUID:4E49A8D6-D5A2-4FC2-93A0-0411D8D19E88, iso3166-2003-data.txt,#
```

This file has one line for each internal taxonomy that is supplied. Each line has the following format:

```
<taxonomy ID> = <tModelKey>,<data filename>,<data file delimiter>
```

The following table describes the tokens in the format.

Table 249. Tokens in the format of the `taxonomyConfig.properties` file. The table lists the different tokens along with a description for each one.

Token	Description
<taxonomy ID>	The JAXR provider uses this value internally to identify each taxonomy. This value does not have to be the same as the taxonomy ID in the corresponding taxonomy data file.
<tModelKey>	The tModelKey element of the corresponding UDDI tModel entity, which is the id of the corresponding JAXR ClassificationScheme.
<data filename>	The name of the corresponding taxonomy data file.
<data file delimiter>	The delimiter character used in the taxonomy data file. All internal taxonomies that are supplied use the number sign (#), but user-supplied internal taxonomies might use different delimiter characters.

b. Add a new line for the new taxonomy to the copy of the `taxonomyConfig.properties` file. Do not remove any existing taxonomies from the file, because this makes them unavailable to the JAXR provider.

4. Add the copied `taxonomyConfig.properties` file to the Java class path, ahead of the `jaxruddi.jar` file.
5. If there are any JAXR client programs still running that were started before you added the new taxonomy to the `taxonomyConfig.properties` file, create a new connection to pick up the new taxonomy.

JAXR provider for UDDI internal taxonomies

The Java API for XML Registries (JAXR) provider for UDDI supplies a number of internal taxonomies.

Note: From WebSphere Application Server Version 8.0, Java API for XML Registries (JAX-R) APIs are deprecated. The Java Platform, Enterprise Edition (Java EE) 6 platform began the deprecation process for JAX-R because it is based on Universal Description, Discovery and Integration (UDDI) 2 technology, which is no longer relevant. If your applications use JAX-R, then you might consider using UDDI 3.

The following table shows the internal taxonomies that the JAXR provider for UDDI supplies.

Table 250. JAXR provider for UDDI internal taxonomies. The table lists the different internal taxonomies as well as their ClassificationScheme name and ClassificationScheme identification numbers.

Taxonomy	ClassificationScheme name (UDDI tModel name)	ClassificationScheme id (UDDI Version 2 tModelKey)
NAICS 1997	ntis-gov:naics:1997	UUID:C0B9FE13-179F-413D-8A5B-5004DB8E5BB2
NAICS 2002	ntis-gov:naics:2002	UUID:C0B9FE13-179F-413D-8A5B-5004DB8E5BB2
UNSPSC 3.1	unspsc-org:unspsc:3-1	UUID:DB77450D-9FA8-45D4-A7BC-04411D14E384
UNSPSC 7	unspsc-org:unspsc	UUID:CD153257-086A-4237-B336-6BDCBDCC6634
ISO3166 2003	ubr-uddi-org:iso-ch:3166-2003	UUID:4E49A8D6-D5A2-4FC2-93A0-0411D8D19E88

The tModel entities that correspond to all these taxonomies are available in the UDDI Version 3 registry. If you use the JAXR provider to access a UDDI Version 2 registry, only the tModel entities that correspond to the NAICS 1997, UNSPSC 3.1, and ISO3166 taxonomies are available.

Each internal taxonomy is loaded into memory once for each JAXR Connection. The classification scheme of the taxonomy is created when the connection is created. At this time, the associated UDDI tModel entity is obtained from the registry and used to populate the ClassificationScheme attributes. The concept object

tree of the taxonomy is not created until the first time the user requests the ClassificationScheme object. All subsequent requests for the same internal taxonomy that use the same connection return the same object tree.

Do not modify any part of the concept object tree programmatically. There is only one classification scheme and concept object tree for each internal taxonomy for each connection, and if you modify the concept tree programmatically, all future requests for this taxonomy that use the same connection return the modified objects, which might not be valid. If you modify the concept tree programmatically, the associated taxonomy data file does not change. To change the values in a user-defined internal taxonomy, change the taxonomy data file, then create a new connection to pick up the changes in a new concept tree.

Similarly, do not modify an internal classification scheme programmatically, except to modify and then save a user-defined internal classification scheme. A new connection is not required to pick up programmatic changes.

JAXR provider logging and messages

The Java API for XML Registries (JAXR) provider for UDDI uses UDDI4J logging, commons logging, and some standard messages.

Note: From WebSphere Application Server Version 8.0, Java API for XML Registries (JAX-R) APIs are deprecated. The Java Platform, Enterprise Edition (Java EE) 6 platform began the deprecation process for JAX-R because it is based on Universal Description, Discovery and Integration (UDDI) 2 technology, which is no longer relevant. If your applications use JAX-R, then you might consider using UDDI 3.

UDDI4J Logging

The JAXR provider for UDDI uses UDDI4J Version 2 to communicate with the UDDI registry. UDDI4J has its own logging. To switch on UDDI4J logging, set the org.uddi4j.logEnabled system property to `true`. The XML request and response bodies of every UDDI request are sent to the standard error log.

Trace Entry, exit, exception, warning, and debug trace is provided by Commons Logging (JCL). Trace is created only if the JAXR client configures it. Entry, exit, and debug trace uses the debug level of logging. Exception and warning trace uses the information level of logging. Additionally, information-level logging is provided before each UDDI4J request is made.

Standard error log messages

The InternalTaxonomyManager, EnumerationManager, and PostalSchemeManager objects send warning messages to the System.err log if there is an error condition that does not justify an exception, but does require an information message. For example, warning messages are sent if a file contains a line that is not valid, or if a tModel entity that corresponds to an internal taxonomy cannot be found in the registry.

Chapter 38. Developing Work area

This page provides a starting point for finding information about work areas, a WebSphere extension for improving developer productivity.

Work areas provide a capability much like that of global variables. They enable efficient sharing of information across a distributed application.

For example, you might want to add profile information as each customer enters your application. By placing this information in a work area, it is available throughout your application, eliminating the need to hand-code a solution or to read and write information to a database.

Developing applications that use work areas

Developing applications that use work areas

Applications interact with the work area service by implementing the UserWorkArea interface. This interface defines all of the methods used to create, manipulate, and terminate work areas.

About this task

```
package com.ibm.websphere.workarea;

public interface UserWorkArea {
   void begin(String name);
   void complete() throws NoWorkArea, NotOriginator;

   String getName();
   String[] retrieveAllKeys();
   void set(String key, java.io.Serializable value)
      throws NoWorkArea, NotOriginator, PropertyReadOnly;
   void set(String key, java.io.Serializable value, PropertyModeType mode)
      throws NoWorkArea, NotOriginator, PropertyReadOnly;
   java.io.Serializable get(String key);
   PropertyModeType getMode(String key);
   void remove(String key)
      throws NoWorkArea, NotOriginator, PropertyFixed;
}
```

Attention: Enterprise JavaBeans (EJB) applications can use the UserWorkArea interface only within the implementation of methods in either the remote or local interface, or both; likewise, servlets can use the interface only within the service method of the HTTPServlet class. Use of work areas within any life cycle method of a servlet or enterprise bean is considered a deviation from the work area programming model and is not supported.

The work area service defines the following exceptions for use with the UserWorkArea interface:

NoWorkArea
: Raised when a request requires an associated work area but none is present.

NotOriginator
: Raised when a request attempts to manipulate the contents of an imported work area.

PropertyReadOnly
: Raised when a request attempts to modify a read-only or fixed read-only property.

PropertyFixed
: Raised by the remove method when the designated property has one of the fixed modes.

Procedure

1. Access a partition by either:
   - Accessing the UserWorkArea partition, to access the UserWorkArea partition.

- Accessing a user-defined work area partition, to access a user-defined work area.

The following steps use the UserWorkArea partition as an example; however, you can use a user-defined partition in the same way.

2. Begin a new work area.

   Use the begin method to create a new work area and associate it with the calling thread. A work area is scoped to the thread that began the work area and is not accessible by multiple threads. The begin method takes a string as an argument; the string is used to name the work area. The argument must not be null, which causes the java.lang.NullPointer exception to be raised. In the following code example, the application begins a new work area with the name SimpleSampleServlet:

```
public class SimpleSampleServlet {
...
   try {
      ...
      userWorkArea = (UserWorkArea)jndi.lookup(
         "java:comp/websphere/UserWorkArea");
   }
   ...

   userWorkArea.begin("SimpleSampleServlet");
   ...
}
```

   The begin method is also used to create nested work areas; if a work area is associated with a thread when the begin method is called, the method creates a new work area nested within the existing work area.

   The work area service makes no use of the names associated with work areas; You can name work areas in any way that you choose. Names are not required to be unique, but the usefulness of the names for debugging is enhanced if the names are distinct and meaningful within the application. Applications can use the getName method to return the name associated with a work area by the begin method.

3. Set properties in the work area.

   An application with a current work area can insert properties into the work area and retrieve the properties from the work area. The UserWorkArea interface provides two set methods for setting properties and a get method for retrieving properties. The two-argument set method inserts the property with the property mode of normal. The three-argument set method takes a property mode as the third argument. Both set methods take the key and the value as arguments. The key is a String; the value is an object of the type java.io.Serializable. None of the arguments can be null, which causes the java.lang.NullPointer exception to be raised.

   The SimpleSample application below uses objects of two classes, the SimpleSampleCompany class and the SimpleSampleProperty class, as values for properties. The SimpleSampleCompany class is used for the site identifier, and the SimpleSamplePriority class is used for the priority. These classes are shown in following code example:

```
public class SimpleSampleServlet {
   ...
   userWorkArea.begin("SimpleSampleServlet");

   try {
      // Set the site-identifier (default is Main).
      userWorkArea.set("company",
         SimpleSampleCompany.Main, PropertyModeType.read_only);

      // Set the priority.
      userWorkArea.set("priority", SimpleSamplePriority.Silver);
   }

   catch (PropertyReadOnly e) {
     // The company was previously set with the read-only or
     // fixed read-only mode.
     ...
   }

    catch (NotOriginator e) {
```

```
      // The work area originated in another process,
      // so it can't be modified here.
      ...
   }

   catch (NoWorkArea e) {
      // There is no work area begun on this thread.
      ...
   }

   // Do application work.
   ...
}
```

The get method takes the key as an argument and returns a Java Serializable object as the value associated with the key. For example, to retrieve the value of the company key from the work area, the code example above uses the get method on the work area to retrieve the value.

Setting property modes. The two-argument set method on the UserWorkArea interface takes a key and a value as arguments and inserts the property with the default property mode of normal. To set a property with a different mode, applications must use the three-argument set method, which takes a property mode as the third argument. The values used to request the property modes are as follows:

- **Normal**: PropertyModeType.normal
- **Fixed normal**: PropertyModeType.fixed_normal
- **Read-only**: PropertyModeType.read_only
- **Fixed read-only**: PropertyModeType.fixed_readonly

4. Manage local work with a work area.
5. Complete the work area.

   After an application has finished using a work area, it must complete the work area by calling the complete method on the UserWorkArea interface. This terminates the association with the calling thread and destroys the work area. If the complete method is called on a nested work area, the nested work area is terminated and the parent work area becomes the current work area. If there is no work area associated with the calling thread, a NoWorkArea exception is created. Every work area must be completed, and work areas can be completed only by the originating process. For example, if a server attempts to call the complete method on a work area that originated in a client, a NotOriginator exception is created. Work areas created in a server process are never propagated back to an invoking client process.

   Attention: The work area service claims full local-remote transparency. Even if two beans happen to be deployed in the same server, and therefore the same JVM and process, a work area begun on an invocation from another is completed and the bean in which the request originated is always in the same state after any remote call.

   The following code example shows the completion of the work area created in the client application.

```
public class SimpleSampleServlet {
   ...
   userWorkArea.begin("SimpleSampleServlet");
   userWorkArea.set("company",
       SimpleSampleCompany.Main, PropertyModeType.read_only);
   userWorkArea.set("priority", SimpleSamplePriority.Silver);
   ...

   // Do application work.
   ...

   // Terminate the work area.
   try {
      userWorkArea.complete();
   }

   catch (NoWorkArea e) {
      // There is no work area associated with this thread.
      ...
   }

   catch (NotOriginator e) {
      // The work area was imported into this process.
```

```
        ...
      }
     ...
  }
```

The following code example shows the sample application completing the nested work area that it created earlier in the remote invocation.

```
public class SimpleSampleBeanImpl implements SessionBean {

    public String [] test() {
      ...

      // Begin a nested work area.
      userWorkArea.begin("SimpleSampleBean");
      try {
        userWorkArea.set("company",
                         SimpleSampleCompany.London_Development);
      }
      catch (NotOriginator e) {
      }

      SimpleSampleCompany company =
         (SimpleSampleCompany) userWorkArea.get("company");
      SimpleSamplePriority priority =
         (SimpleSamplePriority) userWorkArea.get("priority");

      // Complete all nested work areas before returning.
      try {
        userWorkArea.complete();
      }
      catch (NoWorkArea e) {
      }
      catch (NotOriginator e) {
      }
   }
}
```

Example

- Work area object types
- Using the work area partition manager

Work area object types. In the following example, the client creates a work area and inserts two properties into the work area: a site identifier and a priority. The site-identifier is set as a read-only property; the client does not allow recipients of the work area to override the site identifier. This property consists of the key company and a static instance of a SimpleSampleCompany object. The priority property consists of the key priority and a static instance of a SimpleSamplePriority object. The object types are defined as shown in the following code example:

```
public static final class SimpleSampleCompany {
   public static final SimpleSampleCompany Main;
   public static final SimpleSampleCompany NewYork_Sales;
   public static final SimpleSampleCompany NewYork_Development;
   public static final SimpleSampleCompany London_Sales;
   public static final SimpleSampleCompany London_Development;
}

public static final class SimpleSamplePriority {
   public static final SimpleSamplePriority Platinum;
   public static final SimpleSamplePriority Gold;
   public static final SimpleSamplePriority Silver;
   public static final SimpleSamplePriority Bronze;
   public static final SimpleSamplePriority Tin;
}
```

The client then makes an invocation on a remote object. The work area is automatically propagated; none of the methods on the remote object take a work area argument. On the remote side, the request is first handled by the SimpleSampleBean; the bean first reads the site identifier and priority properties from the

work area. The bean then intentionally attempts, and fails, both to write directly into the imported work area and to override the read-only site-identifier property.

The SimpleSampleBean successfully begins a nested work area, in which it overrides the client's priority, then calls another bean, the SimpleSampleBackendBean. The SimpleSampleBackendBean reads the properties from the work area, which contains the site identifier set in the client and priority set in the SimpleSampleBean. Finally, the SimpleSampleBean completes its nested work area, writes out a message based on the site-identifier property, and returns.

Using the work area partition manager. The following code example illustrates the use of the work area partition manager interface. The sample illustrates how to create and retrieve a work area partition programmatically`. Please note that programmatically creating a work area partition is only available on the Java Platform, Enterprise Edition (Java EE) client. To create a work area partition on the server one must use the administrative console. Refer to the Work area partition service article for configuration parameters available to configure a partition.

```
import com.ibm.websphere.workarea.WorkAreaPartitionManager;
import com.ibm.websphere.workarea.UserWorkArea;
import com.ibm.websphere.workarea.PartitionAlreadyExistsException;
import com.ibm.websphere.workarea.NoSuchPartitionException;
import java.lang.IllegalAccessError;
import java.util.Properties;
import javax.naming.InitialContext;

//This sample demonstrates how to retrieve an instance of the
//WorkAreaPartitionManager implementation and how to use that
//instance to create a WorkArea partition and retrieve a partition.
//NOTE: Creating a partition in the way listed below is only available
//on a J2EE client.  To create a partition on the server use the
//WebSphere administrative console.  Retrieving a WorkArea
//partition is performed in the same way on both client and server.

public class Example {

     //The name of the partition to create/retrieve
     String partitionName = "myPartitionName";
     //The name in java naming the WorkAreaPartitionManager instance is bound to
     String jndiName = "java:comp/websphere/WorkAreaPartitionManager";

     //On a J2EE client a user would create a partition as follows:
     public UserWorkArea myCreate(){
         //Variable to hold our WorkAreaPartitionManager reference
         WorkAreaPartitionManager partitionManager = null;
         //Get an instance of the WorkAreaPartitionManager implementation
         try {
             InitialContext initialContext = new InitialContext();
             partitionManager = (WorkAreaPartitionManager) initialContext.lookup(jndiName);
         } catch (Exception e) {  }

         //Set the properties to configure our WorkArea partition
         Properties props = new Properties();
         props.put("maxSendSize","12345");
         props.put("maxReceiveSize","54321");
         props.put("Bidirectional","true");
      props.put("DeferredAttributeSerialization","true");

         //Variable used to hold the newly created WorkArea Partition
         UserWorkArea myPartition = null;

         try{
             //This is the way to create a partition on the J2EE client.  Use the
             //WebSphere Administrative Console to create a WorkArea Partition
             //on the server.
             myPartition = partitionManager.createWorkAreaPartition(partitionName,props);
         }
         catch (PartitionAlreadyExistsException e){  }
         catch (IllegalAccessException e){  }
```

```
        return myPartition;
    }

    //. . . .

    //In order to retrieve a WorkArea partition at some time later or
    //from some other class, do the following (from client or server):
    public UserWorkArea myGet(){
        //Variable to hold our WorkAreaPartitionManager reference
        WorkAreaPartitionManager partitionManager = null;
        //Get an instance of the WorkAreaPartitionManager implementation
        try {
            InitialContext initialContext = new InitialContext();
            partitionManager = (WorkAreaPartitionManager) initialContext.lookup(jndiName);
        } catch (Exception e) {  }

        //Variable used to hold the retrieved WorkArea partition
        UserWorkArea myPartition = null;
        try{
            myPartition = partitionManager.getWorkAreaPartition(partitionName);
        }catch(NoSuchPartitionException e){  }

        return myPartition;
    }
}
```

What to do next

For additional information about work area, see the com.ibm.websphere.workarea package in the API. The generated API documentation is available in the information center table of contents from the path **Reference** > **APIs - Application programming interfaces**.

Configuring work area partitions

Configuring work area partitions

About this task

The work area partition service extends the work area service by allowing the creation of multiple work areas with more configuration options than what is available to the UserWorkArea partition. Follow these steps to create and configure a work area partition:

Procedure

1. Create a user defined partition on the server.
   a. Start the administrative console.
   b. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **Business process services** > **Work area partition service**.
   c. Click **New**.
   d. On the settings page for work area partitions, specify values such as the partition name, maxSendSize and maxReceiveSize, then click OK.
   e. Save the new configuration.
   f. Restart the server to apply the new configuration.
2. Create a user defined partition on the client. Use the createWorkAreaPartition method described in the The Work area partition manager interface article to programmatically create a partition. Refer to the Example: Using the work area partition manager article for an example of using this method.

Results

You have created a work area partition.

What to do next

Retrieve the partition through the work area partition manager interface and use it as defined by the work area service and the UserWorkArea interface. Refer to the Example: Using the work area partition manager article for an example.

Work area partition service

The work area partition service is an extension of the work area service that enables the creation of multiple custom work areas. The work area partition service is an optional service to users. Any user that currently uses the work area service and the UserWorkArea partition can continue using it in the same manner. The UserWorkArea partition is created automatically (if it has not been disabled) by the work area partition service. By allowing a user the option to create their own work area partition through the work area partition service, they can have more control over configuration and access to their partition.

The work area partition service is essentially a factory for creating instances of the UserWorkArea interface. Applications interact with work areas by using the UserWorkArea interface and its implementation. This interface defines all of the methods used to create, manipulate, and complete work areas. The work area partition service allows users to create their own named instance of the UserWorkArea interface. Each named instance is called a user-defined work area partition, or partition for short. Each instance of the UserWorkArea interface (partition) is separate from other user-defined partitions. Furthermore, you can configure a partition with various options to provide qualities of service that are unique to a use case for an individual user. Any configuration option made within the work area partition service panel does not affect the work area service.

Unlike the UserWorkArea partition, which is publicly known, work areas created by the work area partition service are accessible to, and known only by, the creator. However, the work area partition service does not strictly enforce that a partition is accessed and/or operated on exclusively by the partition creator. There are no limitations should the creator want to publish their work area partition and make it publicly available by binding their partition reference in Java naming or by other means. However, the work area partition service does try to hide a partition as much as possible should a user not want others to know about a certain partition. The work area partition service does not enable a person to determine or query the names of all the partitions that have been created; however, it does not restrict the partitions from being accessed by users other than the creator of that partition. The context of a partition, such as the UserWorkArea partition or a user-defined partition, is scoped to a single thread and is not accessible by multiple threads.

The work area partition reference that is returned to a user implements javax.naming.Referenceable and com.ibm.websphere.UserWorkArea, therefore a user can bind their partition into a name to make their partition publicly available. An alternative to using Java naming to bind and access the partition is to use the work area partition manager interface. Anyone can access the work area partition manager interface; therefore, if a user wants to make their partition publicly available, they simply need to publish their partition name. Other users can then call the getWorkAreaPartition method on the work area partition manager interface with the published name.

The WorkAreaPartitionManager.createWorkAreaPartition method can only be used from a Java Platform, Enterprise Edition (Java EE) client. To create a work area partition on the server side, one must use the administrative console. On the server side a work area partition must be created during server startup because each partition needs to be register with the appropriate Web and Enterprise JavaBeans (EJB) collaborators before the server has started. Custom work area partitions are created by the work area partition service and defined by the UserWorkArea interface.

The work area partition service also allows a user to configure partitions with additional properties that are not available on the UserWorkArea partition, such as bidirectional propagation of work area partition context and deferred attribute serialization. These properties are available as configuration properties when creating a partition. For a complete list of the configuration properties that are available when creating a

partition, see the "Configurable Work Area Partition Properties" section in the Work area partition manager interface article. The properties are defined as follows:

Bidirectional propagation of work area context

If a remote invocation is issued from a thread associated with a work area, a copy of the work area is automatically propagated to the target object, which can use or ignore the information in the work area as necessary. If the calling application has a nested work area associated with it, a copy of the nested work area and all its ancestors are propagated to the target application. The target application can locally modify the information, as allowed by the property modes, by creating additional nested work areas; this information is propagated to any remote objects that it invokes.

Whether context changes propagate back to a calling application from a remote application depends on the configuration of the work area partition. If a user creates a partition to be bidirectional by selecting the Bidirectional property during partition creation, changes made by a remote application propagate back to the calling application, meaning that changes made to the work area context by a downstream process will propagate back upstream. The UserWorkArea partition is not configured (and can never be configured) to be bidirectional, therefore context changes only flow to downstream processes and do not propagate back upstream.

Example: Bidirectional propagation of work area context

Whether context changes propagate back to a calling application from a remote application depends on the configuration of the work area partition. If a user creates a bidirectional partition, changes made by a remote application propagate back to the calling application. Changes made to the work area context by a downstream process propagate back upstream. The figure Distribution of work area context when configured for bidirectional propagation illustrates this relationship during a remote call to the server. For this illustration, the client and server must have created a partition with the same name.

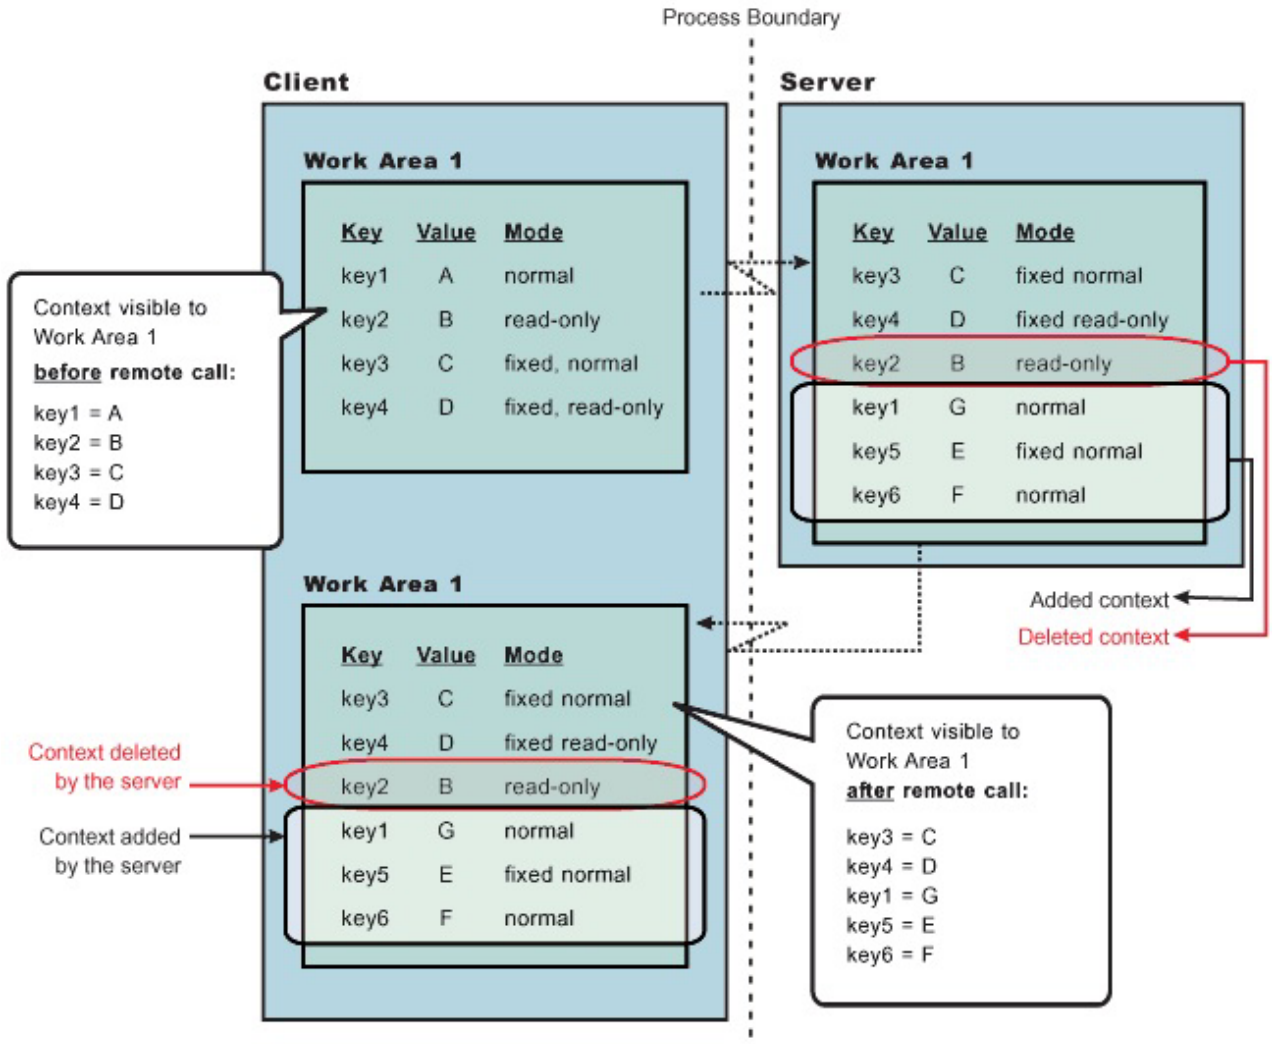


Figure 7. Distribution of work area context when configured for bidirectional propagation. This figure illustrates the distribution of work area context when the service is configured for bidirectional propagation.

When the client makes a remote call to the server, the server receives the context set by the client process. The server then can make changes to this context or add to it. In this illustration, the server overwrites the value at **key1**, removes the property at **key2**, and adds two new properties at **key5** and **key6**. When the server application returns to the client, the work area context is propagated back to the client and unmarshalled. The current work area is then updated with the new context. Note that if the partition is not configured as bidirectional and the server tries to change or remove context in Work Area 1, it receives a com.ibm.websphere.workarea.NotOriginator exception because the client was the originator of the work area. The server can retrieve the context in Work Area 1. This is the main distinction between bidirectional propagation of context and non-bidirectional propagation.

Example: Bidirectional propagation of nested work area context

If a remote application needs to add context to a work area that is only used by itself or any other remote objects, the remote application must begin another work area. By beginning a new work area, the additional context is scoped to that application and does not flow back to the calling application. The major benefit of nesting work areas is that nesting work areas allows an application to scope work area context to a given application. Taking the illustration one step further, if the server has begun a work area before overwriting the value at **key1**, removing the property at **key2**, or adding new properties at **key5** and **key6**;

those changes would not have propagated back to the client. This is shown in the figure Distribution of nested work area context when configured for bidirectional propagation. You can also see from this figure that the client does not receive the context from the nested work area started by the server.

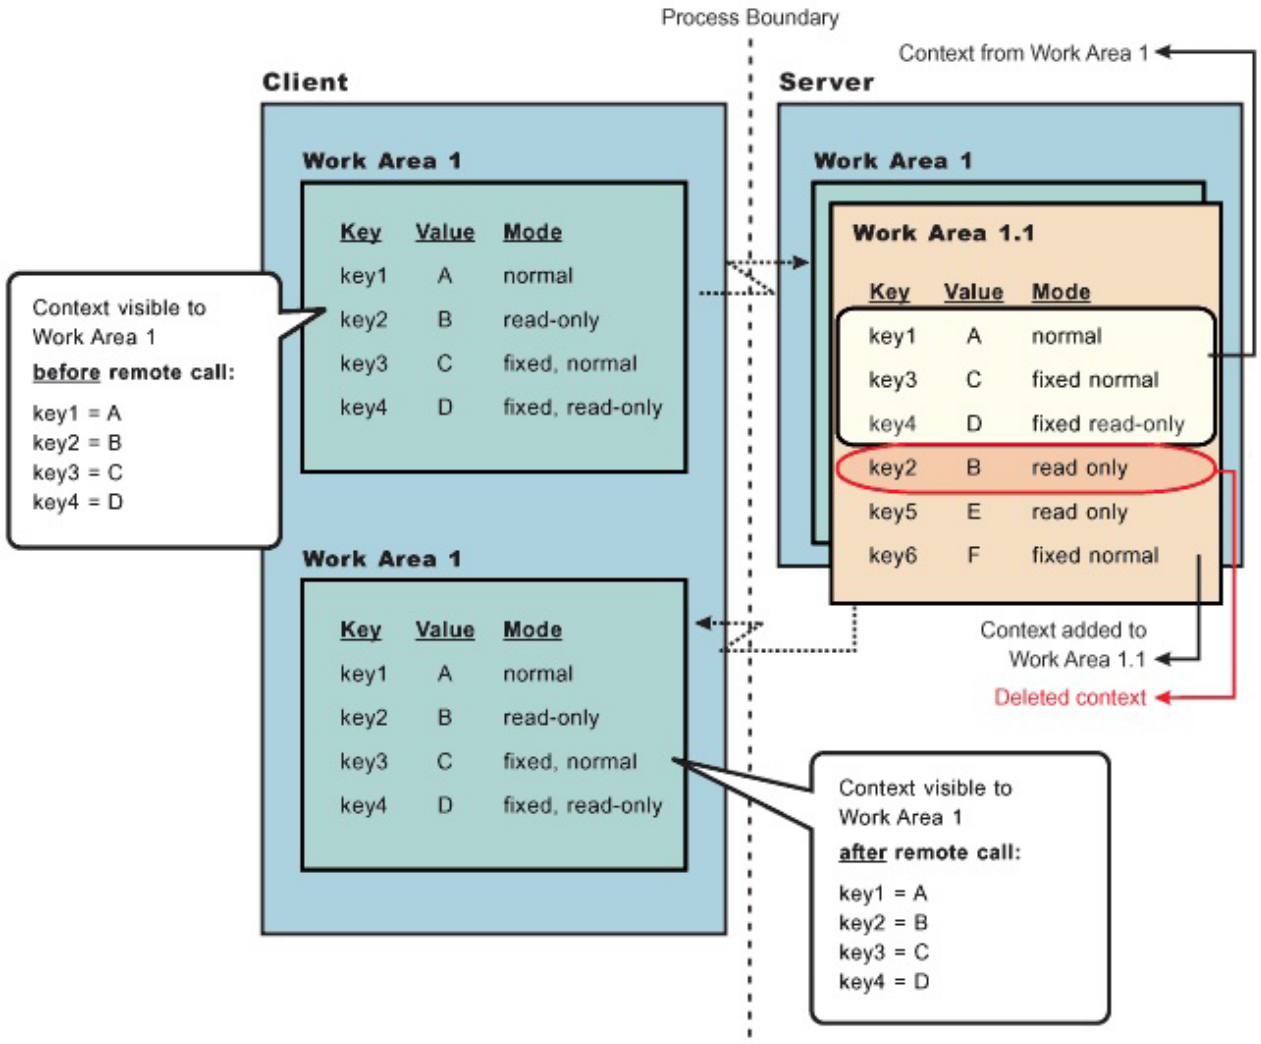

Figure 8. Distribution of nested work area context when configured for bidirectional propagation. This figure illustrates the distribution of nested work area context when the service is configured for bidirectional propagation.

Deferred attribute serialization of work area context

By default, on each set operation the attribute set into a work area is automatically serialized by the work area service. On each subsequent get operation on that same attribute it is deserialized and returned to the requester. This gives the work area service complete control of the attribute such that any changes to a mutable object are not reflected in the work area's copy of the attribute unless a user specifically resets the attribute into the work area. However, this can potentially lead to excessive serialization and deserialization.

Excessive serialization and deserialization can result in observable performance degradation under heavy load. The deferred attribute serialization configuration property is a caching feature that reduces serialization and deserialization operations. When deferred attribute serialization is enabled in a client or server process by selecting the Deferred Attribute Serialization field during the creation of the work area, attributes set into the work area service are not automatically serialized during the set operation. Rather, a

reference to the attribute is stored in the work area. If the attribute is mutable, then changes to the object are reflected in the work area's reference to that attribute. When a get operation is performed on that attribute, the reference to that object is returned and no deserialization is performed.

Attributes are not serialized until the thread with which the attribute is associated makes a remote IIOP invocation. At that point, the attribute is serialized and the serialized form of the attribute is cached. If the attribute is not reset into the work area, changes to the original attribute are still reflected within the attribute contained within the work area because the work area still holds a cached reference to the original object. However, if the work area has not been told that the attribute has changed by resetting the attribute into the work area, subsequent remote requests continue to use the cached serialized version of the attribute and direct changes to the mutable attribute are not propagated. This is an important distinction between enabling and not enabling the deferred attribute serialization configuration property, and a user must pay close attention to this difference and how mutable objects are handled when enabling deferred attribute serialization. The work area service releases cached references and cached serialized versions of attributes when any of the following conditions occur:

- An attribute is reset or removed.
- The work area is explicitly completed by the application.
- Server component ends execution of the request during which the work area was begun.
- Client process which began the work area terminates.

Partition context propagation across process boundaries

Work area context automatically propagates from client to server when a client makes a remote call to a server. For example, if a client is configured with three different work area partitions when it makes a remote call to a server, server1, the context associated with each partition on the client thread propagates to server1. If the same three partitions have been created on server1, the context is unmarshalled to the appropriate partition. However, if none or only a few of the three partitions have been created on server1, only the context associated with a partition that is resident on both the client and server is unmarshalled. The context associated with a partition that is not resident on server1 is still resident on server1 but is not accessible. The context associated with partitions that are not resident on server1 must remain resident on server1 in case another remote call is made to a different server. Going one step further, if server1 makes a call to another server, server2, that has the same partitions as the client, server2 receives the context for the partitions that were not resident on server1. Any partitions that reside on server1 that did not reside on the client now have their context propagated to server2.

For more information about work area, see the com.ibm.websphere.workarea package in the Application Programming Interface (API). The generated API documentation is available in the information center table of contents from the path **Reference** > **APIs - Application Programming Interfaces**.

The Work area partition manager interface

Applications interact with the work area partition service by using the work area partition manager interface. A user can retrieve an instance of the work area partition manager interface out of naming and use the methods that are defined in the following section.

An implementation of the work area partition manager interface is bound in Java naming at `java:comp/websphere/WorkAreaPartitionManager`. This interface is responsible for creating, retrieving, and manipulating work area partitions:

```
package com.ibm.websphere.workarea;

import com.ibm.websphere.workarea.UserWorkArea;
import com.ibm.websphere.workarea.PartitionAlreadyExistsException;
import com.ibm.websphere.workarea.NoSuchPartitionException;
import java.util.Properties;

public interface WorkAreaPartitionManager {
```

```
  //Returns an instance of a work area partition for the given name, or throws an exception if the
  //partition name doesn't exists.
  public UserWorkArea getWorkAreaPartition(String partitionName) throws NoSuchPartitionException;

  //Returns a new instance of a work area partition (an implementation of the UserWorkArea interface)
  //or throws an exception if the partition name already exists.  The createWorkAreaPartition should
  //only be used within a Java EE platform client and NOT on the
  //server.  To create a work area partition on the server, use the WebSphere administrative
  //console.
  public UserWorkArea createWorkAreaPartition(String partitionName, Properties props) throws
     PartitionAlreadyExistsException, java.lang.IllegalAccessException;
  }
}
```

EJB applications can use the work area partition manager interface only within the implementation of methods in either the remote or local interface, or both; likewise, servlets can use the interface only within the service method of the HTTPServlet class. Use of work areas within any life cycle method of a servlet or enterprise bean is considered a deviation from the work area programming model and is not supported.

Programmatically creating a work area partition through the createWorkAreaPartition method is only available on the Java EE client. To create a work area partition on the server, use the WebSphere administrative console as described in the Configuring work area partitions article. All partitions in a server process must be created before server startup is complete so that the work area service can register with the appropriate container collaborators. Therefore, calling the createWorkAreaPartition method in a server process after the server starts results in a java.lang.IllegalAccessException exception. The createWorkAreaPartition method can be called in a Java EE application client at any time.

Configurable Work Area Partition Properties

This section applies to the use of the createWorkAreaPartition method on the WorkAreaPartitionManager interface. As is described above, this method should only be used on a Java EE client. To create a partition on the server, please see Configuring work area partitions.

The "createWorkAreaPartition" method on the WorkAreaPartitionManager interface takes a java.util.Properties objects. This Properties object, and the properties it contains, is used to define the work area partition. Below is an example of creating a Properties object and setting a property:

Attention: A more detailed example of the usage of the WorkAreaPartitionManager can be found in Example: Using the work area partition manager.

```
java.util.Properties props = new java.util.Properties():
props.put("maxSendSize","12345");
```

Acceptable key/values pairs (properties) for defining a partition are as follows:

- *maxSendSize* - Indicates the maximum size (bytes) of a work area that can be sent on a remote call. Acceptable values are:
  - "-1" = Uses the default size of 32767.
  - "0" = Unlimited size, this value will not be policed which might help performance a bit depending on the number of work area an application has.
  - "1" = Integer.MAX_VALUE
- *maxReceiveSize* - Indicates the maximum size (bytes) of a work area that can be received. Acceptable values are:
  - "-1" = Uses the default size of 32767.
  - "0" = Unlimited size, this value will not be policed which might help performance a bit depending on the number of work area an application has.
  - "1" = Integer.MAX_VALUE

- *Bidirectional* - Indicates if work area context that is changed by a downstream process should be propagated back upstream to the originator of that context. For a more complete description of this property, refer to the "Bidirectional propagation of work area context" in the Work area partition service article. Acceptable values are:
  - "true" = Context changes will be returned from a remote call.
  - "false" = Context changes will not be returned from a remote call.

  Attention: The default setting is "false."
- *DeferredAttributeSerialization* - Indicates if the serialization of attribute should be optimized to occur exactly once per process. For a more complete description of this property, refer to the "Deferred attribute serialization of work area context" section in the Work area partition service article. Acceptable values are:
  - "true"
    - When an attribute is set into the work area, it will not be serialized until a remote request is made.
    - If the value is unchanged by response, the serialized form will be used for subsequent requests; the live object will be retrieved via getters.
    - When requests are made during a remote request, a value is deserialized on demand exactly once. The serialized form is used for subsequent requests from this remote process on this distributed thread; subsequent requests in process for the same attribute returns the already deserialized value. There are risks with concurrency with DeferredAttributeSerialization. After serialization in a client process, updates to the attribute are no longer reflected in the work area's copy until the value is explicitly reset through the UserWorkArea interface. Changes made to a retrieved reference in a downstream process are not propagated to subsequent downstream requests (or returned on the reply as a changed value) unless explicitly reset through the UserWorkArea interface.
  - "false"
    - When an attribute is set into the work area, it is immediately serialized and the bytes are stored.
    - When an attribute is retrieved from the work area, it is always deserialized from stored bytes.

  Attention: The default value is "false."
- *EnableWebServicePropagation* - Indicates if work area context must propagate on a WebService call. Acceptable values are:
  - "true" = Context propagates on a WebService call.
  - "false" = Context does not propagate on a WebService call.

  Attention: The default value is "false."

Exceptions

The work area partition service defines the following exceptions for use with the work area partition manager interface:

PartitionAlreadyExistsException
: This exception is raised by the createWorkAreaPartition method on the WorkAreaPartitionManager implementation if a user tries to create a work area partition with a partition name that already exists. Partition names must be unique.

NoSuchPartitionException
: This exception is raised by the getWorkAreaPartition method on the WorkAreaPartitionManager implementation if a user requests a work area partition with a partition name that does not exist.

java.lang.IllegalAccessException
: This exception is raised by the createWorkAreaPartition method on the WorkAreaPartitionManager implementation if a user tries to create a work area partition during run time on a server process. This method can only be used on a Java EE client process. In the server process, a partition must be created using the administrative console.

For additional information about work area, see the com.ibm.websphere.workarea package in the application programming interface (API). The generated API documentation is available in the information center table of contents from the path **Reference** > **APIs - Application Programming Interfaces**.

Example: Using the work area partition manager

The example below demonstrates the use of the work area partition manager interface. The sample illustrates how to create and retrieve a work area partition programmatically`. Please note that programmatically creating a work area partition is only available on the Java Platform, Enterprise Edition (Java EE) client. To create a work area partition on the server one must use the administrative console. Refer to the Work area partition service article for configuration parameters available to configure a partition.

```
import com.ibm.websphere.workarea.WorkAreaPartitionManager;
import com.ibm.websphere.workarea.UserWorkArea;
import com.ibm.websphere.workarea.PartitionAlreadyExistsException;
import com.ibm.websphere.workarea.NoSuchPartitionException;
import java.lang.IllegalAccessError;
import java.util.Properties;
import javax.naming.InitialContext;

//This sample demonstrates how to retrieve an instance of the
//WorkAreaPartitionManager implementation and how to use that
//instance to create a WorkArea partition and retrieve a partition.
//NOTE: Creating a partition in the way listed below is only available
//on a J2EE client.  To create a partition on the server use the
//WebSphere administrative console.  Retrieving a WorkArea
//partition is performed in the same way on both client and server.

public class Example {

     //The name of the partition to create/retrieve
     String partitionName = "myPartitionName";
     //The name in java naming the WorkAreaPartitionManager instance is bound to
     String jndiName = "java:comp/websphere/WorkAreaPartitionManager";

     //On a J2EE client a user would create a partition as follows:
     public UserWorkArea myCreate(){
         //Variable to hold our WorkAreaPartitionManager reference
         WorkAreaPartitionManager partitionManager = null;
         //Get an instance of the WorkAreaPartitionManager implementation
         try {
             InitialContext initialContext = new InitialContext();
             partitionManager = (WorkAreaPartitionManager) initialContext.lookup(jndiName);
         } catch (Exception e) {  }

         //Set the properties to configure our WorkArea partition
         Properties props = new Properties();
         props.put("maxSendSize","12345");
         props.put("maxReceiveSize","54321");
         props.put("Bidirectional","true");
      props.put("DeferredAttributeSerialization","true");

         //Variable used to hold the newly created WorkArea Partition
         UserWorkArea myPartition = null;

         try{
             //This is the way to create a partition on the J2EE client.  Use the
             //WebSphere Administrative Console to create a WorkArea Partition
             //on the server.
             myPartition = partitionManager.createWorkAreaPartition(partitionName,props);
         }
         catch (PartitionAlreadyExistsException e){  }
         catch (IllegalAccessException e){  }
```

```
        return myPartition;
    }

    //. . . .

    //In order to retrieve a WorkArea partition at some time later or
    //from some other class, do the following (from client or server):
    public UserWorkArea myGet(){
        //Variable to hold our WorkAreaPartitionManager reference
        WorkAreaPartitionManager partitionManager = null;
        //Get an instance of the WorkAreaPartitionManager implementation
        try {
            InitialContext initialContext = new InitialContext();
            partitionManager = (WorkAreaPartitionManager) initialContext.lookup(jndiName);
        } catch (Exception e) {  }

        //Variable used to hold the retrieved WorkArea partition
        UserWorkArea myPartition = null;
        try{
            myPartition = partitionManager.getWorkAreaPartition(partitionName);
        }catch(NoSuchPartitionException e){  }

        return myPartition;
    }
}
```

Work area partition collection

Use this page to manage the work area service.

The work area partition service supports the definition of custom work area partitions.

To view this administrative console page, click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **Business Process Services** > **Work area partition service**.

Name

Specifies the name of the work area partition that is used to retrieve the partition. This name must be unique.

Description

Specifies the description of the work area partition.

Enable service at server startup

Specifies whether the server attempts to start the specified service when the server starts.

Bidirectional

Permits applications to modify the context of a work area that is imported by a Java EE request; modified properties are propagated back to the requestor environment. This option is disabled by default.

Maximum send size

Specifies the maximum size of data that can be sent within a single work area. (0 = no limit; -1 = default)

A value of 0 means there is no limit to the data sent. The default value of -1 represents 32768 bytes of data sent.

Maximum receive size

Specifies the maximum size of data that can be received within a single work area. (0 = no limit; -1 = default)

A value of 0 means there is no limit to the data received. The default value of -1 represents 32768 bytes of data received.

Deferred attribute serialization

Specifies whether attribute serialization is deferred until the work area is propagated on a remote invocation.

Enable Web service propagation

Specifies whether the work area partition is propagated on Web service requests. This option is disabled by default.

Work area partition settings

Use this page to modify the work area partition settings.

The work area partition service supports the definition of custom work area partitions.

To view this administrative console page, click **Servers > Server types > WebSphere application servers >** *server_name*. Under **Container Settings**, expand **Business Process Services** then click **Work area partition service**. Click on a *work_area_partition_name*.

Name

Specifies the name of the work area partition that is used to retrieve the partition. This name must be unique.

Description

Specifies the description of the work area partition.

Enable service at server startup

Specifies whether the server attempts to start the specified service when the server starts.

Bidirectional

Permits applications to modify the context of a work area that is imported by a Java EE request; modified properties are propagated back to the requestor environment. This option is disabled by default.

Maximum send size

Specifies the maximum size of data that can be sent within a single work area. (0 = no limit; -1 = default)

Information	Value
Data type	Integer
Units	Bytes
Default	32768
Range	-1, 0 (no limit) and 1 to 2147483647

Maximum receive size

Specifies the maximum size of data that can be received within a single work area. (0 = no limit; -1 = default)

Information	Value
Data type	Integer
Units	Bytes

Information	Value
Default	32768
Range	-1, 0 (no limit) and 1 to 2147483647

Deferred attribute serialization
Specifies whether attribute serialization is deferred until the work area is propagated on a remote invocation. This option is disabled by default.

Enable Web service propagation
Specifies whether the work area partition is propagated on Web service requests. This option is disabled by default.

Accessing a user defined work area partition

About this task

The work area partition service provides a Java Naming and Directory Interface (JNDI) binding to an implementation of the work area partition manager interface under the name java:comp/websphere/WorkAreaPartitionManager. Applications that need to access their partition can perform a lookup on that JNDI name and then use the getWorkAreaPartition method on the work area partition manager, as shown in the following code example:

Example

```
import com.ibm.websphere.workarea.*;
import javax.naming.*;

public class SimpleSampleServlet {
  ...

        //Variable to hold our WorkAreaPartitionManager implementation
        WorkAreaPartitionManager partitionManager = null;
        try {
            InitialContext initialContext = new InitialContext();
            partitionManager = (WorkAreaPartitionManager)
           initialContext.lookup("java:comp/websphere/WorkAreaPartitionManager");
        } catch (Exception e) {...}

        //Variable used to hold the retrieved WorkArea Partition
        UserWorkArea myPartition = null;
        try{
            myPartition = partitionManager.getWorkAreaPartition(partitionName);
        }catch(NoSuchPartitionException e){...}
}
```

What to do next

The next step is to use the begin method to create a new work area and associate it with the calling thread, as described in the Beginning a new work area topic.

Propagating work area context over Web services

WebSphere Application Server Version 6.1 introduces the option to propagate work area context on a Web service call. Prior to WebSphere Application Server Version 6.1, work area context was only propagated over RMI/IIOP calls. The work area application programming interfaces (APIs) have not changed to implement this propagation. You can use the work area APIs as they have in the past and as outlined in the work area documentation. However, by default, work area context is not propagated on a Web service call, you must enable this option.

Procedure

1. Enable a server to propagate work area context on a Web service call.
   a. Start the administrative console.
   b. Select **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **Business Process Services** .
      - To enable the work area service, (the UserWorkArea partition) to propagate its context on a Web service call:
        – Select **Work area service**.
      - To enable an individual partition to propagate its context on a Web service call:
        – Select **Work area partition service**.
        – Select a partition.
   c. Check the EnableWebServicePropagation field to enable Web service propagation.
   d. Save the new configuration and restart the server to apply the new configuration.
2. Enable a client to propagate work area context on a Web service call:

   Note: The steps below are for the work area service (the UserWorkArea partition). For user defined partitions the EnableWebServicePropagation property must be set when creating a partition on the client, refer to the The Work area partition manager interface article.

   a. Set the property com.ibm.websphere.workarea.EnableWebServicePropagation to true when invoking the launchClient script found in the $WAS_HOME/bin directory. For example, to set this property to true, add the following system properties to the launchClient invocation as needed: -CCDcom.ibm.websphere.workarea.EnableWebServicePropagation=true
   b. Set the property com.ibm.websphere.workarea.EnableWebServicePropagation in a property file that is used by the launchClient script. Refer to the Running a Java EE client application with launchClient for additional information.

Chapter 39. XML applications

This page provides a starting point for finding information about XML applications.

Overview of XML support

You can use the XML support provided with this product to work with web applications that process data using standard XML technologies like Extensible Stylesheet Language Transformations (XSLT), XML Path Language (XPath), and XML Query Language (XQuery).

XML-structured data has become the predominant format for data interchange. XML data is navigated, queried, or transformed in almost every existing WebSphere application.

Since first being standardized, XML usage in application-development environments has grown significantly to include many scenarios. WebSphere Application Server is a leading platform for the latest application development standards, including XML.

Note: IBM WebSphere Application Server Version 8.5 delivers critical technology that provides application developers with support for the following key World Wide Web Consortium (W3C) XML standards:

- Extensible Stylesheet Language Transformations (XSLT) 2.0
- XML Path Language (XPath) 2.0
- XML Query Language (XQuery) 1.0

These new and updated W3C XML standards offer application developers numerous advanced capabilities for building XML applications. Specific benefits delivered in the XPath 2.0, XSLT 2.0, and XQuery 1.0 standards include the following:

- Simpler XML application development and improved developer productivity
- Improved ability to query large amounts of data stored in XML outside of a database with XQuery 1.0
- Improved XML-application performance through new features introduced in the W3C specifications to address previous shortcomings
- Improved XML-application reliability with new support for XML schema-aware processing and validation

Note: If you want to use XPath 1.0 or XSLT 1.0 (not in backwards-compatibility mode), continue to use Java API for XML Processing (JAXP) in Java 2 Platform, Standard Edition (J2SE) 6.0 and 7.0.

For more information about these W3C XML standards, go to W3C XQuery 1.0 and XSLT 2.0 Become Standards: Tools to Query, Transform, and Access XML and Relational Data.

The product provides the IBM XML Application Programming Interface in support of these standards. This application programming interface invokes a runtime engine that is capable of executing XPath 2.0, XSLT 2.0, and XQuery 1.0 as well as manipulating the returned XML data.

The product also includes the IBM Thin Client for XML with WebSphere Application Server. The thin client allows access to the same XML API and runtime functionality (XPath 2.0, XSLT 2.0, and XQuery 1.0) available in the full product. The thin client can be copied to multiple clients running Java SE in support of a WebSphere Application Server Version 8.5 installation.

XSLT 2.0, XPath 2.0, and XQuery 1.0 major new functions

Valuable features have been added to XPath 2.0, XSLT 2.0, and XQuery 1.0 reflecting productivity and feature improvements beyond the XPath 1.0 and XSLT 1.0 standards.

XPath 2.0

- XPath 2.0 has been improved to support the XPath 2.0 and XQuery 1.0 Data Model (XDM), which is based on sequences of heterogeneous items including nodes and primitive types. This replaces and improves on the XPath 1.0 node-set support and becomes the foundation of XSLT 2.0 and XQuery 1.0 data navigation.
- XPath 2.0 adds an extensive collection of functions and operators to allow for an easier programming experience, replacing the XPath 1.0 requirement for proprietary extension mechanisms. These functions and operators help with date and time handling, enhance the string manipulation, support regular expression matching and tokenization, extend the number handling, and add functions for sequence manipulation.
- XPath 2.0 supports schema-aware processing, which allows for data navigation based on XML schema information for not only built-in schema types, but also user-defined schema types.
- XPath 2.0 adds condition (if/then/else branches), iterative (for loops), and quantified expressions (some and every tests) typical of other languages.
- XPath 2.0 adds named collations across multiple functions allowing for locale-specific operation.
- XPath 2.0 provides a backwards-compatibility mode to run most XPath 1.0 expressions unchanged.

XSLT 2.0

- XSLT 2.0 is based on XPath 2.0, allowing XSLT 2.0 to take advantage of all new XPath 2.0 features. Temporary trees have been added to allow navigation of constructed trees during transformation. User-defined functions can be defined in the XSLT language and are callable using XPath 2.0.
- XSLT 2.0 can write to multiple result documents in a single stylesheet execution.
- XSLT 2.0 supports regular expressions to analyze and separate strings.
- XSLT 2.0 allows variables and parameters to be typed, therefore improving the reliability of stylesheets and functions.
- XSLT 2.0 supports schema-aware processing, which allows XSLT 2.0 to check for valid input, temporary trees, and output documents.
- XSLT 2.0 supports initial named templates, which allows the processor to start with a defined template instead of having to match the input document, a feature commonly used with loading documents programmatically using the XPath 2.0 collection and document functions.
- Comparisons in sorting, grouping, and keys are supported with any data type and can use locale-specific named collations.
- XHTML has been added to XSLT 2.0 as a valid output format.
- The next-match instruction allows the same node to be processed with multiple templates.
- The character-map instruction allows fine grained control of serialization of characters.
- XSLT 2.0 added addition instructions for transforming and formatting dates and times.
- XSLT 2.0 added support for tunnel parameters, which allows parameters to be passed through multiple template calls without having to declare the parameter in each template call.
- XSLT 2.0 added multiple mode support to allow templates to apply to specific modes of processing within a stylesheet.
- Unparsed text can be incorporated into the data processed by a stylesheet, which then can be tokenized with the new regular expression support.
- XSLT 2.0 provides a backwards-compatibility mode to run most XSLT 1.0 stylesheets unchanged.

XQuery 1.0

- XQuery 1.0 is based on XPath 2.0, allowing XQuery 1.0 to take advantage of all new XPath 2.0 features. XQuery 1.0 builds on XPath 2.0 to provide full XML Query capability.

- XQuery's FLOWR (For, Let, Order by, Where, Return) expression allows for complicated joins across XML datasets. FLOWR allows for query of large documents or collections of documents. XQuery allows for the mixture of direct XML construction along with computed content returned from FLOWR expressions.
- XQuery has the ability to define functions and variables with syntax that is familiar to users of other languages, allowing larger programs to be defined around the data-query operations.
- XQuery 1.0 supports schema-aware processing, which allows input and constructed documents and elements to be validated.
- XQuery module support allows queries to be broken up into reusable fragments.

Overview of the XML Samples application

The XML Samples application is written to be used with the XML specifications and other documents. However, the most important function that these samples provide is a place to begin experimenting with the XML API and the supported specifications.

Limitations

The XML Samples application is not intended for deployment to production servers. It is for development and educational purposes only. All source code is provided as is for you to use, copy, and modify without royalty payment when you develop applications that run with WebSphere software. You can use the sample code either for your own internal use, for redistribution as part of an application, or in your products.

Content

- The simple API invocation examples included in the samples are intended as simple examples of using the major new features of XPath 2.0, XSLT 2.0, and XQuery 1.0.
  - XPath 2.0 examples
    - Sample 1: Simple XPath invocation

      Shows how to invoke XPath
    - Sample 2: Invoking XPath 1.0 under an XPath 2.0 run time in backwards compatibility mode

      Shows an example that demonstrates differences between XPath 1.0 and XPath 2.0 as well as how to run existing XPath 1.0 statements under XPath 2.0 in backwards-compatibility mode
    - Sample 3: Invoking schema aware XPath 2.0 expressions

      Shows how to run schema-aware expressions; shows how to load schema documents, how to validate input documents, and how to declare namespace prefixes
    - Sample 4: XPath 2.0 - document function (relative URIs) with input and output documents

      Shows how to invoke XPath using the document function with relative URIs
    - Sample 5: XPath running in compiled mode

      Shows how to invoke XPath in compiled mode
    - Sample 6: XPath running in pre-compiled mode

      Shows how to invoke XPath in pre-compiled mode
    - Sample 7: XPath 2.0 collation support

      Shows how to invoke XPath with collation support
  - XSLT 2.0 examples
    - Sample 1: Simple XSLT invocation

      Shows how to invoke XSLT
    - Sample 2: Invoking XSLT 1.0 under an XSLT 2.0 run time in backwards compatibility mode

      Shows differences between XPath 1.0 and XPath 2.0 and how to run existing XSLT 1.0 stylesheets under a XSLT 2.0 processor in backwards-compatibility mode

- Sample 3: XSLT 2.0 updated for-each support

  Shows how to use the XSLT 2.0 for-each functionality
- Sample 4: XSLT 2.0 grouping support

  Shows how to use the capability offered by xsl:for-each-group
- Sample 5: XSLT 2.0 regular expression support

  Shows how to use XSLT 2.0 regular-expression support to work with data in structured legacy formats within XML strings
- Sample 6: XSLT 2.0 date formatting

  Shows how to use XSLT 2.0 date formatting with internationalization
- Sample 7: XSLT 2.0 multiple results

  Shows how to use an XSLT 2.0 result-document instruction to write to multiple outputs simultaneously
- Sample 8: XSLT 2.0 tunnel parameters

  Shows how to use XSLT 2.0 tunnel parameters to allow values to be set and accessible during stylesheet processing
- Sample 9: XSLT 2.0 stylesheet functions

  Shows how to use the XSLT 2.0 stylesheet functions
- Sample 10: XSLT 2.0 initial template

  Shows how to use the XSLT 2.0 initial-template functionality
- Sample 11: XSLT 2.0 template with multiple modes

  Shows how to use the XSLT 2.0 template with multiple modes functionality
- Sample 12: XSLT 2.0 XHTML support - no output method specified

  Shows how to use XSLT 2.0 XHTML support with the XHTML output method
- Sample 13: XSLT 2.0 XHTML support - output method specified

  Shows how to use XSLT 2.0 XHTML support with the XHTML output method
- Sample 14: XSLT 2.0 character maps

  Shows how to use XSLT 2.0 character maps functionality
- Sample 15: XSLT 2.0 "as" attribute

  Shows how to use the XSLT 2.0 "as" attribute functionality
- Sample 16: XSLT 2.0 embedded stylesheets

  Shows how to use the XSLT 2.0 embedded stylesheets functionality
- Sample 17: XSLT 2.0 running in compiled mode

  Shows how to run XSLT in compiled mode
- Sample 18: XSLT 2.0 running in pre-compiled mode

  Shows how to run XSLT in pre-compiled mode
- Sample 19: XSLT 2.0 undeclare-prefixes serialization parameter

  Shows how to use the XSLT undeclare-prefix parameter when producing XML output that is Version 1.1 or higher
- Sample 20: XSLT 2.0 next-match

  Shows how to use the XSLT next-match functionality
- Sample 21: XSLT 2.0 usage of XPath 2.0 collection function

  Shows how to use the collection function
- Sample 22: XSLT 2.0 schema awareness - input validation (valid)

  Shows how to use the stylesheets and schemas to validate input documents
- Sample 23: XSLT 2.0 schema awareness - input validation (invalid)

  Shows how to use the stylesheets and schemas to validate input documents

- Sample 24: XSLT 2.0 schema awareness - temporary tree (valid)
  Shows how to use the validation attribute to validate temporary trees
- Sample 25: XSLT 2.0 schema awareness - temporary tree (invalid)
  Shows how to use the validation attribute to validate temporary trees
- Sample 26: XSLT 2.0 schema awareness - output document (valid)
  Shows how to use the validation attribute to validate the main output document
- Sample 27: XSLT 2.0 schema awareness - output document (invalid)
  Shows how to use the validation attribute to validate the main output document
- Sample 28: XSLT 2.0 schema awareness - element(*, T) function
  Shows how to use the stylesheets and schemas to match on element types instead of names
- Sample 29: XSLT 2.0 use-when
  Shows how to use the use-when functionality
- Sample 30: XSLT 2.0 collation support
  Shows how to use the for-each-group functionality with collations
- Sample 31: Using stylesheet-declared external functions
  Shows how to declare external functions within a stylesheet

– XQuery 1.0 examples
  - Sample 1: Simple XQuery invocation
    Shows how to invoke simple XQuery FLOWR expressions
  - Sample 2: XQuery FLWOR support - using doc function and cross document joins
    Shows how to invoke an XQuery that joins data from multiple documents
  - Sample 3: XQuery declare functions and variables
    Shows how to define and use XQuery functions and variables
  - Sample 4: XQuery TypeDeclaration support
    Shows how to use the TypeDeclaration functionality
  - Sample 5: XQuery running in compiled mode
    Shows how to run XQuery functions in compiled mode
  - Sample 6: XQuery running in pre-compiled mode
    Shows how to invoke XQuery in pre-compiled mode
  - Sample 7: XQuery operations on types (typeswitch, cast as)
    Shows how to use operations on types
  - Sample 8: XQuery schema awareness - input validation (valid)
    Shows how to validate the input document passed to the query
  - Sample 9: XQuery schema awareness - input validation (invalid)
    Shows how to validate the input document passed to the query
  - Sample 10: XQuery schema awareness - node validation (valid)
    Shows how to validate an element using the validate expression
  - Sample 11: XQuery schema awareness - node validation (invalid)
    Shows how to validate an element using the validate expression
  - Sample 12: XQuery schema awareness - element(*, T) function
    Shows how to use schema awareness to match on element types instead of names
  - Sample 13: XQuery modules support
    Shows how commonly used functions and variables can be put in a reusable library module
  - Sample 14: XQuery modules support with schema
    Shows how modules interact with schema support

- Sample 15: Using query-declared external functions

  Shows how to declare external functions within a query

- The Blog Comment Checker examples show how you can search all or your Blogger™ web publishing service blogs for questionable comments. They are examples of high-level applications that use XPath 2.0, XSLT 2.0, and XQuery 1.0.
  - XPath Blog Checker
  - XSLT Blog Checker
  - XQuery Blog Checker
  - Database Integration Checker

Using the XML API to perform operations

You can use the IBM XML Application Programming Interface (API) to perform operations that use the new and updated W3C XML standards.

Before you begin

Limitations of the processor:

- When using the namespace axis, only the namespaces declared on the current node are accessible through the namespace axis (rather than all of the namespaces that are in scope for the current node) if the input document supplied is a StreamSource, SAXSource, or StAXSource.
- When evaluating some string functions and operations, the processor might not handle Unicode characters with code points above #xFFFF correctly; it might incorrectly treat the surrogate pair in the UTF-16 encoding of the character as two separate characters.
- Whitespace text nodes might not be stripped from elements that have complex type with element-only content. When matching children of such an element, use a sequence type that matches only elements such as element() to avoid processing these text nodes.
- The column number reported in an error message relating to an operator expression might not point to the operand that is actually in error. Consider both operands when determining the cause of the error.
- Using a variable declared in an XQuery typeswitch clause as an operand in an arithmetic expression might cause an error.

  When using the variable declared in an XQuery typeswitch clause in an arithmetic expression such as in the following example, the processor might incorrectly report a type error.

  ```
  typeswitch (.)
  case $a as xs:integer return ($a + 1)
  default return 17
  ```

  To work around this limitation, cast the variable to the expected type. For example:

  ```
  typeswitch (.)
  case $a as xs:integer return (($a cast as xs:integer) + 1)
  default return 17
  ```

Procedure

- Perform basic operations.
- Precompile.
- Use resolvers.

- Use external variables and functions.
- Create items and sequences.
- Work with collations.
- Execute using the command-line tools.
- Use a message handler and manage exceptions.

Building and running a sample XML application

You can use the IBM WebSphere Application Server XML thin client, the `com.ibm.xml.thinclient_8.5.0.jar` file, to build a sample XML application. You can also use the API documentation to improve your understanding of the XML API.

Before you begin

1. Install the product.
2. Locate the `com.ibm.xml.thinclient_8.5.0.jar` file.

   You can find the `com.ibm.xml.thinclient_8.5.0.jar` file in your installation tree; for example:

   - *app_server_root*`/runtimes/com.ibm.xml.thinclient_8.5.0.jar`

To see how to build and use an application, refer to the sample application that is packaged with the product.

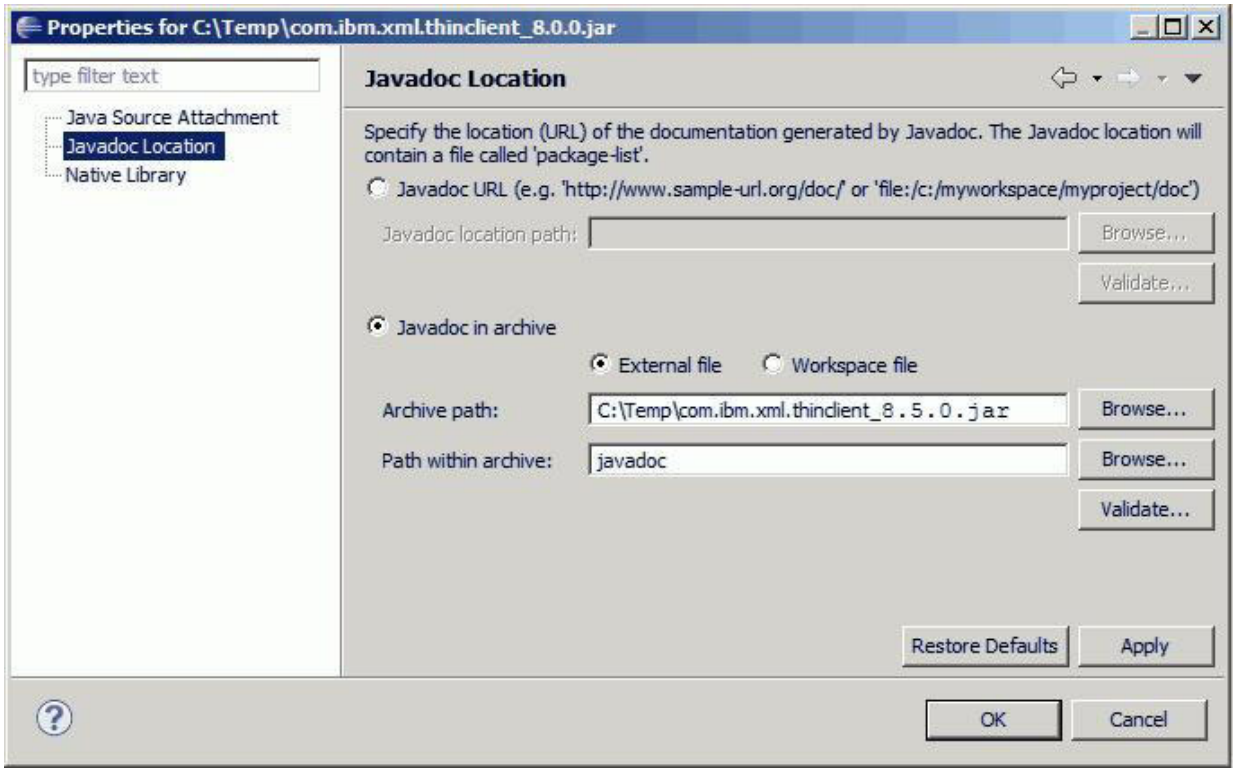
About this task

Follow this procedure when you build and run a sample XML application.

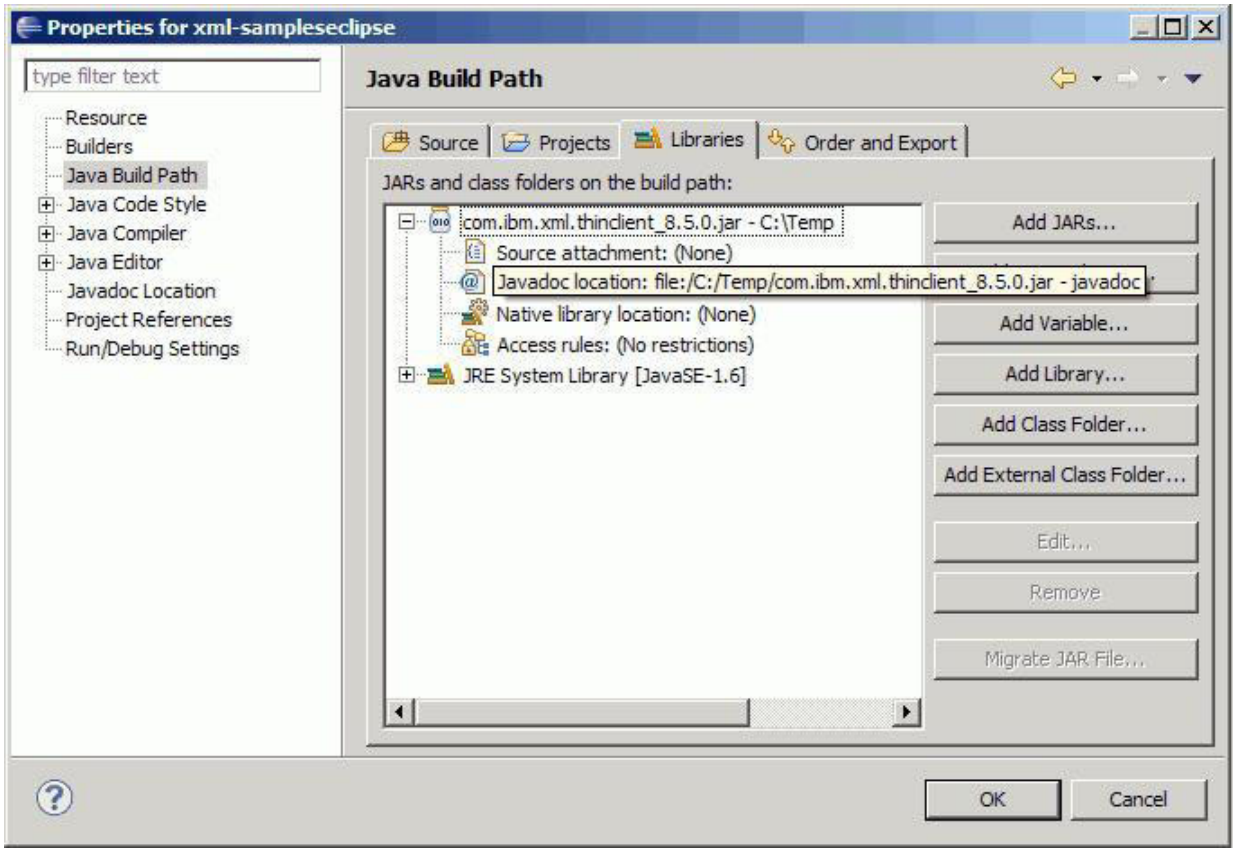
Procedure

1. For build time, include the `com.ibm.xml.thinclient_8.5.0.jar` file in the build-time class path while developing your sample XML application.

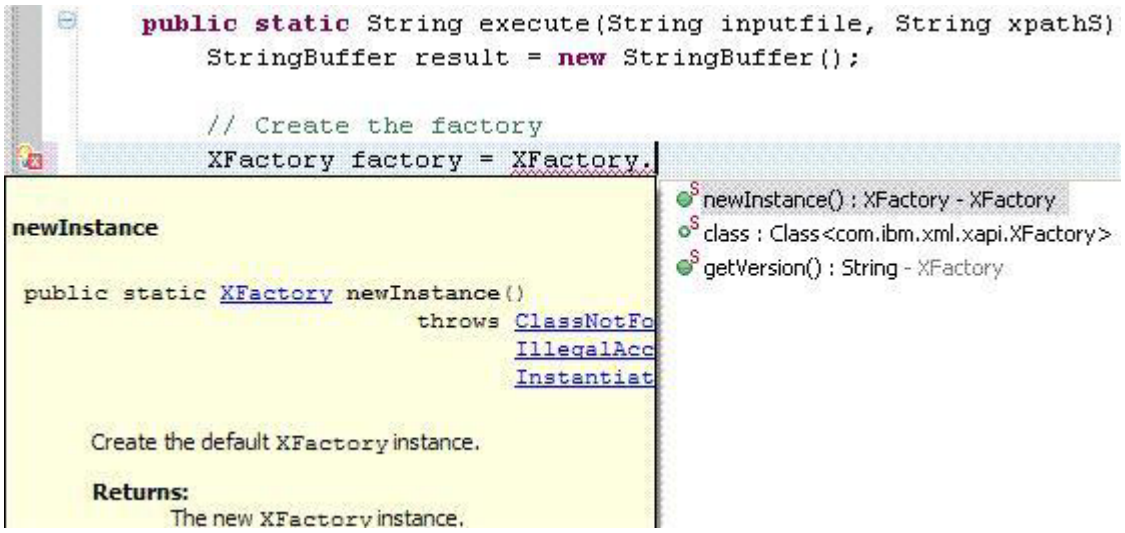
   Also, attach the API documentation from the `javadoc` directory that is inside the `com.ibm.xml.thinclient_8.5.0.jar` file.



The results of these actions are shown in the following image:



When complete, your application should compile; and when using context completion, you should have access to the API documentation as shown here:



2. Deploy your application.

Running the IBM Thin Client for XML

The IBM Thin Client for XML with WebSphere Application Server allows applications to take advantage of IBM XML technology components in a simple Java environment. Such applications can directly access the XML API to process XPath, XQuery, and XSL in a Java SE runtime environment. You can bundle the Thin Client for XML library with your application by using the WebSphere Application Server installation. The Thin Client for XML also extends the choice of Java SE runtime environment. It can be run in IBM Java Runtime Environments (JREs) packaged with WebSphere Application Server as well as in the Windows and Linux JREs from Oracle Corporation, the JREs that are downloaded from the Oracle Corporation website, or the JRE that is downloaded from the HP website.

Before you begin

Before you can use the API provided by the Thin Client for XML you must obtain the Thin Client for XML Java archive (JAR) file. This can be accomplished by installing WebSphere Application Server. The Thin Client for XML JAR file, `com.ibm.xml.thinclient_8.5.0.jar`, is located in the *app_server_root*`\runtimes` directory.

Copy the JAR file, `com.ibm.xml.thinclient_8.5.0.jar`, to other machines to enable access to the XML API. Copies of the Thin Client for XML are subject to the terms and conditions of the license agreement for the WebSphere Application Server Version 8.5 product from which you obtained the Thin Client for XML. Refer to the license agreements for correct usage and other limitations.

The Thin Client for XML with WebSphere Application Server runs on distributed operating systems with Java SE Development Kit (JDK) support, including Java 6.0 and Java 7.0.

About this task

Run the Thin Client for XML by completing this procedure.

Procedure

Invoke the client application.
Run the following Java command:

```
java_install_root/bin/java
-classpath com.ibm.xml.thinclient_8.5.0.jar:list_of_your_application_jars_and_classes
fully_qualified_class_name_to_run
```

Performing basic operations

You can use this information to help you to perform basic XPath, XSLT, and XQuery operations.

Procedure

- Perform basic XPath operations.
- Perform basic XSLT operations.
- Perform basic XQuery operations.
- View the results.
- Serialize the results.
- Navigate with XSequenceCursor.
- Navigate with XTreeCursor.

Overview of the XML API

The product provides the IBM XML Application Programming Interface in support of the XML standards. This application programming interface invokes a runtime engine that is capable of executing XPath 2.0, XSLT 2.0, and XQuery 1.0 as well as manipulating the returned XML data.

Supported input and result types:

The API supports standard implementations of Java API for XML Processing (JAXP) input and result types.

The following standard implementations of the JAXP Source interface are supported as the input to the execute methods of an executable object (XPathExecutable, XQueryExecutable, and XSLTExecutable) as well as to other methods that take a Source object such as XItemFactory.item(Source), XDynamicContext.bind(QName, Source), and so on. They are also accepted for the stylesheet parameter to the XFactory.prepareXSLT methods. These classes are all included in the Java 6.0 and Java 7.0 versions of the JRE. Refer to the Java API documentation for more information.

- javax.xml.transform.stream.StreamSource
- javax.xml.transform.dom.DOMSource
- javax.xml.transform.sax.SAXSource
- javax.xml.transform.stax.StAXSource

The XSourceResolver.getSource method can return any of the previous implementations of source as well as a further implementation, XItemSource, provided by the API. This allows results from a previous query or transformation to be used as input to a new query or transformation without first serializing to a DOM or stream. The XItemSource can simply be initialized with the XItemView instance and returned by the XSourceResolver implementation.

The following standard implementations of the JAXP Result interface are supported for those execute methods that take a result as well as other methods that take a result object such as the export methods on XItemView and XSequenceCursor. These classes are included in the Java 6.0 and Java 7.0 versions of the JRE. Refer to the Java API documentation for more information.

- javax.xml.transform.stream.StreamResult
- javax.xml.transform.dom.DOMResult
- javax.xml.transform.sax.SAXResult
- javax.xml.transform.stax.StAXResult

A further implementation of the Result interface, XSequenceCursorResult, is provided by the API to allow a result to be returned as an XSequenceCursor. The execute methods on the executable objects that do not take a result object return the result as an XSequenceCursor already; therefore, this is primarily for use with XSLT multiple result documents. An implementation of XResultResolver can return an

XSequenceCursorResult to the processor and the processor will populate the XSequenceCursorResult with the XSequenceCursor and the associated output parameters during processing. After the transformation is complete the XSequenceCursor can be retrieved by the application by calling the getSequenceCursor method on the XSequenceCursorResult object. The output parameters can be retrieved by calling the getOutputParameters method. The output parameters then can be used on a call to the XSequenceCursor exportSequence method.

The XFactory class:

This is a quick overview of the methods that the XFactory class provides. The individual methods are discussed in detail in other articles in the information center.

The XFactory class is the main factory class for creating executables for XPath, XQuery, and XSLT. It is also the means for creating instances of other classes and factories such as the XStaticContext, XDynamicContext, XItemFactory, and XSequenceTypeFactory classes. An instance of XFactory maintains a set of registered schemas as well and can be validating or non-validating. A validating factory produces schema-aware executables and ensures that source documents get validated against the set of registered schemas before they are processed. If different sets of stylesheets or expressions need different sets of schemas, these can be kept separate by using more than one XFactory instance. An XFactory instance can be created by calling the static newInstance() method on the XFactory class. The instance is thread safe as long as the settings remain stable.

Here is an example of using the XFactory class.

```
// Create a new XFactory
XFactory factory = XFactory.newInstance();

// Create an XPath executable
XPathExecutable executable = factory.prepareXPath("/something/bar[2]");

// Create a new XStaticContext
XStaticContext staticContext = factory.newStaticContext();

// Create an XPath executable that is compiled in backwards
// compatibility mode
staticContext.setXPathCompatibilityMode(XStaticContext.XPATH1_0_BC_COMPATIBILITY);
XPathExecutable bcExecutable = factory.prepareXPath("/something/bar[2]", staticContext);

// Set validating
factory.setValidating(true);

// Register a schema
factory.registerSchema(new StreamSource("myschema.xsd"));

// Create a schema aware XPath executable
staticContext = factory.newStaticContext();
staticContext.declareNamespace("something", "http://myschema/something");
XPathExecutable schemaExecutable =
   factory.prepareXPath("/something:something/bar[2] instance of element(bar, something:barType)", staticContext);

// Get the item factory for this XFactory (the two are related
// since the item factory depends on the schemas that are
// registered with XFactory).
XItemFactory itemFactory = factory.getItemFactory();
```

Relationship of the processor to the Java API for XML Processing (JAXP):

In most cases, you will need to migrate any of your applications that used the Java API for XML Processing (JAXP) to use the current API.

The XSLT and XPath processing portions of JAXP are defined with reference to XSLT 1.0 and XPath 1.0. JAXP does not have provisions for XSLT 2.0 and XPath 2.0 processing. In particular, there are situations in which an XSLT 2.0 or an XPath 2.0 processor must produce a result that is different from that produced by an XSLT 1.0 or an XPath 1.0 processor given identical input and an identical stylesheet or expression. Therefore, it is not possible to instantiate the current processor using JAXP.

JAXP also does not have support for sequences, XQuery 1.0, or the many current data types that are available in XSLT 2.0, XPath 2.0, and XQuery 1.0. JAXP also is limited in the forms that input and output can take. All these things make it a poor fit for processing XSLT 2.0 stylesheets as well as XPath 2.0 and XQuery 1.0 expressions.

The following examples demonstrate common migration scenarios and how to write code using the current API that is equivalent to code that you might have written using JAXP.

Processing an XSLT stylesheet using the API

The following example demonstrates how to process an XSLT stylesheet and apply it to some input to produce an instance of the javax.xml.transform.Result interface.

```
XFactory factory = XFactory.newInstance();
XSLTExecutable style = factory.prepareXSLT(new StreamSource("style.xsl"));
style.execute(new StreamSource("input.xml"), new StreamResult(System.out));
```

Processing an XPath expression using the API

The following example demonstrates how to process an XPath expression and apply it to some input.

```
XFactory factory = XFactory.newInstance();
XPathExecutable pathExpr = factory.prepareXPath("/doc/child[@id='N1378']");

// Process input from a StreamSource
XSequenceCursor result1 = pathExpr.execute(new StreamSource("input.xml"));

// Process input from a DOM node
XSequenceCursor result2 = pathExpr.execute(new DOMSource(node));
```

Resolving URI references

If you used instances of the JAXP URIResolver interface to resolve references to the XSLT document() function, you can now use the XSourceResolver interface to accomplish the same thing. To resolve references to the document() function or the fn:doc() function, you can set an instance of the XSourceResolver interface on an instance of the XDynamicContext interface; to resolve references to stylesheets imported through xsl:import and xsl:include declarations, you can set an instance of the XSourceResolver interface on an instance of the XStaticContext interface.

The following example shows how you might set up an instance of the XSourceResolver interface that treats input documents as XSLT stylesheets and uses them to generate the input data for reference to the doc or document functions in another XSLT stylesheet.

```
final XFactory factory = XFactory.newInstance();
XSLTExecutable style = factory.prepareXSLT(new StreamSource("style.xsl"));
XDynamicContext dContext = factory.newDynamicContext();

// Create and set an instance of an anonymous inner class as the
// XSourceResolver
dContext.setSourceResolver(new XSourceResolver() {
    // Create an item to use as the initial context node for
    // transformations in the getSource method
    private XItemView fDummyNode =
        factory.getItemFactory()
            .item(new StreamSource(
                new StringReader("<doc/>")));

    // Resolve URIs by loading the resource as an XSLT stylesheet
    // and evaluating it - return the result as the Source to use
    public Source getSource(String href, String base) {
        java.net.URI baseURI;
        try {
            // Get base URI object
            baseURI = new java.net.URI(base);
        } catch (java.net.URISyntaxException use) {
            throw new RuntimeException(use);
        }
        // Resolved relative reference against base URI
        String resolvedURI = baseURI.resolve(href).toString();

        // Prepare and execute the stylesheet
        XItemView transformResult =
            factory.prepareXSLT(new StreamSource(resolvedURI))
                .execute(fDummyNode);
```

```
        return new XItemSource(transformResult);
    }
});

XSequenceCursor result = style.execute(new StreamSource("input.xml"), dContext);
```

Defining extension functions and external functions

Using JAXP for XPath expression evaluation, you could register an instance of the XPathFunctionResolver interface to supply the implementations of extension functions that your XPath expressions might call. The XSLT portion of JAXP does not have an equivalent mechanism.

With the current API, you can declare extension functions on an instance of the XStaticContext interface, specifying the expected types of the arguments and the expected type of the result of calling the function, and you can register the implementations of extension functions on an instance of the XDynamicContext interface. Your XSLT stylesheet and XPath and XQuery expressions can call any extension functions that you register.

Setting the values of stylesheet parameters and external variables

Using JAXP, you could supply the initial values of stylesheet parameters by calling the Transformer.setParameter method and you could supply the values of variables for XPath expressions by supplying an instance of the XPathVariableResolver interface. Using the API, you can declare variables using the declareVariable() methods of the XStaticContext interface, specifying a variable name and the expected type of the variable. You can supply the values of stylesheet parameters, XPath variables, and XQuery external variables through one of the bind() methods of the XDynamicContext interface.

The following example shows how you might use a variable in an XPath expression to look up product entries in a catalog based on the product identifier.

```
XFactory factory = XFactory.newInstance();
XStaticContext sContext = factory.newStaticContext();

// Declare the XPath variable "query-id" in the static context
QName queryIdVar = new QName("query-id");
sContext.declareVariable(queryIdVar, XTypeConstants.STRING_QNAME);

// Prepare the XPath expression
XItemFactory itemFactory = factory.getItemFactory();
XPathExecutable expr =
    factory.prepareXPath("/catalog/product[id eq $query-id]", sContext);

XItemView catalog = itemFactory.item(new StreamSource("catalog.xml"));
XDynamicContext dContext = factory.newDynamicContext();

// Set the value of the "query-id" variable, and evaluate the
// expression with that variable value
dContext.bind(queryIdVar, "ID43785");
XSequenceCursor product1 = expr.execute(catalog, dContext);

// Set the value of the "query-id" variable, and evaluate the
// expression with the new variable value
dContext.bind(queryIdVar, "ID18574");
XSequenceCursor product2 = expr.execute(catalog, dContext);
```

Identity transformation

Another operation that is frequently used in JAXP is the identity transformation. This is a convenient way of transforming data from one form to another—for example, serializing a DOM tree, or producing a DOM tree from SAX events. It is possible to perform identity transformations using the API. See “Performing basic XSLT operations” on page 1863 for an example.

Prepare-time and execution-time configuration

In JAXP you supply much of the runtime configuration information for XSLT stylesheets – the values of stylesheet parameters, URIResolvers, and so on—directly on the objects that are used to perform transformations – instances of the Transformer interface and the TransformerHandler interface. Similarly,

you supply configuration information for the preparation of stylesheets and XPath expressions directly on instances of the TransformerFactory and XPathFactory classes in JAXP.

With the API, you can supply configuration information that is needed at the time a stylesheet or an expression is prepared—namespace bindings, the types of external functions or variables, and so on—using an instance of the XStaticContext interface. Similarly, you can provide any configuration information that is needed to evaluate a stylesheet or expression—the values of variables, settings of output parameters, and so on—on an instance of the XDynamicContext interface, which you can pass as an argument to the execute methods of the XExecutable interface and its subinterfaces.

This separation of the configuration information into a separate object makes the API more thread safe. Your application can use the same instance of the XExecutable interface on different threads without any synchronization. This stands in contrast to JAXP, where instances of the Transformer, TransformerHandler and XPathExpression interfaces are not thread safe; every thread that uses them has to synchronize access to shared instances of those objects or create distinct copies that are specific to each thread.

Handling errors

In JAXP, you could supply an instance of the ErrorHandler interface to control how the processor should respond to errors. In the API, you can achieve this by supplying an instance of the XMessageHandler interface on an instance of the XStaticContext interface for preparation-time errors or the XDynamicContext interface for execution-time errors.

Performance tips:

Follow these tips to improve performance when using XPath, XQuery, and XSLT.

Table 251. Performance tips. Follow these tips to improve performance.

Language	Tip
XPath	Using // can be an expensive operation. Making the path more explicit (a/b/c rather than a//c) can improve performance. This is especially important when the path starts at or near the root of a large document.
	The last() function, because it requires fully evaluating the sequence to count the items, can be an expensive operation.
	Positional predicates with constant values, such as [3], are usually more efficient than those with values that are computed or that are retrieved from variables.
XQuery	Consider calling the registerImportedSchemas method on the XQueryExecutable instance if the query imports one or more schemas and the same query will be executed more than once. If registerImportedSchemas is not called, the imported schemas will be loaded every time one of the execute methods is called. By default, imported schemas can only be used to validate result trees; but calling this method has the same effect as registering the schemas with the XFactory, which means that they will be used to validate input documents.

Table 251. Performance tips (continued). Follow these tips to improve performance.

Language	Tip
XSLT	Parameters are slower to access than variables. If you do not need to supply the value of the parameter externally, use a variable.
	Using xsl:key elements and the key() function can be an efficient way to retrieve node sets.
	Pattern matching and apply-templates dispatch are usually faster than the xsl:if or xsl:when statements.
	Positional predicates in match patterns are usually expensive.
	In general, simpler match patterns such as "address" are less expensive to process than complicated ones such as "/purchaseorder/shipping/customer/postal/address". Take advantage of your knowledge of the document's structure and your stylesheet's behavior to avoid unnecessarily overspecifying.
	For some data models, the xsl:skip-space operation must be applied during document navigation rather than during document load. This can add some execution-time overhead.
	Consider calling the registerImportedSchemas method on the XSLTExecutable instance if the stylesheet imports one or more schemas and the same stylesheet will be executed more than once. If registerImportedSchemas is not called, the imported schemas will be loaded every time one of the execute methods is called. By default, imported schemas can only be used to validate result trees; but calling this method has the same effect as registering the schemas with the XFactory, which means that they will be used to validate input documents.
XPath, XQuery, and XSLT	Decoding and encoding is expensive. Generally, UTF-8 and UTF-16 can be read and written more quickly than other encodings.

XSLT 2.0, XPath 2.0, and XQuery 1.0 implementation-specific behaviors:

Table 252. Implementation-defined behaviors.

This table lists XSLT 2.0, XPath 2.0, and XQuery 1.0 implementation-defined behaviors for the API.

Feature	Description	Specification	Error Code	Documented Behavior
multi preserve-strip-space matched	It is a recoverable dynamic error if an element in the source document matches both an xsl:strip-space and an xsl:preserve-space declaration.	XSLT 2.0 Section 4.4	XTRE0270	The processor does not return an error and recovers by selecting the xsl:strip-space or xsl:preserve-space declaration that occurs last in declaration order.
pattern evaluation	Any dynamic error or type error that occurs during the evaluation of a pattern against a particular node is treated as a recoverable error even if the error would not be recoverable under other circumstances. The optional recovery action is to treat the pattern as not matching that node.	XSLT 2.0 Section 5.5.4		The processor does not return an error and recovers by treating the pattern as not matching that node.
multiple templates matched	It is a recoverable dynamic error if the conflict resolution algorithm for template rules leaves more than one matching template rule. The optional recovery action is to select, from the matching template rules that are left, the one that occurs last in declaration order.	XSLT 2.0 Section 6.4	XTRE0540	The processor does not return an error and recovers by selecting the template that occurs last in declaration order.
invalid value-xml space	It is a recoverable dynamic error if the name of a constructed attribute is xml:space and the value is not either default or preserve. The optional recovery action is to construct the attribute with the value as requested. This applies whether the attribute is constructed using a literal result element or by using the xsl:attribute, xsl:copy, or xsl:copy-of instructions.	XSLT 2.0 Section 11.1.2	XTRE0795	The processor does not return an error and constructs the attribute with the value as requested.

Table 252. Implementation-defined behaviors (continued).

This table lists XSLT 2.0, XPath 2.0, and XQuery 1.0 implementation-defined behaviors for the API.

Feature	Description	Specification	Error Code	Documented Behavior
invalid fragment in document uri	When a URI reference supplied to the document function contains a fragment identifier, it is a recoverable dynamic error if one of the following is true: • the media type is not one that is recognized by the processor • the fragment identifier does not conform to the rules for fragment identifiers for that media type • if the fragment identifier selects something other than a sequence of nodes (if it selects a range of characters within a text node, for example) The optional recovery action is to ignore the fragment identifier and return the document node. (Note that the recovery option is different from that in XSLT 1.0)	XSLT 2.0 Section 16.1	XTRE1160	The processor ignores the fragment identifier and returns the document node. No warning is returned.
same resource for multiple results	It is a recoverable dynamic error for a transformation to generate two or more final result trees with URIs that identify the same physical resource. The optional recovery action is implementation-dependent because it may be impossible for the processor to detect the error.	XSLT 2.0 Section 19.1	XTRE1495	The processor returns an error.
read and write to same resource	It is a recoverable dynamic error for a stylesheet to write to an external resource and read from the same resource during a single transformation, whether or not the same URI is used to access the resource in both cases. The optional recovery action is implementation-dependent; implementations are not required to detect the error condition.	XSLT 2.0 Section 19.1	XTRE1500	The processor does not attempt to detect this error condition.
disable output escaping not supported	It is a recoverable dynamic error if an xsl:value-of or xsl:text instruction specifies that output escaping is to be disabled and the implementation does not support this. The optional recovery action is to ignore the disable-output-escaping attribute.	XSLT 2.0 Section 20.2	XTRE1620	The processor does not provide the ability to disable output escaping and ignores the disable-output-escaping attribute without warning.
disable output escaping for not serialized	It is a recoverable dynamic error if an xsl:value-of or xsl:text instruction specifies that output escaping is to be disabled when writing to a final result tree that is not being serialized. The optional recovery action is to ignore the disable-output-escaping attribute.	XSLT 2.0 Section 20.2	XTRE1630	The processor does not provide the ability to disable output escaping and ignores the disable-output-escaping attribute without warning.

Table 252. Implementation-defined behaviors (continued).

This table lists XSLT 2.0, XPath 2.0, and XQuery 1.0 implementation-defined behaviors for the API.

Feature	Description	Specification	Error Code	Documented Behavior
integer overflow	On overflow and underflow situations during xs:integer arithmetic operations, implementations that support limited-precision integer operations must select from the following options: • Always raising an error (FOAR0002) • Providing an implementation-defined mechanism that allows users to choose between raising an error and returning a result that is modulo the largest representable integer value	XQuery 1.0 and XPath 2.0 Functions and Operators Section 6.2	FOAR0002	The processor provides a mechanism to enable overflow detection for integer operations through the `com.ibm.xml.xapi.XStaticContext.setIntegerMathMode(int)` method, which can be called with the constants `INTEGER_MATH_MODE_OVERFLOW_DETECTION` or `INTEGER_MATH_MODE_LIMITED_PRECISION` (defined on the XStaticContext interface) to choose between the two options. A third option, `INTEGER_MATH_MODE_ARBITRARY_PRECISION`, is provided to allow arbitrary precision integers.
double float overflow	For xs:float and xs:double arithmetic operations, overflow behavior must conform to IEEE 754-1985, which allows the following options: • Raising an error (FOAR0002) using an overflow trap • Returning INF or -INF • Returning the largest (positive or negative) non-infinite number	XQuery 1.0 and XPath 2.0 Functions and Operators Section 6.2		The processor returns INF or -INF.
double float underflow	For xs:float and xs:double arithmetic operations, underflow behavior must conform to IEEE 754-1985, which allows the following options: • Raising an error (FOAR0002) using an underflow trap • Returning INF or -INF • Returning 0.0E0, +/- 2**Emin, or a denormalized value where Emin is the smallest possible xs:float or xs:double exponent	XQuery 1.0 and XPath 2.0 Functions and Operators Section 6.2		The processor returns 0.0E0.
invalid use of doctype-system or standalone attr	It is a serialization error to specify the doctype-system parameter or to specify the standalone parameter with a value other than omit if the instance of the data model contains text nodes or multiple element nodes as children of the root node. The serializer must either signal the error or recover by ignoring the request to output a document type declaration or standalone parameter.	SR Section 5	SEPM0004	The processor returns a serialization error.
invalid xml output encoding	A serialization error occurs if the output method is XML and an output encoding other than UTF-8 or UTF-16 is requested and the serializer does not support that encoding. The serializer must return the error (SESU0007) or recover by using UTF-8 or UTF-16 instead.	SR Section 5.1.2	SESU0007	The processor returns a serialization error.

Table 252. Implementation-defined behaviors (continued).

This table lists XSLT 2.0, XPath 2.0, and XQuery 1.0 implementation-defined behaviors for the API.

Feature	Description	Specification	Error Code	Documented Behavior
error or recovery	Some dynamic errors are classed as recoverable errors. When a recoverable error occurs, the processor may signal the error (by reporting the error condition and terminating execution) or take a defined recovery action and continue processing.	XSLT 2.0 Section 2.9		The processor recovers from many of the recoverable errors but signals an error in some cases. Consult this table to determine the implementation-defined behavior of each type of recoverable error.
signal type errors statically	Whether or not type errors are signaled statically is implementation defined.	XSLT 2.0 Section 2.9		The processor detects type errors statically whenever possible; but there are cases where the error cannot be detected at compile time. In these cases, the error is detected at run time.
handling serialization errors	The handling of serialization errors is implementation defined.	XSLT 2.0 Section 20		Error messages are sent to a `com.ibm.xml.xapi.XMessageHandler` implementation that has been registered using the `setXMessageHandler` method on the `com.ibm.xml.xapi.XDynamicContext` interface.
base output URI	The way in which a base output URI is established is implementation defined.	XSLT 2.0 Section 2.3⌂		Users can set the base output URI using the `setBaseOutputURI` method on the `com.ibm.xml.xapi.XDynamicContext` interface.
extension attributes	Implementations may allow extension attributes to modify the behavior of extension functions and extension instructions or to influence the behavior of the serialization methods xml, xhtml, html, or text to the extent that the behavior of the serialization method is implementation defined or implementation-dependent.	XSLT 2.0 Section 3.3		The processor recognizes the indent-amount attribute on xsl:output declarations to specify how many spaces are used for each indentation level when indentation is enabled. The attribute must be from one of the following namespaces: • http://www.ibm.com/xmlns/prod/xltxe-j • http://xml.apache.org/xalan • http://xml.apache.org/xslt See the additional serialization params item later in the table.
user-defined data elements	An implementation may attach an implementation-defined meaning to user-defined data elements that appear in particular namespaces. The set of namespaces that are recognized for such data elements is implementation defined.	XSLT 2.0 Section 3.6.2		The processor does not recognize any user-defined data elements.
user-defined types	Support for additional user-defined or implementation-defined types is implementation defined.	XPath 2.0 Data Model Section 2.6		A schema-aware processor is supported.
undefined type behavior	Some typed values in the data model are undefined. Attempting to access an undefined property is always an error. Behavior in these cases is implementation defined and the host language is responsible for determining the result.	XPath 2.0 Data Model Section 2.5.2, Bullet 4.d	FOTY0012	The processor returned an error. Error messages are sent to a `com.ibm.xml.xapi.XMessageHandler` implementation that has been registered using the `setXMessageHandler` method on the `com.ibm.xml.xapi.XDynamicContext` interface.
namespace node representation	Representation of namespaces, that is whether or not they are represented as nodes, is implementation dependent.	XPath 2.0 Data Model Section 6.4		The namespace axis is supported.
locate stylesheet module	After resolving against the base URI, the way in which the URI reference from the href attribute of an xsl:include or xsl:import declaration is used to locate a representation of a stylesheet module and the way in which the stylesheet module is constructed from that representation are implementation defined. In particular, which URI schemes are supported, whether fragment identifiers are supported, and what media types are supported are implementation defined.	XSLT 2.0 Section 3.10.1		Users may provide an `com.ibm.xml.xapi.XSourceResolver` implementation through the `com.ibm.xml.xapi.XStaticContext.setSourceResolver(XSourceResolver)` method. The `XSourceResolver` is used by the processor to resolve URIs from xsl:include and xsl:import declarations (therefore, the user may decide which URIs to support), and its `getSource(String, String)` method must return a JAXP Source object. If no `XSourceResolver` is given, the processor handles the file URI scheme and those supported by the `java.net.URL.openConnection()` method. A URI fragment may be used to select an embedded stylesheet module within a source XML document. The fragment must identify an xsl:stylesheet element in the document by using the value of one of its attributes that is an xml:id attribute or is defined in a DTD as being of type ID or is defined in a schema as being of type xs:ID. There is no built-in support for non-XML media types, but users may use an `XSourceResolver` implementation to provide the processor with an XML representation of non-XML data.

Table 252. Implementation-defined behaviors (continued).

This table lists XSLT 2.0, XPath 2.0, and XQuery 1.0 implementation-defined behaviors for the API.

Feature	Description	Specification	Error Code	Documented Behavior
extension functions	Extension functions The XSLT 2.0 specification defines how extension instructions and extension functions are invoked, but the facilities for creating new extension instructions and extension functions are implementation defined.	XSLT 2.0 Section 18.1		Extension functions are supported through the processor's `XStaticContext.declareFunction` and `XDynamicContext.bindFunction` methods. Alternatively, it is also possible to declare extension functions directly within a stylesheet or query. The old style of extension functions supported in the parser and the processor are also supported for backwards compatibility; however, only 1.0 types are supported with the old style. See the API documentation for more information. It is recommended that you declare extension functions directly in your stylesheet or through the API for extension functions whenever possible rather than use the old style.
extension instructions	Extension instructions The XSLT 2.0 specification defines how extension instructions and extension functions are invoked, but the facilities for creating new extension instructions and extension functions are implementation defined.	XSLT 2.0 Section 18.2	XTDE1450	User-defined extension instructions are not supported. Extension instructions must be protected with a fallback instruction; otherwise, the stylesheet will fail to compile. The redirect extension is supported for backwards compatibility; however, it is recommended that you use the XSLT 2.0 xsl:result-document instruction because this is more portable.
backwards-compatiblility	Whether a particular XSLT 2.0 implementation supports backwards-compatible behavior is implementation defined.	XSLT 2.0 Section 3.8		The backwards-compatibility feature as described in the XSLT 2.0 specification is supported.
in-scope collations for use-when	In-scope collations for use-when expressions	XSLT 2.0 Section 3.12		The only collation available during the evaluation of a use-when is the Unicode code-point collation.
current date time for use-when	Current date and time for use-when expressions	XSLT 2.0 Section 3.12		The current date time is the current date time of the system as retrieved by calling the `java.util.GregorianCalendar getInstance()` method.
implicit timezone for use-when	Implicit time zone for use-when expressions	XSLT 2.0 Section 3.12		The implicit time zone is the time zone of the system as retrieved by calling the `java.util.TimeZone getDefault()` method.
maximum number of decimal digits	Maximum number of total digits in decimal digits is implementation defined , but they must be at least 18 digits.	XSLT 2.0 Section 4.6		The implementation uses the `java.math.BigDecimal` class, which supports nearly unlimited precision, except that the number of digits to the right of the decimal place is limited to Integer.MAX_VALUE. Truncation is only required in the case of division, where there is the possibility of non-terminating decimals. The precision of the fractional part of the result is limited to 18 digits. The rounding mode in this case is ROUND_HALF_UP, where discarded fractions of 0.5 or later are rounded up (away from zero) and lesser fractions are rounded down.
year component values	For the xs:date, xs:time, xs:dateTime, xs:gYear, and xs:gYearMonth types: the range of values of the year component (which must be at least +0001 to +9999), and the maximum number of fractional second digits (which must be at least 3)	XSLT 2.0 Section 4.6		The year component of the xs:date, xs:dateTime, xs:gYear, and xs:gYearMonth types has the range -(10^9-1) to (10^9)-1. The maximum number of fractional seconds digits supported for the xs:time and xs:dateTime types is three.
duration	For the xs:duration type: the maximum absolute values of the years, months, days, hours, minutes, and seconds components	XSLT 2.0 Section 4.6		The maximum absolute values for the duration components are: • year: 178956970 • month: 2147483647 • day: 106751991167 • hour: 2562047788015 • minute: 153722867280912 • second: 9223372036854775 Three digits of precision are supported for milliseconds.
year month duration	For the xdt:yearMonthDuration type: the maximum absolute value expressed as an integer number of months	XSLT 2.0 Section 4.6		The maximum absolute value for the xs:yearMonthDuration type is 2147483647 months.
day time duration	For the xdt:dayTimeDuration type: the maximum absolute value expressed as a decimal number of seconds	XSLT 2.0 Section 4.6		The maximum absolute value for the xs:dayTimeDuration type is 9223372036854775 seconds.

Table 252. Implementation-defined behaviors (continued).

This table lists XSLT 2.0, XPath 2.0, and XQuery 1.0 implementation-defined behaviors for the API.

Feature	Description	Specification	Error Code	Documented Behavior
value maximum length	For the xs:string, xs:hexBinary, xs:base64Binary, xs:QName, xs:anyURI, xs:NOTATION types and types derived from them: the maximum length of the value	XSLT 2.0 Section 4.6		The theoretical maximum length is 2^31 - 1; however, the system is likely to run out of memory long before that limit is reached.
sequence length	Maximum number of items in a sequence	XSLT 2.0 Section 4.6		The theoretical maximum number of items is 2^31 - 1; however, the system is likely to run out of memory long before that limit is reached.
statically known collations	Set of in-scope collations	XSLT 2.0 Section 5.4.1 XPath 2.0 Section 2.1.1 XQuery 1.0 Section 2.1.1		Any URI is considered to be in the set of in-scope collations. Every URI that is used as a collation URI must be associated with a Java Collator at execution time.
implicit timezone	Implicit time zone	XSLT 2.0 Section 5.4.3.2 XPath 2.0 Section 2.1.2 XQuery 1.0 Section 2.1.2		The implicit time zone can be set using the `XDynamicContext.setImplicitTimeZone(Duration)` method in the processor. If the implicit time zone is not set, the system time zone is used as retrieved through the `java.util.TimeZone.getDefault()` method.
default collection	Default collection This is the sequence of nodes that would result from calling the fn:collection function with no arguments. The value of the default collection may be initialized by the implementation.	XSLT 2.0 XPath 2.0 Section 2.1.2	FODC0004	The default collection is determined by the XCollectionResolver registered with the XDynamicContext. If no XCollectionResolver is registered an error is returned and the empty sequence is used. For more information about the XCollectionResolver interface, refer to the API documentation.
stylesheet parameter	Supply stylesheet parameter value when executing a transformation A top-level xsl:param element declares a stylesheet parameter. A stylesheet parameter is a global variable with the additional property that its value can be supplied by the caller when a transformation is initiated.	XSLT 2.0 Section 9.5		If a value for a parameter is bound in the XDynamicContext, that value is used; otherwise, the default value specified in the stylesheet for the parameter is used. To bind values to parameters, use the `XDynamicContext.bind()` methods.

Table 252. Implementation-defined behaviors (continued).

This table lists XSLT 2.0, XPath 2.0, and XQuery 1.0 implementation-defined behaviors for the API.

Feature	Description	Specification	Error Code	Documented Behavior
stylesheet function override mechanism	Override a stylesheet function to a function provided by the implementer; pertains to the xsl:function element The optional override attribute defines what happens if this function has the same name and arity as a function provided by the implementer or made available in the static context using an implementation-defined mechanism. If the override attribute has the value yes, this function is used in preference; if it has the value no, the other function is used in preference. The default value is yes. Specifying override="yes" ensures interoperable behavior—the same code will execute with all processors. Specifying override="no" is useful when writing a fallback implementation of a function that is available with some processors but not others—it allows the vendor's implementation of the function (or a user's implementation written as an extension function) to be used in preference to the stylesheet implementation.	XSLT 2.0 Section 10.3		If the override attribute had the value of yes, stylesheet functions can override the following: • extension functions declared in the `XStaticContext` using the `XStaticContext.declareFunction()` methods and bound in the `XDynamicContext` using the `XDynamicContext.bindFunction()` methods • old style extension functions supported in XSLT4J and XL TXE-J 1.0 See Using extension functions. • EXSLT extension functions implemented by the processor Stylesheet functions cannot be made to override any of the core functions defined in the XSLT 2.0 specification or the XQuery 1.0 and XPath 2.0 Functions and Operators specification.
normalize copied xml id	When an xml:id attribute is copied using either the xsl:copy or xsl:copy-of instruction, it is implementation defined whether the value of the attribute is subjected to attribute value normalization—that is, effectively applying the normalize-space XQuery 1.0 and XPath 2.0 Functions and Operators function.	XSLT 2.0 Section 11.9		Neither the xsl:copy and xsl:copy-of instructions apply the normalize-space function on xml:id attributes; so all white spaces are preserved.
numbering sequences supported	Numbering sequences supported Which numbering sequences, additional to those listed previously, are supported is implementation defined. If an implementation does not support a numbering sequence represented by the given token, it must use a format token of 1.	XSLT 2.0 Section 12.3		The processor only supports the standard sets of numbering sequences.
bounds on range of numbers	Lower and upper bounds on the range of numbers For the standard numbering sequences, any upper bound imposed by the implementation must not be less than 1000 (one thousand) and any lower bound must not be greater than 1. Numbers that fall outside this range must be formatted using the format token 1. The numbering sequence associated with the format token 1 has a lower bound of 0 (zero).	XSLT 2.0 Section 12.3		• Alphabet values: arbitrary precision when in integer arbitrary precision mode, otherwise 0 to 2^63 - 1 • Digit values: arbitrary precision when in integer arbitrary precision mode, otherwise 0 to 2^63 - 1 • Roman values: 0 - 9999 • Word number: 0 - 19999

Table 252. Implementation-defined behaviors (continued).

This table lists XSLT 2.0, XPath 2.0, and XQuery 1.0 implementation-defined behaviors for the API.

Feature	Description	Specification	Error Code	Documented Behavior
default language for numbering	Default language for numbering The lang attribute specifies which language's conventions are to be used; it has the same range of values as xml:lang (see the XML 1.0 specification). If no lang value is specified, the language that is used is implementation defined. The set of languages for which numbering is supported is implementation defined. If a language is requested that is not supported, the processor uses the language that it would use if the lang attribute were omitted.	XSLT 2.0 Section 12.3		The default language for number formatting is always set to en-US.
languages for numbering	Set of languages for numbering Many numbering sequences are language sensitive.	XSLT 2.0 Section 12.3		The languages supported are based on International Component Unicode (ICU) and languages supported by the JVM.
combinations for numbering	Combinations of values of the format token, the language, and the ordinal attribute for numbering	XSLT 2.0 Section 12.3		The processor only supports the ordinal value of yes. Any other values for the ordinal attribute are ignored as if the ordinal attribute was not specified.
data-type for sort	Effect of the data-type attribute for xsl:sort If this has the effective value text, the atomized sort key values are converted to strings before being compared. If it has the effective value number, the atomized sort key values are converted to doubles before being compared. The conversion is done by using the string-FO or number-FO function as appropriate. If the data-type attribute has any other effective value, the value must be a lexical QName with a non-empty prefix and the effect of the attribute is implementation defined.	XSLT 2.0 Section 13.1.2		The supported values for the data-type attribute are 'text' and 'number'. For any other valid values, a warning message is issued and the data-type attribute is ignored.
collation uri	Manner in which the URI is associated with an actual collation rule or algorithm The lang and case-order attributes are ignored if a collation attribute is present. But in the absence of a collation attribute, these attributes provide input to an implementation-defined algorithm to locate a suitable collation. Facilities in XSLT 2.0 and XPath 2.0 that require strings to be ordered rely on the concept of a named collation. A collation is a set of rules that determine whether two strings are equal and, if not, which of them is to be sorted before the other. A collation is identified by a URI, but the manner in which this URI is associated with an actual rule or algorithm is implementation defined	XSLT 2.0 Section 13.1.3		Collation URIs are associated with a Java Collator through the API using one of the `XDynamicContext.bindCollation` methods.

Table 252. Implementation-defined behaviors (continued).

This table lists XSLT 2.0, XPath 2.0, and XQuery 1.0 implementation-defined behaviors for the API.

Feature	Description	Specification	Error Code	Documented Behavior
lang case-order determine collation	Which lang and case-order attributes determine a collation algorithm for sort	XSLT 2.0 Section 13.1.3		The processor retrieves a locale based on the value of the lang attribute. It then creates a Java collator using the `java.text.Collator.getInstance(Locale)` method. The compare method of the collator is overridden to handle the case-order attribute if specified. If the lang attribute was not specified, the processor proceeds as previous using the default locale returned by the Java method `Locale.getDefault()`.
default collation for sort	Default collation for sort If none of the collation, lang or case-order attributes is present in xsl:sort, the collation is chosen in an implementation-defined way. It is not required that the default collation for sorting should be the same as the default collation used when evaluating XPath expressions. (see Section 5.4.1: Initializing the Static Context and Section 3.6.1: The default-collation attribute)	XSLT 2.0 Section 13.1.3		The processor uses the default locale returned by the Java method `Locale.getDefault()` to create a Java collator using the `java.text.Collator.getInstance(Locale)` method.
recognized media types	Set of media types recognized by a processor	XSLT 2.0 Section 16.1		The processor only supports XML files.
picture fallback in date formatting	Fallback representation for picture string in the date formatting functions; the format token n, N, or Nn, that indicates that the value of the component is to be output by name, in lowercase, uppercase, or title-case respectively Components that can be output by name include (but are not limited to) months, days of the week, time zones, and eras. If the processor cannot output these components by name for the chosen calendar and language, it must use an implementation-defined fallback representation.	XSLT 2.0 Section 16.5.1		The processor will output [Calendar: AD] as the fallback.
set supported in date formatting functions	Languages, calendars, and countries that are supported in the date-formatting functions	XSLT 2.0 Section 16.5.2, first paragraph		• Supported calendars: AD, ISO, BE • Supported languages and locales: those returned by `java.util.Locale.getAvailableLocales()`
defaults in date formatting functions	Default language, calendar, and country in the date-formatting functions if arguments are omitted or empty	XSLT 2.0 Section 16.5.2, first paragraph		• Default calendar: AD • Default language and locale: those specified by `java.util.Locale.getDefault()`
default language in date formatting functions	Default language in the date-formatting functions If the language argument is omitted, set to an empty sequence, or set to an invalid value or a value that the implementation does not recognize, the processor uses an implementation-defined language.	XSLT 2.0 Section 16.5.2, fourth paragraph		See defaults in date formatting functions.
names abbrev in language in date formatting functions	Names and abbreviations in the date-formatting functions	XSLT 2.0 Section 16.5.2, seventh paragraph		The International Components for Unicode (ICU) website has a Locale Explorer that contains links to tables for each supported locale. The processor uses the short names for the names of the days of the week and the months specified in those tables as the abbreviated forms, and it uses the long names as the unabbreviated forms.
calendar behavior in date formatting functions	Behavior of calendar in date-formatting functions	XSLT 2.0 Section 16.5.2, tenth paragraph		The processor does not support any calendars with a non-null namespace URI. If the QName supplied has a prefix, the AD calendar will be used.

Table 252. Implementation-defined behaviors (continued).

This table lists XSLT 2.0, XPath 2.0, and XQuery 1.0 implementation-defined behaviors for the API.

Feature	Description	Specification	Error Code	Documented Behavior
default calendar in date formatting functions	Default calendar in date-formatting functions	XSLT 2.0 Section 16.5.2, eleventh paragraph		See defaults in date formatting functions.
supported calendars in date formatting functions	Set of calendars supported in date-formatting functions	XSLT 2.0 Section 16.5.2, first paragraph following table of calendars		See set supported in date formatting functions.
system property values	Actual values returned from system properties	XSLT 2.0 Section 16.5.5, second paragraph following the bulleted list		The value of the system property: • xsl:version is 2.0 • xsl:vendor is IBM Corporation • xsl:vendor-url is http://www.ibm.com/ • xsl:product-name is XL Transform and Query Engine for Java • xsl:product-version is 2.0 • xsl:is-schema-aware is yes • xsl:supports-serialization is yes • xsl:supports-backwards-compatibility is yes • xsl:supports-namespace-axis is yes
set of system properties	Set of system properties	XSLT 2.0 Section 16.6.5 and Erratum XT.E14		The processor supports the following: • All the system properties defined in Section 16.6.5 of the XSLT 2.0 specification • New optional xsl:supports-namespace-axis property defined by XSLT Erratum XT.E14
xslmessage	Way in which an xsl:message instruction sends a message	XSLT 2.0 Section 17, first paragraph		According to Section 17 of the XSLT 2.0 specification, xsl:message sends a message in an implementation-defined way to an implementation-defined destination. The processor uses the string value of the document node created by the xsl:message instruction as the message. If the user did not supply an instance of `com.ibm.xml.xapi.XMessageHandler` on the `com.ibm.xml.xapi.XDynamicContext` for the transformation, the message is written to the System.err output stream; and if the effective value of the terminate attribute was yes, the transformation throws an exception. If the user supplied an instance of `com.ibm.xml.xapi.XMessageHandler`, the message is passed on that object's `report()` method. See the API documentation for more information.
xslmessage destination	Output destination for document created by an xsl:message instruction	XSLT 2.0 Section 17, first paragraph		See xslmessage.
error handling in ext functions	Consequences of an error for an extension function to return a string containing characters that are not XML	XSLT 2.0 Section 18.1.2, paragraph following the third note		Section 18.1.2 of the XSLT 2.0 specification⌂ permits several behaviors when an extension function returns a string containing characters that are not permitted in XML, including treating them as if they were permitted. That is the behavior that the processor implements.
external objects	Way in which external objects are represented in the type system	XSLT 2.0 Section 18.1.3, second paragraph		Data objects whose values are of types that do not map to built-in types as described in “Mapping XML types to Java types” on page 1858 are not supported.

Table 252. Implementation-defined behaviors (continued).

This table lists XSLT 2.0, XPath 2.0, and XQuery 1.0 implementation-defined behaviors for the API.

Feature	Description	Specification	Error Code	Documented Behavior
final result tree delivery	Way in which a final result tree is delivered to an application	XSLT 2.0 Section 19, third paragraph		As described in Section 19.1 of the XSLT 2.0 specification, an implementation may allow a final result tree to be serialized or provide additional mechanisms through which they may be processed. In the processor, a final result tree may be serialized or it may delivered to an application in the form of a `java.xml.transform.Result` object or a `com.ibm.xml.xapi.XSequenceCursor` object. If the URI of the final result tree is not equal to the base output URI, and: • the user supplied a `com.ibm.xml.xapi.XResultResolver` on the `com.ibm.xml.xapi.XDynamicContext`, the result tree will be delivered to the application in the form of the `javax.xml.transform.Result` object returned by `com.ibm.xml.xapi.XResultResolver.getResult()`; • otherwise, the result tree is serialized to the location specified by the URI using `java.net.URL.openConnection()`. A final result tree whose URI is equal to the base output URI is delivered to the application using any `javax.xml.transform.Result` object specified on the `com.ibm.xml.xapi.XExecutable.execute` method used to invoke the transformation, or as the `com.ibm.xml.xapi.XSequenceCursor` returned from the `com.ibm.xml.xapi.XExecutable.execute()` method if that method's signature contains no `javax.xml.transform.Result` argument. If the result tree is delivered in the form of a `javax.xml.transform.stream.StreamResult`, it is serialized to the location specified by the `StreamResult`; if it is delivered as an instance of any other subclass of `Result` or as an `XSequenceCursor`, the result tree is delivered in the form appropriate for that API. Refer to the API documentation for additional information.
URI restriction	Restrictions on form of absolute URI used in an href	XSLT 2.0 Section 19.1, third paragraph following the second note		As described in Section 19.1 of the XSLT 2.0 specification, an implementation may place implementation-defined limitations on an absolute URI that is the value of an href attribute on an xsl:result-document instruction. With the processor, • If the user supplies an `com.ibm.xml.xapi.XResultResolver on the com.ibm.xml.xapi.XDynamicContext` in which the stylesheet is evaluated, there are no limitations on the form of such an absolute URI. • If there is no user-supplied `XResultResolver`, the only restrictions are that if the href attribute is an absolute URI that: – uses the file protocol, the user must have permission to open an output stream to that file – uses some other protocol, the user must have permission to create an output stream to the URI, using the Java equivalent new `java.net.URL(href).openConnection().getOutputStream()`
final result tree location	Location to which final result trees are serialized	XSLT 2.0 Section 2.3 see base output URI		By default, final result tree URIs will be interpreted relative to the base URI of the main output document. If another location is desired, an `XResultResolver` implementation can be registered with the dynamic context to implement user-defined behaviors. Use the `XDynamicContext.setResultResolver()` method to register the `XResultResolver` implementation. The base URI that is used can also be changed by calling the `XDynamicContext.setBaseOutputURI()` method.
default output encoding	Default value of the encoding attribute in xsl:output	XSLT 2.0 Section 20		The default output encoding is UTF-8.
byte-order-mark for UTF-8	Byte-order-mark for UTF-8	XSLT 2.0 Section 20		The default value is no, meaning that no BOM is produced at the start of UTF-8 files.
additional normalization form	Additional normalization form for serialization	XSLT 2.0 and XQuery 1.0 Serialization Section 19.1 Section 20 Section 5.1.8		No implementation-defined normalization forms are provided.

Table 252. Implementation-defined behaviors (continued).

This table lists XSLT 2.0, XPath 2.0, and XQuery 1.0 implementation-defined behaviors for the API.

Feature	Description	Specification	Error Code	Documented Behavior
output version	Permitted and default value of the version attribute in xsl:output	XSLT 2.0 Section 20		The default for XML or XHTML is 1.0; users may explicitly specify 1.0 or 1.1. For HTML, the default is 4.0.
static-typing in stylesheet	Interaction of XSLT 2.0 stylesheets with the static typing feature of XPath 2.0	XSLT 2.0 and XPath 2.0 XSLT 2.0 Section 21 XPath 2.0 Section F.1		This XSLT processor does not currently have a mechanism for requesting that its XPaths perform static typing.
built in types	Type definitions available within a stylesheet	XSLT 2.0 Section 3.13		The processor is schema aware as defined in Section 3.13 of the XSLT 2.0 specification.
namespace for additional error codes	Namespace that is used if additional error QNames are defined by the implementation	XSLT 2.0 Section 2.9		When appropriate, the processor does include the specified error code or code(s) in the text of its messages within square brackets. Additional errors are generally expressed similarly but without a specification prefix on the error identifier. Error conditions are not presented as QNames; applications that wish to respond to errors programmatically must parse these error identifiers off the front of the error-message strings.
unparsed text encoding	Mechanism for determining encoding of an external source	XSLT 2.0 Section 16.2		The processor does not implement any additional heuristics. Encoding resolution proceeds immediately to step 5, and UTF-8 is assumed.
available documents	Mechanism for obtaining a document node and a media type given an absolute URI	XSLT 2.0 Section 2.3 Section 16.1		The default source resolution behavior for documents loaded using the XPath fn:doc function is to resolve relative URIs based on the base URI from the static context. If the base URI is not available, the current working directory is used. Absolute URIs are used unchanged. The default source resolution behavior for documents loaded using the XSLT document function is described in the XSLT 2.0 specification Multiple Source Documents. If no base URI is available, the current working directory is used. If the application needs to either constrain or extend these behaviors, it is possible to plug in an implementation of `XSourceResolver` to the `XDynamicContext` through the `setSourceResolver()` method.
additional output methods	Support for implementation-defined output method	XSLT 2.0 and XQuery 1.0 Serialization Section 3		The processor does not implement any additional output methods.
additional serialization params	Effect of additional serialization parameters on the output of the serializer	XSLT 2.0 and XQuery 1.0 Serialization Section 3 XSLT 2.0 Section 20		The processor implements the following additional serialization parameters: • INDENT AMOUNT: Specifies the number of spaces to use when the indent serialization parameter is enabled. Use the `XOutputParameters.setIndentAmount()` method or the xalan:indent-amount can be specified in the xsl:output element of an XSL stylesheet using the indent-amount attribute. • BC MODE: Enables backwards-compatibility mode for the serializer. If enabled and no output method is specified, XML will be used as a default. If disabled, the rules of XSLT 2.0 will be followed when no output method is specified. Use the `XOutputParameters.setBackwardsCompatible()` method to enable. For XSL stylesheets where the version is less than 2.0, backwards-compatibility mode is enabled by default.
additional normalization-form	Support for additional Unicode Normalization form	XSLT 2.0 and XQuery 1.0 Serialization Section 5.1.8		No implementation-defined normalization forms are provided.
option in encoding phase	Effect of an option that allows the encoding phase to be skipped so that the result of serialization is a stream of Unicode characters	XSLT 2.0 and XQuery 1.0 Serialization Section 4		No such option is provided by the processor.

Table 252. Implementation-defined behaviors (continued).

This table lists XSLT 2.0, XPath 2.0, and XQuery 1.0 implementation-defined behaviors for the API.

Feature	Description	Specification	Error Code	Documented Behavior
cdata sec mechanism	Alternative mechanism requested by the user to create CDATA sections	SR Section 5.1.4 of XSLT 2.0 and XQuery 1.0 Serialization		The processor does not provide an alternative mechanism for creating CDATA sections.
unicode version	Supported version of Unicode	XPath 2.0 Appendix D XQuery 1.0 Appendix D		The processor supports the version of Unicode supported by the host JRE—namely, Unicode Standard Version 4.0 for Java 6 and Unicode Standard Version 6.0 for Java 7.
trace function	Trace function The destination of the trace output is implementation defined.	XQuery 1.0 and XPath 2.0 Functions and Operators Section 4		When using the fn:trace() function, the result will be passed to the `com.ibm.xml.xapi.XMessageHandler` (formerly `com.ibm.xml.xapi.XErrorHandler`). It is up to the user to specify their own `XMessageHandler` to handle the trace results reported by the processor. Trace-message type is indicated by `XMessageHandler.TRACE`.
recovery for under overflow integer operations	Mechanism that allows users to choose between raising an error and returning a result that is modulo the largest representable integer value during overflow or underflow arithmetic operations	XQuery 1.0 and XPath 2.0 Functions and Operators Section 6.2		The processor provides a mechanism to enable overflow detection for integer operations through the `com.ibm.xml.xapi.XStaticContext.setIntegerMathMode(int)` method, which can be called with the constants INTEGER_MATH_MODE_OVERFLOW_DETECTION or INTEGER_MATH_MODE_LIMITED_PRECISION to choose between the two options. A third option is provided to allow arbitrary precision integers.
digits truncation	If the number of digits in the result of a numeric operation exceeds the number of digits that the implementation supports, the result is truncated or rounded in an implementation-defined manner.	XQuery 1.0 and XPath 2.0 Functions and Operators Section 6.2 Section 3.2.3 of XML Schema Part 2: Datatypes Second Edition		The implementation uses the java.math.BigDecimal class, which supports nearly unlimited precision except that the number of digits to the right of the decimal place is limited to Integer.MAX_VALUE. Truncation is only required in the case of division, where there is the possibility of non-terminating decimals. The precision of the fractional part of the result is limited to 18 digits. The rounding mode in this case is ROUND_HALF_UP, where discarded fractions of 0.5 or later are rounded up (away from zero) and lesser fractions are rounded down.
collation abilities	Ability of specified collation to decompose strings into collation units suitable for substring matching is an-implementation-defined-property of a collation.	XQuery 1.0 and XPath 2.0 Functions and Operators Section 7.5		If the Java Collator specified in a call to the `bindCollation` method of the `XDynamicContext` interface is an instance of the `RuleBasedCollator` class, the associated collation URI can be used with one of the functions that performs collation-based substring matching.
year value limits	Maximum number of digits for year values. All minimally conforming processors must support year values with a minimum of 4 digits (YYYY) and a minimum fractional second precision of 1 millisecond or three digits (s.sss); however, conforming processors may set larger implementation-defined-limits on the maximum number of digits that they support in these two situations.	XQuery 1.0 and XPath 2.0 Functions and Operators Section 10.1.1		The year component of the types xs:date, xs:dateTime, xs:gYear, and xs:gYearMonth has the range -(10^9-1) to (10^9)-1.
fractional second precision	Maximum number of digits for fractional second values	XQuery 1.0 and XPath 2.0 Functions and Operators Section 10.1.1		The maximum number of fractional seconds digits supported for the xs:time and xs:dateTime types is 3.

Table 252. Implementation-defined behaviors (continued).

This table lists XSLT 2.0, XPath 2.0, and XQuery 1.0 implementation-defined behaviors for the API.

Feature	Description	Specification	Error Code	Documented Behavior
doc function	Various aspects of the processing provided by fn:doc are implementation defined. Implementations may provide external configuration options that allow any aspect of the processing to be controlled by the user.	XQuery 1.0 and XPath 2.0 Functions and Operators Section 15.5.4		Users may provide an `com.ibm.xml.xapi.XSourceResolver` implementation through the `com.ibm.xml.xapi.XDynamicContext.setSourceResolver(XSourceResolver)` method. The `XSourceResolver` is used by the fn:doc implementation to resolve URIs (thus the user may decide which URIs to support), and its `getSource(String, String)` method must return a JAXP Source object. If no `XSourceResolver` is given, the processor handles the file URI scheme and those supported by the `java.net.URL.openConnection()` method. It does not process URI fragments. There is no built-in support for non-XML media types, but users may use an `XSourceResolver` implementation to provide the processor with an XML representation of non-XML data. DTD validation and schema validation may be applied to the source document depending on the validation setting. The validation setting may be set on `com.ibm.xml.xapi.XFactory` instances using the `setValidating` method, and this setting is inherited by objects created by the `XFactory`. If a `com.ibm.xml.xapi.XDynamicContext` instance is provided to the execute or `executeToList` method of a `com.ibm.xml.xapi.XExecutable` instance, its validation setting is used; otherwise, the setting of the `XExecutable` instance itself is used. The processor does not provide a recovery mechanism for errors in retrieving the resource or parsing or validating its content. The processor does not provide an option to relax the requirement for the fn:doc function to return stable results.
decimal operator precision	For xs:decimal values, the number of digits of precision returned by the numeric operators is implementation defined.	XQuery 1.0 and XPath 2.0 Functions and Operators Section 6.2, last paragraph		The number of digits of precision is the minimum required to represent the exact result without rounding, except in the case of division, where the number of digits of precision for the fractional part of the result is limited to 18.
collection doc stability	User option to evaluate the function without a guarantee of stability in addition to the manner in which such user options are provided	XQuery 1.0 and XPath 2.0 Functions and Operators Sections 15.5.4 and 15.5.6		The processor does not provide an option to relax the requirement for the fn:doc or fn:collection functions to return stable results.
decimal precision	Number of decimal digits supported in xs:decimal The result of casting a string to xs:decimal when the resulting value is not too large or too small but nevertheless has too many decimal digits to be accurately represented, is implementation defined.	XQuery 1.0 and XPath 2.0 Functions and Operators Section 17.1.1		The implementation uses the `java.math.BigDecimal` class, which supports nearly unlimited precision, except that the number of digits to the right of the decimal place is limited to Integer.MAX_VALUE. Memory would be exhausted before this limit is reached.
returns warning	Circumstances in which warnings are returned, and the ways in which warnings are handled	XQuery 1.0 and XPath 2.0 Functions and Operators Section 2.3 XPath 2.0 Section 2.3.1 XQuery 1.0 Section 2.3.1		The user can provide an implementation of `com.ibm.xml.xapi.XMessageHandler` using the `setMessageHandler()(XMessageHandler)` method on either `com.ibm.xml.xapi.XStaticContext` or `com.ibm.xml.xapi.XDynamicContext` for static and dynamic warnings respectively. The `report(int, String, XSourceLocation, Exception)` method of XMessageHandler will be called for each warning, with the first argument equal to `XMessageHandler.WARNING`. If no `XMessageHandler` is provided, warnings are printed to the standard error output stream. Warnings are returned in situations where the processor takes some action to avoid an error condition, such as substituting a default value for an invalid value, that the user might want to correct in the future.

Table 252. Implementation-defined behaviors (continued).

This table lists XSLT 2.0, XPath 2.0, and XQuery 1.0 implementation-defined behaviors for the API.

Feature	Description	Specification	Error Code	Documented Behavior
report error	Method by which errors are reported to the external processing environment	XQuery 1.0 and XPath 2.0 Functions and Operators Section 2.3 XPath 2.0 Section 2.3.2 XQuery 1.0 Section 2.3.2		The user can provide an implementation of `com.ibm.xml.xapi.XMessageHandler` using the `setMessageHandler()(XMessageHandler)` method on either `com.ibm.xml.xapi.XStaticContext` or `com.ibm.xml.xapi.XDynamicContext` for static and dynamic errors respectively. The `report(int, String, XSourceLocation, Exception)` method of `XMessageHandler` will be called for each error, with the first argument equal to either `XMessageHandler.ERROR` or `XMessageHandler.FATAL_ERROR`. If no `XMessageHandler` is provided, errors are printed to the standard error output stream.
XML 1.0 or XML 1.1 rules	Whether the processor is based on XML 1.0 or XML 1.1 rules for names and supported characters	XPath 2.0 Appendix D XQuery 1.0 Appendix D		The processor follows XML 1.1 rules for the definitions of NCName and supported characters as well as for end-of-line handling and attribute value normalization.
default order of empty sequences	Whether the default handling of empty sequences in "order by" is "empty least" or "empty greatest"	XQuery 1.0 Section 3.8.3		The processor uses the default set by a call to the `XStaticContext` method `setDefaultOrderForEmptySequences`. Otherwise, the default setting is "empty greatest".
pragmas supported	The names and semantics of any XQuery extension expressions (pragmas) supported	XQuery 1.0 Section 3.14	XQST0079	The processor does not recognize or support any extension expressions.
options supported	The names and semantics of any XQuery option declarations supported	XQuery 1.0 Section 4.16		The processor currently supports the java-extension option for declaring extension functions within a query. See the API documentation for more information.
external function parameter passing	Protocols supported for passing parameters to external functions from XQuery and for returning a result	XQuery 1.0 Section 4.15		Extension functions are supported through the processor's `XStaticContext.declareFunction` and `XDynamicContext.bindFunction` methods. See the API documentation for more information.
invoking serialization	The means by which serialization is invoked for the result of evaluating an XQuery query	XQuery 1.0 Section 2.2.4		If an instance of the `javax.xml.transform.stream.StreamResult` interface is supplied on an evaluate method of an `XQueryExecutable` instance, the processor will serialize the result of the query. You can also serialize an `XSequenceCursor` that results from evaluating a query by calling one of the `exportSequence` methods.
default serialization parameters	The default values of the byte-order-mark, encoding, media-type, normalization-form, omit-xml-declaration, standalone, and version serialization parameters	XQuery 1.0 Section 2.2.4 Appendix C.3		The settings of the serialization parameters can be specified on an instance of the XOutputParameters interface. • The default setting of the byte-order-mark serialization parameter is yes for the UTF-16 encoding, and it is no otherwise. • The default setting of the encoding serialization parameter is UTF-8. • The default setting of the media-type serialization parameter is text/xml in the case of the xml output method, text/html in the case of the html and xhtml output methods, and text/plain in the case of the text output method. • The default setting of the normalization-form serialization parameter is none. • The default setting of the omit-xml-declaration serialization parameter is no. • The default setting of the standalone serialization parameter is no. • The default setting of the version serialization parameter is 1.0 for the xml and xhtml output methods and 4.01 for the html output method.
unsuccessful external function call	The effect of an unsuccessful call to an external function	XQuery 1.0 Appendix D		The processor will first report an error to any instance of the `XMessage` handler interface that is supplied and will then throw an exception if a call from XQuery to an external function is unsuccessful for any of (but not limited to) the following reasons: • because the function name is not bound to a function definition using the `XDynamicContext.bindFunction` method • the number or types of arguments supplied does not match the number or types expected by the implementation of the function • some error or exception is thrown by the implementation of the function

Table 252. Implementation-defined behaviors (continued).

This table lists XSLT 2.0, XPath 2.0, and XQuery 1.0 implementation-defined behaviors for the API.

Feature	Description	Specification	Error Code	Documented Behavior
locate module imports	The process by which the specific modules to be imported by a module import are identified if the Module Feature is supported (including processing of location hints if any)	XQuery 1.0 Section 4.11		If an XModuleResolver is registered with the XStaticContext, it is used to get Source objects for the modules. If no XModuleResolver is registered or if it returns null, the processor attempts to load one module for each location hint. Relative URIs are resolved against the base URI from the static context if available. If the base URI is not available, relative location hints are interpreted as file paths relative to the current working directory. Absolute location hints are used as is. If a module cannot be loaded for a particular location hint, the processor moves on to the next hint. An error message is emitted only if no modules can be loaded for a namespace.

The following is implementation-specific information related to XSLT 1.0 support:

- The system-property function does not support Java system properties
- If the value of an attribute contains a tab, carriage return or line-feed character with the HTML output method, the processor will serialize the actual character rather than a character reference as part of the attribute value. Either is permitted by the XSLT 2.0 and XQuery 1.0 Serialization Recommendation and by the HTML 4.01 Recommendation, but previous versions of IBM XSLT processors would serialize the character as a character reference in such a context.

Conformance statements:

The processor is an implementation of the XSL Transformations (XSLT) Version 2.0 and the XQuery 1.0 W3C recommendations. See section 21 of the XSLT 2.0 recommendation and section 5 of the XQuery 1.0 recommendation for more information about conformance criteria for processors.

It implements the first editions of the XSLT 2.0, XQuery 1.0, and XPath 2.0 recommendations, with the levels of conformance described in this article, as well as all errata published in the proposed edited recommendations of the second editions of the XSLT 2.0, XQuery 1.0, XPath 2.0 and ancillary recommendations.

- XSL Transformations (XSLT) Version 2.0 (Second Edition)
- XQuery 1.0: An XML Query Language (Second Edition)
- XML Path Language (XPath) 2.0 (Second Edition)
- XQuery 1.0 and XPath 2.0 Functions and Operators (Second Edition)
- XQuery 1.0 and XPath 2.0 Data Model (XDM) (Second Edition)
- XSLT 2.0 and XQuery 1.0 Serialization (Second Edition)

This includes support for the fn:element-with-id function and the XSLT xsl:supports-namespace-axis system property.

XSLT 2.0 conformance

The processor conforms to XSLT 2.0 as a schema-aware XSLT processor. It also supports the following optional features of XSLT 2.0:

- serialization feature
- backwards-compatibility feature

For a complete list of implementation-defined features, read “XSLT 2.0, XPath 2.0, and XQuery 1.0 implementation-specific behaviors” on page 1839.

XQuery 1.0 conformance

The processor has minimal conformance to XQuery 1.0. It also supports the following optional features of XQuery 1.0:

- full axis feature
- serialization feature
- schema-import feature
- schema-validation feature
- module feature

For a complete list of implementation-defined features, read “XSLT 2.0, XPath 2.0, and XQuery 1.0 implementation-specific behaviors” on page 1839.

Data Model conformance

The processor supports normative construction of an instance of the XQuery/XPath Data Model from an Infoset or from a PSVI. By default, construction of the instance of the Data Model will be from an Infoset. If the setValidating method of an XFactory instance is called with a value of true, any instance of the Data Model that the processor creates will be constructed from PSVI.

For more information, “Performing basic XQuery operations” on page 1867.

The processor supports both XML 1.0 and XML 1.1.

Extension support

The processor supports the following additional extensions:

- indent-amount extension attribute of xsl:output
- selection of EXSLT extension functions
- redirect extension element

xalan:indent-amount extension attribute of xsl:output

If the value of the indent serialization parameter is yes for an explicit or an implicit xsl:result-document instruction in an XSLT stylesheet, the processor will use the value of any indent-amount extension attribute on the associated xsl:output declaration to determine the amount by which indentation should be increased for every level of element nesting in the serialized result.

The indent-amount extension attribute is in the http://xml.apache.org/xalan namespace.

EXSLT extension functions

In order to facilitate migration of XSLT 1.0 stylesheets, the processor supports many extension functions defined by the EXSLT community initiative. In many cases, these functions duplicate functions that have been included in XSLT 2.0, XPath 2.0 and XQuery 1.0.

For more information about EXSLT, see the EXSLT website.

EXSLT common functions

The processor supports only the node-set common extension function. This function is made redundant by the fact that XSLT 2.0 does not restrict the operations that can be performed on temporary trees.

The EXSLT common functions are in the namespace http://exslt.org/common.

EXSLT dates-and-times functions

The EXSLT dates-and-times functions provide facilities for manipulating date and time values. Most of these functions are redundant with the inclusion of the new date and time data types from XML Schema in XSLT 2.0, XQuery 1.0, and XPath 2.0.

The EXSLT dates-and-times functions are in the namespace http://exslt.org/dates-and-times.

EXSLT dynamic functions

The processor supports only the evaluate dynamic extension function.

The EXSLT dynamic functions are in the namespace http://exslt.org/dynamic.

EXSLT math functions
The EXSLT math functions provide facilities for several commonly used mathematical operations. Only the math:abs, math:max, math:min, and math:highest functions have been made redundant in XSLT 2.0, XQuery 1.0, and XPath 2.0.

The EXSLT math functions are in the namespace http://exslt.org/math.

EXSLT set functions
The EXSLT set functions define facilities for performing set operations on sequences of nodes. These have been made redundant by the new intersect and except set operations and the << and >> node comparison operations introduced in XSLT 2.0, XQuery 1.0, and XPath 2.0.

The EXSLT set functions are in the namespace http://exslt.org/sets.

EXSLT string functions
The EXSLT string functions provide facilities for string manipulation. The tokenize and split functions have been made redundant by the new operations for string manipulation in XSLT 2.0, XQuery 1.0, and XPath 2.0, including the fn:tokenize function and the xsl:analyze-string instruction.

The EXSLT string functions are in the namespace http://exslt.org/strings.

xalan:redirect extension element
The redirect extension element provides a means of directing output from an XSLT stylesheet to more than one output destination. This extension element is made redundant by the new xsl:result-document instruction of XSLT 2.0.

The redirect extension element is in the http://xml.apache.org/xalan namespace.

Choosing between the compiler and the interpreter

You can use either the compiler and the interpreter for preparing and executing an XQuery expression, XPath expression, or XSLT stylesheet. Choosing which one to use is very application specific and depends on several factors.

About this task

This article is about choosing between the compiler and interpreter when you are preparing the expression, query, or stylesheet during the application run time.

Expressions, queries, and stylesheets can also be prepared ahead of time (precompiled). This is the most efficient option because the preparation is done ahead of time instead of during the application run time, but precompiling might not be applicable to all applications. See the articles related to precompiling for more details.

Procedure

Use the setUseCompiler(true) method on the XStaticContext to use the compiler, and use the setUseCompiler(false) method to use the interpreter.
The default is to use the interpreter for preparing an XQuery expression, XPath expression, or XSLT stylesheet.
It takes longer to prepare a compiled executable than an interpreted executable, but a compiled executable generally runs faster; therefore, there is a trade off between the cost of preparing a compiled executable and the improved execution-time efficiency.

Table 253. Differences between using the compiler and the interpreter.

Consider these factors when choosing between compiling and interpreting.

Factor	Description
Number of input documents that the executable will be used to process	If the executable will be used only to process a few input documents, it might not be worth the extra time needed to create a compiled executable because the improved efficiency of the executable might not make up for the extra prepare time. If the executable will be used to process many input documents, it might be worth the extra prepare time.
Size of the input documents	Larger input documents take longer to process; therefore, it might be worth the extra prepare time to create a compiled executable in order to get a more efficient executable object to handle the larger documents.
Size of the expression, query, or stylesheet	It takes longer to prepare a larger expression, query, or stylesheet; therefore, this affects the preparation time and execution time trade off.

Example

```
// Create a new XFactory
XFactory factory = XFactory.newInstance();

// Create a new XStaticContext
XStaticContext staticContext = factory.newStaticContext();

//Use the compiler
sc.setUseCompiler(true);

//Use the interpreter
sc.setUseCompiler(false);
```

Using static and dynamic contexts

You can use the two context interfaces that the XML API provides—XStaticContext and XDynamicContext.

About this task

Static context

The static context is used to configure prepare-time characteristics.

Note: Prepare-time refers to the execution of one of the prepare methods on XFactory or the execution of one of the compile methods on XCompilationFactory.

Static context defines items that are needed to prepare executables, items such as the names and types of external variables and functions that will be available at run time as well as compilation modes like backwards compatibility, math mode, and so on. These items do not change across invocations.

Dynamic context

The dynamic context is used to configure execution-time characteristics.

Dynamic context defines items that are unique to each invocation of an executable, items such as the values for external variables, external function implementations, and resolvers to external inputs or results. These items might change across invocations.

Prepare-time characteristics are not set directly on the XFactory instance so that it can be thread safe. The same is true for execution-time characteristics; they are kept in a separate object from the XExecutable instance so that the executable object itself is thread safe.

The prepare and execute steps themselves are separate because preparation takes time and it would be inefficient to prepare for every execution. Having separate steps allows an expression, query, or stylesheet to be prepared once and the resulting executable object then can be used to process any number of input documents.

Procedure

- Use the static context, XStaticContext, to configure prepare-time characteristics.

Prepare-time characteristics are built directly into the executable object; therefore, after an executable object has been created with a certain set of characteristics, they are fixed and cannot be changed. If an executable object for the same expression, query, or stylesheet is required that has different characteristics, a new one must be generated.

Examples of methods on XStaticContext used for setting prepare-time characteristics:

setUseCompiler
The executable object that is generated is very different for compiled and interpreted; therefore, this is a prepare-time characteristic.

declareVariable
The type of a variable affects how the expression, query, or stylesheet gets compiled and therefore is a prepare-time characteristic.

On the other hand, binding the value of a variable is an execution-time characteristic, and the value can be different for each execution.

setSourceResolver
A source resolver registered at prepare time is used to resolve includes and imports.

A source resolver can also be registered at execution time, but it is used for a different purpose.

- Use the dynamic context, XDynamicContext, to configure execution-time characteristics.

  Execution-time characteristics can be different on each call to the execute method of an executable object.

  Examples of methods on XDynamicContext used for setting execution-time characteristics:

  bind methods
  The bind methods on XDynamicContext interface are used to supply a value for a variable. The value can be different for each execution.

  setSourceResolver
  A source resolver registered at execution time is used to resolve input documents loaded with the XPath fn:doc function or the XSLT fn:document function.

  setXSLTInitialTemplate
  Identify the initial template to invoke for an XSL transformation.

What to do next

The XPath, XQuery, and XSLT specifications also have the concepts of static and dynamic context. For more information, see the following web pages:

- XPath Static Context
- XPath Dynamic Context
- XQuery Static Context
- XQuery Dynamic Context
- XSLT Static Context
- XSLT Dynamic Context

The XStaticContext and XDynamicContext interfaces merge settings from all three languages (XPath, XQuery, and XSLT). To find out which settings apply to which language refer to the “Performing Basic Operations” article for that language in the related tasks listed below.

Mapping XML types to Java types

You can use this mapping between XML types and Java types when using external functions and variables. They are recommended mappings only; other types might work subject to type promotion, casting rules, and the range of values representable by the target type.

Procedure

- Use this table to map between built-in types and Java types when using external functions and variables.

Table 254. Built-in and Java types. This table maps built-in types to Java types.

Built-in Types	Java Types
xs:anyURI	java.lang.String
xs:boolean	boolean, java.lang.Boolean
xs:base64Binary	byte[]
xs:hexBinary	byte[]
xs:date	javax.xml.datatype.XMLGregorianCalendar
xs:dateTime	javax.xml.datatype.XMLGregorianCalendar
xs:time	javax.xml.datatype.XMLGregorianCalendar
xs:duration	javax.xml.datatype.Duration
xs:dayTimeDuration	javax.xml.datatype.Duration
xs:yearMonthDuration	javax.xml.datatype.Duration
xs:gDay	javax.xml.datatype.XMLGregorianCalendar
xs:gMonth	javax.xml.datatype.XMLGregorianCalendar
xs:gMonthDay	javax.xml.datatype.XMLGregorianCalendar
xs:gYear	javax.xml.datatype.XMLGregorianCalendar
xs:gYearMonth	javax.xml.datatype.XMLGregorianCalendar
xs:decimal	java.math.BigDecimal
xs:integer	java.math.BigInteger
xs:nonPositiveInteger	java.math.BigInteger
xs:negativeInteger	java.math.BigInteger
xs:long	long, java.lang.Long
xs:int	int, java.lang.Integer
xs:short	short, java.lang.Short
xs:byte	byte, java.lang.Byte
xs:nonNegativeInteger	java.math.BigInteger
xs:unsignedLong	java.math.BigInteger
xs:unsignedInt	long
xs:unsignedShort	int
xs:unsignedByte	short
xs:positiveInteger	java.math.BigInteger
xs:double	double, java.lang.Double
xs:float	float, java.lang.Float
xs:QName	javax.xml.namespace.QName
xs:NOTATION	javax.xml.namespace.QName
xs:string	java.lang.String
xs:normalizedString	java.lang.String
xs:token	java.lang.String
xs:language	java.lang.String
xs:NMTOKEN	java.lang.String
xs:Name	java.lang.String
xs:NCName	java.lang.String
xs:ID	java.lang.String
xs:IDREF	java.lang.String
xs:ENTITY	java.lang.String
xs:untypedAtomic	java.lang.String
List	com.ibm.xml.xapi.XItemView[]
Union	com.ibm.xml.xapi.XItemView

Table 254. Built-in and Java types (continued). This table maps built-in types to Java types.

Built-in Types	Java Types
All of the above-listed built-in types	com.ibm.xml.xapi.XItemView
	com.ibm.xml.xapi.XSequenceCursor
Complex types (types that represent nodes in the XML document)	com.ibm.xml.xapi.XItemView
	com.ibm.xml.xapi.XSequenceCursor
	org.w3c.dom.Node

The mapping also applies to retrieving values from an XItemView. The XItemView getDoubleValue method returns Java primitive double; the getDateValue, getTimeValue, and getDateTimeValue methods all return an XMLGregorianCalendar; and so on.

If you want to use an external function in your XPath or XQuery expressions and it takes a built-in type as the argument, the actual Java method signature can specify any of the indicated Java types. If you want to use an external function, my:power(arg1 as xs:int, arg2 as xs:int) for example, to calculate the value of the first argument raised to the power of the second argument, you could write a Java method taking two Java primitive int arguments that performs the calculation.

- Use this table to map between sequence types and Java types when using external functions and variables.

Table 255. Sequence and Java types. This table maps sequence types to Java types.

Sequence Types	Java Types
All sequence types	com.ibm.xml.xapi.XSequenceCursor
Sequence type known to be a singleton (a sequence containing only one item)	com.ibm.xml.xapi.XItemView
	One of the types listed in the built-in types to Java types mapping table
Sequence type known to contain only nodes and no atomic items	org.w3c.dom.NodeList
	org.w3c.dom.traversal.NodeIterator

Performing basic XPath operations

You can use the XPathExecutable instances that are created using XFactory.prepareXPath methods to evaluate XPath expressions.

About this task

XPath expressions can be passed to the XFactory.prepareXPath method using a JAXP StreamSource object or using a plain Java string object. The resulting XPathExecutable instance is thread safe and can be reused to evaluate an XPath expression on multiple XML input documents.

Procedure

- Use the XStaticContext object with the prepareXPath method to pass in settings that affect how the XPath expression is prepared.

  If no XStaticContext object is provided, the default setting is used.

  XStaticContext settings relevant to XPath:

  declareFunction
  Declare a Java extension function

  declareNamespace
  Declare a namespace prefix and associate it with a namespace URI to be used as part of an XPath expression

  declareVariable
  Declare a variable externally to be used as part of an XPath expression

  setBaseURI
  Set the base URI used in the resolution of relative URIs (such as by the fn:resolve-uri function)

The default is the base URI of the expression, query, or stylesheet if the base URI is available. If the base URI is not available, the current working directory is used.

setDefaultCollation
Set the default collation URI for string comparison operations

The default is the Unicode code point collation URI.

setDefaultElementTypeNamespace
Specify the URI of the default element or type namespace

Use an empty string to make it unspecified.

The default is an empty string.

setDefaultFunctionNamespace
Specify the URI of the default function namespace

Use an empty string to make it unspecified.

The default is "http://www.w3.org/2005/xpath-functions".

setIntegerMathMode
Set the integer math mode to one of the following:

INTEGER_MATH_MODE_LIMITED_PRECISION
Limit to 18-digit precision for xs:integer (default)

INTEGER_MATH_MODE_ARBITRARY_PRECISION
Allow users to have arbitrary precision for xs:integer

INTEGER_MATH_MODE_OVERFLOW_DETECTION
Generate an error if an overflow is detected

setMessageHandler()
Set the message handler for prepare-time errors

The default behavior is to print errors, warnings, and informational messages to System.err and to generate an XProcessException in the case of an unrecoverable error when compilation cannot continue. If the message handler that is registered does not generate its own exception in the case of an unrecoverable error, an XProcessException occurs.

setUseCompiler
Indicate whether to generate a compiled executable or an interpreted executable

A compiled executable takes longer to generate but runs faster than an interpreted executable. The default is interpreted.

setXPathCompatibilityMode
Sets the compatibility mode to be used when evaluating XPath expressions

The options are as follows:

XPATH2_0_PURE_COMPATIBILITY (default)
Use the default behavior defined by XPath 2.0 in evaluating expressions.

XPATH1_0_BC_COMPATIBILITY
Use the backwards-compatibility behavior defined by XPath 2.0 that yields results that are most consistent with those that would be produced by an XPath 1.0 processor.

XPATH_LATEST_VERSION
Use the default behavior defined by the most recent version of XPath supported by the processor.

- Provide an XDynamicContext object that can be used to pass settings to the XPathExecutable.execute method.

These settings affect the behavior during the execution when the processor is evaluating an XPath expression.

If no XDynamicContext object is provided, the default setting is used.

XDynamicContext settings relevant to XPath:

bind Bind a value to an external variable

bindCollation
Binds an instance of the java.text.Collator class to a particular collation URI for use in string comparisons that use that collation URI

bindFunction
Bind an external function so that it can be used as part of an XPath expression

bindSequence
Bind a sequence value to an external variable

setCollectionResolver
Set the collection resolver used to resolve documents loaded with the XPath fn:collection function

The default behavior is for references to the fn:collection function to return an empty sequence.

setImplicitTimeZone
Set the implicit time zone

The default is to use the system time zone as retrieved through the Java method java.util.TimeZone.getDefault().

setMessageHandler()
Set the message handler for excution-time errors

The default behavior is to print errors, warnings and informational messages to System.err and to generate an XProcessException in the case of an unrecoverable error. If the message handler that is registered does not generate its own exception in the case of an unrecoverable error, an XProcessException occurs.

setSourceResolver
Set the source resolver used to resolve documents loaded with the XPath fn:doc function

The default behavior is to resolve documents based on the base URI from the static context. If the base URI is not available, the current working directory is used.

- Use schemas with XPath expression evaluation.

  For schema-aware XPath evaluation and validating the input XML file, schema files can be registered using the XFactory.registerSchema() method or you can declare the xsi:schemaLocation directive in their input XML files. In either case, validation needs to be enabled using the XFactory.setValidating() method.

Example

The following is a basic example of preparing and executing an interpreted XPath expression.

```
// Create a string for the XPath expression
String expression = "/doc/something";

// Create the factory
XFactory factory = XFactory.newInstance();

// Create an XPath executable for the expression
XPathExecutable xPathExecutable = factory.prepareXPath(expression);

// Create the input XML source
String xml = "<doc><something>something is selected</something></doc>";

// Execute the expression and store the results in an XSequenceCursor
XSequenceCursor xSequenceCursor = xPathExecutable.execute(new StreamSource(new ByteArrayInputStream(xml.getBytes())));
```

The following is a basic example of preparing and executing a compiled XPath expression.

```
// Create a string for the XPath expression
String expression = "/doc/something";

// Create the factory
XFactory factory = XFactory.newInstance();

// Create a new static context from the factory
XStaticContext xStaticContext = factory.newStaticContext();

// Set the mode to compile for the processor
xStaticContext.setUseCompiler(true);

// Create an XPath executable for the expression
XPathExecutable xPathExecutable = factory.prepareXPath(expression, xStaticContext);

// Create the input XML source
String xml = "<doc><something>something is selected</something></doc>";

// Execute the expression and store the results in an XSequenceCursor
XSequenceCursor xSequenceCursor = xPathExecutable.execute(new StreamSource(new ByteArrayInputStream(xml.getBytes())));
```

The following is a basic example of preparing and executing interpreted XPath expressions with schema validation.

```
// Create a string for the XPath expression
String expression = "/doc/byte cast as my:derived1-byte-enumeration-Type";

// Create the factory
XFactory factory = XFactory.newInstance();

// Create the schema source
String schema = "<xsd:schema xmlns:xsd='http://www.w3.org/2001/XMLSchema'" +
          " targetNamespace='http://www.schematype.ibm.com/UDSimple'" +
          " xmlns:my='http://www.schematype.ibm.com/UDSimple'" +
          " xmlns:smokey='http://www.schematype.ibm.com/UDSimple'>"
          + "  <xsd:simpleType name='derived1-byte-enumeration-Type'>"
          + "   <xsd:restriction base='xsd:byte'>"
          + "     <xsd:enumeration value='1' />"
          + "     <xsd:enumeration value='-1' />"
          + "     <xsd:enumeration value='0' />"
          + "     <xsd:enumeration value='127' />"
          + "     <xsd:enumeration value='-128' />"
          + "     <xsd:enumeration value='32' />"
          + "     <xsd:enumeration value='-32' />"
          + "     <xsd:enumeration value='8' />"
          + "     <xsd:enumeration value='-8' />"
          + "     <xsd:enumeration value='2' />"
          + "     <xsd:enumeration value='-2' />"
          + "   </xsd:restriction>"
          + "  </xsd:simpleType>"
          + "</xsd:schema>";
// Load schema
factory.registerSchema(new StreamSource(new ByteArrayInputStream(schema.getBytes())));

// Turn on validation
factory.setValidating(true);

// Create a new static context from the factory
XStaticContext xStaticContext = factory.newStaticContext();

// Add new namespace
xStaticContext.declareNamespace("my", "http://www.schematype.ibm.com/UDSimple");

// Create an XPath executable for the expression
XPathExecutable xPathExecutable = factory.prepareXPath(expression, xStaticContext);

// Create the input XML source
String xml = "<doc>" +
             "    <byte>1</byte>" +
             "</doc>";

// Execute the expression and store the results in an XSequenceCursor
XSequenceCursor xSequenceCursor = xPathExecutable.execute(new StreamSource(new ByteArrayInputStream(xml.getBytes())));
```

Performing basic XSLT operations

You can use the XSLTExecutable instances that are created using XFactory.prepareXSLT methods to perform XSLT transformations.

About this task

XSLT stylesheets can be passed to the XFactory.prepareXSLT method using a JAXP Source object. The resulting XSLTExecutable instance is thread safe and can be reused to transform multiple input documents.

Procedure

- Use the XStaticContext object with the prepareXSLT method to pass in settings that affect how the XSLT stylesheet is prepared.

  If no XStaticContext object is provided, the default settings are used.

  XStaticContext methods for changing settings relevant to XSLT:

  declareFunction
  Declare a Java extension function

  setBaseURI
  Set the base URI used in the resolution of relative URIs (such as by the fn:resolve-uri function)

  The default is the base URI of the expression, query, or stylesheet if the base URI is available. If the base URI is not available, the current working directory is used.

  setSourceResolver
  Set the source resolver used for includes and imports

  The default source resolution behavior is to use the base URI of the expression, query, or stylesheet if available to resolve imports and includes. If the base URI is not available, the current working directory is used.

  setMessageHandler
  Set the message handler for prepare-time errors and other messages

  The default behavior is to print errors, warnings, and informational messages to System.err and to generate an XProcessException in the case of an unrecoverable error when preparation cannot continue. If the message handler that is registered does not generate its own exception in the case of an unrecoverable error, an XProcessException occurs.

  setIntegerMathMode
  Set the integer math mode to one of the following:

  INTEGER_MATH_MODE_LIMITED_PRECISION (default)
  Use Java long to represent an integer value

  INTEGER_MATH_MODE_ARBITRARY_PRECISION
  Use Java BigInteger to represent an integer value

  INTEGER_MATH_MODE_OVERFLOW_DETECTION
  Use limited precision and generate execution-time errors when overflow is detected

  See the XML API documentation for long and BigInteger for more information about the range of values supported for these types.

  setUseCompiler
  Indicate whether to generate a compiled executable or an interpreted executable

  A compiled executable takes longer to generate but runs faster than an interpreted executable.

  The default is interpreted.

  setDefaultCollation
  Set the default collation used for string comparison operations when the comparison operation does not specify a collation URI explicitly and there is no default collation URI declared within the stylesheet that is in scope for the operation

The default is the Unicode code-point collation URI.

- Provide an XDynamicContext object that can be used to pass settings to the XSLTExecutable.execute method.

  The XDynamicContext object passed in to the XSLTExecutable.execute command defines the settings for that execution.

  If no XDynamicContext object is provided, the default settings are used.

  XDynamicContext methods for changing settings relevant to XSLT:

  bind Bind a value to an XSLT parameter

  If no value is bound, the default value in the stylesheet is used.

  bindSequence
  Bind a sequence of values to an XSLT parameter

  If no value is bound, the default value in the stylesheet is used.

  bindFunction
  Bind a Java method object to an extension function name as declared in the XStaticContext

  setBaseOutputURI
  Set the base output URI to be used when resolving result documents

  The default is to use the base URI of the main result document if available. If the base URI is not available, the current working directory is used.

  setMessageHandler
  Set the message handler for execution-time errors and other messages

  The default behavior is to print errors, warnings and informational messages to System.err and to generate an XProcessException in the case of an unrecoverable error. If the message handler that is registered does not generate its own exception in the case of an unrecoverable error, an XProcessException occurs.

  The message handler registered with the dynamic context is also used for calls to XPath fn:trace and fn:error functions as well as the XSLT xsl:message instruction.

  setImplicitTimeZone
  Set the implicit time zone

  The default is to use the system time zone as retrieved through the Java method java.util.TimeZone.getDefault().

  setResultResolver
  Set the result resolver used to resolve the href specified in xsl:result-document instructions

  The default behavior is to use the base output URI to resolve result documents.

  setSourceResolver
  Set the source resolver used to resolve documents loaded with the XPath fn:doc function and the XSLT fn:document function

  The default behavior is to resolve documents based on the base URI from the static context for fn:doc and for fn:document if no base node is supplied. If the base URI is not available, the current working directory is used.

  setXSLTInitialMode
  Set the initial mode

  If no initial mode is specified, the unnamed default mode is used.

  setXSLTInitialTemplate
  Set the initial template rule

If no initial template rule is specified, the initial template is chosen according to the rules of the xsl:apply-templates instruction for processing the initial context node in the initial mode.

bindCollation

Bind a Java Collator object or a Locale to a collation URI

If the collation URI is referenced in the stylesheet but no Collator or Locale is bound to it (with the exception of the Unicode code-point collation URI, which is bound by default), an error is raised.

setCollectionResolver

Set the collection resolver used to resolve URIs specified in calls to the XPath fn:collection function to a collection of nodes

If the fn:collection function is invoked and no collection resolver is registered an error is raised.

- Achieve an identity transformation by calling the exportItem method on an XItemView object created from a source using the XItemFactory.

  An identity XSLTExecutable cannot be created by preparing a null stylesheet.
- Achieve schema-aware transformations.

  For schema-aware transformations, the processor picks up schemas registered with the XFactory instance through the registerSchema method or through the registerImportedSchemas method of the XSLTExecutable instance. But you should use the xsl:import-schema declaration to import them into the stylesheet as well, because this makes the stylesheet more portable.

  For validating input documents, the schemas can be registered with the XFactory instance or declared in the XML file using the xsi:schemaLocation directive. In either case, validation needs to be enabled using the XFactory class setValidating method

Example

The following is a basic example of preparing and executing an interpreted transformation.

```
// Create the factory
XFactory factory = XFactory.newInstance();

// Create a StreamSource for the stylesheet
StreamSource stylesheet = new StreamSource("simple.xsl");

// Create an XSLT executable for the stylesheet
XSLTExecutable executable = factory.prepareXSLT(stylesheet);

// Create the input source
Source input = new StreamSource("simple.xml");

// Create the result
Result result = new StreamResult(System.out);

// Execute the transformation
executable.execute(input, result);
```

The following is a basic example of preparing and executing a compiled transformation.

```
// Create the factory
XFactory factory = XFactory.newInstance();

// Create a StreamSource for the stylesheet
StreamSource stylesheet = new StreamSource("simple.xsl");

// Create a new static context
XStaticContext staticContext = factory.newStaticContext();

// Enable the compiler
staticContext.setUseCompiler(true);

// Create an XSLT executable for the stylesheet
XSLTExecutable executable = factory.prepareXSLT(stylesheet, staticContext);

// Create the input source
Source input = new StreamSource("simple.xml");

// Create the result
```

```
Result result = new StreamResult(System.out);

// Execute the transformation
executable.execute(input, result);
```

The following is a basic example of creating an identity transformation.

```
// Create the factory
XFactory factory = XFactory.newInstance();

// Create the item factory
XItemFactory itemFactory = factory.getItemFactory();

// Create the input source
Source input = new StreamSource("simple.xml");

// Create the XItemView object from the input source
XItemView item = itemFactory.item(input);

// Create an XOutputParameters object
XOutputParameters params = factory.newOutputParameters();

// Set parameters
params.setMethod("xml");
params.setEncoding("UTF-8");
params.setIndent(true);

// Create the result
Result result = new StreamResult(System.out);

// Serialize to the result
item.exportItem(result, params);
```

The following is a basic example of creating a schema-aware transformation.

```
// Create the factory
XFactory factory = XFactory.newInstance();

// Enable validation
factory.setValidating(true);

// Create the schema source
StreamSource schema = new StreamSource("schema.xsd");

// Register the schema
factory.registerSchema(schema);

// Create the stylesheet source
StreamSource stylesheet = new StreamSource("schema.xsl");

// Create an XSLT executable for the stylesheet
XSLTExecutable executable = factory.prepareXSLT(stylesheet);

// Create the input source
StreamSource input = new StreamSource("schema.xml");

// Create the result
StreamResult result = new StreamResult(System.out);

// Execute the transformation
executable.execute(input, result);
```

Performing basic XQuery operations

You can use the XQueryExecutable instances that are created using XFactory.prepareXQuery methods to evaluate XQuery expressions.

About this task

XQuery expressions can be passed to the XFactory.prepareXQuery method using a JAXP StreamSource object or using a plain Java string object. The resulting XQueryExecutable instance is thread safe and can be reused to evaluate an XQuery expression on multiple XML input documents.

Procedure

- Use the XStaticContext object with the prepareXQuery method to pass in settings that affect how the XQuery expression is prepared.

  If no XStaticContext object is provided, the default setting is used.

  XStaticContext settings relevant to XQuery:

declareFunction
Declare a Java extension function

declareNamespace
Declare a namespace prefix and associate it with a namespace URI to be used as part of an XQuery expression

declareVariable
Declare a variable externally to be used as part of an XQuery expression

setBaseURI
Set the base URI used in the resolution of relative URIs (such as by the fn:resolve-uri function)

The default is the base URI of the expression, query, or stylesheet if the base URI is available. If the base URI is not available, the current working directory is used.

setBoundarySpacePolicy
Specify whether to preserve or strip white space

The options are as follows:

BOUNDARY_SPACE_STRIP (default)

BOUNDARY_SPACE_PRESERVE

setConstructionMode
Specify whether to preserve the type of element and attribute nodes or strip them

The options are as follows:

CONSTRUCTION_MODE_PRESERVE (default)

CONSTRUCTION_MODE_STRIP

setCopyNamespacesModeInherit
Specify whether to inherit or ignore the namespace when copying element nodes

The options are as follows:

COPY_NAMESPACES_MODE_INHERIT (default)

COPY_NAMESPACES_MODE_NO_INHERIT

setCopyNamespacesModePreserve
Specify whether to preserve or strip the namespace when copying element nodes

The options are as follows:

COPY_NAMESPACES_MODE_PRESERVE (default)

COPY_NAMESPACES_MODE_NO_PRESERVE

setDefaultCollation
Set the default collation URI for string comparison operations

The default is the Unicode code point collation URI.

setDefaultElementTypeNamespace
Specify the URI of the default element or type namespace

Use an empty string to make it unspecified.

The default is an empty string.

setDefaultFunctionNamespace
Specify the URI of the default function namespace

Use an empty string to make it unspecified.

The default is "http://www.w3.org/2005/xpath-functions".

setDefaultOrderForEmptySequences
Set the behavior for default order on empty sequences to greatest or least

The options are as follows:

DEFAULT_ORDER_FOR_EMPTY_SEQUENCES_LEAST (default)

DEFAULT_ORDER_FOR_EMPTY_SEQUENCES_GREATEST

setIntegerMathMode
Set the integer math mode to one of the following:

INTEGER_MATH_MODE_LIMITED_PRECISION
Limit to 18-digit precision for xs:integer (default)

INTEGER_MATH_MODE_ARBITRARY_PRECISION
Allow users to have arbitrary precision for xs:integer

INTEGER_MATH_MODE_OVERFLOW_DETECTION
Generate an error if an overflow is detected

setMessageHandler()
Set the message handler for prepare-time errors

The default behavior is to print errors, warnings, and informational messages to System.err and to generate an XProcessException in the case of an unrecoverable error when compilation cannot continue. If the message handler that is registered does not generate its own exception in the case of an unrecoverable error, an XProcessException occurs.

setModuleResolver
Set the module resolver used for module imports

The default module resolution behavior is to attempt to locate one module for each location hint specified in the module import. The default resolution behavior for each location hint is to resolve relative URIs against the base URI from the static context, if the base URI is available, or to interpret them as file paths relative to the current working directory, if the base URI is not available. Absolute URIs are used unchanged. If a module cannot be located for a location hint, the processor ignores it unless no modules can be loaded for the namespace, in which case the processor emits an error message.

setOrderingMode
Specify whether the results returned by certain path expressions, union, intersect, and except expressions as well as FLWOR expressions that have no order by clause are ordered or unordered

The options are as follows:

ORDERING_MODE_ORDERED (default)

ORDERING_MODE_UNORDERED

setUseCompiler
Indicate whether to generate a compiled executable or an interpreted executable

A compiled executable takes longer to generate but runs faster than an interpreted executable.

The default is interpreted.

- Provide an XDynamicContext object that can be used to pass settings to the XQueryExecutable.execute method.

  These settings affect the behavior during the execution when the processor is evaluating an XQuery expression.

  If no XDynamicContext object is provided, the default setting is used.

  XDynamicContext settings relevant to XQuery:

bind Bind a value to an external variable

bindCollation
Binds an instance of the java.text.Collator class to a particular collation URI for use in string comparisons that use that collation URI

bindFunction
Bind an external function so that it can be used as part of an XQuery expression

bindSequence
Bind a sequence value to an external variable

setCollectionResolver
Set the collection resolver used to resolve documents loaded with the XPath fn:collection function

The default behavior is for references to the fn:collection function to return an empty sequence.

setImplicitTimeZone
Set the implicit time zone

The default is to use the system time zone as retrieved through the Java method java.util.TimeZone.getDefault().

setMessageHandler()
Set the message handler for execution-time errors

The default behavior is to print errors, warnings and informational messages to System.err and to generate an XProcessException in the case of an unrecoverable error. If the message handler that is registered does not generate its own exception in the case of an unrecoverable error, an XProcessException occurs.

setSourceResolver
Set the source resolver used to resolve documents loaded with the XPath fn:doc function

The default behavior is to resolve documents based on the base URI from the static context. If the base URI is not available, the current working directory is used.

- Execute XQuery expressions with schema awareness.

  To validate the input XML files with XQuery, schema files can be registered using the XFactory.registerSchema() method or users can declare the xsi:schemaLocation directive in their input XML files. In either case validation needs to be enabled using the XFactory.setValidating() method. XQuery only supports validating the input XML file for now.

Example

The following is a basic example of preparing and executing an interpreted XQuery expression.

```
// Create a string for the XQuery expression
String expression = "/doc/name[@first='David']";

// Create the factory
XFactory factory = XFactory.newInstance();

// Create the XQueryExecutable
XQueryExecutable xQueryExecutable = factory.prepareXQuery(expression);

// Create the input XML source
String xml = "<doc<name first='John'>Wrong</name><name first='David'>Correct</name></doc>";

// Execute the expression and store the results in an XSequenceCursor
XSequenceCursor xSequenceCursor = xQueryExecutable.execute(new StreamSource(new ByteArrayInputStream(xml.getBytes())));
```

The following is a basic example of preparing and executing a compiled XQuery expression.

```
// Create a string for the XQuery expression
String expression = "/doc/name[@first='David']";

// Create the factory
XFactory factory = XFactory.newInstance();
```

```
// Create a new static context from the factory
XStaticContext xStaticContext = factory.newStaticContext();

// Set the mode to compile for the processor
xStaticContext.setUseCompiler(true);

// Create the XQueryExecutable
XQueryExecutable xQueryExecutable = factory.prepareXQuery(expression, xStaticContext);

// Create the input XML source
String xml = "<doc><name first='John'>Wrong</name><name first='David'>Correct</name></doc>";

// Execute the expression and store the results in an XSequenceCursor
XSequenceCursor xSequenceCursor = xQueryExecutable.execute(new StreamSource(new ByteArrayInputStream(xml.getBytes())));
```

The following is a basic example of preparing and executing interpreted XQuery expressions with schema awareness.

```
// Create a string for the XQuery expression
String expression = "/my:doc/name[@first='David']/@first";

// Create the factory
XFactory factory = XFactory.newInstance();

// Create the schema source
String schema = "<xsd:schema xmlns:xsd='http://www.w3.org/2001/XMLSchema'" +
            " targetNamespace='http://www.schematype.ibm.com/UDSimple'" +
            " xmlns:my='http://www.schematype.ibm.com/UDSimple'" +
            " xmlns:smokey='http://www.schematype.ibm.com/UDSimple'>"
                    +" <xsd:element name='doc'>"
                    +   "<xsd:complexType> "
                    +   "<xsd:sequence>"
                    +   "<xsd:element name='name' minOccurs='0' maxOccurs='unbounded'>"
                    +  "<xsd:complexType>"
                    +   "<xsd:attribute name='first' type='xsd:string' use='optional'/>"
                    +  "</xsd:complexType>"
                    +   "</xsd:element>"
                    +  "</xsd:sequence>"
                    +  "</xsd:complexType>"
                    + "</xsd:element>"
                    + "</xsd:schema>";

// Load the schema
factory.registerSchema(new StreamSource(new ByteArrayInputStream(schema.getBytes())));

// Turn on validation
factory.setValidating(true);

// Create a new static context from the factory
XStaticContext xStaticContext = factory.newStaticContext();

// Add a new namespace
xStaticContext.declareNamespace("my", "http://www.schematype.ibm.com/UDSimple");

// Create the XQueryExecutable
XQueryExecutable xQueryExecutable = factory.prepareXQuery(expression, xStaticContext);

// Create the input XML source
String xml = "<my:doc xmlns:my='http://www.schematype.ibm.com/UDSimple'>" +
             "<name first='John'/><name first='David'/></my:doc>";

// Execute the expression and store the results in an XSequenceCursor
XSequenceCursor xSequenceCursor = xQueryExecutable.execute(new StreamSource(new ByteArrayInputStream(xml.getBytes())));
```

Viewing the results

After your application has prepared or loaded the XExecutable object for an XPath expression (an XPathExecutable object), an XSLT stylesheet (an XSLTExecutable object), or an XQuery expression (an XQueryExecutable object), you apply the XExecutable object to some input and then do something with the result. The source of the input that you provide and what you would like to do with the result determine which of the execute methods you use.

Procedure

- View XPath results.

  In the case of an XPath expression, the execute methods on the XPathExecutable interface return an instance of the XSequenceCursor class that contains the sequence that results from evaluating the expression with the given context item and dynamic context, if any.

  There is also a set of executeToList methods on the XPathExecutable interface. These methods return the sequence as an instance of the java.util.List<XItemView> interface, where each item in the

sequence that results from evaluating the XPath expression is represented in the list as an instance of the XItemView interface. The entries in that list are in the same order as in the sequence that resulted from evaluating the XPath expression.

The following example shows how to get the cost of each item on a purchase order as an XSequenceCursor.

```
XFactory factory = XFactory.newInstance();
XPathExecutable expr =
    factory.prepareXPath(
        "/purchaseOrder/item/(@unit-price * @quantity)");
XSequenceCursor exprResult = expr.execute(new StreamSource("input.xml"));
```

The following example shows how to get the cost of each item on a purchase order in an instance of the java.util.List interface.

```
XFactory factory = XFactory.newInstance();
XPathExecutable expr =
    factory.prepareXPath(
        "/purchaseOrder/item/(@unit-price * @quantity)");
List<XItemView> exprResult =
   expr.executeToList(new StreamSource("input.xml"));
```

- Use the XItemView interface.

  You can access each item in a sequence using the methods on the XItemView interface. You can use the XItemView.isAtomic() method to determine whether the item is an atomic value or a node. If the item is an atomic value, you can use the getValueType() method on the XItemView interface. This method returns an instance of the enumerated type XTypeConstants.Type. If the atomic value is an instance of a built-in atomic type or a user-defined type derived from a built-in atomic type, the result of the getValueType() method is the enumerated value corresponding to that type. For an atomic value that could be of a user-defined derived type, you also might find it handy to use the XItemView.getValueTypeName() method to determine the precise type of the value.

  Given the type of an atomic value, you then can use the appropriate method to get the value.

```
XFactory factory = XFactory.newInstance();
XPathExecutable expr =
    factory.prepareXPath(
        "sum(/purchaseOrder/item/(@unit-price * @quantity))");
XItemView exprResult =
   expr.execute(new StreamSource(purchaseOrder));
double totalCost = 0.0;

// Decide how to get result based on the type of the value
switch (exprResult.getValueType()) {
case DOUBLE: {
    totalCost = exprResult.getDoubleValue();
    break;
}
case FLOAT: {
    totalCost = exprResult.getFloatValue();
    break;
}
case INTEGER: {
    totalCost = exprResult.getLongValue();
    break;
}
case DECIMAL: {
    totalCost = exprResult.getDecimalValue().doubleValue();
    break;
}
default: {
    System.err.println("Unexpected type for result");
}
}
```

The XItemView interface also extends the XNodeView interface, so if the result of calling the XItemView.isAtomic() method is false – that is, the item is a node – you can use the methods inherited from the XNodeView interface to access information about the node. The XNodeView.getNodeQName() method will return the name of the node and the XNodeView.getKind() method will return a value of the enumerated type XNodeView.Kind indicating what sort of node the item is: XNodeView.DOCUMENT, XNodeView.ELEMENT, and so on.

```
XFactory factory = XFactory.newInstance();

// Prepare an expression to get the first node whose string value matches a given query string
XPathExecutable expr =
    factory.prepareXPath(
        "(/descendant-or-self::node()/(self::node()|@*)[. = 'search'])[1]");
XItemView exprResult =
```

```
   expr.execute(new StreamSource(inputFile));

// Print the kind of node found and its name, if appropriate
switch (exprResult.getKind()) {
case ELEMENT: {
    System.out.print("Element " + exprResult.getNodeQName().toString());
    break;
}
case ATTRIBUTE: {
    System.out.print("Attribute " + exprResult.getNodeQName().toString());
    break;
}
case COMMENT: {
    System.out.print("Comment ");
    break;
}
case PROCESSING_INSTRUCTION: {
    System.out.print("PI " + exprResult.getNodeQName().toString());
}
}
```

You can also explore the tree that contains a node using the XTreeCursor interface.

- View XSLT and XQuery results.

  All the execute and executeToList methods available from the XPathExecutable interface are actually inherited from the XExecutable interface, so they are available for use on instances of the XSLTExecutable interface or the XQueryExecutable interface as well. In the case of an instance of the XQueryExecutable interface, the object the method returns contains the sequence that resulted from evaluating the query. In the case of the XSLTExecutable interface, the sequence contains the document node of the primary result of evaluating the stylesheet, if there is any.

  The XSLTExecutable and XQueryExecutable interfaces also define execute methods that accept an instance of the javax.xml.transform.Result interface. The result object that your application supplies will contain the primary result of evaluating the stylesheet, in the case of the XSLTExecutable interface, or the result of evaluating your query, in the case of XQueryExecutable.

  The following example produces a DOM tree as the result of a transformation, and stores the tree in the instance of the DOMResult class that is passed as an argument to the XSLTExecutable.execute method.

```
XFactory factory = XFactory.newInstance();
XSLTExecutable style = factory.prepareXSLT(new StreamSource("style.xsl"));
DOMResult res = new DOMResult();
style.execute(new StreamSource("purchase.xml"), res);
Node node = res.getNode();
```

  The following example produces an instance of the XSequenceCursor interface as the result of transformation.

```
XFactory factory = XFactory.newInstance();
XSLTExecutable style = factory.prepareXSLT(new StreamSource("style.xsl"));
XSequenceCursor xformResult =
        style.execute(new StreamSource("purchase.xml"));
```

- Use the XResultResolver and XSLT.

  An XSLT 2.0 stylesheet can produce more than one result document by using the xsl:result-document instruction. The primary result of the transformation is produced for any result tree that the stylesheet constructs that is not contained in an xsl:result-document instruction or that is contained in an xsl:result-document instruction that has an href attribute whose effective value is a zero-length string. The primary result is returned to your application using the various means described above.

  If your stylesheet evaluates an xsl:result-document instruction that has an href attribute whose effective value is not a zero-length string, by default that result is written to an output stream. The URI of the output stream is determined by resolving the effective value of the href attribute against the setting of the base output URI in the dynamic context.

  You can override this default behavior by supplying an instance of the XResultResolver interface on the XDynamicContext you use for the transformation. The getResult method on the XResultResolver interface is called if any xsl:result-document instructions are invoked; the result of the getResult method is an instance of the Result interface where the result of the xsl:result-document instruction is directed. Using the XResultResolver interface allows your application to decide on a case by case basis where to direct the result of all the xsl:result-document instructions in your stylesheets. If your application did not

supply an instance of the Result interface for the primary result on the execute method of the XSLTExecutable interface, the getResult method of XResultResolver is called for the primary result as well.

If the getResult method of XResultResolver returns a null reference, the default behavior is restored for that particular result—that is, the result is written to an output stream, in the case of a secondary result, or returned from as the result of the execute method as an instance of the XSequenceCursor interface, in the case of the primary result.

The following example uses an instance of the XResultResolver interface to capture all the results produced by a stylesheet as instances of the XSequenceCursorResult class in the variable allResults. The application then could extract the instance of the XSequenceCursor interface that each instance of the XSequenceCursorResult class contains using the XSequenceCursorResult.getSequenceCursor() method.

```
final ArrayList<XSequenceCursorResult> allResults =
            new ArrayList<XSequenceCursorResult>();
XFactory factory = XFactory.newInstance();
XDynamicContext context = factory.newDynamicContext();

// Create XResultResolver that saves XSequenceCursorResult
// instances in allResults
context.setResultResolver(new XResultResolver() {
        public Result getResult(String href, String base) {
            XSequenceCursorResult result =
                    new XSequenceCursorResult();
            allResults.add(result);
            return result;
        }
    });

XSLTExecutable style = factory.prepareXSLT(new StreamSource("style.xsl"));
style.execute(new StreamSource("purchase.xml"), context);

// All results, including the primary, are now available from the allResults variable.
```

Serializing the results

After your application has evaluated an XPath or XQuery expression or performed a transformation with an XSLT stylesheet, you might want to write the output as an actual XML document represented as a file or as a Java string. The process of rendering results as an XML document is known as serialization.

Procedure

- Serialize an XSequenceCursor.

  Your application can call the XSequenceCursor.exportSequence method to serialize a sequence that is represented by an instance of the XSequenceCursor interface. The arguments on this method are an instance of the javax.xml.transform.Result interface and optionally an instance of the XOutputParameters interface.

  If the instance of the Result interface is also an instance of the javax.xml.transform.stream.StreamResult class, the sequence is serialized as described in the XSLT 2.0 and XQuery 1.0 Serialization Recommendation. The StreamResult object can contain an instance of the java.io.Writer class or the java.io.OutputStream class, where the processor will write the serialized sequence.

  You can create an instance of the XOutputParameters interface by calling XFactory.newOutputParameters() and call the methods on that object to override the default serialization parameter settings.

```
XFactory factory = XFactory.newInstance();
XPathExecutable expr = factory.prepareXPath("/purchaseOrder/item[@price > 1000]");
XSequenceCursor exprResult = expr.execute(new StreamSource(inputFile));

System.out.println("Items purchased costing more than $1000");
if (exprResult != null) {
    // Set indenting in order to pretty-print result
    XOutputParameters params = factory.newOutputParameters();
    params.setIndent(true);
    exprResult.exportSequence(new StreamResult(System.out), params);
} else {
    System.out.println("None found");
}
```

  You can also call one of the getOutputParameters() methods on an instance of the XSLTExecutable interface to get the serialization parameters that are associated with a particular output definition in an

XSLT stylesheet. Use the XSLTExecutable.getOutputParameters(javax.xml.namespace.QName) method to get the serialization parameters for a named output definition or the no-argument XSLTExecutable.getOutputParameters() method to get those of the unnamed output definition. You might want do this to perform some post-processing on the result of the transformation using the instance of the XSequenceCursor interface that the transformation produces before serializing the result. If you change the settings of the serialization parameters in the instance of the XOutputParameters interface returned by one of the XSLTExecutable.getOutputParameters() methods, it will not affect the output definition in the stylesheet.

```
XFactory factory = XFactory.newInstance();
XSLTExecutable style = factory.prepareXSLT(new StreamSource("style.xsl"));
XSequenceCursor xformResult = style.execute(new StreamSource("purchase.xml");

XOutputParameters params = style.getOutputParameters(new QName("my-output-definition"));
params.setMethod(XOutputParameters.METHOD_XHTML);
xformResult.exportSequence(new StreamResult("output.html"), params);
```

Note that according to the XSLT 2.0 and XQuery 1.0 Serialization Recommendation, a serialization error results if the sequence that is to be serialized contains attribute nodes or namespace nodes. If the sequence that you need to serialize might contain attribute or namespace nodes, get the values of those nodes as strings or some other appropriate type and serialize those values instead.

- Serialize a single item.

  You can also serialize just the current item in an instance of the XSequenceCursor interface by using one of the exportItem methods. The exportItem methods are inherited from the XItemView interface, so they can be called on an instance of that interface as well.

  As with the exportSequence method described above, the arguments of the exportItem method are an instance of the javax.xml.transform.Result interface and optionally an instance of the XOutputParameters interface. The effect of calling exportItem is identical to the effect of calling exportSequence with a sequence that consists of just the current item.

- Serialize the result of a transformation or query directly.

  Your application can also serialize the result of an XSLT transformation or XQuery expression directly by supplying an instance of the javax.xml.transform.Result interface on the XSLTExecutable.execute method or XQueryExecutable.execute method. The serialization parameter settings are determined by the attributes of any applicable xsl:output declaration or xsl:result-document instruction in the case of an XSLT stylesheet, and are always the default values in the case of the result of an XQuery expression.

```
XFactory factory = XFactory.newInstance();
XSLTExecutable style = factory.prepareXSLT(new StreamSource("style.xsl"));
style.execute(new StreamSource("purchase.xml"),
              new StreamResult("output.xml"));
```

If your application supplies an instance of the XResultResolver interface on a transformation, your application can direct each final result tree to a different destination.

- Use identity transformation.

  You can use the XML API to transform XML data contained in an instance of javax.xml.transform.Source directly to an instance of a javax.xml.transform.Result. This is often referred to as an identity transformation. See “Performing basic XSLT operations” on page 1863 for an example.

Navigating with XSequenceCursor

The XSequenceCursor interface gives you a view of your sequence data.

About this task

A sequence in the XPath and XQuery Data Model contains zero or more atomic values, nodes, or a mixture of both. An instance of the XSequenceCursor interface always contains at least one item. If a sequence is empty, it is always represented by a null reference.

Procedure

- At any given time, an instance of the XSequenceCursor interface is positioned to give you access to one of the items in a sequence. It is positioned initially at the first item in the sequence; and you can move forward or backward in the sequence, one item at a time, using the toNext() or toPrevious() methods, respectively.

  If the toNext() method or toPrevious() method is able to position the XSequenceCursor instance to the next or previous item in the sequence—that is, if there actually is a next or previous item—the method returns true. If the XSequenceCursor instance is already positioned at the last item in the case of the toNext() method or the first item in the case of the toPrevious() method, the method returns false and the instance of the XSequenceCursor interface remains positioned at the same item as before the call.

  The typical way of processing a sequence that is contained in an instance of the XSequenceCursor interface is as shown in the following example:

```
XFactory factory = XFactory.newInstance();
XPathExecutable expr = factory.prepareXPath("1 to 10");
XSequenceCursor exprResult = expr.execute();
long sum = 0;

// If exprResult is null, it means the result sequence is empty
if (exprResult != null) {
    do {
        // Get each value as a primitive Java long value, and accumulate
        sum = sum + exprResult.getLongValue();

        // Advance exprResult to the next item in the sequence
    } while (exprResult.toNext());
}

System.out.println("Sum is " + sum);
```

  The XSequenceCursor interface extends the XItemView interface. You can use the methods inherited from the XItemView interface to access the value and the type of the item in the sequence at which the XSequenceCursor is currently positioned.

- If your application needs to refer to more than one item in the sequence at the same time, you can call the method XSequenceCursor.getSingletonItem() to get an instance of the XItemView interface containing the data associated with the current item in the instance of the XSequenceCursor interface.

  If you change the position of that instance of the XSequenceCursor interface through a call to the toNext() method or the toPrevious() method, the instance of the XItemView interface that was returned by an earlier call to the XSequenceCursor.getSingletonItem() method will still refer to that earlier item.

  Consider the following example, which counts the number of items in a sequence that have the same type and value as the first item.

```
XFactory factory = XFactory.newInstance();

// Make a path expression whose result contains ordered part number as first item
// and all part numbers used by products in the catalog as the subsequent items
XPathExecutable expr =
    factory.prepareXPath(
        "string(/order/item/@part-num),doc('catalog.xml')/catalog/product/part/string(@part-num)");

// Read the invoice file
XSequenceCursor exprResult = expr.execute(new StreamSource(invoiceFile));

int sameAsFirstCount = 0;

// If exprResult is null, it means the result sequence is empty
if (exprResult != null) {
    // Get the first item in the result sequence
    XItemView firstItem = exprResult.getSingletonItem();

    // currentItem always refers to the current item in the result sequence
    XItemView currentItem = exprResult;
    do {
        // Get the type of the first item
        XTypeConstants.Type itemType = firstItem.getValueType();

        // Ensure the type of the first item is the same as the type of
        // the current item, and compare their values as Java objects
        if (itemType == currentItem.getValueType()
                && firstItem.getObjectValue(itemType)
                        .equals(currentItem.getObjectValue(itemType))) {
            sameAsFirstCount++;
        }

        //Advance exprResult (and currentItem) to the next item in the sequence
```

```
    } while (exprResult.toNext());
}

System.out.println("Number of items same as the first == "+(sameAsFirstCount-1));
```

The variable firstItem is created by the XSequenceCursor.getSingletonItem() method, so it always refers to the first item in the sequence. The variable currentItem contains a reference to the XSequenceCursor object, however, so it is always positioned at the current item in the sequence.

- If you ever need to access the items in the sequence non-sequentially, you might find it convenient to use the exportAsList method on the XSequenceCursor interface.

  This method returns an instance of the java.util.List<XItemView> interface that contains the items in your sequence in sequence order.

Navigating with XTreeCursor

You can use the XTreeCursor interface to view your data.

About this task

Suppose the sequence that results from evaluating an XPath or XQuery expression or an XSLT stylesheet contains nodes. You will find it very convenient to access the contents of those nodes by applying further XPath or XQuery expressions to those nodes. However, you might also choose to navigate through the tree structure associated with a node directly through the XML API.

Procedure

- If the result of calling the XItemView.isAtomic() method is false—that is, the context item is a node—your application can call the XItemView.getXTreeCursor() method to gain direct access to the tree that contains the node.

  The XSequenceCursor interface extends XItemView, so calling the XSequenceCursor.getXTreeCursor() method returns an instance of the XTreeCursor interface that you can use to access the node on which the instance of the XSequenceCursor interface is positioned.
- The XTreeCursor interface also extends the XItemView interface; therefore, you can use the methods inherited from the XItemView interface to access information about the node on which your instance of the XTreeCursor interface is currently positioned.

  In particular, you can use the XTreeCursor.getXTreeCursor() method to create another instance of the XTreeCursor interface that you can use to navigate through the tree independently of the instance of the XTreeCursor interface from which it was created.

Example

The following example shows how you can use the methods on the XTreeCursor interface to navigate through the tree containing your XML data.

```
/* Contents of library.xml

<library>
  <book title='Ulysses'><author><first>James</first><last>Joyce</last></author></book>
  <book title='Ada'><author><first>Vladimir</first><last>Nabokov</last></author></book>
</library>
*/

XItemFactory factory = XFactory.newInstance().getItemFactory();
XItemView item = factory.item(new StreamSource("library.xml"));

// 'tree' is initially positioned at the same node as
// 'item' - that is, the document node of the input
XTreeCursor tree = item.getTreeCursor();

// Position tree cursor to "library" element
tree.toFirstChild();

// Position tree cursor to white-space text node
tree.toFirstChild();

// Position to first "book" element
tree.toNextSibling();
```

```
// Position to white-space text node
tree.toNextSibling();

// Position to second "book" element
tree.toNextSibling();

// Create a second instance of XTreeCursor that is initially
// positioned at the same node as 'tree' - that is, the
// second "book" element
XTreeCursor secondBook = tree.getTreeCursor();

// Position 'tree' to "library" element
tree.toParent();

// Position 'secondBook' to "title" attribute
secondBook.toFirstAttribute();
```

The following example navigates through all the nodes in a tree in a depth-first fashion.

```
XItemFactory factory = XFactory.newInstance().getItemFactory();
XItemView item = factory.item(new StreamSource("library.xml"));

XTreeCursor tree = item.getTreeCursor();
boolean hasMoreNodes = true;

do {
    // Process current node

    if (tree.toFirstAttribute()) {
        do {
            // Process attributes
        } while (tree.toNextAttribute());
        tree.toParent();
    }

    if (tree.toFirstNamespace()) {
        do {
            // Process namespaces
        } while (tree.toFirstNamespace());
        tree.toParent();
    }

    boolean foundNext = false;

    // If the current node has a child, visit it next
    // If there's no child, go to the next sibling
    if (tree.toFirstChild() || tree.toNextSibling()) {
        foundNext = true;

    // If there's no child and no sibling, find an
    // ancestor's sibling instead.
    } else {
        do {
            hasMoreNodes = tree.toParent();
            if (hasMoreNodes) {
                foundNext = tree.toNextSibling();
            }
        } while (hasMoreNodes && !foundNext);
    }
} while (hasMoreNodes);
```

Precompiling

You can use this information to help you to precompile an expression, query, or stylesheet.

Procedure

- Precompile using the command-line tool.
- Precompile in Java.
- Load a precompiled executable.

Precompiling using the command-line tools

You can use the CompileXSLT tool to precompile one or more stylesheets, use the CompileXPath tool to precompile one or more XPath expressions, and use the CompileXQuery tool to precompile one or more XQuery expressions.

About this task

Note: See “Precompiling using ANT tasks” on page 1884 for information about using the TaskCompileXPath, TaskCompileXQuery, and TaskCompileXSLT ANT tasks as alternatives to using the CompileXPath, CompileXQuery, and CompileXSLT commands.

Procedure

- **Compile XSLT**

  Location

  The product includes the following script that sets up the environment and invokes the tool.

  Syntax

  Parameters

  -out *output*

  Uses the name *output* as the base name for the generated classes

  By default, the base name is XSLTModule.

  This option is ignored if compiling multiple stylesheets.

  -dir *directory*

  Specifies a destination directory for the generated classes

  The default is the current working directory.

  -pkg *package*

  Specifies a package name prefix for all generated classes

  The default is the Java default package.

  -func name=*funcName* **type=***funcType* **argtype=***argType*

  Adds a function binding to the static context for a single item

  This simply declares the function, and a method object for the function also must be bound to the dynamic context at execution time.

  funcName

  Specifies the name of the function (expressed localPart,namespaceURI)

  funcType

  Specifies the return type of the function (expressed localPart,namespaceURI)

  argType

  Specifies the types of the function arguments (expressed localPart,namespaceURI) and is optional

  This option can be used multiple times.

  If the value of any option contains a blank space, enclose it in quotation marks.

  This option can be used multiple times.

  For example:

```
-func name=getId,http://example.org type=integer,http://www.w3.org/2001/XMLSchema argtype=string,http://www.w3.org/2001/XMLSchema
```

  -baseURI *URI*

  Specifies the base URI of the containing element

  -imm *int*

  Sets the integer math mode, which is a constant representing the level of precision required and whether overflow detection is required when working with xs:integer values

  Valid values include:

1 Values need only support the minimum precision required for a minimally conforming processor (18 digits).

2 Values should support an arbitrary number of digits of precision; no overflow should occur.

3 Values need only support the minimum precision required for a minimally conforming processor (18 digits); but any overflow condition should be detected and error FOAR0002 should be raised.

-i Forces the compiler to read the stylesheet from standard in

-v Prints the version of the compiler

-h Prints the usage statement

stylesheet
Full path to a file containing an XSL stylesheet to be compiled

The following is a basic example of compiling a stylesheet using the CompileXSLT tool:

- **Compile an XPath expression**

Location
The product includes the following script that sets up the environment and invokes the tool.

Syntax

Parameters

-out *output*
Uses the name *output* as the base name for the generated classes

By default, the base is XPathModule.

This option is ignored if compiling multiple expressions.

-dir *directory*
Specifies a destination directory for the generated executable

The default is the current working directory.

-pkg *package*
Specifies a package name prefix for all generated classes

The default is the Java default package.

-cpm *mode*
Specifies an alternate XPath compatibility mode.

For example, use 1.0 for compatibility with XPath Version 1.0.

-ns *prefix*=*URI*
Specifies a namespace for use during static processing

If the value of any option contains a blank space, enclose it in quotation marks.

This option can be used multiple times. In the case of multiple -ns arguments with the same prefix, the last one prevails.

-schema *URI*
Specifies any schema document that is used to populate the in-scope schema definitions

This option can be used multiple times.

-func name=*funcName* **type=***funcType* **argtype=***argType*
Adds a function binding to the static context for a single item

This simply declares the function, and a method object for the function also must be bound to the dynamic context at execution time.

funcName
Specifies the name of the function (expressed localPart,namespaceURI)

funcType
Specifies the return type of the function (expressed localPart,namespaceURI)

argType
Specifies the types of the function arguments (expressed localPart,namespaceURI) and is optional

This option can be used multiple times.

If the value of any option contains a blank space, enclose it in quotation marks.

This option can be used multiple times.

For example:

```
-func name=getId,http://example.org type=integer,http://www.w3.org/2001/XMLSchema argtype=string,http://www.w3.org/2001/XMLSchema
```

-var name=*varName* **type=***varType*
Adds a variable binding to the static context for a single item

This simply declares the variable, and a value also must be bound to the XDynamicContext at execution time.

varName
Specifies the name of the variable (expressed localPart[, namespaceURI])

If the variable is in no namespace, the namespace URI should be omitted.

Localpart is a required value.

varType
Specifies the type of the variable (expressed localPart,namespaceURI)

If the value of any option contains a blank space, enclose it in quotation marks.

This option can be used multiple times.

For example:

```
-var name=la,"http://www.ibm.com/Los Angeles" type=boolean,http://www.w3.org/2001/XMLSchema
```

-baseURI *URI*
Specifies the base URI of the containing element

-dnet *URI*
Specifies a default namespace URI for element and type names

The namespace URI, if present, is used for any unprefixed QName appearing in a position where an element or type name is expected.

-dnf *URI*
Specifies a default namespace URI for function names

The namespace URI, if present, is used for any unprefixed QName appearing in a position where a function name is expected.

-imm *int*
Sets the integer math mode, which is a constant representing the level of precision required and whether overflow detection is required when working with xs:integer values

Valid values include:

1 Values need only support the minimum precision required for a minimally conforming processor (18 digits).

2 Values should support an arbitrary number of digits of precision; no overflow should occur.

3 Values need only support the minimum precision required for a minimally conforming processor (18 digits); but any overflow condition should be detected and error FOAR0002 should be raised.

-v Prints the version of the compiler

-h Prints the usage statement

xpathfile
Full path to a file containing an XPath expression to be compiled

-i Forces the compiler to read the XPath expression from standard in

The following is a basic example of compiling an XPath expression using the CompileXPath tool:

- **Compile an XQuery expression**

Location
The product includes the following script that sets up the environment and invokes the tool.

Syntax

Parameters

-out *output*
Uses the name *output* as the base name for the generated classes

By default, the base name is XQueryModule.

This option is ignored if compiling multiple expressions.

-dir *directory*
Specifies a destination directory for the generated classes

The default is the current working directory.

-pkg *package*
Specifies a package name prefix for all generated classes

The default is the Java default package.

-func name=*funcName* **type=***funcType* **argtype=***argType*
Adds a function binding to the static context for a single item

This simply declares the function, and a method object for the function also must be bound to the dynamic context at execution time.

funcName
Specifies the name of the function (expressed localPart,namespaceURI)

funcType
Specifies the return type of the function (expressed localPart,namespaceURI)

argType
Specifies the types of the function arguments (expressed localPart,namespaceURI) and is optional

This option can be used multiple times.

If the value of any option contains a blank space, enclose it in quotation marks.

This option can be used multiple times.

For example:

```
-func name=getId,http://example.org type=integer,http://www.w3.org/2001/XMLSchema argtype=string,http://www.w3.org/2001/XMLSchema
```

-baseURI *URI*
Specifies the base URI of the containing element

-dnet *URI*
Specifies a default namespace URI for element and type names

The namespace URI, if present, is used for any unprefixed QName appearing in a position where an element or type name is expected.

-dnf *URI*
Specifies a default namespace URI for function names

The namespace URI, if present, is used for any unprefixed QName appearing in a position where a function name is expected.

-imm *int*
Sets the integer math mode, which is a constant representing the level of precision required and whether overflow detection is required when working with xs:integer values

Valid values include:

1 Values need only support the minimum precision required for a minimally conforming processor (18 digits).

2 Values should support an arbitrary number of digits of precision; no overflow should occur.

3 Values need only support the minimum precision required for a minimally conforming processor (18 digits); but any overflow condition should be detected and error FOAR0002 should be raised.

-bsp *int*
Specifies the boundary space policy

Valid values include:

1 Preserve white spaces

2 Strip white spaces

This is the default value.

-csm *int*
Specifies the construction mode

Valid values include:

1 Preserve

The type of a constructed element node is xs:anyType, and all attribute and element nodes copied during node construction retain their original types.

This is the default value.

2 Strip

The type of a constructed element node is xs:untyped, all element nodes copied during node construction receive the type xs:untyped, and all attribute nodes copied during node construction receive the type xs:untypedAtomic.

-cnmi *int*
Specifies the inherit part of the copy-namespaces

Valid values include:

1 Inherit

Inherit mode should be used in namespace binding assignment when an existing element node is copied by an element constructor.

This is the default value.

2 No inherit

No-inherit mode should be used in namespace binding assignment when an existing element node is copied by an element constructor.

-cnmp *int*
Specifies the preserve part of the copy-namespaces

Valid values include:

1 Preserve

Preserve mode should be used in namespace binding assignment when an existing element node is copied by an element constructor.

This is the default value.

2 No preserve

No-preserve mode should be used in namespace binding assignment when an existing element node is copied by an element constructor.

-eso *int*
Specifies the empty sequence order

Valid values include:

1 Greatest

2 Least

This is the default value.

-ordm *int*
Specifies the ordering mode

Valid values include:

1 Ordered results are to be returned by certain path expressions, union, intersect, and except expressions, as well as FLWOR expressions that have no order by clause

This is the default value.

2 Unordered results are to be returned by certain path expressions, union, intersect, and except expressions, as well as FLWOR expressions that have no order by clause

-v Prints the version of the compiler

-h Prints the usage statement

xqueryfile
Full path to a file containing an XQuery expression to be compiled

-i Forces the compiler to read the stylesheet from standard in

The following is a basic example of compiling an XQuery expression using the CompileXQuery tool:

Precompiling using ANT tasks

You can use the TaskCompileXPath, TaskCompileXQuery, and TaskCompileXSLT ANT tasks as alternatives to using the CompileXPath, CompileXQuery, and CompileXSLT commands.

About this task

ANT task elements:

argType

This element indicates the types of the function arguments expressed in terms of the localpart and namespaceURI.

Parameters specified as nested elements:

localpart

A nested localpart element must be specified to provide the local part of the qualified name.

namespaceURI

A nested namespaceURI element can be specified to indicate the namespaceURI.

Example:

```
<argType>
  <localpart>boolean</localpart>
  <namespaceURI>"http://www.w3.org/2001/XMLSchema"</namespaceURI>
</argType>
```

baseURI

This element specifies the base URI of the containing element.

Example:

```
<baseURI>"http://www.ibm.com/Los Angeles"</baseURI>
```

bsp This element specifies the Boundary Space Policy.

Valid values include:

- 1 = preserve white spaces
- 2 = strip white spaces

The default value is 2 (strip white spaces).

Example:

```
<bsp>1</bsp>
```

cnmi This element specifies the inherit part of the copy-namespaces.

Valid values include:

- 1 = inherit

  Inherit mode should be used in namespace binding assignment when an existing element node is copied by an element constructor.
- 2 = no inherit

  No-inherit mode should be used in namespace binding assignment when an existing element node is copied by an element constructor.

The default is 1 (inherit).

Example:

```
<cnmi>2</cnmi>
```

cnmp This element specifies the preserve part of the copy-namespaces.

Valid values include:

- 1 = preserve

  Preserve mode should be used in namespace binding assignment when an existing element node is copied by an element constructor.
- 2 = no preserve

No-preserve mode should be used in namespace binding assignment when an existing element node is copied by an element constructor.

The default is 1 (preserve).

Example:

```
<cnmp>2</cnmp>
```

cpm This element specifies an alternate XPath Compatibility Mode.

Valid values are:

- Latest
- 1.0
- 2.0

For example: use 1.0 for compatibility with XPath Version 1.0.

The default is 2.0.

Example:

```
<cpm>1.0</cpm>
```

csm This element specifies the Construction Mode.

Valid values include:

- 1 = preserve

  The type of a constructed element node is xs:anyType, and all attribute and element nodes copied during node construction retain their original types.
- 2 = strip

  The type of a constructed element node is xs:untyped, all element nodes copied during node construction receive the type xs:untyped, and all attribute nodes copied during node construction receive the type xs:untypedAtomic.

The default value is 1 (preserve).

Example:

```
<csm>2</csm>
```

dir This element specifies a destination directory for the executables.

The default is the current working directory.

If the value contains a blank space, enclose it in quotation marks.

Example:

```
<dir>C:/precompiledXSLT</dir>
```

dnet This element specifies a default namespace URI for element and type names.

The namespace URI, if present, is used for any unprefixed QName appearing in a position where an element or type name is expected.

Example:

```
<dnet>http://example.org/ibm</dnet>
```

dnf This element specifies a default namespace URI for function names.

The namespace URI, if present, is used for any unprefixed QName appearing in a position where a function name is expected.

Example:

```
<dnf>http://my.org</dnf>
```

eso This element specifies the Empty Sequence Order.

Valid values include:

- 1 = greatest
- 2 = least

The default value is 2 (empty sequences least).

Example:

```
<eso>1</eso>
```

function

For the CompileXSLT, CompileXPath, and CompileXQuery tasks, this element defines and binds a function to the static context for a single item. Note that this simply declares the function, and a Method object for the function must also be bound to the dynamic context. Note: this element can be specified multiple times.

Parameters specified as nested elements:

name A nested name element must be specified to indicate the name of the function.

type A nested type element must be specified to indicate the type of the function.

argType

A nested argType element can be specified to indicate the types of the function arguments.

This element is optional and can be specified multiple times.

Example:

```
<function>
  <name>
    <localpart>la</localpart>
    <namespaceURI>"http://www.ibm.com/Los Angeles"</namespaceURI>
  </name>
  <type>
    <localpart>boolean</localpart>
    <namespaceURI>http://www.w3.org/2001/XMLSchema</namespaceURI>
  </type>
</function>
```

imm This element sets the integer math mode, which is a constant representing the level of precision required and whether overflow detection is required when working with xs:integer values.

Valid values include:

- 1 = values need only support the minimum precision required for a minimally conforming processor (18 digits)
- 2 = values should support an arbitrary number of digits of precision; no overflow should occur
- 3 = values need only support the minimum precision required for a minimally conforming processor (18 digits) but any overflow condition should be detected and error FOAR0002 raised

Example:

```
<imm>2</imm>
```

inputfile

This element specifies the full path to a file containing an XSL, XPath, or XQuery to be compiled.

Example:

```
<inputfile>C:/XSLT/simple.xsl</inputfile>
```

localpart

This element indicates the local part of a qualified name.

Example:

```
<localpart>la</localpart>
```

name This element indicates the name of the function or variable (expressed in terms of the localpart and namespaceURI).

In the case of a variable that is in no namespace the namespace URI should be omitted.

Parameters specified as nested elements:

localpart
A nested localpart element must be specified to provide the local part of the qualified name.

namespaceURI
A nested namespaceURI element can be specified to indicate the namespaceURI.

Example:

```
<name>
  <localpart>la</localpart>
  <namespaceURI>"http://www.ibm.com/Los Angeles"</namespaceURI>
</name>
```

namespaceURI
This element indicates the namespaceURI part of a qualified name.

If the value contains a blank space. enclose it in quotation marks.

Example:

```
<namespaceURI>"http://www.ibm.com/Los Angeles"</namespaceURI>
```

ns This element specifies a namespace for use during static processing.

The value should be specified as prefix=URI.

If the value contains a blank space, enclose it in quotation marks.

This element can be used multiple times.

Example:

```
<ns>my=http://www.example.com/examples</ns>
```

ordm This element specifies the Ordering Mode.

Valid values include:

- 1 = ordered results are to be returned by certain path expressions, union, intersect, and except expressions, and FLWOR expressions that have no order by clause
- 2 = unordered results are to be returned by certain path expressions, union, intersect, and except expressions, and FLWOR expressions that have no order by clause

The default value is 1 (ordered).

Example:

```
<ordm>2</ordm>
```

out This element specifies the name of the generated executable.

The default executable name is XSLTModule, XPathModule, or XQueryModule depending on the corresponding task.

This option is ignored if compiling multiple files.

Example:

```
<out>sample</out>
```

dir This element specifies a destination directory for the executables. Default is the current working directory.

If the value contains a blank space, enclose it in quotation marks.

Example:

```
<pkg>com.mycompany.precompiled</pkg>
```

schema
This element specifies a schema document that will be used to populate the in-scope schema definitions.

This element can be used multiple times.

Example:

```
<schema>C:/samples/xpath/variousTypesNodeTest.xsd</schema>
```

type This element indicates the type of the function or variable expressed in terms of the localpart and namespaceURI.

Parameters specified as nested elements:

localpart
A nested localpart element must be specified to provide the local part of the qualified name.

namespaceURI
A nested namespaceURI element can be specified to indicate the namespaceURI.

Example:

```
<type>
  <localpart>boolean</localpart>
  <namespaceURI>"http://www.w3.org/2001/XMLSchema"</namespaceURI>
</type>
```

variable

This element defines and binds a variable to the static context for a single item.

This simply declares the variable, and a value must be bound to the dynamic context.

This element can be specified multiple times.

Parameters specified as nested elements:

name A nested name element must be specified to indicate the name of the variable.

type A nested type element must be specified to indicate the type of the variable.

Example:

```
<variable>
  <name>
    <localpart>booleanVar</localpart>
  </name>
  <type>
    <localpart>boolean</localpart>
    <namespaceURI>http://www.w3.org/2001/XMLSchema</namespaceURI>
  </type>
</variable>
```

Procedure

- **Use TaskCompileXPath**

  This task can be used to precompile one or more XPath expressions. The output will be a set of Java classes that subsequently can be used to execute the expressions without the performance overhead of dynamic compilation.

  Parameters specified as nested elements:

  out A nested **out** specifies the name of the generated executable.

  The default executable name is XPathModule.

  dir A nested **dir** specifies a destination directory for the executables.

  The default is the current working directory.

  pkg A nested **pkg** specifies a package name prefix for all generated classes.

  The default is the Java default package.

  cpm A nested **cpm** specifies an alternate XPath Compatibility Mode.

  ns A nested **ns** specifies a namespace for use during static processing.

schema
A nested **schema** specifies a schema document that will be used to populate the in-scope schema definitions.

function
A nested **function** definition can be specified.

This will create a function binding to the static context for a single item.

variable
A nested **variable** definition can be specified.

This will add a variable binding to the static context for a single item.

baseURI
A nested **baseURI** specifies the base URI of the containing element.

dnet A nested **dnet** specifies a default namespace URI for element and type names.

dnf A nested **dnf** specifies a default namespace URI for function names.

imm A nested **imm** sets the integer math mode, which is a constant representing the level of precision required and whether overflow detection is required when working with xs:integer values.

inputfile
A nested **inputfile** specifies the full path to a file containing XPath expression to be compiled.

Note: This element is required and can be used multiple times.

Example:

```
<target name="testXPath">
  <taskdef name="compileXPath" classname="com.ibm.xml.xapi.ant.TaskCompileXPath"/>
  <compileXPath>
    <out>sample</out>
    <dir>"C:/precompiledXPath"</dir>
    <pkg>com.mycompany.precompiled</pkg>
    <variable>
      <name>
        <localpart>booleanVar</localpart>
      </name>
      <type>
        <localpart>boolean</localpart>
        <namespaceURI>http://www.w3.org/2001/XMLSchema</namespaceURI>
      </type>
    </variable>
    <inputfile>C:/XPath/xpath.txt</inputfile>
  </compileXPath>
</target>
```

- **Use TaskCompileXQuery**

  This task can be used to precompile one or more XQuery expressions. The output will be a set of Java classes that subsequently can be used to execute the expressions without the performance overhead of dynamic compilation.

  Parameters specified as nested elements:

  out A nested **out** specifies the name of the generated executable.

  The default executable name is XQueryModule.

  dir A nested **dir** specifies a destination directory for the executables.

  The default is the current working directory.

  pkg A nested **pkg** specifies a package name prefix for all generated classes.

  The default is the Java default package.

  function
  A nested **function** definition can be specified.

This will create a function binding to the static context for a single item.

baseURI
A nested **baseURI** specifies the base URI of the containing element.

dnet A nested **dnet** specifies a default namespace URI for element and type names.

dnf A nested **dnf** specifies a default namespace URI for function names.

imm A nested **imm** sets the integer math mode, which is a constant representing the level of precision required and whether overflow detection is required when working with xs:integer values.

bsp A nested **bsp** specifies the Boundary Space Policy.

csm A nested **csm** specifies the Construction Mode.

cnmi A nested **cnmi** specifies the inherit part of the copy-namespaces.

cnmp A nested **cnmp** specifies the preserve part of the copy-namespaces.

eso A nested **eso** specifies the Empty Sequence Order.

ordm A nested **ordm** specifies the Ordering Mode.

inputfile
A nested **inputfile** specifies the full path to a file containing an XQuery expression to be compiled. Note: this element is required and can be used multiple times.

Example:

```
<target name="testXQuery">
  <taskdef name="compileXQuery" classname="com.ibm.xml.xapi.ant.TaskCompileXQuery"/>
  <compileXQuery>
    <out>sample</out>
    <dir>"C:/precompiledXQuery"</dir>
    <pkg>com.mycompany.precompiled</pkg>
    <inputfile>C:/XQuery/xquery.sq</inputfile>
  </compileXQuery>
</target>
```

- **Use TaskCompileXSLT**

  This task can be used to precompile one or more stylesheets. The output will be a set of Java classes that subsequently can be used to execute transformations without the performance overhead of dynamic compilation.

  Parameters specified as nested elements:

  out A nested **out** specifies the name of the generated executable.

  The default executable name is XSLTModule.

  This element is ignored if compiling multiple stylesheets.

  dir A nested **dir** specifies a destination directory for the executables.

  The default is the current working directory.

  pkg A nested **pkg** specifies a package name prefix for all generated classes.

  The default is the Java default package.

  function
  A nested **function** definition can be specified.

  This will create a function binding to the static context for a single item.

  baseURI
  A nested **baseURI** specifies the base URI of the containing element.

imm A nested **imm** sets the integer math mode, which is a constant representing the level of precision required and whether overflow detection is required when working with xs:integer values.

inputfile
A nested **inputfile** specifies the full path to a file containing an XSL stylesheet to be compiled.

Note: This element is required and can be used multiple times.

Example:

```
<target name="testXSLT">
  <taskdef name="compileXSLT" classname="com.ibm.xml.xapi.ant.TaskCompileXSLT"/>
  <compileXSLT>
    <out>sample</out>
    <dir>"C:/precompiledXSLT"</dir>
    <pkg>com.mycompany.precompiled</pkg>
    <function>
      <name>
        <localpart>la</localpart>
        <namespaceURI>"http://www.ibm.com/Los Angeles"</namespaceURI>
      </name>
      <type>
        <localpart>boolean</localpart>
        <namespaceURI>http://www.w3.org/2001/XMLSchema</namespaceURI>
      </type>
    </function>
    <inputfile>C:/XSLT/simple.xsl</inputfile>
  </compileXSLT>
</target>
```

Precompiling in Java

You can use the XCompilationFactory interface and its various compile and load methods to compile an expression, query, or stylesheet in advance. The Java classes can be loaded at execution time, therefore avoiding the cost of compilation in the application run time.

Procedure

- Retrieve the XCompilationFactory by calling the getCompilationFactory method on the XFactory class.

  An XCompilationFactory instance is associated with a particular XFactory instance, so they share registered schemas. If a new schema is registered with the XFactory instance; therefore, it is visible to the associated XCompilationFactory instance.
- Create a new XCompilationParameters instance by calling the XCompilationFactory newCompilationParameters method, passing in the base class name to use for the generated classes.

  Configure the parameters further by using the set methods described in this table.

Table 256. Valid set methods.

These set methods are defined in the XCompilationParameters interface and are valid for generating a precompiled executable.

Set Methods Valid for Generating a Precompiled Executable	Description	Default
setPackageName	Specify the package name for the generated classes. The value must be a valid Java package name.	Java default package
setDirectoryName	Specify the directory to which the generated classes should be written. The directory must exist.	Current working directory as retrieved by calling the Java System.getProperty method with the property user.dir

  The setClassLoader method is only valid when loading the generated classes using one of the load methods. If the class loader is set at compile time, it is ignored.
- Use one of the compile methods on the XCompilationFactory, passing in the XCompilationParameters, to generate the precompiled executable.

  The compile methods use the XStaticContext just like the XFactory prepare methods to configure prepare-time settings. Note that compilation is implied when the compile methods are used; therefore,

changing the use-compiler setting through the XStaticContext setUseCompiler method has no effect on these methods. If no static context is specified, the default settings are used.

Example

The following is a basic example of precompiling an XPath expression.

```
// Create the factory
XFactory factory = XFactory.newInstance();

// Get the compilation factory
XCompilationFactory compileFactory = factory.getCompilationFactory();

// Create the compilation parameters
XCompilationParameters params = compileFactory.newCompilationParameters("MyXPath");
params.setPackageName("org.example.myxpath");

// Generate the compiled classes
compileFactory.compileXPath("/doc/item[@id > 3000]", params);
```

Appropriate compile methods are available for XQuery and XSLT as well.

Loading a precompiled executable

You can use the XCompilationFactory interface and its various load methods to load a precompiled expression, query, or stylesheet. These load methods load the Java classes and return an XPathExecutable, XQueryExecutable, or XSLTExecutable object respectively.

Procedure

- Retrieve the XCompilationFactory by calling the getCompilationFactory method on the XFactory class.

  An XCompilationFactory instance is associated with a particular XFactory instance, so they share registered schemas. If a new schema is registered with the XFactory instance, therefore, it is visible to the associated XCompilationFactory instance.
- Create a new XCompilationParameters instance by calling the XCompilationFactory newCompilationParameters method, passing in the base class name of the classes to be loaded.

  Configure the parameters further by using the set methods described in this table.

Table 257. Valid set methods.

These are set methods that are defined in the XCompilationParameters interface and are valid for loading a precompiled executable.

Set Methods Valid for Loading a Precompiled Executable	Description	Default
setPackageName	Specify the package name of the classes to load.	Java default package
setClassLoader	Specify the class loader to use.	Class loader that was used to load the processor

  The setDirectoryName method is not valid when loading a precompiled executable because the classpath is used to search for the classes. If the directory name is set, it is ignored. The setDirectoryName method can be used when generating precompiled executables to specify the directory to which you want to write the classes.
- Use one of the load methods on the XCompilationFactory, passing in the XCompilationParameters, to load the precompiled executable.

Example

The following is a basic example of loading a precompiled XPath expression.

```
// Create the factory
XFactory factory = XFactory.newInstance();

// Get the compilation factory
XCompilationFactory compileFactory = factory.getCompilationFactory();

// Create the compilation parameters
XCompilationParameters params = compileFactory.newCompilationParameters("MyXPath");
params.setPackageName( "org.example.myxpath");
```

```
// Load the executable
XPathExecutable executable = compileFactory.loadXPath(params);

// Create the input source
StreamSource input = new StreamSource("simple.xml");

// Execute the XPath expression
XSequenceCursor cursor = executable.execute(input);
```

Appropriate load methods are available for XQuery and XSLT as well.

Using resolvers

You can use this information to help you to use resolvers.

Procedure

- Use source and result resolvers.
- Register a collection resolver.
- Register a schema resolver.
- Use an unparsed text resolver.
- Use a module resolver.

Using source and result resolvers

You can use this information to help you to use source and result resolvers.

Procedure

- Use a source resolver at prepare time.
- Use a source resolver at execution time.
- Use a result resolver at execution time.

Using a source resolver at prepare time:

By specifying a source resolver at the time that an executable is being prepared, you can tell the processor how to interpret the URIs referenced at that time.

Procedure

Specify a source resolver at the time an executable is being prepared.
This tells the processor how to interpret the URIs referenced at that time, in a stylesheet's xsl:import and xsl:include directives for example.
The default source-resolution behavior is to interpret relative URIs in terms of the base URI of the expression, query, or stylesheet if the base URI is available or to interpret them as file paths relative to the current working directory if the base URI is not available. Absolute URIs are used unchanged.
To change this behavior, write a Java class that implements the XSourceResolver interface and register it with the XStaticContext before preparing the stylesheet.
The following is a basic example of how to register the source resolver.

```
XFactory factory = XFactory.newInstance();

// Register the source resolver with the static context
XStaticContext staticContext = factory.newStaticContext();
XSourceResolver sourceResolver=new ASourceResolver(replacementBase);
staticContext.setSourceResolver(sourceResolver);

// Prepare the sylesheet
XSLTExecutable executable = factory.prepareXSLT(new StreamSource(stylesheetFile), staticContext);

XDynamicContext dynamicContext = factory.newDynamicContext();

// Execute the stylesheet
XSequenceCursor cursor = executable.execute(new StreamSource(inputFile), dynamicContext);
```

Using a source resolver at execution time:

By specifying a source resolver at the time that an executable is being executed, you can tell the processor how to interpret the URIs referenced at that time.

Procedure

Specify a source resolver at the time that an executable is being executed.
This tells the processor how to interpret the URIs referenced at that time, in calls to the fn:doc() or document() functions for example.
The default source-resolution behavior is to interpret relative URIs in terms of the base URI of the expression, query, or stylesheet if the base URI is available or to interpret them as file paths relative to the current working directory if the base URI is not available. Absolute URIs are used unchanged.
To change this behavior, write a Java class that implements the XSourceResolver interface and register it with the XDynamicContext before executing the expression, query, or stylesheet.
The following is a basic example of how to register the source resolver.

```
XFactory factory = XFactory.newInstance();

XStaticContext staticContext = factory.newStaticContext();

// Prepare the stylesheet
XSLTExecutable executable = factory.prepareXSLT(new StreamSource(stylesheetFile), staticContext);

XDynamicContext dynamicContext = factory.newDynamicContext();
// Register the source resolver with the dynamic context
XSourceResolver sourceResolver=new ASourceResolver(replacementBase);
dynamicContext.setSourceResolver(sourceResolver);

// Execute the XPath expression
XSequenceCursor cursor = executable.execute(new StreamSource(inputFile), dynamicContext);
```

Using a result resolver at execution time:

By specifying a result resolver at execution time, you can tell the processor how to redirect output URIs specified in the executable.

Procedure

To activate a result resolver, register it with the dynamic context before calling execute().
Result resolvers perform essentially the same function as source resolvers, but on the output side of the processor. They allow you to intercept and redirect output URIs specified in the executable, such as xsl:result-document directives in a stylesheet.
The default resolution behavior is to use the base output URI to resolve result documents if the URI reference is relative. Absolute URIs are used unchanged.
The following is a basic example of a result resolver.

```
class AResultResolver implements XResultResolver
{
    String _replacementBase;

    public AResultResolver(String replacementBase)
    {
      _replacementBase=replacementBase;
    }

    // Resolve URIs by loading the resource as an XSLT stylesheet
    // and evaluating it - return the result as the Source to use
    public Result getResult(String href, String base) {
      String rebasePrefix="rebase://";

      if(href.startsWith(rebasePrefix))
      {
       href=href.substring(rebasePrefix.length());
       base=_replacementBase;
      }

      java.net.URI baseURI;
      Result result=null;
      try {
         // Get base URI object
          baseURI = new java.net.URI(base);
          // Resolved relative reference against base URI
          URI resolvedURI = baseURI.resolve(href);
          // Try to read...
          result = new StreamResult(resolvedURI.toString());
```

```
      } catch (java.net.URISyntaxException use) {
          throw new RuntimeException(use);
     }

      return result;
    }
}
```

The following is a basic example of registering and using the resolver.

```
XFactory factory = XFactory.newInstance();

XStaticContext staticContext = factory.newStaticContext();

// Prepare the stylesheet
XSLTExecutable executable = factory.prepareXSLT(new StreamSource(stylesheetFile), staticContext);

XDynamicContext dynamicContext = factory.newDynamicContext();
// Register the result resolver with the dynamic context
XResultResolver resultResolver=new AResultResolver(replacementBase);
dynamicContext.setResultResolver(resultResolver);

// Execute the XPath expression
XSequenceCursor cursor = executable.execute(new StreamSource(inputFile), dynamicContext);
```

Registering a collection resolver

You can register implementations of the XCollectionResolver interface with the XDynamicContext.

Procedure

Register a collection resolver with the dynamic context.
The XCollectionResolver implementation registered with the XDynamicContext is used at execution time to retrieve the collection of nodes associated with the URI provided in calls to the fn:collection method. If no collection resolver is registered with the XDynamicContext then calls to fn:collection will result in a recoverable error and the empty sequence is used for the collection.
Note that the collection resolver and the fn:collection function are not meant to resolve document URIs. The source resolver and fn:doc function should be used for this purpose.

Example

The following is a basic example of using a collection resolver.

```
XFactory factory = XFactory.newInstance();

// Prepare the XPath expression
XPathExecutable executable = factory.prepareXPath("count(collection('typeA-typeB'))"

// Register the collection resolver with the dynamic context
XCollectionResolver collectionResolver = new ACollectionResolver(factory);
XDynamicContext dynamicContext = factory.newDynamicContext();
dynamicContext.setCollectionResolver(collectionResolver);

// Execute the XPath expression
XSequenceCursor cursor = executable.execute(dynamicContext);
```

The following is a basic example of an XCollectionResolver implementation.

```
public class ACollectionResolver implements XCollectionResolver {

    private XFactory m_factory;

    public ACollectionResolver(XFactory factory) {
        m_factory = factory;
    }

    public XSequenceCursor getCollection(String uri, String base) {

        // Get the default collection
        if (uri.equals("")) {
            return getCollection("default", base);
        }

        // Get the requested collection
        ArrayList<XItemView> list = new ArrayList<XItemView>();
        StringTokenizer tokenizer = new StringTokenizer(uri, "-");
          XSequenceCursor cursor = null;
          while (tokenizer.hasMoreTokens()) {
              String token = tokenizer.nextToken();
              XSequenceCursor temp = getNodes(new StreamSource("collections.xml"), "/doc/" + token);
```

```
            if (cursor == null) {
                cursor = temp;
            } else {
                cursor = cursor.append(temp);
            }
         }
        return cursor;
    }

     private XSequenceCursor getNodes(Source source, String expression) {
         XPathExecutable executable = m_factory.prepareXPath(expression);
         XSequenceCursor cursor = executable.execute(source);
         return cursor;
     }

}
```

Registering a schema resolver

The XSchemaResolver interface can be implemented and the implementation registered with the XFactory to override the default schema resolution behavior. This includes resolution of imports for schemas registered with XFactory using the registerSchema method and resolving schemas imported in XSLT stylesheets using the xsl:import-schema declaration.

About this task

The default behavior for resolving imports within a schema is to use the base URI of the schema to resolve the imported schema's location. The default behavior for XSLT schema imports is to use the base URI of the xsl:import-schema declaration to resolve the location specified in the declaration.

Procedure

Use the setSchemaResolver method on the XFactory class to register a schema resolver.
The getSchema method returns an instance of the java.util.List interface. This is because the definitions of the schema components for a particular namespace can be split across several distinct schema documents. You can use the getSchema method to return all the schema documents for the particular target namespace associated with all the specified location hints.

Example

The following is a basic example of using a schema resolver.

```
XFactory factory = XFactory.newInstance();

// Set validating to true.
factory.setValidating(true);

// Create the schema resolver and register it with the factory.
factory.setSchemaResolver(new ASchemaResolver(replacementBase));

// Prepare the stylesheet.
XSLTExecutable executable = factory.prepareXSLT(new StreamSource(stylesheetFile));

// Execute the transformation.
Source source = new StreamSource(inputFile);
Result result = new StreamResult(System.out);
executable.execute(source, result);
```

The following is a basic example of an XSchemaResolver implementation.

```
class ASchemaResolver implements XSchemaResolver
{
    String _replacementBase;

    public ASchemaResolver(String replacementBase)
    {
        _replacementBase=replacementBase;
    }

    // Resolve URI, returning the Source that URI represents.
    // Implements the "rebase:" pseudo-scheme.
    public List<? extends Source> getSchema(String namespace, List<String> locations, String baseURI) {
        String rebasePrefix="rebase:";

        List<StreamSource> list = new ArrayList<StreamSource>();
        for (int i = 0; i < locations.size(); i++) {
```

```
            String href = locations.get(i);
            String base = baseURI;
            if(href.startsWith(rebasePrefix)) {
                href=href.substring(rebasePrefix.length());
                base=_replacementBase;
            }

            java.net.URI uri;
            StreamSource source=null;
            try {
                // Get base URI object
                uri = new java.net.URI(base);
                // Resolved relative reference against base URI
                URI resolvedURI = uri.resolve(href);
                // Try to read...
                source = new StreamSource(resolvedURI.toString());
            } catch (java.net.URISyntaxException use) {
                throw new RuntimeException(use);
            }

            list.add(source);
        }
        return list;
    }
}
```

Using an unparsed text resolver

The XUnparsedTextResolver interface can be implemented and the implementation registered with the XDynamicContext to override the default resolution behavior for resources loaded through the XSLT unparsed-text function.

About this task

The default resolution behavior for resources loaded through the XSLT unparsed-text function is to resolve relative URIs based on the base URI from the static context. If the base URI is not available, the current working directory is used. Absolute URIs are used unchanged.

Procedure

Use the setUnparsedTextResolver method on the XDynamicContext interface to register an unparsed text resolver.

Example

The following is a basic example of using an unparsed text resolver.

```
XFactory factory = XFactory.newInstance();

// Prepare the stylesheet.
XSLTExecutable executable = factory.prepareXSLT(new StreamSource(stylesheetFile));

// Create the dynamic context and set the unparsed text resolver.
XDynamicContext dynamicContext = factory.newDynamicContext();
AnUnparsedTextResolver resolver = new AnUnparsedTextResolver(replacementBase);
dynamicContext.setUnparsedTextResolver(resolver);

// Execute the transformation.
Source source = new StreamSource(inputFile);
Result result = new StreamResult(System.out);
executable.execute(source, dynamicContext, result);
```

The following is a basic example of an unparsed text resolver implementation.

```
class AnUnparsedTextResolver implements XUnparsedTextResolver
{
    String _replacementBase;

    public AnUnparsedTextResolver(String replacementBase)
    {
        _replacementBase=replacementBase;
    }

    // Resolve URI, returning the resource that URI represents.
    // Implements the "rebase:" pseudo-scheme.
    public String getResource(String href, String encoding, String base) {
        String rebasePrefix="rebase:";

        if (href.startsWith(rebasePrefix)) {
```

```
            href = href.substring(rebasePrefix.length());
            base = _replacementBase;
        }

        try {
            // Get base URI object
            URI uri = new java.net.URI(base);
            // Resolved relative reference against base URI
            URI resolvedURI = uri.resolve(href);
            // Try to read...
            URL url = resolvedURI.toURL();
            URLConnection urlCon = url.openConnection();
            BufferedInputStream stream = new BufferedInputStream(urlCon.getInputStream());
            StringBuffer buffer = new StringBuffer();
            int s;
            while ((s = stream.read())!= -1) {
                // Do any character manipulation here.
                buffer.append((char)s);
            }
            return buffer.toString();
        } catch (Exception e) {
            throw new RuntimeException(e);
        }
    }
}
```

Using resolvers in a J2EE context

When loading artifacts in a Java 2 Platform, Enterprise Edition (J2EE) context, you should consider the special implications that apply when loading resources from local deployment artifacts.

About this task

Loading local resources—through Class.getResource and Class.getResourceAsStream—from J2EE deployment artifacts such as EARs, WARs, and library JAR files can introduce issues when loading related XML artifacts. Loading an initial local resource using these mechanisms will succeed, but artifacts loaded from the initial resource typically will fail to load without specific consideration.

Here is an example of loading documents at execution time from a stylesheet using the XPath fn:doc function. In this case, the default behavior is to resolve documents based on the base URI from the static context.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="2.0" xmlns:xsl="http://www.w3.org/1999/XSL/Transform">
 <xsl:output method="xml" version="1.0" encoding="UTF-8" indent="yes"/>

 <xsl:variable name="names" select="doc('names.xml')"/>

 <xsl:template name="loadnames">
  <xsl:copy-of select="$names"/>
 </xsl:template>

</xsl:stylesheet>
```

If this is loaded with the following Java code in a J2EE environment:

```
// create the factory
XFactory factory = XFactory.newInstance();

// load the XSLT file from a local resource within a J2EE deployment artifact
StreamSource source = new StreamSource(XSLTDocFunction.class.getResourceAsStream("/samplexslts/doc.xsl"));

// Create an XSL transform executable
XSLTExecutable xslTransform = factory.prepareXSLT(source);

// Create the result
Result result = new StreamResult(new ByteArrayOutputStream());

// Create a dynamic context specifying the XSLT initial template
XDynamicContext dc = factory.newDynamicContext();
dc.setXSLTInitialTemplate(new QName("loadnames"));

// Execute the transformation
xslTransform.execute(dc, result);
```

you will receive the following error:

```
IXJXE0364W: FATAL ERROR:  IXJXE0774E: [ERR 0693][ERR FODC0005]
The URI string 'names.xml' does not map to an available document.
```

The reason for this error is that in loading the initial XML artifact (doc.xsl), no static content was established for the base URI. In this case, the processor will fall back to looking in the current working directory, which is meaningless in a J2EE environment.

There are three possible ways to fix this situation. Here are the first two:

- Set the baseURI in the static context.

  Adjusting to set the baseURI on the static context would look like this example:

```
// create the factory
XFactory factory = XFactory.newInstance();

// set the baseURI in the static context
URL dataURL = XSLTSchemaAware.class.getResource("/samplexslts/doc.xsl");
XStaticContext staticContext = factory.newStaticContext();
staticContext.setBaseURI(dataURL.toString());

// load the XSLT file from a local resource within a J2EE deployment artifact
StreamSource source = new StreamSource(XSLTDocFunction.class.getResourceAsStream("/samplexslts/doc.xsl"));

// Create an XSL transform executable
XSLTExecutable xslTransform = factory.prepareXSLT(source, staticContext);

// Create the result
Result result = new StreamResult(new ByteArrayOutputStream());

// Create a dynamic context specifying the XSLT initial template
XDynamicContext dc = factory.newDynamicContext();
dc.setXSLTInitialTemplate(new QName("loadnames"));

// Execute the transformation
xslTransform.execute(dc, result);
```

- Load the resource in a way that allows the processor to know the baseURI.

  Adjusting to load the resource in a way that allows the processor to know the baseURI by passing the absolute URL to the StreamSource constructor would look like the following example:

```
// Create the factory
XFactory factory = XFactory.newInstance();

// Create the source from a URL
URL dataURL = XSLTSchemaAware.class.getResource("/samplexslts/doc.xsl");
StreamSource source = new StreamSource(dataURL.toString());

// Create an XSL transform executable for the expression
XSLTExecutable xslTransform = factory.prepareXSLT(source);

// Create the result
ByteArrayOutputStream baos = new ByteArrayOutputStream();
Result result = new StreamResult(baos);

// Create a dynamic context specifying the XSLT initial template
XDynamicContext dc = factory.newDynamicContext();
dc.setXSLTInitialTemplate(new QName("loadnames"));

// Execute the transformation
xslTransform.execute(dc, result);
```

These two approaches described will work well when all XML artifacts are in a single J2EE deployment unit, but they will fail if XML artifacts are split across J2EE deployment units because there is no single baseURI for all of the XML artifacts.

To have complete control over XML artifact loading to support cases such as artifacts spread across multiple deployment units, use resolvers to completely control loading behavior.

Procedure

Implement the appropriate resolvers and register those resolvers into the static or dynamic context as appropriate.
These XML artifact loading recommendations apply within a J2EE context for all XML artifacts supported by resolvers such as XML documents (fn:doc(), document()), stylesheets (xsl:include, xsl:import), unparsed text, and XML schemas (XSLT import-schema).

Using a module resolver

The XModuleResolver interface can be implemented and the implementation registered with the XStaticContext to override the default XQuery module resolution behavior. Modules are resolved whenever an XQuery module import is encountered.

About this task

The default module resolution behavior is to attempt to locate one module for each location hint specified in the module import. The default resolution behavior for each location hint is to resolve relative URIs against the base URI from the static context, if the base URI is available, or to interpret them as file paths relative to the current working directory, if the base URI is not available. Absolute URIs are used unchanged. If a module cannot be located for a location hint, the processor ignores it unless no modules can be loaded for the namespace, in which case the processor will emit an error message.

Procedure

Use the setModuleResolver method on the XStaticContext interface to register a module resolver. The getModule method returns an instance of the java.util.List interface. This is because there might be more than one module document for a particular namespace and set of location hints.

Example

The following is a basic example of using a module resolver.

```
XFactory factory = XFactory.newInstance();

// Create the static context
XStaticContext staticContext = factory.newStaticContext();

// Create the module resolver and register it with the static context.
staticContext.setModuleResolver(new AModuleResolver(replacementBase));

// Prepare the query.
XQueryExecutable executable = factory.prepareXQuery(new StreamSource(queryFile), staticContext);

// Execute the transformation.
Source source = new StreamSource(inputFile);
Result result = new StreamResult(System.out);
executable.execute(source, result);
```

The following is a basic example of a module resolver implementation.

```
class AModuleResolver implements XModuleResolver
{
    String _replacementBase;

    public AModuleResolver(String replacementBase)
    {
        _replacementBase=replacementBase;
    }

    // Resolve URI, returning the Source that URI represents.
    // Implements the "rebase:" pseudo-scheme.
    public List<? extends Source> getModule(String namespace, List<String> locations, String baseURI) {
        String rebasePrefix="rebase:";

        List<StreamSource> list = new ArrayList<StreamSource>();
        for (int i = 0; i < locations.size(); i++) {
            String href = locations.get(i);
            String base = baseURI;
            if(href.startsWith(rebasePrefix)) {
                href=href.substring(rebasePrefix.length());
                base=_replacementBase;
```

```
            }

            java.net.URI uri;
            StreamSource source=null;
            try {
                // Get base URI object
                uri = new java.net.URI(base);
                // Resolved relative reference against base URI
                URI resolvedURI = uri.resolve(href);
                // Try to read...
                source = new StreamSource(resolvedURI.toString());
            } catch (java.net.URISyntaxException use) {
                throw new RuntimeException(use);
            }

            list.add(source);
        }
        return list;
    }
}
```

Using external variables and functions

You can use this information to help you to use external variables and functions.

Procedure

- Use external variables.
- Use external functions.

Using external variables

The XML API allows you to access external variables from XPath and XQuery expressions as well a stylesheet parameters from XSLT stylesheets.

About this task

External variables are useful when your XML processing depends on information that is not contained in an input document. If you are writing an application that allows users to search for books by title in a library that is stored as XML, for example, you could prepare a single XQuery expression to find books in the library that uses a variable for the book title to be matched. The resulting XQueryExecutable object can be used for each search that the user submits by binding the submitted book title to the variable. The details of using external variables and stylesheet parameters are presented in separate articles for XPath, XQuery, and XSLT.

Procedure

- Use external variables with XPath.
- Use external variables with XQuery.
- Set parameters with XSLT.

Using external variables with XPath:

When using an XPath expression that uses external variables, supply (or bind) values for each variable using an XDynamicContext instance and optionally declare the types of the variables using an XStaticContext instance.

Procedure

- When preparing an XPath expression that uses external variables, declare the types of the variables using an XStaticContext instance.

This step is optional. If a variable is not declared, the processor assumes its type is item()*. In other words, the value of the variable can be a sequence of any length consisting of items of any type. Declaring a type for your variables can help the processor detect some usage errors statically during preparation.

The XStaticContext interface has two declareVariable methods that each have two parameters—one for the name, and one for the type of the variable. The name is always provided as a QName object, but the type can be a QName or an XSequenceType.

Table 258. XStaticContext declareVariable methods.

The following table explains when to use each form of the declareVariable method.

Method Signature	Purpose
declareVariable(QName name, QName type)	Use when value of the variable is a single atomic value The QName must refer to a built-in type or a global type declared in a schema that has been registered on the XFactory instance used to create the XStaticContext instance. If the QName refers to a non-atomic type, then the processor will treat the variable as having the type element(*, ns:type), where ns:type is the given QName. The XTypeConstants interface has convenient constants available that provide a QName object for each built-in type.
declareVariable(QName name, XSequenceType type)	Use when value of the variable is a single node or a sequence of atomic values or nodes

The following example shows how to prepare an XPath expression that uses variables, with two declared in the static context and one not declared.

```
// Create the factory
XFactory factory = XFactory.newInstance();

// Create a new static context from the factory
XStaticContext staticContext = factory.newStaticContext();

// Define QNames for the names of the variables to be declared
final QName taxRate = new QName("taxRate");
final QName partNumbers = new QName("partNumbers");

// Declare a variable called "taxRate" as an xs:float
staticContext.declareVariable(taxRate, XTypeConstants.FLOAT_QNAME);

// Obtain an XSequenceTypeFactory instance from the factory
XSequenceTypeFactory typeFactory = factory.getSequenceTypeFactory();

// Define a sequence type for a sequence of xs:integer values
XSequenceType integerSequence = typeFactory.atomic(XTypeConstants.INTEGER_QNAME, XSequenceType.OccurrenceIndicator.ZERO_OR_MORE);

// Declare a variable called "partNumbers" as a sequence of xs:integer values
staticContext.declareVariable(partNumbers, integerSequence);

// Create an XPath expression that uses the declared variables, as well as another variable "discount"
// that the processor will assume has type item()*
String expression = "sum(for $partNumber in $partNumbers return /inventory/part[@num=$partNumber]/@price) * (1 - $discount) * (1 + $taxRate)";

// Prepare the XPath expression
XPathExecutable xpath = factory.prepareXPath(expression, staticContext);
```

- To execute an XPath expression that uses external variables, supply (or bind) values for each variable using an XDynamicContext instance.

  An error is raised if you do not supply a value for a variable that is used when executing the XPath expression.

  The XDynamicContext has a number of bind, bindItem, and bindSequence methods. Each has two parameters, where the first is a QName object corresponding to the name of the parameter and the second is the value.

Table 259. XDynamicContext bind, bindItem, and bindSequence methods.

The following table explains when to use each form of the XDynamicContext bind, bindItem, and bindSequence methods.

Method	Purpose
bind	Use when binding a single atomic value There is one form of this method for each of the Java types that is used in the standard mapping of built-in types to Java types. There are two additional forms—one that takes a node and one that takes a source. These are used for binding any node from a DOM tree and parsing a new source to yield a document node, respectively.
bindItem	Use when binding a single item as an XItemView object An XItemView object can be obtained from the result of executing another expression or constructed using an XItemFactory instance.
bindSequence	Use when binding sequences of less than or greater than one item There is one form of this method for each of the Java types that is used in the standard mapping of built-in types to Java types; each accepts an array of values the given type. There is an additional form that takes an XSequenceCursor. An XSequenceCursor can be the result of executing another expression or can be constructed using an XItemFactory instance.

The following example executes the XPath expression prepared in the first example, first binding values for each of the variables it uses.

```
// Create a new dynamic context from the factory
XDynamicContext dynamicContext = factory.newDynamicContext();

// Bind an atomic value for the "taxRate" and "discount" variables
dynamicContext.bind(taxRate, 0.13f);
dynamicContext.bind(new QName("discount"), 0.40);

// Bind a sequence of atomic values for the "partNumbers" variable
dynamicContext.bindSequence(partNumbers, new int[] {2, 1, 2, 3, 2});

// Create an XML input document
String xml = "<inventory>" +
"<part num='1' price='9.99'/>" +
"<part num='2' price='4.47'/>" +
"<part num='3' price='12.99'/>" +
"</inventory>";
StreamSource source = new StreamSource(new StringReader(xml));

// Execute the expression
XSequenceCursor result = xpath.execute(source, dynamicContext);
```

Using external variables with XQuery:

When using an XQuery expression that uses external variables, supply (or bind) values for each variable using an XDynamicContext instance and optionally declare the types of the variables using an XStaticContext instance.

Procedure

- When preparing an XQuery expression that uses external variables, declare the types of the variables using an XStaticContext instance.

  Variables declared in the XStaticContext are only visible to the main module. To make an external variable visible to a library module, it must be declared in the prolog of the library module with an external variable declaration.

  Declaring the variable in the XStaticContext is optional. If a variable is not declared, the processor assumes that its type is item()*. In other words, the value of the variable can be a sequence of any length consisting of items of any type. Declaring a type for your variables can help the processor detect some usage errors statically during preparation.

The XStaticContext interface has two declareVariable methods that each have two parameters—one for the name, and one for the type of the variable. The name is always provided as a QName object, but the type can be a QName or an XSequenceType.

Table 260. XStaticContext declareVariable methods.

The following table explains when to use each form of the declareVariable method.

Method Signature	Purpose
declareVariable(QName name, QName type)	Use when value of the variable is a single atomic value The QName must refer to a built-in type or a global type declared in a schema that has been registered on the XFactory instance used to create the XStaticContext instance. If the QName refers to a non-atomic type, then the processor will treat the variable as having the type element(*, ns:type), where ns:type is the given QName. The XTypeConstants interface has convenient constants available that provide a QName object for each built-in type.
declareVariable(QName name, XSequenceType type)	Use when value of the variable is a single node or a sequence of atomic values or nodes

XQuery also allows variables to be declared in the prolog of an XQuery expression. The following XQuery expression uses two variables, one declared in the prolog and one not.

```
declare namespace xs = "http://www.w3.org/2001/XMLSchema";
declare variable $searchTerms as xs:string+ external;

<table>
    <tr><td>Title</td><td>Author</td></tr>
    {
        for $book in /library/book
        let $value := $book/@*[local-name()=$searchField]
        where exists(for $term in $searchTerms return if (contains($value, $term)) then true() else ())
        return
            <tr>
                <td>{ string($book/@title) }</td>
                <td>{ string($book/@author) }</td>
            </tr>
    }
</table>
```

The variable not declared in the XQuery expression itself can be optionally declared using an XStaticContext instance to provide the processor with type information.

The following example shows how to prepare the above XQuery expression, providing a type for the variable not declared in the XQuery expression itself. It assumes that the expression is accessible using the xquerySource source object.

```
// Create the factory
XFactory factory = XFactory.newInstance();

// Create a new static context from the factory
XStaticContext staticContext = factory.newStaticContext();

// Define a QName for the name of the variable to be declared
final QName searchField = new QName("searchField");

// Declare a variable called "searchField" as an xs:string
staticContext.declareVariable(searchField, XTypeConstants.STRING_QNAME);

// Prepare the XQuery expression
XQueryExecutable xquery = factory.prepareXQuery(xquerySource, staticContext);
```

- To execute an XQuery expression that uses external variables, supply (or bind) values for each variable using an XDynamicContext instance.

  The bindings for external variables will be available to the main module and to any library modules that have an external variable declaration in their prolog for that variable.

  An error is raised if you do not supply a value for a variable that is used when executing the XQuery expression.

  The XDynamicContext has a number of bind, bindItem, and bindSequence methods. Each has two parameters, where the first is a QName object corresponding to the name of the parameter and the second is the value.

Table 261. XDynamicContext bind, bindItem, and bindSequence methods.

The following table explains when to use each form of the XDynamicContext bind, bindItem, and bindSequence methods.

Method	Purpose
bind	Use when binding a single atomic value There is one form of this method for each of the Java types that is used in the standard mapping of built-in types to Java types. There are two additional forms—one that takes a node and one that takes a source. These are used for binding any node from a DOM tree and parsing a new source to yield a document node, respectively.
bindItem	Use when binding a single item as an XItemView object An XItemView object can be obtained from the result of executing another expression or constructed using an XItemFactory instance.
bindSequence	Use when binding sequences of less than or greater than one item There is one form of this method for each of the Java types that is used in the standard mapping of built-in types to Java types; each accepts an array of values the given type. There is an additional form that takes an XSequenceCursor. An XSequenceCursor can be the result of executing another expression or can be constructed using an XItemFactory instance.

The following example executes the XQuery expression prepared in the first example, first binding values for each of the variables it uses.

```
// Create a new dynamic context from the factory
XDynamicContext dynamicContext = factory.newDynamicContext();

// Bind an atomic value for the "searchField" variable
dynamicContext.bind(searchField, "title");

// Bind a sequence of atomic values for the "searchTerms" variable
dynamicContext.bindSequence(new QName("searchTerms"), new String[] {"Lost", "Gables"});

// Create an XML input document
String xml = "<library>" +
"<book title='Lost in the Barrens' author='Farley Mowat'/>" +
"<book title='Anne of Green Gables' author='L. M. Montgomery'/>" +
"</library>";
StreamSource source = new StreamSource(new StringReader(xml));

// Execute the expression
XSequenceCursor result = xquery.execute(source, dynamicContext);
```

Setting parameters with XSLT:

To use parameters in an XSLT stylesheet, declare the parameters as global parameters in the stylesheet itself.

Procedure

- Use the as attribute to declare a type for the parameter.

  The following stylesheet declares two parameters, explicitly giving one of them a type.

```
<?xml version="1.0"?>
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
                xmlns:xs="http://www.w3.org/2001/XMLSchema"
                exclude-result-prefixes="xs"
                version="2.0">

  <xsl:param name="targetDate" as="xs:date"/>
  <xsl:param name="window" select="3"/>

  <xsl:template match="/">
    <table>
      <tr><td>Task</td><td>Due</td><td>Status</td></tr>

      <xsl:apply-templates select="todo-list/task[xs:date(@due) le $targetDate + xs:dayTimeDuration(concat('P', $window, 'D'))]">
          <xsl:sort select="@due"/>
      </xsl:apply-templates>
    </table>
  </xsl:template>
```

```
  <xsl:template match="task">
    <tr>
      <td><xsl:value-of select="."/></td>
      <td><xsl:value-of select="format-date(xs:date(@due), '[MNn] [D1o]')"/></td>
      <td>
          <xsl:choose>
          <xsl:when test="xs:date(@due) lt $targetDate">OVERDUE by
             <xsl:value-of select="days-from-duration($targetDate - xs:date(@due))"/> day(s)</xsl:when>
          <xsl:otherwise>Due in <xsl:value-of select="days-from-duration(xs:date(@due) - $targetDate)"/> day(s)</xsl:otherwise>
          </xsl:choose>
      </td>
    </tr>
  </xsl:template>

</xsl:stylesheet>
```

- Prepare an XSLT stylesheet with global parameters in exactly the same way as any other stylesheet because there is no need to declare anything in the static context.

  Assuming that the stylesheet above is available using the xsltSource Source object, the code below prepares the stylesheet.

```
// Create the factory
XFactory factory = XFactory.newInstance();

// Prepare the XSLT stylesheet
XSLTExecutable xslt = factory.prepareXSLT(xsltSource);
```

- To execute an XSLT stylesheet that uses parameters, supply (or bind) values for each parameter using an XDynamicContext instance.

  You must supply a value for any required parameters or an error is raised. For other parameters, if you do not supply a value, a default value is used—either one supplied in the stylesheet or a zero-length string.

  The XDynamicContext has a number of bind, bindItem, and bindSequence methods. Each has two parameters, where the first is a QName object corresponding to the name of the parameter and the second is the value.

Table 262. XDynamicContext bind, bindItem, and bindSequence methods.

The following table explains when to use each form of the XDynamicContext bind, bindItem, and bindSequence methods.

Method	Purpose
bind	Use when binding a single atomic value There is one form of this method for each of the Java types that is used in the standard mapping of built-in types to Java types. There are two additional forms—one that takes a Node object and one that takes a Source object. These are used for binding any node from a DOM tree and parsing a new source to yield a document node, respectively.
bindItem	Use when binding a single item as an XItemView object An XItemView object can be obtained from the result of executing another expression or constructed using an XItemFactory instance.
bindSequence	Use when binding sequences of less than or greater than one item There is one form of this method for each of the Java types that is used in the standard mapping of built-in types to Java types; each accepts an array of values the given type. There is an additional form that takes an XSequenceCursor. An XSequenceCursor can be the result of executing another expression or can be constructed using an XItemFactory instance.

  The following example executes the XSLT stylesheet prepared in the first example, first binding values for each of the parameters it will use. It assumes that a Result object called xsltResult has already been created.

```
// Create an xs:date value for the "targetDate" parameter with date "April 10, 2009"
XMLGregorianCalendar date = DatatypeFactory.newInstance().newXMLGregorianCalendarDate(2009, 4, 10, DatatypeConstants.FIELD_UNDEFINED);

// Create a new dynamic context from the factory
XDynamicContext dynamicContext = factory.newDynamicContext();

// Bind an atomic value for the "targetDate" parameter
dynamicContext.bind(new QName("targetDate"), date);

// Bind an atomic value for the "window" parameter
dynamicContext.bind(new QName("window"), 7);
```

```
// Create an XML input document
String xml = "<todo-list>" +
"<task due='2009-03-31' completed=''>File Quarterly Report</task>" +
"<task due='2009-05-04' completed='2009-04-22'>Review candidate resumes</task> +
"<task due='2009-04-16' completed=''>Order stock</task>" +
"<task due='2009-05-01' completed=''>Buy concert tickets</task>" +
"</todo-list>";
StreamSource source = new StreamSource(new StringReader(xml));

// Execute the stylesheet
xslt.execute(source, dynamicContext, xsltResult);
```

Using external functions

The XML API allows you to use external functions with XPath, XQuery, and XSLT.

About this task

You can define external functions when you want to use operations that are difficult or impossible to express directly by core functions defined in functions and operators, additional functions defined in the XSLT specification, constructor functions named after an atomic type, stylesheet functions defined using xsl:function declaration of XSLT, or user-defined functions in XQuery. Please note that external functions cannot be used to override built-in functions. For example, suppose you are using an external function, my:power(arg1 as xs:double, arg2 as xs:double), to calculate the value of the first argument raised to the power of the second argument; you could write a Java method taking two Java primitive double arguments that performs the calculation. The details of using external functions are presented in separate articles.

Procedure

- Use external functions with XPath.
- Use external functions with XQuery.
- Use external functions with XSLT.

Using external functions with XPath:

When using an XPath expression that uses external functions, declare the function signatures using an XStaticContext instance and supply (or bind) a Java implementation for each function using an XDynamicContext instance.

Procedure

1. When preparing an XPath expression that uses external functions, declare the function signatures using an XStaticContext instance.

   The XStaticContext interface has two declareFunction methods that each have three parameters—one for the name, one for the return type of the function, and an array for the types of the arguments. The name is always provided as a QName object, but the types can be QNames or XSequenceTypes. The function name, return type, and argument types must uniquely identify the function.

Table 263. XStaticContext declareFunction methods.

This table explains when to use each form of the declareFunction method.

Method Signature	Purpose
declareFunction(QName name, QName type, QName[] argTypes)	Use when the return value and arguments of the function are all single atomic values The type QNames must refer to built-in types or global types declared in a schema that has been registered on the XFactory instance used to create the XStaticContext instance. If a QName refers to a non-atomic type, the processor will treat it as the type element(*, ns:type), where ns:type is the given QName. The XTypeConstants interface has convenient constants available that provide a QName object for each built-in type.
declareFunction(QName name, XSequenceType type, XSequenceType[] argTypes)	Use when any of the arguments or the return value of the function is a node or a sequence of atomic values or nodes

The following example shows how to prepare an XPath expression that uses an external function.

```
// Create the factory
XFactory factory = XFactory.newInstance();

// Create a new static context
XStaticContext staticContext = factory.newStaticContext();

// Declare a namespace for the function
staticContext.declareNamespace("my", "http://myfunc");

// Create a QName for the name of the function
QName methodQName = new QName("http://myfunc", "pow");

// Declare the function on the static context
staticContext.declareFunction(methodQName, XTypeConstants.DOUBLE_QNAME, new QName[]{XTypeConstants.DOUBLE_QNAME, XTypeConstants.DOUBLE_QNAME});

// Create an XPath executable for the expression
XPathExecutable executable = factory.prepareXPath("sum(/polynomial/term/(my:pow(2, @power) * @coefficient))", staticContext);
```

2. To execute an XPath expression that uses external functions, supply (or bind) the Java methods that implement the functions using an XDynamicContext instance.

   Use Java reflection to obtain a java.lang.reflect.Method object for the function. If the method is an instance method, an instance object is required when binding this function.

   An error is raised if you do not supply a Java method for a function that is used when executing the XPath expression.

   The XDynamicContext has two bindFunction methods. Each requires a QName object corresponding to the name of the function and a Method object identifying the Java method that will provide the implementation for the function.

Table 264. XDynamicContext bindFunction methods.

This table explains when to use each form of the XDynamicContext bindFunction methods.

Method Name	Purpose
bindFunction(QName qname, Method method)	Use when binding a static method
bindFunction(QName qname, Method method, Object instanceObject)	Use when binding an instance method

The following example executes the XPath expression prepared in the first example, first binding a method for the function it uses. In this example, the static pow(double a, double b) method of the java.lang.Math class is used to provide the implementation for the external function.

```
// Create a new dynamic context
XDynamicContext dynamicContext = factory.newDynamicContext();

// Retrieve the java.lang.reflect.Method object for this function
Method method = Math.class.getMethod("pow", Double.TYPE, Double.TYPE);

// Bind the function to the dynamic context
dynamicContext.bindFunction(methodQName, method);

// Create an XML input document
String xml = "<polynomial>" +
"<term power='2' coefficient='3'/>" +
"<term power='1' coefficient='-2'/>" +
"<term power='0' coefficient='1'/>" +
"</polynomial>";
StreamSource source = new StreamSource(new StringReader(xml));

// Execute the expression
XSequenceCursor result = executable.execute(source, dynamicContext);

// Serialize the result to System.out
result.exportItem(new StreamResult(System.out));
```

Using external functions with XQuery:

When using an XQuery expression that uses external functions, declare the function signatures either in the XQuery prolog as external functions or using an XStaticContext instance. Supply (or bind) a Java implementation for each function using an XDynamicContext instance.

Procedure

1. When preparing an XQuery expression that uses external functions, declare the function signatures in the XQuery prolog or using an XStaticContext instance.

   Functions declared in the XStaticContext are only visible to the main module. For an external function to be visible to a library module, it must be declared in the prolog of that library module.

   The XStaticContext interface has two declareFunction methods that each have three parameters—one for the name, one for the return type of the function, and an array for the types of the arguments. The name is always provided as a QName object, but the types can be QNames or XSequenceTypes. The function name, return type, and argument types must uniquely identify the function.

Table 265. XStaticContext declareFunction methods.

This table explains when to use each form of the declareFunction method.

Method Signature	Purpose
declareFunction(QName name, QName type, QName[] argTypes)	Use when the return value and arguments of the function are all single atomic values The type QNames must refer to built-in types or global types declared in a schema that has been registered on the XFactory instance used to create the XStaticContext instance. If a QName refers to a non-atomic type, the processor will treat it as the type element(*, ns:type), where ns:type is the given QName. The XTypeConstants interface has convenient constants available that provide a QName object for each built-in type.
declareFunction(QName name, XSequenceType type, XSequenceType[] argTypes)	Use when any of the arguments or the return value of the function is a node or a sequence of atomic values or nodes

   The following XQuery expression uses three functions, two of which are declared in the prolog.

```
declare namespace xs = "http://www.w3.org/2001/XMLSchema";
declare namespace trig = "http://www.example.org/trigonometry";
declare function trig:arctan($ratio as xs:double) as xs:double external;
declare function trig:sin($angle as xs:double) as xs:double external;

<ramps>
{
    for $ramp in ramps/ramp
    let $angleRadians := trig:arctan($ramp/height div $ramp/base)
    let $angle := trig:toDegrees($angleRadians)
    let $length := $ramp/height div trig:sin($angleRadians)
    return
        element ramp
        {
            $ramp/height,
            $ramp/base,
            element angle { $angle },
            element length { $length }
        }
}
</ramps>
```

   Assuming that the query above is available using the xquerySource Source object, the code below prepares the query. The function that was not declared in the query itself, trig:toDegrees, is declared on the XStaticContext instance.

```
// Create the factory
XFactory factory = XFactory.newInstance();

// Create a new static context
XStaticContext staticContext = factory.newStaticContext();

// Declare a namespace for the functions
staticContext.declareNamespace("trig", "http://www.example.org/trigonometry");

// Create a QName for the trig:toDegrees function
QName toDegreesQName = new QName("http://www.example.org/trigonometry", "toDegrees");

// Declare the function on the static context
staticContext.declareFunction(toDegreesQName, XTypeConstants.DOUBLE_QNAME, new QName[]{XTypeConstants.DOUBLE_QNAME});

// Create an XQuery executable for the query
XQueryExecutable executable = factory.prepareXQuery(xquerySource, staticContext);
```

2. To execute an XQuery expression that uses external functions, supply (or bind) the Java methods that implement the functions using an XDynamicContext instance.

The bindings for external functions will be available to the main module and to any library modules that have an external function declaration in their prolog for that function.

Use Java reflection to obtain a java.lang.reflect.Method object for the function. If the method is an instance method, an instance object is required when binding this function.

An error is raised if you do not supply a Java method for a function that is used when executing the XQuery expression.

The XDynamicContext has two bindFunction methods. Each requires a QName object corresponding to the name of the function and a Method object identifying the Java method that will provide the implementation for the function.

Table 266. XDynamicContext bindFunction methods.

This table explains when to use each form of the XDynamicContext bindFunction methods.

Method Name	Purpose
bindFunction(QName qname, Method method)	Use when binding a static method
bindFunction(QName qname, Method method, Object instanceObject)	Use when binding an instance method

The following example executes the XQuery expression prepared in the first example, first binding methods for the functions it uses. In this example, the static atan, sin, and toDegrees methods of the java.lang.Math class are used to provide the implementations for the external functions.

```
// Create a new dynamic context
XDynamicContext dynamicContext = factory.newDynamicContext();

// Retrieve the java.lang.reflect.Method object for the trig:toDegrees function
Method toDegreesMethod = Math.class.getMethod("toDegrees", Double.TYPE);

// Bind the function to the dynamic context
dynamicContext.bindFunction(toDegreesQName, toDegreesMethod);

// Create QNames for the trig:arctan and trig:sin functions
QName arctanQName = new QName("http://www.example.org/trigonometry", "arctan");
QName sinQName = new QName("http://www.example.org/trigonometry", "sin");

// Retrieve the java.lang.reflect.Method objects for the trig:arctan and trig:sin functions
// then bind them to the dynamic context
Method arctanMethod = Math.class.getMethod("atan", Double.TYPE);
Method sinMethod = Math.class.getMethod("sin", Double.TYPE);
dynamicContext.bindFunction(arctanQName, arctanMethod);
dynamicContext.bindFunction(sinQName, sinMethod);

// Create an XML input document
String xml = "<ramps>" +
"<ramp><base>4</base><height>4</height></ramp>" +
"<ramp><base>4</base><height>3</height></ramp>" +
"<ramp><base>10</base><height>2</height></ramp>" +
"</ramps>";
StreamSource source = new StreamSource(new StringReader(xml));

// Execute the query
XSequenceCursor result = executable.execute(source, dynamicContext);

// Serialize the result to System.out
result.exportItem(new StreamResult(System.out));
```

Using query-declared external functions with XQuery:

As an alternative to binding Java methods to functions in a query using the API, Java external functions can be declared directly within a query. The only additional configuration required is for bound Java classes to exist on the classpath during query execution.

Procedure

Using the java-extension XQuery option declaration, you can bind a prefix to a Java class.

```
declare option xltxe:java-extension "prefix = className";
```

Note: Any prefix name can be used for the java-extension element as long as it is bound to the `http://www.ibm.com/xmlns/prod/xltxe-j` namespace.

After binding a prefix to a Java class, methods within the bound class can be invoked by specifying the prefix and method name separated by a colon:

prefix:methodName(Params*)

Example

Invoking Static Methods

When preparing an XQuery source that uses query-declared external functions, declare the prefix to Java class binding:

```
declare namespace calc="http://com.example/myApp/Calculator";
declare namespace sf="http://com.example/myApp/standardFormat";

declare namespace xltxe="http://www.ibm.com/xmlns/prod/xltxe-j";
declare option xltxe:java-extension "calc = org.company.Calculator";
declare option xltxe:java-extension "sf = org.standards.Formatter";

sf:format(calc:sqrt(64), "ISO-42.7")
```

Assuming that this query is available through the xquerySource Source object, the following code prepares the query:

```
// Create the factory
XFactory factory = XFactory.newInstance();

// Create an XQuery executable for the query
XQueryExecutable executable = factory.prepareXQuery(xquerySource);
```

The following code executes the query that was prepared in the example:

```
// Create a result object to store the transformation result
Result result = new StreamResult(System.out);

// Execute the XSLT executable
XSequenceCursor xsc = executable.execute();

// Output the result
xsc.exportSequence(res);
```

The example query provided assumes that the org.company.Calculator class contains a static method sqrt() that takes one parameter and the org.standards.Formatter class contains a static method format() that takes two parameters. At prepare time, the classes are not required on the classpath; but they are required during execution of the query.

The following are example implementations of the org.company.Calculator and org.standards.Formatter classes:

```
package org.company;

public class Calculator {
    public static int sqrt(int val) {
        return (int)Math.sqrt(val);
    }
```

```
package org.standards;

public class Formatter {
    public static String format(int val, String pattern) {
        return "Formatting " + val + " using pattern " + pattern;
    }
}
```

Invoking Instance Methods

Invoking instance methods from a class is slightly different from invoking static methods because of the requirement for an instance object. In order to obtain an instance object from a Java class within a query, you must invoke its new constructor:

```
prefix:new(Params*)
```

You can then store the result in an XQuery variable declaration as demonstrated by the following query:

```
declare namespace car="http://com.example/myApp/car";
declare namespace xltxe="http://www.ibm.com/xmlns/prod/xltxe-j";
declare option xltxe:java-extension "car = org.automobile.Car";
declare variable $var := car:new(3);

car:getDoors($var)
```

Assuming that this query is available through the xquerySource Source object, the following code prepares the query.

```
// Create the factory
XFactory factory = XFactory.newInstance();

// Create an XQuery executable for the query
XQueryExecutable executable = factory.prepareXQuery(xquerySource);
```

The following code executes the query prepared in the example:

```
// Create a result object to store the transformation result
Result result = new StreamResult(System.out);

// Execute the XSLT executable
XSequenceCursor xsc = executable.execute();

// Output the result
xsc.exportSequence(res);
```

The example query assumes that org.automobile.Car class contains a constructor that takes an argument of type int. In addition, the org.automobile.Car class also contains an instance method getDoors() that takes no arguments. The syntax for invoking instance methods from query-declared external functions require that the created instance object be passed in as the first argument.

The following is an example implementation of the org.automobile.Car class:

```
package org.automobile;

public class Car {
    private int doors;

    public Car (int doors) {
        this.doors = doors;
    }

    public int getDoors() {
        return doors;
    }
}
```

Inheritance with instance methods is also supported. If the org.automobile.Car class has a subclass org.automobile.Sedan, you can create an instance of the org.automobile.Sedan class and use it to call methods in org.automobile.Car. This is demonstrated by the following query:

```
declare namespace car="http://com.example/myApp/car";
declare namespace sedan="http://com.example/myApp/sedan";
declare namespace xltxe="http://www.ibm.com/xmlns/prod/xltxe-j";
declare option xltxe:java-extension "car = org.automobile.Car";
```

```
declare option xltxe:java-extension "sedan = org.automobile.Sedan";

declare variable $var := sedan:new(5);

car:getDoors($var)
```

The following is an example implementation for org.automobile.Sedan:

```
package org.automobile;

public class Sedan extends Car {
    public Sedan (int doors) {
        super(doors);
    }
}
```

Limitation: The mechanism used for resolving methods in a Java class requires that only one method exists, matching in name and arity. If multiple methods exist with the same name and different arity, an error is thrown.

Using external functions with XSLT:

When using an XSLT stylesheet that uses external functions, declare the function signatures using an XStaticContext instance and supply (or bind) a Java implementation for each function using an XDynamicContext instance.

Procedure

1. When preparing an XSLT stylesheet that uses external functions, declare the function signatures using an XStaticContext instance.

   The XStaticContext interface has two declareFunction methods that each have three parameters—one for the name, one for the return type of the function, and an array for the types of the arguments. The name is always provided as a QName object, but the types can be QNames or XSequenceTypes. The function name, return type, and argument types must uniquely identify the function.

   A stylesheet function could have the same name as an external function. If the stylesheet function has an override attribute with the value of yes, any reference to that function name in the stylesheet is a reference to the stylesheet function; if it has an override attribute with the value of no, it is a reference to the external function.

Table 267. XStaticContext declareFunction methods.

This table explains when to use each form of the declareFunction method.

Method Signature	Purpose
declareFunction(QName name, QName type, QName[] argTypes)	Use when the return value and arguments of the function are all single atomic values The type QNames must refer to built-in types or global types declared in a schema that has been registered on the XFactory instance used to create the XStaticContext instance. If a QName refers to a non-atomic type, then the processor will treat it as the type element(*, ns:type), where ns:type is the given QName. The XTypeConstants interface has convenient constants available that provide a QName object for each built-in type.
declareFunction(QName name, XSequenceType type, XSequenceType[] argTypes)	Use when any of the arguments or the return value of the function is a node or a sequence of atomic values or nodes

The following stylesheet uses an external function referred to by the QName ext:pow.

```
<?xml version="1.0"?>
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
                xmlns:ext="http://www.example.com/functions"
                version="2.0">

    <xsl:output method="text"/>

    <xsl:template match="polynomial">
        <xsl:variable name="p" select="."/>
```

```
        <xsl:for-each select="1 to 5">
            <xsl:text>x = </xsl:text>
            <xsl:value-of select="."/>
            <xsl:text>; </xsl:text>
            <xsl:value-of select="for $t in $p/term return concat($t/@coefficient, 'x^', $t/@power)"
                          separator=" + "/>
            <xsl:text> = </xsl:text>
            <xsl:value-of select="sum($p/term/(ext:pow(current(), @power) * @coefficient))"/>
            <xsl:text>&#xA;</xsl:text>
        </xsl:for-each>
    </xsl:template>

</xsl:stylesheet>
```

Assuming that the stylesheet above is available using the xsltSource Source object, the code below prepares the stylesheet.

```
// Create the factory
XFactory factory = XFactory.newInstance();

// Create a new static context
XStaticContext staticContext = factory.newStaticContext();

// Declare a namespace for the function
staticContext.declareNamespace("ext", "http://www.example.com/functions");

// Create a QName for the name of the function
QName methodQName = new QName("http://www.example.com/functions", "pow");

// Declare the function on the static context
staticContext.declareFunction(methodQName, XTypeConstants.DOUBLE_QNAME, new QName[]{XTypeConstants.DOUBLE_QNAME, XTypeConstants.DOUBLE_QNAME});

// Create an XSLT executable for the stylesheet
XSLTExecutable executable = factory.prepareXSLT(xsltSource, staticContext);
```

2. To execute an XSLT stylesheet that uses external functions, supply (or bind) the Java methods that implement the functions using an XDynamicContext instance.

   Use Java reflection to obtain a java.lang.reflect.Method object for the function. If the method is an instance method, an instance object is required when binding this function.

   An error is raised if you do not supply a Java method for a function that is used when executing the XSLT stylesheet.

   The XDynamicContext has two bindFunction methods. Each requires a QName object corresponding to the name of the function and a Method object identifying the Java method that will provide the implementation for the function.

Table 268. XDynamicContext bindFunction methods.

This table explains when to use each form of the XDynamicContext bindFunction methods.

Method Name	Purpose
bindFunction(QName qname, Method method)	Use when binding a static method
bindFunction(QName qname, Method method, Object instanceObject)	Use when binding an instance method

The following example executes the XSLT stylesheet prepared in the first example, first binding a method for the function it uses. In this example, the static pow(double a, double b) method of the java.lang.Math class is used to provide the implementation for the external function.

```
// Create a new dynamic context
XDynamicContext dynamicContext = factory.newDynamicContext();

// Retrieve the java.lang.reflect.Method object for this function
Method method = Math.class.getMethod("pow", Double.TYPE, Double.TYPE);

// Bind the function to the dynamic context
dynamicContext.bindFunction(methodQName, method);

// Create an XML input document
String xml = "<polynomial>" +
"<term power='2' coefficient='3'/>" +
"<term power='1' coefficient='-2'/>" +
"<term power='0' coefficient='1'/>" +
"</polynomial>";
StreamSource source = new StreamSource(new StringReader(xml));

// Execute the stylesheet
XSequenceCursor result = executable.execute(source, dynamicContext);
```

```
// Serialize the result to System.out
result.exportItem(new StreamResult(System.out), executable.getOutputParameters());
```

Using stylesheet-declared external functions with XSLT:

As an alternative to binding Java methods to functions in a stylesheet using the API, Java external functions can be declared directly within a stylesheet. The only additional configuration required is for bound Java classes to exist on the classpath during stylesheet execution.

Procedure

Using the java-extension element, you can bind a prefix to a Java class.

```
<xltxe:java-extension
prefix = string
class = string />
```

Note: Any prefix name can be used for the java-extension element as long as it is bound to the `http://www.ibm.com/xmlns/prod/xltxe-j` namespace.

After binding a prefix to a Java class, methods within the bound class can be invoked by specifying the prefix and method name separated by a colon:

prefix:methodName(Params*)

Example

Invoking Static Methods

When preparing an XSLT stylesheet that uses stylesheet-declared external functions, declare the prefix to Java class binding:

```
<xsl:stylesheet version="2.0"
     xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
     xmlns:xltxe="http://www.ibm.com/xmlns/prod/xltxe-j"
     xmlns:calc="http://com.example/myApp/calculator"
     xmlns:sf="http://com.example/myApp/standardFormat">

<xltxe:java-extension prefix="calc" class="org.company.Calculator"/>
<xltxe:java-extension prefix="sf" class="org.standards.Formatter"/>

<xsl:template match="/">
     <xsl:value-of select="sf:format(calc:sqrt(64), 'ISO-42.7')"/>
</xsl:template>

</xsl:stylesheet>
```

Assuming that this stylesheet is available through the xsltSource Source object, the following code prepares the stylesheet:

```
// Create the factory
XFactory factory = XFactory.newInstance();

// Create an XSLT executable for the stylesheet
XSLTExecutable executable = factory.prepareXSLT(xsltSource);
```

The following code executes the stylesheet that was prepared in the example:

```
// Create the xml input
String xml = "<doc/>";

// Create a result object to store the transformation result
Result result = new StreamResult(System.out);

// Execute the XSLT executable
executable.execute(new StreamSource(new ByteArrayInputStream(xml.getBytes())), result);
```

The example stylesheet provided assumes that the org.company.Calculator class contains a static method sqrt() that takes one parameter and the org.standards.Formatter class contains a static method format() that takes two parameters. At prepare time, the classes are not required on the classpath; but they are required during execution of the stylesheet.

The following are example implementations of the org.company.Calculator and org.standards.Formatter classes:

```
package org.company;

public class Calculator {
    public static int sqrt(int val) {
        return (int)Math.sqrt(val);
    }
}
```

```
package org.standards;

public class Formatter {
    public static String format(int val, String pattern) {
        return "Formatting " + val + " using pattern " + pattern;
    }
}
```

Invoking Instance Methods

Invoking instance methods from a class is slightly different from invoking static methods because of the requirement for an instance object. In order to obtain an instance object from a Java class within a stylesheet, you must invoke its new constructor:

```
prefix:new(Params*)
```

You can then store the result in an xsl:variable element as demonstrated by the following stylesheet:

```
<xsl:stylesheet version="2.0"
     xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
     xmlns:xltxe="http://www.ibm.com/xmlns/prod/xltxe-j"
     xmlns:car="http://com.example/myApp/car">

<xltxe:java-extension prefix="car" class="org.automobile.Car"/>

<xsl:variable name="var" select="car:new(3)"/>

<xsl:template match="/">
     <xsl:value-of select="car:getDoors($var)"/>
</xsl:template>

</xsl:stylesheet>
```

Assuming that this stylesheet is available through the xsltSource Source object, the following code prepares the stylesheet.

```
// Create the factory
XFactory factory = XFactory.newInstance();

// Create an XSLT executable for the stylesheet
XSLTExecutable executable = factory.prepareXSLT(xsltSource);
```

The following code executes the stylesheet prepared in the example:

```
// Create the xml input
String xml = "<doc/>";

// Create a result object to store the transformation result
Result result = new StreamResult(System.out);
```

```
// Execute the XSLT executable
executable.execute(new StreamSource(new ByteArrayInputStream(xml.getBytes())), result);
```

The example stylesheet assumes that the org.automobile.Car class contains a constructor that takes an argument of type int. In addition, the org.automobile.Car class also contains an instance method getDoors() that takes no arguments. The syntax for invoking instance methods from stylesheet-declared external functions require that the created instance object be passed in as the first argument.

The following is an example implementation of the org.automobile.Car class:

```
package org.automobile;

public class Car {
    private int doors;

    public Car (int doors) {
        this.doors = doors;
    }

    public int getDoors() {
        return doors;
    }
}
```

Inheritance with instance methods is also supported. If the org.automobile.Car class has a subclass org.automobile.Sedan, you can create an instance of the org.automobile.Sedan class and use it to call methods in org.automobile.Car. This is demonstrated by the following stylesheet:

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="2.0"
     xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
     xmlns:xltxe="http://www.ibm.com/xmlns/prod/xltxe-j"
     xmlns:sedan="http://com.example/myApp/sedan"
     xmlns:car="http://com.example/myApp/car">

<xltxe:java-extension prefix="sedan" class="org.automobile.Sedan"/>
<xltxe:java-extension prefix="car" class="org.automobile.Car"/>

<xsl:variable name="var" select="sedan:new(5)"/>

<xsl:template match="/">
     <xsl:value-of select="car:getDoors($var)"/>
</xsl:template>

</xsl:stylesheet>
```

The following is an example implementation for org.automobile.Sedan:

```
package org.automobile;

public class Sedan extends Car {
    public Sedan (int doors) {
        super(doors);
    }
}
```

Limitation: The mechanism used for resolving methods in a Java class requires that only one method exists, matching in name and arity. If multiple methods exist with the same name and different arity, an error is thrown.

Creating items and sequences

You can use this information to help you to create items and sequences using the XItemFactory as well as to use sequence types.

Procedure

- Create items and sequences using the XItemFactory.
- Use sequence types.

Creating items and sequences using the XItemFactory

You can use XItemFactory to create new items and sequences of items of different types.

Procedure

- Use the getItemFactory method in the XFactory class to create instances of XItemFactory and call the appropriate item method to create an item of a specific type.

  An item itself can be a node or an atomic value such as an integer, string, or boolean.

  The following is an example of using the XItemFactory to create new items of different types.

```
// Create an XFactory
XFactory factory = XFactory.newInstance();

// Create an XItemFactory
XItemFactory itemFactory = factory.getItemFactory();

// Create a new atomic item of a type which is the default mapping of the xs:string built-in type to java.lang.String
XItemView stringItem = itemFactory.item("Lets see");

// Create a new atomic item of type int
XItemView intItem = itemFactory.item(3, XTypeConstants.INT_QNAME);

// Create a new atomic item of type boolean
boolean boolValue = false;
XItemView booleanItem = itemFactory.item(boolValue, XTypeConstants.BOOLEAN_QNAME);

 // Create Node type
DocumentBuilderFactory dbf = DocumentBuilderFactory.newInstance();
DocumentBuilder db = dbf.newDocumentBuilder();
// Parse the input file
Document doc = db.parse(INPUT_File);
Node node = doc.getFirstChild();
XItemView item =itemFactory.item(node)

 // Create a new item of complex type from a Source
StreamSource source = new StreamSource(INPUT_File);
XItemView complexItem = itemFactory.item(source);
```

  As shown in the example, you can use item method with one argument as the value of the method and the type is evaluated based on the mapping rules between built-in types and Java types.

- Use the getItemFactory method in the XFactory class to create instances of XItemFactory and call the appropriate sequence method to create an XSequenceCursor that represents a sequence of items providing cursor access to the items in the sequence.

  The following is an example of using XItemFactory to create a homogeneous sequence.

```
// Create an XFactory
XFactory factory = XFactory.newInstance();

// Create an XItemXFactory
XItemFactory itemFactory =xfactory.getItemFactory();

//Create a sequence of int values
XSequenceCursor intSeq = xfactory.sequence(new int[]{1,2,3});

//Create a sequence of String values
XSequenceCursor stringSeq = xfactory.sequence(new String[]{"This", "is", "a", "test"},XTypeConstants.STRING_QNAME );
```

  The following is an example of using the XItemFactory to create a sequence of items of different types.

```
// Create an XFactory
XFactory factory = XFactory.newInstance();

// Create an XItemXFactory
XItemFactory itemFactory = factory.getItemFactory();

//Create an Array of the newly created items
XItemView[] items = new XItemView[2];
items[0] =itemFactory.item(boolValue, XTypeConstants.BOOLEAN_QNAME);
items[1] = itemFactory.item(intValue, XTypeConstants.INT_QNAME);

// Create a sequence of items
XSequenceCursor seq = itemFactory.sequence(items);
```

Using sequence types

You can use sequence types when declaring variables for the return or parameter types of functions.

About this task

In the XML API, sequence types are represented using XSequenceType objects. XSequenceType objects can represent the same set of sequence types as the SequenceType syntax defined in XPath 2.0. XSequenceType objects are created through the XSequenceTypeFactory interface. You can obtain an instance of XSequenceTypeFactory using the getSequenceTypeFactory() method on an XFactory instance.

Procedure

- XSequenceTypeFactory has several methods for creating XSequenceType instances.

  Each method on the XSequenceTypeFactory interface has an XSequenceType.OccurrenceIndicator parameter except for emptySequence(). OccurrenceIndicator is an enum that represents the cardinality of the sequence; ZERO_OR_ONE corresponds to "?" in SequenceType syntax, ZERO_OR_MORE to "*", ONE_OR_MORE to "+", and ONE to no occurrence indicator for sequences of exactly one item.
- The XSequenceTypeFactory interface methods use QNames to refer to the names of nodes such as elements and attributes, and also to types and global element and attribute declarations.

  QNames representing types must refer to built-in types or to types defined in schemas that have been registered with the same XFactory instance used to obtain the XSequenceTypeFactory instance. Similarly, QNames representing global element or attribute declarations must refer to global declarations present in schemas that have been registered with the same XFactory instance.

Example

Table 269. XSequenceTypeFactory methods and examples of sequence types. The following table lists each method of the XSequenceTypeFactory and gives examples of the sequence types (using SequenceType syntax) that each can create.

Method Signature	Example Sequence Types	Comments
emptySequence()	empty-sequence()	
item(OccurrenceIndicator cardinality)	item()*	
atomic(QName typeName, OccurrenceIndicator cardinality)	xs:integer	"sc:type" is a QName referring to a user-defined schema type.
	sc:type+	
documentNode(OccurrenceIndicator cardinality)	document-node()?	
documentNodeWithElement(QName elementNameOrWildcard, QName typeName, boolean nillable, OccurrenceIndicator cardinality)	document-node(element())	"ns:elem" is a QName representing an element name, and "sc:type" is a QName referring to a user-defined schema type. The elementNameOrWildcard and typeName parameters are optional; use null if the element name or type does not matter.
	document-node(element(ns:elem))?	
	document-node(element(*, sc:type?))	
documentNodeWithSchemaElement(QName elementName, OccurrenceIndicator cardinality)	document-node(schema-element(sc:elemDecl))	"sc:elemDecl" is a QName referring to a global element declaration in a schema.
element(QName elementNameOrWildcard, QName typeName, boolean nillable, OccurrenceIndicator cardinality)	element(*)	"ns:elem" is a QName representing an element name, and "sc:type" is a QName referring to a user-defined schema type. The elementNameOrWildcard and typeName parameters are optional; use null if the element name or type does not matter.
	element(ns:elem, sc:type)*	
attribute(QName attributeNameOrWildcard, QName typeName, OccurrenceIndicator cardinality)	attribute()+	"ns:attrib" is a QName representing an attribute name. The attributeNameOrWildcard and typeName parameters are optional; use null if the attribute name or type does not matter.
	attribute(ns:attrib)	
	attribute(ns:attrib, xs:string)?	
schemaElement(QName elementName, OccurrenceIndicator cardinality)	schema-element(sc:elemDecl)*	"sc:elemDecl" is a QName referring to a global element declaration in a schema.
schemaAttribute(QName attributeName, OccurrenceIndicator cardinality)	schema-attribute(sc:attribDecl)	"sc:attribDecl" is a QName referring to a global attribute declaration in a schema.

Table 269. XSequenceTypeFactory methods and examples of sequence types (continued). The following table lists each method of the XSequenceTypeFactory and gives examples of the sequence types (using SequenceType syntax) that each can create.

Method Signature	Example Sequence Types	Comments
processingInstruction(QName piNCName, OccurrenceIndicator cardinality)	processing-instruction()?	"pinst" is an NCName representing the name of a processing instruction.
	processing-instruction("pinst")	
	processing-instruction(pinst)	
comment(OccurrenceIndicator cardinality)	comment()	
text(OccurrenceIndicator cardinality)	text()+	
node(OccurrenceIndicator cardinality)	node()*	

The following example shows how to create XSequenceType objects to represent various sequence types. Some of the results refer to types and declarations from a schema. The example assumes that the schema is available through the schemaSource source object.

```
// Create the factory
XFactory factory = XFactory.newInstance();

// Obtain an XSeqeuenceTypeFactory instance
XSequenceTypeFactory stFactory = factory.getSequenceTypeFactory();

// Create a sequence type for a sequence of xs:integer values: "xs:integer*"
XSequenceType integerSequenceType = stFactory.atomic(
        XTypeConstants.INTEGER_QNAME,
        XSequenceType.OccurrenceIndicator.ZERO_OR_MORE);

// Create a sequence type for a single node: "node()"
XSequenceType nodeType = stFactory.node(OccurrenceIndicator.ONE);

// Define a constant for the target namespace of a schema containing user-defined types and declarations
final String targetNamespace = "http://www.example.org/schema/";

// Register the schema with the XFactory
factory.registerSchema(schemaSource);

// Create a sequence type for exactly one document node with an element of type "employeeRecord" from the schema:
// "document-node(element(*, ns:employeeRecord))"
XSequenceType employeeRecordDocumentType = stFactory.documentNodeWithElement(
        null,
        new QName(targetNamespace, "employeeRecord"),
        false,
        XSequenceType.OccurrenceIndicator.ONE);

// Create a sequence type for an optional attribute matching the attribute declaration "type" in the schema:
// "schema-attribute(ns:type)?"
XSequenceType optionalEmployeeType = stFactory.schemaAttribute(
        new QName(targetNamespace, "type"),
        XSequenceType.OccurrenceIndicator.ZERO_OR_ONE);

// Create a sequence type for one or more atomic values of type "telephoneNumber" from the schema:
// "ns:telephoneNumber+"
XSequenceType telephoneNumbersType = stFactory.atomic(
        new QName(targetNamespace, "telephoneNumber"),
        XSequenceType.OccurrenceIndicator.ONE_OR_MORE);
```

Contents of sample schema:

```
<?xml version="1.0" encoding="UTF-8"?>
<schema xmlns="http://www.w3.org/2001/XMLSchema" xmlns:ns="http://www.example.org/schema/" targetNamespace="http://www.example.org/schema/">
    <complexType name="employeeRecord">
        <sequence>
            <element name="name" type="string"></element>
            <element name="id" type="int"></element>
            <element name="telephone" type="ns:telephoneNumber"></element>
        </sequence>
        <attribute ref="ns:type"></attribute>
    </complexType>

    <simpleType name="telephoneNumber">
        <restriction base="string">
            <pattern value="\d{3}-\d{3}-\d{4}"></pattern>
        </restriction>
    </simpleType>

    <element name="employee" type="ns:employeeRecord"></element>

    <simpleType name="employeeType">
        <restriction base="string">
            <enumeration value="full-time"></enumeration>
```

```
            <enumeration value="part-time"></enumeration>
            <enumeration value="seasonal"></enumeration>
        </restriction>
    </simpleType>

    <attribute name="type" type="ns:employeeType"></attribute>
</schema>
```

Working with collations

XSLT stylesheets and expressions in XQuery and XPath can refer to collations using collation URIs. A collation is a set of culture-specific rules that define how text should be sorted and which differences between two pieces of text are considered significant and which insignificant.

Before you begin

This article assumes some basic familiarity with the java.util.Locale and java.text.Collator classes.

About this task

The processor does not interpret the collation URI in any way -- it treats a collation URI merely as a sort of name for the instance of the Java Collator class that is associated with that URI. The XML API provides mechanisms for specifying what will be the default collation URI at preparation-time and for associating an instance of the Java Collator class with a collation URI at execution-time.

All collation URIs specified through the XML API must be absolute URI references. In an XSLT stylesheet or an XQuery or XPath expression, any relative URI reference that is used in a context where a collation URI is required will be resolved against the base URI from the static context for that expression -- that will ensure that even relative URI references in the stylesheet or expression can be matched with the absolute URI references specified through the XML API.

Limitations:

- If a collation URI is bound with an instance of the Java Collator class that is not an instance of java.text.RuleBasedCollator, certain operations will not be permitted with that collation URI. In particular, the fn:starts-with, fn:ends-with, fn:contains, fn:substring-before and fn:substring-after functions are not supported with that collation URI.
- All instances of Collator that are currently included with the Java runtime environment are also instances of java.text.RuleBasedCollator, so this is for most purposes only a theoretical limitation. However, it is something to be aware of if an application defines its own instances of the Java Collator class or defines subclasses the Collator class that are not also instances of java.text.RuleBasedCollator.

Procedure

- Declare the default collation URI.

  You can specify what collation URI you want to use as the default for string comparison operations by using the method setDefaultCollation method on the XStaticContext interface. The default collation URI from the XStaticContext interface will be used as the collation URI in string comparison operations that do not explicitly specify a collation URI.

  An XQuery expression can override the default collation URI specified on the XStaticContext interface with the declare default collation declaration. Similarly, an XSLT stylesheet can override the default collation URI with the [xsl:]default-collation attribute. XPath does not provide a means of overriding the default collation URI. However, any XPath or XQuery expression or XSLT stylesheet that performs string comparison operations can specify an explicit collation URI to override the default collation URI.

  If you do not explicitly specify a default collation on any instance of the XStaticContext interface you supply when you prepare your XSLT stylesheet or your XQuery or XPath expression, the default collation URI for the stylesheet or expression will be the Unicode code-point collation URI: http://www.w3.org/2005/xpath-functions/collation/codepoint/.

You can use the Unicode code-point collation in situations where characters must be identical Unicode characters to be considered to be equal. The lexicographical ordering defined by this collation is determined by the Unicode code points of the characters -- that is, by their positions on the Unicode code charts. As such, using the Unicode code-point collation will yield much better performance than collations that perform string comparisons in a culture-specific manner, but its unlikely to give very satisfactory results for sorting operations.

The following is a simple example showing how to specify the default collation URI on an instance of the XStaticContext interface.

```
// Setting of default collation URI is not changed - default remains
// the Unicode code point collation URI
XFactory factory = XFactory.newInstance();
XPathExecutable maxPath1 = factory.prepareXPath("max($var)");

// A new default collation URI is specified in the static context
// That URI is used in any string comparison for which no other
// explicit collation URI is specified
XStaticContext sc = factory.newStaticContext();
sc.setDefaultCollation("http://example.org/my-collation");
XPathExecutable maxPath2 = factory.prepareXPath("max($var)", sc);
```

- Bind a collation URI.

  The XML API provides two methods for binding collation URI with an instance of the Java Collator class for an execution. The bindCollation methods on the XDynamicContext method have two arguments: the first argument is a collation URI; the second is either instance of the java.text.Collator class or an instance of the java.util.Locale class. If an instance of the locale class is specified, the processor will use the instance of the Collator class that is appropriate for that locale.

  XSLT, XPath and XQuery define the concept of “Statically Known Collations”. If a reference to a collation URI appears in an XSLT stylesheet or an XPath or XQuery expression, and the collation URI is not one of the Statically Known Collations, a static error is supposed to be reported in some circumstances. However, the processor treats all collation URIs as if they were in the set of Statically Known Collations. This is due to the fact that instances of the Java Collator class are not actually associated with collation URIs until execution time, so it is not possible for the processor to determine statically which collation URIs are not known. Instead, the processor will report a dynamic error if a collation URI that is not bound to an instance of the Collator class is used in a stylesheet or expression.

  You cannot bind the Unicode code-point collation URI to any instance of the Java Collator class. It is always implicitly bound with the Unicode code-point collation.

  The following example demonstrates how you can bind a collation URI with a specific instance of the Java Collator class on an instance of the XDynamicContext interface.

```
XFactory factory = XFactory.newInstance();
XStaticContext sc = factory.newStaticContext();
// Set up a default collation URI
sc.setDefaultCollation("http://example.org/my-collation");

// Prepare an XPath expression that computes fn:max() using the
// collator associated with the default collation URI and again using
// the Unicode code point collation
String expr =
    "max($var)," +
    "max($var,'http://www.w3.org/2005/xpath-functions/collation/codepoint')";
XPathExecutable maxPath =
    factory.prepareXPath(expr, sc);
XDynamicContext dc = factory.newDynamicContext();
// Set the value of the variable $var
dc.bind(new QName("var"),
        new String[] {"encyclopaedia",
                      // U+00E6 is lower case latin ae ligature
                      "encyclop\u00E6dia",
                      "encyclopedia"});
// Set up a Collator for English that does not distinguish between
// capitals, lower-case letters and certain character variants
Collator english =
    (Collator) Collator.getInstance(Locale.ENGLISH).clone();
english.setStrength(Collator.SECONDARY);
// Evaluate the expression with that English collator associated with
// the default collation URI
dc.bindCollation("http://example.org/my-collation", english);
XSequenceCursor maxValues = maxPath.execute(dc);
// Print maximum values - expected results are
// encyclopedia for English collation and
// encyclop\u00E6dia for Unicode code point collation
if (maxValues != null) {
```

```
    do {
        System.out.println(maxValues.getStringValue());
    } while (maxValues.toNext());
}
```

Executing using the command-line tools

You can use the ExecuteXSLT tool to execute a stylesheet, use the ExecuteXPath tool to execute an XPath expression, and use the ExecuteXQuery tool to execute an XQuery expression.

Procedure

- **Execute XSLT**

  Location

  The product includes the following script that sets up the environment and invokes the tool.

  Syntax

  Parameters

  -outputfile *file*

  Specifies that output should go to the specified file

  By default, the output is sent to standard out.

  -baseURI *URI*

  Specifies the base URI of the containing element

  -useCompiler

  Specifies compiler modes

  If this parameter is not specified, the default behavior is to use interpreted mode.

  -bindVar name=*varName* **value=***varValue*

  Bind an atomic value to a variable (XPath, XQuery) or a param (XSLT)

  The value must be valid for the type that was specified in the static context (XPath), in the query (XQuery), or in the stylesheet (XSLT) for the same name.

  varName

  Name of the variable (expressed localPart,namespaceURI)

  Notes:

  - If the variable is in no namespace, the namespace URI should be omitted.
  - If the value of any option contains a blank space, enclose it in quotation marks.
  - Localpart is a required value.

  varValue

  Variable value

  The -bindVar option can be used multiple times.

  For example:

```
-bindVar name=la,"http://www.ibm.com/Los Angeles" value="some value"
```

  -baseOutputURI *URI*

  Specifies the base URI to use when resolving result documents

  The default is either the base URI for the main result document or the current working directory.

  This option only applies when working with XSLT.

-XSLTinitMode *mode*
Specifies a mode to use as the initial mode in an XSLT transformation (expressed localPart,namespaceURI)

This option only applies when working with XSLT.

For example:

```
-XSLTinitMode la,"http://www.ibm.com/Los Angeles"
```

-XSLTinitTemplate *template*
Specifies a named template to use as the initial template in an XSLT transformation (expressed localPart,namespaceURI)

If a named template is not set, the initial template is determined by the initial mode, context node, and template matching rules.

This option only applies when working with XSLT.

For example:

```
-XSLTinitTemplate la,"http://www.ibm.com/Los Angeles"
```

-v Prints the version of the tool

-h Prints the usage statement

-input *file*
Specifies the full path to a file containing an XML artifact against which the stylesheet will be executed

stylesheet
Specifies the full path to a file containing the XSL stylesheet

The following is a basic example of executing a stylesheet using the ExecuteXSLT tool:

- **Execute an XPath expression**

  Location
  The product includes the following script that sets up the environment and invokes the tool.

  Syntax

  Parameters

  -outputfile *file*
  Specifies that output should go to the specified file

  By default, the output is sent to standard out.

  -cpm *mode*
  Specifies an alternate XPath compatibility mode

  Valid values are Latest, 1.0, and 2.0.

  The default is 2.0.

  -ns *prefix*=*URI*
  Specifies a namespace for use during static processing

  If the value of any option contains a blank space, enclose it in quotation marks.

  This option can be used multiple times.

  -schema *URI*
  Specifies any schema document that is used to populate the in-scope schema definitions

  This option can be used multiple times.

-var name=*varName* **type=***varType*

Adds a variable binding to the static context for a single item

This simply declares the variable, and a value also must be bound to the XDynamicContext.

varName

Indicates the name of the variable (expressed localPart,namespaceURI)

If the variable is in no namespace, the namespace URI should be omitted.

Localpart is a required value.

varType

Indicates the type of the variable (expressed localPart[, namespaceURI])

If the value of any option contains a blank space, enclose it in quotation marks.

This option can be used multiple times.

For example:

```
-var name=la,"http://www.ibm.com/Los Angeles" type=boolean,http://www.w3.org/2001/XMLSchema
```

-baseURI *URI*

Specifies the base URI of the containing element

-dnet *URI*

Specifies a default namespace URI for element and type names

The namespace URI, if present, is used for any unprefixed QName appearing in a position where an element or type name is expected.

-useCompiler

Specifies compiler modes

If this parameter is not specified, the default behavior is to use interpreted mode.

-bindVar name=*varName* **value=***varValue*

Bind an atomic value to a variable (XPath, XQuery) or a param (XSLT)

The value must be valid for the type that was specified in the static context (XPath), in the query (XQuery), or in the stylesheet (XSLT) for the same name.

varName

Name of the variable (expressed localPart,namespaceURI)

Notes:

- If the variable is in no namespace, the namespace URI should be omitted.
- If the value of any option contains a blank space, enclose it in quotation marks.
- Localpart is a required value.

varValue

Variable value

The -bindVar option can be used multiple times.

For example:

```
-bindVar name=la,"http://www.ibm.com/Los Angeles" value="some value"
```

-v Prints the version of the tool

-h Prints the usage statement

-input *file*
Specifies the full path to a file containing an XML artifact against which the XPath expression will be executed

xpathfile
Specifies the full path to a file containing the XPath expression

The following is a basic example of executing an XPath expression using the ExecuteXPath tool:

- **Execute an XQuery expression**

Location
The product includes the following script that sets up the environment and invokes the tool.

Syntax

Parameters

-outputfile *file*
Specifies that output should go to the specified file

By default, the output is sent to standard out.

-baseURI *URI*
Specifies the base URI of the containing element

-dnet *URI*
Specifies a default namespace URI for element and type names

The namespace URI, if present, is used for any unprefixed QName appearing in a position where an element or type name is expected.

-useCompiler
Specifies compiler modes

If this parameter is not specified, the default behavior is to use interpreted mode.

-bindVar name=*varName* **value=***varValue*
Bind an atomic value to a variable (XPath, XQuery) or a param (XSLT)

The value must be valid for the type that was specified in the static context (XPath), in the query (XQuery), or in the stylesheet (XSLT) for the same name.

varName
Name of the variable (expressed localPart,namespaceURI)

Notes:

- If the variable is in no namespace, the namespace URI should be omitted.
- If the value of any option contains a blank space, enclose it in quotation marks.
- Localpart is a required value.

varValue
Variable value

The -bindVar option can be used multiple times.

For example:

```
-bindVar name=la,"http://www.ibm.com/Los Angeles" value="some value"
```

-v Prints the version of the tool

-h Prints the usage statement

-input *file*
Specifies the full path to a file containing an XML artifact against which the XQuery expression will be executed

xqueryfile
Full path to a file containing the XQuery expression

The following is a basic example of executing an XQuery expression using the ExecuteXQuery tool:

Using a message handler and managing exceptions

You can use this information to help you to use a message handler and mange exceptions.

Procedure

- Use a message handler.
- Manage exceptions.

Using a message handler

The default behavior for prepare-time and execution-time processing errors and other messages is to print the messages to System.err and for nonrecoverable errors to raise an XProcessException as well. If an error occurs at prepare time, the processor attempts to continue preparation and signal all errors before generating an XProcessException; but no executable is produced. At run time, execution stops at the first occurrence of an error situation.

Procedure

Change the handling of errors by registering an implementation of XMessageHandler to the XStaticContext (for prepare-time errors and other messages) or the XDynamicContext (for execution-time errors and other messages).
The XMessageHandler interface consists of a single report method that has the following parameters:

level One of the following enumerators defined in the XMessageHandler interface:

INFO Indicates that the error is simply informational and will not affect the result

This is also used for the XSLT message instruction when the terminate attribute evaluates to "no."

WARNING
Indicates a warning

The processor recovers from a warning situation, but the result might not be what was expected.

ERROR
Indicates a recoverable error

The processor might recover from this error for the purpose of signaling additional errors, but no result is produced.

FATAL_ERROR
Indicates a nonrecoverable error

The processor cannot recover from this error. It is also used for the XSLT message instruction when the terminate attribute evaluates to "yes."

TRACE
Indicates that the message was generated by a call to the XPath fn:trace function

message
Error message

location
Source location as an XSourceLocation if available

In general, the source location is not available for execution-time errors.

cause Original exception that caused the error if available

If the input document is invalid, for example, the XML parser generates an exception that is passed to the report method through this parameter.

errorItems
Items that were specified for the error-object parameter to the XPath fn:error function

The implementation of XMessageHandler can present the errors and other messages as desired, such as writing to a log file rather than sending the messages to System.err. It may also be more strict and stop compilation or execution after any error including recoverable errors by generating an exception. Because the report method has no throws clause, the exception must be unchecked. The implementation might also choose to ignore informational and warning messages. In short, registering an XMessageHandler allows the application to configure message handling to suit its purposes.
Note that in the case of a nonrecoverable error, if the registered message handler does not generate an exception, an XProcessException is raised by the processor.

Managing exceptions

Various exceptions might occur. Unless otherwise indicated, all exceptions extend RuntimeException and thus are unchecked.

Procedure

- Manage **XProcessException**.

  This exception occurs when the processor finds a nonrecoverable error when preparing or executing an expression, query, or stylesheet as described in the specifications for each language.

  If there are multiple errors at prepare time, the processor attempts to report all of the errors and only generates an XProcessException at the end of preparation or if it reaches a point where it cannot continue. At execution time, however, the first error results in an XProcessException and the end of execution.

  In general, XProcessExceptions should not occur if the expression, query, or stylesheet is syntactically and semantically valid and also valid for the types of input documents that it is meant to process.

  An XProcessException also occurs for an XSLT message instruction where the terminate attribute evaluates to "yes."

  This is the default behavior for handling processing errors and other messages. Applications can register an implementation of the XMessageHandler interface at prepare time or execution time to modify the default behavior.
- Manage an **XViewException**.

  This exception is raised for incorrect use of the XML API itself such as calling one of the XNodeView methods on an item that is atomic.

  See the API documentation for more information about when this exception can occur.
- Manage a **NullPointerException**.

  This exception is raised when a null value is passed to an API method where null is not allowed, such as passing a null prefix or namespace to the XStaticContext declareNamespace method.

  See the XML API documentation for more information about when this exception can occur.
- Manage an **IllegalArgumentException**.

  This exception is raised when an invalid value is passed to an API method, such as calling the XStaticContext setXPathCompatibilityMode method with a value other than one of the predefined settings.

  See the XML API documentation for more information about when this exception can occur.

- Manage **exceptions generated by XFactory.newInstance**.

  The newInstance method on the XFactory class loads the XFactory implementation class and creates a new instance; therefore, any of the following checked exceptions might occur:

  – ClassNotFoundException
  – IllegalAccessException
  – InstantiationException

  These exceptions would likely result if there is a classpath problem or a Java security issue.

Chapter 40. Deploying client applications

Deploying a client application depends on installing appropriate supporting files on the client machine, usually some configuring actions, and adding the program files for the client application. When the client application has been deployed, the application can run.

About this task

The steps required to deploy and run a client application depend on the type of client and the programming model used.

You can install an application client JAR file using the administrative console, wsadmin AdminApp install, or update commands. Install the client module only on a Version 8.0 deployment target (such as server, cluster, and so on).

Complete one or more of the following tasks:

Procedure

- Deploy the client application
- Run an ActiveX client application
- Deploy and run a Java EE client application
- Run the IBM Thin Client for Enterprise JavaBeans

Deploying applet client code

Applet clients are capable of communicating over the HTTP protocol and the RMI-IIOP protocol.

Before you begin

Applet clients have the following setup requirements:
- These clients are available on the Windows platforms. Check the prerequisites page for information on platform support and product prerequisites.
- The browser installation precedes the client code installation.

About this task

Unlike typical applets that are on web servers or WebSphere Application Servers and can only communicate over the HTTP protocol, applet clients can communicate over the HTTP protocol and the RMI-IIOP protocol. This additional capability gives the applet direct access to enterprise beans.

The applet container is the web browser and the Java plug-in combination. You must first install the Application Client for WebSphere Application Server so that the browser recognizes the IBM product Java plug-in.

Procedure

1. Install the Application Client for WebSphere Application Server.
2. Configure required Java runtime parameters.
   a. Click **Start** > **Control panel** .
   b. Select the IBM Control Panel for Java
   c. On the Advanced tab, enter the following parameter values in the Java Runtime Parameters field.

```
-Xmx512M
-Djava.security.policy=<app_client_root>\properties\client.policy
-Dwas.install.root=<app_client_root>
-Djava.ext.dirs=<app_client_root>\java\jre\lib\ext;
<app_client_root>\lib;
<app_client_root>\plugins;
<app_client_root>\lib\ext;
<app_client_root>\installedConnectors\
-Djava.class.path=<app_client_root>\properties
-Dcom.ibm.CORBA.ConfigURL=file:<app_client_root>\properties\sas.client.props
-Dcom.ibm.SSL.ConfigURL=file:<app_client_root>\properties\ssl.client.props
```

Note: These parameter entries are automatically placed into the WebSphere Application Server control panel for the Java plug-in user who installed the WebSphere Application Server Application Client provided you are using a Java SE Development Kit (JDK) prior to JDK 1.5. If the applet is being run by a user other than the person who installed the client, then that user must enter the parameter entries.

For JDK 1.5 and later, this automatic parameter feature is removed.

- The Java Runtime Parameters field is similar to the command prompt when using command line options. Therefore, you can enter most options available from the command prompt (for example, -cp, classpath, and others) in this field as well.

3. Configure use of secure sockets layer (SSL) for secure access to resources. By default, the applet client is configured to have security enabled. If you have administrative security turned on at the server from which you are accessing resources, then you can use SSL when needed. If you decide that the security requirements for applet client applications differ from other types of client applications, then you can create special copies of client property files for applets to use.

Running an ActiveX client application

To run an ActiveX client application that is to use the ActiveX to Enterprise Java Beans (EJB) bridge, you must perform some initial configuration to set appropriate environment variables and to enable the ActiveX to EJB bridge to find its `XJB.JAR` file and the Java run time. This initial configuration sets up the environment within which the ActiveX client application can run.

About this task

To perform the required configuration, complete one or more of the following tasks:

Procedure

1. Start an ActiveX application and configure service programs.
2. Start an ActiveX application and configuring non-service programs

Starting an ActiveX application and configuring service programs

To run an ActiveX service program such as Active Server Page (ASP) that is to use the ActiveX to the Enterprise Java Bean (EJB) bridge, some initial configuration (to set appropriate environment variables and to enable the ActiveX to EJB bridge to find its `XJB.JAR` file and the Java run time) is necessary. This configuration sets up the environment within which the ActiveX service program can run.

Before you begin

The XJB.JClassFactory must find the Java run time dynamic link library (DLL) when initializing. In a service program such as Internet Information Server you cannot specify a path for its processes independently; you must set the process paths in the system PATH variable. This limitation means that you can only have a single Java virtual machine (JVM) version available on a machine using ASP.

About this task

To add the Java Runtime Environment (JRE) directories to your system path, complete one of the following task.

Procedure

On Windows XP systems, complete the following steps:
1. Open the Control Panel, then double-click the **System** icon.
2. Click the **Advanced** tab on the System Properties window.
3. Click **Environment Variables**.
4. Edit the Path variable in the System Variables window.
5. Add the following information to the beginning of the path that is displayed in the Variable Value field:

   `C:\WebSphere\AppClient\Java\jre\bin;C:\WebSphere\AppClient\Java\jre\bin\classic;`

   where `C:\WebSphere\AppClient` is the directory in which you installed the Java client in the WebSphere product.
6. Click **OK** in the Edit System Variable window to apply the changes.
7. Click **OK** in the Environment Variables window.
8. Click **OK** in the System Properties window.
9. Restart Windows XP.

What to do next

After you change the system PATH variable you must reboot the Internet Information Server machine so that Internet Information Server can see the change.

Starting an ActiveX application and configuring non-service programs

To run an ActiveX program initiated from an icon or command line (a non-service program) that is to use the ActiveX to the Enterprise Java Beans (EJB) bridge, you must perform some initial configuration to set appropriate environment variables and to enable the ActiveX to EJB bridge to find its `XJB.JAR` file and the Java run-time environment. This uses a batch file to set up the environment within which the ActiveX program can run.

About this task

To perform the required configuration, complete the following steps:

Procedure

1. Edit the `setupCmdLineXJB.bat` file to specify appropriate values for the environment variables required by the ActiveX to EJB bridge. For more information about these environment variables, see ActiveX to EJB bridge, environment and configuration. For more information about creating a JVM for an ActiveX program, see ActiveX to EJB bridge, initializing the Java virtual machine (JVM). After the ActiveX program has created an XJB.JClassFactory object and called the XJBInit() method, the JVM is initialized and ready for use.
2. Start the ActiveX client application by using one of the following methods:
   - Use the `launchClientXJB.bat` file to start the application. For example:

     ```
     launchClientXJB MyApplication.exe parm1 parm2
     ```

     or

     ```
     launchClientXJB MyApplication.vbp
     ```
   - Use the `setupCmdLineXJB.bat` file to create an environment in which to run the application, then start the application from within that environment.

setupCmdLineXJB.bat, launchClientXJB.bat and other ActiveX batch files

This topic provides reference information about the aids that client applications and client services can use to access the ActiveX to EJB bridge. These enable the ActiveX to Enterprise JavaBeans (EJB) bridge to find its XJB.JAR file and the Java run-time environment.

Location

The include file is located in the was_client_home\aspIncludes directory. You can include the file into your Active Server Pages (ASP) application with the following syntax in your ASP page:

```
<--  #include virtual ="/WSASPIncludes/setupASPXJB.inc" -->
```

This syntax assumes that you have created a virtual directory in Internet Information Server called WSASPIncludes that points to the was_client_home\aspIncludes directory.

Usage notes

The following batch files are provided for client applications to use the ActiveX to EJB bridge:

- setupCmdLineXJB.bat

  Sets the client environment variables.
- launchClientXJB.bat

  Calls the setupCmdLineXJB.bat file and launches the application you specify as its arguments; for example:

  ```
  launchClientXJB.bat myapp.exe parm1 parm2
  ```

  or

  ```
  launchClientXJB MyApplication.vbp
  ```
- Active Server Pages (ASP) include file

  An include file is provided for ASP users to automatically set the following page-level (local) environment variables:
  - com_ibm_websphere_javahome. Path to the Java run-time directory installed with the WebSphere advanced server client.
  - com_ibm_websphere_washome. Path to the WebSphere advanced server client directory.
  - com_ibm_websphere_namingfactory. Sets the Java java.naming.factory.initial system property.
  - com_ibm_websphere_computername. (Optional) Name of the computer where the WebSphere Advanced Server Client is installed. If you intend to talk to a single specific computer, you are recommended to change this value to become the server name that you intend to access.
- System settings

  To enable the ActiveX to EJB bridge to access the Java run-time dynamic link library (DLL), the following directories must exist in the system PATH environment variable:

  ```
  was_client_home\java\jre\bin;was_client_home\java\jre\bin\classic
  ```

  Where was_client_home is the name of the directory where you installed the WebSphere Application Server client (for example, C:\WebSphere\AppClient).

  Note: This technique enables only one Java run time to activate on a machine, therefore all client services on that machine must use the same Java run time. Client applications do not have this limitation because they each have their own private, non-system scope.

Deploying and running a Java EE client application

You can use the **launchClient** command to run a Java Enterprise Edition (EE) client application in an Application Client installation or in a WebSphere Application Server node. Alternatively, you can use Java Web Start on a remote client machine to download and run a Java EE client application, including Thin client application, with a single click from a web browser on that machine.

Procedure

1. Deploy and run a Java EE client application for use with the **launchClient** command.

   After deploying a Java EE client application onto a machine with an Application Client installation or in a WebSphere Application Server node, you can start the application by using the **launchClient** command on that machine.

   a. Deploy the Java EE client application

   b. Start the Java EE client application

2. Deploy and run a Java EE client application by using Java Web Start.

   a. Prepare the Java EE client application ready to be deployed by remote action.

   b. Use Java Web Start on a remote client machine to download and run the Java EE client application.

Deploying a Java EE client application

Deploying a Java EE client application onto the client machines where it is to run includes distributing the EAR file for the client application and configuring resource references for use by the client application.

Before you begin

To run a deployed Java EE client application, the application needs access to a Application Client installation or a WebSphere Application Server installation.

For information about installing the Application Client on a client machine, refer to the Installing Application Client for WebSphere Application Server topic.

Attention: Application Client for WebSphere Application Server ships only with the 32-bit WebSphere Application Server.

About this task

Use this topic only if you later want to use the want to **launchClient** command to run the Java client application on an Application Client installation or in a WebSphere Application Server node.

If you want to download and run a Java EE client application remotely, you can use the Java Web Start to deploy the application onto the remote client machine with a single click from a Web browser on the client machine. For information about using Java Web Start to deploy Java EE client applications, see “Downloading and running a Java EE client application by using Java Web Start”.

Procedure

1. Distribute the EAR file.

   The client machines configured to run a client application must have access to the EAR file.

   - If all the machines in your environment share the same image and platform, run the Application Client Resource Configuration Tool (ACRCT) on one machine to configure the external resources, then distribute the configured EAR file to the other machines.
   - If your environment is set up with a variety of client installations and platforms, run the ACRCT for each unique configuration.

- You can either distribute an EAR file to the correct client machines, or make it available on a network drive.
- Distributing EAR files is the responsibility of the system and network administrator.

2. Configure the resources for the application client. This generally involves using the Application Client Resource Configuration Tool (ACRCT) to configure references for the resources that the application is to use, including resource adapters, resource providers, data sources, and Java Message Service resources. These configurations are stored in the client JAR file within the application EAR file. The client runtime uses these configurations to resolve and create an instance of the resources for the client application.

   For some types of resources, other actions are needed; for example, to install a resource adapter and define environment variable needed to start the client application. More information about the actions for different types of resources is given in other configuring resources topics.

   If you plan to deploy the client application on z/OS, run the ACRCT on Windows. You can also run the ACRCT for distributed platforms locally.

   If the client application defines the local resources, but the resources are installed in a different location, run the ACRCT (**clientConfig** command) on the local machine to change the configuration in the EAR file. For example, the EAR file can contain a DB2 resource, configured as `C:\DB2`. If, however, you installed DB2 in the `D:\Program Files\DB2` directory, use the ACRCT to create a local version of the EAR file.
3. Use the WebSphere Administrative console to install the client application on z/OS.

What to do next

After deploying the Java EE client application, use the **launchClient** command to run the client application.

Starting the Application Client Resource Configuration Tool and opening an EAR file

You can perform many tasks by starting the Application Client Resource Configuration Tool (ACRCT). Many of these tasks also involve then opening an EAR file.

Before you begin

Attention: This task only applies to Java Platform, Enterprise Edition (Java EE) application clients.

About this task

Use these steps to start the Application Client Resource Configuration Tool. When you start the tool, one of the most common tasks that you perform is opening and modifying the components of EAR files.

Procedure

1. Open a command prompt and change to the *app_server_root*`\bin` directory.
2. Run the `clientConfig.bat` file.
3. Open an EAR file within the Application Client Resource Configuration Tool (ACRCT):
   a. Click **File** > **Open**.
   b. Select the file then click **Open**.
4. Save your changes to the file and close the tool:
   a. Click **File** > **Save**.
   b. Click **File** > **Exit**.

Deploying a resource adapter for a Java EE client application

A Java EE client application can use a resource adapter to connect to an enterprise information system (EIS). To use a resource adapter, you need to install it, configure it, and configure related resources.

About this task

The resource adapter support provided for Java EE client applications is a subset of the support provided for application servers. A client resource adapter is used in a non-managed environment and must conform to the J2EE Connector Architecture Specification Version 1.5 or higher. Only outbound connections to the EIS are supported through the ManagedConnectionFactory interfaces. The inbound messaging support (from the EIS), life cycle management, and work management aspects of the specification are not supported on the client.

When running Java EE application clients, the **launchClient** script specifies a system property called **com.ibm.ws.client.installedConnector**, which is set to the same value as the *CLIENT_CONNECTOR_INSTALL_ROOT* variable. This is the default location for installed resource adapters and can be overridden for each **launchClient** call by specifying the **-CCD** parameter. When the client container is activated, all resource adapter subdirectories under the specified default location for the resource adapters directory are added to the classpath. This action allows the client application to use the resource adapters without using the ACRCT to specify any of the client resources.

Procedure

1. Install the resource adapter archive (RAR) file

   For a client application to use a resource adapter, the RAR file must be installed in the directory specified by the environment variable, CLIENT_CONNECTOR_INSTALL_ROOT, defined when the **setupCmdLine** script runs. The **launchClient** tool, Application Client Resource Configuration Tool (ACRCT) and clientRAR tool all use this variable to find the default location of all installed resource adapters.

   To install a RAR file for a client application, use the clientRAR tool.
2. Configure the resource adapter and its resources for the client application Use the Application Client Resource Configuration Tool (ACRCT) to define the resource adapter, connection factories, and administered objects in the EAR file for the client application. The client application uses this configuration to resolve and create an instance of the resource adapter and the other resources.
   a. Configure the resource adapter
   b. Configure a connection factory
   c. Configure administered objects

clientRAR tool:

This topic describes the command line syntax for the client resource adapter installation tool.

If this tool is used to add or delete resource adapters on the server, then only the client can use the resource adapter. If the resource adapter is installed on the server using the wsadmin tool or the administrative console, then do not use the clientRAR tool remove it. Only resource adapters that are installed using the clientRAR tool should be removed using the clientRAR tool.

The command line invocation syntax for the `clientRAR` tool follows:

```
clientRAR [-help | -?] [-CRDcom.ibm.ws.client.installedConnectors=<dir>] <task> <archive>

where
-help, -?
Print the usage information.
-CRDcom.ibm.ws.client.installedConnectors
The directory where resource adapters are installed.
This will override the system property of the same name
(com.ibm.ws.client.installedConnectors).

<task>
The task to perform: add - install, delete - uninstall.
```

```
<archive>
if task=add then this is the fully qualified name of the resource adapter archive file.
If task=delete then this is the filename of the resource adapter archive to be uninstalled.
```

The following examples demonstrate correct syntax.

Configuring resource adapters for the client:

Use the Application Client Resource Configuration Tool (ACRCT) to configure resource adapters for the client.

Procedure

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure new resource adapters. The EAR file contents display in a tree view.
3. Select the JAR file in which you want to configure the new resource adapters from the tree.
4. Expand the JAR file to view its contents.
5. Right-click the Resource Adapters folder, and click **New**.
6. Configure the resource adapter settings in the resulting property dialog.
7. Click **OK**.
8. Click **File > Save** on the menu bar to save your changes.

Resource adapters for the client:

A resource adapter is a system-level software driver that a Java application uses to connect to an enterprise information system (EIS). A resource adapter plugs into an application client and provides connectivity between the EIS and the enterprise application.

Important: This topic is not relevant to the WebSphere MQ resource adapter. WebSphere MQ classes are picked up automatically by the client container (for both stand alone and with a WebSphere Application Server installation).

The resource adapter support for the Java EE client applications is a subset of the support for the server. For any resource adapter installed using the clientRAR tool, the client resource adapter is used in a non-managed environment and must conform to the Java EE Connector Architecture Specification Version 1.5 or higher. Only outbound connections to the EIS are supported through the ManagedConnectionFactory interfaces. The inbound messaging support (from the EIS), life cycle management, and work management aspects of the specification are not supported on the client.

For a client application to use a resource adapter, it must be installed in the directory specified by the environment variable, CLIENT_CONNECTOR_INSTALL_ROOT, defined when the setupCmdLine script runs. The launchClient tool, Application Client Resource Configuration Tool (ACRCT) and clientRAR tool all use this variable to find the default location of all installed resource adapters. To install a resource adapter in the client, use the clientRAR tool. Once the resource adapter is installed, it must be configured using the ACRCT. The client configuration tool adds the resource adapter configuration to the EAR file. Then, connection factories and administered objects are defined.

When running Java EE application clients, the `launchClient` script specifies a system property called `com.ibm.ws.client.installedConnector`, which is set to the same value as the `CLIENT_CONNECTOR_INSTALL_ROOT` variable. This is the default location for installed resource adapters and can be overridden for each `launchClient` call by specifying the `-CCD` parameter. When the client container is activated, all resource adapter subdirectories under the specified default location for the resource adapters directory are added to the classpath. This action allows the client application to use the resource adapters without using the ACRCT to specify any of the client resources.

Using resource adapters is a new mechanism for easily extending client applications.

Resource adapter settings:

Use this panel to view or change the configuration properties of the resource adapter. These configuration properties control how resource adapters are created.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Resource Adapter**. Right-click **Resource Adapter** and click **New**. The following fields appear on the **General** tab.

Name:

The name by which this Resource Adapter is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the Resource Adapters across the product administrative domain.

Information	Value
Data type	String

Description:

A description of this resource adapter for administrative purposes within IBM WebSphere Application Server.

Information	Value
Data type	String

Class Path:

Any additional class path. The path to the resource adapter directory is automatically added.

Information	Value
Data type	String
Default	The path to your Resource Adapter directory.

Native Path:

The native path where the Resource Adapter is located. Enter any additional native class path here.

Information	Value
Data type	String

Resource Adapter Name:

A mandatory field that points to an installed resource adapter subdirectory. The entry does not represent the full directory name for the resource adapter. The full directory name is the installed resource adapter path, plus the resource adapter name.

Information	Value
Data type	String

Installed Resource Adapter Path:

The directory where resource adapters are installed. If you do not complete this field, then the default takes effect.

If you specify the value, `${CONNECTOR_INSTALL_ROOT}`, then this value replaces the value of the `CLIENT_CONNECTOR_INSTALL_ROOT` variable on the machine on which the client application runs. This action allows the application to run easily on different machines, where the client installation might be in different locations.

Information	Value
Data type	String
Default	${CONNECTOR_INSTALL_ROOT}

Configuring new connection factories for resource adapters for the client:

Use the Application Client Resource Configuration Tool (ACRCT) to configure new connection factories for resource adapters for the client.

About this task

Complete this task to configure new connection factories for resource adapters.

Procedure

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure new connection factories. The EAR file contents display in a tree view.
3. Select the JAR file in which you want to configure the new connection factories from the tree.
4. Expand the JAR file to view its contents.
5. Click the Resource Adapters folder.
6. Expand the resource adapter for which you want to create connection factories.
7. Right-click the Connection Factories folder and click **New**.
8. Configure the connection factory properties in the resulting property dialog.
9. Click **OK**.
10. Click **File > Save** on the menu bar to save your changes.

Resource adapter connection factory settings:

Use this panel to view or change the configuration properties of the selected resource adapter connection factory.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Resource Adapters**. Right-click the **Connection Factories** folder, and click **New**. The following fields appear on the **General** tab.

Name:

The name by which this connection factory is known for administrative purposes within WebSphere Application Server. The name must be unique within the resource adapter connection factories across the product administrative domain.

Information	Value
Data type	String

Description:

An optional description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Information	Value
Data type	String

JNDI Name:

The JNDI name that is used to match this resource adapter connection factory definition to the deployment descriptor. This entry should be a `resource-ref` name.

Information	Value
Data type	String

User Name:

The **User Name** used, with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly when getting a connection. If this field is used, then the Properties field `UserName` is ignored.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

The connection factory **User Name** and **Password** properties are used if the calling application does not provide a `userid` and `password` explicitly when getting a connection.

Information	Value
Data type	String

Password:

Specifies an encrypted password. If you complete this field, then the **Password** field in the Properties box is ignored.

If you specify a value for the **UserName** property, you must also specify a value for the **Password** property.

Information	Value
Data type	String

Re-Enter Password:

Confirms the password.

Type:

A drop-down list of all the `connectionFactoryInterfaces` as defined for the factories in the Resource Adapter Archive.

For each **Type**, there is a set of properties specified in the Properties box. This set of properties is constructed by retrieving the properties from each connection definition object. For any existing connection factories that are displayed for updating, this list of properties is overlaid with the properties specified for the objects. When the **Type** field is changed, the properties also change to reflect the correct properties for that type.

Information	Value
Data type	String

Configuring administered objects for resource adapters for the client:

This section helps you configure new administered objects for the client.

Before you begin

Before you configure new administered objects, you must complete the following prerequisites:

1. Install the Resource Adapter Archive file (RAR) using the clientRAR tool.
2. Configure the resource adapter for the `.ear` file, using the Application Client Resource Configuration Tool (ACRCT) tool.

About this task

Complete this task to configure new administered objects for installed resource adapters.

Procedure

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure new administered objects. The EAR file contents display in a tree view.
3. Select the JAR file in which you want to configure the new administered objects from the tree.
4. Expand the JAR file to view its contents.
5. Click the **Resource Adapters** folder.
6. Expand the resource adapter for which you want to create administered objects.
7. Right-click the **Administered Objects** folder and click **New**.
8. Configure the administered object properties in the resulting property dialog.
9. Click **OK**.
10. Click **File > Save** on the menu bar to save your changes.

Administered objects settings:

Use this panel to view or change the configuration properties of the selected administered objects.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Resource Adapters** > *resource_adapter_instance*. Right-click **Administered Objects** and click **New**. The following fields appear on the **General** tab.

The settings for administered objects are handled similarly to connection factories. When updating administered objects, use the same panels that you used to create administered objects.

Name:

The name by which this administered object is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the resource adapter administered objects across the product administrative domain.

Information	Value
Data type	String

Description:

An optional description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Information	Value
Data type	String

JNDI Name:

This entry is a `resource-env-ref` name, a `message-destination-ref` name (if the `message-destination-ref` has no link), or a `message-destination` link.

Information	Value
Data type	String

Type:

A drop-down list of all the administered object class-interface pairs as defined for the admin objects in the Resource Adapter Archive (RAR) file.

For each **Type**, there is a set of properties specified in the Properties box. This set of properties is constructed by retrieving the properties from each administered object definition. For any existing administered objects that are displayed for updating, this list of properties is overlaid with the properties specified for the objects. When the **Type** field is changed, the properties also change to reflect the correct properties for that type.

Information	Value
Data type	String

Enabling client use of data sources

If a Java EE client application accesses a database directly, you must provide the database drivers on the client machine, and configure the data source provider (JDBC provider) and data sources. Instead of accessing the database directly, it is recommended that your client application access the database through an enterprise bean.

About this task

WebSphere Application Server and the Application Client for WebSphere Application Server do not provide client database drivers to be used directly from a Java EE client application. You can contact your database vendor to get client database driver code and licenses.

Data sources configured on the server and looked up on the client do not participate in global transactions.

Instead of accessing the database directly, it is recommended that your client application access the database through an enterprise bean. This technique eliminates the need to have database drivers on the client machine, because the database access is handled by the enterprise bean running on WebSphere Application Server. It also enables the client application to take advantage of the pooling and additional database functions provided by the server.

For a current list of data source providers that are supported on WebSphere Application Server, see the WebSphere Application Server prerequisite website.

Procedure

1. For direct access from a client to the database, install the client database drivers on the client machine. For information about installing database drivers, see the documentation provided by your database vendor.
2. Configure a data source provider and a data source for the client application Use the Application Client Resource Configuration Tool (ACRCT) to define the data source provider and a data source in the EAR file for the client application. The client application uses this configuration to resolve and create an instance of the data source provider and data source.
   a. Configure a new data source provider. This provider describes the JDBC database implementation for your client application.
   b. Configuring a new data source This describes the client properties of the database your client application uses.

Configuring new data source providers (JDBC providers) for application clients:

You can create new data source providers, also known as JDBC providers, for your application client using the Application Client Resource Configuration Tool (ACRCT).

Before you begin

During this task, you create new data source providers, also known as JDBC providers, for your application client. In a separate administrative task, install the Java code for the required data source provider on the client machine on which the application client resides.

About this task

Use this task to connect application clients to relational databases.

Procedure

1. Start the Application Client Resource Configuration Tool (ACRCT) and open the EAR file for which you want to configure the new data source provider. The EAR file contents display in a tree view.
2. Select the JAR file in which you want to configure the new data source provider from the tree.
3. Expand the JAR file to view its contents.
4. Click the Data Source Providers folder. Do one of the following:
   - Right-click the folder and click **New Provider**.
   - Click **Edit > New** on the menu bar.
5. Configure the data source provider properties in the resulting property dialog.
6. Click **OK** when you finish.
7. Click **File > Save** on the menu bar to save your changes.

Example

You can configure data source provider and data source settings.

- Configuring data source provider and data source settings

The following code examples illustrates how to use configure data source provider and data source settings:

```
<resources.jdbc:JDBCProvider xmi:id="JDBCProvider_1" name="jdbcProvider:name"
description="jdbcProvider:description" implementationClassName="jdbcProvider:
ImplementationClass">
<classpath>jdbcProvider:classPath</classpath>
<factories xmi:type="resources.jdbc:WAS40DataSource" xmi:id="WAS40DataSource_1"
name="jdbcFactory:name" jndiName="jdbcFactory:jndiName"
description="jdbcFactory:description" databaseName="jdbcFactory:databasename">
```

```
<propertySet xmi:id="J2EEResourcePropertySet_13">
<resourceProperties xmi:id="J2EEResourceProperty_13" name="jdbcFactory:customName"
value="jdbcFactory:customValue"/>
<resourceProperties xmi:id="J2EEResourceProperty_14" name="user"
value="jdbcFactory:user"/>
<resourceProperties xmi:id="J2EEResourceProperty_15" name="password"
value="{xor}NTs9PBk+PCswLSZlMT4yOg==/>
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_14">
<resourceProperties xmi:id="J2EEResourceProperty_16" name="jdbcProvider:customName"
value="jdbcProvider:customeValue"/>
</propertySet>
</resources.jdbc:JDBCProvider>
```

- Required fields:
  - Data Source Provider Properties page: name
  - Data Source Properties page: name, jndiName
- Special cases:
  - The user name and password fields have no equivalent XMI tags. You must specify these fields in the custom properties.
  - The password is encrypted when you use the Application Client Resource Configuration Tool (ACRCT). If you do not use the ACRCT the field cannot be encrypted.

Example: Configuring data source provider and data source settings:

You can configure data source provider and data source settings.

The purpose of this article is to help you to configure data source provider and data source settings.

- Required fields:
  - Data Source Provider Properties page: name
  - Data Source Properties page: name, jndiName
- Special cases:
  - The user name and password fields have no equivalent XMI tags. You must specify these fields in the custom properties.
  - The password is encrypted when you use the Application Client Resource Configuration Tool (ACRCT). If you do not use the ACRCT the field cannot be encrypted.
- Example:

```
<resources.jdbc:JDBCProvider xmi:id="JDBCProvider_1" name="jdbcProvider:name"
description="jdbcProvider:description" implementationClassName="jdbcProvider:
ImplementationClass">
<classpath>jdbcProvider:classPath</classpath>
<factories xmi:type="resources.jdbc:WAS40DataSource" xmi:id="WAS40DataSource_1"
name="jdbcFactory:name" jndiName="jdbcFactory:jndiName"
description="jdbcFactory:description" databaseName="jdbcFactory:databasename">
<propertySet xmi:id="J2EEResourcePropertySet_13">
<resourceProperties xmi:id="J2EEResourceProperty_13" name="jdbcFactory:customName"
value="jdbcFactory:customValue"/>
<resourceProperties xmi:id="J2EEResourceProperty_14" name="user"
value="jdbcFactory:user"/>
<resourceProperties xmi:id="J2EEResourceProperty_15" name="password"
value="{xor}NTs9PBk+PCswLSZlMT4yOg==/>
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_14">
<resourceProperties xmi:id="J2EEResourceProperty_16" name="jdbcProvider:customName"
value="jdbcProvider:customeValue"/>
</propertySet>
</resources.jdbc:JDBCProvider>
```

Data source provider settings for application clients:

Use this page to create a data source under a JDBC provider which provides the specific JDBC driver implementation class.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file. Right-click **Data Source Providers** > and click **New**. The following fields appear on the **General** tab:

Name:

Specifies the display name for the data source.

For example you can set this field to *Test Data Source*.

Information	**Value**
Data type	String

Description:

Specifies a text description for the resource.

Information	**Value**
Data type	String

Class Path:

A list of paths or `.jar` file names which together form the location for the resource provider classes.

Implementation class:

Use this setting to perform database specific functions.

Information	**Value**
Data type	String
Default	Dependent on JDBC driver implementation class

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Configuring new data sources for application clients:

Learn how to create date sources for application clients.

About this task

During this task, you create new data sources for your application client.

Procedure

1. Click the data source provider for which you want to create a data source in the tree. Take one of the following actions as needed:
   - Configure a new data source provider.
   - Click an existing data source provider.
2. Expand the data source provider to view its Data Sources folder.
3. Click the data source folder. Take one of the following actions as needed:
   - Right click the data source folder and click **New Factory**.
   - Click **Edit > New** on the menu bar.
4. Configure the data source properties in the displayed fields.
5. Click **OK** when you finish.
6. Click **File > Save** on the menu bar to save your changes.

Data source properties for application clients:

Use this page to create or modify the data sources.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Data Source Providers** > *Data source provider instance*. Right-click **Data Sources** and click **New**. The following fields are displayed on the **General** tab:

Name:

Specifies the display name of this data source.

Information	Value
Data type	String

Description:

Specifies a text description of the data source.

Information	Value
Data type	String

JNDI Name:

The application client run time uses this field to retrieve configuration information.

Database Name:

The name of the database to which you want to connect.

User:

Use the user ID with the Password property, for authentication if the calling application does not provide a user ID and password explicitly.

If you specify a value for the User ID property, then you must also specify a value for the Password property. The connection factory User ID and Password properties are used if the calling application does not provide a user ID and password explicitly.

Password:

Use the password with the User ID property, for authentication if the calling application does not provide a user ID and password explicitly.

If you specify a value for the Password property, then you must also specify a value for the User ID property.

Re-Enter Password:

Confirms the password.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Configuring mail providers and sessions for application clients

You can edit the configurations of mail sessions and providers for your application clients using the Application Client Resource Configuration Tool (ACRCT).

About this task

Use the Application Client Resource Configuration Tool (ACRCT) to edit the configurations of mail sessions and providers for your application clients to use.

Procedure

1. Start the ACRCT.
2. Open an EAR file.
3. Locate the mail objects in the tree that is displayed for the EAR file. For example, if your file contains mail sessions, expand **Resources** > ***application*.jar** > **Mail Providers** > ***java_mail_provider_instance*** > **Mail Sessions**.

   In this example, ***java_mail_provider_instance*** is a particular mail provider.

Results

The mail session instances are located in the JavaMail Sessions folder.

Example

You can configure mail provider and mail session settings.

- Configuring mail provider and mail session settings for application clients

The following code examples illustrates how to configure mail provider and mail session settings for application clients:

```
<resources.mail:MailProvider xmi:id="builtin_mailprovider" name="Built-in Mail Provider" description="The built-in mail provider">
  <factories xmi:type="resources.mail:MailSession"
             xmi:id="MailSession_1207766754834" name="MailSession"
             jndiName="mail/session" description="Sample mail session" category="Sample"
             mailTransportHost="smtp.coldmail.com" mailTransportUser="transportUser"
             mailTransportPassword="{xor}Lz4sLChvLTs="
             mailFrom="smith@coldmail.com" mailStoreHost="imap.coldmail.com" mailStoreUser="storeUser"
             mailStorePassword="{xor}Lz4sLChvLTs="
             debug="true" strict="true"
             mailTransportProtocol="builtin_smtp" mailStoreProtocol="builtin_imap">
    <propertySet xmi:id="J2EEResourcePropertySet_1207766778585">
      <resourceProperties xmi:id="J2EEResourceProperty_1207766778585" name="key" type="java.lang.String" value="value" required="false"/>
```

```
    </propertySet>
  </factories>
  <protocolProviders xmi:id="builtin_smtp" protocol="smtp" classname="com.sun.mail.smtp.SMTPTransport" type="TRANSPORT"/>
  <protocolProviders xmi:id="builtin_pop3" protocol="pop3" classname="com.sun.mail.pop3.POP3Store" type="STORE"/>
  <protocolProviders xmi:id="builtin_imap" protocol="imap" classname="com.sun.mail.imap.IMAPStore" type="STORE"/>
  <protocolProviders xmi:id="builtin_smtps" protocol="smtps" classname="com.sun.mail.smtp.SMTPSSLTransport" type="TRANSPORT"/>
  <protocolProviders xmi:id="builtin_pop3s" protocol="pop3s" classname="com.sun.mail.pop3.POP3SSLStore" type="STORE"/>
  <protocolProviders xmi:id="builtin_imaps" protocol="imaps" classname="com.sun.mail.imap.IMAPSSLStore" type="STORE"/>
</resources.mail:MailProvider>
```

- Required fields:
  - Mail Provider Properties page: name, and at least one protocol provider
  - Mail Session Properties page: name, jndiName, outgoing server and protocol, and/or incoming server and protocol
- Special cases:
  - If you use the ACRCT tool, the password field will be encrypted. You cannot encrypt the password field if you do not use the ACRCT tool.

Mail provider settings for application clients:

Use this page to implement the JavaMail API and create mail sessions.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file. Right-click **Mail Providers** > and click **New**. The following fields appear on the **General** tab:

Name:

The name of the JavaMail resource provider.

Description:

An optional description for the resource provider.

Class Path:

Specifies a list of paths or JAR file names which together form the location for the resource provider classes.

Protocol:

Specifies the name of the protocol.

Classname:

Specifies the name of the class implementing the protocol. Leave this field blank if you want to use the default implementation.

Type:

This menu contains the following two values: `TRANSPORT` or `STORE`.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Mail session settings for application clients:

Use this page to configure mail session properties.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Mail Providers** > *mail provider instance*. Right-click **Mail Sessions** and click **New**. The following fields appear on the **General** tab:

Name:

Represents the administrative name of the JavaMail session object.

Description:

Provides an optional description for your administrative records.

JNDI Name:

The application client run time uses this field to retrieve configuration information.

Mail Transport Host:

Specifies the server to connect to when sending mail.

Mail Transport Protocol:

Specifies the transport protocol to use when sending mail.

Mail Transport User:

Specifies the user ID to use when the mail transport host requires authentication.

Mail Transport Password:

Specifies the password to use when the mail transport host requires authentication.

Enable strict Internet address parsing:

Specifies whether the recipient addresses must be parsed strictly in compliance with RFC 822, which is a specifications document issued by the Internet Architecture Board.

This setting is not generally used for most mail applications. RFC 822 syntax for parsing addresses effectively enforces a strict definition of a valid email address. If you select this setting, JavaMail will adhere to RFC 822 syntax and reject recipient addresses that do not parse into valid email addresses (as defined by the specification). If you do not select this setting, JavaMail will not adhere to RFC 822 syntax and will accept recipient addresses that do not comply with the specification. By default, this setting is deselected. You can view the RFC 822 specification at the following URL for the World Wide Web Consortium (W3C): http://www.w3.org/Protocols/rfc822/.

Re-Enter Password:

Confirms the password.

Mail From:

Specifies the mail originator.

Mail Store Host:

Specifies the mail account host (or "domain") name.

Mail Store User:

Specifies the user ID of the mail account.

Mail Store Password:

Specifies the password of the mail account.

Re-Enter Password:

Confirms the password.

Mail Store Protocol:

Specifies the protocol to be used when receiving mail.

Mail Debug:

When `true`, JavaMail interaction with mail servers, along with these mail session properties are printed to the `stdout` file.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Example: Configuring mail provider and mail session settings for application clients:

You can configure mail provider and mail session settings. This topic provides the required fields, special cases, and an example.

The purpose of this topic is to help you configure mail provider and mail session settings.

- Required fields:
  - Mail Provider Properties page: name, and at least one protocol provider
  - Mail Session Properties page: name, jndiName, outgoing server and protocol, and/or incoming server and protocol
- Special cases:
  - If you use the ACRCT tool, the password field will be encrypted. You cannot encrypt the password field if you do not use the ACRCT tool.
- Example:

```
<resources.mail:MailProvider xmi:id="builtin_mailprovider" name="Built-in Mail Provider" description="The built-in mail provider">
  <factories xmi:type="resources.mail:MailSession"
             xmi:id="MailSession_1207766754834" name="MailSession"
             jndiName="mail/session" description="Sample mail session" category="Sample"
             mailTransportHost="smtp.coldmail.com" mailTransportUser="transportUser"
             mailTransportPassword="{xor}Lz4sLChvLTs="
             mailFrom="smith@coldmail.com" mailStoreHost="imap.coldmail.com" mailStoreUser="storeUser"
             mailStorePassword="{xor}Lz4sLChvLTs="
             debug="true" strict="true"
             mailTransportProtocol="builtin_smtp" mailStoreProtocol="builtin_imap">
    <propertySet xmi:id="J2EEResourcePropertySet_1207766778585">
      <resourceProperties xmi:id="J2EEResourceProperty_1207766778585" name="key" type="java.lang.String" value="value" required="false"/>
    </propertySet>
```

```
  </factories>
  <protocolProviders xmi:id="builtin_smtp" protocol="smtp" classname="com.sun.mail.smtp.SMTPTransport" type="TRANSPORT"/>
  <protocolProviders xmi:id="builtin_pop3" protocol="pop3" classname="com.sun.mail.pop3.POP3Store" type="STORE"/>
  <protocolProviders xmi:id="builtin_imap" protocol="imap" classname="com.sun.mail.imap.IMAPStore" type="STORE"/>
  <protocolProviders xmi:id="builtin_smtps" protocol="smtps" classname="com.sun.mail.smtp.SMTPSSLTransport" type="TRANSPORT"/>
  <protocolProviders xmi:id="builtin_pop3s" protocol="pop3s" classname="com.sun.mail.pop3.POP3SSLStore" type="STORE"/>
  <protocolProviders xmi:id="builtin_imaps" protocol="imaps" classname="com.sun.mail.imap.IMAPSSLStore" type="STORE"/>
</resources.mail:MailProvider>
```

Configuring new mail sessions for application clients

You can use the Application Client Resource Configuration Tool (ACRCT) to configure new mail sessions for your application client.

Before you begin

During this task, you configure new mail sessions for your application client. The mail sessions are associated with the pre-configured default mail provider supplied by the product.

Procedure

1. Start the Application Client Resource Configuration Tool (ACRCT) and open the EAR file. The EAR file contents are displayed in a tree view.
2. Select the JAR file in which you want to configure the new JavaMail session.
3. Expand the JAR file to view its contents.
4. Click **Mail Providers > Mail Provider > Mail Sessions**. Complete one of the following actions:
   - Right click the Mail Sessions folder and select **New Factory**.
   - Click **Edit > New** on the menu bar.
5. Configure the Mail Session properties in the displayed fields.
6. Click **OK**.
7. Click **File > Save** on the menu bar to save your changes.

Configuring new URL providers for application clients

You can create URL providers and URLs for your client application using the Application Client Resource Configuration Tool (ACRCT).

Before you begin

During this task, you create URL providers and URLs for your client application. In a separate administrative task, you must install the Java code for the required URL provider on the client machine on which the client application resides.

About this task

Procedure

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure the new URL provider. The EAR file contents display in a tree view.
3. Select the JAR file in which you want to configure the new URL provider from the tree.
4. Expand the JAR file to view the contents.
5. Click the folder called URL Providers. Complete one of the following actions:
   - Right click the folder and select **New**.
   - Click **Edit > New** on the menu bar.
6. Configure the URL provider properties in the resulting property dialog.
7. Click **OK**.
8. Click **File > Save** on the menu bar to save your changes.

Example

- Configuring URL and URL provider settings for application clients

This code example illustrates how to configure URL and URL provider settings for application clients:

```
<resources.url:URLProvider xmi:id="URLProvider_1" name="urlProvider:name"
description="urlProvider:description"
streamHandlerClassName="urlProvider:streamHandlerClass"
protocol="urlProvider:protocol">
<classpath>urlProvider:classpath</classpath>
<factories xmi:type="resources.url:URL" xmi:id="URL_1" name="urlFactory:name"
jndiName="urlFactory:jndiName" description="urlFactory:description"
spec="urlFactory:url">
<propertySet xmi:id="J2EEResourcePropertySet_18">
<resourceProperties xmi:id="J2EEResourceProperty_20" name="urlFactory:customName"
value="urlFactory:customValue"/>
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_19">
<resourceProperties xmi:id="J2EEResourceProperty_21" name="urlProvider:customName"
value="urlProvider:customValue"/>
</propertySet>
</resources.url:URLProvider>
```

- Required fields:
  - URL Properties page: name, jndiName, url
  - URL Provider Properties page: name

URLs for application clients:

A *Uniform Resource Locator* (URL) is an identifier that points to an electronically accessible resource, such as a directory file on a machine in a network, or a document stored in a database.

URLs appear in the format *scheme*:*scheme_information*.

You can represent a *scheme* as `http`, `ftp`, `file`, or another term that identifies the type of resource and the mechanism by which you can access the resource.

In a web browser location or address box, a URL for a file available using HyperText Transfer Protocol (HTTP) starts with `http:`. An example is `http://www.ibm.com`. Files available using File Transfer Protocol (FTP) start with `ftp:`. Files available locally start with `file:`.

The *scheme_information* commonly identifies the Internet machine making a resource available, the path to that resource, and the resource name. The scheme_information for HTTP, FTP and File generally starts with two slashes (//), then provides the Internet address separated from the resource path name with one slash (/). For example,

`http://www.ibm.com/software/webservers/appserv/library.html`.

For HTTP and FTP, the path name ends in a slash when the URL points to a directory. In such cases, the server generally returns the default index for the directory.

URL providers for the Application Client Resource Configuration Tool:

A URL provider implements the function for a particular URL protocol, such as HyperText Transfer Protocol (HTTP). This provider, comprised of a pair of classes, extends the java.net.URLStreamHandler and java.net.URLConnection classes.

Configuring URL providers and sessions using the Application Client Resource Configuration Tool:

You can edit the configurations of URL providers and URLs to be used by your application clients using the Application Client Resource Configuration Tool (ACRCT).

Before you begin

Use the Application Client Resource Configuration Tool (ACRCT) to edit the configurations of URL providers and URLs to be used by your application clients.

About this task

Procedure

1. Start the ACRCT.
2. Open an EAR file.
3. Locate the URL objects in the tree that displays. For example, if your file contains URL providers and URLs, expand **Resources > *application* > .jar > URL Providers > *url_provider_instance***
   where *url_provider_instance* is a particular URL provider.
4. If you expand the tree further, you will also see the URLs folders containing the URL instances for each URL provider instance.

URL settings for application clients:

Use this page to implement the function for a particular URL protocol, such as Hyper Text Transfer Protocol (HTTP).

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **URL Providers** > *URL provider instance*. Right-click **URLs** and click **New**. The following fields appear on the **General** tab.

This provider, comprised of classes, extends the `java.net.URLStreamHandler` and `java.net.URLConnection` classes.

Name:

The administrative name for the URL.

Description:

This is an optional description of the URL for your administrative records.

JNDI Name:

The application client run time uses this field to retrieve configuration information.

URL:

A Uniform Resource Locator (URL) name that points to an Internet or intranet resource. For example: `http://www.ibm.com`.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

URL provider settings for application clients:

Use this page create new URL providers.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file. Right click **URL Providers**, and click **New**. The following fields appear on the **General** tab.

A URL provider implements the function for a particular URL protocol, such as Hyper Text Transfer Protocol (HTTP). This provider, comprised of classes, extends the `java.net.URLStreamHandler` and `java.net.URLConnection` classes.

Name:

Administrative name for the URL.

Description:

Optional description of the URL, for your administrative records.

Class Path:

A list of paths or JAR file names which together form the location for the resource provider classes.

Protocol:

Protocol supported by this stream handler. For example, `nntp`, `smtp`, `ftp`, and so on.

To use the default protocol, leave this field blank.

Stream handler class:

Fully qualified name of a User-defined Java class that extends the `java.net.URLStreamHandler` for a particular URL protocol, such as FTP.

To use the default stream handler, leave this field blank.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Example: Configuring URL and URL provider settings for application clients:

You can configure URL and URL provider settings. This topic provides the required fields and an example.

The purpose of this article is to help you to configure URL and URL provider settings.

- Required fields:
  - URL Properties page: name, jndiName, url

  – URL Provider Properties page: name
- Example:

```
<resources.url:URLProvider xmi:id="URLProvider_1" name="urlProvider:name"
description="urlProvider:description"
streamHandlerClassName="urlProvider:streamHandlerClass"
protocol="urlProvider:protocol">
<classpath>urlProvider:classpath</classpath>
<factories xmi:type="resources.url:URL" xmi:id="URL_1" name="urlFactory:name"
jndiName="urlFactory:jndiName" description="urlFactory:description"
spec="urlFactory:url">
<propertySet xmi:id="J2EEResourcePropertySet_18">
<resourceProperties xmi:id="J2EEResourceProperty_20" name="urlFactory:customName"
value="urlFactory:customValue"/>
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_19">
<resourceProperties xmi:id="J2EEResourceProperty_21" name="urlProvider:customName"
value="urlProvider:customValue"/>
</propertySet>
</resources.url:URLProvider>
```

Configuring new URLs with the Application Client Resource Configuration Tool

You can use URLs for your client application using the Application Client Resource Configuration Tool (ACRCT).

Before you begin

During this task, you create URLs for your client application.

About this task

Procedure

1. Click the URL provider for which you want to create a URL in the tree. Complete one of the following:
   - Configure a new URL provider.
   - Click an existing URL provider.
2. Expand the URL provider to view the URLs folder.
3. Click the URL folder. Complete one of the following actions:
   - Right click the folder and click **New**.
   - Click **Edit -> New** on the menu bar.
4. Configure the URL properties in the displayed fields.
5. Click **OK** when you finish.
6. Click **File > Save** in the menu bar to save your changes.

Configuring Java messaging client resources

To configure Java messaging client resources, you create new JMS provider configurations for your application client. The application client can use a messaging service through the Java Message Service APIs. A JMS provider provides two kinds of J2EE factories. One is a *JMS connection factory*, and the other is a *JMS destination factory*.

Before you begin

In a separate administrative task, install the Java Message Service (JMS) client on the client machine where the application client resides. The messaging product vendor must provide an implementation of the JMS client. For more information, see your messaging product documentation.

Attention: When completing this task, you can either create a new messaging provider, or you can use an existing one.

Procedure

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure the new JMS provider. The EAR file contents are in the displayed tree view.
3. Select the JAR file in which you want to configure the new JMS provider from the tree.
4. Expand the JAR file to view its contents.
5. Optionally right-click **Messaging Providers** and select **New**, if you want to create and use a new messaging provider.
6. Configure the JMS provider properties in the resulting property dialog.
7. Click **OK**.
8. Click **File > Save**.

Asynchronous messaging in WebSphere Application Server using JMS:

WebSphere Application Server supports asynchronous messaging as a method of communication based on the Java Message Service (JMS) programming interface. The JMS interface provides a common way for Java programs (clients and Java Platform, Enterprise Edition (Java EE) applications) to create, send, receive, and read asynchronous requests as JMS messages.

This topic provides a generic overview of asynchronous messaging using the JMS support provided by WebSphere Application Server.

The base support for asynchronous messaging using the JMS API provides the common set of JMS interfaces and associated semantics that define how a JMS client can access the facilities of a JMS provider. This support enables WebSphere product Java EE applications, as JMS clients, to exchange messages asynchronously with other JMS clients, by using JMS destinations (queues or topics). A Java EE application can use JMS queue destinations for point-to-point messaging and JMS topic destinations for publish and subscribe messaging. A Java EE application can explicitly poll for messages on a destination, and then retrieve messages for processing by business logic beans (enterprise beans).

With the base JMS and XA support, the Java EE application uses standard JMS calls to process messages, including any responses or outbound messaging. An enterprise bean can handle responses acting as a sender bean, or within the enterprise bean that receives the incoming messages. Optionally, this process can use two-phase commit within the scope of a transaction. This level of function for asynchronous messaging is called *bean-managed messaging*, and gives an enterprise bean complete control over the messaging infrastructure, for example, connection and session pool management. The common container has no role in bean-managed messaging.

WebSphere Application Server also supports automatic asynchronous messaging using message-driven beans (a type of enterprise bean defined in the Enterprise JavaBeans (EJB) 2.0 specification) and JMS listeners (part of the JMS application server facilities). Messages are automatically retrieved from JMS destinations, optionally within a transaction, then sent to the message-driven bean in a Java EE application, without the application having to explicitly poll JMS destinations.

Java Message Service providers for clients:

Client applications can use messaging resources from three main types of Java Message Service (JMS) providers in WebSphere Application Server: The WebSphere Application Server default messaging provider (which uses service integration as the provider), the WebSphere MQ messaging provider (which uses your WebSphere MQ system as the provider) and third-party messaging providers (which use another company's product as the provider).

IBM WebSphere Application Server supports asynchronous messaging through the use of a JMS provider and its related messaging system. JMS providers must conform to the JMS specification version 1.1. To

use message-driven beans the JMS provider must support the optional Application Server Facility (ASF) function defined within that specification, or support an inbound resource adapter as defined in the JCA specification version 1.5.

Default messaging provider
If you mainly want to use messaging between applications in WebSphere Application Server, perhaps with some interaction with a WebSphere MQ system, the default messaging provider is the natural choice. This provider is based on service integration technologies and is fully integrated with the WebSphere Application Server runtime environment.

WebSphere MQ messaging provider
If your business also uses WebSphere MQ, and you want to integrate WebSphere Application Server messaging applications into a predominately WebSphere MQ network, choose the WebSphere MQ messaging provider, which allows you to define resources for connecting to any queue manager on the WebSphere MQ network.

Third-party messaging provider
You can configure any third-party messaging provider that supports the JMS Version 1.1 unified connection factory. You might want to do this, for example, because of existing investments.

WebSphere applications can use messaging resources provided by any of these JMS providers. However the choice of provider is most often dictated by requirements to use or integrate with an existing messaging system. For example, you may already have a messaging infrastructure based on WebSphere MQ. In this case you may either connect directly using the included support for WebSphere MQ as a JMS provider, or configure a service integration bus with links to a WebSphere MQ network and then access the bus through the default messaging provider.

Configuring new JMS providers with the Application Client Resource Configuration Tool:

You can create new Java Message Service (JMS) provider configurations for the Application Client. The Application Client makes use of a messaging service through the JMS interfaces.

About this task

During this task, you create new Java Message Service (JMS) provider configurations for the Application Client. The Application Client makes use of a messaging service through the JMS interfaces. A JMS provider provides two kinds of Java Platform, Enterprise Edition (Java EE) resources. One is a JMS connection factory, and the other is a JMS destination.

In a separate administrative task, you must install the JMS client on the client machine where your particular application client resides. The messaging product vendor must provide an implementation of the JMS client. For more information, see your messaging product documentation.

Procedure

1. Start the Application Client Resource Configuration Tool and open the EAR file for which you want to configure the new JMS provider. The EAR file contents are displayed in a tree view.
2. From the tree, select the JAR file in which you want to configure the new JMS provider.
3. Expand the JAR file to view its contents.
4. Right-click **Messaging Providers**. Complete one of the following actions:
   - Right click the folder and select **New**.
   - On the menu bar, click **Edit > New**.
5. In the resulting property dialog, configure the JMS provider properties.
6. Click **OK** when finished.
7. Click **File > Save** on the menu bar to save your changes.

Example

The following code example illustrates how to configure JMS Provider, JMS Connection Factory and JMS Destination settings for application clients.

```
<resources.jms:JMSProvider xmi:id="JMSProvider_3" name="genericJMSProvider:name"
description="genericJMSProvider:description"
externalInitialContextFactory="genericJMSProvider:contextFactoryClass"
externalProviderURL="genericJMSProvider:providerUrl">
<classpath>genericJMSProvider:classpath</classpath>
<factories xmi:type="resources.jms:GenericJMSDestination"
xmi:id="GenericJMSDestination_1" name="jmsDestination:name"
jndiName="jmsDestination:jndiName" description="jmsDestination:description"
externalJNDIName="jmsDestination:externalJndiName" type="QUEUE">
<propertySet xmi:id="J2EEResourcePropertySet_15">
<resourceProperties xmi:id="J2EEResourceProperty_17" name="jmsDestination:customName"
value="jmsDestination:customValue"/>
</propertySet>
</factories>
<factories xmi:type="resources.jms:GenericJMSConnectionFactory"
xmi:id="GenericJMSConnectionFactory_1" name="jmsCF:name" jndiName="jmsCF:jndiName"
description="jmsCF:description" userID="jmsCF:user" password="{xor}NTIsHBllMT4yOg=="
externalJNDIName="jmsCF:externalJndiName" type="QUEUE">
<propertySet xmi:id="J2EEResourcePropertySet_16">
<resourceProperties xmi:id="J2EEResourceProperty_18" name="jmsCF:customName"
value="jmsCF:customValue"/>
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_17">
<resourceProperties xmi:id="J2EEResourceProperty_19"
name="genericJMSProvider:customName" value="genericJMSProvider:customValue"/>
</propertySet>
</resources.jms:JMSProvider>
```

Required fields include:
- JMS Provider Properties page: name, and at least one protocol provider
- JMS Connection Factory Properties page: name, jndiName, destination type
- JMS Destination Properties page: name, jndiName, destination type

Special cases:
- The destination type must be QUEUE, or TOPIC.

JMS provider settings for application clients:

Use this page to configure properties of the Java Message Service (JMS) provider, if you want to use a JMS provider other than the default messaging provider or the WebSphere MQ as a JMS provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file. Right click **Messaging Providers**, and click **New**. The following fields appear on the **General** tab.

Name:

The name by which the JMS provider is known for administrative purposes.

Information	**Value**
Data type	String

Description:

A description of the JMS provider, for administrative purposes.

Information	Value
Data type	String

Class Path:

A list of paths or `.jar` file names which together form the location for the resource provider classes.

Context factory class:

The Java class name of the initial context factory for the JMS provider.

For example, for an LDAP service provider the value has the form: `com.sun.jndi.ldap.LdapCtxFactory`.

Information	Value
Data type	String

Provider URL:

The JMS provider URL for external JNDI lookups.

For example, an LDAP URL for a JMS provider has the form: `ldap://hostname.company.com/contextName`.

Information	Value
Data type	String

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Default Provider connection factory settings:

Use this panel to view or change the configuration properties of the selected JMS connection factory for use with the internal product Java Message Service (JMS) provider that is installed with WebSphere Application Server. These configuration properties control how connections are created between the JMS provider and the service integration bus that it uses

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Default Provider**. Right-click **Connection Factories** and click **New**. The following fields appear on the **General** tab.

Settings that have a default value display the appropriate value. Any settings that have fixed values have a drop down menu.

Name:

The name of the connection factory.

Information	Value
Data type	String

Description:

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Information	Value
Data type	String

JNDI Name:

The JNDI name that is used to match this Resource Adapter connection factory definition to the deployment descriptor. This entry is a `resource-ref` name.

Information	Value
Data type	String

User Name:

The **User Name** used with the **Password** property for connecting to an application.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

The connection factory **User ID** and **Password** properties are used if the calling application does not provide a `userid` and `password` explicitly. If a user name and password are specified, then an authentication alias is created for the factory where the password is encrypted.

Information	Value
Data type	String

Password:

The password used to authenticate connection to an application.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

Information	Value
Data type	String

Re-Enter Password:

Confirms the password.

Bus Name:

The name of the bus to which the connection factory connects.

Information	Value
Data type	String

Client Identifier:

The name of the client. Required for durable topic subscriptions.

Information	Value
Data type	String

Nonpersistent Messaging Reliability:

The reliability applied to nonpersistent JMS messages sent using this connection factory.

If you want different reliability delivery options for individual JMS destinations, you can set this property to **As bus** destination. The reliability is then defined by the Reliability property of the bus destination to which the JMS destination is assigned.

Information	Value
Default	ReliablePersistent
Range	**None** There is no message reliability for nonpersistent messages. If a nonpersistent message cannot be delivered, it is discarded. **Best effort nonpersistent** Messages are never written to disk, and are thrown away if memory cache overruns. **Express nonpersistent** Messages are written asynchronously to persistent storage if memory cache overruns, but are not kept over server restarts. **Reliable nonpersistent** Messages can be lost if a messaging engine fails, and can be lost under normal operating conditions. **Reliable persistent** Messages can be lost if a messaging engine fails, but are not lost under normal operating conditions. **Assured persistent** Highest degree of reliability where assured message delivery is supported. **As Bus destination** Use the delivery option configured for the bus destination.

Persistent Message Reliability:

The reliability applied to persistent JMS messages sent using this connection factory.

If you want different reliability delivery options for individual JMS destinations, you can set this property to **As bus destination**. The reliability is then defined by the Reliability property of the bus destination to which the JMS destination is assigned.

Information	Value
Default	ReliablePersistent
Range	**None** There is no message reliability for nonpersistent messages. If a nonpersistent message cannot be delivered, it is discarded. **Best effort nonpersistent** Messages are never written to disk, and are thrown away if memory cache overruns. **Express nonpersistent** Messages are written asynchronously to persistent storage if memory cache overruns, but are not kept over server restarts. **Reliable nonpersistent** Messages can be lost if a messaging engine fails, and can be lost under normal operating conditions. **Reliable persistent** Messages can be lost if a messaging engine fails, but are not lost under normal operating conditions. **Assured persistent** Highest degree of reliability where assured message delivery is supported. **As Bus destination** Use the delivery option configured for the bus destination.

Durable Subscription Home:

The name of the durable subscription home.

Information	Value
Data type	String

Share durable subscriptions:

Controls whether or not durable subscriptions are shared across connections with members of a server cluster.

Normally, only one session at a time can have a TopicSubscriber for a particular durable subscription. This property enables you to override this behavior, to enable a durable subscription to have multiple simultaneous consumers.

Information	Value
Data type	Selection list
Default	In cluster

Information	Value
Range	**In cluster** Allows sharing of durable subscriptions when connections are made from within a server cluster. **Always shared** Durable subscriptions can be shared across connections. **Never shared** Durable subscriptions are never shared across connections.

Read Ahead:

Controls the read-ahead optimization during message delivery.

Information	Value
Default	Default
Range	Default, AlwaysOn and AlwaysOff

Target:

The name of the Workload Manager target group containing the messaging engine.

Information	Value
Data type	String

Target Type:

The type of Workload Manager target group that contains the messaging engine.

Information	Value
Default	BusMember
Range	BusMember, Custom, ME

Target Significance:

The priority of significance for the target specified.

Information	Value
Default	Preferred
Range	Preferred, Required

Target Inbound Transport Chain:

The name of the protocol that resolves to a group of messaging engines.

Information	Value
Data type	String

Provider Endpoints:

The list of comma separated endpoints used to connect to a bootstrap server.

Type a comma-separated list of endpoint triplets with the syntax: host:port:protocol.

Information	Value
Example	`merlin:7276:BootstrapBasicMessaging,Gandalf:5557:BootstrapSecureMessaging` where `BootstrapBasicMessaging` corresponds to the remote protocol InboundBasicMessaging (JFAP-TCP/IP).
Default	• If the host name is not specified, then the default `localhost` is used as a default value. • If the port number is not specified, then `7276` is used as a default value. • If the chain name is not specified, a predefined chain, such as `BootstrapBasicMessaging`, is used as a default value.

Connection Proximity:

The proximity that the messaging engine should have to the requester.

Information	Value
Default	Bus
Range	Bus, Host, Cluster, Server

Temporary Queue Name Prefix:

The prefix to apply to the names of temporary queues. This name is a maximum of 12 characters.

Information	Value
Data type	String

Temporary Topic Name Prefix:

The prefix to apply to the names of temporary topics. This name is a maximum of 12 characters.

Information	Value
Data type	String

Default Provider queue connection factory settings:

Use this panel to view or change the configuration properties of the selected JMS queue connection factory for use with the internal product Java Message Service (JMS) provider that is installed with WebSphere Application Server. These configuration properties control how connections are created between the JMS provider and the service integration bus that it uses

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Default Provider**. Right-click **Queue Connection Factories** and click **New**. The following fields appear on the **General** tab.

Settings that have a default value display the appropriate value. Any settings that have fixed values have a drop down menu.

Name:

The name of the queue connection factory.

Information	Value
Data type	String

Description:

A description of this queue connection factory for administrative purposes within WebSphere Application Server.

Information	Value
Data type	String

JNDI Name:

The JNDI name that is used to match this queue connection factory definition to the deployment descriptor. This entry is a `resource-ref` name.

Information	Value
Data type	String

User Name:

The **User Name** used, with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly. If this field is used, then the Properties field `UserName` is ignored.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

The connection factory **User Name** and **Password** properties are used if the calling application does not provide a `userid` and `password` explicitly. If a user name and password are specified, then an authentication alias is created for the factory where the password is encrypted.

Information	Value
Data type	String

Password:

The password used to create an encrypted. If you complete this field, then the Password field in the Properties box is ignored.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

Information	Value
Data type	String

Re-Enter Password:

Confirms the password.

Bus Name:

The name of the bus to which the queue connection factory connects.

Information	Value
Data type	String

Client Identifier:

The client identifier. Required for durable topic subscriptions.

Information	Value
Data type	String

Nonpersistent Messaging Reliability:

The reliability applied to nonpersistent JMS messages sent using this connection factory.

If you want different reliability delivery options for individual JMS destinations, you can set this property to **As bus** destination. The reliability is then defined by the Reliability property of the bus destination to which the JMS destination is assigned.

Information	Value
Default	ReliablePersistent
Range	**None** There is no message reliability for nonpersistent messages. If a nonpersistent message cannot be delivered, it is discarded. **Best effort nonpersistent** Messages are never written to disk, and are thrown away if memory cache overruns. **Express nonpersistent** Messages are written asynchronously to persistent storage if memory cache overruns, but are not kept over server restarts. **Reliable nonpersistent** Messages can be lost if a messaging engine fails, and can be lost under normal operating conditions. **Reliable persistent** Messages can be lost if a messaging engine fails, but are not lost under normal operating conditions. **Assured persistent** Highest degree of reliability where assured message delivery is supported. **As Bus destination** Use the delivery option configured for the bus destination.

Persistent Message Reliability:

The reliability applied to persistent JMS messages sent using this connection factory.

If you want different reliability delivery options for individual JMS destinations, you can set this property to **As bus destination**. The reliability is then defined by the Reliability property of the bus destination to which the JMS destination is assigned.

Information	Value
Default	ReliablePersistent
Range	**None** There is no message reliability for nonpersistent messages. If a nonpersistent message cannot be delivered, it is discarded. **Best effort nonpersistent** Messages are never written to disk, and are thrown away if memory cache overruns. **Express nonpersistent** Messages are written asynchronously to persistent storage if memory cache overruns, but are not kept over server restarts. **Reliable nonpersistent** Messages can be lost if a messaging engine fails, and can be lost under normal operating conditions. **Reliable persistent** Messages can be lost if a messaging engine fails, but are not lost under normal operating conditions. **Assured persistent** Highest degree of reliability where assured message delivery is supported. **As Bus destination** Use the delivery option configured for the bus destination.

Read Ahead:

Controls the read-ahead optimization during message delivery.

Information	Value
Default	Default
Range	Default, AlwaysOn and AlwaysOff

Target:

The name of the Workload Manager target group containing the messaging engine.

Information	Value
Data type	String

Target Type:

The type of Workload Manager target group that contains the messaging engine.

Information	Value
Default	BusMember
Range	BusMember, Custom, Destination, ME

Target Significance:

The priority of significance for the target specified.

Information	Value
Default	Preferred
Range	Preferred, Required

Target Inbound Transport Chain:

The name of the protocol that resolves to a group of messaging engines.

Information	Value
Data type	String

Provider Endpoints:

The list of comma separated endpoints used to connect to a bootstrap server.

Type a comma-separated list of endpoint triplets with the syntax: host:port:protocol.

Information	Value
Example	`localhost:7777:BootstrapBasicMessaging` where `BootstrapBasicMessaging` corresponds to the remote protocol InboundBasicMessaging (JFAP-TCP/IP).
Default	• If the host name is not specified, then the default `localhost` is used as a default value. • If the port number is not specified, then `7276` is used as a default value. • If the chain name is not specified, a predefined chain, such as `BootstrapBasicMessaging`, is used as a default value.

Connection Proximity:

The proximity that the messaging engine should have to the requester.

Information	Value
Default	Bus, Cluster, Server
Range	Bus, Host

Temporary Queue Name Prefix:

The prefix to apply to the names of temporary queues. This name is a maximum of 12 characters.

Information	Value
Data type	String

Default Provider topic connection factory settings:

Use this panel to view or change the configuration properties of the selected JMS topic connection factory for use with the internal product Java Message Service (JMS) provider that is installed with WebSphere Application Server. These configuration properties control how connections are created between the JMS provider and the service integration bus that it uses.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Default Provider**. Right-click **Topic Connection Factories** and click **New**. The following fields appear on the **General** tab.

Settings that have a default value display that appropriate value. Any settings that have fixed values have a drop down menu.

Name:

The name of the topic connection factory.

Information	**Value**
Data type	String

Description:

A description of this topic connection factory for administrative purposes within IBM WebSphere Application Server.

Information	**Value**
Data type	String

JNDI Name:

The JNDI name that is used to match this topic connection factory definition to the deployment descriptor. This entry is a `resource-ref` name.

Information	**Value**
Data type	String

User Name:

The **User Name** used, with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly. If this field is used, then the Properties field `UserName` is ignored.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

The connection factory **User Name** and **Password** properties are used if the calling application does not provide a `userid` and `password` explicitly. If a user name and password are specified, then an authentication alias is created for the factory where the password is encrypted.

Information	**Value**
Data type	String

Password:

The password used to create an encrypted. If you complete this field, then the Password field in the Properties box is ignored.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

Information	Value
Data type	String

Re-Enter Password:

Confirms the password.

Bus Name:

The name of the bus to which the topic connection factory connects.

Information	Value
Data type	String

Client Identifier:

The name of the client. This field is required for durable topic subscriptions.

Information	Value
Data type	String

Nonpersistent Messaging Reliability:

The reliability applied to nonpersistent JMS messages sent using this connection factory.

If you want different reliability delivery options for individual JMS destinations, you can set this property to **As bus** destination. The reliability is then defined by the Reliability property of the bus destination to which the JMS destination is assigned.

Information	Value
Default	ReliablePersistent

Information	Value
Range	**None** There is no message reliability for nonpersistent messages. If a nonpersistent message cannot be delivered, it is discarded. **Best effort nonpersistent** Messages are never written to disk, and are thrown away if memory cache overruns. **Express nonpersistent** Messages are written asynchronously to persistent storage if memory cache overruns, but are not kept over server restarts. **Reliable nonpersistent** Messages can be lost if a messaging engine fails, and can be lost under normal operating conditions. **Reliable persistent** Messages can be lost if a messaging engine fails, but are not lost under normal operating conditions. **Assured persistent** Highest degree of reliability where assured message delivery is supported. **As Bus destination** Use the delivery option configured for the bus destination.

Persistent Message Reliability:

The reliability applied to persistent JMS messages sent using this connection factory.

If you want different reliability delivery options for individual JMS destinations, you can set this property to **As bus destination**. The reliability is then defined by the Reliability property of the bus destination to which the JMS destination is assigned.

Information	Value
Default	ReliablePersistent

Information	Value
Range	**None** There is no message reliability for nonpersistent messages. If a nonpersistent message cannot be delivered, it is discarded. **Best effort nonpersistent** Messages are never written to disk, and are thrown away if memory cache overruns. **Express nonpersistent** Messages are written asynchronously to persistent storage if memory cache overruns, but are not kept over server restarts. **Reliable nonpersistent** Messages can be lost if a messaging engine fails, and can be lost under normal operating conditions. **Reliable persistent** Messages can be lost if a messaging engine fails, but are not lost under normal operating conditions. **Assured persistent** Highest degree of reliability where assured message delivery is supported. **As Bus destination** Use the delivery option configured for the bus destination.

Durable Subscription Home:

The name of the durable subscription home.

Information	Value
Data type	String

Share durable subscriptions:

Controls whether or not durable subscriptions are shared across connections with members of a server cluster.

Normally, only one session at a time can have a TopicSubscriber for a particular durable subscription. This property enables you to override this behavior, to enable a durable subscription to have multiple simultaneous consumers.

Information	Value
Data type	Selection list
Default	In cluster

Information	Value
Range	**In cluster** Allows sharing of durable subscriptions when connections are made from within a server cluster. **Always shared** Durable subscriptions can be shared across connections. **Never shared** Durable subscriptions are never shared across connections.

Read Ahead:

Controls the read-ahead optimization during message delivery.

Information	Value
Default	Default
Range	Default, AlwaysOn and AlwaysOff

Target:

The name of the Workload Manager target group containing the messaging engine.

Information	Value
Data type	String

Target Type:

The type of Workload Manager target group that contains the messaging engine.

Information	Value
Default	BusMember
Range	BusMember, Custom, ME

Target Significance:

The priority of significance for the target specified.

Information	Value
Default	Preferred
Range	Preferred, Required

Target Inbound Transport Chain:

The name of the protocol that resolves to a group of messaging engines.

Information	Value
Data type	String

Provider Endpoints:

The list of comma separated endpoints used to connect to a bootstrap server.

Type a comma-separated list of endpoint triplets with the syntax: host:port:protocol.

Information	Value
Example	`localhost:7777:BootstrapBasicMessaging` where `BootstrapBasicMessaging` corresponds to the remote protocol InboundBasicMessaging (JFAP-TCP/IP).
Default	• If the host name is not specified, then the default `localhost` is used as a default value. • If the port number is not specified, then `7276` is used as a default value. • If the chain name is not specified, a predefined chain, such as `BootstrapBasicMessaging`, is used as a default value.

Connection Proximity:

The proximity that the messaging engine should have to the requester.

Information	Value
Default	Bus
Range	Bus, Host, Cluster, Server

Temporary Topic Name Prefix:

The prefix to apply to the names of temporary topics. This name is a maximum of 12 characters.

Information	Value
Data type	String

Default Provider queue destination settings:

Use this panel to view or change the configuration properties of the selected JMS queue destination for use with the internal product Java Message Service (JMS) provider that is installed with WebSphere Application Server.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Default Provider**. Right-click **Queue Destinations**. Click **New**. The following fields appear on the **General** tab.

Name:

The name of the queue destination factory. You must complete this field.

Information	Value
Data type	String

Description:

A description of this queue destination for administrative purposes within WebSphere Application Server.

Information	Value
Data type	String

JNDI Name:

The JNDI name used to match this definition to a deployment descriptor `resource-env-ref` name.

Information	Value
Data type	String

Queue Name:

The name of the queue.

Information	Value
Data type	String

Delivery Mode:

The delivery mode for messages sent to this destination.

Information	Value
Data type	String
Range	Application, Persistent or NonPersistent
Default	Application

Time to Live:

The default length of time from its dispatch time that a message sent to this destination should be retained by the system, where **0** indicates that time to live value does not expire. Value from the producer is used if the Time to Live field is not completed.

Information	Value
Data type	Integer
Units	Milliseconds

Priority:

The priority for messages sent to this destination. The value from the producer is used if not completed.

Information	Value
Data type	Integer
Range	0 to 9 with **0** as the lowest priority and **9** as the highest priority

Read Ahead:

Used to control read-ahead optimization during message delivery.

Information	Value
Data type	String
Range	AsConnection, AlwaysOn and AlwaysOff

Information	Value
Default	AsConnection

Default Provider topic destination settings:

Use this panel to view or change the configuration properties of the selected JMS topic destination for use with the internal product Java Message Service (JMS) provider that is installed with WebSphere Application Server.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Default Provider**. Right-click **Topic Destinations**, and click **New**. The following fields appear on the **General** tab.

Name:

The name of the topic destination entry.

Information	Value
Data type	String

Description:

A description of the entry.

Information	Value
Data type	String

JNDI Name:

The JNDI name used to match this definition to a deployment descriptor `resource-env-ref` name.

Information	Value
Data type	String

Topic Space:

The name of the topic space. This field is required.

Information	Value
Data type	String
Default	DEFAULT_TOPIC_SPACE

Topic Name:

The name of the topic. This field is required.

Information	Value
Data type	String

Delivery Mode:

The default mode for messages sent to this destination.

Information	Value
Data type	String
Range	Application, Persistent or NonPersistent
Default	Application

Time to Live:

The default length of time from its dispatch time that a message sent to this destination should be retained by the system, where **0** indicates that time to live value does not expire. Value from the producer is used if not completed.

Information	Value
Data type	Long
Units	Milliseconds

Priority:

The priority for messages sent to this destination. Value from producer is used if not completed.

Information	Value
Data type	Integer
Range	0 to 9 with **0** as the lowest priority and **9** as the highest priority

Read Ahead:

Used to control read-ahead optimization during message delivery.

Information	Value
Data type	String
Range	AsConnection, AlwaysOn and AlwaysOff
Default	AsConnection

WebSphere MQ Provider queue connection factory settings for application clients:

Use this panel to view or change the configuration properties of the selected queue connection factory for use with the WebSphere MQ Java Message Service (JMS) provider. These configuration properties control how connections are created between the JMS provider and WebSphere MQ.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file and click **Messaging Providers** > **WebSphere MQ Provider**. Right click **Queue Connection Factories**, and click **New**. The following fields are displayed on the **General** tab.

Note:

- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ for JMS resources, see the *Using Java* section of the WebSphere MQ information center.
- In WebSphere MQ, names can have a maximum of 48 characters, except for channels which have a maximum of 20 characters.

A queue connection factory for the JMS provider has the following properties.

Name:

The name by which this queue connection factory is known for administrative purposes within WebSphere Application Server. The name must be unique within the JMS connection factories across the WebSphere administrative domain.

Information	Value
Data type	String

Description:

A description of this connection factory for administrative purposes within WebSphere Application Server.

Information	Value
Data type	String
Default	Null

JNDI Name:

The application client run time uses this field to retrieve configuration information.

User ID:

The user ID used, with the password property, for authentication if the calling application does not provide a user ID and password explicitly.

If you specify a value for the user ID property, you must also specify a value for the password property.

The connection factory user ID and password properties are used if the calling application does not provide a user ID and password explicitly; for example, if the calling application uses the method createQueueConnection(). The JMS client flows the user ID and password to the JMS server.

Information	Value
Data type	String

Password:

The password used, with the user ID property, for authentication if the calling application does not provide a user ID and password explicitly.

If you specify a value for the user ID property, you must also specify a value for the password property.

Information	Value
Data type	String
Default	Null

Re-Enter Password:

Confirms the password.

Queue Manager:

The name of the WebSphere MQ queue manager for this connection factory.

Connections created by this factory connect to that queue manager.

Information	Value
Data type	String

Enter Hostname and Port Information:

This radio button is selected by default and, if selected, enables the host and port properties and disables the connection name list property.

Information	Value
Data type	Radio button
Default	Selected

Host:

The name of the host on which the WebSphere MQ queue manager runs for client connection only.

Information	Value
Data type	String
Default	Null
Range	A valid TCP/IP host name

Port:

The TCP/IP port number used for connection to the WebSphere MQ queue manager, for client connection only.

This port must be configured on the WebSphere MQ queue manager.

Information	Value
Data type	Integer
Default	Null
Range	A valid TCP/IP port number, configured on the WebSphere MQ queue manager.

Enter Connection Name List Information:

If selected, this radio button enables the connection name list property and disables the host and port name properties. Select this radio button if you want to connect to a multi-instance queue manager.

Information	Value
Data type	Radio button
Default	Cleared

Connection Name List:

A comma-separated list of host and port information which can be used to connect to a multi-instance queue manager.

The format of the list is:

```
host[(port)],[host[(port)]]
```

where port is optional and defaults to 1414 if it is not set. For example:

```
hostname1,hostname2(1415)
```

For further information about multi-instance queue managers, see the WebSphere MQ information center.

This property must only be used for connecting to a multi-instance queue manager. It must not be used for connecting to a list of distinct queue managers as that can result in transaction integrity issues.

Channel:

The name of the channel used for connection to the WebSphere MQ queue manager, for client connection only.

Information	**Value**
Data type	String
Default	Null
Range	1 through 20 ASCII characters

Transport type:

Specifies whether the WebSphere MQ client connection or JNDI bindings are used for connection to the WebSphere MQ queue manager. The external JMS provider controls the communication protocols between JMS clients and JMS servers. Tune the transport type when you are using non-ASF nonpersistent, nondurable, nontransactional messaging or when you want to satisfy security issues and the client is local to the queue manager node.

Information	**Value**
Data type	Enum
Units	Not applicable
Default	BINDINGS
Range	**BINDINGS** JNDI bindings are used to connect to the queue manager. BINDINGS is a shared memory protocol and can only be used when the queue manager is on the same node as the JMS client and poses security risks that must be addressed through the use of EJB roles. **CLIENT** WebSphere MQ client connection is used to connect to the queue manager. CLIENT is a typical TCP-based protocol. **DIRECT** For WebSphere MQ Event Broker using DIRECT mode. DIRECT is a lightweight sockets protocol used in nontransactional, nondurable, and nonpersistent Publish/Subscribe messaging. DIRECT only works for clients and message-driven beans using the non-ASF protocol. **QUEUED** QUEUED is a standard TCP protocol.

Information	Value
Recommended	**Queue connection factory transport type** BINDINGS is faster by 30% or more, but it requires correctly set up EJB roles to guarantee security. If you have security concerns and need to use CLIENT then you should make appropriate use of SSL to secure the connection to the queue manager. **Topic connection factory transport type** DIRECT is the fastest type and must be used where possible. Use BINDINGS when you want to satisfy additional security tasks and the queue manager is local to the JMS client. QUEUED is the fallback for all other cases. WebSphere MQ 5.3 before CSD2 with the DIRECT setting can lose messages when used with message-driven beans and under load. This loss also happens with client-side applications unless the broker maxClientQueueSize is set to 0. You can set this value to 0 with the command: `#wempschangeproperties WAS_nodeName_server1 -e default -o DynamicSubscriptionEngine -n maxClientQueueSize -v 0 -x executionGroupUUID` where executionGroupUUID can be found by starting the broker and looking in the Event Log/Applications for event 2201. This value is usually ffffffff-0000-0000-000000000000. **Note:** The WebSphere MQ 5.3 JMS cannot be used within WebSphere Application Server Version 6.1 because WebSphere Application Server Version 6.1 has a Java 5 runtime. Therefore, cross-memory connections cannot be established with WebSphere MQ 5.3 queue managers. This can result in a performance degradation if you were previously using WebSphere MQ 5.3 and BINDINGS for your connections and move to CLIENT network connections in migrating to WebSphere Application Server Version 6.1. If you are using WebSphere MQ 5.3 for z/OS, you might also need to install an additional feature pack. When running on 64-bit z/OS, the Transport type must be set to CLIENT because the 64-bit WebSphere MQ z/OS is not currently available, and BINDINGS mode cannot be used to connect to 31-bit WebSphere MQ z/OS. You might also need to purchase an additional WebSphere MQ feature pack for this support.

Client ID:

The JMS client identifier used for connections to the WebSphere MQ queue manager.

Information	Value
Data type	String

CCSID:

The coded character set identifier for use with the WebSphere MQ queue manager.

This coded character set identifier (CCSID) must be one of the CCSIDs supported by WebSphere MQ.

Information	Value
Data type	String

For more information about supported CCSIDs, and about converting between message data from one coded character set to another, see the *System Administration* and *Application Programming Reference* sections of the WebSphere MQ information center.

Message Retention:

Select this check box to specify that unwanted messages are to be left on the queue. Otherwise, unwanted messages are handled according to their disposition options.

Information	Value
Data type	Enum
Units	Not applicable
Default	Cleared
Range	**Selected** Unwanted messages are left on the queue. **Cleared** Unwanted messages are handled according to their disposition options.

Temporary model:

The name of the model definition used to create temporary connection factories if a connection factory does not already exist.

Information	Value
Data type	String
Range	1 through 48 ASCII characters

Temporary queue prefix:

The prefix used for dynamic queue naming.

Information	Value
Data type	String

Fail if quiesce:

Specifies whether applications return from a method call if the queue manager has entered a controlled failure.

Information	Value
Data type	Check box
Default	Selected

Local Server Address:

Specifies the local server address.

Information	Value
Data type	String

Polling Interval:

Specifies the interval, in milliseconds, between scans of all receivers during asynchronous message delivery

Information	Value
Data type	Integer

Information	Value
Units	Milliseconds
Default	5000

Rescan interval:

Specifies the interval in milliseconds between which a topic is scanned to look for messages that have been added to a topic out of order.

This interval controls the scanning for messages that have been added to a topic out of order with respect to a WebSphere MQ browse cursor.

Information	Value
Data type	Integer
Units	Milliseconds
Default	5000

SSL cipher suite:

Specifies the cipher suite to use for SSL connection to WebSphere MQ.

Set this property to a valid cipher suite provided by your JSSE provider. The value must match the CipherSpec specified on the SVRCONN channel as the **Channel** property.

You must set this property, if you set the **SSL Peer Name** property.

SSL certificate store:

Specifies a list of zero or more Certificate Revocation List (CRL) servers used to check for SSL certificate revocation. If you specify a value for this property, you must use WebSphere MQ JVM at Java 2 version 1.4.

The value is a space-delimited list of entries of the form:
`ldap://hostname:[port]`

A single slash (/) follows this value. If *port* is omitted, the default LDAP port of 389 is assumed. At connect-time, the SSL certificate presented by the server is checked against the specified CRL servers. For more information about CRL security, see the information about “Working with Certificate Revocation Lists” in the *Security* section of the WebSphere MQ information center.

SSL peer name:

For SSL, a *distinguished name* skeleton that must match the name provided by the WebSphere MQ queue manager. The distinguished name is used to check the identifying certificate presented by the server at connection time.

If this property is not set, such certificate checking is performed.

The SSL peer name property is ignored if **SSL Cipher Suite** property is not specified.

This property is a list of attribute name and value pairs separated by commas or semicolons. For example:
`CN=QMGR.*, OU=IBM, OU=WEBSPHERE`

The example given checks the identifying certificate presented by the server at connect-time. For the connection to succeed, the certificate must have a Common Name beginning QMGR., and must have at least two Organizational Unit names, the first of which is IBM and the second WEBSPHERE. Checking is not case-sensitive.

For more details about distinguished names and their use with WebSphere MQ, see the information about "Distinguished Names" in the WebSphere MQ information center.

Connection pool:

Specifies an optional set of connection pool settings.

Connection pool properties are common to all J2C connectors.

The application server pools connections and sessions with the JMS provider to improve performance. This connection pooling is independent from any WebSphere MQ connection pooling. You must configure the connection and session pool properties appropriately for your applications, otherwise you might not get the connection and session behavior that you want.

Change the size of the connection pool if concurrent server-side access to the JMS resource exceeds the default value. The size of the connection pool is set on a per queue or topic basis.

Information	**Value**
Data type	Check box
Default	Selected

Client reconnect options:

Specifies whether a client mode connection reconnects automatically, or not, in the event of a communications or queue manager failure. This property is ignored unless the connection factory is being used in a thin or managed client environment.

Information	**Value**
Data type	Drop-down list
Default	DISABLED
Range	**DISABLED** The client reconnection does not automatically occur. **ASDEF** The value from the DefRecon attribute from the channels stanza of the client configuration file is used. If there is no DefRecon value specified then this setting has the same effect as a value of DISABLED. **RECONNECT** Reconnection occurs to any queue manager consistent with the value of the queue manager attribute, which might be a different queue manager from that to which the connection was originally connected. **QMGR** Reconnection only occurs to the queue manager to which the connection was originally connected.

For more information about automatic client reconnection, see the WebSphere MQ information center.

Client reconnect timeout:

The maximum number of seconds that a client mode connection spends attempting to automatically reconnect to a queue manager after a communications or queue manager failure. This parameter is ignored unless the connection factory is being used in a thin or managed client environment. Whether this parameter is used or not depends on the value of the client reconnect options parameter.

Information	Value
Data type	Integer
Units	Seconds
Default	1800
Range	A value greater than zero and up to 2147483647

For more information about automatic client reconnection, see the WebSphere MQ information center.

WebSphere MQ Provider topic connection factory settings for application clients:

Use this panel to view or change the configuration properties of the selected topic connection factory for use with the WebSphere MQ Java Message Service (JMS) provider. These configuration properties control how connections are created between the JMS provider and WebSphere MQ.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **WebSphere MQ Provider**. Right-click **Topic Connection Factories** and click **New**.

Note:

- The property values that you specify must match the values that you specified when configuring WebSphere MQ product JMS resources. For more information about configuring WebSphere MQ JMS resources, see the *Using Java* section of the WebSphere MQ information center.
- In WebSphere MQ, names can have a maximum of 48 characters, except for channels which have a maximum of 20 characters.

MA0C broker: When creating a WebSphere Application Server Version 6 topic connection factory for the MA0C broker, consider the following attribute values:

BrokerControlQueue
This value is fixed at SYSTEM.BROKER.CONTROL.QUEUE for the MA0C broker and is the queue the broker reads from.

BrokerVersion
Set this value to BASIC for the MA0C broker.

ClientID
Set this value to whatever you like for the MA0C broker (the value is string and is merely an identifier for your client application).

XA Enabled
Set this value to TRUE or FALSE for the MA0C broker (the setting you use is a performance enhancement flag - you probably want to set this value to 'true' most of the time).

BrokerMessage Selection
This value is fixed at CLIENT for the MA0C broker because the broker relies on client side message selection.

Direct Broker Authorization Type
This value is not required by the MA0C broker.

A topic connection factory for the WebSphere MQ JMS provider has the following properties.

Name:

The name by which this topic connection factory is known for administrative purposes within WebSphere Application Server. The name must be unique within the JMS provider.

Information	Value
Data type	String

Description:

A description of this topic connection factory for administrative purposes within WebSphere Application Server.

Information	Value
Data type	String

JNDI Name:

The Java Naming and Directory Interface (JNDI) name that is used to bind the topic connection factory into the application server name space.

As a convention, use the fully qualified JNDI name; for example, in the form jms/*Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Information	Value
Data type	String
Units	En_US ASCII characters
Range	1 through 45 ASCII characters

User ID:

The user ID used, with the password property, for authentication if the calling application does not provide a user ID and password explicitly.

If you specify a value for the user ID property, you must also specify a value for the password property.

The connection factory user ID and password properties are used if the calling application does not provide a user ID and password explicitly, for example, if the calling application uses the method createTopicConnection(). The JMS client flows the user ID and password to the JMS server.

Information	Value
Data type	String

Password:

The password used, with the user ID property, for authentication if the calling application does not provide a user ID and password explicitly.

If you specify a value for the user ID property, you must also specify a value for the password property.

Information	Value
Data type	String

Re-Enter Password:

Confirms the password.

Queue Manager:

The name of the WebSphere MQ queue manager for this connection factory. Connections created by this connection factory connect to this queue manager.

Information	Value
Data type	String

Enter Hostname and Port Information:

This radio button is selected by default and, if selected, enables the host and port properties and disables the connection name list property.

Information	Value
Data type	Radio button
Default	Selected

Host:

The name of the host on which the WebSphere MQ queue manager runs for client connections only.

Information	Value
Data type	String
Range	A valid TCP/IP host name

Port:

The TCP/IP port number used for connection to the WebSphere MQ queue manager, for client connection only.

This port must be configured on the WebSphere MQ queue manager.

Information	Value
Data type	Integer
Range	A valid TCP/IP port number, configured on the WebSphere MQ queue manager.

Enter Connection Name List Information:

If selected, this radio button enables the connection name list property and disables the host and port name properties. Select this radio button if you want to connect to a multi-instance queue manager.

Information	Value
Data type	Radio button
Default	Cleared

Connection Name List:

A comma-separated list of host and port information which can be used to connect to a multi-instance queue manager.

The format of the list is:

```
host[(port)],[host[(port)]]
```

where port is optional and defaults to 1414 if it is not set. For example:

```
hostname1,hostname2(1415)
```

For further information about multi-instance queue managers, see the WebSphere MQ information center.

This property must only be used for connecting to a multi-instance queue manager. It must not be used for connecting to a list of distinct queue managers as that can result in transaction integrity issues.

Channel:

The name of the channel used for client connections to the WebSphere MQ queue manager, for client connection only.

Information	**Value**
Data type	String
Range	1 through 20 ASCII characters

Transport Type:

Whether WebSphere MQ client connection or JNDI bindings are used for connection to the WebSphere MQ queue manager.

Information	**Value**
Data type	Enum
Default	BINDINGS
Range	**CLIENT** WebSphere MQ client connection is used to connect to the WebSphere MQ queue manager. **BINDINGS** JNDI bindings are used to connect to the WebSphere MQ queue manager.

Client ID:

The JMS client identifier used for connections to the WebSphere MQ queue manager.

Information	**Value**
Data type	String

CCSID:

The coded character set identifier to use with the WebSphere MQ queue manager.

This coded character set identifier (CCSID) must be one of the CCSIDs that WebSphere MQ supports. See the properties for the topic destination for more details.

Information	Value
Data type	String
Units	Integer
Range	1 through 65535

Broker Control Queue:

The name of the broker control queue to which all command messages (except publications and requests to delete publications) are sent.

Information	Value
Data type	String
Units	En_US ASCII characters
Range	1 through 48 ASCII characters

Broker Queue Manager:

The name of the WebSphere MQ queue manager that provides the Publisher and Subscriber message broker.

Information	Value
Data type	String
Units	En_US ASCII characters
Range	1 through 48 ASCII characters

Broker Publish Queue:

The name of the broker input queue that receives all publication messages for the default stream.

The name of the broker's input queue (stream queue) that receives all publication messages for the default stream. Applications can also send requests to delete publications on the default stream to this queue.

Information	Value
Data type	String
Units	En_US ASCII characters
Range	1 through 48 ASCII characters

Broker Subscribe Queue:

The name of the broker queue from which nondurable subscription messages are retrieved.

The name of the broker queue from which nondurable subscription messages are retrieved. The subscriber specifies the name of the queue when it registers a subscription.

Information	Value
Data type	String
Units	En_US ASCII characters
Range	1 through 48 ASCII characters

Broker CCSubQ:

The name of the broker queue from which nondurable subscription messages are retrieved for a ConnectionConsumer request. This property applies only for use of the web container.

Information	Value
Data type	String
Units	En_US ASCII characters
Range	1 through 48 ASCII characters

Broker Version:

Whether the message broker is provided by the WebSphere MQ MA0C SupportPac or newer versions of WebSphere family message broker products.

Information	Value
Data type	Enum
Default	Advanced
Range	**Advanced** The message broker is provided by newer versions of WebSphere family message broker products (WebSphere MQ Integrator and WebSphere MQ Publish and Subscribe). **Basic** The message broker is provided by the WebSphere MQ MA0C SupportPac (WebSphere MQ - Publish and Subscribe).

Cleanup level:

The level of cleanup provided by the publish or subscribe cleanup utility.

Information	Value
Data type	Enum
Default	SAFE
Range	**ASPROP** **NONE** **STRONG**

Cleanup interval:

The interval, in milliseconds, between background executions of the publish/subscribe cleanup utility.

Information	Value
Data type	Integer
Units	Milliseconds
Default	6000

Message selection:

Where broker message selection is performed.

Information	Value
Data type	Enum
Default	BROKER

Information	Value
Range	**BROKER** Message selection is performed at the broker location. **Message CLIENT** Message selection is performed at the client location.

Publish acknowledge interval:

The interval, in number of messages, between publish requests that require acknowledgment from the broker.

Information	Value
Data type	Integer
Default	25

Sparse subscriptions:

Enables sparse subscriptions.

Information	Value
Data type	Check box
Default	Cleared

Status refresh interval:

The interval, in milliseconds, between transactions to refresh the publish or subscribe status.

Information	Value
Data type	Integer
Default	6000

Subscription store:

Where WebSphere MQ stores data relating to active JMS subscriptions.

Information	Value
Data type	Enum
Default	MIGRATE
Range	**MIGRATE** **QUEUE** **BROKER**

Multicast:

Whether this connection factory uses multicast transport.

Information	Value
Data type	Enum

Information	Value
Default	NOT USED
Range	**NOT USED** This connection factory does not use multicast transport. **ENABLED** This connection factory always uses multicast transport. **ENABLED_IF_AVAILABLE** This connection factory uses multicast transport. **ENABLED_RELIABLE** This connection factory uses reliable multicast transport. **ENABLED_RELIABLE_IF_AVAILABLE** This connection factory uses reliable multicast transport if available.

Direct authentication:

Whether to use direct broker authorization.

Information	Value
Data type	Enum
Default	NONE
Range	**NONE** Direct broker authorization is not used. **PASSWORD** Direct broker authorization is authenticated with a password. **CERTIFICATE** Direct broker authorization is authenticated with a certificate.

Proxy Host Name:

The host name of a proxy to be used for communication with WebSphere MQ.

Information	Value
Data type	String

Proxy Port:

The port number of a proxy to be used for communication with WebSphere MQ.

Information	Value
Data type	Integer
Default	0

Fail if quiesce:

Whether applications return from a method call if the queue manager has entered a controlled failure.

Information	Value
Data type	Check box
Default	Selected

Local Server Address:

The local server address.

Information	Value
Data type	String

Polling Interval:

The interval, in milliseconds, between scans of all receivers during asynchronous message delivery.

Information	Value
Data type	Integer
Units	Milliseconds
Default	5000

Rescan interval:

The interval in milliseconds between which a topic is scanned to look for messages that have been added to a topic out of order.

The rescan interval controls the scanning for messages that have been added to a topic out of order with respect to a WebSphere MQ browse cursor.

Information	Value
Data type	Integer
Units	Milliseconds
Default	5000

SSL cipher suite:

The cipher suite to use for SSL connection to WebSphere MQ.

Set this property to a valid cipher suite provided by your JSSE provider. The value must match the CipherSpec specified on the SVRCONN channel as the **Channel** property.

You must set this property, if you set the **SSL Peer Name** property.

SSL certificate store:

A list of zero or more Certificate Revocation List (CRL) servers that are used to check for SSL certificate revocation. If you specify a value for this property, you must use WebSphere MQ JVM at Java 2 version 1.4.

The value is a space-delimited list of entries of the form:

`ldap://`*`hostname`*`:[`*`port`*`]`

A single slash (/) follows this value. If *port* is omitted, the default LDAP port of 389 is assumed. At connect-time, the SSL certificate presented by the server is checked against the specified CRL servers.

For more information about CRL security, see the information about “Working with Certificate Revocation Lists” in the *Security* section of the WebSphere MQ information center.

SSL peer name:

For SSL, a *distinguished name* skeleton that must match the name provided by the WebSphere MQ queue manager. The distinguished name is used to check the identifying certificate presented by the server at connection time.

If this property is not set, such certificate checking is performed.

The SSL peer name property is ignored if **SSL Cipher Suite** property is not specified.

This property is a list of attribute name and value pairs separated by commas or semicolons. For example:

```
CN=QMGR.*, OU=IBM, OU=WEBSPHERE
```

The example given checks the identifying certificate presented by the server at connect-time. For the connection to succeed, the certificate must have a Common Name beginning QMGR., and must have at least two Organizational Unit names, the first of which is IBM and the second WEBSPHERE. Checking is not case-sensitive.

For more details about distinguished names and their use with WebSphere MQ, see the information about “Distinguished Names” in the Security section of the WebSphere MQ information center.

Connection pool:

An optional set of connection pool settings.

Connection pool properties are common to all J2C connectors.

The application server pools connections and sessions with the JMS provider to improve performance. This connection pooling is independent from any WebSphere MQ connection pooling. You must configure the connection and session pool properties appropriately for your applications, otherwise you might not get the connection and session behavior that you want.

Change the size of the connection pool if concurrent server-side access to the JMS resource exceeds the default value. The size of the connection pool is set on a per queue or topic basis.

Information	**Value**
Data type	Check box
Default	Selected

Client reconnect options:

Specifies whether a client mode connection reconnects automatically, or not, in the event of a communications or queue manager failure. This property is ignored unless the connection factory is being used in a thin or managed client environment.

Information	**Value**
Data type	Drop-down list
Default	DISABLED

Information	Value
Range	**DISABLED** The client reconnection does not automatically occur. **ASDEF** The value from the DefRecon attribute from the channels stanza of the client configuration file is used. If there is no DefRecon value specified then this setting has the same effect as a value of DISABLED. **RECONNECT** Reconnection occurs to any queue manager consistent with the value of the queue manager attribute, which might be a different queue manager from that to which the connection was originally connected. **QMGR** Reconnection only occurs to the queue manager to which the connection was originally connected.

For more information about automatic client reconnection, see the WebSphere MQ information center.

Client reconnect timeout:

The maximum number of seconds that a client mode connection spends attempting to automatically reconnect to a queue manager after a communications or queue manager failure. This parameter is ignored unless the connection factory is being used in a thin or managed client environment. Whether this parameter is used or not depends on the value of the client reconnect options parameter.

Information	Value
Data type	Integer
Units	Seconds
Default	1800
Range	A value greater than zero and up to 2147483647

For more information about automatic client reconnection, see the WebSphere MQ information center.

WebSphere MQ Provider queue destination settings for application clients:

Use this panel to view or change the configuration properties of the selected queue destination for use with the WebSphere MQ product Java Message Service (JMS) provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file and click **Messaging Providers** > **WebSphere MQ Provider**. Right-click **Queue Destinations** and click **New**. The following fields are displayed on the **General** tab.

Note:

- The property values that you specify must match the values that you specified when configuring JMS resources for WebSphere MQ. For more information about configuring JMS resources for WebSphere MQ, see *Using Java* in the WebSphere MQ information center.
- In WebSphere MQ, names can have a maximum of 48 characters.

A queue for use with the WebSphere MQ product JMS provider has the following properties.

Name:

The name by which the queue is known for administrative purposes within WebSphere Application Server.

Information	Value
Data type	String

Description:

A description of the queue, for administrative purposes within WebSphere Application Server.

Information	Value
Data type	String

JNDI Name:

The application client runtime environment uses this field to retrieve configuration information.

Persistence:

Whether all messages sent to the destination are persistent, nonpersistent or have their persistence defined by the application.

Information	Value
Data type	Enum
Default	APPLICATION_DEFINED
Range	**Application defined** Messages on the destination have their persistence defined by the application that put them onto the queue. **Queue defined** [WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties. **Persistent** Messages on the destination are persistent. **Nonpersistent** Messages on the destination are not persistent.

Priority:

Whether the message priority for this destination is defined by the application or the **Specified priority** property.

Information	Value
Data type	Enum
Units	Not applicable
Default	APPLICATION_DEFINED
Range	**Application defined** The priority of messages on this destination is defined by the application that put them onto the destination. **Queue defined** [WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties. **Specified** The priority of messages on this destination is defined by the **Specified priority** property. *If you select this option, you must define a priority on the **Specified priority** property.*

Specified Priority:

If the **Priority** property is set to `Specified`, specify the message priority for this queue, in the range 0 (lowest) through 9 (highest).

Information	Value
Data type	Integer
Units	Message priority level
Range	0 (lowest priority) through 9 (highest priority)

Expiry:

Whether the expiry timeout value for this queue is defined by the application or the by **Specified expiry** property or whether messages on the queue never expire (have an unlimited expiry time out).

Information	Value
Data type	Enum
Units	Not applicable
Default	APPLICATION_DEFINED
Range	**Application defined** The expiry timeout for messages on this queue is defined by the application that put them onto the queue. **Specified** The expiry timeout for messages on this queue is defined by the **Specified expiry** property. If you select this option, you must define a timeout on the **Specified expiry** property. **Unlimited** Messages on this queue have no expiry timeout and those messages never expire.

Specified Expiry:

If the **Expiry timeout** property is set to `Specified`, type here the number of milliseconds (greater than 0) after which messages on this queue expire.

Information	Value
Data type	Integer
Units	Milliseconds
Range	Greater than or equal to 0 • 0 indicates that messages never time out • Other values are an integer number of milliseconds

Base Queue Name:

The name of the queue to which messages are sent, on the queue manager specified by the **Base queue manager name** property.

Information	Value
Data type	String

Base Queue Manager Name:

The name of the WebSphere MQ queue manager to which messages are sent.

This queue manager provides the queue specified by the **Base queue name** property.

Information	Value
Data type	String
Units	En_US ASCII characters
Range	A valid WebSphere MQ Queue Manager name, as 1 through 48 ASCII characters

CCSID:

The coded character set identifier to use with the WebSphere MQ queue manager.

This coded character set identifier (CCSID) must be one of the CCSIDs supported by WebSphere MQ queue manager. See the WebSphere MQ messaging provider queue and topic advanced properties settings for more details.

Information	Value
Data type	String

Integer encoding:

If native encoding is not enabled, select whether integer encoding is normal or reversed.

Information	Value
Data type	Enum
Default	NORMAL
Range	**NORMAL** Normal integer encoding is used. **REVERSED** Reversed integer encoding is used. For more information about encoding properties, see *Using Java* in the WebSphere MQ information center.

Decimal encoding:

If native encoding is not enabled, select whether decimal encoding is normal or reversed.

Information	Value
Data type	Enum
Default	NORMAL
Range	**NORMAL** Normal decimal encoding is used. **REVERSED** Reversed decimal encoding is used. For more information about encoding properties, see *Using Java* in the WebSphere MQ information center.

Floating point encoding:

If native encoding is not enabled, select the type of floating point encoding.

Information	Value
Data type	Enum
Default	IEEENORMAL

Information	Value
Range	**IEEENORMAL** IEEE normal floating point encoding is used. **IEEEREVERSED** IEEE reversed floating point encoding is used. **S390** S390 floating point encoding is used. For more information about encoding properties, see *Using Java* in the WebSphere MQ information center.

Native encoding:

Indicates that the queue destination uses native encoding (appropriate encoding values for the Java platform) when you select this check box.

Information	Value
Data type	Enum
Default	Cleared
Range	**Cleared** Native encoding is not used, so specify the following properties for integer, decimal and floating point encoding. **Selected** Native encoding is used (to provide appropriate encoding values for the Java platform). For more information about encoding properties, see *Using Java* in the WebSphere MQ information center.

Target client:

Whether the receiving application is JMS compliant or is a traditional WebSphere MQ application.

Information	Value
Data type	Enum
Default	WebSphere MQ
Range	**WebSphere MQ** The target is a traditional WebSphere MQ application that does not support JMS. **JMS** The target application supports JMS.

Message body:

Specifies whether an application processes the RFH version 2 header of a WebSphere MQ message as part of the JMS message body.

Information	Value
Data type	Drop-down list
Default	UNSPECIFIED

Information	Value
Range	**UNSPECIFIED** When sending messages, the WebSphere MQ messaging provider does or does not generate and include an RFH version 2 header, depending on the value of the Append RFH version 2 headers to messages sent to this destination property. When receiving messages, the WebSphere MQ messaging provider acts as if the value is set to JMS. **JMS** When sending messages, the WebSphere MQ messaging provider automatically generates an RFH version 2 header and includes it in the WebSphere MQ message. When receiving messages, the WebSphere MQ messaging provider sets the JMS message properties according to values in the RFH version 2 header (if these value are present); it does not present the RFH version 2 header as part of the JMS message body. **MQ** When sending messages, the WebSphere MQ messaging provider does not generate an RFH version 2 header. When receiving messages, the WebSphere MQ messaging provider presents the RFH version 2 header as part of the JMS message body.

ReplyTo destination style:

Specifies the format of the JMSReplyTo field.

Information	Value
Data type	Drop-down list
Default	DEFAULT
Range	**DEFAULT** The default value is equivalent to the information in the RFH version 2 header. **MQMD** Use the value supplied in the MQMD. This populates the reply to queue manager field with the value from the MQMD, equivalent to the default behaviour of WebSphere MQ Version 6.0.2.4 and 6.0.2.5. **RFH2** Use the value supplied in the RFH version 2 header. If the sending application set a JMSReplyTo value, then that value is used.

MQMD read enabled:

Specifies whether an application can read the values of MQMD fields from JMS messages that have been sent or received using the WebSphere MQ messaging provider.

Information	Value
Data type	Check box
Default	Cleared
Range	**Cleared** Applications cannot read the values of the MQMD fields. **Selected** Applications can read the values of the MQMD fields.

MQMD write enabled:

Specifies whether an application can write the values of MQMD fields to JMS messages that will be sent or received using the WebSphere MQ messaging provider.

Information	Value
Data type	Check box

Information	Value
Default	Cleared
Range	**Cleared** Applications cannot write the values of the MQMD fields. **Selected** Applications can write the values of the MQMD fields.

MQMD message context:

Defines the message context options specified when sending messages to a destination.

Information	Value
Data type	Drop-down list
Default	DEFAULT
Range	**DEFAULT** The MQOPEN API call and the MQPMO structure specify no explicit message context options. **SET_IDENTITY_CONTEXT** The MQOPEN API call specifies the message context option MQOO_SET_IDENTITY_CONTEXT, and the MQPMO structure specifies MQPMO_SET_IDENTITY_CONTEXT. **SET_ALL_CONTEXT** The MQOPEN API call specifies the message context option MQOO_SET_ALL_CONTEXT, and the MQPMO structure specifies MQPMO_SET_ALL_CONTEXT.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

WebSphere MQ Provider topic destination settings for application clients:

Use this panel to view or change the configuration properties of the selected topic destination for use with the WebSphere MQ product Java Message Service (JMS) provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **WebSphere MQ Provider**. Right click **Topic Destinations**, and click **New**. The following fields are displayed on the **General** tab.

Note:

- The property values that you specify must match the values that you specified when configuring JMS resources for WebSphere MQ. For more information about configuring JMS resources for WebSphere MQ, see *Using Java* in the WebSphere MQ information center.
- In WebSphere MQ, names can have a maximum of 48 characters.

A topic destination is used to configure the properties of a JMS topic for the associated JMS provider. A topic for use with the WebSphere MQ product JMS provider has the following properties.

Name:

The name by which the topic is known for administrative purposes within WebSphere Application Server.

Information	Value
Data type	String

Description:

A description of the topic for administrative purposes within WebSphere Application Server.

Information	Value
Data type	String

JNDI Name:

The application client runtime environment uses this field to retrieve configuration information.

Persistence:

Whether all messages sent to the destination are persistent, nonpersistent, or have their persistence defined by the application.

Information	Value
Data type	Enum
Default	APPLICATION_DEFINED
Range	**Application defined** Messages on the destination have their persistence defined by the application that put them in the queue. **Queue defined** [WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties. **Persistent** Messages on the destination are persistent. **Nonpersistent** Messages on the destination are not persistent.

Priority:

Whether the message priority for this destination is defined by the application or the **Specified priority** property.

Information	Value
Data type	Enum
Default	APPLICATION_DEFINED
Range	**Application defined** The priority of messages on this destination is defined by the application that put them in the destination. **Queue defined** [WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties. **Specified** The priority of messages on this destination is defined by the **Specified priority** property. If you select this option, you must define a priority for the **Specified priority** property.

Specified Priority:

If the **Priority** property is set to `Specified`, specify the message priority for this queue, in the range 0 (lowest) through 9 (highest).

If the **Priority** property is set to `Specified`, messages sent to this queue have the priority value specified by this property.

Information	Value
Data type	Integer
Units	Message priority level
Range	0 (lowest priority) through 9 (highest priority)

Expiry:

Whether the expiry timeout for this queue is defined by the application or by the **Specified expiry** property, or whether messages on the queue never expire (have an unlimited expiry timeout).

Information	Value
Data type	Enum
Default	APPLICATION_DEFINED
Range	**Application defined** The expiry timeout for messages on this queue is defined by the application that put them in the queue. **Specified** The expiry timeout for messages in this queue is defined by the **Specified expiry** property. If you select this option, you must define a timeout value for the **Specified expiry** property. **Unlimited** Messages on this queue have no expiry timeout, and these messages never expire.

Specified Expiry:

If the **Expiry timeout** property is set to `Specified`, type the number of milliseconds (greater than 0) after which messages on this queue expire.

Information	Value
Data type	Integer
Units	Milliseconds
Range	Greater than or equal to 0 • 0 indicates that messages never time out. • Other values are an integer number of milliseconds.

Base Topic Name:

The name of the topic to which messages are sent.

Information	Value
Data type	String

CCSID:

The coded character set identifier to use with the WebSphere MQ queue manager.

This coded character set identifier (CCSID) must be one of the CCSIDs that WebSphere MQ supports.

Information	Value
Data type	String
Units	Integer
Range	1 through 65535

Integer encoding:

If native encoding is not enabled, select whether integer encoding is normal or reversed.

Information	Value
Data type	Enum
Default	NORMAL
Range	**NORMAL** Normal integer encoding is used. **REVERSED** Reversed integer encoding is used. For more information about encoding properties, see *Using Java* in the WebSphere MQ information center.

Decimal encoding:

If native encoding is not enabled, select whether decimal encoding is normal or reversed.

Information	Value
Data type	Enum
Default	NORMAL
Range	**NORMAL** Normal decimal encoding is used. **REVERSED** Reversed decimal encoding is used. For more information about encoding properties, see *Using Java* in the WebSphere MQ information center.

Floating point encoding:

If native encoding is not enabled, select the type of floating point encoding.

Information	Value
Data type	Enum
Default	IEEENORMAL
Range	**IEEENORMAL** IEEE normal floating point encoding is used. **IEEEREVERSED** IEEE reversed floating point encoding is used. **S390** S/390® floating point encoding is used. For more information about encoding properties, see *Using Java* in the WebSphere MQ information center.

Native encoding:

Indicates that the queue destination uses native encoding (appropriate encoding values for the Java platform) when you select this check box.

Information	Value
Data type	Enum
Default	Cleared
Range	**Cleared** Native encoding is not used, so specify the previous properties for integer, decimal and floating point encoding. **Selected** Native encoding is used (to provide appropriate encoding values for the Java platform). For more information about encoding properties, see *Using Java* in the WebSphere MQ information center.

BrokerDurSubQueue:

The name of the broker queue from which durable subscription messages are retrieved.

The subscriber specifies the name of the queue when it registers a subscription.

Information	Value
Data type	String
Units	En_US ASCII characters
Range	1 through 48 ASCII characters

BrokerCCDurSubQueue:

The name of the broker queue from which durable subscription messages are retrieved for a ConnectionConsumer. This property applies only for use of the web container.

Information	Value
Data type	String
Units	En_US ASCII characters
Range	1 through 48 ASCII characters

Target Client:

Whether the receiving application is JMS compliant or is a traditional WebSphere MQ application.

Information	Value
Data type	Enum
Default	WebSphere MQ
Range	**WebSphere MQ** The target is a traditional WebSphere MQ application that does not support JMS. **JMS** The target application supports JMS.

Message body:

Specifies whether an application processes the RFH version 2 header of a WebSphere MQ message as part of the JMS message body.

Information	Value
Data type	Drop-down list
Default	UNSPECIFIED

Information	Value
Range	**UNSPECIFIED** When sending messages, the WebSphere MQ messaging provider does or does not generate and include an RFH version 2 header, depending on the value of the Append RFH version 2 headers to messages sent to this destination property. When receiving messages, the WebSphere MQ messaging provider acts as if the value is set to JMS. **JMS** When sending messages, the WebSphere MQ messaging provider automatically generates an RFH version 2 header and includes it in the WebSphere MQ message. When receiving messages, the WebSphere MQ messaging provider sets the JMS message properties according to values in the RFH version 2 header (if these value are present); it does not present the RFH version 2 header as part of the JMS message body. **MQ** When sending messages, the WebSphere MQ messaging provider does not generate an RFH version 2 header. When receiving messages, the WebSphere MQ messaging provider presents the RFH version 2 header as part of the JMS message body.

ReplyTo destination style:

Specifies the format of the JMSReplyTo field.

Information	Value
Data type	Drop-down list
Default	DEFAULT
Range	**DEFAULT** The default value is equivalent to the information in the RFH version 2 header. **MQMD** Use the value supplied in the MQMD. This populates the reply to queue manager field with the value from the MQMD, equivalent to the default behaviour of WebSphere MQ Version 6.0.2.4 and 6.0.2.5. **RFH2** Use the value supplied in the RFH version 2 header. If the sending application set a JMSReplyTo value, then that value is used.

Multicast:

Whether this connection factory uses multicast transport.

Information	Value
Data type	Enum
Default	AS_CF
Range	**AS_CF** This connection factory uses multicast transport. **DISABLED** This connection factory does not use multicast transport. **NOT_RELIABLE** This connection factory always uses multicast transport. **RELIABLE** This connection factory uses multicast transport when the topic destination is not reliable. **ENABLED** This connection factory uses reliable multicast transport.

MQMD read enabled:

Specifies whether an application can read the values of MQMD fields from JMS messages that have been sent or received using the WebSphere MQ messaging provider.

Information	Value
Data type	Check box
Default	Cleared
Range	**Cleared** Applications cannot read the values of the MQMD fields. **Selected** Applications can read the values of the MQMD fields.

MQMD write enabled:

Specifies whether an application can write the values of MQMD fields to JMS messages that will be sent or received using the WebSphere MQ messaging provider.

Information	Value
Data type	Check box
Default	Cleared
Range	**Cleared** Applications cannot write the values of the MQMD fields. **Selected** Applications can write the values of the MQMD fields.

MQMD message context:

Defines the message context options specified when sending messages to a destination.

Information	Value
Data type	Drop-down list
Default	DEFAULT
Range	**DEFAULT** The MQOPEN API call and the MQPMO structure specify no explicit message context options. **SET_IDENTITY_CONTEXT** The MQOPEN API call specifies the message context option MQOO_SET_IDENTITY_CONTEXT, and the MQPMO structure specifies MQPMO_SET_IDENTITY_CONTEXT. **SET_ALL_CONTEXT** The MQOPEN API call specifies the message context option MQOO_SET_ALL_CONTEXT, and the MQPMO structure specifies MQPMO_SET_ALL_CONTEXT.

Generic JMS connection factory settings for application clients:

Use this panel to view or change the configuration properties of the selected Java Message Service (JMS) connection factory for use with the associated JMS provider. These configuration properties control how connections are created between the JMS provider and the messaging system that it uses.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > *new_JMS_Provider_instance*. Right-click **Connection Factories**, and click **New**. The following fields are displayed on the **General** tab.

A Java Message Service (JMS) connection factory creates connections to JMS destinations. The JMS connection factory is created by the associated JMS provider. A JMS connection factory for a generic JMS provider (other than the internal default messaging provider or WebSphere MQ as a JMS provider) has the following properties:

Name:

The name by which this JMS connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the associated JMS provider.

Information	Value
Data type	String

Description:

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Information	Value
Data type	String
Default	Null

JNDI Name:

The application client run time uses this field to retrieve configuration information.

User ID:

Indicates the user ID used with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

The connection factory **User ID** and **Password** properties are used if the calling application does not provide a userid and password explicitly; for example, if the calling application uses the method createQueueConnection(). The JMS client flows the `userid` and `password` to the JMS server.

Information	Value
Data type	String

Password:

The password used with the **User ID** property for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

Information	Value
Data type	String
Default	Null

Re-Enter Password:

Confirms the password entered in the **Password** field.

External JNDI Name:

The JNDI name that is used to bind the queue into the application server name space.

As a convention, use the fully qualified JNDI name, for example, `jms/`*`Name`*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI API by the platform.

Information	**Value**
Data type	String

Connection Type:

Whether this JMS destination is a queue (for point-to-point) or topic (for publication or subscription).

Select one of the following options:

Queue
A JMS queue destination for point-to-point messaging.

Topic A JMS topic destination for publish subscribe messaging.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Generic JMS destination settings for application clients:

Use this panel to view or change the configuration properties of the selected JMS destination for use with the associated JMS provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > *new JMS Provider instance*. Right-click **Destinations**, and click **New**. The following fields are displayed on the **General** tab.

A JMS destination is used to configure the properties of a JMS destination for the associated generic JMS provider. Connections to the JMS destination are created by the associated JMS connection factory. A JMS destination for use with a generic JMS provider (not the default messaging provider or WebSphere MQ as a JMS provider) has the following properties.

Name:

The name by which the queue is known for administrative purposes within WebSphere Application Server.

Information	**Value**
Data type	String

Description:

A description of the queue, for administrative purposes.

JNDI Name:

The JNDI name of the actual (physical) name of the JMS destination bound into JNDI.

External JNDI Name:

The JNDI name that is used to bind the queue into the application server name space.

As a convention, use the fully qualified JNDI name; for example, in the form jms/*Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Information	Value
Data type	String

Destination Type:

Whether this JMS destination is a queue (for point-to-point) or topic (for publishing or subscribing).

Select one of the following options:
Queue
A JMS queue destination for point-to-point messaging.
Topic A JMS topic destination for pub/sub messaging.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Example: Configuring JMS provider, JMS connection factory and JMS destination settings for application clients:

You can configure JMS Provider, JMS Connection Factory and JMS Destination settings. This topic provides the required fields, special cases, and an example.

The purpose of this article is to help you to configure JMS Provider, JMS Connection Factory and JMS Destination settings.
- Required fields include:
  - JMS Provider Properties page: name, and at least one protocol provider
  - JMS Connection Factory Properties page: name, jndiName, destination type
  - JMS Destination Properties page: name, jndiName, destination type
- Special cases:
  - The destination type must be `QUEUE`, or `TOPIC`.
- Example:

```
<resources.jms:JMSProvider xmi:id="JMSProvider_3" name="genericJMSProvider:name"
description="genericJMSProvider:description"
externalInitialContextFactory="genericJMSProvider:contextFactoryClass"
```

```
externalProviderURL="genericJMSProvider:providerUrl">
<classpath>genericJMSProvider:classpath</classpath>
<factories xmi:type="resources.jms:GenericJMSDestination"
xmi:id="GenericJMSDestination_1" name="jmsDestination:name"
jndiName="jmsDestination:jndiName" description="jmsDestination:description"
externalJNDIName="jmsDestination:externalJndiName" type="QUEUE">
<propertySet xmi:id="J2EEResourcePropertySet_15">
<resourceProperties xmi:id="J2EEResourceProperty_17" name="jmsDestination:customName"
value="jmsDestination:customValue"/>
</propertySet>
</factories>
<factories xmi:type="resources.jms:GenericJMSConnectionFactory"
xmi:id="GenericJMSConnectionFactory_1" name="jmsCF:name" jndiName="jmsCF:jndiName"
description="jmsCF:description" userID="jmsCF:user" password="{xor}NTIsHBllMT4yOg=="
externalJNDIName="jmsCF:externalJndiName" type="QUEUE">
<propertySet xmi:id="J2EEResourcePropertySet_16">
<resourceProperties xmi:id="J2EEResourceProperty_18" name="jmsCF:customName"
value="jmsCF:customValue"/>
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_17">
<resourceProperties xmi:id="J2EEResourceProperty_19"
name="genericJMSProvider:customName" value="genericJMSProvider:customValue"/>
</propertySet>
</resources.jms:JMSProvider>
```

Configuring new JMS connection factories for application clients

Use this task to create a new Java Message Service (JMS) connection factory configuration for your application client.

Procedure

1. Click the JMS provider for which you want to create a connection factory in the tree. Complete one of the following actions:
   - Configure a new JMS provider.
   - Click an existing JMS provider.
2. Expand the JMS provider to view its Connection Factories folder.
3. Click the connection factory folder, and complete one of the following actions:
   - Right-click the folder and select**New**.
   - Click **Edit > New** on the menu bar.
4. Configure the JMS connection factory properties in the displayed fields.
5. Click **OK** when you finish.
6. Click **File > Save** on the menu bar to save your changes.

Configuring new JMS destinations for application clients

Use this task to create a new Java Message Service (JMS) destination configuration for your application client.

Procedure

1. Click the JMS provider in the tree for which you want to create a destination. Complete one of the following actions:
   - Configure a new JMS provider.
   - Click an existing JMS provider.
2. Expand the JMS provider to view its Destinations folder.
3. Click the provider folder, and complete one of the following actions:
   - Right-click the folder and select **New**.
   - Click **Edit > New** on the menu bar.
4. Configure the JMS destination properties in the displayed fields.

5. Click **OK** when you finish.
6. Click **File > Save** on the menu bar to save your changes.

Configuring new resource environment providers for application clients

You can create new resource environment provider configurations for your application client using the Application Client Resource Configuration Tool (ACRCT).

Before you begin

During this task, you create new resource environment provider configurations for your application client.

About this task

To configure a new resource environment provider, perform the following steps:

Procedure

1. Start the Application Configuration Resource Tool and open the EAR file for which you want to configure the new Java Message Service (JMS) provider. The EAR file contents display in a tree view.
2. Select from the tree the JAR file in which you want to configure the new JMS provider.
3. Expand the JAR file to view its contents.
4. Click the **Resource Environment Providers** folder. Take one of the following actions:
   - Right-click the provider folder, and click **New**.
   - Click **Edit > New** on the menu bar.
5. Configure the JMS provider properties in the displayed fields.
6. Click **OK** when you finish.
7. Click **File > Save** on the menu bar to save your changes.

Resource environment provider settings for application clients:

Use this page to specify resource environment entry properties.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected Java Archive (JAR) file. Right-click **Resource Environment Providers**, and click **New**. The following fields are displayed on the **General** tab:

Name:

Specifies the administrative name for the resource environment provider.

Description:

Specifies a description of the resource environment provider for your administrative records.

Class Path:

Specifies the path to the JAR file that contains the implementation classes for the resource environment provider.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Configuring new resource environment entries for application clients

You can create new resource environment entries for your client application using the Application Client Resource Configuration Tool (ACRCT).

Before you begin

During this task, you create new resource environment entries for your client application.

About this task

Procedure

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure the new resource environment entry. The EAR file contents are in the displayed tree view.
3. Click the desired resource environment provider, and complete the following action to configure new providers:
   - Configure a new resource environment provider.
4. Expand the resource environment provider to view the Resource Environment Entries folder.
5. Click the resource environment entries folder, and complete one of the following actions:
   - Right-click the folder and select **New**.
   - Click **Edit > New** on the menu bar.
6. Configure the resource environment entry properties in the displayed fields.
7. Click **OK**.
8. Click **File > Save** on the menu bar to save your changes.

Resource environment entry settings for application clients:

Use this page to specify resource environment entry properties.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Resource Environment Providers** > *resource environment instance*. Right-click **Resource Environment Entries**, and click **New**. The following fields appear on the **General** tab:

Name:

Specifies the administrative name for the resource environment entry.

Description:

Specifies a description of the URL for your administrative records.

JNDI Name:

Specifies the Java Naming and Directory Interface (JNDI) name for the resource, including any naming subcontexts.

Use this name to link to the binding information of the platform. The binding associates the resources defined in the deployment descriptor of the module to the actual (or physical) resources bound into JNDI by the platform.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Example: Configuring Resource Environment settings:

You can configure Resource Environment settings. This topic provides the required fields and an example.

The purpose of this topic is to help you configure Resource Environment settings.
- Required fields:
  - Resource Environment Provider page: **Name**
  - Resource Environment Entry page: **Name, JNDI Name**
- Example:

```
<resources.env:ResourceEnvironmentProvider xmi:id="ResourceEnvironmentProvider_1"
name="resourceEnvProvider:name" description="resourceEnvProvider:description">
<classpath>resourceEnvProvider:classpath</classpath>
<factories xmi:type="resources.env:ResourceEnvEntry" xmi:id="ResourceEnvEntry_1"
name="resourceEnvEntry:name" jndiName="resourceEnvEntry:jndiName"
description="resourceEnvEntry:description">
<propertySet xmi:id="J2EEResourcePropertySet_20">
<resourceProperties xmi:id="J2EEResourceProperty_22"
name="resourceEnvEntry:customName" value="resourceEnvEntry:customValue"/>
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_21">
<resourceProperties xmi:id="J2EEResourceProperty_23"
name="resourceEnvProvider:customName" value="resourceEnvProvider:customValue"/>
</propertySet>
</resources.env:ResourceEnvironmentProvider>
```

Example: Configuring resource environment custom settings for application clients:

You can configure resource environment custom settings.

The purpose of this topic is to help you configure resource environment custom settings.
- The custom page applies to every resource type. You can specify as many custom names and values as you need.
- Example:

```
<propertySet xmi:id="J2EEResourcePropertySet_20">
<resourceProperties xmi:id="J2EEResourceProperty_22"
name="resourceEnvEntry:customName" value="resourceEnvEntry:customValue"/>
</propertySet>
```

Running a Java EE client application with launchClient

After deploying a Java EE client application onto a machine with an Application Client installation or in a WebSphere Application Server node, you can start the application by using the **launchClient** command on that machine.

Before you begin

Before you can use the **launchclient** command to run a Java EE client application, you must have deployed the application.

This task only applies to Java EE client applications.

About this task

The Java Platform, Enterprise Edition (Java EE) specification requires support for a client container that runs Java applications (known as Java EE client applications) and provides Java EE services to the applications. Java EE services include naming, security, and resource connections.

Procedure

1. Enter the following command to launch Java EE application clients:

   `app_client_root/bin/launchClient`

2. Pass parameters to the `launchClient` command or to your application client program as well. The `launchClient` command allows you to do both. The `launchClient` command requires that the first parameter is either:
   - An EAR file specifying the application client to launch.
   - A request for `launchClient` usage information.

   The following example illustrates the command line invocation syntax for the launchClient tool:

   `launchClient [-profileName pName | -JVMOptions options | -help | -?] userapp [-CCname=value] [app args]`

   where

   - *userapp* is the path and the name of the EAR file that contains the application client.
   - *-CCname=value* is the client container name-value pair parameter. See the client container parameters section, for supported name-value pair arguments.
   - *app args* are arguments that pass to the application client.
   - *-profileName* defines the profile of the Application Server process in a multi-profile installation. The -profileName option is not required for running in a single profile environment or in an Application Clients installation.

     The default is default_profile.
   - *-JVMOptions* is a valid Java standard or non-standard option string. Insert quotation marks around the string.
   - *-help, -?* prints the usage information.

   All other parameters intended for the `launchClient` command must begin with the -CC prefix.

   Parameters that are not EAR files, or usage requests, or that do not begin with the -CC prefix, are ignored by the application client run time, and are passed directly to the application client program.

   The `launchClient` command retrieves parameters from three places:
   - The command line
   - A properties file
   - System properties

   The parameters are resolved in the order listed above, with command line values having the highest priority and system properties the lowest. Using this prioritization you can set and override default values.

3. Specify the server name.

   By default, the launchClient command uses the localhost for the `BootstrapHost` property value.

   This setting is effective for testing your application client when it is installed on the same computer as the server. However, in other cases override this value with the name of your server. You can override the `BootstrapHost` value by invoking `launchClient` command with the following parameters:

   ```
   launchClient myapp.ear -CCBootstrapHost=abc.midwest.mycompany.com
   ```

   You can also override the default by specifying the value in a properties file and passing the file name to the launchClient shell.

Security is controlled by the server. You do not need to configure security on the client because the client assumes that security is enabled. If server security is not enabled, then the server ignores the security request, and the application client functions as expected.

Example

You can store launchClient values in a properties file, which is a good method for distributing default values. You can then override one or more values on the command line. The format of the file is one `launchClient -CC` parameter per line without the `-CC` prefix. For example:

```
 verbose=true classpath=/usr/lpp/mydir/util.jar;/usr/lpp/mydir/harness.jar;/usr/lpp
/production/G19/global.jar BootstrapHost=abc.westcoast.mycompany.com tracefile=/usr
/lpp/WebSphere/mylog.txt
```

launchClient tool

This topic describes the Java Platform, Enterprise Edition (Java EE) command line syntax for the launchClient tool for WebSphere Application Server.

You can use the **launchClient** command from a node within a WebSphere Application Server, Network Deployment environment. However, do not attempt to use the **launchClient** command from the Deployment Manager.

Important: All users who run commands from a specific profile must have authority to modify files that are created by other users that use the same profile. Otherwise, you might see a permission denied error in the log files. To avoid this issue, consider one of the following policies:

- Use a separate installation for distinct user authorities
- Always use the same user for all of the commands that are run in a given profile
- Ensure that all users of a specific profile belong to the same group. In addition, ensure that each user of a group has the read and write authority to the files that are created by other members in the same profile.

The following example illustrates the command line invocation syntax for the launchClient tool:

`launchClient [-profileName pName | -JVMOptions options | -help | -?] userapp [-CCname=value] [app args]`

where

- *userapp* is the path and the name of the EAR file that contains the application client.
- *-CCname=value* is the client container name-value pair parameter. See the client container parameters section, for supported name-value pair arguments.
- *app args* are arguments that pass to the application client.
- *-profileName* defines the profile of the Application Server process in a multi-profile installation. The -profileName option is not required for running in a single profile environment or in an Application Clients installation.

  The default is `default_profile`.
- *-JVMOptions* is a valid Java standard or nonstandard option string, except `-cp` or `-classpath`. Insert quotation marks around the string.
- *-help, -?* prints the usage information.

The first parameter must be `-help`, `-?` or contain no parameter at all. The `-profileName pName` and `-JVMOptions` options are optional parameters. If used, they must appear before the `<userapp>` parameter. All other parameters are optional and can appear in any order after the *userapp* parameter. The Java EE Application client run time ignores any optional parameters that do not begin with a `-CC` prefix and passes those parameters to the application client.

Client container parameters

Supported arguments include:

-CCadminConnectorHost
Specifies the host name of the server from which configuration information is retrieved.

The default is the value of the -CCBootstrapHost parameter or the value, localhost, if the -CCBootstrapHost parameter is not specified.

-CCadminConnectorPort
Indicates the port number for the administrative client function to use. The default value is 8880 for SOAP connections and 2809 for Remote Method Invocation (RMI) connections.

-CCadminConnectorType
Specifies how the administrative client connects to the server. Specify RMI to use the RMI connection type, or specify SOAP to use the SOAP connection type. The default value is SOAP.

-CCadminConnectorUser
Administrative clients use this user name when a server requires authentication. If the connection type is SOAP, and security is enabled on the server, this parameter is required.

-CCadminConnectorPassword
The password for the user name that the -CCadminConnectorUser parameter specifies.

-CCaltDD
The name of an alternate deployment descriptor file. This parameter is used with the -CCjar parameter to specify the deployment descriptor to use. Use this argument when a client JAR file is configured with more than one deployment descriptor. Set the value to null to use the client JAR file standard deployment descriptor.

-CCBootstrapHost
The name of the host server you want to connect to initially. The format is:
your_server_of_choice.com

-CCBootstrapPort
The server port number. If you do not specify this argument, the WebSphere Application Server default value is used.

-CCclassLoaderMode
Specifies the class loader mode. If PARENT_LAST is specified, the class loader loads classes from the local class path before delegating the class loading to its parent. The classes loaded for the following are affected:

- Classes defined for the Java EE application client
- Resources defined in the Java EE application
- Classes specified on the manifest of the Java EE client JAR file
- Classes specified using the -CCclasspath option

If PARENT_LAST is not specified, then the default mode, PARENT_FIRST, causes the class loader to delegate the loading of classes to its parent class loader before attempting to load the class from its local class path.

-CCclasspath
A class path value. When you launch an application, the system class path is used. If you want to access classes that are not in the EAR file or part of the system class paths, specify the appropriate class path here. Multiple paths can be concatenated.

-CCD
Use this option to have the WebSphere Application Server set the specified system property during initialization. Do not use the equals (=) character after the -CCD. For example:

-CCDcom.ibm.test.property=testvalue. You can specify multiple -CCD parameters. The general format of this parameter is -CCD<property key>=<property value>. For example, -CCDI18NService.enable=true.

-CCdumpJavaNameSpace
Controls generation of a dump of the java: name space for the application that is launched, which can be used for debugging purposes. A value of **true** generates a dump in short format, and includes the name and object type for each binding. A value of **long** generates a dump in long format, and includes additional information for each binding over short format, such as the local object type and string representation of the local object. The default value is **false**, and does not generate a dump.

-CCexitVM
Use this option to have the WebSphere Application Server call the System.exit() method after the client application completes. The default is false.

-CCinitonly
Use this option to initialize application client run time for ActiveX application clients without launching the client application. The default is false.

-CCjar
The name of the client Java Archive (JAR) file that resides within the EAR file for the application you wish to launch. Use this argument when you have multiple client JAR files in the EAR file.

-CCpropfile
Indicates the name of a properties file that contains launchClient properties. Specify the properties without the -CC prefix in the file, with the exception of the securityManager, securityMgrClass and securityMgrPolicy properties. See the following example: verbose=true.

-CCproviderURL
Provides bootstrap server information that the initial context factory can use to obtain an initial context. WebSphere Application Server initial context factory can use either a Common Object Request Broker Architecture (CORBA) object URL or an Internet Inter-ORB Protocol (IIOP) URL. CORBA object URLs are more flexible than IIOP URLs and are the recommended URL format to use. This value can contain more than one bootstrap server address. This feature can be used when attempting to obtain an initial context from a server cluster. You can specify bootstrap server addresses, for all servers in the cluster, in the URL. The operation will succeed if at least one of the servers is running, eliminating a single point of failure. The address list does not process in a particular order. For naming operations, this value overrides the -CCBootstrapHost and -CCBootstrapPort parameters. A CORBA object URL specifying multiple systems is illustrated in the following example:

```
-CCproviderURL=corbaloc:iiop:myserver.mycompany.com:9810,:mybackupserver.mycompany.com:2809
```

This value is mapped to the java.naming.provider.url system property.

-CCsecurityManager
Enables and runs the WebSphere Application Server with a security manager. The default is disable.

-CCsecurityMgrClass
Indicates the fully qualified name of a class that implements a security manager. Only use this argument if the -CCsecurityManager parameter is set to enable. The default is java.lang.SecurityManager.

-CCsecurityMgrPolicy
Indicates the name of a security manager policy file. Only use this argument if the -CCsecurityManager parameter is set to enable. When you enable this parameter, the java.security.policy system property is set. The default is *app_server_root*/properties/client.policy.

-CCsoapConnectorPort
The Simple Object Access Protocol (SOAP) connector port. If you do not specify this argument, the WebSphere Application Server default value is used.

-CCtrace
Use this option to obtain debug trace information. You might need this information when reporting a problem to IBM customer support. The default is `false`. For more information, read the Enabling trace topic.

-CCtracefile
Indicates the name of the file to which trace information is written. The default is to write output to the console.

-CCtraceMode
Specifies the trace format to use for tracing. If the valid value, `basic`, is not specified the default is advanced. Basic tracing format is a more compact form of tracing.

-CCverbose
This option displays additional information messages. The default is `false`.

If you are using an EJB client application with security enabled, edit the `sas.client.props` file, which is located in the *profile_root*`/properties` directory. Within the file, change the `com.ibm.CORBA.loginSource` value to *none*.

For more information on the `sas.client.props` utility, refer to the Manually encoding passwords in properties files and the PropFilePasswordEncoder command reference topics.

RMI connection with security. Used with the EJB and administrative client application.

Using Jacl:

```
wsadmin.sh -conntype RMI -port  rmiportnumber -user userid
-password password
```

Using Jython:

```
wsadmin.sh -lang jython -conntype RMI -port  rmiportnumber -user userid
-password password
```

rmiportnumber for your connection displays in the administrative console as BOOTSTRAP_ADDRESS.

Attention: On the AIX, HP-UX, Linux, IBM i, Solaris, and z/OS operating systems, the use of -password option may result in security exposure as the password information becomes visible to the system status program, such as ps command, which can be invoked by other users to display all of the running processes. Do not use this option if security exposure is a concern. Instead, specify user and password information in the `soap.client.props` file for SOAP connector or `sas.client.props` file for RMI connector. The `soap.client.props` and `sas.client.props` files are located in the properties directory of your WebSphere Application Server profile.

If Kerberos (KRB5) is enabled for administrative authentication, the authentication target supports BasicAuth and KRB5. To use KRB5, update the `sas.client.props`, `soap.client.props`, and `ipc.client.props` files, according to the connector type.

Attention: When using Kerberos authentication, the user password does not flow across the wire. A one-way hash of password is used to identify the client.

The following examples demonstrate correct syntax.

```
./launchClient.sh /usr/earfiles/myapp.ear -CCBootstrapHost=myWASServer -CCverbose=true app_parm1 app_parm2
```

Specifying the directory for an expanded EAR file

You can archive the `Manifest.mf` client Java Archive (JAR) files instead of automatically cleaning them up after the application exits.

Before you begin

Each time the launchClient tool is called, it extracts the Enterprise Archive (EAR) file to a random directory name in the temporary directory on your hard drive. Then the tool sets up the thread ClassLoader to use the extracted EAR file directory and JAR files included in the `Manifest.mf` client Java Archive (JAR) file. In a normal J2EE Java client, these files are automatically cleaned up after the application exits. This cleanup occurs when the client container shutdown hook is called. To avoid extracting the EAR file (and removing the temporary directory) each time the launchClient tool is called, complete the following steps:

Procedure

1. Specify a directory to extract the EAR file by setting the `com.ibm.websphere.client.applicationclient.archivedir` Java system property. If the directory does not exist or is empty, the EAR file is extracted normally. If the EAR file was previously extracted, the launchClient tool reuses the directory.
2. Delete the directory before running the launchClient tool again, if you need to update your EAR file. When you call the `launchClient` command, it extracts the new EAR file to the directory. If you do not delete the directory or change the system property value to point to a different directory, the launchClient tool reuses the currently extracted EAR file and does not use your changed EAR file. When specifying the `com.ibm.websphere.client.applicationclient.archivedir` property, make sure that the directory you specify is unique for each EAR file you use. For example, do not point the `MyEar1.ear` and the `MyEar2.ear` files to the same directory.

Downloading and running a Java EE client application using Java Web Start

Learn about the Java Web Start technology that is provided by the Java Standard Edition runtime environment to deploy Java Enterprise Edition application clients, including Thin application clients, on the remote client machine with a single click from a web browser on the client machine.

Before you begin

The supported client platforms for deploying application clients using the Java Web Start are the same as the IBM Application Client for WebSphere Application Server supported platforms, except Linux on Power® and OS/400® operating systems.

Before you begin this task, see the following topics to understand Java Web Start technology and its components:

- “Java Web Start architecture for deploying application clients” on page 2023
- “Client application Java Network Launcher Protocol deployment descriptor file” on page 2024
- “ClientLauncher class” on page 2027

Note: The Sun Java Web Start, which is available from Sun Microsystems, is not compatible with the IBM Runtime Environment, Java 2 Technology Edition, which is provided by WebSphere Application Server and the IBM Application Client. The IBM Runtime Environment contains some additional functionality that is not supported in the Sun Java Web Start. Also, the IBM Runtime Environment uses a different packaging structure than the Sun Java Web Start. Use the IBM Runtime Environment.

About this task

To deploy application clients using Java Web Start, the client machine must have at least a Java SE runtime environment installed. The Java SE runtime environment includes the Java Web Start, which implements the JSR 56: Java Network Launching Protocol and API. The application clients Enterprise

Archive (EAR) file is a Java archive (JAR) resource in a JNLP descriptor file that resides on a central server. The JNLP descriptor file also specifies the runtime environment requirement for running the application.

WebSphere Application Server provides a launcher class to launch the Java EE application client in the application client container inside of Java Web Start. The client machine might not have the IBM Application Client for WebSphere Application Server installed. If this is the case, create and install an application client container and runtime package as a runtime environment through Java Web Start. The JNLP descriptor file specifies this runtime environment as the required runtime environment for running the Java EE application client.

WebSphere Application Server also provides command-line utility programs to create this application client container and runtime package from an existing IBM Application Client for WebSphere Application Server installation, as well as an installer class to install this package as a runtime environment for the application client container and also the Java Runtime Environment (JRE) in the IBM Application Client for WebSphere Application Server installation. To run the Java EE application client, the EAR file is deployed as a JAR resource that is described in the JNLP descriptor file.

Procedure

1. Identify the client machine operating system, and install the corresponding IBM Application Client for WebSphere Application Server on a development machine. For example, if the Java EE application clients are targeted to run on Windows operating systems, install the IBM Application Client for WebSphere Application Server for Windows.
2. Run the utility programs to create the application client container and runtime package.
   a. Use the “buildClientRuntime tool” on page 2032 utility to create the package.
   b. Use the “buildClientLibJars tool” on page 2024 utility to create the JAR files containing the launcher and the installer class. This utility also zips up the properties files in the <app_client_root>/ properties directory.
3. Create the runtime installer JNLP descriptor file. The JNLP response must be included in the JNLP version ID to indicate the current runtime version in the response header, for example, `x-java-jnlp-version-id=1.6.0`. Using a servlet of a JavaServer Pages (JSP) file to provide a dynamic JNLP response.
4. Create the Java EE application client launch JNLP descriptor file.
5. Package the application client container runtime environments and the Java EE application in an Enterprise Archive (EAR) file. Depending on your preferred deployment strategy, the files can be in two separate Web modules, or combined into one.
6. All JAR resources must be Java signed, including the Java EE application client EAR file.
7. Deploy the Enterprise Archive file on an application server, and start the application. The Java EE application client is ready to be deployed.

Example

A Java Web Start deployment Sample is included in the client samples. This Sample demonstrates the steps to deploy a Java EE application client with an automated ANT script. The Sample has a servlet to generate the runtime installer JNLP response with JNLP version ID, for example, `x-java-jnlp-version-id`.

Important: When the application client initially launches using Java Web Start from Sun Microsystems Java SE Runtime Environment 6.0, it installs the Application Client runtime, which includes the IBM JRE. An null pointer exception (NPE) is thrown from the `com.sun.deploy.services.WPlatformService.getSecureRandom()` method. This is a known bug in Sun Java SE 6 (http://bugs.sun.com/bugdatabase/view_bug.do?bug_id=6505528). If you experience this exception, relaunch the application. The NPE only occurs on the first launch of the application client.

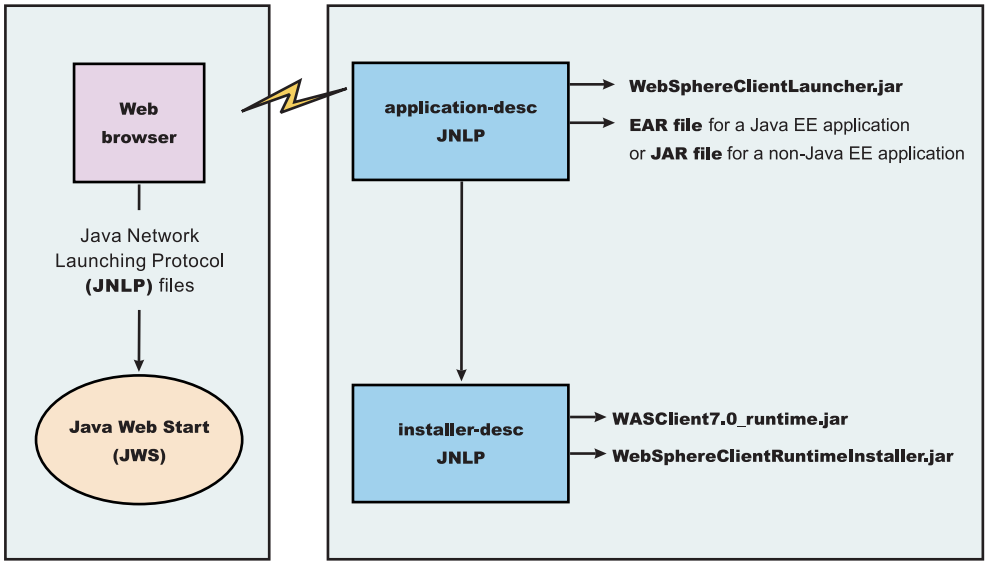
Java Web Start architecture for deploying application clients

Java Web Start is an application-deployment technology that includes the portability of applets, the maintainability of servlets and JavaServer Pages (JSP) file technology, and the simplicity of mark-up languages such as XML and HTML. It is a Java application that allows full-featured Java EE client applications to be launched, deployed and updated from a standard Web server. The Java Web Start client is used with platforms that support a web browser.

Upon launching Java Web Start for the first time, you might download new client applications from the Web. Each time you launch JWS thereafter, you can initiate applications either through a link on a web page or (in Windows) from desktop icons or the Start menu. You can deploy applications quickly using Java Web Start, cache applications on the client machine, and launch applications remotely offline. Additionally, because Java Web Start is built from the Java Platform, Enterprise Edition (Java EE) infrastructure, the technology inherits the complete security architecture of the Java EE platform.

The technology underlying Java Web Start is the Java Network Launching Protocol & API (JNLP). Java Web Start is a JNLP client and it reads and parses a JNLP descriptor file (JNLP file). Based on the JNLP descriptor, it downloads appropriate pieces of a client application and any of its dependencies. If any of the pieces of the application are already cached on the client machine, then those components are not downloaded again, unless they have been updated on the server machine. After you download and cache the client application, JWS launches it natively on the client machine.

The following diagram shows an overview of launching a client application, include the Application Client for WebSphere Application Server as a dependent resource, using Java Web Start.



The web browser running on a client machine connects to a web application located on a server machine. The client application JNLP descriptor file is downloaded and processed by Java Web Start on the client machine.

In this diagram, there are two JNLP descriptor files:

- Client application JNLP descriptor (application-desc in the diagram)
- Application Clients run-time installer JNLP descriptor (installer-desc in the diagram)

Each of these JNLP descriptor files, the client application (JAR or EAR) and the dependent resource JAR files are packaged as web applications in an EAR file. This EAR file is deployed to an Application server. The client machine with JWS installed uses a web browser to connect to the URL of the client application JNLP descriptor file to download and run the client application.

Using Java Web Start from Java SE Runtime Environment 6.0 or later is highly recommended. All the platforms supported by the application client for WebSphere Application Server are supported.

You can use the following:

- Java Web Start on the Java Standard Edition Developer Kits that IBM provides, packaged in Application Client for WebSphere Application Server
- Java Web Start on Java SE 6 Development Kit or Java SE Runtime Environment 6.0, which you can download from the Oracle website for Windows, Linux and Solaris operating systems
- Java Web Start on HP-UX JDK or JRE for Java Platform, Standard Edition, Version 6, which you can download from the HP website

buildClientLibJars tool:

For a Java Platform, Enterprise Edition (Java EE) application client application and or Thin application client application to be launched using Java Web Start (JWS), the properties files bundled in Application Client for WebSphere Application Server must be installed in the Java Web Start. Use this tool to create those property JAR files. The Java Web Start client is used with platforms that support a web browser.

The buildClientLibJars tool copies the JAR files from the Application Client for WebSphere Application Server installation and creates a `properties.jar` file, which contains the properties files from the Application Clients installation properties directory to a specified location. When this property is created, the tool uses the value of `keystore`, `storepass`, `alias` and `storetype` to sign all of the JAR files in the specified location.

```
Windows usage: buildClientLibJars.bat  [-help] [-verbose] destdir keystore storepass alias storetype

Unix usage:    buildClientLibJars.sh  [-help] [-verbose] destdir keystore storepass alias storetype
```

where:

- `-help` will display the message
- `-verbose` will turn on verbose message
- `destdir` will output the destination directory name
- `keystore` is the key store file
- `storepass` is the key store password
- `alias` key is the alias name
- `storetype` is the key store type

Client application Java Network Launcher Protocol deployment descriptor file

The deployment descriptor file is the main Java Network Launcher Protocol (JNLP) descriptor file for the client application.

Location

The client application has an Application Clients runtime dependency that provides the following:

- Java SE Runtime Environment from IBM
- Application Clients run-time properties
- SSL KeyStore and TrustStore file
- Application Clients run-time library JAR files (optional for Thin Application client applications)

If the Application Clients run-time dependency is not met, it is downloaded and installed in Java Web Start (JWS), as described by the Application Clients run-time installer JNLP descriptor file. For example:

```
<j2se version="1.6" href="http://your_server.com/jws/wasappclient/download.jnlp"/>
```

Usage notes

The client application must also include the `WebSphereClientLauncher.jar` file, which contains the launcher class, com.ibm.websphere.client.launcher.ClientLauncher, that completes one of the following actions:

- If it is a Java Platform, Enterprise Edition (Java EE) Application client application (that is the resources for the application contain an EAR file with a client application), the EAR file must be specified as a JAR resource so that it can be downloaded to JWS and specified in the system property, `com.ibm.websphere.client.launcher.ear`. See "JNLP descriptor file for a Java EE Application client application" for an example.
- If it is a Thin Application client application, the Thin Application client application JAR file must be specified as a JAR resource so that it can be downloaded to JWS and the name of the class containing main method entry point is specified in the system property, `com.ibm.websphere.launcher.main`. See "JNLP descriptor file for a Thin Application client application" on page 2026 for an example.

The JNLP specification requires all the resource (JAR or EAR) files used in a JNLP file to be signed.

You can specify the –CC arguments defined in the launchClient tool for a J2EE Application client application in application arguments section of the JNLP descriptor files. However, only –CCD is supported for a Thin Application client application to define system properties and the JNLP <property> tag can also be used to define system properties. See the following example for details:

```
<property name="java.naming.provider.url" value="corbaloc:iiop:myserver.com:9089"/>
```

For a J2EE Application client application, specify the following application arguments as defined in the JNLP.

1. Specify your target server provider URL, as shown in the following example:

   ```
   <argument> >-CCDjava.naming.provider.url =corbaloc:iiop:myserver.mydomain.com:9080 </argument>
   ```

2. Specify the SSL Key File and SSL Trust File location. These files are expected to be available in the client machine. To use the ones in the Application Clients run-time dependency installed in JWS cache, specify these application arguments:

   ```
   <argument> -CCDcom.ibm.ssl.keyStore=${WAS_ROOT}/etc/key.p12 </argument>
   <argument> -CCDcom.ibm.ssl.trustStore=${WAS_ROOT}/etc/trust.p12 </argument>
   ```

3. Specify the initial naming context factor, as shown in the following example:

   ```
   <argument>-CCDjava.naming.factory.initial=com.ibm.websphere.naming.WsnInitialContextFactory </argument>
   ```

   For a Thin Application client application, you also need to specify the actual location of the `sas.client.props` and `ssl.client.props` files located in the Application Clients runtime dependency that is installed in the JWS cache.

   ```
   <argument>-CCDcom.ibm.CORBA.ConfigURL=file:${WAS_ROOT}/properties/sas.client.props </argument>
   <argument>-CCDcom.ibm.SSL.ConfigURL=file:${WAS_ROOT}/properties/ssl.client.props </argument>
   ```

   If any of the default settings in the `sas.client.props` and `sas.client.props` file need modifying, use the –CCD to change the settings through the system properties, as shown in the following example:

   ```
   <argument>-CCDjavacom.ibm.CORBA.securityEnabled=false </argument>
   ```

   Important: The ${WAS_ROOT} token used in the JNLP file is replaced by the launcher class, com.ibm.websphere.client.launcher.ClientLauncher, to the actual location of the Application Clients run-time dependency installation in the JWS cache. If you are using JSP to dynamically create this JNLP description file, you must escape this token because it has a different meaning in JSP 2.0. See the following example for details:

   ```
   <argument>-CCDcom.ibm.ssl.keyStore=\${WAS_ROOT}/etc/key.p12 </argument>
   <argument>-CCDcom.ibm.ssl.trustStore=\${WAS_ROOT}/etc/trust.p12 </argument>
   ```

JNLP descriptor file for a Java EE Application client application:

The deployment descriptor file is the main Java Network Launcher Protocol (JNLP) descriptor file for the client application.

Here is an example of the client application JNLP descriptor file for a Java EE Application client application:

```
<?xml version="1.0" encoding="utf-8"?>
<!--

JNLP descriptor file for a Thin Application client application:

The deployment descriptor file is the main Java Network Launcher Protocol (JNLP) descriptor file for the client application. If it is a Thin Application client application, then the launcher class uses the current JVM from the Application Clients run-time dependency and invokes the Thin Application client application main method.

Here is an example of the JNLP descriptor file for a Thin Application client application.

```
 This sample program is provided AS IS and may be used, executed, copied and modified

ClientLauncher class:

The class, com.ibm.websphere.client.installer.ClientLauncher, contains a main() method that is called by Java Web Start (JWS) to launch the client application. The Java Web Start client is used with platforms that support a web browser.

This client is packaged in the `WebSphereClientLauncher.jar` file that is located in the Application Client for WebSphere Application Server installation under the <*app_client_root*>/ lib/webstart directory.

The launcher class requires that the following properties are defined. These properties are not defined in a separate properties file. Instead, the properties are defined as part of the Java Network Launching Protocol (JNLP) files.

com.ibm.websphere.client.launcher.main
If the client application is a Thin Application client, then this property should be specified. It specifies the class where the main entry point of the client application resides.

com.ibm.websphere.client.launcher.ear
If the client application is a Java Platform, Enterprise Edition (Java EE) Application client, then this property should be specified. It specifies the name of the EAR file to be executed. This property takes precedence over com.ibm.websphere.client.launcher.main. However, only one of the two properties should be specified.

Application client launcher for Java Web Start:

The application client launcher for Java Web Start is a Java class, com.ibm.websphere.client.installer.ClientLauncher, which has a main() method that Java Web Start calls to start the application client container and to invoke the application client's main() method. It provides similar functions as the **`lauchClient`** command line tool to start application clients from the command line.

The com.ibm.websphere.client.launcher.ClientLauncher class is packaged in the WebSphereClientLauncher.jar file under the <app_client_root>/lib/webstart directory.

The launcher tool requires that the following properties are defined.

com.ibm.websphere.client.launcher.main
If the client that is to be run is a thin client, then this property should be specified. It specifies the class where the main entry point of the application resides. It is the main class name for a Thin application client. If it is set, the launcher will not start the client container, it will rather invoke the main method for the application directly. However, if `com.ibm.websphere.client.launcher.ear` is also set, it will be ignored.

com.ibm.websphere.client.launcher.ear
If the client that is to run is the Java Platform, Enterprise Edition (Java EE) client, then this property should be specified. It specifies the name of the ear file to be executed. This property takes precedence over `com.ibm.websphere.client.launcher.main` although only one of the two properties should be specified.

These properties are not defined in a separate properties file. Instead, they are defined as part of the Java Network Launching Protocol files.

When `com.ibm.websphere.client.launcher.ear` is set, the application client launcher for JWS supports almost all of the –CC arguments as the **`lauchClient`** command line tool supports. However, if only `com.ibm.websphere.client.launcher.main` is set, the launcher will only support the –CCD argument. The following table shows the comparison of the supported –CC arguments for the **`launchClient`** command line tool and the application client launcher for JWS:

Table 270. Comparison of the supported –CC arguments for the **`launchClient`** *command line tool and the application client launcher for JWS. Comparison of the supported –CC arguments*

-CC argument	launchClient	Application client launcher for JWS
-CCverbose	Yes	Yes
-CCjar	Yes	Yes
-CCclasspath	Yes	N/A

Table 270. Comparison of the supported –CC arguments for the **launchClient** *command line tool and the application client launcher for JWS (continued). Comparison of the supported –CC arguments*

-CC argument	launchClient	Application client launcher for JWS
-CCadminConnectorHost	Yes	Yes
-CCadminConnectorPort	Yes	Yes
-CCadminConnectorType	Yes	Yes
-CCadminConnectorUser	Yes	Yes
-CCaltDD	Yes	Yes
-CCBootstrapHost	Yes	Yes
-CCBootstrapPort	Yes	Yes
-CCproviderURL	Yes	Yes
-CCinitonly	Yes	N/A
-CCtrace	Yes	Yes
-CCtracefile	Yes	Yes
-CCsecurityManager	Yes	N/A
-CCsecurityMgrClass	Yes	N/A
-CCsecurityMgrPolicy	Yes	N/A
-CCD	Yes	Yes
-CCexitVM	Yes	Yes
-CCdumpJavaNameSpace	Yes	Yes
-CCsoapConnectorPort	Yes	Yes
-CCtraceMode	Yes	Yes
-CCclassLoaderMode	Yes	Yes

Macro expansion is supported for the –CCD argument by the application client launcher for JWS. The launcher will automatically substitute certain macro keys (enclosed with ${...}) with the calculated value at runtime. For example, if a macro key is used in the –CCD argument in the application client JNLP manifest file,

```
<argument>-CCDcom.ibm.ssl.keyStore= ${WAS_ROOT}/etc/key.p12</argument>
```

it will be expanded to the JWS cache installation root location and the argument will become:

```
-CCDcom.ibm.ssl.keyStore=/home/tiu/.java/deployment/cache/javaws/ext/E1134532441112/etc/key12.p12
```

The following table shows the three macro keys that are currently supported and will be substituted by the launcher:

Table 271. Currently supported macro keys. Supported macro keys

Macro key	Value
${WAS_ROOT}	Installation root location within the JWS cache that is used by the application client container and runtime installer for JWS.
${JAVA_HOME}	Location of Java home. The return value of System.getProperty(“java.home”).
${USER_HOME}	Location of user home. The return value of System.getProperty(“user.home”).

Preparing the application client run time dependency component for Java Web Start

To launch a Java Platform, Enterprise Edition (Java EE) application client application, a Thin application client application, or both using Java Web Start (JWS), a Java Runtime Environment implementation Java archive (JAR) that IBM provides, the library JAR files and properties files bundled in Application Client for WebSphere Application Server must be installed in the JWS. Learn the steps to build the application client run time dependency component from an application client installation. It is packaged as a web application archive (WAR) file that can be installed in an application Server.

Before you begin

Install the Application Client for WebSphere Application Server for the operating system to which the client application deploys. If there is a requirement to deploy the client application to multiple operating systems, the application client run time dependency component must be built separately for each operating system that client application supports.

Procedure

1. Install the Application Client for WebSphere Application Server for the client application supported operating systems.
2. Change the directory to the installation bin directory.
3. Run the “buildClientRuntime tool” on page 2032 to generate the application client run time JAR file, which contains the Java Standard Edition Runtime Environment, the run time library JAR files, properties files, and the SSL KeyStore and TrustStore files from the application client installation.
4. Run the buildClientLibJars tools to package up the properties files in the properties directory of the application client installation into a properties.jar file in the specified location. The buildClientLibJars tools will also copy the `WebSphereClientLauncher.jar` file and `WebSphereClientRuntimeInstaller.jar` file from the application client installation to the specified location. All jar files in the specified location will be signed by the provided certificate.

   For example, if you are using Version 7.0 and using the test certificate that is included in the application client installation:

   ```
   buildClientLibJars C:\Temp\webstart ..\etc\DummyClientKeyFilejar WebAS "websphere dummy client" JKS
   ```
5. Create a JavaServer Pages (JSP) file or use a servlet to generate the application client run time installer Java Network Launching Protocol (JNLP) descriptor to respond to Java Web Start request. See the Java Web Start deployment sample in the application client installation.
6. Package the two signed JAR files, `WASClient7.0_windows.jar` and `WebSphereClientRuntimeInstaller.jar`, and the JSP file or servlet for generating the Application Client run time installer JNLP descriptor into a web application archive (WAR) file. This WAR file is packaged into an EAR file that can be deployed to an application server. See the Java Web Start deployment sample in the application client installation.

Results

Your web application is ready to serve the application client run time and the JRE environment.

Example

```
<!-- This sample program applies to WebSphere Application Server, Version 6.1.
It is provided AS IS and may be used, executed, copied and modified
without royalty payment by customer (a) for its own instruction and study, (b) in order
to develop applications designed to run with an IBM WebSphere product, either for customer's
own internal use or for redistribution by customer, as part of such an application, in
customer's own products.

```

1. Specifies that the file is a JNLP mime type so that the browser can process the JNLP file.
2. Specifies the exact version of this Application Client run time dependency component in the response by setting the HTTP header field: `x-java-jnlp-version-id`.
3. Specifies the required JRE version to run the installer program.
4. Specifies the installer `WebSphereClientRuntimeInstaller.jar` file, which contains the ClientRuntimeInstaller class.
5. Specifies a system property that defines the version of Application Client run time dependency component. This version is registered to the JNLP client.
6. Specifies resources for a particular platform. Each supported client application platform needs its own separate JAR file.
7. Specifies the Application Client run time dependency component JAR file.
8. Specifies the program to call that starts a JVM for the client application.

buildClientRuntime tool:

For a Java Platform, Enterprise Edition (Java EE) application client application and or Thin application client application to be launched using Java Web Start (JWS), the library JAR files bundled in Application Client for WebSphere Application Server must be installed in the Java Web Start. Use this tool to build those JAR files. The Java Web Start client is used with platforms that support a web browser.

The buildClientRuntime tool builds the required components from the WebSphere Application Server clients installation into the JAR file specified on the command. This JAR file contains:

- License files
- Java SE Runtime Environment 6 (JRE 6) that IBM provides
- Application Clients runtime properties and configuration
- SSL KeyStore and TrustStore files
- Runtime library JAR files

In the case of building an Application Clients runtime JAR file only for serving Thin Application client applications and not for Java EE Application client applications, the runtime library JAR files and the Application Clients runtime properties files are not included, except the configuration files, `sas.client.props`, `ssl.client.props` and `soap.client.props`, located in the `WAS_ROOT/properties` directory. The Java Web Start client is used with platforms that support a web browser.

The command-line invocation syntax for the buildClientRuntime tool is shown in the following example:

```
Windows Usage:    buildClientRuntime.bat  [-help] [-verbose] outfile keystore storepass alias storetype

Unix Usage:         buildClientRuntime.sh    [-help] [-verbose] outfile keystore storepass alias storetype
```

where:

- -help will display the message
- -verbose will turn on verbose message
- outfile is the output file name
- keystore is the key store file
- storepass is the key store password
- alias is the key alias name
- storetype is the key store type

ClientRuntimeInstaller class:

This section provides information on the ClientRuntimeInstaller class.

This class, com.ibm.websphere.client.installer.ClientRuntimeInstaller, contains a main() method that Java Web Start (JWS) calls to install the Application Client for WebSphere Application Server run-time dependency component in JWS cache. It is packaged in `WebSphereClientRuntimeInstaller.jar` file located in the Application Client for WebSphere Application Server installation in the *<app_server_root>*/`JWS` directory.

Specify the `WebSphereClientRuntimeInstaller.jar` file and the Application Client run-time dependency component JAR file as JAR resources in the Application Client run-time installer Java Network Launcher Protocol (JNLP) descriptor file. See the following example for details:

```
<jar href="Launcher/WebSphereClientRuntimeInstall.jar" main="true"/>
<jar href="Launcher/WASClient6.1_windows.jarRuntimeInstall.jar" main="true"/>
```

The ClientRuntimeInstaller class main method requires the following properties to be set in the JNLP file:

com.ibm.websphere.client.jre.version
Specifies a Java Runtime Environment (JRE) version name that is to be used when referring to the Application Client run-time dependency component.

com.ibm.websphere.client.jre.launch.java
Specifies the relative location of the javaw.exe program in the Application Client run-time dependency component JAR file.

The previously mentioned properties, JRE version name and the location of the javaw.exe program are registered to the Java Web Start Application Manager, as shown in the following example:

```
<property name="com.ibm.websphere.client.jre.version" value="WASclient6.1"/>
<property name="com.ibm.websphere.client.jre.launch.java" value="java\jre\bin\javaw.exe"/>
```

Using the Java Web Start sample

The EAR file, `WasAppClientRuntime.ear`, is provided in the *app_client_root*/`samples/bin/WasAppClientRuntime` directory of the Client Application for WebSphere Application Server installation. This EAR file provides a sample Application Clients run-time installer JNLP descriptor file and a sample Application Clients run-time library component JNLP descriptor file. Follow the steps in this task to build the Application Clients run-time dependency component and the Application Clients run-time library component. Add these components to the `WebSphereClientRuntime.ear` file, and then install the EAR file in an Application Server to be used by the client application.

About this task

There is a new Java Web Start sample available in the client sample gallery for WebSphere Application Server V7.0. Refer to the client sample gallery in the Application Client for WebSphere Application Server product. The name of the new sample is “Java Web Start Deployment Sample”.

Installing Java Web Start

Learn about the steps that are necessary to install Java Web Start (JWS).. Java Web Start technology is provided by the Java SE runtime environment to deploy Java EE application clients (including Thin application clients) on the remote client machine with a single click from a web browser on the client machine.

Before you begin

Before you begin this task, see the “Preparing the application client run time dependency component for Java Web Start” on page 2030 topic to understand Java Web Start (JWS) technology and components.

Note: The Sun Java Web Start, which is available from Sun Microsystems, is not compatible with the IBM Runtime Environment, Java 2 Technology Edition, which is provided by WebSphere Application Server and the IBM Application Client. The IBM Runtime Environment contains some additional functionality that is not supported in the Sun Java Web Start. Also, the IBM Runtime Environment uses a different packaging structure than the Sun Java Web Start. Use the IBM Runtime Environment.

About this task

Complete the following steps to install JWS:

Procedure

1. Install IBM Application Client for WebSphere Application Server.
2. Change your directory to the `javaws` path.
   - *client_install_root*`\java\jre\lib\javaws`
3. Run the update settings script from the path mentioned in the previous step.
   - Run the `updateSetting.sh` script
4. Change your path to the JWS installed path. For example, enter:
   - *client_install_root*`\java\jre\javaws`
5. Run `javaws` from the path mentioned in the previous step.
   - Run `./javaws` command.

Using a static JNLP file with Java Web Start for Application clients

Do not use JSP to dynamically generate a JNLP file, otherwise the JNLP jsp page cannot be opened in some IE browsers.

About this task

To use a static JNLP file, you will need to add the following mime type mapping in the web.xml file:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-app id="WebApp_ID" version="2.4" xmlns="http://java.sun.com/xml/ns/j2ee"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="http://java.sun.com/xml/ns/j2ee
http://java.sun.com/xml/ns/j2ee/web-app_2_4.xsd">
       <display-name>
       WAS Client runtime for Java Web Start</display-name>
       <welcome-file-list>
              <welcome-file>index.html</welcome-file>
              <welcome-file>index.htm</welcome-file>
              <welcome-file>index.jsp</welcome-file>
              <welcome-file>default.html</welcome-file>
              <welcome-file>default.htm</welcome-file>
              <welcome-file>default.jsp</welcome-file>
       </welcome-file-list>
       <mime-mapping>
```

```
        <extension>jnlp</extension>
        <mime-type>application/x-java-jnlp-file</mime-type>
        </mime-mapping>
</web-app>
```

Running the IBM Thin Client for Enterprise JavaBeans (EJB)

An EJB Client is a Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP) Java Platform, Standard Edition (Java SE) application that accesses remote Enterprise Java Beans from a server through Java Naming and Directory Interface (JNDI) look up. IBM Thin Client for EJB offers a smaller footprint and is easy to deploy to a Java SE environment and an Eclipse Rich Client Platform (RCP) environment. You can bundle the IBM Thin Client for EJB library using the WebSphere Application Server installation or the Application Client for WebSphere Application Server installation with your application. The IBM Thin Client for EJB also extends the choice of Java SE runtime. It can be run in the Java Runtime Environment (JRE) that is packaged with the WebSphere Application Server product, the JRE that is downloaded from the Oracle website, or the JRE that is downloaded from the HP website.

Before you begin

The IBM Thin Client for EJB can access version 2.x and version 3.x EJB on the WebSphere Application Server using the JNDI lookup, but it cannot access version 3.x EJB through resource injection. Resource injection is supported if the client application is a Java Platform, Enterprise Edition (Java EE) Application Client running within the Java Platform, Enterprise Edition (Java EE) Application Client Container.

Before you set up an EJB Thin Client environment, obtain the Java archive (JAR) file for the EJB Thin Client for WebSphere Application Server. To obtain the EJB Thin Client for WebSphere Application Server, install WebSphere Application Server or Application Client. The EJB Thin Client for WebSphere Application Server file, `com.ibm.ws.ejb.thinclient.zos_8.5.0.jar`, is located in the *app_server_root*`\runtimes` directory. `Use the com.ibm.ws.ejb.thinclient.zos_8.5.0.jar` for any client that is running on z/OS. Determining the client to use depends on the client platform, and not the platform of the server you are connecting to.

Copy the Java archive (JAR) file for the IBM Thin Client for EJB with WebSphere Application Server product, `com.ibm.ws.ejb.thinclient.zos_8.5.0.jar` and the `endorsed_apis_8.5.0.jar` files, to other machines to create a lightweight client environment that enables communications with the products. Copies of the IBM Thin Client for EJB are subject to the same terms and conditions of the license agreement for the WebSphere product where you obtained the Thin Client for EJB. Refer to the license agreements for correct usage and other limitations.

Copy the *app_server_root*`\runtimes\endorsed\endorsed_apis_8.5.0.jar` file into the default directory, `JAVA_JRE\lib\endorsed`. Alternatively, you can use the java.endorsed.dirs property to specify a directory of your choice. If you choose to use an alternative directory, it is a best practice to only include the endorsed_apis JAR file.

Important: The Pluggable Application Client is deprecated. It is replaced by the IBM Thin Client for EJB.

Attention: When running the IBM Thin Client for EJB, and the `-Djava.util.logging.manager=com.ibm.ws.bootstrap.WsLogManager` command line option is used, a ClassDefNotFoundError error is thrown. The use of WsLogManager is not supported in the IBM Thin Client for EJB, but you can use another Java logging manager.

About this task

Run the IBM Thin Client for EJB, by completing the following steps.

Procedure

1. Invoke the client application. Run the following Java command:

   Add the following system properties to the Java command if you want authentication and SSL enabled:

   ```
   export LIBPATH=<app_server_root>/lib:$LIBPATH
   <java_install_root>/bin/java
   -classpath com.ibm.ws.ejb.thinclient.zos_8.5.0.jar:<list_of_your_application_jars_and_classes>
   -Djava.naming.provider.url=iiop://<your_application_server_machine_name>
   -Dcom.ibm.SSL.ConfigURL=file:///home/user1/ssl.client.props
   -Dcom.ibm.CORBA.ConfigURL=file:///home/user1/sas.client.props
   <fully_qualified_class_name_to_run>
   ```

2. Provide IIOP authentication configuration and Client SSL Configuration. Add the following system properties to the Java command:

   ```
   -Dcom.ibm.SSL.ConfigURL=file:///home/user1/ssl.client.props
   -Dcom.ibm.CORBA.ConfigURL=file:///home/user1/sas.client.props
   ```

   You can obtain the `ssl.client.props` file and `sas.client.props` file from the WebSphere Application Server installation and modify the file to suit your environment. You must, at a minimum, update the location of the key files in the `ssl.client.props` file to the match location of your target environment. For example,

   ```
   -Dcom.ibm.ssl.keyStore=/home/user1/etc/key.p12
   -Dcom.ibm.ssl.trustStore=/home/user1/etc/trust.p12
   ```

3. Run your client application:

   - Enter the following command if you have copied the endorsed_apis_8.5.0.jar file into the `JAVA_JRE\lib\endorsed` default directory; for example:

     ```
     %JAVA_HOME%\bin\java -Dcom.ibm.SSL.ConfigURL=file:\\\home\sample\ssl.client.props <your_client_application>
     ```

   - Enter the following command if you have copied the endorsed_apis_8.5.0.jar file into a directory other than the default `JAVA_JRE\lib\endorsed` directory; for example:

     ```
     %JAVA_HOME%\bin\java
     -Djava.endorsed.dirs=<directory_that_includes_endorsed_apis_8.5.0.jar>
     -Dcom.ibm.SSL.ConfigURL=file:\\\home\sample\ssl.client.props <your_client_application>
     ```

What to do next

Enable trace for the IBM Thin Client for EJB by adding the following to the Java command.

```
-Dcom.ibm.ejs.ras.lite.traceSpecification=*=all
```

Running Java thin client applications

You can run Java thin client applications on machines installed with either a WebSphere Application Client installation or a WebSphere Application Server installation.

About this task

Important: Java thin clients are not packaged with JDBC provider classes. For example, the WebSphere Application Server Version 7.0 Java thin client is not packaged with Apache Derby 10.2 classes. Likewise, the version 6.1 Java thin client is not packaged with Cloudscape Version 5.1, Cloudscape Version 10.0, or Cloudscape version 10.1 classes. Therefore, to utilize the JDBC provider classes (such as Apache Derby, Oracle, DB2, Informix, or Sybase) on a Java thin client, you must:

1. Add the classes to your Java thin client application environment.
2. Make the classes visible to the Java thin client application. To do this, add the path to the classes in the client classpath within the script that launched the client program.

Otherwise, any attempt to load a database class (such as through the JNDI lookup of a datasource) results in a ClassNotFoundException.

The Java invocation to run a Java thin client application varies between a client and a server. If your Java thin client application needs to run on both a client installation and a server installation, follow the steps in the Running a Java thin client application on a server machine topic.

Procedure

- “Running a Java thin client application on a client machine” on page 2038
- “Running a Java thin client application on a server machine” on page 2039

Example

Your Java thin application client no longer needs additional code to set security providers if you have enabled security for your WebSphere Application Server instance. This code found in IBM i Java thin or pluggable application clients should be removed to prevent migration and compatibility problems. The java.security file from your WebSphere instance in the properties directory is now used to configure the security providers.

- Running the thin or pluggable application client with security enabled

Running the thin or pluggable application client with security enabled. The following code examples illustrates how security providers were set programmatically in the main() method and occurred prior to any code that accessed enterprise beans:

```
import java.security.*;
  ...
  if (System.getProperty("os.name").equals("OS/400")) {

    // Set the default provider list first.
    Provider jceProv = null;
    Provider jsseProv = null;
    Provider sunProv = null;

    // Allow for when the Provider is not needed, when
    // it is not in the client application's classpath.
    try {
      jceProv = new com.ibm.crypto.provider.IBMJCE();
    }
    catch (Exception ex) {
 ex.printStackTrace();
    throw new Exception("Unable to acquire provider.");
 }

    try {
      jsseProv = new com.ibm.jsse.JSSEProvider();
    }
    catch (Exception ex) {
 ex.printStackTrace();
    throw new Exception("Unable to acquire provider.");
 }

    try {
      sunProv = new sun.security.provider.Sun();
    }
    catch (Exception ex) {
 ex.printStackTrace();
    throw new Exception("Unable to acquire provider.");
 }

    // Enable providers early and ahead of other providers
    // for consistent performance and function.
    if ( (null != sunProv) && (1 != Security.insertProviderAt(sunProv, 1)) ) {
      Security.removeProvider(sunProv.getName());
      Security.insertProviderAt(sunProv, 1);
    }
    if ( (null != jceProv) && (2 != Security.insertProviderAt(jceProv, 2)) ) {
```

```
      Security.removeProvider(jceProv.getName());
      Security.insertProviderAt(jceProv, 2);
    }
    if ( (null != jsseProv) && (3 != Security.insertProviderAt(jsseProv, 3)) ) {
      Security.removeProvider(jsseProv.getName());
      Security.insertProviderAt(jsseProv, 3);
    }

    // Adjust default ordering based on admin/startstd properties file.
    // Maximum allowed in property file is 20.
    String provName;
    Class  provClass;
    Object provObj =  null;

    for (int i = 0; i < 21; i++) {
      provName = System.getProperty("os400.security.provider."+ i);

      if (null != provName) {

        try {
          provClass = Class.forName(provName);
          provObj = provClass.newInstance();
        }
        catch (Exception ex) {
          // provider not found
          continue;
        }

        if (i != Security.insertProviderAt((Provider) provObj, i)) {

          // index 0 adds to end of existing list
          if (i != 0) {
            Security.removeProvider(((Provider) provObj).getName());
            Security.insertProviderAt((Provider) provObj, i);
          }
        }
      } // end if (null != provName)
    } // end for (int i = 0; i < 21; i++)
  } // end if ("os.name").equals("OS/400")
```

For examples of Java thin client applications, refer to the Samples section of the information center.

Running a Java thin client application on a client machine

To run a Java thin client application on a machine with Application Client for WebSphere Application Server installed, use the setup Client command then start the application.

Before you begin

Before performing this task, you must install the Java thin application client from the Application Client for WebSphere Application Server installation.

Procedure

1. Set up the client application environment. Run the setupClient command.

   app_client_root/AppClient/bin/setupClient.sh

2. Run a Java command to invoke your client application.

   ```
   $JAVA_HOME/bin/java $WAS_LOGGING
   -classpath "$WAS_CLASSPATH: <list_of_your_application_jars_and_classes>"
   -Djava.ext.dirs=$JAVA_JRE/lib/ext:$WAS_EXT_DIRS:$WAS_HOME/plugins:$WAS_HOME/lib/WMQ/java/lib"
   -Djava.naming.provider.url=iiop://<your_application_server_machine_name>
   -Djava.naming.factory.initial=com.ibm.websphere.naming.WsnInitialContextFactory
   $SERVER_ROOT $CLIENTSAS $CLIENTSSL <fully_qualified_class_name_to_run>
   ```

Running a Java thin client application on a server machine

To run a Java thin client application on a machine with WebSphere Application Server installed, use the setupClient command then start the application.

Before you begin

You must install WebSphere Application Server before performing this task.

Procedure

1. Set up the Thin application client environment.

   Use the setupCmdLine shell.

   profile_root/bin/setupCmdLine.sh

2. Run the application client.

   Perform one of the following methods:

   - Run a Java command to call your main class directly.

     ```
     "$JAVA_HOME/bin/java" $WAS_LOGGING
     -Djava.security.auth.login.config="$USER_INSTALL_ROOT/properties/wsjaas_client.conf"
     -Djava.ext.dirs="$JAVA_HOME/jre/lib/ext:$WAS_EXT_DIRS:$WAS_HOME/plugins: $WAS_HOME/lib/WMQ/java/lib"
     -Djava.naming.provider.url=<an_IIOP_URL_or_a_corbaloc_URL_to_your
     application_server_machine_name>
     -Djava.naming.factory.initial=com.ibm.websphere.naming.WsnInitialContextFactory
     -Dserver.root="$WAS_HOME" $USER_INSTALL_PROP "$CLIENTSAS" "$CLIENTSSL"
     -classpath "$WAS_CLASSPATH:<list_of_your_application_jars_and_classes>"
     <fully_qualified_class_name_to_run> <your_application_parameters>
     ```

     For more information on IIOP and corbaloc URLs, see Developing applications that use JNDI.

   - Enter a command to use the WebSphere Application Server launcher.

     ```
     "$JAVA_HOME/bin/java" $WAS_LOGGING
     -Djava.security.auth.login.config="$USER_INSTALL_ROOT/properties/wsjaas_client.conf"
      "-Dws.ext.dirs=<list_of_your_application_jars_and_classes>
     $WAS_EXT_DIRS:$WAS_USER_DIRS"
     -Djava.naming.provider.url=<an_IIOP_URL_or_a_corbaloc_URL_to_your
     application_server_machine_name>
     -Djava.naming.factory.initial=com.ibm.websphere.naming.WsnInitialContextFactory

Chapter 41. Deploying data access resources

This page provides a starting point for finding information about data access. Various enterprise information systems (EIS) use different methods for storing data. These backend data stores might be relational databases, procedural transaction programs, or object-oriented databases.

The flexible IBM WebSphere Application Server provides several options for accessing an information system backend data store:

- Programming directly to the database through the JDBC 4.0 API, JDBC 3.0 API, or JDBC 2.0 optional package API.
- Programming to the procedural backend transaction through various J2EE Connector Architecture (JCA) 1.0 or 1.5 compliant connectors.
- Programming in the bean-managed persistence (BMP) bean or servlets indirectly accessing the backend store through either the JDBC API or JCA-compliant connectors.
- Using container-managed persistence (CMP) beans.
- Using the IBM data access beans, which also use the JDBC API, but give you a rich set of features and function that hide much of the complexity associated with accessing relational databases.

Service Data Objects (SDO) simplify the programmer experience with a universal abstraction for messages and data, whether the programmer thinks of data in terms of XML documents or Java objects. For programmers, SDOs eliminate the complexity of the underlying data access technology such as, JDBC, RMI/IIOP, JAX-RPC, and JMS, and message transport technology such as, java.io.Serializable, DOM Objects, SOAP, and JMS.

Deploying data access applications

Deploying a data access application includes more than installing your web application archive (WAR) or enterprise archive (EAR) file onto a server. Deployment can include tasks for configuring your application to use the data access resources of the server and overall runtime environment.

Before you begin

You can deploy only application code that is assembled into the appropriate modules. See the topic, Assembling data access applications for guidelines, for this process.

About this task

Perform the following steps if your application requires access to a relational database (RDB). When your application requires access to a different type of enterprise information system (EIS), such as an object-oriented database or the Customer Information Control System (CICS), consult the topics, Relational resource adapters and JCA, and Accessing data using Java EE Connector Architecture connectors.

Procedure

1. If your RDB configuration does not exist, do the following steps:
   a. Create a database to hold the data.
   b. Create tables required by your application.
      If your application uses container managed persistence (CMP) entity beans to access the data You can create the tables using the data definition language (DDL) generated from the enterprise bean configuration. For more information, see the topic, Recreating database tables from the exported table data definition language.

If your application uses bean managed persistence (BMP) entity beans, or *does not* **use entity beans**

You must use your database server interfaces to create the tables.

The Enterprise JavaBeans (EJB) to RDB Mapping wizard of an assembly tool is also used to create your database tables for either type of entity bean. Select the top-down mapping option in the wizard. However, this option does not give you direct control in naming the RDB elements or choosing column types. Additionally, because the top-down process is automatic, it might not provide mappings to reflect the precise relationships that you intend.

If you use Rational Application Developer, consult the information center about the mapping wizard. To learn about all of your assembly tool options, see the assembly tools topic in this information center.

c. Check the data source minimum required settings by vendor to see any database vendor requirements for connecting to an application server. See the topic, Data source minimum required settings, by vendor, for instructions.

2. Optional: Map your entity beans to the database tables through the meet-in-the-middle mapping option of an assembly tool. Complete this step only if you did not create your database schema through the top-down mapping option, did not generate your mapping relationships through bottom-up mapping, or did not generate mappings during the application assembly process. For information about the top-down mapping option see the information center for Rational Application Developer.
3. Install your application onto the application server. See the topic, Installing enterprise application files. When you install the application, you can alter data access settings that were made during application assembly, or, if they were omitted from the assembly process, set them for the first time. These settings include resource bindings and resource authentication aliases, which are addressed in the following substeps:
   a. Bind application resource references to the data sources, or other resource objects, that provide database connectivity. For details on the concept of binding, see the topic, Data source lookups for enterprise beans and web modules.

      Tip: After deployment, you can use the WebSphere Application Server administrative console to alter resource bindings. Click **Applications** > **Application Types** > **Webphere enterprise applications** > ***application_name***, and select the link to the appropriate mapping page. For example, if you want to alter the binding of an EJB module resource, you might click **Map data sources for all 2.x CMP beans**. For a web module resource, click **Resource references**.

   b. Define authentication alias data for resources that must be authenticated with the backend through *container-managed* authorization. In this security configuration, WebSphere Application Server performs EIS signon for data source or connection factory connections. Consult the topic, J2EE connector security for detailed reference on resource authentication.
4. Start the deployed application files using the administrative console, the wsadmin scripting tool **`startApplication`** command, or your own Java program.
5. Save the changes to your administrative configuration.
6. Test the application. For example, point a web browser at the URL for a deployed application and examine the performance of the application.

What to do next

If the application does not perform as wanted, update the application, then save and test it again.

Available resources

Use this page to select configured resources that you want to bind to the resource references of the enterprise beans or web modules in your application.

To view this administrative console page:

1. Click **Applications** > **Application Types** > **Websphere enterprise applications** > ***application_name***.
2. Click the link for any of these resource configuration pages:
   - **Resource references**
   - **Map data sources for all 2.x CMP beans**
   - **Provide default data source mapping for modules containing 2.x entity beans**
3. Locate the table row of the EJB or web module that you want to map to a different resource.
4. Within the row, locate the JNDI name of the resource that is currently bound to the EJB or web module.
5. Click **Browse**.

   You now see **Available resources**.

Each table row corresponds to a resource that you can bind to your enterprise bean or web module.

Select
Select the resource that you want to bind to the resource reference of your module.

JNDI name
The Java Naming and Directory Interface (JNDI) name of the resource that you want to bind to the resource reference of your module.

Information	Value
Data type	String

Scope
The scope of the resource. Note that this administrative console page displays only resources that are configured for a scope at which your application operates.

Description
The text description of the resource.

Map data sources for all 1.x CMP beans
Use this page to designate how the container-managed persistence (CMP) 1.x beans of an application map to data sources that are available to the application.

To view this administrative console page, click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name*** > **Map data sources for all 1.x CMP beans**.

Guidelines for using this administrative console page:

- The table depicts the 1.x CMP bean contents of your application.
- Each table row corresponds to a CMP bean within a specific EJB module. A row shows the JNDI name of the data source mapping target of the bean *only* if you bound them together during application assembly or installation. For every data source that is displayed, you see the corresponding security configuration.
- To set your mappings:
  1. Select a row. Be aware that if you check multiple rows on this page, the data source mapping target that you select in step 2 applies to all of those CMP beans.
  2. Click **Browse** to select a data source from the new page that is displayed, the Available Resources page. The Available Resources page shows all data sources that are available mapping targets for your CMP beans.
  3. Click **Apply**. The console displays the 1.x CMP bean data sources page again. In the rows that you previously selected, you now see the JNDI name of the new resource mapping target.

4. *Before* you click **OK** to save your new configuration, set the security parameters for the data source. Use the following steps.

- To specify data source security settings:
  1. Select one or more rows in the table.
  2. Type in a user name and password that comprise the authentication alias for signing on to the data source. If these entries are not listed in the application Java Platform, Enterprise Edition (Java EE) Connector (J2C) authentication data list, you must input them into the list after saving your settings on this page. Read the information center topic on managing Java EE Connector Architecture authentication data entries for more information.
  3. Click **Apply** that immediately follows the user name and password input fields.
- Repeat all of the previous steps as necessary.
- Click **OK** to save your settings.

Select
Select the check boxes of the rows that you want to edit.

EJB
The name of an enterprise bean in the application.

EJB Module
The name of the module that contains the enterprise bean.

URI
Specifies location of the module relative to the root of the application EAR file.

JNDI name
The Java Naming and Directory Interface (JNDI) name of the data source that is configured for the enterprise bean.

Information	Value
Data type	String

User name
The user name and password that comprise the authentication alias for securing the data source.

Map default data sources for modules containing 1.x entity beans
Use this page to set the default data source mapping for EJB modules that contain 1.x container-managed persistence (CMP) beans. Unless you configure individual data sources for your 1.x CMP beans, this default mapping applies to all beans within the module.

To view this administrative console page, click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name*** > **Map default data sources for modules containing 1.x entity beans**.

Guidelines for using this administrative console page:

- The page displays a table that depicts the EJB modules in your application that contain 1.x CMP beans.
- Each table row corresponds to a module. A row shows the JNDI name of the data source mapping target of the EJB module *only* if you bound them together during application assembly. For every data source that is displayed, you see the corresponding security configuration.
- To set your default data source mappings:
  1. Select a row. Be aware that if you check multiple rows on this page, the data source mapping target that you select in step 2 applies to all of those EJB modules.

2. Click **Browse** to select a data source from the new page that is displayed, the Available Resources page. The Available Resources page shows all data sources that are available mapping targets for your EJB modules.
3. Click **Apply**. The console displays the 1.x entity bean data sources page again. In the rows that you previously selected, you now see the JNDI name of the new resource mapping target.
4. *Before* you click **OK** to save your new configuration, set the security parameters for the data source. Use the following steps.

- To specify security settings for the default data source:
  1. Select a row. Be aware that if you check multiple rows on this page, the security settings that you select later apply to all of those data sources.
  2. Type in a user name and password that comprise the authentication alias for signing on to the data source. If these entries are not listed in the application Java Platform, Enterprise Edition (Java EE) Connector (J2C) authentication data list, you must input them into the list after saving your settings on this page. Read the information center topic on managing Java EE Connector Architecture authentication data entries for more information.
  3. Click **Apply** that immediately follows the user name and password input fields.
- Repeat all of the previous steps as necessary.
- Click **OK** to save your work.

Select
Select the check boxes of the rows that you want to edit.

EJB Module
The name of the module that contains the 1.x enterprise beans.

URI
Specifies location of the module relative to the root of the application EAR file.

JNDI name
The Java Naming and Directory Interface (JNDI) name of the default data source for the EJB module.

Information	Value
Data type	String

User name
The user name and password that comprise the authentication alias for securing the data source.

Map data sources for all 2.x CMP beans settings
Use this page to map container-managed persistence (CMP) 2.x beans of an application to data sources that are available to the application.

To view this administrative console page, click **Applications** > **Application Types** > **Websphere enterprise applications** > ***application_name*** > **Map data sources for all 2.x CMP beans**.

Each table row corresponds to a CMP bean within a specific EJB module. A row shows the JNDI name of the data source mapping target of the bean only if you bound them together during application assembly. For every data source that is displayed, you see the corresponding security configuration.

Set Multiple JNDI names
Specify the Java Naming and Directory Interface (JNDI) name for multiple EJB modules. Select one or more EJB modules from the table, and select a JNDI name from this list to configure the EJB modules with that JNDI name.

Information	Value
Data type	Drop-down list

Set Authorization Type

Specify the authorization type for securing the data source. Select one or more EJB modules from the table to set the authorization type.

Select either **Container** or **Application** from the displayed list. Container-managed authorization indicates that WebSphere Application Server performs signon to the data source. Application-managed authorization indicates that the enterprise bean code performs signon.

Modify Resource Authentication Method

Specify the authorization type and the authentication method for securing the data source. Select one or more EJB modules from the table to modify the resource authentication method.

You can choose between the following authentication methods:

- **None**:
  1. Determine which data source configurations to designate with no authentication method.
  2. Select the appropriate table rows.
  3. Select **None** from the list of authentication method options that precede the table.
  4. Click **Apply**.
- **Use default method (many-to-one mapping)**:
  1. Determine which data source configurations to designate with the WebSphere Application Server DefaultPrincipalMapping login configuration. Apply this option to each data source individually if you want to designate different authentication data aliases. See the information center topic on J2EE Connector security for more information on the default mapping configuration.
  2. Select the appropriate table rows.
  3. Select **Use default method (many-to-one mapping)** from the list of authentication method options that precede the table.
  4. Select an authentication data entry or alias from the list.
  5. Click **Apply**.
- **Use Kerberos authentication**: Specifies to use the Kerberos authentication method.
  1. Ensure that you have configured the Kerberos authentication mechanism in the application server.
  2. Select the appropriate table row.
  3. Select **Use Kerberos authentication** from the list of authentication method options that precede the table.
  4. Select an application login configuration from the list.
  5. Click **Apply**.
  6. To edit the properties of the custom login configuration, click **Mapping Properties** in the table cell.

  The application server will attempt to verify that you are connecting to the correct type of database when you select this option.
- **Use trusted connections (one-to-one mapping)**:
  1. Determine which data source configurations to designate with a custom Java Authentication and Authorization Service (JAAS) login configuration. See the information center topic on J2EE Connector security for more information on custom JAAS login configurations.
  2. Select the appropriate table row.
  3. Ensure that the database to which the modules will connect is configured for trusted connections.
  4. Select **Use trusted connections (one-to-one mapping)** from the list of authentication method options that precede the table.

5. Select an application login configuration from the list.
6. Click **Apply**.

The application server will attempt to verify that you are connecting to the correct type of database when you select this option.

- **Custom login configuration**:
  1. Determine which data source configurations to designate with a custom Java Authentication and Authorization Service (JAAS) login configuration. See the information center topic on J2EE Connector security for more information on custom JAAS login configurations.
  2. Select the appropriate table row.
  3. Select **Use custom login configuration** from the list of authentication method options that precede the table.
  4. Select an application login configuration from the list.
  5. Click **Apply**.
  6. To edit the properties of the custom login configuration, click **Mapping Properties** in the table cell.

Select
Select the check boxes of the rows that you want to edit.

EJB
The name of an enterprise bean in the application.

EJB Module
The name of the module that contains the enterprise bean.

URI
Specifies location of the module relative to the root of the application EAR file.

Target resource JNDI name
Specifies the resource to which the CMP bean is bound.

Resource authorization
Specifies the current setting for the resource authorization type.

Modify this setting with **Set authorization type**.

Map data sources for all 2.x CMP beans
Use this page to set the default data source mapping for EJB modules that contain 2.x container-managed persistence (CMP) beans. Unless you configure individual data sources for your 2.x CMP beans, this default mapping applies to all beans within the module.

To view this administrative console panel, click **Applications** > **Application Types** > **Websphere enterprise applications** > ***application_name*** > **Map data sources for all 2.x CMP beans** .

This panel displays a table that depicts the EJB modules in your application that contain 2.x CMP beans. Each table row corresponds to a module. A row shows the JNDI name of the data source mapping target of the EJB module only if you bound them together during application assembly. For every data source that is displayed, you see the corresponding security configuration.

Set Multiple JNDI Names
Specifies the JNDI name to bind to one or more modules. Select one or more modules, click **Set Multiple JNDI Names**, and select the JNDI name for the resource to which you would like to bind the module.

Set Authorization Type

Specifies the authorization type that you to use for the modules. Select one or more modules, click **Set Authorization Type**, and select the authorization type.

You can choose:

- Per application - indicates that the enterprise bean code performs signon.
- Container - indicates that the application server performs signon to the data source.

Modify Resource Authentication Method

Specifies the resource authentication method for the modules that you have configured with container-managed authorization. Select one or more modules, click **Modify Resource Authentication Method**, and select the authentication method.

You can choose between the following authentication methods:

- **None**:
  1. Determine which data source configurations to designate with no authentication method.
  2. Select the appropriate table rows.
  3. Select **None** from the list of authentication method options that precede the table.
  4. Click **Apply**.
- **Use default method (many-to-one mapping)**:
  1. Determine which data source configurations to designate with the WebSphere Application Server DefaultPrincipalMapping login configuration. Apply this option to each data source individually if you want to designate different authentication data aliases. See the information center topic on J2EE Connector security for more information on the default mapping configuration.
  2. Select the appropriate table rows.
  3. Select **Use default method (many-to-one mapping)** from the list of authentication method options that precede the table.
  4. Select an authentication data entry or alias from the list.
  5. Click **Apply**.
- **Use Kerberos authentication**: Specifies to use the Kerberos authentication method.
  1. Ensure that you have configured the Kerberos authentication mechanism in the application server.
  2. Select the appropriate table row.
  3. Select **Use Kerberos authentication** from the list of authentication method options that precede the table.
  4. Select an application login configuration from the list.
  5. Click **Apply**.
  6. To edit the properties of the custom login configuration, click **Mapping Properties** in the table cell.

  The application server will attempt to verify that you are connecting to the correct type of database when you select this option.
- **Use trusted connections (one-to-one mapping)**:
  1. Determine which data source configurations to designate with a custom Java Authentication and Authorization Service (JAAS) login configuration. See the information center topic on J2EE Connector security for more information on custom JAAS login configurations.
  2. Select the appropriate table row.
  3. Ensure that the database to which the modules will connect is configured for trusted connections.
  4. Select **Use trusted connections (one-to-one mapping)** from the list of authentication method options that precede the table.
  5. Select an application login configuration from the list.
  6. Click **Apply**.

The application server will attempt to verify that you are connecting to the correct type of database when you select this option.

- **Custom login configuration**:
  1. Determine which data source configurations to designate with a custom Java Authentication and Authorization Service (JAAS) login configuration. See the information center topic on J2EE Connector security for more information on custom JAAS login configurations.
  2. Select the appropriate table row.
  3. Select **Use custom login configuration** from the list of authentication method options that precede the table.
  4. Select an application login configuration from the list.
  5. Click **Apply**.
  6. To edit the properties of the custom login configuration, click **Mapping Properties** in the table cell.

Select
Select the check boxes of the rows you want to edit.

EJB Module
Specifies the name of the module that contains the 2.x enterprise beans.

URI
Specifies location of the module relative to the root of the application EAR file.

JNDI name
Specifies the Java Naming and Directory Interface (JNDI) name of the default data source for the EJB module.

Information	Value
Data type	String

Resource authorization
Specifies the authorization type and the authentication method for securing the data source.

Extended Datasource Properties
When selected, you will be directed to a panel on which you can specify extended properties that the module can use for the DB2 data source.

The application server will attempt to verify that you are connecting to the correct type of database when you select this option.

Installing a resource adapter archive

The application server uses the classes and other code that comprise a resource adapter archive (RAR) to support the resource adapters that you configure.

Before you begin

A RAR file, which is often called a Java EE Connector Architecture (JCA) connector, must comply with the JCA Specification. You can meet these requirements by using a supported assembly tool to assemble a collection of Java archive (JAR) files, other runnable components, and utility classes into a deployable resource adapter archive (RAR). You can then install the RAR file in the application server.

When you are using optimized local adapters, set up your server environment in the daemon group before installing the `ola.rar` file in the application server. The `ola.rar` file is located in the `WAS_HOME/installableApps` directory.

You can also use the wsadmin scripting file, olaRar.py, to install the RAR file.

To read about setting up your server environment, see the topic, Enabling the server environment to use optimized local adapters. You can read about the `olaRar.py` script in the topic, olaRar.py scripting file.

About this task

A resource adapter archive provides the classes and other code to support a resource adapter for access to a specific EIS, such as the Customer Information Control System (CICS). Therefore, you can only configure resource adapters for an EIS after you install the appropriate RAR file.

Important: When you use the **Install RAR** dialog to install a RAR file, the scope you define on the Resource Adapters page has no effect on where the RAR file is installed. You can install RAR files only at the node level, which you specify on the Install RAR page. To set the scope of an RAR file to a specific cluster, or server, after you install the RAR file at each node level, create a copy of the RAR file with the appropriate cluster or server scope.

Procedure

1. Navigate to the **Resource adapter** panel. Click **Resources** > **Resource Adapters** > **Resource adapters**.
2. Install a new resource adapter archive.
   a. Click **Install RAR**. A dialog opens for installing a RAR file and configuring the associated resource adapter. Only click **New** if you want to configure a new resource adapter for a previously installed RAR file.
   b. Browse to find the appropriate RAR file.
      - If your RAR file is located on your local workstation, select **Local path**, and browse to find the file.
      - If your RAR file is located on your server, select **Remote file system**, and specify the fully qualified path to the file.
   c. Click **Next**.
3. Configure the resource adapter name and any other properties needed under *General Properties*. For more details on the settings that you can configure, such as the J2C connection factories, see the topics Installing resource adapters within applications and Configuring resource adapters.
4. Click **OK**.
5. Optional: Create a copy of the RAR file with a different scope level. After you install the RAR file at each node level, you can create another copy of the file that has a specific server or cluster as the scope for that file.

   Note:
   - If you do not create a copy of your RAR at the cluster scope, then you must create identical factories (connection factories, admin object, and activation specifications) at the node level for each of your nodes in the cluster. By creating the copy of your RAR, you provide a placeholder for your factories and circumvent the need to create identical factories at the node level for each of your nodes in the cluster.
   - You must still install the RAR binaries (files, such as jars and xml deployment files) on each node for the RAR to operate successfully.

   a. Click **Resources**.
   b. Click **Resource Adapters**.
   c. Select the scope level and then click **NEW**.
   d. Choose the RAR file from the installed archive path.
   e. Click **OK**.

Results

You have installed a resource adapter archive that provide access to the EIS when it is properly configured. If you must configure more settings, or change some settings that were configured during the installation process, refer to the topic on configuring a resource adapter in the administrative console for more information.

Installing resource adapters embedded within applications

Install resource adapters in your applications so they can access outside data sources.

Before you begin

The JCA Version 1.6 specification adds support for Java annotations in RAR modules. For more information on annotation support see the topic, JCA 1.6 support for annotations in RAR modules.

About this task

Procedure

1. Assemble an application with RAR modules in it. See the topic Assembling applications for more information.
2. Install the application. Follow the steps in the topic Installing a new application.

   In the **Map modules to servers** step, specify target servers or clusters for each RAR file. Be sure to map all other modules that use the resource adapters defined in the RAR modules to the same targets. Also, specify the web servers as targets that serve as routers for requests to this application. The plug-in configuration file (`plugin-cfg.xml`) for each web server is generated based on the applications that are routed through it.

   In the **Metadata for modules** step of installing an application, you can set or unset the metadata-complete flag as discussed in the topic, JCA 1.6 support for annotations in RAR modules.

   Note: When installing a RAR file on a server, the application server looks for the manifest (MANIFEST.MF) for the connector module. The application server first looks for the RAR file's `connectorModule.jar` file and loads the manifest from the `connectorModule.jar` file. If the class path entry is in the manifest from the `connectorModule.jar`file, the RAR uses that class path.

   To ensure that the installed connector module finds the classes and resources that it needs, check the Class path setting for the RAR using the administrative console. For more information on how to check this setting, see the topics Resource adapter settings and WebSphere relational resource adapter settings.
3. Click **Finish** > **Save** to save the changes.
4. Create connection factories for the newly installed application.

   See the topic, Configuring connection factories for resource adapters within applications to view the steps to complete this step.

Results

Note: A given native library can only be loaded one time for each instance of the Java virtual machine (JVM). Because each application has its own class loader, separate applications with embedded RAR files cannot both use the same native library. The second application receives an exception when it tries to load the library.

If any application deployed on the application server uses an embedded RAR file that includes native path elements, then you must always ensure that you shut down the application server cleanly, with no outstanding transactions. If the application server does not shut down cleanly it performs *recovery* upon server restart and loads any required RAR files and native libraries. On

completion of recovery, do not attempt any application-related work. Shut down the server and restart it. No further recovery is attempted by the application server on this restart, and normal application processing can proceed.

Install RAR

Use this page to install a resource archive (RAR) file in one of two ways. You can either upload a RAR file from the local file system, or specify an existing RAR file on a server. The RAR file must be installed at the node level, and you can select the node on this page.

To view this page in the administrative console click **Resources** > **Resource Adapters** > **Resource Adapters** > **Install RAR**.

For information about installing a resource adapter, see the topic, Installing a resource adapter archive (RAR) file.

Scope

Specifies the scope of the resource adapter. Only applications that are installed within this scope can use this adapter.

Local file system

Specifies the path of a RAR that resides on the same server as the console.

Information	Value
Data type	String

Remote file system

Specifies the path of a RAR that resides on one of the nodes of the cell.

Information	Value
Data type	String

Deploying SQLJ applications

Use Structured Query Language in Java (SQLJ) to develop data access applications that connect to DB2 databases. SQLJ is a set of programming extensions that enable you to use the Java programming language to embed statements that provide SQL (Structured Query Language) database requests.

About this task

The advantages of developing applications with SQLJ include improved performance and a shorter, more efficient development cycle. You can achieve the following with SQL:

- Improve performance by using static SQL statements.
- Reduce the development cycle:
  - Write less code with the simpler SQLJ syntax, which reduces the number of lines of code that is required to execute statements, set parameters, and retrieve parameters.
  - Detect programming errors earlier in the development phase with the online check function, which performs data type validation and schema validation. See the DB2 documentation for a complete list of customization options.

Consider using SQLJ in situations where dynamic SQL is not needed, and where applications use DB2 as the database server.

The application server includes enhanced SQLJ support for applications that use container-managed persistence (CMP). The enhanced support includes the following items: include:

- Deploying CMP beans during the application installation in the application server.

- Customizing and binding SQLJ profiles with the administrative console or scripting.
- Customizing and binding SQLJ applications again without needing to reinstall the application.

These enhancements reduce the complexity of installing, deploying, and customizing SQLJ applications for both container-managed and bean-managed persistence.

Procedure

1. Acquire the required drivers to deploy an SQLJ application in the application server. You need the following files, depending on the JDBC provider that you use:

JDBC provider type	Required files
DB2 Using IBM JCC Driver This driver is also known as: • IBM Data Server Driver for JDBC and SQLJ • IBM DB2 Driver for JDBC and SQLJ • IBM DB2 Universal JDBC Driver.	db2jcc.jar or db2jcc4.jar
DB2 Universal JDBC driver (deprecated)	db2jcc.jar

2. Deploy the SQLJ application.
   - Deploy applications that use container-managed persistence (CMP):
     - "Deploying SQLJ applications that use container-managed persistence (CMP)" with the DB2 Using IBM JCC Driver.
     - "Deploying SQLJ applications that use container-managed persistence (CMP) with the ejbdeploy tool" on page 2054.
   - "Deploying SQLJ applications that use bean-managed persistence, servlets, or sessions beans" on page 2056.
   - "Using embedded SQLJ with the DB2 for z/OS Legacy driver" on page 2066 (deprecated).
3. Customize and bind the SQLJ profiles. Before the application server can use an SQLJ application, the SQLJ statements must be processed for the database server. By default, four DB2 packages are created in the database; one package is created for each isolation level. The customization process augments the profiles with information that is specific to the database. If you do not customize the SQLJ profiles, the SQLJ application uses dynamic SQL like a JDBC application.
   - "Customizing and binding profiles for Structured Query Language in Java (SQLJ) applications" on page 2057.
   - Customize and bind SQLJ profiles with the wsadmin scripting tool. See the topic, Customizing and binding SQLJ profiles with the wsadmin tool.
   - "Customizing and binding SQLJ profiles with the db2sqljcustomize tool" on page 2060.

Deploying SQLJ applications that use container-managed persistence (CMP)

Embed Structured Query Language in Java (SQLJ) statements in your applications to maximize the efficiency of transactions with your databases. Before your applications can take advantage of SQLJ, you must deploy the application and customize the SQLJ profiles that are created. The application server provides functionality to use SQLJ as the persistence mechanism for enterprise beans that use container-managed persistence. Deploy the CMP beans in the application server to enable SQLJ support.

Before you begin

You need an application that uses SQLJ and container-managed persistence. Develop this application in Rational Application Developer or another development tool.

About this task

Deploy SQLJ applications in the application server to simplify the process of SQLJ translation and bean deployment. The application server includes these new features for SQLJ support:

- Deploying CMP beans during the application installation in the application server.
- Customizing and binding SQLJ profiles with the administrative console or scripting.
- Customizing and binding SQLJ applications again without needing to reinstall the application.

You can also deploy the SQLJ application using the ejbdeploytool. Read the topic on deploying SQLJ applications that use container-managed persistence (CMP) with the ejbdeploy tool for more information.

Procedure

1. Create a top-down mapping to a DB2 database.
2. From your DB2 installation, copy the `sqlj.zip` file to a directory on your workstation.
3. Deploy the EAR file in the administrative console.
   a. Click **Applications** > **Install New application**.
   b. Select **Local file system** or **Remote file system**, and browse to the EAR file.
   c. Select **Detailed - Show all installation options and parameters**. Click **Next**.
   d. In **Step 1: Select installation options**, select **Deploy enterprise beans**. Configure any other options, and click **Next**.
   e. In **Step 3: Provide options to perform the EJB deploy**, select **SQLJ** for **Deploy EJB option - Database access type**.
   f. Enter the location of the `sqlj.zip` file in the **SQLj class path** field.
   g. Complete the installation process for the application.

What to do next

After the enterprise application is deployed, customize the SQLJ profiles using the administrative console, scripting, or the db2sqljcustomize tool:

- For administrative console support, read the topic on customizing and binding profiles for Structured Query Language in Java (SQLJ) applications.
- For scripting support, read the topic on the application management command group for the AdminTask object.
- For use of the db2sqljcustomize tool, read the topic on customizing and binding SQLJ profiles with the db2sqljcustomize tool.

Deploying SQLJ applications that use container-managed persistence (CMP) with the ejbdeploy tool

Embed Structured Query Language in Java (SQLJ) statements in your applications to maximize the efficiency of transactions with your databases. Before your applications can take advantage of SQLJ, you must deploy the application and customize the SQLJ profiles that are created. The application server provides functionality to use SQLJ as the persistence mechanism for enterprise beans that use container-managed persistence. Use the ejbdeploy tool to deploy the application.

About this task

You can deploy SQLJ applications with the ejbdeploy tool to deploy the enterprise application in a stand-alone environment.

Alternatively, the application server includes enhanced SQLJ support for applications that use container-managed persistence (CMP). The new features include:

- Deploying CMP beans during the application installation in the application server.

- Customizing and binding SQLJ profiles with the administrative console or scripting.
- Customizing and binding SQLJ applications again without needing to reinstall the application.

These enhancements reduce the complexity of installing, deploying, and customizing SQLJ applications for both container-managed and bean-managed persistence.Read the topic on deploying SQLJ applications that use container-managed persistence (CMP) for more information.

Procedure

1. Create a top-down mapping to a DB2 database.
2. From your DB2 installation, copy the `sqlj.zip` file to a directory on your workstation.
3. Modify the Java build path of your enterprise bean JAR project to include the `sqlj.zip` file.
4. Use Rational Application Developer or the DB2 SQLJ translator to automatically translate SQLJ.
   - Use Rational Application Developer:
     a. From the Project Navigator, click ***EJB_JAR_PROJECT_NAME*** > ***SOURCE_FOLDER*** > **META-INF** > **backends** > ***database_version***.
     b. Open Map.mapxmi in the Mapping editor.
     c. On the **Overview** panel, highlight the name of your JAR project in the Enterprise Beans column. You must highlight the name of the JAR project, not the name of one of the enterprise beans that is listed.
     d. On the **Properties** panel, expand **SQLJ**.
     e. Set **Is using SQLJ?** to `True`.
     f. Set **Translator Module** to the fully qualified path of the sqlj.zip file on your workstation.
     g. Save the Map.mapxmi file.
     h. Export the enterprise archive (EAR) file.
   - Use the DB2 SQLJ translator. This tool creates a .java version of your .sqlj file and a serialized profile, with a .ser extension, that is used later in processing. Refer to the DB2 documentation for more information on the SQLJ translator tool.
5. Deploy the EAR file with the ejbdeploy tool.
   a. Verify that the app_server_root/bin directory is in your class path.
   b. Run the ejbdeploy command utility with the `-sqlj` option. The ejbdeploy command will generate an EAR file with the name you specify and an Ant script with the name *application_name*.ear.xml.

      For example: :

      ```
      ejbdeploy d:\application_name.ear
                working d:\deployed_application_name.ear
                -sqlj
                -dbvendor DB2UDB_V81
                -cp "C:\PROGRA~1\IBM\SQLLIB\java\sqlj.zip"
      ```

      Note: Supply the location of the SQLJ translator sqlj.zip file with -cp, which is the class path option The ejbdeploy command does not access `sqlj.zip` from your system class path.
6. Choose the option for customization.
   - Use the application server's SQLJ support. Install the deployed application to customize the SQLJ profiles with the application server or scripting.
     a. Install the enterprise application in the application server.

        Note: Do not select **Deploy enterprise beans** during the application installation process in the administrative console. If you redeploy the enterprise beans from the administrative console, you will lose the customization changes that you have made.
     b. Customize the SQLJ profiles.
        – For administrative console support, read the topic on customizing and binding profiles for Structured Query Language in Java (SQLJ) applications.

  - For scripting support, read the topic on the application management command group for the AdminTask object.
- Customize and bind the SQLJ profiles with the db2sqljcustomize tool. Read the topic on customizing and binding SQLJ profiles with the db2sqljcustomize tool.

Deploying SQLJ applications that use bean-managed persistence, servlets, or sessions beans

You can embed Structured Query Language in Java (SQLJ) statements in your applications to maximize the efficiency of transactions with your databases. Before your applications can take advantage of SQLJ, deploy the application and customize the created SQLJ profiles. You can use Rational Application Developer or the DB2 SQLJ translator to translate the application before deploying it on the application server.

Before you begin

Create an SQLJ application using Rational Application Developer or another development tool.

About this task

To deploy SQLJ applications that do not use container-managed persistence, translate the SQLJ application first to configure it for the application server environment. After translation, customize the SQLJ profiles in the application server, with scripting, or with the db2sqljcustomizer tool.

SQLJ support for applications that use bean-managed persistence include these features:

- Customizing and binding SQLJ profiles with the administrative console or scripting.
- Customizing and binding SQLJ applications again without reinstalling the application.

Procedure

1. Optional: Create a backup copy of your .java file. For example if your file is called `MyServlet.java`, copy `MyServlet.java` to `MyServlet.java.bkup`.
2. Optional: Rename your .java file to a file name with an `.sqlj` extension. For example, if your application is a servlet named `MyServlet.java`, rename `MyServlet.java` to `MyServlet.sqlj`
3. Optional: Edit the SQLJ file to convert the JDBC syntax to SQLJ syntax. When using SQLJ, if you want connection management for the application server to function properly, specify correct connection contexts.

   For example, convert the following JDBC operation:

   ```
   Connection con = dataSource.getConnection();
   Statement stmt = con.createStatement();
   stmt.execute("INSERT INTO users VALUES (1, 'user1')");
   con.commit();
   ```

   to the following SQLJ:

   ```
   // At the top of the file and just below the import statements, define Connection_Context
   #sql context Connection_context;
   .
   .
   Connection con = dataSource.getConnection();
   .
   .
   Connection_context ctx1 = new Connection_context(con);
   .
   .
   #sql [ctx1] {INSERT INTO users VALUES (1, 'user1')};
   .
   .
   con.commit(); ctx1.close();
   ```

When you run the SQLJ translator, the `.java` file that is created has the same name as your old `.java` file. This provides you with a seamless transition to the SQLJ technology.

4. From your DB2 installation, copy the `sqlj.zip` file to a directory on your workstation. Modify the Java build path of your enterprise bean Java archive (JAR) file project to include the `sqlj.zip` file.
5. Use Rational Application Developer or the DB2 SQLJ translator to automatically translate SQLJ.
   - Use Rational Application Developer:
     a. In the Project Navigator, right-click your JAR project, and select **Add SQLJ Support...**.
     b. Select the check boxes for the applications for which you want SQLJ support.
     c. In the **SQLJ JAR file** field, type the fully qualified path to the `sqlj.zip` file that you previously copied to your workstation.
     d. Click **Finish**.
     e. Export the enterprise archive (EAR) file.
   - Use the DB2 SQLJ translator. This tool creates a `.java` version of the `.sqlj` file and a serialized profile, with an `.ser` extension, that is used later in processing. Refer to the DB2 documentation for more information about the SQLJ translator tool.
6. Package your JAR file for the enterprise application.
7. Install the application onto the application server, or customize the profiles with the db2sqljcustomize tool.
   - Customize the profiles with the application server.
     a. Package the JAR file for your enterprise beans, servlets, and any `.ser` files into an enterprise archive.
     b. Install the application in the application server, and customize SQLJ profiles with the administrative console or the wsadmin tool.

        Note: Do not select **Deploy enterprise beans** during the application installation process in the administrative console. If you redeploy the enterprise beans from the administrative console, you lose the customization changes that you have made.

        The application server provides enhanced support for SQLJ applications. Install the SQLJ application in the application server, and you can customize and bind SQLJ profiles through the administrative console or scripting:
        – To customize the SQLJ profiles with the administrative console, read the topic about customizing and binding profiles for Structured Query Language in Java (SQLJ) applications.
        – To customize SQLJ profiles with scripting, read the topic about the application management command group for the AdminTask object.
   - To use the db2sqljcustomize tool, read the topic about customizing and binding SQLJ profiles with the db2sqljcustomize tool for more information.

Customizing and binding profiles for Structured Query Language in Java (SQLJ) applications

Simplify the process of customizing and binding SQLJ profiles for your applications by performing these functions in the administrative console or with scripting. SQLJ profiles must be customized and bound before the enterprise application can use the application's embedded SQL.

Before you begin

You must have an SQLJ application that has already been deployed and installed in the application server.

For SQLJ applications that use container-managed persistence, you can deploy the application in two ways:

- Deploy the SQLJ application in the application server. See the topic on deploying SQLJ applications that use container-managed persistence (CMP) for more information.

- Deploy SQLJ applications with the ejbdeploy tool. See the topic on deploying SQLJ applications that use container-managed persistence (CMP) with the ejbdeploy tool.

For SQLJ application that use bean-managed persistence, see the topic on deploying SQLJ applications that use bean-managed persistence, servlets, or session beans.

About this task

To take advantage of SQLJ applications in the application server, you need to customizing the SQLJ profiles that contain the embedded SQL statements. By default, four DB2 packages are created in the database; one for each isolation level. The customization process augments the profiles with information that is specific to the DB2 database. The database uses this information at run time.

In addition to profile customization, you need to bind the customized profiles to the DB2 database. Profile binding should only take place after the SQLJ profiles are customized.

You can also customize and bind profiles with scripting or the db2sqljcustomize tool:

- For scripting support, read the topic on the application management command group for the AdminTask object.
- For information on the db2sqljcustomize tool, read the topic on customizing and binding SQLJ profiles with the db2sqljcustomize tool for more information. If you customize profiles with the db2sqljcustomize tool, you will need to reinstall the application.

Procedure

1. Make sure the necessary database tables exist, as described in the topic on deploying data access applications.
2. Navigate to the SQLJ application that is installed in the application server. Click **Applications** > **Websphere enterprise applications** > ***app_name***.

   Note: Do not run multiple sessions of the administrative console to customize and bind profiles that are in the same EAR file.
3. Navigate to the SQLJ profiles section. Click **SQLj profiles**. When you click this link, the application server expands the EAR file for the application into a temporary directory; there might be a delay before the panel for SQLJ profiles is displayed.
4. Select **Customize and bind profiles** or **Bind packages**. Choose your option based on the profiles with which you are working:
   - If your profiles have not been customized, or you want to customize the profiles again, choose **Customize and bind profiles**.
   - If the profiles are already customized, choose **Bind packages**.
5. Choose to select profiles or a profile group to customize and bind.
   - Select profiles from the list that is provided.
     a. Select the profiles from the list and click **Add**. The list displays the SQLJ profiles that are present in the enterprise application.

        Note:
        – Select more than one profile by holding CTRL.
        – Select a contiguous list of profiles by selecting the first profile name, holding SHIFT, and selecting the last profile. You will select the first profile, last profile, and any profiles in the middle.

     b. Select **Customize/bind the selected SQLj profiles as a group** This option specifies that the application server will create a .grp file that contains the SQLj profiles that are processed. You can use the .grp file for other binding operations in the future. After you have completed this panel and click **OK**, you will be given an option to download the .grp file.

- Select **Use a profile group file to specify profiles to customize/bind**. Select this to specify a profile group to process. Click **Browse...** to locate the file on the system.

6. Complete the necessary information to connect to the database. You need to complete the following fields:

   Database URL
   Specifies the URL of the database to which the profile/s will be bound. The typical syntax is:
   `jdbc:db2://<host name="">:<port>/<database name="">.</database></port></host> or`

   or
   fully_qualified_host_name:*port*

   User Specifies the user ID for the database administrator on the server where the database is located.

   Password
   Specifies the password for the database administrator on the server where the database is located.

   Additional options
   Specifies additional options to use during the customization and bind processes. See the DB2 documentation for a complete list of customization options.

   Class path
   Specifies the class path where sqlj.zip, and db2jcc.jar or db2jcc4.jar are located.

7. Click **OK**.

   Note: If you are processing a large enterprise application, or you are processing many SQLJ profiles, the process might take longer than the default timeout for the administrative console. The default connection timeout for the application server's administrative console is set to 30 minutes. If the default timeout is reached and you lose the connection to the server, you can check the system output log for the final results of the customization and bind process.

   To prevent this disconnection, configure the console session timeout to a longer period of time. After a successful customization and binding process, check the system output log for the total processing time. Use that time period as a basis for the new timeout value. For information about how to configure the console timeout, see the topic on changing the console session expiration.

Results

After the application server finishes processing the SQLJ profiles, you will see the results from the customization and binding. The results panel displays messages from the database server, as well as summary results from the application server.

If the operation completed successfully, the following message will be printed to the system log:

```
ADMA0507I=ADMA0507I: The SQLJ operation on application {0} completed successfully.  Exit code: {1}
ADMA0507I.explanation=This informational message indicates the program status.
ADMA0507I.useraction=No user action is required.
```

If the operation did not complete successfully, the following message will be printed to the system out log:

```
ADMA0506I=ADMA0506I: The SQLJ operation on application {0} did not complete successfully.  Exit code: {1}
ADMA0506I.explanation=The SQLJ operation encountered a problem.  This informational message indicates
the program status. Prior messages in the command output give details of the problem.
ADMA0506I.useraction=Check the command output for the cause of the problem.
```

Customizing and binding SQLJ profiles with the db2sqljcustomize tool

Customize and bind SQLJ profiles with the db2sqljcustomize tool before you install the SQLJ application in the application server.

Before you begin

To perform this task, you must have SQLJ application that has been deployed, but the application should not be installed in the application server. If the application is already installed in the application server, you will need to reinstall the application after you customize the profiles. You also need serialized profiles for the SQLJ application.

For SQLJ applications that use container-managed persistence, you can deploy the application in two ways:

- Deploy the SQLJ application in the application server. See the topic on deploying SQLJ applications that use container-managed persistence (CMP) for more information.
- Deploy SQLJ applications with the ejbdeploy tool. See the topic on deploying SQLJ applications that use container-managed persistence (CMP) with the ejbdeploy tool.

For SQLJ application that use bean-managed persistence, see the topic on deploying SQLJ applications that use bean-managed persistence, servlets, or sessions beans.

About this task

To take advantage of SQLJ applications in the application server, you need to customize the SQLJ profiles. The customization process augments the profiles with information that is specific to the DB2 database. The database uses this information at run time. By default, four DB2 packages are created in the database; one package is created for each isolation level.

The application server supports customizing and binding the SQLJ profiles in the administrative console or with scripting:

- For administrative console support, read the topic on customizing and binding profiles for Structured Query Language in Java (SQLJ) applications.
- For scripting support, see the topic on the application management command group for the AdminTask object.

Procedure

1. Make sure the necessary database tables exist, as described in the topic on deploying data access applications.
2. Transfer the serialized profiles to the environment on which you installed your application. Alternatively, use the Java `jar` command to extract the serialized profiles from the JAR file in your installed EAR directory.
3. Add the location for the SQLJ profiles and the application's JAR file to your environment's class path.
4. Make sure the necessary database tables exist, as described in the topic on deploying data access applications.
5. Optional: If your application is not running in a clustered environment, you can use the Ant script to make customization easier. If you run a batch SQLJ customization against an EAR file with the ejbdeploy tool, the tool produces an Ant script that is named *application_name*.ear.xml. You can use this script file to run the DB2 customizer program against the serialized profiles in all of the enterprise bean JAR files for the associated EAR file. The script updates each enterprise bean's JAR file with a serialized profile and replaces the JAR files in the existing EAR file with the modified versions.
   a. Change the values of the database URL, and the database user and password properties in ejbdeploy.sqlj.properties. This file is a common file to all Ant scripts that are generated by the ejbdeploy command. The ejbdeploy.sqlj.properties script defines the global properties for:
      - Database URL - db.url

- User - db.user
- Password - db.password

The Ant script uses the URL, user, and password properties in the serialized profile to customize the profile. By default, the properties for the serialized profile are created from the global properties.

b. Run the Ant script, specifying the `properties` target. For example:

```
ws_ant -buildfile application_name.ear.xml properties
```

This script creates the properties file, *application_name*.ear.properties. The *application_name*.ear.properties file contains properties that specify the default names for the packages corresponding to each serialized profile in the EAR file. This is a sample properties file:

```
url.MyEJB1.jar.DB2UDBNT_V8_1=jdbc:db2://localhost:50000/MyDB1
user.MyEJB1.jar.DB2UDBNT_V8_1=dbuser
password.MyEJB1.jar.DB2UDBNT_V8_1=dbpassword
pkg.MyEJB1.jar.DB2UDBNT_V8_1=TEST
url.MyEJB2.jar.DB2UDBNT_V8_1=jdbc:db2://localhost:50000/MyDB2
user.MyEJB2.jar.DB2UDBNT_V8_1=dbuser
password.MyEJB2.jar.DB2UDBNT_V8_1=dbpassword
pkg.MyEJB2.jar.DB2UDBNT_V8_1=WORK
```

c. Use the DB2 Control Center to identify the packages that are installed in the database. The DB2 SQLJ customizer requires a type 4 database URL in the form of:

```
jdbc:db2://host-name:port/database-name
```

It also requires a user and password. The value of the port is 50000, unless you change it when you install DB2.

d. Change the names that are used by the script file to ensure that the names for each customization profile do not conflict with existing package names that are in the database. Ant scripts that are generated for different EAR files use the same package names by default, and the script will overwrite existing packages unless you change the names. Overwritten packages can cause errors at run time.

DB2 uses the first seven characters of the package name. The DB2 customizer uses this name to create four packages in the database. For example, if you specify the name TEST, the DB2 customizer will create packages called TEST1, TEST2, TEST3, and TEST4.

e. Run the Ant script. The Ant script updates the original EAR file with the modified serialized profiles.

Note: Verify that you have db2jcc.jar in the class path. This file should have been added to the class path environment variable when DB2 V8 FixPak1 was installed.

A sample Ant command looks like this:

```
ws_ant -Dwork.dir=tmp
       -Dscript.property.file=other.properties
       -buildfile application_name.ear.xml
```

where:

- `-buildfile` specifies the XML file to create.
- `-Dscript.property.file` specifies a different properties file. This parameter is optional. If you want your Ant script to use a another file instead of *application_name*.ear.properties, specify the Dscript.property.file property when you run the script.
- `-Dwork.dir` specifies a temporary working directory for the script. The script will create and delete files and subdirectories in this directory. If the working directory contains existing files and directories with the same name as the files and directories used by the script, the script will erase or overwrite the files and directories. This script creates and uses a directory called `tmp` as its working directory.

f. Proceed to installing the application in the application server..

6. Run the db2sqljcustomize tool to customize the SQLJ profiles that correspond to each enterprise bean's JAR file. When you generate your deployment code, serialized profiles (files with a .ser extension) that are specific to your application are created. These profiles exist in the same directory as your SQLJ files, and the files must be customized to the environment before they can be used. When you run the DB2 SQLJ customizer against the serialized profiles, you create static SQL in the database that DB2 will use at run time. The customization phase creates four database packages that contain static SQL, one for each isolation level.
   a. Optional: Consider using the SQLJ customizer tool to enable context caching for your application's data source connections. DB2 V8.1 fix pack 6 provides the new caching option with the db2sqljcustomize tool called db2optimize. You can run this option if your application uses the explicit connection context instead of the default context.

      Note:

      - SQLJ context caching support requires the DB2 with IBM JCC driver or Version 2.2 or later of the DB2 Universal JDBC Driver with APAR PQ87786 applied.
      - If you want to enable context caching for an application or BMP bean that caches connections across transaction boundaries, you cannot use shareable connections. Use the get/use/close pattern of connection usage when you invoke the db2optimize option, or an object closed exception occurs. The following code gives an example of incorrect connection usage for context caching:

        ```
        utx.begin();
             cons =ds.getConnection(
             request.getParameter("db.user"),
             request.getParameter("db.password"));
                 cmctx1 = new CM_context(cons);
                 #sql [cmctx1] {DELETE FROM cmtest WHERE id=1};
         utx.commit();
               //The next statement verifies the result:
                 #sql [cmctx1] cursor1 = {SELECT id, name FROM cmtest WHERE id=1};
        ```

        In this case, the `Select` statement elicits an object closed exception. To prevent the exception from occurring, close the connection before committing the transaction. Then get a new connection and a new context before running the `Select` statement.

      The following example code demonstrates proper syntax for running the option on the serialized profile:

      ```
      sqlj -db2optimize SQLJTransactionTest.sqlj
      db2sqljcustomize -url jdbc:db2://localhost:50000/dbname -user USER_NAME -password PASSWORD
      SQLJTransactionTest_SJProfile0.ser
      ```

   b. Run the db2sqljcustomize tool to customize the SQLJ profiles. After you successfully run the db2sqljcustomize command, customized profiles exist in the directory from which you issued the command. If you run the db2sqljcustomize command from the directory that contains the serialized profiles that were not customized, the customized versions will overwrite previous versions that have the same file names.

      The recommended syntax for running the db2sqljcustomize command is:

      ```
      db2sqljcustomize -url JDBC_URL -user USER_NAME  -password PASSWORD
      [-rootpkgname PACKAGE_NAME] SERIALIZED_PROFILE1 SERIALIZED_PROFILE2 ...
      ```

      where:

      - *JDBC_URL* is the JDBC URL that is used to access the DB2 system where your tables reside.
      - *USER_NAME* is a valid user name for the DB2 system where your tables reside.
      - *PASSWORD* is the password for the specified user name.
      - *PACKAGE_NAME* is a valid partitioned data set (PDS) member name, up to seven characters long. Each of the four packages that are created by the profile customizer begin with this name and are appended with a number from 1 to 4. If you customize only one serialized profile, this value defaults to a shortened version of the serialized profile name and the -rootpkgname

parameter is not required. If you customize more than one serialized profile with the same command, there is no default value and the -rootpkgname parameter is required.

- *SERIALIZED_PROFILE#* is the name of the serialized profile that you are customizing.
  - To customize more than one serialized profile with the same command, list multiple files, separated by spaces.
  - Alternatively, you can specify the `-rootpkgname` parameter to customize more than one serialized profile with the same command.

Note: The following options provide more control over the customization process:

- `-automaticbind yes` specifies to run the DB2 SQLJ customizer against the serialized profiles to create static SQL in the database that the database will use at run time. The customization phase creates four database packages that contain static SQL, one for each isolation level.
- `-onlinecheck NO and -bindoptions "VALIDATE RUN"` specifies settings to bypass errors during a profile customization and ensure a successful customization.

7. Update the JAR file for the enterprise beans with the serialized profiles.
8. Use the `jar` command to replace the serialized profiles in your JAR file with the customized profiles.

   Note: The customized files must be placed in a location that is part of the application class path, and they must exist ahead of the serialized profiles that are not customized in your JAR file. If you decide to replace the serialized profiles in your JAR file, maintain the directory structure in which the profiles exist.
9. Package the JAR file for the enterprise bean, servlets, and serialized profiles into an enterprise archive (EAR) file.
10. Install the application in the application server.

    Note: Do not select **Deploy enterprise beans** during the application installation process in the administrative console. If you redeploy the enterprise beans from the administrative console, you will lose the customization changes that you have made.

SQLJ profiles and pureQuery bind files settings

Use this page to do customization and binding for the Structured Query Language in Java (SQLJ) profiles for DB2 that are included in this application. You can also use this page to do binding for pureQuery bind files in the application. You can view SQLJ profiles for other database types, but you cannot change these profiles. PureQuery bind files are only valid for DB2. Use SQLJ or pureQuery to develop data access applications that connect to DB2 databases. SQLJ is a set of programming extensions that enable a programmer to use the Java programming language to embed statements that provide SQL database requests. PureQuery provides an alternate set of APIs that can be used instead of JDBC to access the DB2 database.

To view this administrative console page, click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name*** > **SQLJ profiles and pureQuery bind files**.

Advantages of developing applications with SQLJ include improved performance and a shorter, more efficient development cycle. With SQLJ, you can:

- Improve performance by using static SQL statements.
- Reduce the development cycle by:
  - Writing less code with the simpler SQLJ syntax, which reduces the amount of code that is required to execute statements, and set and retrieve parameters.
  - Detecting programming errors earlier in the development phase with the online check function, which performs data type and schema validation. Activate this function by running it as an option with the **db2sqljcustomize** command. See the DB2 documentation for a complete description of the SQLJ customize command.

DB2 pureQuery run time is an alternative set of APIs to JDBC or SQLJ. Advantages of developing applications with pureQuery include allowing SQL execution to be either dynamic or static. In addition to improved performance by using static SQL statements, pureQuery has better problem determination and diagnosis because it allows for errors at the DB2 server to be related back to application artifacts rather than to SQL that was generated by an application generator.

Customize and bind profiles:

Specifies that the application server processes the SQLJ profiles that you select from this application.

Note: This selection does not apply to pureQuery. If selected, this option is ignored when processing pureQuery bind files.

By default, one DB2 package is created in the database for each isolation level. The customization process augments the profile or profiles with information that is specific for the DB2 database for use at run time. Typically, the customization process should run after the SQLJ application has been translated and before the application is started. If you do not run the customization step, the SQLJ application uses dynamic SQL like a JDBC application.

Binding DB2 SQLJ profiles involves the process of binding the customized SQLJ profiles to the DB2 database.

Bind packages:

Specifies that the application server binds the SQLJ profiles that you select to the DB2 database server.

Note: This selection does not apply to pureQuery. If selected, this option is ignored when processing pureQuery bind files.

Bind packages from the SQLJ application that have already been customized.

Select and order the profiles to customize/bind:

Specifies the profiles to process from the list that is provided.

- Select a profile or group of profiles from the **Available profiles**, and click **Add** to add the profile that is selected to **Selected Profiles**.
- Select a profile or group of profiles from the **Selected Profiles**, and click **Remove** to add the profile that is selected to **Available profiles**.

When SQLJ or pureQuery profiles have been added to **Selected Profiles**, select profiles from that list and use **Move Up** or **Move Down** to change the order in which the profiles are processed.

Customize/bind the selected SQLJ profiles as a group:

Specifies that the application server creates a .grp file that contains the SQLJ profiles that you selected.

Note: This selection does not apply to pureQuery. If selected, this option is ignored when processing pureQuery bind files.

When you click **OK**, there is an option on the next page to download the `.grp` file.

Use a profile group file to specify profiles to customize/bind:

Specifies a profile group file from the local file system to customize or bind.

Database URL:

Specifies the URL of the database to which the profile or profiles are bound.

The typical syntax is:
`jdbc:db2://host_name:port_name/database_name`

User:

Specifies the user ID for the database administrator on the server where the database is located.

Password:

Specifies the password for the database administrator on the server where the database is located.

Additional options:

Specifies additional options to use during the customization and bind processes.

Options for pureQuery binding uses the following syntax:
`-bindoptions "BLOCKING NO"`

For more information about pureQuery bind options, refer to the DB2 pureQuery Bind Utility topic.

Class path:

Specifies the class path where the `sqlj.zip`, and `db2jcc.jar` or `db2jcc4.jar` files for SQLJ are located. Specifies the class path where the `pdq.jar`, `pdqmgt.jar`, `db2jcc.jar`, and `db2jcc_license_cisuz.jar` files for pureQuery are located.

Download SQLJ profile group

Use this panel to download the group file for the Structured Query Language in Java (SQLJ) profiles that are bound together as a single package on the DB2 database server. You can use the file when performing future customization or binding work on the application. Click the link that is provided to download the profile group to your local file system. The group file has a filename extension of .grp and a HTTP Content-Type of text/plain.. Your web browser settings might cause the browser to display the file contents rather than prompting you for a download destination. If this happens, you can manually copy and paste the contents into your own .grp file.

Note: This topic does not apply to IBM Optim PureQuery Runtime. IBM Optim PureQuery Runtime does not support binding pureQuery bind files as a group.

Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***app_name*** > **SQLJ profiles and pureQuery bind files**. When you are selecting the profiles to customize and bind, select **Customize/bind the selected SQLJ profiles as a group** to view this console panel.

Review results

Use this panel to review the results from the customization and binding process for the Structured Query Language in Java (SQLJ) profiles or pureQuery bind files. Use SQLJ or IBM Optim PureQuery Runtime to develop data access applications that connect to DB2 databases. SQLJ is a set of programming extensions that enable a programmer to use the Java programming language to embed statements that provide SQL (Structured Query Language) database requests. IBM Optim PureQuery Runtime provides an alternate set of APIs that can be used instead of JDBC to access the DB2 database.

Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name*** > **SQLj profiles and pureQuery bind**. Select profiles to customize and bind, complete the necessary fields, and click **OK** to view this console panel.

Review results:

Displays the results of the customization and bind process. The field shows information that is received from the database and summary statements from the application server.

Using embedded SQLJ with the DB2 for z/OS Legacy driver

Structured Query Language in Java (SQLJ) is a set of programming extensions that enable a programmer, using the Java programming language, to embed statements that provide Structured Query Language (SQL) database requests. You can use the DB2 for z/OS Legacy driver with your data access applications.

About this task

Notes:

1. To use SQLJ with WebSphere Application Server for z/OS and the DB2 for z/OS Legacy Driver, install DB2 APAR PQ76442.
2. Container Managed Persistence (CMP) beans generated using SQLJ are not supported by the DB2 for z/OS Legacy Driver. Use the DB2 Universal Driver for CMPs that are generated using SQLJ.

Following are the steps required to develop applications with SQLJ that run on WebSphere Application Server for z/OS v6.0 using the DB2 for z/OS Legacy driver.

Procedure

1. Design your application in Rational Application Developer according to your requirements, using SQLJ when necessary. For example, if you develop a bean called Test that uses BMP, code TestBean.sqlj (instead of TestBean.java).
   a. From your DB2 for z/OS installation, copy the `db2sqljclasses.zip` file to a directory on your workstation, then modify the Java Build Path of your EJB Java archive (JAR) project to include the `db2sqljclasses.zip` file.
   b. Translate your SQLJ code according to the following steps:
      1) Locate your SQLJ file, then use ASCII mode transfer to FTP it to an HFS in your z/OS environment.
      2) Use the sqlj command to translate your SQLJ code into Java code. Two files are produced, one with a `.java` extension and the other with an `.ser` extension.

         ```
         sqlj -compile=false SQLJ_FILE_NAME
         ```

      3) Use ASCII mode transfer for the `.java` file and BINARY mode transfer for the `.ser` file to move these files back to the directory on your workstation where the SQLJ file resides.
      4) Refresh the project.
   c. Generate deployment code for your application.
   d. Export your EAR file.
2. Install your application
   a. Create a data source with the DB2 for zOS Local JDBC Provider (RRS). When you define your JDBC Provider and data source, the default values are sufficient for providing SQLJ support.
   b. Install your application into WebSphere Application Server.

      Use the data source you created in Step 1 to resolve your resource references.
3. Customize your serialized profiles When you generate your deployment code, serialized profiles, or files with an `.ser` extension, that are specific to your application, are created. These profiles must be customized in a z/OS environment before they can be used.
   a. Use binary transfer to transfer the serialized profiles to the z/OS environment on which you installed your application. Alternatively, use the Java jar command to extract the serialized profiles from the EJB JAR file in your installed EAR directory.

b. Use the db2profc command to customize your serialized profiles. You can get information about the various options associated with this command from the DB2 documentation; however, here are the minimum requirements to customize your profile:

   ```
   db2profc -pgmname=PROGRAM_NAME PROFILE_NAME
   ```

   - Where:
     - *PROGRAM_NAME* must be a valid MVS PDS member name, and can be up to seven characters.
     - *PROFILE_NAME* is the name of the serialized profile that you want to customize. You must run db2profc one time for each profile.
   - The profile customizer creates four DBRM data sets in the PDS *USERNAME*.DBRMLIB.DATA. The member names of the DBRMs begin with what you specified as *PROGRAM_NAME*.
   - Ensure that your CLASSPATH environment variable includes:
     - The location of the serialized profile
     - The EJB JAR file in your installed EAR directory
   - Allocate a PDS to contain the DBRMs that are created. Name this PDS *USERNAME*.DBRMLIB.DATA, where *USERNAME* is the user who implements the db2profc command.

     The following fields are an example:

     ```
     Space units=TRACK
     Primary quantity=15
     Secondary quantity=5
     Directory blocks=10
     Record format=FB
     Record length=80
     Block size=27920
     Data set name type=PDS
     ```

c. Place the existing serialized profiles, which are now customized, into a location that is part of the application classpath and that is ahead of the serialized profiles that exist in your EJB JAR file.

   The output of the DB2 profile customizer and the input file have the same name. Move the output file ahead of the original serialized profile in the classpath. Alternatively, you can move the customized profile into the EJB JAR file, replacing the original. It is recommended that you replace the original file.

   IMPORTANT: If you run the db2profc command from the directory where the serialized profile exists, the profile customizer overwrites the serialized profile. Because you need only the customized version after the profile customizer has run, this is not a problem.

d. Bind your DBRMs into a package.

   Note: You must create your database tables before binding your DBRMs. If you do not, the bind job fails.

   The db2profc customization command creates a series of DBRMs that must be bound into packages. For each customized profile, four DBRMs are created.

   These DBRMs:

   - Are located in *USERNAME*.DBRMLIB.DATA
   - All have names that begin with what you specified as *PROGRAM_NAME*
   - Are numbered from 1-through-4

     For example, if you log in as IBMUSER, and you specify -pgmname=TESTBMP, then run the db2profc command, the four data sets, TESTBMP1, TESTBMP2, TESTBMP3, AND TESTBMP4 are created and placed in the PDS IBMUSER.DBRMLIB.DATA.

     These data sets must be bound into packages with isolation of UR, CS, RS, and RR. You must run a bind for each serialized profile that you customize.

e. After you bind all of the DBRMs into packages, bind the packages into a plan. Name the plan whatever you like.

IMPORTANT: You must also include the JDBC packages in the package list (PKLIST) of your new plan. The default names for the JDBC packages to include are DSNJDBC.DSNJDBC1, ..., DSNJDBC.DSNJDBC4. If your installation did not use the default names for the JDBC packages, contact your DB2 administrator to determine the names of the JDBC packages that you need to include.

Following is a sample job used to bind a new plan.

- One serialized profile was created while logged on as IBMUSER.
- **-pgmname=TESTBMP** was specified to run db2profc.
- The new plan is named SQLJPLAN.

```
//BBOOLS  JOB (516B,1025),'IBMUSER',MSGCLASS=H,CLASS=A,PRTY=14,
//         NOTIFY=&SYSUID,TIME=1440,USER=IBMUSER,PASSWORD=IBMUSER,
//         MSGLEVEL=(1,1)
//*******************************************************************
//BINDOLS  EXEC PGM=IKJEFT01,DYNAMNBR=20
//DBRMLIB  DD  DSN=IBMUSER.DBRMLIB.DATA,DISP=SHR
//*        DD  DSN=MVSDSOM.DB2710.SDSNDBRM,DISP=SHR
//SYSTSPRT DD  SYSOUT=*
//SYSPRINT DD  SYSOUT=*
//SYSUDUMP DD  SYSOUT=*
//SYSTSIN  DD  *

 DSN SYSTEM(DB2)

 BIND -
     PACKAGE(TESTBMP) -
     QUALIFIER(IBMUSER) -
     MEMBER(TESTBMP1) -
     VALIDATE(BIND) -
     ISOLATION(UR) -
     SQLERROR(NOPACKAGE) -

  PKLIST(TESTBMP.*                  -
         DSNJDBC.*                ) -
  ACTION(REPLACE) RETAIN            -
```

```
  VALIDATE(BIND)

END
/*
```

f. Grant the appropriate authority to your new plan. Use an interface to DB2, such as SPUFI, to grant the authority. Issue this command:

```
GRANT EXECUTE ON PLAN PLANNAME TO APPSERVERID
```

Where:

- *PLANNAME* is the name of the plan that you bound.
- *APPSERVERID* is the ID under which WebSphere Application Server runs; for example, CBSYMSR1.

4. Configure your data source to use your new plan
   a. From the WebSphere Application Server for z/OS Administrative Console, navigate to your Data Source and select Custom Properties.
   b. Select the Custom Property **planName**.
   c. Update the value of **planName** with what you named your plan when it was bound.
   d. Set **enableSQLJ** to **true**.
5. Stop and restart your server.
6. Run your application.

Directory conventions

References in product information to *app_server_root*, *profile_root*, and other directories imply specific default directory locations. This article describes the conventions in use for WebSphere Application Server.

Default product locations - z/OS

app_server_root
: Refers to the top directory for a WebSphere Application Server node.

  The node may be of any type—application server, deployment manager, or unmanaged for example. Each node has its own *app_server_root*. Corresponding product variables are *was.install.root* and *WAS_HOME*.

  The default varies based on node type. Common defaults are *configuration_root*/AppServer and *configuration_root*/DeploymentManager.

configuration_root
: Refers to the mount point for the configuration file system (formerly, the configuration HFS) in WebSphere Application Server for z/OS.

  The *configuration_root* contains the various *app_server_root* directories and certain symbolic links associated with them. Each different node type under the *configuration_root* requires its own cataloged procedures under z/OS.

  The default is /wasv8config/*cell_name*/*node_name*.

plug-ins_root
: Refers to the installation root directory for Web Server Plug-ins.

profile_root
: Refers to the home directory for a particular instantiated WebSphere Application Server profile.

  Corresponding product variables are *server.root* and *user.install.root.*

  In general, this is the same as *app_server_root*/profiles/*profile_name*. On z/OS, this will always be *app_server_root*/profiles/default because only the profile name "default" is used in WebSphere Application Server for z/OS.

smpe_root

Refers to the root directory for product code installed with SMP/E or IBM Installation Manager.

The corresponding product variable is *smpe.install.root*.

The default is `/usr/lpp/zWebSphere/V8R5`.

Installing a resource adapter archive

The application server uses the classes and other code that comprise a resource adapter archive (RAR) to support the resource adapters that you configure.

Before you begin

A RAR file, which is often called a Java EE Connector Architecture (JCA) connector, must comply with the JCA Specification. You can meet these requirements by using a supported assembly tool to assemble a collection of Java archive (JAR) files, other runnable components, and utility classes into a deployable resource adapter archive (RAR). You can then install the RAR file in the application server.

When you are using optimized local adapters, set up your server environment in the daemon group before installing the `ola.rar` file in the application server. The `ola.rar` file is located in the `WAS_HOME/installableApps` directory.

You can also use the wsadmin scripting file, olaRar.py, to install the RAR file.

To read about setting up your server environment, see the topic, Enabling the server environment to use optimized local adapters. You can read about the `olaRar.py` script in the topic, olaRar.py scripting file.

About this task

A resource adapter archive provides the classes and other code to support a resource adapter for access to a specific EIS, such as the Customer Information Control System (CICS). Therefore, you can only configure resource adapters for an EIS after you install the appropriate RAR file.

Important: When you use the **Install RAR** dialog to install a RAR file, the scope you define on the Resource Adapters page has no effect on where the RAR file is installed. You can install RAR files only at the node level, which you specify on the Install RAR page. To set the scope of an RAR file to a specific cluster, or server, after you install the RAR file at each node level, create a copy of the RAR file with the appropriate cluster or server scope.

Procedure

1. Navigate to the **Resource adapter** panel. Click **Resources** > **Resource Adapters** > **Resource adapters**.
2. Install a new resource adapter archive.
   a. Click **Install RAR**. A dialog opens for installing a RAR file and configuring the associated resource adapter. Only click **New** if you want to configure a new resource adapter for a previously installed RAR file.
   b. Browse to find the appropriate RAR file.
      - If your RAR file is located on your local workstation, select **Local path**, and browse to find the file.
      - If your RAR file is located on your server, select **Remote file system**, and specify the fully qualified path to the file.
   c. Click **Next**.

3. Configure the resource adapter name and any other properties needed under *General Properties*. For more details on the settings that you can configure, such as the J2C connection factories, see the topics Installing resource adapters within applications and Configuring resource adapters.
4. Click **OK**.
5. Optional: Create a copy of the RAR file with a different scope level. After you install the RAR file at each node level, you can create another copy of the file that has a specific server or cluster as the scope for that file.

   Note:

   - If you do not create a copy of your RAR at the cluster scope, then you must create identical factories (connection factories, admin object, and activation specifications) at the node level for each of your nodes in the cluster. By creating the copy of your RAR, you provide a placeholder for your factories and circumvent the need to create identical factories at the node level for each of your nodes in the cluster.
   - You must still install the RAR binaries (files, such as jars and xml deployment files) on each node for the RAR to operate successfully.

   a. Click **Resources**.
   b. Click **Resource Adapters**.
   c. Select the scope level and then click **NEW**.
   d. Choose the RAR file from the installed archive path.
   e. Click **OK**.

Results

You have installed a resource adapter archive that provide access to the EIS when it is properly configured. If you must configure more settings, or change some settings that were configured during the installation process, refer to the topic on configuring a resource adapter in the administrative console for more information.

Installing resource adapters embedded within applications

Install resource adapters in your applications so they can access outside data sources.

Before you begin

The JCA Version 1.6 specification adds support for Java annotations in RAR modules. For more information on annotation support see the topic, JCA 1.6 support for annotations in RAR modules.

About this task

Procedure

1. Assemble an application with RAR modules in it. See the topic Assembling applications for more information.
2. Install the application. Follow the steps in the topic Installing a new application.

   In the **Map modules to servers** step, specify target servers or clusters for each RAR file. Be sure to map all other modules that use the resource adapters defined in the RAR modules to the same targets. Also, specify the web servers as targets that serve as routers for requests to this application. The plug-in configuration file (`plugin-cfg.xml`) for each web server is generated based on the applications that are routed through it.

   In the **Metadata for modules** step of installing an application, you can set or unset the metadata-complete flag as discussed in the topic, JCA 1.6 support for annotations in RAR modules.

Note: When installing a RAR file on a server, the application server looks for the manifest (MANIFEST.MF) for the connector module. The application server first looks for the RAR file's `connectorModule.jar` file and loads the manifest from the `connectorModule.jar` file. If the class path entry is in the manifest from the `connectorModule.jar`file, the RAR uses that class path.

To ensure that the installed connector module finds the classes and resources that it needs, check the Class path setting for the RAR using the administrative console. For more information on how to check this setting, see the topics Resource adapter settings and WebSphere relational resource adapter settings.

3. Click **Finish** > **Save** to save the changes.
4. Create connection factories for the newly installed application.

   See the topic, Configuring connection factories for resource adapters within applications to view the steps to complete this step.

Results

Note: A given native library can only be loaded one time for each instance of the Java virtual machine (JVM). Because each application has its own class loader, separate applications with embedded RAR files cannot both use the same native library. The second application receives an exception when it tries to load the library.

If any application deployed on the application server uses an embedded RAR file that includes native path elements, then you must always ensure that you shut down the application server cleanly, with no outstanding transactions. If the application server does not shut down cleanly it performs *recovery* upon server restart and loads any required RAR files and native libraries. On completion of recovery, do not attempt any application-related work. Shut down the server and restart it. No further recovery is attempted by the application server on this restart, and normal application processing can proceed.

Install RAR

Use this page to install a resource archive (RAR) file in one of two ways. You can either upload a RAR file from the local file system, or specify an existing RAR file on a server. The RAR file must be installed at the node level, and you can select the node on this page.

To view this page in the administrative console click **Resources** > **Resource Adapters** > **Resource Adapters** > **Install RAR**.

For information about installing a resource adapter, see the topic, Installing a resource adapter archive (RAR) file.

Scope

Specifies the scope of the resource adapter. Only applications that are installed within this scope can use this adapter.

Local file system

Specifies the path of a RAR that resides on the same server as the console.

Information	Value
Data type	String

Remote file system

Specifies the path of a RAR that resides on one of the nodes of the cell.

Information	Value
Data type	String

Chapter 42. Deploying EJB applications

This page provides a starting point for finding information about enterprise beans.

Based on the Enterprise JavaBeans (EJB) specification, enterprise beans are Java components that typically implement the business logic of Java Platform, Enterprise Edition (Java EE) applications as well as access data.

Deploying EJB 3.x enterprise beans

EJB module settings

Use this page to configure and manage a specific deployed EJB module.

Note: You cannot start or stop an individual EJB module for modification. You must start or stop the appropriate application entirely.

To view this administrative console page, click **Applications** > **Application Types** > **WebSphere enterprise applications** > **application_name** > **Manage Modules** > **module_name**.

Attention: If an application is running, changing an application setting causes the application to restart. On stand-alone servers, the application restarts after you save the change. On multiple-server products, the application restarts after you save the change and files synchronize on the node where the application is installed. To control when synchronization occurs on multiple-server products, deselect **Synchronize changes with nodes** on the Console preferences page.

URI

Specifies location of the module relative to the root of the application EAR file. The URI must match the URI of a ModuleRef URI in the deployment descriptor of the deployed application (EAR).

Alternate deployment descriptor

Specifies an alternate deployment descriptor for the module as defined in the application deployment descriptor according to the Java Platform, Enterprise Edition (Java EE) specification.

Starting weight

Specifies the order in which modules are started when the server starts. The module with the lowest starting weight is started first.

If the application deployment descriptor specifies the `<initialize-in-order>true</initialize-in-order>` element, the default starting weights reflect the order that is specified in the deployment descriptor. Otherwise, the defaults are determined based on module type (RAR modules start before EJB modules, which start before web modules).

Information	Value
Data type	Integer
Default	5000
Range	Greater than 0

Directory conventions

References in product information to *app_server_root*, *profile_root*, and other directories imply specific default directory locations. This article describes the conventions in use for WebSphere Application Server.

Default product locations - z/OS

app_server_root
Refers to the top directory for a WebSphere Application Server node.

The node may be of any type—application server, deployment manager, or unmanaged for example. Each node has its own *app_server_root*. Corresponding product variables are *was.install.root* and *WAS_HOME*.

The default varies based on node type. Common defaults are *configuration_root*/AppServer and *configuration_root*/DeploymentManager.

configuration_root
Refers to the mount point for the configuration file system (formerly, the configuration HFS) in WebSphere Application Server for z/OS.

The *configuration_root* contains the various *app_server_root* directories and certain symbolic links associated with them. Each different node type under the *configuration_root* requires its own cataloged procedures under z/OS.

The default is /wasv8config/*cell_name*/*node_name*.

plug-ins_root
Refers to the installation root directory for Web Server Plug-ins.

profile_root
Refers to the home directory for a particular instantiated WebSphere Application Server profile.

Corresponding product variables are *server.root* and *user.install.root.*

In general, this is the same as *app_server_root*/profiles/*profile_name*. On z/OS, this will always be *app_server_root*/profiles/default because only the profile name "default" is used in WebSphere Application Server for z/OS.

smpe_root
Refers to the root directory for product code installed with SMP/E or IBM Installation Manager.

The corresponding product variable is *smpe.install.root*.

The default is /usr/lpp/zWebSphere/V8R5.

Deploying EJB modules

When you deploy an Enterprise JavaBeans (EJB) module, you install that module on a server that has been configured to support deployed modules.

Before you begin

Assemble one or more EJB modules, assemble one or more web modules, and assemble them into a Java EE application.

For an overview about the changes to the EJB deployment model for EJB 3.x, see the topic EJB 3.x deployment overview.

Procedure

1. Prepare the deployment environment. See the topic Preparing to host applications.
2. Update the configuration for each EJB module as needed for the deployment environment.
3. Required: If a module has dependencies on Java 5-specific extensions, such as generics, annotations, and so on, then you must run the EJBDeplolycommand-line tool separately and before installing the module or application containing it. This is because the administrative console and the wsadmin command-line tool do not allow for specifying the ejbdeploy -complianceLevel 5.0 option.

It is only necessary to run the EJBDeploy tool for EJB 2.1 modules containing entity beans.

4. Address potential interoperability issues.

   There can be unexpected results if a WebSphere stack product, or another product, that runs on a version of Application Server that does not support EJB 3.x attempts to remotely invoke a method on an EJB 3.x compliant enterprise bean on a separate server that is running a version Application Server that supports EJB 3.x. If these products attempt to invoke a method through the enterprise bean's EJB 3.x remote business interface, they might encounter exceptions that were introduced in EJB 3.x that will be pushed back to the environment that is not EJB 3.x compliant.

   This scenario could also be an issue for an administrator of an environment that includes a combination of stack products that contain a mixture of EJB 3.x compliant and non-compliant instances of Application Server.

   The following is a list of the exception classes that have been introduced in EJB 3.0:

   - javax.ejb.ConcurrentAccessException
   - javax.ejb.EJBAccessException
   - javax.ejb.EJBTransactionRequiredException
   - javax.ejb.EJBTransactionRolledbackException
   - javax.ejb.NoSuchEJBException

   a. Ensure that Application Server is updated to 7.0.0.3.

   b. Manually copy the <*app_server_root*>/runtimes/ejb3exceptions.jar file from Application Server to a directory on each of the stack products installations, or other product installations, that you will use as the EJB 3.x client.

   c. Ensure that the directory that contains the ejb3exceptions.jar file is in the class path. One possible location for the JAR file that would satisfy this requirement is the <*app_server_root*>/lib directory on a server that is not EJB 3.x compliant.

      Note: Just like the EJB thin client jars, if an update becomes available, users must copy the ejb3exceptions.jar file again after installing the version of the WebSphere Application Server containing the updated version.

5. Deploy the application. See the topic Deploying and administering enterprise applications.

What to do next

If you specify that the EJBDeploy tool be run during application installation and the installation fails with a NameNotFoundException message, ensure that the input Java archive (JAR) or enterprise archive (EAR) file does not contain source files. Either remove the source files or include all dependent classes and resource files on the class path. If there are source files in the input JAR or EAR file, the EJB deployment tools runs a rebuild before generating the deployment code.

If the module deploys successfully, test and debug the module. See the topic Diagnosing problems (using diagnosis tools).

EJB 3.0 and EJB 3.1 deployment overview

Learn about the Enterprise JavaBeans (EJB) 3.0 and 3.1 deployment model, including *Just-In-Time* (JIT) deployment.

All Java Enterprise Edition (Java EE) application server products have some form of EJB deployment phase in which your application is customized to run in that particular implementation of the application server. Typically, this is accomplished by a deployment tool that is specific to the application server and generates code to bridge your EJB interface and implementation code to the application server's implementation for an EJB container. Some application server products' deployment tools alter the bytecodes of your application classes, rather than generating code, but the end result is similar.

Application Server bridges your EJB interface with its implementation by generating code that encapsulates your EJB implementation classes, connecting them to Application Server's EJB container. This enables the EJB container to host your enterprise beans and provide services to them. If one or more of your enterprise beans has remote interfaces defined, Application Server generates additional code to provide the remote function.

For more information about packaging your EJB module, see the topic that covers the EJB 3.x module packaging overview.

EJBDeploy Tool

Historically, EJB deployment in the Application Server product has been performed by the EJBDeploy tool, which is included with WebSphere Application Server and packaged with the development tools for the WebSphere products.

The EJBDeploy tool introspects the external interfaces for your enterprise beans, generates the wrapper code as .java files, and compiles the code using the javac compiler to produce .class files that are packaged in your EJB module with your application code. The EJBDeploy tool also runs the rmic tool against the remote EJB interfaces in the application, producing additional *stub* and *tie* class files that interact with the Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP) Object Request Broker (ORB), providing remote object support.

For modules previous to EJB 3.0, you ran the EJBDeploy tool when you installed the application on Application Server or before you installed the application from the command-line tool or a development tool.

Just-In-Time (JIT) deployment

EJB 3.0 support in Application Server introduced a new feature called JIT deployment.

With JIT deployment, the EJB container dynamically generates the wrapper, stub, and tie classes in-memory when the application is running. Additionally, the web container and application client containers dynamically generate the stub class that is required for remote EJB invocations.

Effectively, this means that you do not need to process EJB 3.0 or 3.1 modules, web modules that invoke EJB 3.0 or 3.1 beans, or client modules that invoke EJB 3.0 or 3.1 beans through the EJBDeploy tool before you run them in Application Server.

createEJBStubs tool

In most cases the Just-In-Time deployment feature can dynamically generate the RMI-IIOP stub classes that are required for invocation of remote EJB interfaces. There are some instances in which these stub classes are not dynamically generated. For EJB 3.0 or 3.1 clients that are not running inside an EJB 3.x enabled web container, EJB container, or client container, you must generate the stub classes with the createEJBStubs tool and ensure that the generated stubs are available in the client environment's class path. Typically, you would accomplish this by copying the generated stubs to the location where the client's business interface class resides.

The createEJBStubs tool must be used to generate client-side stubs for the following environments:

- "Bare" Java Standard Edition (SE) clients, where a Java SE Java Virtual Machine (JVM) is the client environment.
- Containers in Application Server environments prior to Version 7 that do not have the Feature Pack for EJB 3.0 applied.
- Environments that are not WebSphere Application Server environments.

Interoperability

There can be unexpected results if a WebSphere stack product, or another product, that runs on a version of Application Server that does not support EJB 3.0 or 3.1 attempts to remotely invoke a method on an EJB 3.x compliant enterprise bean on a separate server that is running a version Application Server that supports EJB 3.0 or 3.1. If these products attempt to invoke a method through the enterprise bean's EJB 3.x remote business interface, they might encounter exceptions that were introduced in EJB 3.0 that will be pushed back to the environment that is not EJB 3.x compliant.

This scenario could also be an issue for an administrator of an environment that includes a combination of stack products that contain a mixture of EJB 3.x compliant and non-compliant instances of Application Server.

The following is a list of the exception classes introduced in EJB 3.0:

- javax.ejb.ConcurrentAccessException
- javax.ejb.EJBAccessException
- javax.ejb.EJBTransactionRequiredException
- javax.ejb.EJBTransactionRolledbackException
- javax.ejb.NoSuchEJBException

Refer to the EJB module deployment step to address potential interoperability issues.

EJB 2.x Modules

EJB 2.x modules that have been converted to be EJB 3.0 or EJB 3.1 modules should have all WebSphere Application Server generated files (including stub and tie classes) removed prior to EJB deployment in the Application Server product.

EJBDEPLOY relationships – troubleshooting tips

Use this information to troubleshoot information for EJBDEPLOY problems.

DB2 for z/OS Version 7.x

Problems might exist when EJBDeploy creates a data relationship in DB2 for z/OS Version 7.x. EJBDeploy creates a table with a composite of the two primary keys of the EJBs that are related to each other. If the composite keys are larger than 254 characters, DB2 for z/OS V7.x does not accept this relationship and the following error can occur:

```
DSNT408I SQLCODE = -613, ERROR:  THE PRIMARY KEY OR A UNIQUE CONSTRAINT
IS TOO LONG OR HAS TOO MANY COLUMNS
DSNT418I SQLSTATE   = 54008 SQLSTATE RETURN CODE
```

This problem can be seen when the primary keys that are created for the two related beans have primary keys that are strings. This results in the composite being made up of 2 varchar(250) primary keys for a total of 500, which is greater than 254 maximum in DB2 for z/OS version 7.x.

Things to consider when utilizing top-down mappings to ensure you do not experience this problem:

- Top-down mappings are a guideline and must be reviewed with the DBA.
- Schemas that are created top-down by EJBDeploy are designed only for testing, and as a guideline for the actual schema required. The use of the meet-in-the-middle mapping does not present this problem.
- The composite key constraint problem is not experienced when using DB2 V8, which has 2K maximum key lengths.

EJBDEPLOY_JVM_ARGS:

Set the EJBDEPLOY_JVM_ARGS property to override Java virtual machine (JVM) options that are passed to the code that deploys EJBs (ejbdeploy.sh). Set this property in one of the following locations: *deploymentmanager*/bin/setupCmdLine.sh or *appServerHome*/bin/setupCmdLine.sh

For example, the following specifies that unqualifed SQL should be generated:

```
export EJBDEPLOY_JVM_ARGS="-DEJBDEPLOY_GENERATE_UNQUALIFIED_SQL=true"
```

The converter that is defined for the primary key is not invoked on its foreign key value

The mapping for primary key fields to database columns may use a converter to transform the key values. If a container-managed persistence (CMP) bean uses a converter to map its primary key, and that bean has a relationship where the bean at the other end holds a foreign key, the mapping for the foreign key will not use the converter.

The following errors might occur, indicating that the converter defined for the primary key is not invoked on its foreign key value. During the run of the ejbDeploy command , you receive the following message:

```
No type mapping defined for Java datatype1 to Database datatype2
```

During run time, the application does not find the CMP bean at the other end of the relationship.

To work around this limitation, define your own foreign key in the database table, and create a mapping that uses the same converter as defined for the primary key on the enterprise beans at the other end of its relationship.

Directory conventions

References in product information to *app_server_root*, *profile_root*, and other directories imply specific default directory locations. This article describes the conventions in use for WebSphere Application Server.

Default product locations - z/OS

app_server_root
: Refers to the top directory for a WebSphere Application Server node.

  The node may be of any type—application server, deployment manager, or unmanaged for example. Each node has its own *app_server_root*. Corresponding product variables are *was.install.root* and *WAS_HOME*.

  The default varies based on node type. Common defaults are *configuration_root*/AppServer and *configuration_root*/DeploymentManager.

configuration_root
: Refers to the mount point for the configuration file system (formerly, the configuration HFS) in WebSphere Application Server for z/OS.

  The *configuration_root* contains the various *app_server_root* directories and certain symbolic links associated with them. Each different node type under the *configuration_root* requires its own cataloged procedures under z/OS.

  The default is /wasv8config/*cell_name*/*node_name*.

plug-ins_root
: Refers to the installation root directory for Web Server Plug-ins.

profile_root
: Refers to the home directory for a particular instantiated WebSphere Application Server profile.

  Corresponding product variables are *server.root* and *user.install.root.*

In general, this is the same as *app_server_root*/profiles/*profile_name*. On z/OS, this will always be *app_server_root*/profiles/default because only the profile name "default" is used in WebSphere Application Server for z/OS.

smpe_root

Refers to the root directory for product code installed with SMP/E or IBM Installation Manager.

The corresponding product variable is *smpe.install.root*.

The default is /usr/lpp/zWebSphere/V8R5.

Chapter 43. Deploying messaging resources

This page provides a starting point for finding information about deploying asynchronous messaging resources for enterprise applications with WebSphere Application Server.

WebSphere Application Server supports asynchronous messaging based on the Java Message Service (JMS) and the Java EE Connector Architecture (JCA) specifications, which provide a common way for Java programs (clients and Java EE applications) to create, send, receive, and read asynchronous requests, as messages.

JMS support enables applications to exchange messages asynchronously with other JMS clients by using JMS destinations (queues or topics). Some messaging providers also allow WebSphere Application Server applications to use JMS support to exchange messages asynchronously with non-JMS applications; for example, WebSphere Application Server applications often need to exchange messages with WebSphere MQ applications. Applications can explicitly poll for messages from JMS destinations, or they can use message-driven beans to automatically retrieve messages from JMS destinations without explicitly polling for messages.

WebSphere Application Server supports the following messaging providers:

- The WebSphere Application Server default messaging provider (which uses service integration as the provider).
- The WebSphere MQ messaging provider (which uses your WebSphere MQ system as the provider).
- Third-party messaging providers that implement either a JCA Version 1.5 resource adapter or the ASF component of the JMS Version 1.0.2 specification.

Deploying enterprise applications

You can deploy an enterprise application to use JMS, or to use message-driven beans.

About this task

Enterprise applications can use JMS APIs directly to explicitly poll for messages on a JMS destination, then retrieve messages for processing by business logic beans (enterprise beans).

Message-driven beans can also be used as asynchronous message consumers. When a message arrives at the destination, the EJB container invokes the message-driven bean automatically without an application having to explicitly poll the destination.

Procedure

- Deploy an enterprise application to use JMS.
- Deploy an enterprise application to use message-driven beans.

Deploying an enterprise application to use JMS

You can deploy an enterprise application to use JMS.

About this task

This task description assumes that you have an .EAR file, which contains an application enterprise bean with code for JMS, that can be deployed in WebSphere Application Server.

To deploy an enterprise application to use JMS, complete the following steps:

Procedure

1. Configure the deployment attributes for the application, as described in Assembling applications.
2. Use the WebSphere Application Server administrative console to install the application.

   This stage is a standard WebSphere Application Server task, as described in Installing applications.

Deploying enterprise applications developed as message-driven beans

You can deploy an enterprise application developed as a message-driven bean in WebSphere Application Server.

About this task

Message-driven beans can be used as asynchronous message consumers. When a message arrives at the destination, the EJB container invokes the message-driven bean automatically without an application having to explicitly poll the destination.

Procedure

- Deploy an enterprise application to use message-driven beans with JCA 1.5-compliant resources. You can configure message-driven beans as listeners on a Java EE Connector Architecture (JCA) 1.5 resource adapter, such as the default messaging provider or the WebSphere MQ messaging provider in WebSphere Application Server.
- Deploy an enterprise application to use message-driven beans with listener ports. Listener ports are stabilized. For more information, read the article on stabilized features. You should only deploy your application against a listener port for compatability with existing message-driven bean applications. Otherwise, you should deploy your application against JCA 1.5-compliant resources.

Deploying an enterprise application to use message-driven beans with JCA 1.5-compliant resources

Message-driven beans can be configured as listeners on a Java EE Connector Architecture (JCA) 1.5 resource adapter, such as the default messaging provider or the WebSphere MQ messaging provider in WebSphere Application Server.

Before you begin

This task assumes that you have an EAR file that contains an enterprise application, developed as a message-driven bean, that can be deployed in WebSphere Application Server.

Note: You can continue to deploy message-driven beans against a listener port. You might want to do this for compatability with existing message-driven bean applications. However, listener ports are stabilized, and you should plan to migrate all your message-driven beans to use JCA 1.5-compliant or 1.6-compliant resources.

About this task

You deploy message-driven beans against JCA 1.5-compliant resources, and configure the resources as deployment descriptor attributes and (for EJB 3) as annotations.

Procedure

1. For each message-driven bean in the application, create a J2C activation specification.
2. For each message-driven bean in the application, configure the J2C deployment attributes, as described in “Configuring deployment attributes for a message-driven bean against JCA 1.5-compliant resources” on page 2085.
3. Use the WebSphere Application Server administrative console to install the application.

Configuring deployment attributes for a message-driven bean against JCA 1.5-compliant resources:

You can configure the message-driven bean deployment attributes for a Java EE Connector Architecture (JCA) 1.5-compliant enterprise application, to override the deployment attributes defined within the application EAR file.

Before you begin

This task assumes that you have an EAR file that contains an enterprise application, developed as a message-driven bean, that can be deployed in WebSphere Application Server.

Note: You can continue to configure message-driven beans against a listener port. You might want to do this for compatability with existing message-driven bean applications. However, listener ports are stabilized, and you should plan to migrate all your message-driven beans to use JCA 1.5-compliant or 1.6-compliant resources.

About this task

You configure the deployment attributes of a message-driven bean application by using an assembly tool. Detailed steps given in this task are for Rational Application Developer, but other tools have very similar steps.

Procedure

1. Start your assembly tool.
2. Edit the application EAR file. For example, use the Rational Application Developer import wizard to import the EAR file into the assembly tool. To start the import wizard:
   a. Click **File** > **Import** > **EAR file**.
   b. Click **Next**, then select the EAR file.
   c. Click **Finish**.
3. Open the deployment attributes for editing. In the Java EE Hierarchy view, right-click the EJB module for the message-driven bean then click **Open With** > **Deployment Descriptor Editor**. A property dialog notebook for the message-driven bean is displayed in the property pane.
4. Review and, if needed, change the deployment attributes.
   a. In the property pane, select the **Bean** tab.
   b. Under **Activation Configuration**, review the attributes.

      Note: For EJB 3 message-driven beans, you can instead use an EJB 3 annotation to configure the activation configuration properties. Do not use an EJB 3 annotation to change or replace what is specified in the bean deployment descriptor. If an activation configuration property is specified in both places, the value used is the one that is given in the deployment descriptor.

      `acknowledgeMode`
      This attribute determines how the session acknowledges any messages it receives.
      `Auto Acknowledge`
      The session automatically acknowledges delivery of each message.
      `Dups OK Acknowledge`
      The session lazily acknowledges the delivery of messages. This setting is likely to result in the delivery of some duplicate messages if JMS fails, so it should be used only by consumer applications that are tolerant of duplicate messages.

      `destinationType`
      This attribute determines whether the message-driven bean uses a queue or topic destination.
      `Queue` The message-driven bean uses a queue destination.

Topic The message-driven bean uses a topic destination.

subscriptionDurability
This attribute determines whether a JMS topic subscription is durable or nondurable.

Durable
A subscriber registers a durable subscription with a unique identity that is retained by JMS. Subsequent subscriber objects with the same identity resume the subscription in the state it was left in by the earlier subscriber. If there is no active subscriber for a durable subscription, JMS retains the subscription messages until they are received by the subscription or until they expire.

Nondurable
Nondurable subscriptions last for the lifetime of their subscriber object. This means that a client sees the messages published on a topic only while its subscriber is active. If the subscriber is not active, the client is missing messages published on its topic.

A nondurable subscriber can only be used in the same transactional context (for example, a global transaction or an unspecified transaction context) that existed when the subscriber was created.

messageSelector
This attribute determines the JMS message selector that is used to select which messages the message-driven bean receives. For example:

```
JMSType='car' AND color='blue' AND weight>2500
```

The selector string can refer to fields in the JMS message header and fields in the message properties. Message selectors cannot reference message body values.

c. Specify bindings deployment attributes.

Under **WebSphere Bindings**, select the **JCA Adapter** option then specify the bindings deployment attributes:

ActivationSpec JNDI name
This attribute specifies the JNDI name of the activation specification that is used to deploy this message-driven bean. This name must match the name of an activation specification that you define to WebSphere Application Server.

ActivationSpec Authorization Alias
This attribute specifies the name of an authentication alias used for authentication of connections to the JCA resource adapter. An authentication alias specifies the user ID and password that is used to authenticate the creation of a new connection to the JCA resource adapter.

Destination JNDI name
This attribute specifies the JNDI name that the message-driven bean uses to look up the JMS destination in the JNDI namespace.

5. Save your changes to the deployment descriptor:
   a. Close the deployment descriptor editor.
   b. When prompted, click **Yes** to indicate that you want to save changes to the deployment descriptor.
6. Verify the archive files.
7. From the pop-up menu for the project, click **Deploy** to generate EJB deployment code.
8. Optional: Test your completed module on a WebSphere Application Server installation.

   Right-click a module, click **Run on Server**, then follow the instructions in the displayed wizard.

   Restriction: **Run on Server** works on the Windows, Linux/Intel, and AIX operating systems only. You cannot deploy remotely to a WebSphere Application Server installation on a UNIX operating system such as Solaris.

Important: Use **Run on Server** for unit testing only. When an application is published remotely, the assembly tool overwrites the server configuration file for that server. Do not use on production servers.

What to do next

After assembling your application, use a systems management tool to deploy the EAR file onto the application server that will run the application; for example, use the administrative console as described in Deploying and managing applications.

Configuring servant regions for message-driven beans with JCA version 1.5 resource adapters:

For any message-driven beans (MDBs) that are not driven by asynchronous messaging or the IMS Connect for Java (IC4J) resource adapter, you must redefine the servant region for those beans that are connected to Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) Version 1.5 resource adapters that support inbound message processing.

About this task

If the application server is configured with one or more message-driven beans (MDBs) that do not use asynchronous messaging and are bound to a Java EE Connector Architecture (JCA) Version 1.5 resource adapter, and the resource adapter supports inbound message processing, the adapter must be defined to run only a maximum of 1 servant region. If you use the IMS Connect for Java (IC4J) resource adapter or an adapter that is driven by asynchronous messaging, you can configure the servant regions through the adapter configuration.

Note: If the application server is configured with one or more message-driven beans (MDBs) that are bound to service integration messaging or WebSphere MQ messaging using a resource adapter, which means that the MDBs use activation specifications rather than listener ports, then you must enable the Control Region Adjunct (CRA) process for the application server. To include starting the CRA process as part of starting an application server, either select **Enable JCA based inbound message delivery** on the JMS provider settings panel, or use the manageWMQ command.

Procedure

1. Open the administrative console.
2. Select **Servers > Server Types > WebSphere application servers**.
3. Select the server you want to configure.
4. Under Server Infrastructure, expand **Java and Process Management**.
5. Select **Process Definition**.
6. Select **Servant**.
7. Under Additional Properties, select **Environment Entries**. This causes a panel with the heading Application servers > *server* > Process Definition > Servant > Custom Properties to appear.
8. Select **New**. A panel with three General Properties fields appears. This is where you create the environment variable for controlling the number of servant regions.
9. In the Name field, enter **wlm_maximumSRcount**.
10. In the Value field, enter **1**. A servant can be configured to a maximum of 1 servant region by using the administrative console.
11. Select **Apply**.

Deploying an enterprise application to use message-driven beans with listener ports

Define the listener ports for your application. For each message-driven bean in the application, configure the deployment attributes to match the listener port definitions. Install the application, specifying the name of the listener port to use for late responses.

Before you begin

Listener ports are stabilized. For more information, read the article on stabilized features. You should only deploy your application against a listener port for compatability with existing message-driven bean applications. Otherwise, you should deploy your application against JCA 1.5-compliant resources.

If you have existing message-driven beans that use the WebSphere MQ messaging provider (or a compliant third-party JMS provider) with listener ports, and instead you want to use EJB 3 message-driven beans with listener ports, these new beans can continue to use the same messaging provider.

This task assumes that you have an EAR file, which contains an enterprise application developed as a message-driven bean, that can be deployed in WebSphere Application Server.

Procedure

1. Define the listener ports for your application, by using the WebSphere Application Server administrative console as described in Creating a new listener port.
2. For each message-driven bean in the application, configure the deployment attributes to match the listener port definitions, as described in "Configuring deployment attributes for a message-driven bean against a listener port."
3. Install the application, as described in Installing enterprise application files with the console.

   When you install the application, you are prompted to specify the name of the listener port that the application is to use for late responses. Select the listener port, then click **OK**.

Configuring deployment attributes for a message-driven bean against a listener port:

You can configure the message-driven beans deployment attributes for an enterprise bean, to override the deployment attributes defined within the application EAR file.

Before you begin

Listener ports are stabilized. For more information, read the article on stabilized features. You should only configure your application against a listener port for compatability with existing message-driven bean applications. Otherwise, you should configure your application against JCA 1.5-compliant resources.

If you have existing message-driven beans that use the WebSphere MQ messaging provider (or a compliant third-party JMS provider) with listener ports, and instead you want to use EJB 3 message-driven beans with listener ports, these new beans can continue to use the same messaging provider.

This task assumes that you have an EAR file that contains an enterprise application, developed as a message-driven bean, that can be deployed in WebSphere Application Server.

About this task

You configure the deployment attributes of a message-driven bean application by using an assembly tool. Detailed steps given in this task are for Rational Application Developer, but other tools have very similar steps.

Procedure

1. Start your assembly tool.

2. Edit the application EAR file. For example, use the Rational Application Developer import wizard to import the EAR file into the assembly tool. To start the import wizard:
   a. Click **File** > **Import** > **EAR file**.
   b. Click **Next**, then select the EAR file.
   c. Click **Finish**.
3. Open the deployment attributes for editing. In the Java EE Hierarchy view, right-click the EJB module for the message-driven bean then click **Open With** > **Deployment Descriptor Editor**. A property dialog notebook for the message-driven bean is displayed in the property pane.
4. Specify general deployment attributes.
   a. In the property pane, select the **Bean** tab.
   b. On the main panel, configure the **Transaction type** attribute.

      This attribute determines whether the message-driven bean manages its own transactions, or whether the container manages transactions on behalf of the bean.

      Bean The message-driven bean manages its own transactions.

      Container
      The container manages transactions on behalf of the bean.
5. Under **Activation Configuration**, review the following attributes:

   Note: For EJB 3 message-driven beans, you can instead use an EJB 3 annotation to configure the activation configuration properties. Do not use an EJB 3 annotation to change or replace what is specified in the bean deployment descriptor. If an activation configuration property is specified in both places, the value used is the one that is given in the deployment descriptor.

   acknowledgeMode
   This attribute determines how the session acknowledges any messages it receives.

   Auto Acknowledge
   The session automatically acknowledges delivery of each message.

   Dups OK Acknowledge
   The session lazily acknowledges the delivery of messages. This setting is likely to result in the delivery of some duplicate messages if JMS fails, so it should be used only by consumer applications that are tolerant of duplicate messages.

   destinationType
   This attribute determines whether the message-driven bean uses a queue or topic destination.

   Queue The message-driven bean uses a queue destination.

   Topic The message-driven bean uses a topic destination.

   subscriptionDurability
   This attribute determines whether a JMS topic subscription is durable or nondurable.

   Durable
   A subscriber registers a durable subscription with a unique identity that is retained by JMS. Subsequent subscriber objects with the same identity resume the subscription in the state it was left in by the earlier subscriber. If there is no active subscriber for a durable subscription, JMS retains the subscription messages until they are received by the subscription or until they expire.

   Nondurable
   Nondurable subscriptions last for the lifetime of their subscriber object. This means that a client sees the messages published on a topic only while its subscriber is active. If the subscriber is not active, the client is missing messages published on its topic.

   A nondurable subscriber can only be used in the same transactional context (for example, a global transaction or an unspecified transaction context) that existed when the subscriber was created.

messageSelector
This attribute determines the JMS message selector that is used to select which messages the message-driven bean receives. For example:

```
JMSType='car' AND color='blue' AND weight>2500
```

The selector string can refer to fields in the JMS message header and fields in the message properties. Message selectors cannot reference message body values.

6. Specify the bindings deployment attribute.
   a. Under **WebSphere Bindings**, specify the following attribute:
      Listener port name
      Type the name of the listener port for this message-driven bean.
7. Save your changes to the deployment descriptor:
   a. Close the deployment descriptor editor.
   b. When prompted, click **Yes** to indicate that you want to save changes to the deployment descriptor.
8. Verify the archive files.
9. From the pop-up menu for the project, click **Deploy** to generate EJB deployment code.
10. Optional: Test your completed module on a WebSphere Application Server installation.
    Right-click a module, click **Run on Server**, then follow the instructions in the displayed wizard.

    Restriction: **Run on Server** works on the Windows, Linux/Intel, and AIX operating systems only. You cannot deploy remotely to a WebSphere Application Server installation on a UNIX operating system such as Solaris.

    Important: Use **Run on Server** for unit testing only. When an application is published remotely, the assembly tool overwrites the server configuration file for that server. Do not use on production servers.

What to do next

After assembling your application, use a systems management tool to deploy the EAR file onto the application server that will run the application; for example, use the administrative console as described in Deploying and managing applications.

Chapter 44. Deploying OSGi applications

You deploy an OSGi application by adding an enterprise bundle archive (EBA) asset to a business-level application.

About this task

You can add an EBA asset to a business-level application by using the administrative console, or by using wsadmin commands.

The WebSphere Application Server administrative console and the OSGi Applications command-line console provide commands that you can use to explore or debug bundles running on an application server.

Procedure

- Deploy an OSGi application as a business-level application.

  Import an OSGi application as an enterprise bundle archive (EBA) asset, then add the asset to a business-level application by creating a composition unit. Optionally, add a composite bundle extension to the composition unit..
- Debug bundles at run time.

  You can use either the WebSphere Application Server administrative console or the wsadmin-based OSGi Applications command-line console to explore or debug the bundles associated with a specific OSGi application or shared bundle framework..

Deploying an OSGi application as a business-level application

Import an OSGi application as an enterprise bundle archive (EBA) asset, then add the asset to a business-level application by creating a composition unit. Optionally, add a composite bundle extension to the composition unit.

Before you begin

This topic assumes that you have already created an enterprise OSGi application packaged as an EBA file, for example as described in “Creating an OSGi application” on page 668. You might also have developed a composite bundle extension, as described in Extending a deployed OSGi application.

In addition to specifying the configuration information for the EBA asset through the following procedure, you can also change it later as described in Modifying the configuration of an OSGi composition unit. For example, if you update a bundle in an EBA asset, or replace a composite bundle extension, you might introduce a resource that requires additional configuration, such as a new or changed Blueprint resource reference, or security role mapping.

About this task

To deploy an OSGi application in WebSphere Application Server, you import your OSGi application (EBA file) as an asset and create an empty business-level application. You then add a composition unit to the business-level application. This composition unit consists of the new EBA asset plus configuration information for the context roots, virtual hosts, security role mappings, and web application or Blueprint resource bindings for your OSGi application. The composition unit can also include composite bundle extensions.

Note:

- An EBA file can be imported into only one asset.

- An EBA asset can be added to only one business-level application.
- One or more composite bundle extensions can be added to a composition unit.

A business-level application is scoped to cell scope, therefore only one instance of a given OSGi application can be deployed in a cell.

This topic describes the specific task of deploying an OSGi application and any composite bundle extensions as a business-level application. The more generalized task of creating any business-level application is described in Creating business-level applications.

Each step can be completed using either the administrative console or wsadmin commands. You can also create an empty business-level application or add a composition unit using programming.

Demonstration of this task (4 min) 

Procedure

1. Import the EBA file as an asset.

   Note: You can import the asset before or after you create the empty business-level application. An EBA file can be imported into only one asset.

   To import the EBA file using the administrative console, navigate to **Applications** > **New Application** > **New Asset**. For more information, see Importing assets.

   To import the EBA file using the **importAsset** command, enter (for example) the following command:

   ```
   AdminTask.importAsset(["-storageType", "FULL",
                          "-source", com.ibm.ws.eba.helloWorldService.eba])
   ```

   For more information, see the step “Import assets to your configuration” in topic Setting up business-level applications using wsadmin scripting.

   Notes:

   - When you import the EBA file as an asset, it is checked for any bundle dependencies. If the OSGi application has dependencies on bundles that are not included in the EBA file, the dependencies are resolved against any configured bundle repositories. Asset registration cannot complete unless all missing dependencies are available from configured bundle repositories.
   - When asset registration completes, if the asset requires bundles to be downloaded from bundle repositories, a warning message is displayed telling you to save your changes to the master configuration after completing the asset import. When you save changes, the missing dependencies are downloaded from the configured bundle repositories.
   - If the asset uses Java 2 security, the security permissions are displayed. This information comes from the `META-INF/permissions.perm` file for your application. For more information, see Java 2 security and OSGi Applications.
   - Do not add the asset to a business-level application until the bundle download has completed. You can view the download status of the bundles from the administrative console, or by calling the areAllDownloadsComplete () method of the BundleCacheManager MBean. See Interacting with the OSGi bundle cache.

2. Create an empty business-level application.

   To create an empty business-level application using the administrative console, navigate to **Applications** > **New Application** > **New Business Level Application**. For more information, see the step “Create an empty business-level application” in topic Creating business-level applications with the console.

   To create an empty business-level application using the **createEmptyBLA** command, enter (for example) the following command:

```
AdminTask.createEmptyBLA('[-name "helloWorld"
                           -description "helloWorld OSGi sample"]')
```

For more information, see the step “Create an empty business-level application” in topic Setting up business-level applications using wsadmin scripting.

To create an empty business-level application using programming, see Creating an empty business-level application using programming.

3. Add the EBA asset to the business-level application as a composition unit.

   An EBA asset can be added to only one business-level application. An OSGi composition unit consists of an EBA asset, (optionally) one or more composite bundle extensions, and some or all of the following configuration information:

   - Mappings from the composition unit to a target application server, web server, or cluster.
   - Configuration of the session manager, context roots or virtual hosts of the application.
   - Mappings from enterprise beans to JNDI names.
   - Bindings to any associated web applications or blueprint resource references.
   - Mappings from security roles to particular users or groups.

   To add the asset to the business-level application as a composition unit, use one of the following methods:

   - “Adding an EBA asset to a composition unit by using the administrative console.”
   - “Adding an EBA asset to a composition unit by using wsadmin commands” on page 2096.
   - Adding a composition unit using programming.

4. Optional: Add a composite bundle as an extension to the composition unit.

   After you import the enterprise bundle archive (EBA) file for your OSGi application as an asset, you can update versions of existing bundles but you cannot add extra bundles to the asset. However, after you have added the asset as a composition unit to a business-level application, you can extend the business-level application by adding one or more composite bundles to the composition unit.

5. Save your changes to the master configuration.

   If you are using wsadmin commands, enter the following command:

   ```
   AdminConfig.save()
   ```

What to do next

You are now ready to start your business-level application.

Adding an EBA asset to a composition unit by using the administrative console

Use the administrative console to add a composition unit that consists of a previously-imported EBA asset plus configuration information. The configuration information can include HTTP session management, context roots, virtual hosts, security roles, run-as roles, JNDI mappings for Session enterprise beans, JNDI mappings for EJB references, and web application or Blueprint resource reference bindings for your OSGi application.

Before you begin

You can add an EBA asset to a business-level application by using the administrative console as described in this topic, or by using the **addCompUnit** command as described in “Adding an EBA asset to a composition unit by using wsadmin commands” on page 2096.

An EBA asset can be added to only one business-level application. A business-level application is scoped to cell scope, therefore only one instance of a given OSGi application can be deployed in a cell.

This task makes the following assumptions:

- You have already imported the EBA file as an asset (as described in “Deploying an OSGi application as a business-level application” on page 2091), then saved your changes to the master configuration (which causes any bundle dependencies to be downloaded from configured bundle repositories).
- You have already defined the target virtual hosts. To check existing virtual hosts by using the administrative console, click **Environment** > **Virtual hosts**.
- You have already created the JCA authentication alias that you want to associate with each Blueprint resource reference. To check existing JCA authentication aliases using the administrative console, click **Security** > **Global security** > **[Authentication] Java Authentication and Authorization Service** > **J2C authentication data**.

About this task

An OSGi composition unit consists of an EBA asset, (optionally) one or more composite bundle extensions, and some or all of the following configuration information:

- Mappings from the composition unit to a target application server, web server, or cluster.
- Configuration of the session manager, context roots or virtual hosts of the application.
- Mappings from enterprise beans to JNDI names.
- Bindings to any associated web applications or blueprint resource references.
- Mappings from security roles to particular users or groups.

You use the Set options settings wizard to add a new composition unit to a business-level application. The contents of the asset determine the specific steps in the wizard. This topic describes the main elements that you configure when adding an EBA asset. For a general description of all the elements that the wizard might prompt you to configure, see Creating business-level applications with the console.

In addition to specifying the configuration information for the EBA asset through the following procedure, you can also change it later as described in Modifying the configuration of an OSGi composition unit. For example, if you update a bundle in an EBA asset, or replace a composite bundle extension, you might introduce a resource that requires additional configuration, such as a new or changed Blueprint resource reference, or security role mapping.

Procedure

1. Start the administrative console.
2. Add the previously-imported asset (the `.eba` file) as a deployed asset.
   a. If you have just created a new business-level application, the general properties for the business-level application are already displayed, including the option **[Deployed assets] Add** > **Add Asset**. Otherwise, navigate to **Applications** > **Application Types** > **Business-level applications** > ***application_name*** > **[Deployed assets] Add** > **Add Asset**. A list of available assets is displayed.
   b. Select the asset to add, then click **Continue**. The Set options settings wizard is displayed.
3. Wizard step: Set options.

   Change the composition unit settings as needed, then click **Next**. For more information, see Set options settings.
4. Wizard step: Map composition unit to a target.

   Select the deployment target application server or web server. For more information, see Map target settings.
5. Wizard step: Map context root for web modules.

   Select a web application bundle (WAB) from the list, then enter the context root for the WAB. For example, `/sample`. For more information, see Context root for web modules [Settings].
6. Wizard step: Map virtual hosts for web modules.

The list of available WABs in this asset is displayed. For each WAB, you can change the associated virtual host by selecting a different one from the list. If you specify an existing virtual host in the `ibm-web-bnd.xml` or `.xmi` file for a WAB, the specified virtual host is set by default. Otherwise, the default virtual host setting is `default_host`. For more information, see Virtual hosts for web modules [Settings].

7. Wizard step: Map security roles to users or groups.

   Change the security mapping as needed. For more information, see Security role to user or group mapping [Settings].

8. Wizard step: Map RunAs roles to users

   You can map a specified user identity and password to a RunAs role. This mapping enables you to specify application-specific privileges for individual users, so that they can run specific tasks using another user identity. For more information, see RunAs roles for users [Collection].

9. Wizard step: Bind Blueprint resource references.

   The list of available Blueprint resource references in this asset is displayed. For each reference, you can optionally select an authentication alias from the list. Default authentication aliases (from `ibm-eba-bnd.xml` files) are offered only if they exist on every target server or cluster. For more information, see Blueprint resource references [Settings].

10. Wizard step: Map web module resource references to resources.

    The list of available web application resource references in this asset is displayed. That is, resources of type resource-ref (resource reference), as defined in the Java specification JSR-250: Common Annotations for the Java Platform. For each reference, specify the JNDI name under which the resource is known in the runtime environment. Optionally, set authentication properties and extended data source custom properties, which affect how the resource is accessed at run time. To specify the JNDI name mapping, either type the JNDI name into the box, or click **Browse...** then select the resource reference from the list of available resources. To modify the authentication method, or to set extended data source custom properties that apply to the database connection, select a single reference then click **Modify Resource Authentication Method...** or **Extended Properties...**. For more information, see Web module resource references [Settings].

11. Wizard step: Bind web module message destination references to administered objects.

    The list of available web application message destination and resource environment references in this asset is displayed. That is, resources of type message-destination-ref (message destination reference) or resource-env-ref (resource environment reference), as defined in the Java specification JSR-250: Common Annotations for the Java Platform. For each reference, specify the JNDI name under which the resource is known in the runtime environment. For more information, see Web module message destination references [Settings].

12. Wizard step: Provide EJB JNDI names

    For each Session enterprise bean in the composition unit, you can specify the JNDI name by which the enterprise bean is known in the runtime environment. For more information, see EJB JNDI names [Settings].

13. Wizard step: Map EJB References

    For each EJB reference that is defined in either an ejb-jar.xml file, a web.xml file, or an @EJB annotation in the composition unit, you can specify the JNDI name by which the EJB reference is known in the runtime environment. For more information, see EJB references [Settings].

14. Wizard step: Map EJB resource references to resources

    The list of available EJB resource references in this asset is displayed. That is, resources of type resource-ref (resource reference), as defined in the Java specification JSR-250: Common Annotations for the Java Platform. For each reference, specify the JNDI name under which the resource is known in the runtime environment. For more information, see EJB resource references [Settings].

15. Wizard step: Bind EJB message destination references to administered objects

    The list of available EJB message destination and resource environment references in this asset is displayed. That is, resources of type message-destination-ref (message destination reference) or

resource-env-ref (resource environment reference), as defined in the Java specification JSR-250: Common Annotations for the Java Platform. For each reference, specify the JNDI name under which the resource is known in the runtime environment. For more information, see EJB message destination references [Settings].

16. Wizard step: Bind listeners for message-driven beans

    For each message-driven bean (MDB) that is defined in either an ejb-jar.xml file or an @MessageDriven annotation in the composition unit, you can specify the settings necessary to bind an MDB listener to the MDB. By binding a listener to an MDB, you configure the association of the MDB with the JMS destination from which the MDB receives messages. For more information, see Listeners for message-driven beans [Settings].

17. Wizard step: Summary

    A summary of your selections is displayed. To complete the creation of the composition unit, click **Finish**. If there are settings that you want to change, click **Previous** to review the settings.

18. Save your changes to the master configuration.

Results

The product creates composition units for the application, module, or shared library relationships. The unit names are shown in lists of deployed assets on the settings page of your business-level application. To view the settings page, click **Applications** > **Application Types** > **Business-level applications** > ***application_name***.

What to do next

Note: After you import the enterprise bundle archive (EBA) file for your OSGi application as an asset, you can update versions of existing bundles but you cannot add extra bundles to the asset. However, after you have added the asset as a composition unit to a business-level application, you can extend the business-level application by adding one or more composite bundles to the composition unit. See Adding or removing extensions for an OSGi composition unit.

You are now ready to start your business-level application.

Adding an EBA asset to a composition unit by using wsadmin commands

You can use the **addCompUnit** command and the **AdminConfig** commands to add a composition unit that consists of a previously-imported enterprise bundle archive (EBA) asset plus configuration information. The configuration information can include HTTP session management, context roots, virtual hosts, security roles, run-as roles, JNDI mappings for Session enterprise beans, JNDI mappings for EJB references, and web application or Blueprint resource reference bindings for your OSGi application.

Before you begin

You can add an EBA asset to a business-level application by using wsadmin commands as described in this topic, or by using the administrative console as described in “Adding an EBA asset to a composition unit by using the administrative console” on page 2093.

An EBA asset can be added to only one business-level application. A business-level application is scoped to cell scope, therefore only one instance of a given OSGi application can be deployed in a cell.

This task makes the following assumptions:

- You have already imported the EBA file as an asset (for example by using the **importAsset** command as described in step 2 of Setting up business-level applications using wsadmin scripting), then saved your changes to the master configuration (which causes any bundle dependencies to be downloaded from configured bundle repositories).

- You have already defined the target virtual hosts. To check existing virtual hosts using the wsadmin tool, issue the following jython command:

  ```
  print AdminConfig.list('VirtualHost')
  ```
- You have already created the JCA authentication alias that you want to associate with each Blueprint resource reference (for more information, see Configuring new Java 2 Connector authentication data entries using wsadmin).

About this task

An OSGi composition unit consists of an EBA asset, (optionally) one or more composite bundle extensions, and some or all of the following configuration information:

- Mappings from the composition unit to a target application server, web server, or cluster.
- Configuration of the session manager, context roots or virtual hosts of the application.
- Mappings from enterprise beans to JNDI names.
- Bindings to any associated web applications or blueprint resource references.
- Mappings from security roles to particular users or groups.

To create and configure all elements of the composition unit except the HTTP session manager, you use the **addCompUnit** command. To configure the HTTP session manager, you use the **AdminConfig** commands to configure the deployed object represented by the *appDeploy* variable. The composition unit must be created before the session management options can be applied to it, so you must run the **addCompUnit** command before you configure the HTTP session manager.

In addition to specifying the configuration information for the EBA asset through the following procedure, you can also change it later as described in Modifying the configuration of an OSGi composition unit by using wsadmin commands. For example, if you update a bundle in an EBA asset, or replace a composite bundle extension, you might introduce a resource that requires additional configuration, such as a new or changed Blueprint resource reference, or security role mapping.

Procedure

1. Create and configure all elements of the composition unit except the HTTP session manager.

   Each of the following substeps describes the syntax for adding a single element to the composition unit. However, to create the composition unit you run the **addCompUnit** command only once. Therefore, when you run the command, you must combine these elements together. An example of the combined syntax is given after the separate substeps.

   For several of the elements, the values you specify include bundle identifiers. If your EBA asset includes or references composite bundles, the command syntax is slightly different. For clarity, the differences for composite bundles are described, step by step, in a linked topic.

   a. Add the previously-imported asset (the `.eba` file) as a deployed asset.

      The parameters for this aspect of the command are as follows:

      -blaID
      Specifies the configuration ID of the business-level application.

      -cuSourceID
      Specifies the ID of the EBA asset that is being added to the business-level application.

      -CUOptions
      Specifies the following additional properties for the composition unit.
      - parentBLA
      - backingID
      - name
      - description

- startingWeight
- startedOnDistributed
- restartBehaviorOnUpdate

-MapTargets
Specifies additional properties for the composition unit target mapping. That is, it specifies the deployable unit URI (which, for an EBA asset, is `ebaDeploymentUnit`) and the target node and server, or the target cluster. To add an additional target, you use the plus sign character (+) as a prefix.

-ActivationPlanOptions
Specifies additional properties for the composition unit activation plan. That is, it specifies the deployable unit URI and a list of runtime components. For an EBA asset, use default values as shown in the example that follows.

If the target is one cluster, the Jython syntax for this aspect of the command is as follows:

```
AdminTask.addCompUnit('[
  -blaID WebSphere:blaname=bla_name
  -cuSourceID WebSphere:assetname=asset_name.eba
  -CUOptions [
    [WebSphere:blaname=bla_name.eba
    WebSphere:assetname=asset_name.eba
    cu_name "optional_cu_description" 1 false DEFAULT]]
  -MapTargets [[ebaDeploymentUnit WebSphere:cluster=cluster_name]]
  -ActivationPlanOptions [[default ""]]
  ...
]')
```

For example:

```
AdminTask.addCompUnit('[
  -blaID WebSphere:blaname=helloWorldService
  -cuSourceID WebSphere:assetname=com.ibm.ws.eba.helloWorldService.eba
  -CUOptions [
    [WebSphere:blaname=helloWorldService.eba
    WebSphere:assetname=com.ibm.ws.eba.helloWorldService.eba
    com.ibm.ws.eba.helloWorldService_0001.eba "" 1 false DEFAULT]]
  -MapTargets [[ebaDeploymentUnit WebSphere:cluster=cluster1]]
  -ActivationPlanOptions [[default ""]]
  ...
]')
```

If the target is two servers, the Jython syntax for this aspect of the command is as follows::

```
AdminTask.addCompUnit('[
  -blaID WebSphere:blaname=bla_name
  -cuSourceID WebSphere:assetname=asset_name.eba
  -CUOptions [
    [WebSphere:blaname=bla_name.eba
    WebSphere:assetname=asset_name.eba
    cu_name "optional_cu_description" 1 false DEFAULT]]
  -MapTargets [
    [ebaDeploymentUnit WebSphere:node=node_name,server=server_name+
                       WebSphere:node=node2_name,server=server2_name]]
  -ActivationPlanOptions [[default ""]]
  ...
]')
```

For example:

```
AdminTask.addCompUnit('[
  -blaID WebSphere:blaname=helloWorldService
  -cuSourceID WebSphere:assetname=com.ibm.ws.eba.helloWorldService.eba
  -CUOptions [
    [WebSphere:blaname=helloWorldService.eba
    WebSphere:assetname=com.ibm.ws.eba.helloWorldService.eba
    com.ibm.ws.eba.helloWorldService_0001.eba "" 1 false DEFAULT]]
```

```
  -MapTargets [[ebaDeploymentUnit WebSphere:node=node01,server=server1+
                                  WebSphere:node=node01,server=web1]]
  -ActivationPlanOptions [[default ""]]
  ...
]')
```

b. Map context root for web modules.

Context roots determine where the web pages of a particular web application bundle (WAB) are found at run time. The context root that you specify here is combined with the defined server mapping to compose the full URL that you enter to access the pages of the WAB. For example, if the application server default host is `www.example.com:8080` and the context root of the WAB is `/sample`, the web pages are available at `www.example.com:8080/sample`.

The Jython syntax for this aspect of the command is as follows.

Note: For composite bundles, the syntax is slightly different. See Step: Map context root for web modules in composite bundles.

The list of bundles under the **ContextRootStep** must contain all the WABs contained in the OSGi application.

```
AdminTask.addCompUnit('[
  ...
  -ContextRootStep [
    [bundle_symbolic_name_1 bundle_version_1 context_root_1]
    [bundle_symbolic_name_2 bundle_version_2 context_root_2]]
  ...
]')
```

For example, for an EBA file that contains two WABs (`com.ibm.ws.eba.helloWorldService.web` at version 1.0.0, which is to be mapped to `/hello/web`, and `com.ibm.ws.eba.helloWorldService.withContextRoot` at version 0.9.0, which is to be mapped to `/hello/service`), this aspect of the command is as follows:

```
AdminTask.addCompUnit('[
  ...
  -ContextRootStep [
    [com.ibm.ws.eba.helloWorldService.web 1.0.0 "/hello/web"]
    [com.ibm.ws.eba.helloWorldService.withContextRoot 0.9.0 "/hello/service"]]
  ...
]')
```

c. Bind listeners for message-driven beans

For each message-driven bean (MDB) that is defined in either an ejb-jar.xml file or an @MessageDriven annotation in the composition unit, you can specify the settings necessary to bind an MDB listener to the MDB. By binding a listener to an MDB, you configure the association of the MDB with the JMS destination from which the MDB receives messages.

The Jython syntax for this aspect of the command is as follows.

Note: For composite bundles, the syntax is slightly different. See Step: Bind listeners for message-driven beans in composite bundles

```
AdminTask.addCompUnit('[
  ...
  -MDBBindingsStep [
    [bundle_symbolic_name_1 bundle_version_1 uri_1
       activation_spec_1 destination_jndi_name_1 authentication_alias_1]
    [bundle_symbolic_name_2 bundle_version_2 uri_2
       activation_spec_2 destination_jndi_name_2 authentication_alias_2]]
  ...
]')
```

In the following example, an EBA file contains two EJB bundles, `com.ibm.ws.eba.currencyService` at version 1.0.0, and `com.ibm.ws.eba.accountService` at version 0.9.0. The currencyService bundle contains a message-driven bean called `ExchangeRateMDB`, bound to an activation specification with

a JNDI name of eis/ExchangeRate_Act_Spec; the destination JNDI name that is defined in the activation specification is overridden by a destination whose JNDI name is jms/ExchangeRateQueue, and the authentication alias that is defined in the activation specification is overridden by an authentication alias called ExchangeRate_Auth_Alias. The accountService bundle contains an MDB called CustomerDetailsMDB, bound to an activation specification with a JNDI name of eis/CustomerDetails_Act_Spec; the destination JNDI name that is defined in the activation specification is overridden by a destination whose JNDI name is jms/CustomerDetailsQueue, and the authentication alias that is defined in the activation specification is overridden by an authentication alias called CustomerDetails_Auth_Alias.

```
AdminTask.addCompUnit('[
  ...
  -MDBBindingsStep [
    [com.ibm.ws.eba.currencyService 1.0.0 META-INF/ejb-jar.xml/ExchangeRateMDB
      eis/ExchangeRate_Act_Spec jms/ExchangeRateQueue ExchangeRate_Auth_Alias]
    [com.ibm.ws.eba.accountService 0.9.0 META-INF/ejb-jar.xml/CustomerDetailsMDB
      eis/CustomerDetails_Act_Spec jms/CustomerDetailsQueue CustomerDetails_Auth_Alias]]
  ...
]')
```

d. Provide EJB JNDI names

For each Session enterprise bean in the composition unit, you can specify the JNDI name by which the enterprise bean is known in the runtime environment.

The Jython syntax for this aspect of the command is as follows.

Note: For composite bundles, the syntax is slightly different. See Step: Provide EJB JNDI names in composite bundles

```
AdminTask.addCompUnit('[
  ...
  -EJBMappingsStep [
    [bundle_symbolic_name_1 bundle_version_1 ejb_name_1
       ejb_interface_1 ejb_iterface_type_1 jndi_name_1]
    [bundle_symbolic_name_2 bundle_version_2 ejb_name_2
       ejb_interface_2 ejb_iterface_type_2 jndi_name_2]]
  ...
]')
```

In the following example, an EBA file contains two EJB bundles, com.ibm.ws.eba.currencyService at version 1.0.0, and com.ibm.ws.eba.accountService at version 0.9.0. The currencyService bundle contains an enterprise bean called ExchangeRate_ejb, with a Local interface called com.ibm.ws.eba.ejb.ExchangeRate, that is mapped to a JNDI name of ejb/ExchangeRate. The accountService bundle contains an enterprise bean called CustomerDetails_ejb, with a Remote interface called com.ibm.ws.eba.ejb.CustomerDetails, that is mapped to a JNDI name of ejb/CustomerDetails.

```
AdminTask.addCompUnit('[
  ...
  -EJBMappingsStep [
    [com.ibm.ws.eba.currencyService 1.0.0 ExchangeRate_ejb
      com.ibm.ws.eba.ejb.ExchangeRate Local ejb/ExchangeRate]
    [com.ibm.ws.eba.accountService 0.9.0 CustomerDetails_ejb
      com.ibm.ws.eba.ejb.CustomerDetails Remote ejb/CustomerDetails]]
  ...
]')
```

e. Map EJB references

For each EJB reference that is defined in either an ejb-jar.xml file, a web.xml file, or an @EJB annotation in the composition unit, you can specify the JNDI name by which the EJB reference is known in the runtime environment.

The Jython syntax for this aspect of the command is as follows.

Note: For composite bundles, the syntax is slightly different. See Step: Map EJB references in composite bundles

```
AdminTask.addCompUnit('[
  ...
  -EJBRefStep [
    [bundle_symbolic_name_1 bundle_version_1 uri_1
       ejb_reference_name_1 business_interface_1 jndi_name_1]
    [bundle_symbolic_name_2 bundle_version_2 uri_2
       ejb_reference_name_2 business_interface_2 jndi_name_2]]
  ...
]')
```

The *uri* parameter specifies the location where the EJB reference is defined.

In the following example, an EBA file contains two bundles, `com.ibm.ws.eba.currencyService` at version 1.0.0, and `com.ibm.ws.eba.accountService` at version 0.9.0. The currencyService bundle contains an EJB reference called `ExchangeRate`, from the `CurrencyExchange` enterprise bean, defined in `META-INF/ejb-jar.xml`, that is mapped to a JNDI name of `ejb:ExchangeRate`. The accountService bundle contains an EJB reference called `CustomerDetails`, defined in `web.xml`, that is mapped to a JNDI name of `ejb:CustomerDetails`.

```
AdminTask.addCompUnit('[
  ...
  -EJBRefStep [
    [com.ibm.ws.eba.currencyService 1.0.0 META-INF/ejb-jar.xml/CurrencyExchange
      ExchangeRate com.ibm.ws.eba.ejb.ExchangeRate ejb:ExchangeRate]
    [com.ibm.ws.eba.accountService 0.9.0 WEB-INF/web.xml
      CustomerDetails com.ibm.ws.eba.ejb.CustomerDetails ejb:CustomerDetails]]
  ...
]')
```

f. Map EJB resource references to resources

Binding a resource reference maps a resource dependency of an enterprise bean to an actual resource available in the server runtime environment. At a minimum, you can be achieve this mapping by specifying the JNDI name under which the resource reference is known in the runtime environment. By default, the JNDI name is retrieved from pre-existing bindings, or set to the value of the mapped-name specified in the resource reference definition. Use this option to bind resources of type resource-ref (resource reference), as defined in the Java specification JSR-250: Common Annotations for the Java Platform.

The Jython syntax for this aspect of the command is as follows.

Note: For composite bundles, the syntax is slightly different. See Step: Map EJB resource references to resources in composite bundles

```
AdminTask.addCompUnit('[
  ...
  -EJBResourceRefs [
    [
    bundle_symbolic_name
    bundle_version
    ejb_name
    resource_reference_id
    resource_type
    target_jndi_name
    resource_authentication_method
    mapping_properties
    extended_properties
    ]]
  ...
]')
```

The *mapping_properties* parameter defines arbitrary name and value pairs for extended data source properties, in the following format (one continuous string):

```
WebSphere:name=property_name1,value=property_value1,description=property_description1
+WebSphere:name=property_name2,value=property_value2,description=property_description2
+ ...
```

The *extended_properties* parameter defines extended data source custom properties in the following format (one continuous string):

```
property_name1=property_value1+property_name2=property_value2+ ...
```

For example:

```
AdminTask.addCompUnit('[
  ...
  -EJBResourceRefs [
    [com.ibm.ws.eba.currencyService 1.0.0 ExchangeRate
     dataSource1 javax.sql.DataSource ref/ds1 ClientContainer
     "WebSphere:name=mprop1,value=val1,description=desc1"
     "exprop1=expropval1+exprop2=expropval2"]
    [com.ibm.ws.eba.accountService 0.9.0 CustomerDetails
     dataSource2 javax.sql.DataSource ref/ds2 WSLogin "" ""]]
  ...
]')
```

g. Bind EJB message destination references to administered objects.

Binding a message destination reference or resource environment reference maps a resource dependency of an enterprise bean to an actual resource available in the server runtime environment. At a minimum, you can achieve this mapping by specifying the JNDI name under which the message destination reference or resource environment reference is known in the runtime environment. By default, the JNDI name is retrieved from pre-existing bindings, or set to the value of the mapped-name specified in the message destination reference definition. Use this option to bind resources of type message-destination-ref (message destination reference) or resource-env-ref (resource environment reference), as defined in the Java specification JSR-250: Common Annotations for the Java Platform.

The Jython syntax for this aspect of the command is as follows.

Note: For composite bundles, the syntax is slightly different. See Step: Bind EJB message destination references to administered objects in composite bundles.

```
AdminTask.addCompUnit('[
  ...
  -EJBMsgDestRefs [
    [
    bundle_symbolic_name
    bundle_version
    ejb_name
    resource_reference_id
    resource_type
    target_jndi_name
    ]]
  ...
]')
```

For example:

```
AdminTask.addCompUnit('[
  ...
  -EJBMsgDestRefs [
    [com.ibm.ws.eba.currencyService 1.0.0 ExchangeRate
     jms/myQ javax.jms.Queue jms/workQ]
    [com.ibm.ws.eba.accountService 0.9.0 CustomerDetails
     jms/myT javax.jms.Topic jms/notificationTopic]]
  ...
]')
```

h. Map virtual hosts for web modules.

You use a virtual host to associate a unique port with a web application. The aliases of a virtual host identify the port numbers defined for that virtual host. A port number specified in a virtual host

alias is used in the URL that is used to access artifacts such as servlets and JavaServer Page (JSP) files in a web application. For example, the alias `myhost:8080` is the *host_name:port_number* portion of the URL `http://myhost:8080/sample`.

Each WAB that is contained in a deployed asset must be mapped to a virtual host. WABs can be installed on the same virtual host, or dispersed among several virtual hosts.

If you specify an existing virtual host in the `ibm-web-bnd.xml` or `.xmi` file for a WAB, the specified virtual host is set by default. Otherwise, the default virtual host setting is `default_host`, which provides several port numbers through its aliases:

80 An internal, insecure port used when no port number is specified
9080 An internal port
9443 An external, secure port

Unless you want to isolate your WAB from other WABs or resources on the same node, `default_host` is a suitable virtual host. In addition to `default_host`, WebSphere Application Server provides `admin_host`, which is the virtual host for the administrative console system application. `admin_host` is on port 9060. Its secure port is 9043. Do not select `admin_host` unless the WAB relates to system administration.

The Jython syntax for this aspect of the command is as follows.

Note: For composite bundles, the syntax is slightly different. See Step: Map virtual hosts for web modules in composite bundles.

```
AdminTask.addCompUnit('[
  ...
  -VirtualHostMappingStep [
    [bundle_symbolic_name_1 bundle_version_1
    web_module_name_1 virtual_host_1]
    [bundle_symbolic_name_2 bundle_version_2
     web_module_name_2 virtual_host_2]]
  ...
]')
```

For example, for an EBA file containing two WABs (`com.ibm.ws.eba.helloWorldService.web` at version 1.0.0, which is to be mapped to `default_host`, and `com.ibm.ws.eba.helloWorldService.withContextRoot` at version 0.9.0, which is to be mapped to `test_host`), this aspect of the command is as follows:

```
AdminTask.addCompUnit('[
  ...
  -VirtualHostMappingStep [
    [com.ibm.ws.eba.helloWorldService.web 1.0.0
    "HelloWorld service" default_host]
    [com.ibm.ws.eba.helloWorldService.withContextRoot 0.9.0
    "HelloWorld second service" test_host]]
  ...
]')
```

i. Map security roles to users or groups.

The Jython syntax for this aspect of the command is as follows:

```
AdminTask.addCompUnit('[
  ...
  -MapRolesToUsersStep [
    [role_name everyone?
    all_authenticated_in_realm?
    usernames groups]]
  ...
]')
```

Key:

- *role_name* is a role name defined in the application.
- *everyone?* is set to `Yes` or `No`, to specify whether everyone is in the role.

- *all_authenticated_in_realm?* is set to `Yes` or `No`, to specify whether all authenticated users can access the application realm.
- *usernames* is a list of WebSphere Application Server user names, separated by the "|" character.
- *groups* is a list of WebSphere Application Server groups, separated by the "|" character.

Note: For *usernames*, and *groups*, the empty string "" means "use the default or existing value". The default value is usually that no users or groups are bound to the role. However, when an application contains an `ibm-application-bnd.xmi` file, the default value for *usernames* is obtained from this file. If you are deploying an application that contains an `ibm-application-bnd.xmi` file, and you want to remove the bound users, specify just the "|" character (which is the separator for multiple user names). This setting explicitly specifies "no users", and therefore guarantees that no users are bound to the role.

For example:

```
AdminTask.addCompUnit('[
  ...
  -MapRolesToUsersStep [
    [ROLE1 No Yes "" ""]
    [ROLE2 No No WABTestUser1 ""]
    [ROLE3 No No "" WABTestGroup1]
    [ROLE4 Yes No "" ""]]
  ...
]')
```

For more information about the -MapRolesToUsersStep option, see the information for the $AdminApp install command “MapRolesToUsers” option. This is the equivalent option for Java EE applications. For more general information, see Security role to user or group mapping.

j. Map RunAs roles to users

You can map a specified user identity and password to a RunAs role. This mapping enables you to specify application-specific privileges for individual users, so that they can run specific tasks using another user identity. The Jython syntax for this aspect of the command is as follows:

```
AdminTask.addCompUnit('[
  ...
  -MapRunAsRolesToUsersStep [
    [role_name user_name password]]
]')
```

For example:

```
AdminTask.addCompUnit('[
  ...
  -MapRunAsRolesToUsersStep [
    [Role1 User1 password1]
    [AdminRole User3 password3]]
]')
```

For more information about the -MapRunAsRolesToUsers option, see the information for the $AdminApp install command “MapRunAsRolesToUsers” option. This is the equivalent option for Java EE applications. For more general information, see Map RunAs roles to users.

k. Add authentication aliases to Blueprint resource references.

Blueprint components can access WebSphere Application Server resource references. Each reference is declared in a Blueprint XML file, and can be secured using a Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) authentication alias. Each bundle in an OSGi application can contain any number of resource reference declarations in its various Blueprint XML files.

When you secure resource references, those resource references can be bound only to JCA authentication aliases that exist on every server or cluster on which the application is deployed. An OSGi application can be deployed to multiple servers and clusters that are in the same security

domain. Therefore, each JCA authentication alias must exist in either the security domain of the target servers and clusters, or the global security domain.

You must declare the resource references in the Blueprint XML file. For example:

```
<blueprint xmlns="http://www.osgi.org/xmlns/blueprint/v1.0.0"
  xmlns:rr="http://www.ibm.com/appserver/schemas/8.0/blueprint/resourcereference">
  <!-- Other Blueprint declarations ... -->

  <rr:resource-reference id="resourceRef"
          interface="javax.sql.DataSource"
          filter="(osgi.jndi.service.name=jdbc/Account)">
    <rr:res-auth>Container</rr:res-auth>
    <rr:res-sharing-scope>Shareable</rr:res-sharing-scope>
  </rr:resource-reference>
</blueprint>
```

This declaration includes the resource reference ID (for example `resourceRef`), the service filter (for example `jdbc/Account`), the authentication type (for example `Container`), and the sharing setting (for example `Shareable`).

The Blueprint resource references to authentication alias bindings for each bundle are stored in a file `ibm-eba-bnd.xml` in the `META-INF` directory of that bundle. If an OSGi application contains any of these files when it is deployed as an asset, these files provide the default authentication alias values that are used when binding the resource references. For example:

```
<eba-bnd>
  <resource-ref>
    <jndi-name>jdbc/Acount</jndi-name>
    <authentication-alias>Alias1</authentication-alias>
    <interface>javax.sql.DataSource</interface>
    <authentication>Container</authentication>
    <sharing-scope>Shareable</sharing-scope>
    <id>resourceRef</id>
  </resource-ref>
</eba-bnd>
```

The Jython syntax for this aspect of the command is as follows.

Note: For composite bundles, the syntax is slightly different. See Step: Add authentication aliases to Blueprint resource references in composite bundles.

```
AdminTask.addCompUnit('[
  ...
  -BlueprintResourceRefBindingStep [
    [
    bundle_symbolic_name
    bundle_version
    blueprint_resource_reference_id
    interface_name
    jndi_name
    authentication_type
    sharing_setting
    authentication_alias_name
    ]]
  ...
]')
```

Note: The value for *jndi_name* must match the JNDI name that you declare in the **filter** attribute of the resource reference element in the Blueprint XML file.

For example, for an EBA file that contains a bundle `com.ibm.ws.eba.helloWorldService.properties.bundle.jar` at Version 1.0.0, which is to be bound to authentication alias `alias1`, the command is as follows:

```
AdminTask.addCompUnit('[
  ...
  -BlueprintResourceRefBindingStep[
```

```
    [com.ibm.ws.eba.helloWorldService.properties.bundle 1.0.0 resourceRef
    javax.sql.DataSource jdbc/Account Container Shareable alias1]]
  ...
]')
```

l. Bind web module message destination references to administered objects.

Binding a resource reference maps a resource dependency of the web application to an actual resource available in the server runtime environment. At a minimum, you can achieve this mapping by specifying the JNDI name under which the resource is known in the runtime environment. By default, the JNDI name is the resource ID that you specified in the `web.xml` file during development of the web application bundle (WAB). Use this option to bind resources of type message-destination-ref (message destination reference) or resource-env-ref (resource environment reference), as defined in the Java specification JSR-250: Common Annotations for the Java Platform.

The Jython syntax for this aspect of the command is as follows.

Note: For composite bundles, the syntax is slightly different. See Step: Bind web module message destination references to administered objects in composite bundles.

```
AdminTask.addCompUnit('[
  ...
  -WebModuleMsgDestRefs [
    [
    bundle_symbolic_name
    bundle_version
    resource_reference_id
    resource_type
    target_jndi_name
    ]]
  ...
]')
```

For example:

```
AdminTask.addCompUnit('[
  ...
  -WebModuleMsgDestRefs [
    [com.ibm.ws.eba.helloWorldService.web 1.0.0
    jms/myQ javax.jms.Queue
    jms/workQ]
    [com.ibm.ws.eba.helloWorldService.web 1.0.0
    jms/myT javax.jms.Topic
    jms/notificationTopic]]
  ...
]')
```

m. Map web module resource references to resources.

Binding a resource reference maps a resource dependency of the web application to an actual resource available in the server runtime environment. At a minimum, you can achieve this mapping by specifying the JNDI name under which the resource is known in the runtime environment. By default, the JNDI name is the resource ID that you specified in the `web.xml` file during development of the web application bundle (WAB). Use this option to bind resources of type resource-ref (resource reference), as defined in the Java specification JSR-250: Common Annotations for the Java Platform.

The Jython syntax for this aspect of the command is as follows.

Note: For composite bundles, the syntax is slightly different. See Step: Map web module resource references to resources in composite bundles.

```
AdminTask.addCompUnit('[
  ...
  -WebModuleResourceRefs [
    [
    bundle_symbolic_name
```

```
      bundle_version
      resource_reference_id
      resource_type
      target_jndi_name
      login_configuration
      login_properties
      extended_properties
      ]]
    ...
]')
```

For example:

```
AdminTask.addCompUnit('[
  ...
  -WebModuleResourceRefs [
    [com.ibm.ws.eba.helloWorldService.web 1.0.0
    jdbc/jtaDs javax.sql.DataSource
    jdbc/helloDs "" "" ""]
    [com.ibm.ws.eba.helloWorldService.web 1.0.0
    jdbc/nonJtaDs javax.sql.DataSource
    jdbc/helloDsNonJta "" "" "extprop1=extval1"]]
  ...
]')
```

Note: If you use multiple extended properties, the jython syntax is `"extprop1=extval1,extprop2=extval2"`.

In the following example, the jython syntax from the previous individual substeps is combined so that, by running the **addCompUnit** command once only, a composition unit is created and added to a business-level application.

Note: If your EBA asset includes or references composite bundles, the command syntax is slightly different. For an equivalent example, see Example: Using the **addCompUnit** command to add an EBA asset that includes composite bundles.

```
AdminTask.addCompUnit('[
  -blaID WebSphere:blaname=helloWorldService
  -cuSourceID WebSphere:assetname=com.ibm.ws.eba.helloWorldService.eba
  -CUOptions [
    [WebSphere:blaname=helloWorldService.eba
    WebSphere:assetname=com.ibm.ws.eba.helloWorldService.eba
    com.ibm.ws.eba.helloWorldService_0001.eba "" 1 false DEFAULT]]
  -MapTargets [[ebaDeploymentUnit WebSphere:cluster=cluster1]]
  -ActivationPlanOptions [[default ""]]
  -ContextRootStep [
    [com.ibm.ws.eba.helloWorldService.web 1.0.0 "/hello/web"]
    [com.ibm.ws.eba.helloWorldService.withContextRoot 0.9.0 "/hello/service"]]
  -EJBMappingsStep [
    [com.ibm.ws.eba.currencyService 1.0.0 ExchangeRate_ejb
      com.ibm.ws.eba.ejb.ExchangeRate Local ejb/ExchangeRate]
    [com.ibm.ws.eba.accountService 0.9.0 CustomerDetails_ejb
      com.ibm.ws.eba.ejb.CustomerDetails Remote ejb/CustomerDetails]]
  -EJBRefStep [
    [com.ibm.ws.eba.currencyService 1.0.0 META-INF/ejb-jar.xml/CurrencyExchange
      ExchangeRate com.ibm.ws.eba.ejb.ExchangeRate ejb:ExchangeRate]
    [com.ibm.ws.eba.accountService 0.9.0 WEB-INF/web.xml
      CustomerDetails com.ibm.ws.eba.ejb.CustomerDetails ejb:CustomerDetails]]
  -EJBResourceRefs [
    [com.ibm.ws.eba.currencyService 1.0.0 ExchangeRate
     dataSource1 javax.sql.DataSource ref/ds1 ClientContainer
     "WebSphere:name=mprop1,value=val1,description=desc1"
     "exprop1=expropval1+exprop2=expropval2"]
    [com.ibm.ws.eba.accountService 0.9.0 CustomerDetails
     dataSource2 javax.sql.DataSource ref/ds2 WSLogin "" ""]]
  -EJBMsgDestRefs [
```

```
    [com.ibm.ws.eba.currencyService 1.0.0 ExchangeRate
     jms/myQ javax.jms.Queue jms/workQ]
    [com.ibm.ws.eba.accountService 0.9.0 CustomerDetails
     jms/myT javax.jms.Topic jms/notificationTopic]]
  -VirtualHostMappingStep [
    [com.ibm.ws.eba.helloWorldService.web 1.0.0
    "HelloWorld service" default_host]
    [com.ibm.ws.eba.helloWorldService.withContextRoot 0.9.0
    "HelloWorld second service" test_host]]
  -MapRolesToUsersStep [
    [ROLE1 No Yes "" ""]
    [ROLE2 No No WABTestUser1 ""]
    [ROLE3 No No "" WABTestGroup1]
    [ROLE4 Yes No "" ""]]
  -MapRunAsRolesToUsersStep [
    [Role1 User1 password1]
    [AdminRole User3 password3]]
  -BlueprintResourceRefBindingStep[
    [com.ibm.ws.eba.helloWorldService.properties.bundle 1.0.0 resourceRef
    javax.sql.DataSource jdbc/Account
    Container Shareable alias1]]
  -WebModuleMsgDestRefs [
    [com.ibm.ws.eba.helloWorldService.web 1.0.0
    jms/myQ javax.jms.Queue
    jms/workQ]
    [com.ibm.ws.eba.helloWorldService.web 1.0.0
    jms/myT javax.jms.Topic
    jms/notificationTopic]]
  -WebModuleResourceRefs [
    [com.ibm.ws.eba.helloWorldService.web 1.0.0 jdbc/jtaDs javax.sql.DataSource
    jdbc/helloDs "" "" ""]
    [com.ibm.ws.eba.helloWorldService.web 1.0.0 jdbc/nonJtaDs javax.sql.DataSource
    jdbc/helloDsNonJta "" "" "extprop1=extval1"]]
]')
```

2. Configure the HTTP session manager.

   To configure the HTTP session manager, you use the **AdminConfig** commands to configure the deployed object represented by the *appDeploy* variable. Session management for OSGi applications is configured in the same way as for enterprise applications, except for a minor difference in syntax when getting the deployed object.

   a. Get the deployed object.

      Use the instructions given in Configuring applications for session management using scripting. Note that, for enterprise applications, you use the following two line script:

      ```
      deployments = AdminConfig.getid('/Deployment:myApp/')
      appDeploy = AdminConfig.showAttribute(deployments, 'deployedObject')
      ```

      For OSGi applications, the equivalent script is the following single line:

      ```
      appDeploy = AdminTask.getOSGiApplicationDeployedObject('-cuName cu_name')
      ```

      where *cu_name* is the name of the composition unit. For example:

      ```
      appDeploy = AdminTask.getOSGiApplicationDeployedObject('
        -cuName com.ibm.ws.eba.helloWorldService_0001.eba')
      ```

   b. Create the session management options.

      Use the instructions given in Configuring applications for session management using scripting. The command usage for creating the session management options is exactly the same for enterprise applications and OSGi applications.

What to do next

After using these commands, save your changes to the master configuration by using the following command:

```
AdminConfig.save()
```

Note: After you import the enterprise bundle archive (EBA) file for your OSGi application as an asset, you can update versions of existing bundles but you cannot add extra bundles to the asset. However, after you have added the asset as a composition unit to a business-level application, you can extend the business-level application by adding one or more composite bundles to the composition unit. See Adding or removing extensions for an OSGi composition unit using wsadmin commands.

You are now ready to start your business-level application.

Adding an EBA asset that includes composite bundles by using the addCompUnit command

You can use the **addCompUnit** command to add a composition unit that contains a previously-imported enterprise bundle archive (EBA) asset plus configuration information. If the EBA asset includes composite bundles, the command syntax is slightly different.

Before you begin

For a full description of how you specify this configuration information, see “Adding an EBA asset to a composition unit by using wsadmin commands” on page 2096. When you work through that task, each step where the syntax is different for composite bundles is linked to an equivalent step in this task.

About this task

An OSGi composition unit includes an EBA asset and some or all of the following configuration information:

- Mappings from the composition unit to a target application server, web server, or cluster.
- Configuration of the session manager, context roots or virtual hosts of the application.
- Mappings from enterprise beans to JNDI names.
- Bindings to any associated web applications or blueprint resource references.
- Mappings from security roles to particular users or groups.

For several of the elements, the values you specify include bundle identifiers. If your EBA asset includes or references composite bundles, the command syntax is slightly different. The differences for composite bundles are described in the following steps.

Procedure

- Map context root for web modules in composite bundles.

  The Jython syntax for this aspect of the command is as follows:

  ```
  AdminTask.addCompUnit('[
    ...
    -ContextRootStep [
      [bundle_symbolic_name_1 bundle_version_1 context_root_1]
      [bundle_symbolic_name_2 bundle_version_2 context_root_2]]
    ...
  ]')
  ```

  For composite bundles, the bundle symbolic name has the following syntax:

  ```
  CBA.symbolic.name_CBA.bundle.version/WAB.symbolic.name
  ```

  For example, for a composite bundle `com.ibm.ws.eba.helloWorldCBA` at version 1.0.0 that contains two WABs (`com.ibm.ws.eba.helloWorldService.web` at version 1.0.0, which is to be mapped to `/hello/web`,

and com.ibm.ws.eba.helloWorldService.withContextRoot at version 0.9.0, which is to be mapped to /hello/service), this aspect of the command is as follows:

```
AdminTask.addCompUnit('[
  ...
  -ContextRootStep [
    [com.ibm.ws.eba.helloWorldCBA_1.0.0/com.ibm.ws.eba.helloWorldService.web 1.0.0
    "/hello/web"]
    [com.ibm.ws.eba.helloWorldCBA_1.0.0/com.ibm.ws.eba.helloWorldService.withContextRoot 0.9.0
    "/hello/service"]]
  ...
]')
```

Note: For bundles other than composite bundles, the syntax is slightly different. See Step: Map context root for web modules.

- Bind listeners for message-driven beans in composite bundles

  The Jython syntax for this aspect of the command is as follows.

```
AdminTask.addCompUnit('[
  ...
  -MDBBindingsStep [
    [bundle_symbolic_name_1 bundle_version_1 uri_1
       activation_spec_1 destination_jndi_name_1 authentication_alias_1]
    [bundle_symbolic_name_2 bundle_version_2 uri_2
       activation_spec_2 destination_jndi_name_2 authentication_alias_2]]
  ...
]')
```

  For composite bundles, the bundle symbolic name has the following syntax:

```
CBA.symbolic.name_CBA.bundle.version/EJBbundle.symbolic.name
```

  In the following example, a composite bundle com.ibm.ws.eba.financeCBA, at version 1.0.0, contains two EJB bundles, com.ibm.ws.eba.currencyService at version 1.0.0, and com.ibm.ws.eba.accountService at version 0.9.0. The currencyService bundle contains a message-driven bean called ExchangeRateMDB, bound to an activation specification with a JNDI name of eis/ExchangeRate_Act_Spec; the destination JNDI name that is defined in the activation specification is overridden by a destination whose JNDI name is jms/ExchangeRateQueue, and the authentication alias that is defined in the activation specification is overridden by an authentication alias called ExchangeRate_Auth_Alias. The accountService bundle contains an MDB called CustomerDetailsMDB, bound to an activation specification with a JNDI name of eis/CustomerDetails_Act_Spec; the destination JNDI name that is defined in the activation specification is overridden by a destination whose JNDI name is jms/CustomerDetailsQueue, and the authentication alias that is defined in the activation specification is overridden by an authentication alias called CustomerDetails_Auth_Alias.

```
AdminTask.addCompUnit('[
  ...
  -MDBBindingsStep [
    [com.ibm.ws.eba.financeCBA_1.0.0/com.ibm.ws.eba.currencyService 1.0.0
     META-INF/ejb-jar.xml/ExchangeRateMDB eis/ExchangeRate_Act_Spec
     jms/ExchangeRateQueue ExchangeRate_Auth_Alias]
    [com.ibm.ws.eba.financeCBA_1.0.0/com.ibm.ws.eba.accountService 0.9.0
     META-INF/ejb-jar.xml/CustomerDetailsMDB eis/CustomerDetails_Act_Spec
     jms/CustomerDetailsQueue CustomerDetails_Auth_Alias]]
  ...
]')
```

Note: For bundles other than composite bundles, the syntax is slightly different. See Step: Bind listeners for message-driven beans

- Provide EJB JNDI names in composite bundles

  The Jython syntax for this aspect of the command is as follows.

```
AdminTask.addCompUnit('[
  ...
  -EJBMappingsStep [
    [bundle_symbolic_name_1 bundle_version_1 ejb_name_1
       ejb_interface_1 ejb_interface_type_1 jndi_name_1]
    [bundle_symbolic_name_2 bundle_version_2 ejb_name_2
       ejb_interface_2 ejb_interface_type_2 jndi_name_2]]
  ...
]')
```

For composite bundles, the bundle symbolic name has the following syntax:

```
CBA.symbolic.name_CBA.bundle.version/EJBbundle.symbolic.name
```

In the following example, a composite bundle `com.ibm.ws.eba.financeCBA`, at version 1.0.0, contains two EJB bundles, `com.ibm.ws.eba.currencyService` at version 1.0.0, and `com.ibm.ws.eba.accountService` at version 0.9.0. The currencyService bundle contains an enterprise bean called `ExchangeRate_ejb`, with a Local interface called `com.ibm.ws.eba.ejb.ExchangeRate`, that is mapped to a JNDI name of `ejb/ExchangeRate`. The accountService bundle contains an enterprise bean called `CustomerDetails_ejb`, with a Remote interface called `com.ibm.ws.eba.ejb.CustomerDetails`, that is mapped to a JNDI name of `ejb/CustomerDetails`.

```
AdminTask.addCompUnit('[
  ...
  -EJBMappingsStep [
    [com.ibm.ws.eba.financeCBA_1.0.0/com.ibm.ws.eba.currencyService 1.0.0 ExchangeRate_ejb
      com.ibm.ws.eba.ejb.ExchangeRate Local ejb/ExchangeRate]
    [com.ibm.ws.eba.financeCBA_1.0.0/com.ibm.ws.eba.accountService 0.9.0 CustomerDetails_ejb
      com.ibm.ws.eba.ejb.CustomerDetails Remote ejb/CustomerDetails]]
  ...
]')
```

Note: For bundles other than composite bundles, the syntax is slightly different. See Step: Provide EJB JNDI names

- Map EJB references in composite bundles

  The Jython syntax for this aspect of the command is as follows.

```
AdminTask.addCompUnit('[
  ...
  -EJBRefStep [
    [bundle_symbolic_name_1 bundle_version_1 uri_1
       ejb_reference_name_1 business_interface_1 jndi_name_1]
    [bundle_symbolic_name_2 bundle_version_2 uri_2
       ejb_reference_name_2 business_interface_2 jndi_name_2]]
  ...
]')
```

  The *uri* parameter specifies the location where the EJB reference is defined.

  For composite bundles, the bundle symbolic name has the following syntax:

```
CBA.symbolic.name_CBA.bundle.version/EJBbundle.symbolic.name
```

  In the following example, a composite bundle `com.ibm.ws.eba.financeCBA`, at version 1.0.0, contains two bundles, `com.ibm.ws.eba.currencyService` at version 1.0.0, and `com.ibm.ws.eba.accountService` at version 0.9.0. The currencyService bundle contains an EJB reference called `ExchangeRate`, from the `CurrencyExchange` enterprise bean, defined in `META-INF/ejb-jar.xml` that is mapped to a JNDI name of `ejb:ExchangeRate`. The accountService bundle contains an EJB reference called `CustomerDetails`, defined in `web.xml`, that is mapped to a JNDI name of `ejb:CustomerDetails`.

```
AdminTask.addCompUnit('[
  ...
  -EJBRefStep [
    [com.ibm.ws.eba.financeCBA_1.0.0/com.ibm.ws.eba.currencyService 1.0.0
```

```
      META-INF/ejb-jar.xml/CurrencyExchange ExchangeRate com.ibm.ws.eba.ejb.ExchangeRate
      ejb:ExchangeRate]
    [com.ibm.ws.eba.financeCBA_1.0.0/com.ibm.ws.eba.accountService 0.9.0
      WEB-INF/web.xml CustomerDetails com.ibm.ws.eba.ejb.CustomerDetails ejb:CustomerDetails]]
  ...
]')
```

Note: For bundles other than composite bundles, the syntax is slightly different. See Step: Map EJB references

- Map EJB resource references to resources in composite bundles

  The Jython syntax for this aspect of the command is as follows

```
AdminTask.addCompUnit('[
  ...
  -EJBResourceRefs [
    [
    bundle_symbolic_name
    bundle_version
    ejb_name
    resource_reference_id
    resource_type
    target_jndi_name
    resource_authentication_method
    mapping_properties
    extended_properties
    ]]
  ...
]')
```

  The *mapping_properties* parameter defines arbitrary name and value pairs for extended data source properties, in the following format (one continuous string):

```
WebSphere:name=property_name1,value=property_value1,description=property_description1
+WebSphere:name=property_name2,value=property_value2,description=property_description2
+ ...
```

  The *extended_properties* parameter defines extended data source custom properties in the following format (one continuous string):

```
property_name1=property_value1+property_name2=property_value2+ ...
```

  For composite bundles, the bundle symbolic name has the following syntax:

```
CBA.symbolic.name_CBA.bundle.version/EJBBundle.symbolic.name
```

  For example:

```
AdminTask.addCompUnit('[
  ...
  -EJBResourceRefs [
    [com.ibm.ws.eba.financeCBA_1.0.0/com.ibm.ws.eba.currencyService 1.0.0
     ExchangeRate dataSource1 javax.sql.DataSource ref/ds1 ClientContainer
     "WebSphere:name=mprop1,value=val1,description=desc1"
     "exprop1=expropval1+exprop2=expropval2"]
    [com.ibm.ws.eba.financeCBA_1.0.0/com.ibm.ws.eba.accountService 0.9.0
     CustomerDetails dataSource2 javax.sql.DataSource ref/ds2 WSLogin "" ""]]
  ...
]')
```

Note: For bundles other than composite bundles, the syntax is slightly different. See Step: Map EJB resource references to resources

- Bind EJB message destination references to administered objects in composite bundles.

  The Jython syntax for this aspect of the command is as follows

```
AdminTask.addCompUnit('[
  ...
  -EJBMsgDestRefs [
```

```
    [
    bundle_symbolic_name
    bundle_version
    ejb_name
    resource_reference_id
    resource_type
    target_jndi_name
    ]]
  ...
]')
```

For composite bundles, the bundle symbolic name has the following syntax:

```
CBA.symbolic.name_CBA.bundle.version/EJBBundle.symbolic.name
```

For example:

```
AdminTask.addCompUnit('[
  ...
  -EJBMsgDestRefs [
    [com.ibm.ws.eba.financeCBA_1.0.0/com.ibm.ws.eba.currencyService 1.0.0
     ExchangeRate jms/myQ javax.jms.Queue jms/workQ]
    [com.ibm.ws.eba.financeCBA_1.0.0/com.ibm.ws.eba.accountService 0.9.0
     CustomerDetails jms/myT javax.jms.Topic jms/notificationTopic]]
  ...
]')
```

Note: For bundles other than composite bundles, the syntax is slightly different. See Step: Bind EJB message destination references to administered objects.

- Map virtual hosts for web modules in composite bundles.

  The Jython syntax for this aspect of the command is as follows:

```
AdminTask.addCompUnit('[
  ...
  -VirtualHostMappingStep [
    [bundle_symbolic_name_1 bundle_version_1
    web_module_name_1 virtual_host_1]
    [bundle_symbolic_name_2 bundle_version_2
     web_module_name_2 virtual_host_2]]
  ...
]')
```

  For composite bundles, the bundle symbolic name has the following syntax:

```
CBA.symbolic.name_CBA.bundle.version/WAB.symbolic.name
```

  For example, for a composite bundle `com.ibm.ws.eba.helloWorldCBA` at version 1.0.0 that contains two WABs (`com.ibm.ws.eba.helloWorldService.web` at version 1.0.0, which is to be mapped to `default_host`, and `com.ibm.ws.eba.helloWorldService.withContextRoot` at version 0.9.0, which is to be mapped to `test_host`), this aspect of the command is as follows:

```
AdminTask.addCompUnit('[
  ...
  -VirtualHostMappingStep [
    [com.ibm.ws.eba.helloWorldCBA_1.0.0/com.ibm.ws.eba.helloWorldService.web
    1.0.0 "HelloWorld service" default_host]
    [com.ibm.ws.eba.helloWorldCBA_1.0.0/com.ibm.ws.eba.helloWorldService.withContextRoot
    0.9.0 "HelloWorld second service" test_host]]
  ...
]')
```

  Note: For bundles other than composite bundles, the syntax is slightly different. See Step: Map virtual hosts for web modules.

- Add authentication aliases to Blueprint resource references in composite bundles.

  The Jython syntax for this aspect of the command is as follows.

```
AdminTask.addCompUnit('[
  ...
  -BlueprintResourceRefBindingStep [
    [
    bundle_symbolic_name
    bundle_version
    blueprint_resource_reference_id
    interface_name
    jndi_name
    authentication_type
    sharing_setting
    authentication_alias_name
    ]]
  ...
]')
```

Notes:

- For composite bundles, the bundle symbolic name has the following syntax:

  `CBA.symbolic.name_CBA.bundle.version/embedded_bundle.symbolic.name`
- The value for *jndi_name* must match the JNDI name that you declare in the **filter** attribute of the resource reference element in the Blueprint XML file.

For example, for a composite bundle `com.ibm.ws.eba.helloWorldCBA` at version 1.0.0 that contains a bundle `com.ibm.ws.eba.helloWorldService.properties.bundle.jar` at Version 1.0.0, which is to be bound to authentication alias `alias1`, the command is as follows:

```
AdminTask.addCompUnit('[
  ...
  -BlueprintResourceRefBindingStep[
    [com.ibm.ws.eba.helloWorldCBA_1.0.0/com.ibm.ws.eba.helloWorldService.properties.bundle
    1.0.0 resourceRef javax.sql.DataSource jdbc/Account Container Shareable alias1]]
  ...
]')
```

Note: For bundles other than composite bundles, the syntax is slightly different. See Step: Add authentication aliases to Blueprint resource references.

- Bind web module message destination references to administered objects in composite bundles.

  The Jython syntax for this aspect of the command is as follows

```
AdminTask.addCompUnit('[
  ...
  -WebModuleMsgDestRefs [
    [
    bundle_symbolic_name
    bundle_version
    resource_reference_id
    resource_type
    target_jndi_name
    ]]
  ...
]')
```

  For composite bundles, the bundle symbolic name has the following syntax:

  `CBA.symbolic.name_CBA.bundle.version/WAB.symbolic.name`

  For example:

```
AdminTask.addCompUnit('[
  ...
  -WebModuleMsgDestRefs [
    [com.ibm.ws.eba.helloWorldCBA_1.0.0/com.ibm.ws.eba.helloWorldService.web
    1.0.0
    jms/myQ javax.jms.Queue
    jms/workQ]
```

```
    [com.ibm.ws.eba.helloWorldCBA_1.0.0/com.ibm.ws.eba.helloWorldService.web
    1.0.0
    jms/myT javax.jms.Topic
    jms/notificationTopic]]
  ...
]')
```

Note: For bundles other than composite bundles, the syntax is slightly different. See Step: Bind web module message destination references to administered objects.

- Map web module resource references to resources in composite bundles.

  The Jython syntax for this aspect of the command is as follows.

```
AdminTask.addCompUnit('[
  ...
  -WebModuleResourceRefs [
    [
    bundle_symbolic_name
    bundle_version
    resource_reference_id
    resource_type
    target_jndi_name
    login_configuration
    login_properties
    extended_properties
    ]]
  ...
]')
```

  For composite bundles, the bundle symbolic name has the following syntax:

```
CBA.symbolic.name_CBA.bundle.version/WAB.symbolic.name
```

  For example:

```
AdminTask.addCompUnit('[
  ...
  -WebModuleResourceRefs [
    [com.ibm.ws.eba.helloWorldCBA_1.0.0/com.ibm.ws.eba.helloWorldService.web
    1.0.0
    jdbc/jtaDs javax.sql.DataSource
    jdbc/helloDs "" "" ""]
    [com.ibm.ws.eba.helloWorldCBA_1.0.0/com.ibm.ws.eba.helloWorldService.web
    1.0.0
    jdbc/nonJtaDs javax.sql.DataSource
    jdbc/helloDsNonJta "" "" "extprop1=extval1"]]
  ...
]')
```

  Notes:

  – If you use multiple extended properties, the jython syntax is `"extprop1=extval1,extprop2=extval2"`.

  – For bundles other than composite bundles, the syntax is slightly different. See Step: Map web module resource references to resources.

Example

In the following example, the jython syntax from the previous steps is combined with the additional steps described in “Adding an EBA asset to a composition unit by using wsadmin commands” on page 2096 so that, by running the **addCompUnit** command once only, a composition unit is created and added to a business-level application. In the example, an EBA file `com.ibm.ws.eba.helloWorldService.eba` contains a composite bundle with symbolic name `com.ibm.ws.eba.helloWorldCBA`, at version `1.0.0`. This composite bundle contains two WABs:

- `com.ibm.ws.eba.helloWorldService.web`, at version 1.0.0

- com.ibm.ws.eba.helloWorldService.withContextRoot, at version 0.9.0

The composite bundle also contains a bundle with symbolic name com.ibm.ws.eba.helloWorldService.properties.bundle, at version 1.0.0.

```
AdminTask.addCompUnit('[
  -blaID WebSphere:blaname=helloWorldService
  -cuSourceID WebSphere:assetname=com.ibm.ws.eba.helloWorldService.eba
  -CUOptions [
    [WebSphere:blaname=helloWorldService.eba
    WebSphere:assetname=com.ibm.ws.eba.helloWorldService.eba
    com.ibm.ws.eba.helloWorldService_0001.eba "" 1 false DEFAULT]]
  -MapTargets [[ebaDeploymentUnit WebSphere:cluster=cluster1]]
  -ActivationPlanOptions [[default ""]]
  -ContextRootStep [
    [com.ibm.ws.eba.helloWorldCBA_1.0.0/com.ibm.ws.eba.helloWorldService.web 1.0.0
    "/hello/web"]
    [com.ibm.ws.eba.helloWorldCBA_1.0.0/com.ibm.ws.eba.helloWorldService.withContextRoot 0.9.0
    "/hello/service"]]
  -EJBMappingsStep [
    [com.ibm.ws.eba.financeCBA_1.0.0/com.ibm.ws.eba.currencyService 1.0.0 ExchangeRate_ejb
      com.ibm.ws.eba.ejb.ExchangeRate Local ejb/ExchangeRate]
    [com.ibm.ws.eba.financeCBA_1.0.0/com.ibm.ws.eba.accountService 0.9.0 CustomerDetails_ejb
      com.ibm.ws.eba.ejb.CustomerDetails Remote ejb/CustomerDetails]]
  -EJBRefStep [
    [com.ibm.ws.eba.financeCBA_1.0.0/com.ibm.ws.eba.currencyService 1.0.0
      META-INF/ejb-jar.xml/CurrencyExchange ExchangeRate com.ibm.ws.eba.ejb.ExchangeRate
      ejb:ExchangeRate]
    [com.ibm.ws.eba.financeCBA_1.0.0/com.ibm.ws.eba.accountService 0.9.0
      WEB-INF/web.xml CustomerDetails com.ibm.ws.eba.ejb.CustomerDetails ejb:CustomerDetails]]
  -EJBResourceRefs [
    [com.ibm.ws.eba.financeCBA_1.0.0/com.ibm.ws.eba.currencyService 1.0.0
     ExchangeRate dataSource1 javax.sql.DataSource ref/ds1 ClientContainer
     "WebSphere:name=mprop1,value=val1,description=desc1"
     "exprop1=expropval1+exprop2=expropval2"]
    [com.ibm.ws.eba.financeCBA_1.0.0/com.ibm.ws.eba.accountService 0.9.0
     CustomerDetails dataSource2 javax.sql.DataSource ref/ds2 WSLogin "" ""]]
  -EJBMsgDestRefs [
    [com.ibm.ws.eba.financeCBA_1.0.0/com.ibm.ws.eba.currencyService 1.0.0
     ExchangeRate jms/myQ javax.jms.Queue jms/workQ]

     CustomerDetails jms/myT javax.jms.Topic jms/notificationTopic]]
  -VirtualHostMappingStep [
    [com.ibm.ws.eba.helloWorldCBA_1.0.0/com.ibm.ws.eba.helloWorldService.web
    1.0.0 "HelloWorld service" default_host]
    [com.ibm.ws.eba.helloWorldCBA_1.0.0/com.ibm.ws.eba.helloWorldService.withContextRoot
    0.9.0 "HelloWorld second service" test_host]]
  -MapRolesToUsersStep [
    [ROLE1 No Yes "" ""]
    [ROLE2 No No WABTestUser1 ""]
    [ROLE3 No No "" WABTestGroup1]
    [ROLE4 Yes No "" ""]]
  -MapRunAsRolesToUsersStep [
    [Role1 User1 password1]
    [AdminRole User3 password3]]
  -BlueprintResourceRefBindingStep[
    [com.ibm.ws.eba.helloWorldCBA_1.0.0/com.ibm.ws.eba.helloWorldService.properties.bundle
    1.0.0 resourceRef javax.sql.DataSource jdbc/Account Container Shareable alias1]]
  -WebModuleMsgDestRefs [
    [com.ibm.ws.eba.helloWorldCBA_1.0.0/com.ibm.ws.eba.helloWorldService.web
    1.0.0
    jms/myQ javax.jms.Queue
    jms/workQ]
    [com.ibm.ws.eba.helloWorldCBA_1.0.0/com.ibm.ws.eba.helloWorldService.web
```

```
    1.0.0
    jms/myT javax.jms.Topic
    jms/notificationTopic]]
  -WebModuleResourceRefs [
    [com.ibm.ws.eba.helloWorldCBA_1.0.0/com.ibm.ws.eba.helloWorldService.web
    1.0.0
    jdbc/jtaDs javax.sql.DataSource
    jdbc/helloDs "" "" ""]
    [com.ibm.ws.eba.helloWorldCBA_1.0.0/com.ibm.ws.eba.helloWorldService.web
    1.0.0
    jdbc/nonJtaDs javax.sql.DataSource
    jdbc/helloDsNonJta "" "" "extprop1=extval1"]]
]')
```

Debugging bundles at run time

You can explore or debug the bundles associated with a specific OSGi application or shared bundle framework by using either the WebSphere Application Server administrative console or the wsadmin-based OSGi Applications command-line console.

Debugging bundles at run time by using the WebSphere Application Server administrative console

The WebSphere Application Server administrative console provides panels that you can use to explore or debug a specific set of bundles running on an application server.

You can explore or debug bundles by interrogating the contents of OSGi *frameworks*. A framework contains a collection of bundles, together with the packages and services associated with the bundles. There are two types of framework:

Isolated framework
: An isolated framework contains the bundles that are defined exclusively for a specific application; each OSGi application runs in its own isolated framework. In a network deployment environment, there is one isolated framework for each server on which the application is installed. If an application includes one or more composite bundles, either as part of the application, or as an extension to the application, there is a separate isolated framework for each composite bundle.

Share bundle framework
: There is a shared bundle framework per server, containing all the shared bundles that are available to the applications that are installed on that server. If the applications indirectly reference one or more composite bundles through package dependencies, there is a shared bundle framework for each composite bundle.

You can find the state of the bundles in a framework, and see which bundles import or export certain packages, or which bundles register or consume a particular service. You can also see the values of the headers in the bundle manifest files.

You can navigate trails through bundles, packages, and services. For example, you might navigate the following trail:

1. Select a package.
2. See which bundle exports this package.
3. Find out the services that this bundle registers.
4. Find out which other bundles consume each of these services.
5. Explore the details of each of these bundles.

The panels have a breadcrumb trail that shows you where you are in a trail, and allows you to retrace the steps that you have taken through the trail.

Note: You can view the frameworks for an application only if the application has been started. If the application fails to start, the link to access the framework panels is not available.

The following sections describe all the panels, and the administrative console commands that you can use to display them.

Application OSGi frameworks

This panel lists all the OSGi frameworks that are associated with a given application.

To view this panel in the administrative console, click the following path:

Applications > **Application Types** > **Business-level applications** > ***application_name*** > ***composition_unit_name*** > **[Additional Properties] OSGi application console**

For details of the information that is displayed in this panel, see Application OSGi frameworks [Collection].

Bundles in OSGi framework

This panel lists all the bundles in a given OSGi framework.

To view this panel in the administrative console, click one of the following paths:

- **Applications** > **Application Types** > **Business-level applications** > ***application_name*** > ***composition_unit_name*** > **[Additional Properties] OSGi application console** > ***framework_name***
- From the Packages in OSGi framework [Collection] page, or the Services in OSGi framework [Collection] page, click **Framework bundles**.

For details of the information that is displayed in this panel, see Bundles in OSGi framework [Collection].

Packages in OSGi framework

This panel lists all the packages in a given OSGi framework.

To view this panel in the administrative console, click one of the following paths:

- **Applications** > **Application Types** > **Business-level applications** > ***application_name*** > ***composition_unit_name*** > **[Additional Properties] OSGi application console** > ***framework_name*** > **Framework packages**
- From the Bundles in OSGi framework [Collection] page, or the Services in OSGi framework [Collection] page, click **Framework packages**.

For details of the information that is displayed in this panel, see Packages in OSGi framework [Collection].

Services in OSGi framework

This panel lists all the services in a given OSGi framework.

To view this panel in the administrative console, click one of the following paths:

- **Applications** > **Application Types** > **Business-level applications** > ***application_name*** > ***composition_unit_name*** > **[Additional Properties] OSGi application console** > ***framework_name*** > **Framework services**
- From the Packages in OSGi framework [Collection] page, or the Bundles in OSGi framework [Collection] page, click **Framework services**.

For details of the information that is displayed in this panel, see Services in OSGi framework [Collection].

Packages in bundle

This panel lists all the imported packages and exported packages for a given OSGi bundle.

To view this panel in the administrative console, click one of the following paths:

- **Applications** > **Application Types** > **Business-level applications** > ***application_name*** > ***composition_unit_name*** > **[Additional Properties] OSGi application console** > ***framework_name*** > ***bundle_name*** > **Bundle packages**
- From the Packages in OSGi framework [Collection] page, or the Services in OSGi framework [Collection] page, click **Framework bundles** > ***bundle_name*** > **Bundle packages**.

For details of the information that is displayed in this panel, see Packages in bundle [Collection].

Services in bundle

This panel lists all the services that are registered, and all the services that are consumed, by a given OSGi bundle.

To view this panel in the administrative console, click one of the following paths:

- **Applications** > **Application Types** > **Business-level applications** > ***application_name*** > ***composition_unit_name*** > **[Additional Properties] OSGi application console** > ***framework_name*** > ***bundle_name*** > **Bundle services**
- From the Packages in OSGi framework [Collection] page, or the Bundles in OSGi framework [Collection] page, click **Framework bundles** > ***bundle_name*** > **Bundle services**.

For details of the information that is displayed in this panel, see Services in bundle [Collection].

Bundle details

This panel displays the details of a given bundle, including identification information, the values of headers in the bundle manifest file, and bundle dependencies.

To view this panel in the administrative console, click one of the following paths:

- **Applications** > **Application Types** > **Business-level applications** > ***application_name*** > ***composition_unit_name*** > **[Additional Properties] OSGi application console** > ***framework_name*** > ***bundle_name***
- From the Packages in OSGi framework [Collection] page, or the Services in OSGi framework [Collection] page, click **Framework bundles** > ***bundle_name***.

For details of the information that is displayed in this panel, see Bundle details [Settings].

Package details

This panel displays the details of a given package, including identification information, and the bundles that export and import the package.

To view this panel in the administrative console, click one of the following paths:

- **Applications** > **Application Types** > **Business-level applications** > ***application_name*** > ***composition_unit_name*** > **[Additional Properties] OSGi application console** > ***framework_name*** > **Framework packages** > ***package_name***
- From the Bundles in OSGi framework [Collection] page, or the Services in OSGi framework [Collection] page, click **Framework packages** > ***package_name***.
- From the Bundle details [Settings] page, click **Bundle packages** > ***package_name***.

For details of the information that is displayed in this panel, see Package details [Settings].

Service details

This panel displays the details of a given service, including identification information, the service interfaces, the bundles that have registered or that use the service, and the service properties.

To view this panel in the administrative console, click one of the following paths:

- **Applications** > **Application Types** > **Business-level applications** > ***application_name*** > ***composition_unit_name*** > **[Additional Properties] OSGi application console** > ***framework_name*** > **Framework services** > ***service_identifier***
- From the Packages in OSGi framework [Collection] page, or the Bundles in OSGi framework [Collection] page, click **Framework services** > ***service_identifier***.
- From the Bundle details [Settings] page, click **Bundle services** > ***service_identifier***.

For details of the information that is displayed in this panel, see Service details [Settings].

Debugging bundles at run time by using the command-line console

The OSGi Applications command-line console is a set of wsadmin commands that you can use to explore or debug a specific set of bundles running on an application server. As an aid to debugging applications in a test environment, the console also includes commands to start and stop bundles.

About this task

You can explore or debug bundles by interrogating the contents of OSGi *frameworks*. A framework contains a collection of bundles, together with the packages and services associated with the bundles. There are two types of framework:

Isolated framework
: An isolated framework contains the bundles that are defined exclusively for a specific application; each OSGi application runs in its own isolated framework. In a network deployment environment, there is one isolated framework for each server on which the application is installed. If an application includes one or more composite bundles, either as part of the application, or as an extension to the application, there is a separate isolated framework for each composite bundle.

Share bundle framework
: There is a shared bundle framework per server, containing all the shared bundles that are available to the applications that are installed on that server. If the applications indirectly reference one or more composite bundles through package dependencies, there is a shared bundle framework for each composite bundle.

To work with a framework that is currently running, you first connect to the framework.

Procedure

1. Start the OSGi Applications command-line console.

   At a command prompt, run the `osgiApplicationConsole.bat` command (for Windows systems) or the `osgiApplicationConsole.sh` command (for Linux systems). You can run this command from the *`app_server_root`*`/bin` directory or from any *`profile_root`*`/bin` directory. The command takes the following optional parameters:

   -h The host name of the target machine. For example, `machine1.hursley.ibm.com`.

   -o The port number of the SOAP port of the target server. For example, `8880`.

   -u The user ID, if the wsadmin connection is secured.

   -p The password, if the wsadmin connection is secured.

For example:

```
app_server_root/bin/osgiApplicationConsole -h machine1.hursley.ibm.com -o 8880
```

The wsadmin command prompt is displayed. This instance of wsadmin recognizes OSGi Applications console commands.

2. Connect to an available framework.

   You use the **connect** command to connect to a specific framework.

   If you know the framework name and version number, and the node and server on which the framework is running, you can use this information to connect. For example:

   ```
   wsadmin>connect("com.ibm.ws.eba.helloWorldService.eba", "1.0.0", "wasNode1", "server1")
   ```

   Alternatively, use the **list** command to list all available frameworks and to provide a unique ID for each framework, then use this ID to connect. For example:

   a. List all available frameworks:

      ```
      wsadmin>list()
      ```

      If you are connecting to an individual application server, this command might generate the following system response:

      ```
      ID   Bundle                                Version  Node      Server
      0    SharedBundles                         7.0.0    wasNode1  server1
      1    com.ibm.ws.eba.helloWorldService.eba  1.0.0    wasNode1  server1
      2    com.ibm.ws.eba.obr.fep.eba5.eba       1.0.0    wasNode1  server1
      3    com.ibm.ws.eba.wab.componenttest      1.0.0    wasNode1  server1
      ```

   b. Connect to the com.ibm.ws.eba.helloWorldService.eba framework:

      ```
      wsadmin>connect(1)
      ```

      If the command completes successfully it generates the following system responses:

      ```
      CWSAJ0035I: Connecting to framework com.ibm.ws.eba.helloWorldService.eba_1.0.0
      on node wasNode1 and server server1.
      CWSAJ0036I: Successfully connected to framework com.ibm.ws.eba.helloWorldService.eba_1.0.0.
      ```

   To connect to a different framework, run the **connect** command again. You do not need to disconnect from one framework before connecting to another framework.

3. Work with the connected framework.

   Use one or more of the following commands to work with the framework to which you are connected:

   - List all available frameworks, and indicate the currently connected framework.

     Use the **list** command:

     ```
     wsadmin>list()
     ```

     This command might generate the following system response:

     ```
     ID   Bundle                                Version  Node      Server
     0    SharedBundles                         7.0.0    wasNode1  server1
     1    com.ibm.ws.eba.helloWorldService.eba  1.0.0    wasNode1  server1  <== Connected
     2    com.ibm.ws.eba.obr.fep.eba5.eba       1.0.0    wasNode1  server1
     3    com.ibm.ws.eba.wab.componenttest      1.0.0    wasNode1  server1
     ```

   - Display summary information about each of the bundles in the framework.

     Use the **ss** command:

     ```
     wsadmin>ss()
     ```

     Note: “ss” stands for “short status”.
     This command might generate the following system response:

     ```
     ID      State       Bundle
     0       ACTIVE      org.eclipse.osgi_3.6.1.R36x_v20100806
     1       ACTIVE      com.ibm.samples.websphere.osgi.blog.app_1.0.0
     2       ACTIVE      com.ibm.samples.websphere.osgi.blog_1.0.0
     ```

```
3       ACTIVE      com.ibm.samples.websphere.osgi.blog.persistence_1.0.0
4       ACTIVE      com.ibm.samples.websphere.osgi.blog.web_1.0.0
5       ACTIVE      com.ibm.samples.websphere.osgi.blog.api_1.0.0
```

- Display comprehensive information about all of the bundles in the framework, and the services that they register or consume.

  Use the **bundles** command:

  ```
  wsadmin>bundles()
  ```

  This command might generate the following system response.

  Note: Information about the bundles that you included in your application is listed as bundle 2 and subsequent bundles. Bundles 0 and 1 are system artifacts; do not modify or rely on these bundles. Although the detail for bundle 0 is not shown in the following example, this bundle typically generates much more information than the other bundles.

```

- Display comprehensive information about a given bundle in the framework.

  Use the **bundle** command. Specify the ID of the bundle that you want to examine. The bundle ID values are one of the outputs of the **ss** command.

  This command lists the information associated with the specified bundle. For example the bundle symbolic name, the bundle version, the services that the bundle registers, the services that are consumed by the bundle, and whether the bundle is a fragment or a host bundle.

  For example:

  ```
  wsadmin>bundle(3)
  ```

  This command might generate the following system response:

  ```
  com.ibm.samples.websphere.osgi.blog.persistence_1.0.0 [3]
    Id=3, Status=ACTIVE
  Location=reference:file:/C:/IBM/WebSphere/AppServer/profiles/profile01/

      org.eclipse.osgi_3.6.1.R36x_v20100806 [0]
      com.ibm.samples.websphere.osgi.blog.api_1.0.0 [5]
  ```

- Display header information about a given bundle.

Use the **headers** command. Specify the ID of the bundle that you want to examine. The bundle ID values are one of the outputs of the **ss** command.

For example:

```
wsadmin>headers(2)
```

This command might generate the following system response:

```
Ant-Version = Apache Ant 1.7.1
Bundle-ActivationPolicy = lazy
Bundle-ManifestVersion = 2
Bundle-Name = Blog Core Services Bundle
Bundle-SymbolicName = com.ibm.samples.websphere.osgi.blog
Bundle-Vendor = IBM
Bundle-Version = 1.0.0
Created-By = 2.4 (Your Corporation)
Import-Package = com.ibm.samples.websphere.osgi.logging;version="[1.0.0,1.1.0)",
com.ibm.samples.websphere.osgi.blog.api;version="[1.0.0,1.1.0)",
com.ibm.samples.websphere.osgi.blog.comment.persistence.api;version="[1.0.0,1.1.0)",
com.ibm.samples.websphere.osgi.blog.persistence.api;version="[1.0.0,1.1.0)"
Manifest-Version = 1.0
```

- Display information about the packages that are imported or exported by the framework.

  Use the **packages** command. Optionally, specify either or both of the following parameters to select a particular package or subset of packages:

  bundle ID
  Display information about the exported packages for this bundle.

  The bundle ID values are one of the outputs of the **ss** command.

  package name
  Display information about the specified package.

  Command syntax:

  ```
  wsadmin>packages()
  wsadmin>packages(bundle_id)
  wsadmin>packages(package_name)
  ```

  Example using a bundle ID:

  ```
  wsadmin>packages(5)
  ```

  This command might generate the following system response:

  ```
  com.ibm.samples.websphere.osgi.blog.persistence.api; version="1.0.0"
  <com.ibm.samples.websphere.osgi.blog.api_1.0.0 [5]>
    com.ibm.samples.websphere.osgi.blog_1.0.0 [2] imports
    com.ibm.samples.websphere.osgi.blog.persistence_1.0.0 [3] imports
  com.ibm.samples.websphere.osgi.blog.comment.persistence.api; version="1.0.0"
  <com.ibm.samples.websphere.osgi.blog.api_1.0.0 [5]>
    com.ibm.samples.websphere.osgi.blog_1.0.0 [2] imports
  com.ibm.samples.websphere.osgi.blog.api; version="1.0.0"
  <com.ibm.samples.websphere.osgi.blog.api_1.0.0 [5]>
    com.ibm.samples.websphere.osgi.blog_1.0.0 [2] imports
    com.ibm.samples.websphere.osgi.blog.web_1.0.0 [4] imports
  ```

  Example using a package name:

  ```
  wsadmin>packages("com.ibm.samples.websphere.osgi.blog.comment.persistence.api")
  ```

  This command might generate the following system response:

  ```
  com.ibm.samples.websphere.osgi.blog.comment.persistence.api; version="1.0.0"
  <com.ibm.samples.websphere.osgi.blog.api_1.0.0 [5]>
    com.ibm.samples.websphere.osgi.blog_1.0.0 [2] imports
  ```

- Display information about the services that are currently registered by the framework. For each service this information includes the service interfaces, the bundle that registered the service, and any bundles that consume the service.

Use the **services** command. Optionally, specify either or both of the following parameters to select a particular service or subset of services:

service ID
Display information about a specified service.

filter
Display information about all services that match the filter.

The filter must comply with the OSGi filter format as defined in section 3.2.7 of the OSGi Service Platform Release 4 Version 4.2 Core Specification.

Command syntax:

```
wsadmin>services()
wsadmin>services(service_id)
wsadmin>services("(&(prop1=value_1)(prop2=value_2))")
```

Example using a service ID:

```
wsadmin>services(2)
```

This command might generate the following system response:

```
{org.osgi.service.packageadmin.PackageAdmin}={service.id=2,
service.ranking=2147483647,service.vendor=Eclipse.org - Equinox,
service.pid=0.org.eclipse.osgi.framework.internal.core.PackageAdminImpl}
  Registered by bundle: org.eclipse.osgi_3.6.1.R36x_v20100806 [0]
  Bundles using service:
    org.eclipse.osgi_3.6.1.R36x_v20100806 [0]
```

Example using a single property filter:

```
wsadmin>services("(objectClass=org.osgi.service.packageadmin.PackageAdmin)")
```

This command might generate the following system response:

```
{org.osgi.service.packageadmin.PackageAdmin}={service.id=2,
service.ranking=2147483647,service.vendor=Eclipse.org - Equinox,
service.pid=0.org.eclipse.osgi.framework.internal.core.PackageAdminImpl}
  Registered by bundle: org.eclipse.osgi_3.6.1.R36x_v20100806 [0]
  Bundles using service:
    org.eclipse.osgi_3.6.1.R36x_v20100806 [0]
```

Example using a multiple property filter:

```
wsadmin>services("(&(objectClass=javax.resource.Referenceable)(ibm.private.jndi.object=true))")
```

This command might generate the following system response:

```
{java.lang.reflect.InvocationHandler,com.ibm.websphere.rsadapter.WSDataSource,java.sql.Wrapper,
javax.sql.CommonDataSource,javax.resource.Referenceable,javax.sql.DataSource}={service.id=35,
osgi.jndi.service.name=jdbc/pgc,ibm.private.jndi.object=true}
  Registered by bundle: org.eclipse.osgi_3.6.1.R36x_v20100806 [0]
  No bundles using service.
{java.lang.reflect.InvocationHandler,com.ibm.websphere.rsadapter.WSDataSource,java.sql.Wrapper,
javax.sql.CommonDataSource,javax.resource.Referenceable,javax.sql.DataSource}={service.id=36,
osgi.jndi.service.name=jdbc/DefaultEJBTimerDataSource,ibm.private.jndi.object=true}
  Registered by bundle: org.eclipse.osgi_3.6.1.R36x_v20100806 [0]
  No bundles using service.
{java.lang.reflect.InvocationHandler,com.ibm.websphere.rsadapter.WSDataSource,java.sql.Wrapper,
javax.sql.CommonDataSource,javax.resource.Referenceable,javax.sql.DataSource}={service.id=39,
osgi.jndi.service.name=jdbc/lrsched,ibm.private.jndi.object=true}
  Registered by bundle: org.eclipse.osgi_3.6.1.R36x_v20100806 [0]
  No bundles using service.
{javax.resource.Referenceable,javax.resource.cci.ConnectionFactory}={service.id=40,
osgi.jndi.service.name=eis/jdbc/pgc_CMP,ibm.private.jndi.object=true}
  Registered by bundle: org.eclipse.osgi_3.6.1.R36x_v20100806 [0]
  No bundles using service.
```

- Update the cached runtime information about the framework.

It can take some time for the system to gather the runtime information about the framework and the bundles running within it. Therefore, when you run the `osgiApplicationConsole` command, the command-line console caches the runtime information. If you make changes to the currently selected framework, for example by updating or adding bundles, these changes are not reflected in the output of the command-line console commands until you run the **refresh** command.

Note: You can also update this runtime information by restarting the OSGi Applications command-line console. However, you then have to reconnect to the framework. It is quicker to use the **refresh** command.

Command syntax:

```
wsadmin>refresh()
```

- Stop a bundle.

  Use the **stop** command to stop the bundle specified by a given bundle ID. The bundle ID values are one of the outputs of the **ss** command.

  Note:

  – The OSGi Applications command-line console is intended primarily as a method of debugging applications. In a production environment, you would normally use the administrative console or equivalent administrative commands to start and stop applications.

  – Do not use the **stop** command on any bundles under the shared bundle framework, on system bundles, or on the bundles that represent system artifacts (bundle ID 0 and 1), otherwise serious errors can result.

  For example:

  ```
  wsadmin>stop(5)
  ```

  This command might generate the following system response:

  ```
  CWSAJ0042I: Stopping Bundle com.ibm.samples.websphere.osgi.blog.api_1.0.0.
  CWSAJ0034I: Bundle com.ibm.samples.websphere.osgi.blog.api stopped successfully.
  ```

- Start a bundle.

  Use the **start** command to start the bundle specified by a given bundle ID. The bundle ID values are one of the outputs of the **ss** command.

  Note:

  – The OSGi Applications command-line console is intended primarily as a method of debugging applications. In a production environment, you would normally use the administrative console or equivalent administrative commands to start and stop applications.

  – Do not use the **start** command on any bundles under the shared bundle framework, on system bundles, or on bundles that represent applications (bundle ID 0 and 1), otherwise serious errors can result.

  For example:

  ```
  wsadmin>start(5)
  ```

  This command might generate the following system response:

  ```
  CWSAJ0040I: Starting Bundle com.ibm.samples.websphere.osgi.blog.api_1.0.0.
  CWSAJ0032I: Bundle com.ibm.samples.websphere.osgi.blog.api started successfully.
  ```

- Display help information about the console commands.

  Use the **help** command to display a summary of the runtime commands and their uses.

  Command syntax:

  ```
  wsadmin>help()
  ```

This command generates the following system response:

```
CWSAJ0025I:      OSGi application console

Display commands: These commands work only if connected to a framework

ss()                - This command gives the summary information about the installed bundles.
bundles()           - This command gives comprehensive information about the installed bundles.
packages()          - This command gives information about the imported/exported packages.
services()          - This command gives information about the registered Services.

bundle(<bundleID>)  - This command gives information about the specified bundle
headers(<bundleID>) - This command gives information about the headers associated with the
                      specified bundle
packages(<bundle ID>) - This command gives information about the exported packages for this bundle.
packages(<package Name>) - This command gives information about the specified package.
services(<service ID>) - This command gives information about the specified service.
services(<OSGI Filter>) - This command gives information about the services matching the filter.

refresh() - This command refreshes the internal OSGi application console cache with the latest
            information about the state of the framework.

Framework commands:

list() - This command lists the available frameworks that you can connect to.
connect(<Framework id>) - This command connects to the specified framework.
connect(<Bundle Name>, <Bundle Version>, <Node Name>, <Server Name>)
                 - This command connects to the specified framework.

Controlling Bundles:

start(<bundleID>) - This command starts the requested bundle.
stop(<bundleID>   - This command stops the requested bundle.
```

Chapter 45. Deploying SCA composites

This page provides a starting point for finding information about Service Component Architecture (SCA) composites, which consist of components that implement business functions in the form of services.

You typically do not deploy SCA composites directly onto a product server. To deploy SCA composites, you import SCA composites as assets to the product repository and add the assets to business-level applications.

Deploying SCA business-level applications

Deploying an Service Component Architecture (SCA) business-level application consists of creating an empty business-level application and then adding SCA assets, shared libraries, business-level applications, and other artifacts as composition units to the empty business-level application.

Before you begin

Develop the artifacts to go in the application and configure the target server or cluster. You must deploy SCA composite assets of a business-level application to a Version 8.x target or to a Version 7.0 target that is enabled for the Feature Pack for SCA.

If your SCA composite or application uses OASIS support, you must deploy the SCA asset or application to a Version 8.5 target.

If your SCA composite or application uses Feature Pack for SCA Version 1.0.1 functionality, you must deploy the SCA asset or application to a Version 8.x target or to a feature pack Version 1.0.1.0 target. Version 1.0.1 functionality includes:

- Java Message Service (JMS) bindings
- Atom bindings
- HTTP bindings with a wire format of JSON-RPC
- Java Platform, Enterprise Edition (Java EE) integration modules (`implementation.jee`, `implementation.web`, or `implementation.ejb` components)
- SCA Spring component implementations
- OSGi applications as SCA component implementations
- Service Data Objects (SDO) composites

About this task

When creating a business-level application, you can configure the application enough to enable it to run on the server. Later, you can configure the application and its contents further, start or stop the application, and otherwise manage its activity.

The topics in this section describe how to deploy and administer a business-level application or its contents using the administrative console. You can also use programming or wsadmin scripting.

Procedure

- Import assets to a repository.
- Create an SCA business-level application that has SCA assets, shared libraries, or business-level applications.
- Start the application.
- Stop the application.
- Update SCA composite artifacts.
- Update the application and its configuration units.

- View the composite definition of an SCA asset composition unit.
- View SCA domain information.
- View or edit JMS bindings on references and services of SCA composites.
- Delete the application.

What to do next

After making changes to administrative configurations of your applications in the administrative console, ensure that you save the changes.

Importing assets

You must register application business logic such as Java Platform, Enterprise Edition (Java EE) archives, libraries, and other resource files with the product configuration as assets before you can add the assets to one or more business-level applications. Importing an asset registers it with the product configuration.

Before you begin

This topic assumes that you have one or more application binary files that you want to add to a business-level application. You must register those binary files as assets before you can add them to the business-level application.

About this task

Before a business-level application that uses an asset can be started on the target run time, the asset binaries must be extracted to a deployer-defined location on the file system that is local to the target run time. Importing an asset extracts binaries to a location that is local to the target run time.

The application server run time that reads the asset binaries either at application start time or while serving an incoming client request determines the extraction format of the asset binaries. The extraction format might include unzipping of Java archive (JAR) or compressed (zip) files.

This topic describes how to import an asset using the administrative console. Alternatively, you can use the wsadmin tool or programming.

Procedure

1. Click **Applications** > **New Application** > **New Asset** in the console navigation tree.
2. On the Upload asset page, specify the asset package to import.
   a. Specify the full path name of the asset.
   b. Click **Next**.
3. On the Select options for importing an asset page, specify asset settings.
   You typically can click **Next** and use the default values.
   a. Optional: For **Asset description**, specify a brief description of the asset.
   b. Optional: For **Asset binaries destination URL**, specify the target location of the asset.
      This setting specifies the location to which the product extracts the asset. After an asset is imported, the product looks for the asset in this location when a running application uses the asset.
      If you do not specify a value, the product installs the asset to the default location, `${`*profile_root*`}/installedAssets/`*asset_name*`/BASE/`.
   c. Optional: For **Asset type aspects**, examine the asset content type and version specified by the product. You cannot change this setting value.
      The type aspect typically denotes the type of application contents, such as a specification to which the application is written. For example, an enterprise bean (EJB) that supports the EJB Version 2.0 specification has the aspects `type=EJB,version=2.0`.

If the type aspect is `none` and if the asset is a JAR file, then the product associates a `javarchive` type aspect with the asset by default.

d. For **File permissions**, specify any file permissions that are set on asset binary files so the target run time can read or run the asset. Importing the asset extracts its binary files on the disk local to the target runtime environment.

   Try importing the asset using the default value. For detailed information on the **File permissions** setting, refer to the Select options for importing an asset page online help.

   Restriction: OSGi applications do not use a **File permissions** setting.

e. For **Current asset relationships**, add assets that the asset you are importing needs to run or remove assets that are not needed.

   When the product imports a JAR asset, the product detects asset relationships automatically by matching the dependencies defined in the JAR manifest with the assets that are already imported into the administrative domain.

f. For **Validate asset**, specify whether the product validates the asset.

   The setting is deselected by default. This **false** (**no**) value is appropriate for most assets. Only select **true** (**yes**) to validate an asset when needed.

   The product does not save the value specified for **Validate asset**. Thus, if you select to validate the asset (**yes**) now and later update the asset, when you update the asset you must enable this setting again for the product to validate the updated files.

   Restriction: OSGi applications do not use a **Validate asset** setting.

g. Click **Next**.

4. On the Summary page, click **Finish**.

Results

Several messages are displayed, indicating whether your asset is imported successfully.

An asset can contain multiple deployable objects as defined by the application contents of that asset. A *deployable object* is a part of the asset that you can map to a deployment target such as an application server or a cluster. If the product imports the asset successfully, then appropriate deployable objects are identified in the asset and are further used when a composition unit is created from that asset.

If the asset importing is not successful, read the messages and try importing the asset again. Correct the values noted in the messages.

What to do next

If the product imports the asset successfully and displays the list of assets on the Assets page, then click **Save**.

Add a composition unit to a business-level application using the asset that you imported. An asset included in a business-level application is represented by a composition unit.

Upload asset settings

Use this page to specify the asset to register with the asset repository. You can add registered assets to a business-level application.

To view this administrative console page, click **Applications** > **New application** > **New Asset**.

Importing an asset registers the asset with the asset repository.

The product manages the contents of a registered asset as a single entity. The contents of a registered asset must be accessible to application servers, web servers and other runtime environments that use the asset.

During asset importing, asset files typically are uploaded from a client workstation running the browser to the server running the administrative console, where they are registered. In such cases, use the web browser running the administrative console to select files to upload to the server.

Path to the asset:

Specifies the fully qualified path to the asset.

Specify one of the following supported assets:
- A single file, such as an enterprise bean (EJB) file
- An archive of files, such as a Java archive (JAR) or a compressed `.zip` file
- An archive of archives, such as an enterprise archive (EAR) or shared library file

Use **Local file system** if the browser and asset files are on the same machine (whether or not the server is on that machine, too).

Use **Remote file system** if the asset file resides on any node in the current cell context. Only supported assets are shown during the browsing. Also use **Remote file system** to specify an asset file that is already residing on the machine running the application server. For example, the field value might be *profile_root*`/installableApps/my_bean.ejb`. After the asset file is transferred, the **Remote file system** value shows the path of the temporary location on the server.

Asset settings

Use this page to specify options for the registration of an asset with the asset repository. Default values for the options are used if you do not specify a value. If the asset is an OSGi application, additional information about bundle download status is displayed.

To view this administrative console page, click **Applications** > **Application Types** > **Assets** > ***asset_name***. This page is similar to the Select options for importing an asset page on the asset import and update wizards.

Asset name:

Specifies a logical name for the asset. An asset name must be unique within a cell and cannot contain an unsupported character.

An asset name cannot begin with a period (`.`), cannot contain leading or trailing spaces, and cannot contain any of the following characters:

Table 272. Characters that you cannot use in a name. The product does not support these characters in a name.

Unsupported characters		
/ forward slash	**$** dollar sign	**'** single quote mark
**** backslash	**=** equal sign	**"** double quote mark
***** asterisk	**%** percent sign	**|** vertical bar
, comma	**+** plus sign	**<** left angle bracket
: colon	**@** at sign	**>** right angle bracket
; semi-colon	**#** hash mark	**&** ampersand (and sign)
? question mark	**]]>** No specific name exists for this character combination	

This **Asset name** field is the same as the **Name** setting on an Assets page.

Information	Value
Data type	String

Asset description:

Specifies a description for the asset.

Asset binaries destination URL:

Specifies the directory to which the product imports the asset file.

Information	Value
Data type	String
Units	Full path name

Asset type aspects:

Specifies the type of asset content. Examples of asset type include Java archive (JAR) files, shared libraries, enterprise application archive (EAR) files, and enterprise bundle archive (EBA) files.

The asset type suggests the content of the asset. An asset packaged as a JAR file might contain a web module, portlet, or web service. An asset packaged as an EBA file contains an OSGi application.

This setting is read-only. You cannot edit this setting.

Information	Value
Data type	String
Units	File type
Default	none

File permissions:

Specifies access permissions for asset binaries that the product expands to the asset binaries destination URL.

Restriction: OSGi applications do not use a **File permissions** setting.

You can specify file permissions in the text field. You can also set some of the commonly used file permissions by selecting them from the list. List selections overwrite file permissions set in the text field.

You can set one or more of the following file permission strings in the list. Selecting multiple options combines the file permission strings.

Table 273. File permission string sets for list options. Select a list option or specify a file permission string in the text field.

Multiple-selection list option	File permission string set
Allow all files to be read but not written to	`.*=755`
Allow executables to execute	`.*\.dll=755#.*\.so=755#.*\.a=755#.*\.sl=755`
Allow HTML and image files to be read by everyone	`.*\.htm=755#.*\.html=755#.*\.gif=755#.*\.jpg=755`

Instead of using the multiple-selection list to specify file permissions, you can specify a file permission string in the text field. File permissions use a string that has the following format:

file_name_pattern=permission#file_name_pattern=permission

where *file_name_pattern* is a regular expression file name filter (for example, `.*\\.jsp` for all JSP files), *permission* provides the file access control lists (ACLs), and `#` is the separator between multiple entries of *file_name_pattern* and *permission*. If `#` is a character in a *file_name_pattern* string, use `\#` instead.

If multiple file name patterns and file permissions in the string match a uniform resource identifier (URI) within the asset, then the product uses the most stringent applicable file permission for the file. For example, if the file permission string is `.*\\.jsp=775#a.*\\.jsp=754`, then the `abc.jsp` file has file permission 754.

Tip: Using regular expressions for file matching pattern compares an entire string URI against the specified file permission pattern. You must provide more precise matching patterns using regular expressions as defined by Java programming API. For example, suppose the product processes the following directory and file URIs during a file permission operation:

Table 274. Example URIs for file permission operations. Results are shown following this table.

Number	Example URL
1	/opt/WebSphere/profiles/AppSrv01/installedApps/MyCell/MyApp.ear/MyWarModule.war
2	/opt/WebSphere/profiles/AppSrv01/installedApps/MyCell/MyApp.ear/MyWarModule.war/MyJsp.jsp
3	/opt/WebSphere/profiles/AppSrv01/installedApps/MyCell/MyApp.ear/MyWarModule.war/META-INF/MANIFEST.MF
4	/opt/WebSphere/profiles/AppSrv01/installedApps/MyCell/MyApp.ear/MyWarModule.war/WEB-INF/classes/MyClass.class
5	/opt/WebSphere/profiles/AppSrv01/installedApps/MyCell/MyApp.ear/MyWarModule.war/mydir/MyClass2.class
6	/opt/WebSphere/profiles/AppSrv01/installedApps/MyCell/MyApp.ear/MyWarModule.war/META-INF

The file pattern matching results are:
- `MyWarModule.war` does not match any of the URIs
- `.*MyWarModule.war.*` matches all URIs
- `.*MyWarModule.war$` matches only URI 1
- `.*\\.jsp=755` matches only URI 2
- `.*META-INF.*` matches URIs 3 and 6
- `.*MyWarModule.war/.*/.*\.class` matches URIs 4 and 5

If you specify a directory name pattern for **File permissions**, then the directory permission is set based on the value specified. Otherwise, the **File permissions** value set on the directory is the same as its parent. For example, suppose you have the following file and directory structure:

```
/opt/WebSphere/profiles/AppSrv01/installedApps/MyCell/MyApp.ear/MyWarModule.war/MyJsp.jsp
```

and you specify the following file pattern string:

```
.*MyApp.ear$=755#.*\.jsp=644
```

The file pattern matching results are:
- Directory `MyApp.ear` is set to 755
- Directory `MyWarModule.war` is set to 755
- Directory `MyWarModule.war` is set to 755

Important: Regardless of the operation system, always use a forward slash (/) as a file path separator in file patterns.

Access permissions specified here are at the asset level. You can also specify access permissions for asset binaries in the node-level configuration. The node-level file permissions specify the maximum (most lenient) permissions that can be given to asset binaries. Access permissions specified here at asset level can only be the same as or more restrictive than those specified at the node level.

Information	Value
Data type	String

Current asset relationships:

Specifies the assets to which this asset is related.

To add or remove a relationship, use the Manage relationships page:

1. Click **Manage Relationships**. The **Selected** list on the right lists the current asset relationships.
2. To add a relationship, select an asset in the **Available** list on the left and click **>>**.
3. To remove a relationship, select an asset in the **Selected** list on the right and click **<<**.
4. Click **OK**.

Information	Value
Data type	String
Default	none

Validate asset:

Specifies whether the product examines the asset references specified during asset importing or updating and, if validation is enabled, warns you of incorrect references or fails the operation.

Restriction: OSGi applications do not use a **Validate asset** setting.

An asset typically refers to resources using data sources for container-managed persistence (CMP) beans or using resource references or resource environment references defined in deployment descriptors. The validation checks whether the resource referred to by the asset is defined in the scope of the deployment target of that asset.

Select `true` (enable the check box) for resource validation and to stop operations that fail as a result of incorrect resource references. Select `false` (empty check box) for no resource validation.

Information	Value
Data type	String
Default	false (empty check box)

EBA Dependencies:

For an enterprise bundle archive (EBA) asset, displays the current bundle download status for all bundles in the asset. This item is only displayed if your asset is an EBA asset, which means that it contains an OSGi application.

You cannot update an EBA asset until bundle downloads are complete from any previous update, and until the business-level application that uses the asset has picked up the previous updates by being restarted. Before you try and update bundle versions, you can use the EBA dependency information to check the bundle download status of the asset. The status displayed is one of the following values:

- Bundles downloading...
- Bundle downloads are complete.
- No bundles downloads are required.

Note: In addition to the information given here, you can also check the bundle download status indirectly, by checking the status of the associated EBA composition unit as described in Checking and updating the EBA asset version used by a business-level application.

If bundle downloads for the asset are complete, or no bundle downloads are required, you can update the asset using either of the methods described in Maintaining bundle versions for an EBA asset.

If bundle downloads for the asset are complete, and a new version of the EBA asset is available, restart the business-level application to bring the EBA composition unit up-to-date and to run the newer configuration.

SCA application package deployment

The product supports deployment of many types of Service Component Architecture (SCA) artifacts as composition units of business-level applications. Typical artifacts include Java archive (JAR) files, compressed `.zip` files, and web application archive (WAR) files.

The following outlines the details about deployment of SCA artifacts:
- Deployment of JAR or compressed files
- Deployment of WAR files
- Notes and limitations

Deployment of JAR or compressed files

- The product supports one composite file for each package. The product determines which composite file to support using the following process:
  1. The SCA deployment extension looks for the `META-INF/sca-contribution.xml` file, gets the name of each deployable composite defined in the file, and uses QName values to find the actual composite file names under any directory for that composite. If more than one composite is found in the `sca-contribution.xml` file, you can select the composite to deploy.
  2. If there is no `META-INF/sca-contribution.xml` file defined, the SCA deployment extension looks for a composite file in the `META-INF/sca-deployables` directory.
- The product validates SCA composites for inconsistencies with SCA specifications.

  One specification requirement is that the names of top-level components must be unique. Thus, the product validates top-level component name uniqueness.

  Tip: Top-level components are also called domain components, with the top-level or domain typically the cell on multiple-server installations and the server scope on single-server installations.

  The product validates all composite files in a JAR or compressed file, regardless of the file location in the archive or whether the `sca-contribution.xml` file references the composite file. The product does not validate all services and references.

  The product writes warning and error messages resulting from the validation tests to the `SystemOut.log` file. Refer to the log file to learn about inconsistencies with specifications in your SCA composites.

  Note: This topic references one or more of the application server log files. As a recommended alternative, you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using `SystemOut.log` , `SystemErr.log`, `trace.log`, and `activity.log` files on distributed and IBM i systems. You can also use HPEL in conjunction with your native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.
- The product uses the following process for QName resolution:

  - The product uses the QName to resolve composite files included in the top-level composite that use the element. For example, the `<include name="mynamespace:MyService"/>` statement looks for a composite file whose composite name is `MyService` and whose targetNameSpace is `mynamespace`. The following rules apply:
    - **name**: Use the outer composite.
    - **namespace declarations**: Merged into the outer composite.
    - **targetNamespace**: Use the outer composite (must be the same).
    - **local**: Use the composite (preferably the same but not required).
    - **requires(intents) and policySets**: Must be compatible, and aggregated into the outer composite.

    Deployable composite files must have name and targetNamespace values. The name and targetNamespace values are combined to form the QName of a composite file.
  - When a composite is used as a component implementation in the top-level composite, the composite is also resolved using the QName. For example, the `<implementation.composite name="mynamespace:MyComposite"/>` statement causes the product administration to look for a composite file whose composite name is `MyComposite` and whose targetNamespace is `mynamespace`.
- A JAR file can contain other JAR files at the top level. The contained JAR files are available on the classpath. However, any archives inside those JAR files are not available. The product supports one level of embedded JAR files.

Deployment of WAR files

- A composite file in a WAR file must be named `default.composite`. A composite file that is not in a WAR file can have any name.
- The `default.composite` composite file must be inside a WAR file in the `META-INF/sca-deployables` directory.
- The `META-INF/sca-deployables` directory must contain no more than one composite file. If there is more than one composite file in the `META-INF/sca-deployables` directory, then the product returns a validation error and stops the WAR file deployment.

  However, you can place other composite files in directories other than `META-INF/sca-deployables`, and reference those composite files in the top-level composite under the `META-INF/sca-deployables` directory.
- The product does not support having a `sca-contribution.xml` file inside the WAR file under the `META-INF` directory. If the product finds a `sca-contribution.xml` file, then the product returns a validation error and stops the WAR file deployment.

Notes and limitations

- The product does not provide administration console pages for configuring contributions.
- If you import a package or namepace from a different contribution, or JAR (`contribution.xml`), you might need to import that contribution as an asset before importing your own asset.

  For example, suppose your Contribution A imports a JAR file from Contribution B. You might need to import Contribution B and then Contribution A as assets. Contribution A depends on Contribution B so you must import Contribution B before importing Contribution A.
- You cannot use a local interface across a class loader boundary. Use a remotable interface to cross a class loader boundary.

Creating SCA business-level applications

You can create an empty business-level application and then add Service Component Architecture (SCA) assets, shared libraries, business-level applications, and other artifacts as composition units to the empty business-level application.

Before you begin

Configure the target application server. You must deploy SCA composite assets of a business-level application to a Version 8.x server or cluster (target) or to a Version 7.0 target that is enabled for the Feature Pack for SCA.

If your SCA composite or application uses OASIS support, you must deploy the SCA asset or application to a Version 8.5 target.

If your SCA composite or application uses Feature Pack for SCA Version 1.0.1 functionality, you must deploy the SCA asset or application to a Version 8.x target or to a feature pack Version 1.0.1.0 target. Version 1.0.1 functionality includes:

- Java Message Service (JMS) bindings
- Atom bindings
- HTTP bindings with a wire format of JSON-RPC
- Java Platform, Enterprise Edition (Java EE) integration modules (`implementation.jee`, `implementation.web`, or `implementation.ejb` components)
- SCA Spring component implementations
- OSGi applications as SCA component implementations
- Service Data Objects (SDO) composites

Optionally, determine what assets or other files that you want to add to your business-level application and whether your application files can run on your deployment targets.

About this task

You can create business-level applications using the administrative console, the wsadmin tool, or programming.

You create SCA business-level applications the same way as for non-SCA business-level applications. However, when you use an SCA asset in a business-level application, function that applies only to applications that use SCA composites becomes available. For example, you can access administrative console pages that apply only to applications that use SCA composites.

Procedure

1. Select a way to create your business-level application.

Table 275. Ways to create SCA business-level applications. You can create a business-level application using the administrative console, wsadmin scripts, or programming.

Option	Method
Administrative console business-level application creation wizard See “Creating SCA business-level applications with the console” on page 2139.	Click **Applications** > **New Application** > **New Business Level Application** and follow instructions in the wizard. For example use of the console to create a business-level application that has an SCA asset, see “Example: Creating an SCA business-level application with the console” on page 2170.

2. Create your business-level application using the administrative console, wsadmin, or programming.
3. Save the changes to your administrative configuration.

   When saving the configuration, synchronize the configuration with the nodes where the application is expected to run.

Results

The name of the application is shown in the list on the Business-level applications page.

What to do next

After you create a business-level application, you can do the following to add composition units to it:

1. Import any SCA or other assets needed by your business-level application.
2. Add assets, shared libraries, or other business-level applications as composition units.

   When you add an asset, you must specify a target that supports SCA composites. Specify only a single server or cluster as the target. Do not map an SCA composition unit to multiple servers or clusters.

   If the asset or application uses OASIS support, specify a Version 8.5 target.

   If the asset or application uses Feature Pack for SCA Version 1.0.1 functionality, specify a Version 8.x target or a feature pack Version 1.0.1.0 target.

   For applications that use `implementation.osgiapp`, add the enterprise bundle archive (EBA) asset as a composition unit to the business-level application before adding the SCA asset as a composition unit.
3. Save the changes to your administrative configuration.
4. Start the business-level application.

If the application does not run as desired, edit the application configuration, then save and run it again.

If the business-level application does not start, ensure that the deployment target to which the application maps is running and try starting the application again. If SCA composite assets do not start, ensure that each asset is mapped to a deployment target that supports SCA composites.

When an SCA application fails to start, multiple first failure data capture (FFDC) entries are logged for a single error. The FFDC log entries pertain to the same problem and are not different issues related to the failure. Use the information provided in the FFDC log entries to fix the problem and try starting the SCA application again.

If an asset composition unit uses an Enterprise JavaBeans (EJB) binding and does not start because it has a `non-WebSphere target of "null"`, delete the asset composition unit and add it again to the business-level application. Specify a target that supports SCA composites when you add the asset to the business-level application. You cannot change the target after deployment.

If the `META-INF/sca-deployables` directory has multiple SCA composite files and the application does not start because the product `cannot obtain the CompUnitInfoLoader value`, place only the file that contains the composite in the `META-INF/sca-deployables` directory. You can place the other composite files anywhere else within the archive.

If the SCA application uses security, the target must be in the global security domain.

In multiple-node environments, synchronize the nodes after you save changes to the target before starting the business-level application.

For applications that use `implementation.osgiapp` in multiple-node environments, target the EBA composition unit to the same server or cluster as the SCA composition unit.

Creating SCA business-level applications with the console

You can create an empty business-level application and then add Service Component Architecture (SCA) assets, shared libraries, or business-level applications as composition units to the empty business-level application.

Before you begin

Configure the target application server. You must deploy SCA composite assets of a business-level application to a Version 8.x server or cluster (target) or to a Version 7.0 target that is enabled for the Feature Pack for SCA.

If your SCA composite or application uses Feature Pack for SCA Version 1.0.1 functionality, you must deploy the SCA asset or application to a Version 8.5 target or to a feature pack Version 1.0.1.0 target. Version 1.0.1 functionality includes:

- Java Message Service (JMS) bindings
- Atom bindings
- HTTP bindings with a wire format of JSON-RPC
- Java Platform, Enterprise Edition (Java EE) integration modules (`implementation.jee`, `implementation.web`, or `implementation.ejb` components)
- SCA Spring component implementations
- OSGi applications as SCA component implementations
- Service Data Objects (SDO) composites

Also, determine an application name. Optionally, determine which assets, shared libraries, or business-level applications that the new business-level application needs.

About this task

You can create a business-level application that has SCA assets using the administrative console. Alternatively, you can use the wsadmin scripting tool or programming.

You can add an asset or shared library composition unit to multiple business-level applications. However, each composition unit for the same asset must have a unique composition unit name. You can add a business-level application composition unit to more than one business-level application.

You must target an SCA composition unit to a single server or cluster, and not to multiple servers or clusters.

Procedure

1. Create an empty business-level application.
   a. Click **Applications** > **New Application** > **New Business-level Application**.
   b. On the New business-level application page, specify a unique name for the application and a description, and then click **Apply**.
   c. On the business-level application settings page, click **Save**.

   The name and description are shown in the list of applications on the Business-level applications page. Because the application is empty, its status is `Unknown`.
2. Add one SCA asset to your business-level application. The product adds the asset as a composition unit of your business-level application.
   a. Import the SCA asset.
   b. Go to the business-level application settings page.

      Click **Applications** > **Application Types** > **Business-level applications** > ***application_name***.
   c. On the business-level application settings page, specify the type of composition unit to add.

      Although you can add an asset, shared library, or business-level application to your business-level application, the logic is in your SCA asset. Add the SCA asset as a composition unit.

      Under **Deployed assets**, click **Add** > **Add Asset**.
   d. On the Add page, select one unit from the list of available units, and then click **Continue**.

On the Add page, you might be able to select multiple deployable SCA composites. However, you can deploy only one deployable SCA composite at a time. Select only one unit and click **Continue**. If you select multiple units, the product deploys only one of those units.

For applications that use `implementation.osgiapp`, add the enterprise bundle archive (EBA) asset as a composition unit to the business-level application before adding the SCA asset as a composition unit.

e. On the Set options page, change the composition unit settings as needed, and then click **Next**.

This page is not shown if you have multiple deployable unit assets.

f. On the Map composition unit to a target page, specify one target server that supports SCA composites, and then click **Next**.

The target server can be an existing cluster. To map the composition unit to a cluster, select the existing cluster from the **Available** list, click **Add**, and then click **Next**. The cluster name is shown in the **Current targets** list as `WebSphere:cluster=`*`cluster_name`*.

You must specify only a single server or cluster as the target, and not map an SCA composition unit to multiple servers or clusters.

If you are adding an SCA asset that uses security, specify a target server that is in the global security domain.

For applications that use `implementation.osgiapp` in multiple-node environments, target the EBA composition unit to the same server or cluster as the SCA composition unit.

This page is not shown when you add a business-level application.

g. On the Relationship options page, click **Next** to accept the default values.

The relationships in SCA applications are set at the asset level. Either the asset must be defined as an SCA contribution or, in the asset view, a relationship must be set to another asset. When a relationship is set to another asset manually at the asset level, the relationship only exposes all the packages within the asset to the other depended asset. The namespaces are not exposed.

This page is shown only for SCA assets that have multiple deployable or composition units.

h. On the Set Java EE composition unit relationship page, associate SCA components with Java EE applications and then click **Next**.

Java EE applications are also known as enterprise applications or enterprise archive (EAR) files. An SCA composite definition can specify an EAR file to use on the `archive` attribute of an `implementation.jee` tag. Use this page to associate SCA components in this business-level application to the EAR files named in the composite definition. If your SCA application does not use EAR files, take the default values and click **Next**.

i. On the Map security roles to users or groups page, specify security roles for users or groups as needed, and then click **Next**.

This page is only shown for SCA assets that use security.

j. On the Map RunAs roles to users page, map a user identity and password to RunAs roles as needed, and then click **Next**.

This page is only shown for SCA assets that use security.

k. On the Map virtual host page, specify a virtual host that hosts web services for each SCA composite, and then click **Next**. By default, composites map to `default_host`.

This page is only shown for SCA assets that contain a web service binding.

l. On the Attach policy set page, attach a policy set and assign policy set bindings as needed, and then click **Next**.

This page is only shown for SCA assets that use web services.

m. On the Summary page, click **Finish**. Several messages are displayed, indicating whether the product adds the unit to the business-level application successfully. A message having the format `Completed res=[WebSphere:cuname=`*`unit_name`*`]` indicates that the addition is successful. Click **Manage application**.

If the product adds the unit successfully, the name of the unit is shown in a list of deployed assets on the business-level application settings page.

If the unit addition is not successful, read the messages and add the unit again. Correct the problems noted in the messages.

n. On the Adding composition unit to the business-level application page, click **Save**.

3. Optional: Add one or more assets, shared libraries, or business-level applications to your business-level application.

   Repeat Step 2 to add another asset or add a shared library or business-level application.

Results

A business-level application that contains the specified composition units.

What to do next

After you create the application, save the changes to your configuration and start the application as needed.

If a composite asset is deployed to a target that does not support SCA composites, the SCA composite does not start. You must deploy an SCA asset to a target that supports SCA composites.

Map virtual host settings for SCA composites:

Use this page to map Service Component Architecture (SCA) composites that use a web service binding to a virtual host. You must map the composites to the virtual host that hosts the web services.

This administrative console page displays in the business-level application creation and update wizards. To view the Map virtual host page, the asset that you add to a business-level application must contain a web service binding. To view this page, do the following:

1. Import an asset that contains a web service binding.
2. Create a business-level application to which to add the asset.
3. Click **Applications** > **Application Types** > **Business-level applications** > ***application_name*** > **Add** > **Add Asset**.
4. On the Add composition unit page, select the asset that contains a web service binding, and click **Continue**.
5. On the Set options page, change the settings as needed and click **Next**.
6. On the Map composition unit to a target page, specify target servers as needed and click **Next**.
7. On the Define relationship with existing composition units page, change the settings as needed and click **Next**.
8. Continue changing settings as needed and click **Next** on any other pages until the Map virtual host page is displayed in the wizard.

Composite Name:

Specifies the name of the composite that uses a web service binding in the SCA artifact.

Virtual Host:

Specifies a virtual host to associate with the composite.

Select the virtual host that hosts the web services for the composite. By default, the product associates a component with the `default_host` virtual host.

Set Java EE composition unit relationships for SCA composites:

Use this page to associate Service Component Architecture (SCA) components in an SCA composite with Java Platform, Enterprise Edition (Java EE) applications, otherwise known as *enterprise applications* or *enterprise archive (EAR) files*.

An SCA composite definition can define Java EE applications as component implementations. You can define an EAR asset on an `archive` attribute of the `implementation.jee` tag for the component and use the application deployed from the asset as its implementation. On this page, associate SCA components in a business-level application with the EAR files named in the composite definition.

This administrative console page displays in the business-level application creation and update wizards. To view the Set Java EE composition unit relationship page, the asset that you add to a business-level application must contain an SCA composite. To view this page, complete the following actions:

1. Import an asset that contains an SCA composite.
2. Create a business-level application to which to add the asset.
3. Click **Applications** > **Application Types** > **Business-level applications** > ***application_name*** > **Add** > **Add Asset**.
4. On the Add composition unit page, select the SCA composite asset and click **Continue**.
5. On the Set options page, change the settings as needed and click **Next**.
6. On the Map composition unit to a target page, specify target servers as needed and click **Next**.
7. On the Define relationship with existing composition units page, change the settings as needed and click **Next**.
8. Continue changing settings as needed and click **Next** on any other pages until the Set Java EE composition unit relationship page is displayed in the wizard.

Component Name:

Specifies the name of an SCA component in the SCA composite that you are deploying.

EAR Asset Name:

Specifies the name of the enterprise application, or EAR file, that the SCA component uses.

An EAR asset is an EAR file that has been imported as an asset. The EAR asset name must match the `archive` attribute on the `implementation.jee` tag in the SCA composite definition.

Associated Java EE Composition Unit:

Specifies the composition unit name of the EAR asset. Select the Java EE composition unit that the SCA component uses. To associate an SCA component with an EAR file, the EAR file must be a composition unit of your SCA business-level application.

If the Java EE composition unit that you want to associate with an SCA component is not in the drop-down list, import the EAR file that is named by the `archive` attribute on the `implementation.jee` tag of the SCA composite definition as an asset. Then, add the EAR asset as a composition unit of this business-level application.

You can use the **Import an asset** and **Add an asset** links on this page to add EAR files as assets and make them composition units of your SCA business-level application.

Attach policy set settings:

Use this page to attach a policy set and assign policy set bindings for the composite defined in a Service Component Architecture (SCA) application.

This administrative console page displays in the Create new business-level application wizard. To have the Attach policy set page in the wizard, the SCA component in the asset that you add to a business-level application must use a web service binding, `binding.ws`, and the composite file or annotation must specify the intents or policy sets. To view this page, do the following:

1. Import an asset that uses a web service binding and a composite file or annotation that specifies the intents or policy sets.
2. Create a business-level application to which to add the asset.
3. Click **Applications** > **Application Types** > **Business-level applications** > ***application_name*** > **Add** > **Add Asset**.
4. On the Add composition unit page, select the asset that uses a web service binding, and click **Continue**.
5. On the Set options page, change the settings as needed and click **Next**.
6. On the Map composition unit to a target page, specify target servers as needed and click **Next**.
7. On the Define relationship with existing composition units page, change the settings as needed and click **Next**.
8. Continue changing settings as needed and click **Next** on any other pages until the Attach policy set page is displayed in the wizard.

To attach or detach a policy set or to assign a policy set binding, do the following:

1. Select a composite, component, service, reference, or binding from **Name**. The **Name** list is nested, indicating parent-child relationships. When you select a parent, the children are automatically selected.
2. Click the desired button.

Table 276. Button descriptions. Use the buttons to attach or detach policy sets and to assign policy set bindings.

Button	Resulting action
Attach	Attaches a policy set to the selected composite, component, service, reference, or binding. When the **Include default policy sets** option is not enabled, the options for this button contain user-created policy sets only. When the **Include default policy sets** option is not enabled and no user-created policy sets exist, then there are no button options. You can select **Include default policy sets** to display the default policy set options. When the **Include default policy sets** option is enabled, the options for this button include both default policy sets and any user-created policy sets. To attach a policy set, select a composite, component, service, reference, or binding from **Name** and click **Attach** > ***policy_set_option***. To close the menu list, click **Attach**.
Detach Policy Set	Detaches a policy set from the selected composite, component, service, reference, or binding.
Assign Service Policy Set Binding	Assigns a service policy set binding to the selected composite, component, service, reference, or binding. There are two default options: **Default** specifies to assign the default service policy set binding. **Provider Sample** specifies to assign a policy set binding that is provided with the product to the service. If you are deploying the composition unit to a server or cluster that belongs to a security domain, the list of policy set bindings consists of bindings that have been defined in the security domain to which the composition unit is being deployed.

Table 276. Button descriptions (continued). Use the buttons to attach or detach policy sets and to assign policy set bindings.

Button	Resulting action
Assign Reference Policy Set Binding	Assigns a reference policy set binding to the selected composite, component, service, reference, or binding. There are two default options: **Default** specifies to assign the default reference policy set binding. **Client Sample** specifies to assign a policy set binding that is provided with the product to the reference. If you are deploying the composition unit to a server or cluster that belongs to a security domain, the list of policy set bindings consists of bindings that have been defined in the security domain to which the composition unit is being deployed.

Include default policy sets:

Specifies whether to include default policy sets. Default policy sets specify common quality of service (QoS) behavior for generic message format.

Before selecting this option, determine whether the default policy sets provide adequate QoS characteristics for your services.

By default, this option is not enabled.

Name:

Specifies a composite, component, service, reference, or binding in the artifact.

The **Name** list is nested, indicating parent-child relationships. When you select a parent, the children are automatically selected.

Intents:

Specifies the aggregate of the intents from the composite file and the annotations. SCA intents are used to describe the abstract policy requirements of a component.

The intents shown include any intents inherited from a parent.

Matched Policy Sets:

Specifies policy sets that potentially satisfy the intents.

You can include default policy sets by enabling the **Include default policy sets** check box. To exclude default policy sets, deselect the check box.

Attached Policy Set:

Specifies attached policy sets. If no value is shown, then the composite, component, service, reference, or binding is not attached to a policy set.

To attach a policy set, select a composite, component, service, reference, or binding and click an **Attach** option.

To detach a policy set, use **Detach Policy Set**. You can detach any policy set, including pre-attached policy sets.

Policy Set Binding:

Specifies service and reference policy set bindings. If no value is shown, then the composite, component, service, reference, or binding is not assigned to a policy set binding.

To assign a policy set binding, select a composite, component, service, reference, or binding and click an **Assign Service Policy Set Binding** or **Assign Reference Policy Set Binding** option.

To reset the bindings, select the **Default** option. For example, select **Assign Service Policy Set Binding** > **Default** or **Assign Reference Policy Set Binding** > **Default**.

Map security roles to users or groups collection for SCA composites:

Use this page to view and manage mappings of security roles to users and groups that are used with the Service Component Architecture (SCA) composites.

To view this administrative console page, click **Applications** > **Application Types** > **Business-level applications** > ***application_name*** > ***deployed_asset_composition_unit_name*** > **Map security roles to users or groups**. This page is the same as the Map security roles to users or groups page in the Create new business-level application wizard. To view this page, your composition unit must support SCA security.

Different roles can have different security authorizations. Mapping users or groups to a role authorizes those users or groups to access applications defined by the role. Users, groups, and roles are defined when an application is installed or configured.

To map a role to a user or group, enable the Select check box beside the role name in the list and click a button. On the displayed page, specify one or more users or groups to map to the role.

Table 277. Button descriptions. Use the buttons to map security roles to users, groups, or special subjects.

Button	Resulting action
Map Users	Displays the Map users or groups page on which you can specify the users to have the selected security role.
Map Groups	Displays the Map users or groups page on which you can specify the groups to have the selected security role.
Map Special Subjects	Maps special subjects according to the option that you select: **None** specifies to map none of the special subjects to the role. **All Authenticated in Application's Realm** specifies to map all of the authenticated users to a specified role. When you map all authenticated users to a specified role, all of the valid users in the current registry who have been authenticated can access resources that are protected by this role. **All Authenticated in Trusted Realms** specifies to map all of the authenticated users in the trusted realms to a specified role. This option gives all authenticated users who belong to the user registry access to the application's realm and all authenticated users who belong to user registries access to realms which are trusted by the current security domain. **Everyone** specifies to map everyone to a specified role. When you map everyone to a role, anyone can access the resources that are protected by this role and, essentially, there is no security.

Role:

Specifies a security role.

Special Subjects:

Specifies which special subjects are mapped to the security role. This option applies only when an application uses multiple realms.

None Specifies to map none of the special subjects to the role.

All Authenticated in Application's Realm
Specifies to map all of the authenticated users to a specified role. When you map all authenticated users to a specified role, all of the valid users in the current registry who have been authenticated can access resources that are protected by this role.

All Authenticated in Trusted Realms
Specifies to map all of the authenticated users in the trusted realms to a specified role. All authenticated users who belong to the user registry that is mapped to the application's realm and all authenticated users who belong to user registries that are mapped to realms which are trusted by the current security domain are successfully authorized.

Everyone
Specifies to map everyone to a specified role. When you map everyone to a role, anyone can access the resources that are protected by this role and, essentially, there is no security.

To change the value, select the role, click **Map Special Subjects**, and select an option.

Users:

Lists the users that are mapped to the specified role within this application.

Users from the non-default realm are displayed as *user*`@`*realm*.

Groups:

Lists the groups that are mapped to this specified role within this application.

Map RunAs roles to users collection for SCA composites:

Use this page to map a specified user identity and password to a RunAs role for a Service Component Architecture (SCA) composite. This page enables you to specify application-specific privileges for individual users to run specific tasks using another user identity.

To view this administrative console page, click **Applications** > **Application Types** > **Business-level applications** > ***application_name*** > ***deployed_asset_composition_unit_name*** > **Map RunAs roles to users**. This page is the same as the Map RunAs roles to users page in the Create new business-level application wizard.

To view this page, the components in your composition unit must contain predefined RunAs roles and support SCA security. RunAs roles are used by components that need to run as a particular role for recognition while interacting with another component.

Username:

Specifies a user name for the RunAs role user.

This user already maps to the role specified in the Mapping users and groups to roles page. You can map the user to its appropriate role by either mapping the user to that role directly or mapping a group that contains the user to that role. After you specify the user name and password for the user and select a RunAs role, click **Apply**.

Password:

Specifies the password for the RunAs user.

Role:

Specifies a security role for a user within this application.

The authorization policy is only enforced when security is enabled.

User:

Lists the user that is mapped to the specified role within this application.

Composition unit settings

Use this page to view composition unit settings and to change the configuration properties of a composition unit. The specific settings that are available for configuration can vary, depending upon the contents of the composition unit. For example, there are additional configuration settings if the asset contained in the composition unit is an SCA composite, or an OSGi application.

To view this administrative console page, click **Applications** > **Application Types** > **Business-level applications** > ***application_name*** > ***deployed_asset_name***. The deployed asset is a composition unit of the business-level application.

- "Settings that are common to all composition units"
- "Additional composition unit settings for SCA composites" on page 2150
- "Additional composition unit settings for OSGi applications" on page 2150

Settings that are common to all composition units:

Name:

Specifies a logical name for the composition unit. You cannot change the name on this page.

Description:

Specifies a description for the composition unit.

Backing ID:

Specifies a unique identifier for a composition unit that is registered in the application management domain.

The identifier has the format `WebSphere:`*`unit_type`*`name=`*`unit_name`*. For example, for the `MyApp.jar` asset, the backing identifier might be `WebSphere:assetname=MyApp.jar`.

You cannot change the identifier on this page.

Information	Value
Data type	String
Units	Configuration unit identifier

Starting weight:

Specifies the order in which composition units are started when the server starts. The starting weight is like the startup order. The composition unit with the lowest starting weight is started first.

The value that you set for **Starting weight** determines the importance or weight of a composition unit within the business level application. For example, for the most important composition unit within a business-level application, specify 1 for **Starting weight**. For the next most important composition unit within the business-level application, specify 2 for **Starting weight**, and so on.

Note: Assign composition units upon which other composition units depend a lower starting weight than the dependent composition units. If a composition unit is not started and running before its dependent composition units, java.lang.ClassNotFoundException errors might result when you attempt to start the application or its modules.

Information	Value
Data type	Integer
Default	1
Range	0 to 2147483647

Start on distribution:

Specifies whether to start the composition unit when the product distributes the composition unit to other locations.

The default is not to start the composition unit.

This setting applies to asset or shared library composition units. This setting does not apply when the composition unit is a business-level application.

Information	Value
Data type	Boolean
Default	false

Recycle behavior on update:

Specifies whether the product restarts the composition unit after the composition unit is updated.

The default is to restart the composition unit after partial updating of the composition unit.

This setting applies to asset or shared library composition units. This setting does not apply when the composition unit is a business-level application.

Table 278. Option descriptions. Specifies whether to restart an asset or shared library composition unit.

Option	Description
ALL	Restarts the composition unit after the entire composition unit is updated
DEFAULT	Restarts the composition unit after the part of the composition unit is updated
NONE	Does not restart the composition unit after the composition unit is updated

Target mapping:

Specifies the current targets for the composition unit.

To change the deployment targets, click **Modify targets** then select a different set of deployment targets from the list of available clusters and servers.

For SCA, you must specify only a single server or cluster as the target. Do not map an SCA composition unit to multiple servers or clusters.

Note: When you change the deployment target of composition units in a business-level application, the startup order changes to the same order in which you remap composition unit targets, even if the starting weight for all composition units is set to 1. To avoid java.lang.ClassNotFoundException errors when attempting to start the remapped composition units, remap targets for composition units in the same order as that used to add the composition units or, after remapping, check starting weights to ensure that composition units upon which other composition units depend are started first.

Additional composition unit settings for SCA composites:

SCA composite components:

Specifies the component names and component implementations of SCA composites in the application.

Table 279. Column descriptions. Provides the name of each component and the name of the class or code implementing the component.

Column	Description
Component Name	Specifies the name of a component associated with the SCA composite.
Component Implementation	Specifies the name of the class or code implementing the component.

None indicates that the SCA composite does not have defined components.

SCA composite properties:

Specifies the names and values of SCA composite properties in the application.

Table 280. Column descriptions. Provides the name and value of SCA composite properties.

Column	Description
Property Name	Specifies the name of an SCA composite property.
Property Value	Specifies the value of the property.

None indicates that the SCA composite does not have defined name-value properties.

SCA composite wires:

Specifies the sources and targets of wires in the SCA composite.

Table 281. Column descriptions. Provides the source and target of wires.

Column	Description
Wire Source	Specifies the source of a wire in the SCA composite.
Wire Target	Specifies the target of the wire.

None indicates that the SCA composite does not have defined wires.

Additional composition unit settings for OSGi applications:

OSGi application deployment status:

The deployment status shows whether updates are available for the EBA asset that is contained in the composition unit. If a new version of an EBA asset is available, and all bundle downloads for the asset are complete, you can update the EBA composition unit so that the business-level application uses the latest configuration. You do not have to update the composition unit every time you update the asset.

There are four distinct deployment statuses for an EBA composition unit:

Using latest OSGi application deployment.
The composition unit is running the latest configuration of the backing asset and any CBA extensions.

New OSGi application deployment not yet available because it requires bundles that are still downloading.
The backing asset is currently undergoing a bundle version update, or bundles are downloading for a CBA extension.

New OSGi application deployment available.
The backing asset is available at a newer configuration than the configuration that is currently running in this composition unit, or a CBA extension has been added or replaced.

New OSGi application deployment cannot be applied because bundle downloads have failed.
The last bundle version update for the backing asset or CBA extension did not succeed, and therefore the newer configuration is not yet available.

If the status is "New OSGi application deployment available", the **Update to latest deployment ...** button is available. Click this button to bring the EBA composition unit up-to-date and run the updated business-level application. If any of the updates need configuration changes, a wizard prompts you to update the configuration information.

When you save the changes to the EBA composition unit, the associated business-level application is updated to use the new configuration. If the business-level application is running, the bundle and configuration updates are applied immediately. If possible (that is, depending on the nature of the updates) the system applies the updates without restarting the application. Updates that pull in new use bundles at run time prompt a full restart of the application. Updates that pull in new provision bundles might also prompt a full application restart.

JMS binding settings for SCA composites

Use this page to view property settings for a Java Message Service (JMS) binding that connects Service Component Architecture (SCA) composite references or services. Also use this page to edit resources of the JMS binding. The settings shown on this page define a `binding.jms` element.

To view this administrative console page, your composition unit must support a JMS binding reference or service. In the administrative console, do the following:

1. Click **Applications** > **Application Types** > **Business-level applications** > ***application_name*** > ***deployed_asset_composition_unit_name***.
2. From the composition unit settings page for SCA composites, select to view references or services:
   - For an SCA component reference, click **SCA Composite Components** > ***SCA_component_reference_name*** > **SCA Component References** > ***reference_name*** > **Bindings** > **JMS binding**.
   - For an SCA component service, click **SCA Composite Components** > ***SCA_component_service_name*** > **SCA Component Services** > ***service_name*** > **Bindings** > **JMS binding**.

You can use a JMS binding to identify existing JMS resources using Java Naming and Directory Interface (JNDI) names.

- General properties (read-only)
- Resources
- Response resources
- Request header properties for a reference (read-only)
- "Response header properties" on page 2155 for a service (read-only)

General properties:

Specifies property settings that apply to all `binding.jms` elements. The settings pertain to both services and references. You cannot edit the settings.

JMS binding URI
Specifies a uniform resource identifier (URI) that identifies properties such as the destination, connection factory and activation specification to be used to send or receive the JMS message.

The URI has the following format:

```
jms: jms_destination?
connectionFactoryName=connection_factory_name &
destinationType={queue|topic} &
deliveryMode=delivery_mode &
timeToLive=time_to_live &
priority=priority &
user_property=user_property_value & ...
```

Correlation schema
Specifies the correlation scheme used when sending reply or callback messages.

Valid values are `requestmsgidtocorrelid` (the default), `requestcorrelidtocorrelid`, and `none`.

Initial context factory
Specifies the name of the initial context factory used to obtain a JNDI initial context.

This setting is optional. If no factory is specified, the WebSphere Application Server initial context factory is used.

JNDI URL
Specifies the uniform resource locator (URL) for the JNDI provider.

Request connection
Specifies a `binding.jms` element that is present in a composite definition file.

A request is a message that is sent to an SCA service or sent by an SCA reference.

Response connection
Specifies a `binding.jms` element that is present in a composite definition file.

A response is a message received by a reference (that is, a reply from an invoked service) or a message sent by a service in response to a previous request message. A response in SCA is always a reply to a previous request.

Request wire format
Specifies the component definition element name of a wire that connects SCA composites.

For example, `wireFormat.jmsObject`.

A request is a message that is sent to an SCA service or sent by an SCA reference.

Response wire format
Specifies the component definition element name of a wire that connects SCA composites.

For example, `wireFormat.jmsObject`.

A response is a message received by a reference (that is, a reply from an invoked service) or a message sent by a service in response to a previous request message. A response in SCA is always a reply to a previous request.

Resources:

Specifies resources for the JMS binding. You can both read and edit resource settings for **Destination JNDI name**, **Activation specification JNDI name**, and **Connection factory JNDI name**. All other resource settings are read-only.

Destination type
Specifies the type of the request destination. Permitted values are `queue` (the default value) and `topic`. When `topic` is specified, then all the operations in the interface that correspond to the binding must be one-way.

This setting is for both services and references and is read-only.

`@type` is the destination type.

Destination JNDI name
Specifies an optional parameter that gives the JNDI name of a destination to which the binding is connected. For example, `jms/InvokeService_Callback`.

You can set a destination name for both services and references.

`@name` is the JNDI name of the destination.

Destination create
Specifies whether to create a destination for the binding.

Valid values are `ifnotexist` (the default), `always`, and `never`. When the value is `ifnotexist`, the product dynamically creates destination resources necessary for the SCA composite, if those resources do not exist and relate to the default messaging provider. The product creates the resources when adding the SCA composite to a business-level application.

The product validates a composite definition when adding an SCA asset to a business-level application. If the validation results in an error, the product does not add the asset to the application. If the value is `always` and the destination exists, deployment stops with an error.

Activation specification JNDI name
Specifies the activation specification that the binding uses to connect to a JMS destination to process request messages. The value must be a JNDI name.

You can set an activation specification for services only.

The attributes of this element follow those defined for the destination element.

Activation specification create
Specifies whether to create an activation specification for the binding. You can create an activation specification for services only.

Valid values are `ifnotexist` (the default), `always`, and `never`. When the value is `ifnotexist`, the product dynamically creates activation specification resources necessary for the SCA composite, if those resources do not exist and relate to the default messaging provider. If the value is `always` and the activation specification exists when the SCA composite is added to a business-level application, deployment stops with an error.

Connection factory JNDI name
Specifies the connection factory that the binding uses to process request messages. The value must be a JNDI name.

You can set a connection factory JNDI name for references only.

The attributes of this property follow those defined for the destination element. This property is mutually exclusive with the activationSpec property.

Connection factory create
Specifies whether to create a connection factory for the binding. You can create a connection factory for references only.

Valid values are `ifnotexist` (the default), `always`, and `never`. When the value is `ifnotexist`, the product dynamically creates connection factory resources necessary for the SCA composite, if those resources do not exist and relate to the default messaging provider. If the value is `always` and the connection factory exists when the SCA composite is added to a business-level application, deployment stops with an error.

Response resources:

Specifies the resources used for handling response messages, receiving responses for a reference, and for sending responses from a service. A response element defines the destination and either the connection factory or activation specification elements for handling response messages.

Response resources pertain to both services and references. You can both read and edit resource settings for **Response destination JNDI name** and **Response connection factory JNDI name**. All other resource settings are read-only.

Response destination type
Specifies the type of the response destination. Permitted values are `queue` (the default value) and `topic`. When `topic` is specified, then all the operations in the interface that corresponds to the binding must be one-way.

This setting is for both services and references and is read-only.

Response destination JNDI name
Specifies the destination that is to be used to process responses by this binding. Attributes are the same as for the parent destination element. For example, `jms/InvokeService_Response`.

You can set a destination name for both services and references.

Response destination create
Specifies whether to create a response destination for the binding.

Valid values are `ifnotexist` (the default), `always`, and `never`. When the value is `ifnotexist`, the product dynamically creates response destination resources necessary for the SCA composite, if those resources do not exist and relate to the default messaging provider. If the value is `always` and the response destination exists when the SCA composite is added to a business-level application, deployment stops with an error.

Response connection factory JNDI name
Specifies the connection factory that the binding uses to process response messages. The value must be a JNDI name.

You can set a response connection factory for both services and references.

The attributes of this element follow those defined for the destination element. This element is mutually exclusive with the activationSpec element.

Response connection factory create
Specifies whether to create a response connection factory that the binding can use to process response messages.

Valid values are `ifnotexist` (the default), `always`, and `never`. When the value is `ifnotexist`, the product dynamically creates response connection factory resources necessary for the SCA composite, if those resources do not exist and relate to the default messaging provider. If the value is `always` and the response connection factory exists when the SCA composite is added to a business-level application, deployment stops with an error.

Request header properties:

Specifies JMS header properties that apply to requests from a reference. You cannot edit the header properties.

If a JMS header property is specified, the property must not appear in the URI.

JMS type
Specifies a JMS type to use in the JMS header property using `@JMSType`.

JMS correlation ID
Specifies a JMS correlation identification to use in the JMS header property using `@JMSCorrelationID`.

JMS delivery mode
Specifies a JMS delivery mode to use in the JMS header property using `@JMSDeliveryMode`.

JMS time to live
Specifies a JMS time to live to use in the JMS header property using `@JMSTimeToLive`.

JMS priority
Specifies a JMS priority to use in the JMS header property using `@JMSPriority`.

Header property
Specifies a value to use for the specified JMS user property.

Response header properties:

Specifies JMS header properties that apply to responses from a service for outbound messages. You cannot edit the header properties.

If a JMS header property is specified, the property must not appear in the URI.

JMS type
Specifies a JMS type to use in the JMS header property using `@JMSType`.

JMS correlation ID
Specifies a JMS correlation identification to use in the JMS header property using `@JMSCorrelationID`.

JMS delivery mode
Specifies a JMS delivery mode to use in the JMS header property using `@JMSDeliveryMode`.

JMS time to live
Specifies a JMS time to live to use in the JMS header property using `@JMSTimeToLive`.

JMS priority
Specifies a JMS priority to use in the JMS header property using `@JMSPriority`.

Header property
Specifies a value to use for the specified JMS user property.

Provide HTTP endpoint URL information settings for SCA composites

Use this page to specify endpoint Universal Resource Locator (URL) prefix information for Service Component Architecture (SCA) composites accessed by web service bindings. The information is used to form complete endpoint addresses.

To view this administrative console page, click **Applications** > **Application Types** > **Business-level applications** > ***application_name*** > ***deployed_asset_composition_unit_name*** > **Provide HTTP endpoint URL information**.

Default SCA URL prefixes:

Shows the predefined default endpoint URL prefixes for SCA composites that are accessed by Hypertext Transfer Protocol (HTTP) or Hypertext Transfer Protocol Secure (HTTPS) for service endpoints.

The field shows both unsecure and secure custom endpoint URL values separated by a space. For example:

```
http://theHost:9081 https://theHost:9044
```

For each endpoint URL prefix, the format is *protocol*://*host_name*:*port_number*. The protocol is either http or https. In this example, *host_name* is theHost and *port_number* is the port used in the endpoint URL.

To use the default endpoint URL prefixes, deselect the **Override default SCA URL prefixes** check box.

Override default SCA URL prefixes:

Specifies whether to use a custom endpoint URL prefix when the service has a proxied front end. The endpoint URL prefixes are those of the proxy server. You must specify proxied endpoints when deploying services that use the web service binding in a clustered configuration.

To specify a custom endpoint URL prefix, do the following:

1. Select the **Override default SCA URL prefixes** check box.
2. For **HTTP host name**, specify the host name of the unsecure custom endpoint. For example: myHost
3. For **HTTP port**, specify the port of the unsecure custom endpoint. For example: 9081
4. For **HTTPS host name**, specify the host name of the secure custom endpoint. For example: myHost
5. For **HTTPS port**, specify the port of the secure custom endpoint. For example: 9044
6. Click **OK**.

SCA composite component settings

Use this page to view and edit the attributes associated with a Service Component Architecture (SCA) component.

To view this administrative console page, click **Applications** > **Application Types** > **Business-level applications** > ***application_name*** > ***deployed_asset_name*** > ***SCA_composite_component_name***.

Components are configured instances of implementations. Components provide and consume services. More than one component can use and configure the same implementation, where each component configures the implementation differently. For example each component might configure a reference of the same implementation to consume a different service.

An implementation defines the aspects configurable by a component in the form of a component type. The component type is in effect a description of the contract honored by the implementation.

A reference represents a requirement that the implementation has on a service provided by another component.

Component name:

Specifies the component name of the attribute.

Implementation:

Specifies the name of the class or configuration file that contains the component implementation.

For implementation.java, the Java class is shown. For other implementations, the name of the resource identified by the implementation is shown:

- For implementation.jee, the archive name is shown.
- For implementation.spring, the application context file is shown.
- For implementation.osgiapp, the application symbolic name and version is shown.

Type:

Specifies the type of attribute. In this case, the type is `Component`.

SCA component services:

Specifies the names of the services.

SCA component references:

Specifies the names and targets of component references. You can edit the reference target for customization.

SCA component properties:

Specifies the **Property Input Source** and **Property Value** for each property.

Options for **Property Input Source** include the following:

- **XPath** indicates the source attribute of the property.
- **File** indicates the file attribute of the property.
- **Value** indicates the property element value.

SCA component reference settings

Use this page to view and edit the attributes associated with a Service Component Architecture (SCA) component reference.

To view this administrative console page, click **Applications** > **Application Types** > **Business-level applications** > ***application_name*** > ***deployed_asset_composition_unit_name*** > ***SCA_composite_component_name*** > ***reference_name***.

SCA component references within an implementation represent links to services the implementation uses that must be provided by other components in the SCA system. For a composite, you can wire references of components within the composite (component references) to references of the composite (composite references), indicating that the component references must be resolved by services outside the composite.

References use bindings to describe the access methods used to invoke the services.

Under **Additional Properties**, click **View domain** to view a list of services available in the current cell or domain. This can be helpful when updating the **Target** setting value, for example.

Reference name:

Specifies the reference name of the attribute.

Type:

Specifies the type of attribute. In this case, it is `Reference`.

Reference target URI:

Specifies one or more target service uniform resource identifiers (URIs), depending on the multiplicity setting. Each target wires the reference to a component service that resolves the reference. Targets can contain a list of targets separated by a space, in the form **`target1 target2`**.

Bindings:

Specifies the URI of the binding.

Supported bindings include the SCA default binding, enterprise bean (EJB) binding, web service binding, Java Message Service (JMS) binding, Atom binding, and HTTP binding.

SCA component service settings

Use this page to view and edit the attributes associated with a component service.

To view this administrative console page, click **Applications** > **Application Types** > **Business-level applications** > ***application_name*** > ***deployed_asset_composition_unit_name*** > ***SCA_composite_component_name*** > ***service_name***.

Services are used to publish services provided by implementations, so that they are addressable by other components.

A service published by a component can be provided by a service of a component defined within the component, or it can be provided by a component reference. The latter case allows the republication of a service with a new address or new bindings.

Service name:

Specifies the service name of the attribute.

Type:

Specifies the type of attribute. In this case, `Service`.

Work manager JNDI name:

Specifies the Java Naming and Directory Interface (JNDI) name of the work manager.

Bindings:

Specifies the uniform resource identifier (URI) of the binding.

Supported bindings include the SCA default binding, enterprise bean (EJB) binding, web service binding, Java Message Service (JMS) binding, Atom binding, and HTTP binding.

Service provider policy sets and bindings collection for SCA composites

Use this page to attach and detach policy sets to a composition unit, a service provider, its endpoints, or operations of a Service Component Architecture (SCA) composite. You can select the default bindings, create new application-specific bindings, or use bindings that you created for an attached policy set. You can view or change whether the service provider can share its current policy configuration.

To view this administrative console page, your composition unit must use web services and support SCA. Click **Applications** > **Application Types** > **Business-level applications** > ***application_name*** > ***deployed_asset_composition_unit_name*** > **Service provider policy sets and bindings** .

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

To attach or detach a policy set or binding, do the following:

1. Select a composition unit, service, endpoint, or operation. The **Composition unit/Service/Endpoint/ Operation** list is nested, indicating parent-child relationships.
2. Click the desired button.

Table 282. Button descriptions. Use the buttons to attach or detach policy sets and to assign policy set bindings.

Button	Resulting action
Attach	Attaches a policy set to the selected composition unit, service, endpoint, or operation. To attach a policy set, select a unit, service, endpoint, or operation and click **Attach** > ***policy_set_option***. To close the menu list, click **Attach**.
Detach Policy Set	Detaches a policy set from the selected composition unit, service, endpoint, or operation. After the policy set is detached, if there is no policy set attached to an upper-level service resource, the **Attached Policy Set** column displays **None** and the **Binding** column displays **Not applicable**. If there is a policy set attached to an upper-level service resource, the **Attached Policy Set** column displays ***policy_set_name*** **(inherited)** and the binding used for the upper-level attachment is applied. The binding name is displayed followed by **(inherited)**.
Assign Binding	Assigns a policy set binding to the selected composition unit, service, endpoint, or operation. The options include the following: **Default** Specifies the default binding for the selected service reference, endpoint, or operation. You can specify client and provider default bindings to be used at the cell level or global security domain level, for a particular server, or for a security domain. The default bindings are used when an application-specific binding has not been assigned to the attachment. When you attach a policy set to a service resource, the binding is initially set to the default. If you do not specifically assign a binding to the attachment point using this Assign Binding action, the default specified at the nearest scope is used. For any policy set attachment, the run time checks to see if the attachment includes a binding. If so, it uses that binding. If not, the run time checks in the following order and uses the first available default binding: 1. Default general bindings for the server 2. Default general bindings for the domain in which the server resides 3. Default general bindings for the global security domain **New Application Specific Binding** Select this option to create a new application-specific binding for the policy set attachments. The new binding you create is used for the selected resources. If you select more than one resource, ensure that all selected resources have the same policy set attached. **Provider sample** Select this option to use the Provider sample binding. **Provider sample V2** Select this option to use the Provider sample V2 binding when you are using either the Kerberos V5 WSSecurity default or the TrustServiceKerberosDefault policy sets. **Saml Bearer Provider sample** Select this option to use the Saml Bearer Provider sample. The Saml Bearer Provider sample extends the Provider sample binding to support SAML Bearer token usage scenarios. You can use this sample with any of the SAML bearer token default policy sets. **Saml HoK Symmetric Provider sample** Select this option to use the Saml HoK Symmetric Provider sample. The Saml HoK Symmetric Provider sample extends the Provider sample binding to support SAML holder-of-key (HoK) symmetric key token usage scenarios. You can use this sample with one of the SAML HoK Symmetric key default policy sets: either SAML11 HoK Symmetric WSSecurity default or SAML20 HoK Symmetric WSSecurity default.

Composition unit/Service/Endpoint/Operation:

Specifies the name of the composition unit and the associated service providers, endpoints or operations.

The Composition unit/Service/Endpoint/Operation column lists the composition unit and the service providers, endpoints, or operations that the composition unit contains.

Attached Policy Set:

Specifies the policy set that is attached to a composition unit, service provider, endpoint, or operation.

The Attached Policy Set column can contain the following values:

- **None**. No policy set is attached, either directly or to a higher-level service resource.
- ***Policy_set_name***. The name of the policy set that is attached directly to the service resource, for example, WS-I RSP.
- ***Policy_set_name*** **(inherited)**. The name of the policy set that is not attached directly to a service resource, but that is attached to a higher-level service resource.

When the value in the column is a link, click the link to view or change settings about the attached policy set.

Binding:

Specifies the binding configuration that is available for a service provider, endpoint, or operation.

The Binding column can contain the following values:

- **Not applicable**. No policy set is attached, either directly or to a higher-level service resource.
- ***Binding_name*** or **Default**. The binding name is displayed if a policy set is attached directly and an application-specific binding or a general binding is assigned, for example, `MyBindings1`. **Default** is displayed if a policy set is attached directly but the service resource uses the default bindings.
- ***Binding_name*** **(inherited)** or **Default (inherited)**. A service resource inherits the bindings from an attachment to a higher-level resource.

When the value in the Binding column is a link, click the link to view or change settings about the binding.

References policy sets and bindings collection for SCA composites

Use this page to attach and detach policy sets to a composition unit, a service reference, its endpoints, or operations of a Service Component Architecture (SCA) composite. You can select the default bindings, create new application-specific bindings, or use bindings that you created for an attached policy set. You can view or change whether the service reference can share its current policy configuration.

To view this administrative console page, your composition unit must use web services and support SCA. Click **Applications** > **Application Types** > **Business-level applications** > ***application_name*** > ***deployed_asset_composition_unit_name*** > **References policy sets and bindings**.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

To attach or detach a policy set or binding, do the following:

1. Select a composition unit, service, endpoint, or operation. The **Composition unit/Service/Endpoint/ Operation** list is nested, indicating parent-child relationships.
2. Click the desired button.

Table 283. Button descriptions. Use the buttons to attach or detach client policy sets and to assign policy set bindings.

Button	Resulting action
Attach Client Policy Set	Attaches a client policy set to the selected composition unit, service, endpoint, or operation. To attach a policy set, select a composition unit, service, endpoint, or operation and click **Attach Client Policy Set** > ***policy_set_option***. To close the menu list, click **Attach Client Policy Set**.
Detach Client Policy Set	Detaches a client policy set from the selected composition unit, service, endpoint, or operation. After the policy set is detached, if there is no policy set attached to an upper-level service resource, the **Attached Client Policy Set** column displays **None** and the **Binding** column displays **Not applicable**. If there is a policy set attached to an upper-level service resource, the **Attached Client Policy Set** column displays ***policy_set_name*** **(inherited)** and the binding used for the upper-level attachment is applied. The binding name is displayed followed by **(inherited)**.

Table 283. Button descriptions (continued). Use the buttons to attach or detach client policy sets and to assign policy set bindings.

Button	Resulting action
Assign Binding	Assigns a policy set binding to the selected composition unit, service, endpoint, or operation. The options include the following: **Default** Specifies the default binding for the selected service, endpoint, or operation. You can specify client and provider default bindings to be used at the cell level or global security domain level, for a particular server, or for a security domain. The default bindings are used when an application-specific binding has not been assigned to the attachment. When you attach a policy set to a service resource, the binding is initially set to the default. If you do not specifically assign a binding to the attachment point using this Assign Binding action, the default specified at the nearest scope is used. For any policy set attachment, the run time checks to see if the attachment includes a binding. If so, it uses that binding. If not, the run time checks in the following order and uses the first available default binding: 1. Default general bindings for the server 2. Default general bindings for the domain in which the server resides 3. Default general bindings for the global security domain **New Application Specific Binding** Select this option to create a new application-specific binding for the policy set attachments. The new binding you create is used for the selected resources. If you select more than one resource, ensure that all selected resources have the same policy set attached. **Client sample** Select this option to use the Client sample binding. **Client sample V2** Select this option to use the Client sample V2 binding when you are using either the Kerberos V5 WSSecurity default or the TrustServiceKerberosDefault policy sets. **Saml Bearer Client sample** Select this option to use the Saml Bearer Client sample. The Saml Bearer Client sample extends the Client sample binding to support SAML Bearer token usage scenarios. You can use this sample with any of the SAML bearer token default policy sets. **Saml HoK Symmetric Client sample** Select this option to use the Saml HoK Symmetric Client sample. The Saml HoK Symmetric Client sample extends the Client sample binding to support SAML holder-of-key (HoK) symmetric key token usage scenarios. You can use this sample with one of the SAML HoK Symmetric key default policy sets: either SAML11 HoK Symmetric WSSecurity default or SAML20 HoK Symmetric WSSecurity default.

Composition unit/Service/Endpoint/Operation:

Specifies the name of the composition unit and the associated service references, endpoints or operations.

The Composition unit/Service/Endpoint/Operation column lists the service composition unit and the service references, endpoints, or operations that the composition unit contains.

Attached Client Policy Set:

Specifies the policy set that is attached to a composition unit, service reference, endpoint, or operation.

The Attached Client Policy Set column can contain the following values:

- **None**. No policy set is attached, either directly or to a higher-level service resource.
- ***Policy_set_name***. The name of the policy set that is attached directly to the service resource, for example, WS-I RSP.
- ***Policy_set_name* (inherited)**. The name of the policy set that is not attached directly to a service resource, but that is attached to a higher-level service resource.

When the value in the column is a link, click the link to view or change settings about the attached policy set.

Binding:

Specifies the binding configuration that is available for a service reference, endpoint, or operation.

The Binding column can contain the following values:

- **Not applicable**. No policy set is attached, either directly or to a higher-level service resource.
- ***Binding_name*** or **Default**. The binding name is displayed if a policy set is attached directly and an application-specific binding or a general binding is assigned, for example, `MyBindings1`. **Default** is displayed if a policy set is attached directly but the service resource uses the default bindings.
- ***Binding_name* (inherited)** or **Default (inherited)**. A service resource inherits the bindings from an attachment to a higher-level resource.

When the value in the Binding column is a link, click the link to view or change settings about the binding.

SCA service provider settings

Use this page to manage policy sets for a Service Component Architecture (SCA) web service provider. You can attach and detach policy sets to a service provider, its endpoints, or operations. You can select the default bindings, create new application-specific bindings, or use bindings that you created for an attached policy set. You can view or change whether the service provider can share its current policy configuration.

To view this administrative console page, your composition unit must use web services and support SCA. Click **Services** > **Service providers** > ***service_provider_name***.

Service provider:

Specifies the full QName of the service provider. The QName must be in a format that supports the Java class `javax.xml.namespace.QName`.

For the SCA sample business-level application HelloWorldAsync, the service provider name resembles the following:

```
{http://websphere.ibm.com/HelloWorldServiceComponent/HelloWorldService}HelloWorldService
```

Policy Set Attachments:

Specifies the attached policy sets and assigned bindings for services, endpoints, or operations in the service provider.

To attach or detach a policy set or to assign bindings with system-specific configurations, do the following:

1. Select a service, endpoint, or operation. The **Service/Endpoint/Operation** list is nested, indicating parent-child relationships.
2. Click the desired button.

Table 284. Button descriptions. Use the buttons to attach or detach policy sets and to assign policy set bindings.

Button	Resulting action
Attach	Attaches a policy set to the selected service, endpoint, or operation. To attach a policy set, select a service, endpoint, or operation and click **Attach** > ***policy_set_option***. To close the menu list, click **Attach**.
Detach Policy Set	Detaches a policy set from the selected service, endpoint, or operation. After the policy set is detached, if there is no policy set attached to an upper-level service resource, the **Attached Policy Set** column displays **None** and the **Binding** column displays **Not applicable**. If there is a policy set attached to an upper-level service resource, the **Attached Policy Set** column displays ***policy_set_name*** **(inherited)** and the binding used for the upper-level attachment is applied. The binding name is displayed followed by **(inherited)**.
Assign Binding	Assigns a policy set binding to the selected service, endpoint, or operation. The options include the following: **Default** Specifies the default binding for the selected service reference, endpoint, or operation. You can specify client and provider default bindings to be used at the cell level or global security domain level, for a particular server, or for a security domain. The default bindings are used when an application-specific binding has not been assigned to the attachment. When you attach a policy set to a service resource, the binding is initially set to the default. If you do not specifically assign a binding to the attachment point using this Assign Binding action, the default specified at the nearest scope is used. For any policy set attachment, the run time checks to see if the attachment includes a binding. If so, it uses that binding. If not, the run time checks in the following order and uses the first available default binding: 1. Default general bindings for the server 2. Default general bindings for the domain in which the server resides 3. Default general bindings for the global security domain **New Application Specific Binding** Select this option to create a new application-specific binding for the policy set attachments. The new binding you create is used for the selected resources. If you select more than one resource, ensure that all selected resources have the same policy set attached. **Provider sample** Select this option to use the Provider sample binding. **Provider sample V2** Select this option to use the Provider sample V2 binding when you are using either the Kerberos V5 WSSecurity default or the TrustServiceKerberosDefault policy sets. **Saml Bearer Provider sample** Select this option to use the Saml Bearer Provider sample. The Saml Bearer Provider sample extends the Provider sample binding to support SAML Bearer token usage scenarios. You can use this sample with any of the SAML bearer token default policy sets. **Saml HoK Symmetric Provider sample** Select this option to use the Saml HoK Symmetric Provider sample. The Saml HoK Symmetric Provider sample extends the Provider sample binding to support SAML holder-of-key (HoK) symmetric key token usage scenarios. You can use this sample with one of the SAML HoK Symmetric key default policy sets: either SAML11 HoK Symmetric WSSecurity default or SAML20 HoK Symmetric WSSecurity default.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Service/Endpoint/Operation
Specifies the name of the service and the associated service providers, endpoints or operations.

The Service/Endpoint/Operation column lists the service and the service providers, endpoints, or operations that the service contains.

Attached Policy Set
Specifies the policy set that is attached to a service provider, endpoint, or operation.

The Attached Policy Set column can contain the following values:

- **None**. No policy set is attached, either directly or to a higher-level service resource.
- ***Policy_set_name***. The name of the policy set that is attached directly to the service resource, for example, WS-I RSP.
- ***Policy_set_name* (inherited)**. The name of the policy set that is not attached directly to a service resource, but that is attached to a higher-level service resource.

When the value in the column is a link, click the link to view or change settings about the attached policy set.

Binding
Specifies the binding configuration that is available for a service provider, endpoint, or operation.

The Binding column can contain the following values:

- **Not applicable**. No policy set is attached, either directly or to a higher-level service resource.
- ***Binding_name*** or **Default**. The binding name is displayed if a policy set is attached directly and an application-specific binding or a general binding is assigned, for example, `MyBindings1`. **Default** is displayed if a policy set is attached directly but the service resource uses the default bindings.
- ***Binding_name* (inherited)** or **Default (inherited)**. A service resource inherits the bindings from an attachment to a higher-level resource.

When the value in the Binding column is a link, click the link to view or change settings about the binding.

About policy set bindings

In this release, there are two types of bindings: application-specific bindings and general bindings. Composition units can use both application-specific bindings and general bindings.

Application-specific bindings

You can create application-specific bindings only at a policy set attachment point. These bindings are specific to, and constrained by, the characteristics of the defined policy. Application-specific bindings can provide configuration for advanced policy requirements such as multiple signatures; however, these bindings are reusable only within an application. Also, application-specific bindings have very limited reuse across policy sets.

When you create an application-specific binding for a policy set attachment, the binding begins in a completely unconfigured state. You must add each policy, such as WS-Security or HTTP transport, that you want to override the default binding, and fully configure the bindings for each policy that you add. For WS-Security policy, some high level configuration attributes such as TokenConsumer, TokenGenerator, SigningInfo, or EncryptionInfo might be obtained from the default bindings if they are not configured in the application-specific bindings.

For service providers, you can create application-specific bindings only by selecting **Assign Binding** > **New Application Specific Binding**, on the Service providers policy sets and bindings collection page, for service provider resources that have an attached policy set. Similarly, for service clients, you can create application-specific bindings only by selecting **Assign Binding** > **New Application Specific Binding**, on the Service clients policy sets and bindings collection page, for service client resources that have an attached policy set.

General bindings

You can configure general bindings to be used across a range of policy sets and they can be reused across applications and for trust service attachments. Although general bindings are highly reusable, they cannot provide configuration for advanced policy requirements such as multiple signatures. There are two types of general bindings: general provider policy set bindings and general client policy set bindings.

You can create general provider policy set bindings by clicking **Services** > **Policy sets** > **General provider policy set bindings** > **New** in the general provider policy sets panel, or by clicking **Services** > **Policy sets > General client policy set bindings** > **New** in the general client policy set and bindings panel. For details about defining and managing service client or provider bindings, see the related links. General provider policy set bindings might also be used for trust service attachments.

SCA service client settings

Use this page to manage policy sets for a Service Component Architecture (SCA) web service client. You can attach and detach policy sets to a service reference, its endpoints, or operations. You can select the default bindings, create new application-specific bindings, or use bindings that you created for an attached policy set. You can view or change whether the service reference can share its current policy configuration.

To view this administrative console page, your composition unit must use web services and support SCA. Click **Services** > **Service clients** > ***service_client_name***.

Service client:

Specifies the full QName of the service client. The QName must be in a format that supports the Java class `javax.xml.namespace.QName`.

For the SCA sample business-level application HelloWorldAsync, the service client name resembles the following:

```
{http://websphere.ibm.com/HelloWorldServiceComponent/HelloWorldService}HelloWorldCallbackService
```

This SCA application has the product web service namespace, `http://websphere.ibm.com/`, and the service name in its service client name.

Policy Set Attachments:

Specifies the attached policy sets and assigned bindings for services, endpoints, or operations in the service client.

To attach or detach a policy set or to assign bindings with system-specific configurations, do the following:

1. Select a service, endpoint, or operation. The **Service/Endpoint/Operation** list is nested, indicating parent-child relationships.
2. Click the desired button.

Table 285. Button descriptions. Use the buttons to attach or detach client policy sets and to assign policy set bindings.

Button	Resulting action
Attach Client Policy Set	Attaches a client policy set to the selected service, endpoint, or operation. To attach a policy set, select a service, endpoint, or operation and click **Attach Client Policy Set** > ***policy_set_option***. To close the menu list, click **Attach Client Policy Set**.
Detach Client Policy Set	Detaches a client policy set from the selected service, endpoint, or operation. After the policy set is detached, if there is no policy set attached to an upper-level service resource, the **Attached Client Policy Set** column displays **None** and the **Binding** column displays **Not applicable**. If there is a policy set attached to an upper-level service resource, the **Attached Client Policy Set** column displays ***policy_set_name*** **(inherited)** and the binding used for the upper-level attachment is applied. The binding name is displayed followed by **(inherited)**.

Table 285. Button descriptions (continued). Use the buttons to attach or detach client policy sets and to assign policy set bindings.

Button	Resulting action
Assign Binding	Assigns a policy set binding to the selected service, endpoint, or operation. The options include the following: **Default** Specifies the default binding for the selected service, endpoint, or operation. You can specify client and provider default bindings to be used at the cell level or global security domain level, for a particular server, or for a security domain. The default bindings are used when an application-specific binding has not been assigned to the attachment. When you attach a policy set to a service resource, the binding is initially set to the default. If you do not specifically assign a binding to the attachment point using this Assign Binding action, the default specified at the nearest scope is used. For any policy set attachment, the run time checks to see if the attachment includes a binding. If so, it uses that binding. If not, the run time checks in the following order and uses the first available default binding: 1. Default general bindings for the server 2. Default general bindings for the domain in which the server resides 3. Default general bindings for the global security domain **New Application Specific Binding** Select this option to create a new application-specific binding for the policy set attachments. The new binding you create is used for the selected resources. If you select more than one resource, ensure that all selected resources have the same policy set attached. **Client sample** Select this option to use the Client sample binding. **Client sample V2** Select this option to use the Client sample V2 binding when you are using either the Kerberos V5 WSSecurity default or the TrustServiceKerberosDefault policy sets. **Saml Bearer Client sample** Select this option to use the Saml Bearer Client sample. The Saml Bearer Client sample extends the Client sample binding to support SAML Bearer token usage scenarios. You can use this sample with any of the SAML bearer token default policy sets. **Saml HoK Symmetric Client sample** Select this option to use the Saml HoK Symmetric Client sample. The Saml HoK Symmetric Client sample extends the Client sample binding to support SAML holder-of-key (HoK) symmetric key token usage scenarios. You can use this sample with one of the SAML HoK Symmetric key default policy sets: either SAML11 HoK Symmetric WSSecurity default or SAML20 HoK Symmetric WSSecurity default.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Service/Endpoint/Operation

Specifies the name of the service and the associated service references, endpoints or operations.

The Service/Endpoint/Operation column lists the service and the service references, endpoints, or operations that the service contains.

Attached Client Policy Set

Specifies the policy set that is attached to a service reference, endpoint, or operation.

The Attached Client Policy Set column can contain the following values:

- **None**. No policy set is attached, either directly or to a higher-level service resource.
- ***Policy_set_name***. The name of the policy set that is attached directly to the service resource, for example, WS-I RSP.
- ***Policy_set_name* (inherited)**. The name of the policy set that is not attached directly to a service resource, but that is attached to a higher-level service resource.

When the value in the column is a link, click the link to view or change settings about the attached policy set.

Binding

Specifies the binding configuration that is available for a service reference, endpoint, or operation.

The Binding column can contain the following values:

- **Not applicable**. No policy set is attached, either directly or to a higher-level service resource.
- ***Binding_name*** or **Default**. The binding name is displayed if a policy set is attached directly and an application-specific binding or a general binding is assigned, for example, `MyBindings1`. **Default** is displayed if a policy set is attached directly but the service resource uses the default bindings.
- ***Binding_name* (inherited)** or **Default (inherited)**. A service resource inherits the bindings from an attachment to a higher-level resource.

When the value in the Binding column is a link, click the link to view or change settings about the binding.

About policy set bindings

In this release, there are two types of bindings: application-specific bindings and general bindings. Composition units can use both application-specific bindings and general bindings.

Application-specific bindings

You can create application-specific bindings only at a policy set attachment point. These bindings are specific to, and constrained by, the characteristics of the defined policy. Application-specific bindings can provide configuration for advanced policy requirements such as multiple signatures; however, these bindings are reusable only within an application. Also, application-specific bindings have very limited reuse across policy sets.

When you create an application-specific binding for a policy set attachment, the binding begins in a completely unconfigured state. You must add each policy, such as WS-Security or HTTP transport, that you want to override the default binding, and fully configure the bindings for each policy that you add. For WS-Security policy, some high level configuration attributes such as TokenConsumer, TokenGenerator, SigningInfo, or EncryptionInfo might be obtained from the default bindings if they are not configured in the application-specific bindings.

For service providers, you can create application-specific bindings only by selecting **Assign Binding** > **New Application Specific Binding**, on the Service providers policy sets and bindings collection page, for service provider resources that have an attached policy set. Similarly, for service clients, you can create application-specific bindings only by selecting **Assign Binding** > **New Application Specific Binding**, on the Service clients policy sets and bindings collection page, for service client resources that have an attached policy set.

General bindings

You can configure general bindings to be used across a range of policy sets and they can be reused across applications and for trust service attachments. Although general bindings are highly reusable, they

cannot provide configuration for advanced policy requirements such as multiple signatures. There are two types of general bindings: general provider policy set bindings and general client policy set bindings.

You can create general provider policy set bindings by clicking **Services** > **Policy sets** > **General provider policy set bindings** > **New** in the general provider policy sets panel, or by clicking **Services** > **Policy sets** > **General client policy set bindings** > **New** in the general client policy set and bindings panel. For details about defining and managing service client or provider bindings, see the related links. General provider policy set bindings might also be used for trust service attachments.

Example: Creating an SCA business-level application with the console

You can add many different types of artifacts to business-level applications. For example, you can add applications or modules, Java archives (JAR files), data in compressed files, and other business-level applications. This example describes how to create an empty business-level application and then add a Service Component Architecture (SCA) JAR file to the application using the administrative console.

Before you begin

In a product installation, verify that the target server is configured. As part of configuring the server, determine whether your application files can run on your deployment target. You must deploy SCA composite assets of a business-level application to a Version 8.0 or later server or cluster (target) or to a Version 7.0 target that is enabled for the Feature Pack for SCA.

Download the `helloworld-ws-asynch.jar` SCA sample file from a product download site:

1. Go to the **Samples, Version 8.5** information center.
2. On the **Downloads** tab, click **FTP** or **HTTP** in the **Service Component Architecture** section.
3. In the authentication window, click **OK**.
4. In the **SCA.zip** compressed file, go to the `SCA/installableApps` directory and download the `helloworld-ws-asynch.jar` file.

About this task

For this example, use the administrative console to create a business-level application named HelloWorldAsync that has an SCA JAR file, `helloworld-ws-asynch.jar`, as an asset.

Procedure

1. Create an empty business-level application named `HelloWorldAsync`.
   a. Click **Applications** > **New Application** > **New Business Level Application**.
   b. On the New application page, specify the name `HelloWorldAsync`, optionally add a description, and then click **Apply**.
   c. On the page that is displayed, click the **Save** link.

   The name is shown in the list of applications on the Business-level applications page. Because the application is empty, its status is `Unknown`.
2. Import the SCA JAR asset.
   a. Click **Applications** > **New Application** > **New Asset** in the console navigation tree.
   b. On the Upload asset page, specify the asset package to import, `helloworld-ws-asynch.jar`, and click **Next**.

      The JAR file is in the *app_server_root*/`installableApps` directory.
   c. On the Select options for importing an asset page, click **Next** to accept the default values.
   d. On the Summary page, click **Finish**.
   e. On the Adding asset to repository page, if messages show that the operation completed, click **Manage assets**.
   f. On the Assets page, click the **Save** link.

The file name displays in the list of assets.

3. Add the SCA JAR asset as a composition unit of the business-level application.
   a. Click **Applications** > **Application Types** > **Business-level applications**.
   b. On the Business-level applications page, click the `HelloWorldAsync` application name.
   c. On the business-level application settings page, click **Add** > **Add Asset**.
   d. On the Add page, select the `helloworld-ws-asynch.jar` asset composition unit from the list of available units, and then click **Continue**.
   e. On the Set options page, click **Next** to accept the default values.
   f. On the Map composition unit to a target page, specify a target server that supports SCA composites, and then click **Next**.

      The target server can be an existing cluster. To map the composition unit to a cluster, select the existing cluster from the **Available** list, click **Add**, and then click **Next**. The cluster name is shown in the **Current targets** list as `WebSphere:cluster=`*`cluster_name`*.
   g. On the Define relationship with existing composition units page, click **Next** to accept the default values.
   h. On the Map virtual host page, click **Next** to accept the default values.
   i. On the Summary page, click **Finish**.

      Several messages are displayed. A message having the format `Completed res=[WebSphere:cuname=helloworldws]` indicates that the addition is successful.

      During deployment of the composition unit, you can view the Uniform Resource Identifier (URI) for composite level service of some bindings, along with the service name and binding type. Only the URI is editable. The product does not validate the URI.
   j. If the addition is successful, click **Manage application**.
   k. On the business-level application settings page, click **Save**.

   The asset name and type displays in the list of deployed assets. If you click on the asset name, the composition unit settings page displays, with the asset name in the **SCA Composite Components** list.
4. Start the HelloWorldAsync business-level application.
   a. Click **Applications** > **Application Types** > **Business-level applications**.
   b. On the Business-level applications page, select the check box beside HelloWorldAsync.
   c. Click **Start**.

   When the business-level application is running, a green arrow displays for **Status**. If the business-level application does not start, ensure that the deployment target to which the application maps is running and try starting the application again.

What to do next

Optionally examine, and possibly use in applications, other SCA sample files in the `SCA/installableApps` directory of the downloadable SCA samples.

If the business-level application does not start, ensure that the deployment target to which the application maps is running and try starting the application again. If SCA composite assets do not start, ensure that each asset is mapped to a deployment target that supports SCA composites.

If an asset composition unit uses an Enterprise JavaBeans (EJB) binding and does not start because it has a `non-WebSphere target of "null"`, delete the asset composition unit and add it again to the business-level application. Specify a target that supports SCA composites when you add the asset to the business-level application. You cannot change the target after deployment.

If the SCA application uses security, the target server or cluster must be in the global security domain.

In multiple-node environments, synchronize the nodes after you save changes to the target before starting the business-level application.

Updating SCA composite artifacts

You can view and update Service Component Architecture (SCA) composite artifacts in business-level applications.

Before you begin

Add an SCA artifact as a composition unit to a business-level application.

About this task

You can view and update the following SCA composite artifacts:
- Composite level property definition
- Composite level component property definition
- Composite level component reference definition

You can view and update SCA composite artifacts using the administrative console or the wsadmin tool. This topic describes how to view and update SCA composite artifacts using the administrative console.

Procedure

1. Go to the composition unit settings page for an SCA composite artifact in a business-level application.

   Click **Applications** > **Application Types** > **Business-level applications** > ***application_name*** > ***SCA_deployed_asset_composition_unit_name***.

   The composition unit settings page for an SCA composite artifact has fields that are not shown on the composition unit settings page for a non-SCA artifact:
   - SCA composite components
   - SCA composite properties
   - SCA composite wires
2. Click on a name link in one of these SCA fields to view the settings for an SCA artifact.

   The SCA fields display `None` instead of a name link if the composition unit does not have that particular type of SCA composite.
3. Optional: Update a SCA composite setting value.
   a. Change an existing setting value for the SCA artifact.
   b. Click **OK**.

   The setting value is updated.

Viewing and updating SCA composites in HelloWorldAsync

"Example: Creating an SCA business-level application with the console" on page 2170 describes how to create the HelloWorldAsync business-level application. This application contains an SCA artifact, helloworldws, as a composition unit. You can view and update settings for SCA composites in the helloworldws composition unit using the console.

1. Go to the composition unit settings page for the helloworldws composition unit in the HelloWorldAsync business-level application.

   Click **Applications** > **Application Types** > **Business-level applications** > **HelloWorldAsync** > **helloworldws**.

   From the composition unit settings page, you can view information associated with helloworldws, as well as update composite settings.
2. Click on a link for the SCA artifact to be viewed or updated.

For example, click on the HelloWorldServiceComponent link under **SCA composite components** and, in the page that displays, click on the HelloWorldService link under **Service**. In the Component service settings page that displays, you can specify a setting value for the service.

3. If you update a setting value for the SCA artifact, click **OK**.

What to do next

Save the changes to your administrative configuration.

On multiple-server products, when saving the configuration, synchronize the configuration with the nodes where the application is expected to run.

Viewing SCA composite definitions

You can view information on the definition of a Service Component Architecture (SCA) composite in the administrative console.

Before you begin

The SCA composite must be a composition unit in a business-level application.

About this task

The composite definition provides data on the composite, such as component names and service references. The View composite page displays the composite definition of an SCA deployed asset composition unit.

Procedure

1. Go to the View composite page.

   Click **Applications** > **Application Types** > **Business-level applications** > ***application_name*** > ***SCA_deployed_asset_name*** > **View composite**.

2. Optional: Click **Expand All** or **Collapse All** to more easily browse the page.

Results

The View composite page displays the contents of the composition unit definition.

Example

Suppose the HelloWorldAsync business-level application provided as a sample with the product is installed. Click **Applications** > **Application Types** > **Business-level applications** > **HelloWorldAsync** > **helloworldws** > **View composite**.

The View composite page displays configuration information resembling the following:

```
<composite targetNamespace="http://helloworld" name="helloworldws" >
  <component name="AsynchTranslatorComponent" >
    <implementation.java class="helloworld.impl.AsynchTranslatorComponent" />
      <service name="AsynchTranslatorService">
         <interface.java interface="helloworld.AsynchTranslatorService"
              callbackInterface="helloworld.HelloWorldCallback" />
        <binding.ws/>
          <callback>
              <binding.ws/>
          </callback>
      </service>
  </component>
</composite>
```

What to do next

Browse the page to ensure that it contains the intended configuration information.

Viewing SCA domain information

You can view information on Service Component Architecture (SCA) composites in an SCA domain in the administrative console.

Before you begin

The SCA composite must be a composition unit in a business-level application.

About this task

Viewing SCA domain information enables you to see on one console page information on all components in an SCA domain. The View domain page displays information on available services in the current domain.

Procedure

1. Go to the View domain page.

   Click **Applications** > **Application Types** > **Business-level applications** > ***application_name*** > ***SCA_deployed_asset_name*** > **View domain**.
2. Optional: Click **Expand All** or **Collapse All** to more easily browse the page.

Results

The View domain page lists information on components in the current domain.

Example

Suppose the HelloWorldAsync business-level application provided as a sample with the product is installed. Click **Applications** > **Application Types** > **Business-level applications** > **HelloWorldAsync** > **helloworldws** > **View domain**.

The View domain page displays information resembling the following:

```
<domain name="myCell02">
  <component name = "AsynchTranslatorComponent"
        mapTarget = "WebSphere:cell=myCell02,node=myNode02,server=server1">
    <service name = "AsynchTranslatorService">
      <interface.java interface = "helloworld.AsynchTranslatorService"/>
    </service>
    <reference name = "AsynchTranslatorService" target = ""/>
    <httpurlendpoints name = "endpoints" uri = ""/>
  </component>
</domain>
```

What to do next

Browse the page to ensure that it contains the intended information.

You can export the same domain information to a file using the exportCompositeToDomain command. See “Exporting SCA domain information using scripting.”

Viewing and editing JMS bindings on references and services of SCA composites

You can view information on a Java Message Service (JMS) binding for a Service Component Architecture (SCA) composite in the administrative console. The JMS bindings page of the console displays the settings of a `binding.jms` element. You can use the console page to edit resource and response resource settings.

Before you begin

Configure an SCA composite that uses JMS bindings and add that composite as a composition unit to a business-level application. To view and edit settings for a JMS binding on references, the composite must define a JMS binding in the reference. Similarly, to view and edit settings for a JMS binding on services, the composite must define a JMS binding in the service.

About this task

The JMS bindings page enables you to see JMS binding settings for an SCA composite in the administrative console. The information shown is similar to that shown by running the **viewCompUnit** wsadmin scripting command to view the SCA composite composition unit. However, the console page shows JMS binding settings only, and does not show other information on the composition unit that running **viewCompUnit** returns.

After deployment of an SCA composite that uses JMS bindings, you can edit JMS binding resource or response resource settings that specify Java Naming and Directory Interface (JNDI) names on the JMS bindings page. The editing capabilities are similar to those of the **editCompUnit** scripting command. To edit settings, the JMS resource must exist. The product does not dynamically create JMS resources when you edit a composition unit.

Procedure

1. Go to the JMS bindings page.

   To view this page, your composition unit must support a JMS binding reference or service.

   a. Click **Applications** > **Application Types** > **Business-level applications** > ***application_name*** > ***deployed_asset_composition_unit_name***.

   b. From the composition unit settings page for SCA composites, select to view references or services:

      - For an SCA component reference, click **SCA Composite Components** > ***SCA_component_reference_name*** > **SCA Component References** > ***reference_name*** > **Bindings** > **JMS binding**.
      - For an SCA component service, click **SCA Composite Components** > ***SCA_component_service_name*** > **SCA Component Services** > ***service_name*** > **Bindings** > **JMS binding**.

2. View the JMS binding settings for the composition unit.
3. Edit the **Destination JNDI name**, **Activation specification JNDI name**, **Connection factory JNDI name**, **Response destination JNDI name**, or **Response connection factory JNDI name** settings as needed and click **Apply**.

Results

The JMS bindings page displays property settings for a JMS binding. If you change resource or response resource JNDI name values, the changed values are shown.

Example

Suppose that you have a business-level application named `MyJmsBLA`, which has an SCA composite named `MySCAComposite`. This composite uses a JMS binding on service named `JmsService`, in a composition unit named `myJmsBindingCU`.

1. Click **Applications** > **Application Types** > **Business-level applications** > **MyJmsBLA** > **myJmsBindingCU** > **SCA Composite Components** > **MySCAComposite** > **SCA Component Services** > **JmsService** > **Bindings** > **JMS binding**.

   The JMS bindings page displays general binding settings and settings for a JMS binding on services.
2. Edit the value specified for **Activation specification JNDI name**, and click **Apply**.

   The JMS bindings page displays the changed value.

What to do next

Browse the page to ensure that it contains the binding information.

For information on JMS binding settings, refer to the online help for the JMS bindings page or Section 1.4 of the SCA JMS Binding specification, Version 1.00.

Exporting WSDL and XSD documents

You can export Web Services Description Language (WSDL) and XML schema definition (XSD) documents used by a Service Component Architecture (SCA) composition unit to a location of your choice.

Before you begin

Your SCA business-level application must contain one or more composition units that use a WSDL or XSD document.

A WSDL document is a file that provides a set of definitions that describe a web service in WSDL, an Extensible Markup Language (XML)-based description language.

An XSD document is an instance of an XML schema written in the XML schema definition language. The document has the extension `.xsd`. The prefix `xsd` in the XML elements of an XSD document indicates the XML schema namespace.

About this task

You can export WSDL and XSD documents that are used by an SCA composition unit using the administrative console. In previous releases, you had to use the **`exportWSDLArtifacts`** command to export WSDL and XSD documents.

On the composition unit settings page for an SCA composite, click the **Export WSDL and XSD documents** link and then specify the target location for the files.

The product extracts from the selected composition unit the WSDL and XSD files that are required for web services client development. The files are for the services exposed by the web service binding, `binding.ws`.

Procedure

1. Go to the composition unit settings page for the SCA composite.

   Click **Applications** > **Application Types** > **Business-level applications** > ***application_name*** > ***SCA_deployed_asset_name***.
2. Click the **Export WSDL and XSD documents** link.

3. From the displayed dialog, specify the target directory to which to save the documents.

Results

The WSDL and XSD documents are copied to the target directory.

Example

Suppose you want to export WSDL or XSD documents in the HelloWorldAsync business-level application that the product provides as a sample. Complete the following actions in the administrative console:

1. Click **Applications** > **Application Types** > **Business-level applications** > **HelloWorldAsync** > **helloworldws** > **Export WSDL and XSD documents**.
2. Using the displayed dialog, specify a directory that exists on your computer.

The product adds the `helloworldws_WSDLArtifacts.zip` file to the specified directory. The `helloworldws_WSDLArtifacts.zip` file has one WSDL file, `AsynchTranslatorComponentTranslatorService_wsdlgen.wsdl`.

What to do next

Examine the exported files to ensure that they contain the intended WSDL and XSD documents.

You can export WSDL and XSD documents using the exportWSDLArtifacts command. See Exporting WSDL and XSD documents using scripting.

Deploying OSGi applications that use SCA

You can deploy OSGi and Service Component Architecture (SCA) applications to servers or clusters as assets, which you add to a business-level application by creating composition units.

Before you begin

This topic assumes that you have already created an OSGi application packaged as an enterprise bundle archive (EBA) file and an SCA composite definition packaged as a Java archive (JAR) file.

An SCA composite packaged with a Web archive (WAR) file cannot use the `implementation.osgiapp` component.

About this task

To deploy an OSGi application that uses SCA, create a business-level application that includes the EBA and SCA assets. You can use the administrative console or wsadmin commands to create the business-level application, import the EBA file and SCA composite as assets, and then add the EBA and SCA assets as composition units to the business-level application.

An EBA composition unit consists of the imported asset (the EBA file), plus any configuration information for the OSGi application context roots, virtual hosts, and resource bindings. If a deployed OSGi application is to be extended using composite bundles extensions, apply all extensions to the EBA composition unit (`cu`) and update the OSGi application to the latest deployment version. You must install all service import and exports that are provided by composite bundle extensions before you can add the SCA asset as a composition unit to a business-level application. For information on using and deploying OSGi composite bundle extensions, see the topic on extending a deployed OSGi application.

For `implementation.osgiapp`, the component implementation value for the composition unit is the application symbolic name and version.

The following deployment restrictions apply to EBA files:
- Import an EBA file into only one asset.
- Add an EBA asset to only one business-level application.

For information about these and other restrictions, see the topic on multiple SCA implementation packaging considerations.

Procedure

1. Create a business-level application.

Table 286. Ways to create SCA business-level applications. You can create a business-level application that has OSGi and SCA assets using the administrative console or wsadmin scripts.

Option	Method
Administrative console business-level application creation wizard	Click **Applications** > **New Application** > **New Business Level Application** and follow instructions in the wizard. For example use of the console to create a business-level application that has an SCA asset, see Example: Creating an SCA business-level application with the console.

2. Import OSGi, SCA, or other assets needed by your business-level application.
3. Add the EBA asset as a composition unit to the business-level application.

   You must add the EBA asset before the SCA asset that references it.
4. Add the SCA asset as a composition unit to the business-level application.

   By default, the product assigns the SCA composition unit a higher starting weight value than the value for the OSGi composition unit. When using `implementation.osgiapp`, the SCA composition unit must start after the referenced OSGi composition unit starts. Thus, the SCA composition unit must have a higher starting weight value than the OSGi composition unit. If you override the default values and set a higher starting weight value for the OSGi composition unit than for the SCA composition unit, the business-level application does not start.

   In a Network Deployment environment, target the OSGi composition unit to the same server as the SCA composition unit.

   Note: If a validation error occurs when adding the SCA asset, saying that a service is not found, ensure that the following conditions exist:
   - The service name matches the name of a blueprint service
   - The Blueprint service uses the `services.exported.interfaces` property to export its interface
   - The interface is included in the Application-ExportService header of the application manifest

   The absence of these conditions can cause the validation error. The error resembles the following:

```
com.ibm.wsspi.management.bla.op.OpExecutionException: CWSAM0105E:
The following Service Component Architecture (SCA) Validation errors caused the
CreateScaCodeGen step to fail:
  Service not found for component service:
   Component = HelloWorldComponent Service = helloWorld
```

Results

The business-level application has OSGi and SCA composition units. You can now start the business-level application.

If the ServiceRuntimeException `Unable to access OSGi application framework` occurs when starting the business-level application, ensure that the SCA composition unit has a higher starting weight than the EBA composition unit.

If the ServiceRuntimeException `Unable to obtain service service from application` occurs, check `SystemOut.log` and `SystemErr.log` files for messages from the Blueprint container indicating that the run time cannot start the Blueprint service.

If the java.lang.TypeNotPresentException occurs when starting the business-level application, a bundle that uses one of the supported SCA annotations is not importing the org.osoa.sca.annotations package. Update the bundle manifest to import this package.

Note: This topic references one or more of the application server log files. As a recommended alternative, you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using `SystemOut.log` , `SystemErr.log`, `trace.log`, and `activity.log` files on distributed and IBM i systems. You can also use HPEL in conjunction with your native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.

What to do next

If you must delete a composition unit from the business-level application, delete the SCA composition unit before attempting to delete the EBA composition unit, otherwise the product returns an error. An EBA composition unit that provides the implementation cannot be deleted until the SCA composition unit that uses the `implementation.osgiapp` is deleted.

Multiple SCA implementation packaging considerations

The product supports several implementation technologies that can provide the business logic for SCA service components. Because a primary architectural objective of SCA is to enable you to combine existing services together, it is easy to assume that a single composite with multiple components might have different implementation technologies. However, there are restrictions that limit packaging of multiple SCA implementations.

Business-level application deployment constraints

Before deploying an SCA application, particularly one that uses an OSGi application, consider the following constraints:

- Collocation

  SCA composites can be comprised of a variety of implementation frameworks. Packaging formats for these frameworks include, for example, enterprise archive (EAR) files for Java Platform, Enterprise Edition (Java EE) applications or enterprise bundle archive (EBA) files for OSGi applications. An SCA business-level application must contain both the framework packaging format and the SCA composite that uses it.

  In a Network Deployment environment, when deploying an `implementation.osgiapp` in an SCA composition unit, the EBA composition unit used for the implementation must be in the same business-level application and targeted to the same server or cluster as the SCA composition unit.
- Artifacts or shared libraries

  Business-level applications support shared libraries. It typically is good practice to package interface artifacts (Java interface classes or WSDL/XSD artifacts) in a shared library. Services in applications configured in a business-level application can reference the shared library.

  However, OSGi applications do not support shared configuration libraries. You must package Java interface and WSDL/XSD artifacts in both the SCA contribution Java archive (JAR) file and the EBA asset that is configured in the business-level application.
- Only one deployment

  Only one instance of a given OSGi application, packaged as an EBA file, can be deployed in a Network Deployment cell. An EBA file can contain only one OSGi application. An EBA asset can contain only one

EBA file. An EBA asset can be added to only one business-level application, which is scoped at cell-level. Therefore, you can specify only once that a given OSGi application be an SCA implementation.

To get around this constraint, you can connect to a deployed OSGi application from other applications in the cell, but you cannot include the business logic in another composite.

Class loading

A purpose of the OSGi application framework is to build a class loader structure that is wholly defined by the OSGi service registry and OSGi application design, and avoid class loader problems that affect Java EE servers.

If your applications use different implementation technologies, differences in class loader structures might cause the SCA run time to copy objects from one environment to another. OSGi applications are remote-only interfaces that do not permit pass-by-reference behavior.

Your SCA application must use correct semantics for local and remote interfaces.

Chapter 46. Deploying SIP applications

Use the administrative console to customize your Session Initiation Protocol (SIP) application installation

About this task

When you deploy a Session Initiation Protocol (SIP) application, you can perform various tasks such as installing, starting, stopping, upgrading, and uninstalling the application.

SIP applications are installed as Java Platform, Enterprise Edition (Java EE) applications. You can deploy a SIP application from a graphical interface or from a command line.

Deploying SIP applications through the console

You can deploy a Session Initiation Protocol (SIP) application through the administrative console.

Before you begin

SIP applications are deployed as Java 2 Platform Enterprise Edition (J2EE) applications. In order to process requests, a virtual host must be defined when deploying the SIP application. If there is no virtual host defined for the configured SIP container listen port, the installed application will be inaccessible.

Procedure

1. Open the administrative console.

   In a browser, go to URL `http://`*`hostname`*`:9090/admin`, where *hostname* is the name of the host computer. Enter the appropriate login information, and click **OK**.
2. In the left frame click **Applications** > **Install New Application**.
3. Browse and select a SAR file. Specify the context root, beginning with a slash (/), in the **Context Root** field. For example, if your application is named ThisApplication, type `/ThisApplication`.
4. Click **Next** (under the **Context Root** field not beside the WebSphere Status title). If the SAR file has been assembled correctly, the screen will still have the title “Preparing for the application installation”, but the content will change. If an error message appears, check the contents of the SAR file; in particular, verify the `web.xml` file contents, and try to reload the SAR file.
5. Click **Next**. If you see a screen indicating “Application Security Warnings”, click **Continue**.
6. The **Install New Application** screen should appear with “Step 1: Select application options” highlighted. Select the options you need and click **Next**.
7. “Step 2: Map modules to servers” should appear highlighted now. You can choose the cluster or server where you want to install the application's modules.
   - If you are installing the application in a stand-alone system, click **Next**.
   - If you are installing the application in a clustered system, select **`WebSphere:cell=`*`cellname`*`,cluster=`*`cluster_name`** in the **Clusters and Servers** field, select the check box beside the web module that you want to install, and click **Apply** and **Next**.
8. Now “Step 3: Map virtual hosts for web modules” should appear highlighted. To the right of the application name there should be a drop-down labeled **Virtual Host**.
   - If you are installing the application in a stand-alone system, set the value of the drop-down to **default_host**, and click **Next**.
   - If you are installing the application in a clustered system, set the value of the drop-down to the name of the virtual host that was chosen during setup, and click **Next**.

   Remember: You must define a virtual host for your configured SIP container listen port or else you will not be able to access the application.

9. You should now see “Step 4: Summary” highlighted. In the right panel you will see a **Summary of installation options** table that details your selected options and their values. If you need to change an option, click **Previous** to return to the section where you can make your change. Click **Finish** to install the application with your settings. The screen should display, `Application` *appname*`_sar installed successfully`, where *appname* is the name of the application.
10. Click the **Save to Master Configuration** link. A Save to Master Configuration window appears.
11. In the Save to Master Configuration window, click **Save**. The application has now been saved in the current configuration.
12. To confirm that the installation succeeded, in the left frame click **Applications** > **Enterprise Applications**. The newly installed application should appear in the list of installed applications as *appname*_sar.
13. To start the application so that it can service SIP requests, check the box beside *appname*_sar, and click **Start**. You might also want to look at the logs for a successful startup message.

Results

The application can service SIP requests now.

Deploying SIP applications through scripting

You can deploy a Session Initiation Protocol (SIP) application not only from the administrative console but also from a command line.

About this task

Note: To deploy a SIP application, the application must exist with an enterprise archive (EAR) file, a Session Initiation Protocol (SIP) module (SAR file), or a web application archive (WAR) file.

Use the wsadmin scripting tool to deploy applications from a command line.

Procedure

- Launch a scripting client.

  For more information, see AdminApp object for scripted administration.
- List applications.

  For more information, see Listing applications using the wsadmin scripting tool.
- Install stand-alone archive files.

  For more information about installation, see Installing enterprise applications using wsadmin scripting and Installation options for the AdminApp object.
- Edit application configurations.

  For more information, see Editing application configurations using the wsadmin scripting tool.
- Uninstall applications.

  For more information, see Uninstalling enterprise applications using the wsadmin scripting tool.

Upgrading SIP applications

Follow these steps to upgrade SIP applications.

About this task

Use the following application upgrade procedure to install a new version of a previously installed application without any outage.

Procedure

1. Install version 1 of the application in cluster 1.
2. Create cluster 2.
3. Set cluster 1 as the default cluster.
4. Install version 2 of the application in cluster 2.
5. Change the default cluster at proxy to cluster 2.
6. To shut down Version 1, monitor PMI and watch for the application session for this application to come to zero. When it is at zero or a level you consider okay to lose, stop the application.

Results

New calls will be routed to cluster 2. Old calls will continue to be routed to cluster 1.

Chapter 47. Deploying web applications

This page provides a starting point for finding information about web applications, which are comprised of one or more related files that you can manage as a unit, including:

- HTML files
- Servlets can support dynamic web page content, provide database access, serve multiple clients at one time, and filter data.
- Java ServerPages (JSP) files enable the separation of the HTML code from the business logic in web pages.

IBM extensions to the JSP specification make it easy for HTML authors to add the power of Java technology to web pages, without being experts in Java programming.

Deploying JavaServer Pages and JavaServer Faces files

JSP class loading settings

You can configure a JavaServer Pages (JSP) class to be loaded by either the JSP engine's class loader or by the web module's class loader.

By default, a JSP class is loaded by a unique instance of the JSP engine's class loader. The JSP engine's class loader enables reloading at runtime of a JSP class when the JSP source or one of its dependents is modified. This allows you to reload a single JSP class when necessary, without affecting any other loaded JSP classes.

JSP classes are loaded by the web module's class loader under either of the following scenarios.

1. The JSP engine configuration parameter useFullPackageNames is set to true, and the JSP file is configured as a servlet in the `web.xml` file using the *<servlet-class>* scenario in the table later in this topic.
2. The JSP engine configuration parameters useFullPackageNames and disableJspRuntimeCompilation are both set to true. In this case, you do not need to configure a JSP file does as a servlet in the `web.xml` file.

Configuring JSP files as Servlets

You can configure a JSP file as a servlet in the `web.xml` file. There are two ways to do this. They are described in the table later in this section.

Before you configure a JSP file as a servlet, consider the following.

1. Reloading capability - If runtime reloading of JavaServer Pages files is desired, requests for JavaServer Pages files must be handled by the JSP engine. The *<servlet-class>* scenario in the table later in this section disables runtime JSP file reloading, while the *<jsp-file>* scenario is compatible with reloading.
2. Reducing the number of class loaders - If you do not require runtime reloading of modified JSP pages and you want to reduce the number of class loader instances, then you can use the *<servlet-class>* scenario in the table that follows. Similarly, scenario 2 in section 1 can be used without having to configure a JSP file as a servlet.

Table 287. Example: Configure a JSP file as a servlet in the web.xml file.. Configure a JSP file as a servlet

Scenario	Example	compatible with runtime reloading	multiple class loaders used?	useFullPackageNames
<jsp-file>	<servlet> <servlet-name>jspOne</servlet-name> <jsp-file>jspOne.jsp</jsp-file> </servlet>	Yes	Yes	Can be true or false
<servlet-class>	<servlet> <servlet-name>jspTwo</servlet-name> <servlet-class>_ibmjsp.jspTwo</servlet-class> </servlet>	No	No	Must be true

The JSP batch compiler tool helps you configure JavaServer Pages files as servlets. When useFullPackageNames is true, the JSP batch compiler generates *<servlet>* and *<servlet-mapping>* elements for each JSP file that it successfully translates and compiles. The elements are written to a `web.xml` fragment file named `generated_web.xml` which is located in the binaries `WEB-INF` directory of a web module processed by the JSP file batch compiler (this directory is located within the deployed application's ear file). You can copy and paste all or some of these elements into the `web.xml` file to configure JavaServer Pages files as servlets.

Take note of the location of the `web.xml` that is used by the application server. The application specific configuration is obtained from either the application binaries (the application's ear file) or from the configuration repository. If an application is deployed into WebSphere Application Server with the flag Use Binary Configuration set to true, then the `WEB-INF/web.xml` file is looked for in a web module's binaries directory, not in the configuration repository. Examples of these two locations follow:

- An example of a configuration repository directory is `{WAS_ROOT}/profiles/profilename/config/cells/`*`cellname`*`/applications/`*`enterpriseappname`*`/deployments/`*`deployedname/webmodulename`*
- An example of an application binaries directory is: `{WAS_ROOT}/profiles/`*`profilename`*`/installedApps/`*`nodename`*`/EnterpriseAppName/`*`WebModuleName/`*

If the JSP batch compiler is executed on a pre-deployed application then the `web.xml` file is in the web module's `WEB-INF` directory.

JavaServer Pages (JSP) runtime reloading settings

JavaServer Pages files can be translated and compiled at run time when the JSP file or its dependencies are modified. This is known as JSP reloading.

Note: Use an assembly tool, such as Rational Application Developer, to modify IBM extension and binding files. You can convert extension and binding files within modules from XMI to XML using the IBM Bindings and Extensions Conversion Tool for Multi-Platforms.

JSP reloading is enabled through the reloadEnabled JSP engine parameter in the `WEB-INF/ibm-web-ext.xmi` or `WEB-INF/ibm-web-ext.xml` file.

`ibm-web-ext.xmi` example:

```
<jspAttributes xmi:id="JSPAttribute_1" name="reloadEnabled" value="true"/>
```

`ibm-web-ext.xml` example:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-ext
   xmlns="http://websphere.ibm.com/xml/ns/javaee"
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
```

```
   xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-web-ext_1_0.xsd"
      version="1.0">

   <jsp-attribute name="trackDependencies" value="true" />
   <jsp-attribute name="disableJspRuntimeCompilation" value="true" />
   <jsp-attribute name="reloadEnabled" value="true"/>

   <reload-interval value="5"/>
   <auto-encode-requests value="false"/>
   <auto-encode-responses value="false"/>
   <enable-directory-browsing value="false"/>
   <enable-file-serving value="false"/>
   <pre-compile-jsps value="false"/>
   <enable-reloading value="true"/>
   <enable-serving-servlets-by-class-name value="false" />
</web-ext>
```

Note: For IBM extension and binding files, the .xmi or .xml file name extension is different depending on whether you are using a pre-Java EE 5 application or module or a Java EE 5 or later application or module. An IBM extension or binding file is named ibm-*-ext.xmi or ibm-*-bnd.xmi where * is the type of extension or binding file such as app, application, ejb-jar, or web. The following conditions apply:

- For an application or module that uses a Java EE version prior to version 5, the file extension must be .xmi.
- For an application or module that uses Java EE 5 or later, the file extension must be .xml. If .xmi files are included with the application or module, the product ignores the .xmi files.

However, a Java EE 5 or later module can exist within an application that includes pre-Java EE 5 files and uses the .xmi file name extension.

The `ibm-webservices-ext.xmi`, `ibm-webservices-bnd.xmi`, `ibm-webservicesclient-bnd.xmi`, `ibm-webservicesclient-ext.xmi`, and `ibm-portlet-ext.xmi` files continue to use the .xmi file extensions.

The following table contains suggested reload settings for production and development environments.

Table 288. Suggested reload settings for production and development environments.. Reload settings

Configuration Attribute	Production Environment setting	Development Environment setting
reloadEnabled	false	true
reloadInterval	n/a (ignored if reloadEnabled is false)	approximately 5 seconds
trackDependencies	n/a (ignored if reloadEnabled is false)	true Alternatively, set this to false to improve response time if dependencies are not changing
disableJspRuntimeCompilation	true - Alternatively, set this to false if JSP files are not pre-compiled and therefore need to be compiled on the first request.	false

The default for the reloadEnabled parameter is true. If the reloadEnabled parameter is set to true, a JSP file is reloaded at run time if the JSP file and its class file do not have the same timestamp. In addition, if trackDependencies is set to true then the JSP file is reloaded if the timestamp of any of its dependencies has changed since the JSP class file was last generated. If the reloadEnabled parameter is set to false, a JSP file is still compiled if necessary on the first request to it unless the parameter disableJspRuntimeCompilation is true. For example, when disableJspRuntimeCompilation is false and reloadEnabled is false, a JSP file is compiled on the first request if the class file is outdated. It would not compile on subsequent requests, even if the JSP source file is modified or the class file is deleted,, unless reloadEnabled is true.

Reload interval

The reload interval is set through the reloadInterval JSP engine parameter.

`ibm-web-ext.xmi` example:

```
<jspAttributes xmi:id=JSPAttribute_1 name=reloadInterval value=5/>
```

ibm-web-ext.xml example:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-ext
   xmlns="http://websphere.ibm.com/xml/ns/javaee"
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-web-ext_1_0.xsd"
      version="1.0">

   <jsp-attribute name="trackDependencies" value="true" />
   <jsp-attribute name="disableJspRuntimeCompilation" value="true" />
   <jsp-attribute name="reloadInterval" value="5"/>

   <reload-interval value="5"/>
   <auto-encode-requests value="false"/>
   <auto-encode-responses value="false"/>
   <enable-directory-browsing value="false"/>
   <enable-file-serving value="false"/>
   <pre-compile-jsps value="false"/>
   <enable-reloading value="true"/>
   <enable-serving-servlets-by-class-name value="false" />
</web-ext>
```

If reloading is enabled, the reloadInterval parameter value determines the delay between checks to see if a JSP file is outdated. For example, if reloadInterval is 5, the JSP engine checks to see if a JSP file is outdated only when the last such check was done more than five seconds prior to the current request for the JSP file. Once the reloadInterval is exceeded, reload checking is performed and the reload interval timer is reset to 0 for that JSP file. The larger the reloadInterval, the less frequently the JSP engine checks for the need to reload a JSP file.

Dependency tracking

Dependency tracking is set through the trackDependencies JSP engine parameter.

ibm-web-ext.xmi example:

```
<jspAttributes xmi:id="JSPAttribute_1" name="trackDependencies" value="true"/>
```

ibm-web-ext.xmi example:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-ext
   xmlns="http://websphere.ibm.com/xml/ns/javaee"
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-web-ext_1_0.xsd"
      version="1.0">

   <jsp-attribute name="trackDependencies" value="true" />
   <jsp-attribute name="disableJspRuntimeCompilation" value="true" />
   <jsp-attribute name="reloadInterval" value="5"/>

   <reload-interval value="5"/>
   <auto-encode-requests value="false"/>
   <auto-encode-responses value="false"/>
   <enable-directory-browsing value="false"/>
   <enable-file-serving value="false"/>
   <pre-compile-jsps value="false"/>
   <enable-reloading value="true"/>
   <enable-serving-servlets-by-class-name value="false" />
</web-ext>
```

If reloading is enabled, the trackDependencies parameter value determines whether the JSP engine tracks modifications to the requested JSP file dependencies as well as to the JSP file itself. The three types of dependencies tracked by the JSP engine are:

- files statically included in the JSP file
- tag files that are referenced in the JSP file (excluding tag files that are in JAR files)
- TLDs that are referenced in the JSP file (excluding TLDs that are in JAR files)

Dependency tracking information is always included in the generated class file even if trackDependencies is false. The information is not used by the JSP engine or batch compiler unless the trackDependencies parameter is true. This means that you can enable dependency tracking without having to recompile JSP files.

For example, the toplevel.jsp file statically includes the footer.jspf file. When the toplevel.jsp file is compiled, the path to the footer.jspf file and its timestamp are stored in the toplevel.jsp's class file. As a result, the footer.jspf file is modified and the toplevel.jsp file is requested. Now that the reload interval for the toplevel.jsp file has been exceeded, the JSP engine compares the timestamp stored in the class file with the footer.jspf file timestamp on disk. Because the timestamps are different, the toplevel.jsp file is compiled, picking up the modification to the footer.jspf file. In order for dependency tracking to work, the trackDependencies value must be set to true at the time a JSP file is requested at run time or is processed by the batch compiler.

Disabling compilation

Disablement of run time compilation of JavaServer Pages is set via the disableJspRuntimeCompilation JSP engine parameter.

ibm-web-ext.xmi example:

```
<jspAttributes xmi:id="JSPAttribute_1" name="disableJspRuntimeCompilation" value="true"/>
```

ibm-web-ext.xml example:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-ext
   xmlns="http://websphere.ibm.com/xml/ns/javaee"
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-web-ext_1_0.xsd"
      version=1.0>

   <jsp-attribute name="trackDependencies" value="true" />
   <jsp-attribute name="disableJspRuntimeCompilation" value="true" />
   <jsp-attribute name="reloadInterval" value="5"/>

   <reload-interval value="5"/>
   <auto-encode-requests value="false"/>
   <auto-encode-responses value="false"/>
   <enable-directory-browsing value="false"/>
   <enable-file-serving value="false"/>
   <pre-compile-jsps value="false"/>
   <enable-reloading value="true"/>
   <enable-serving-servlets-by-class-name value="false" />
</web-ext>
```

If the disableJspRuntimeCompilation parameter is set to true, the JSP engine at run time does not translate and compile JSP files; the JSP engine loads only precompiled class files. JSP source files do not need to be present in order for the class files to be loaded. With this option set to true, an application can be installed without JSP source, but must have precompiled class files. There is a web container custom property of the same name that can be used to determine the behavior of all web modules installed in a server. If both the web container custom property and the JSP engine option are set, the JSP engine option takes precedence. Setting the disableJspRuntimeCompilation parameter to true automatically sets reloadEnabled to false.

Reload processing sequence

The processing sequence pertaining to JSP file reloading when trackDependencies is false is shown in Figure 1.

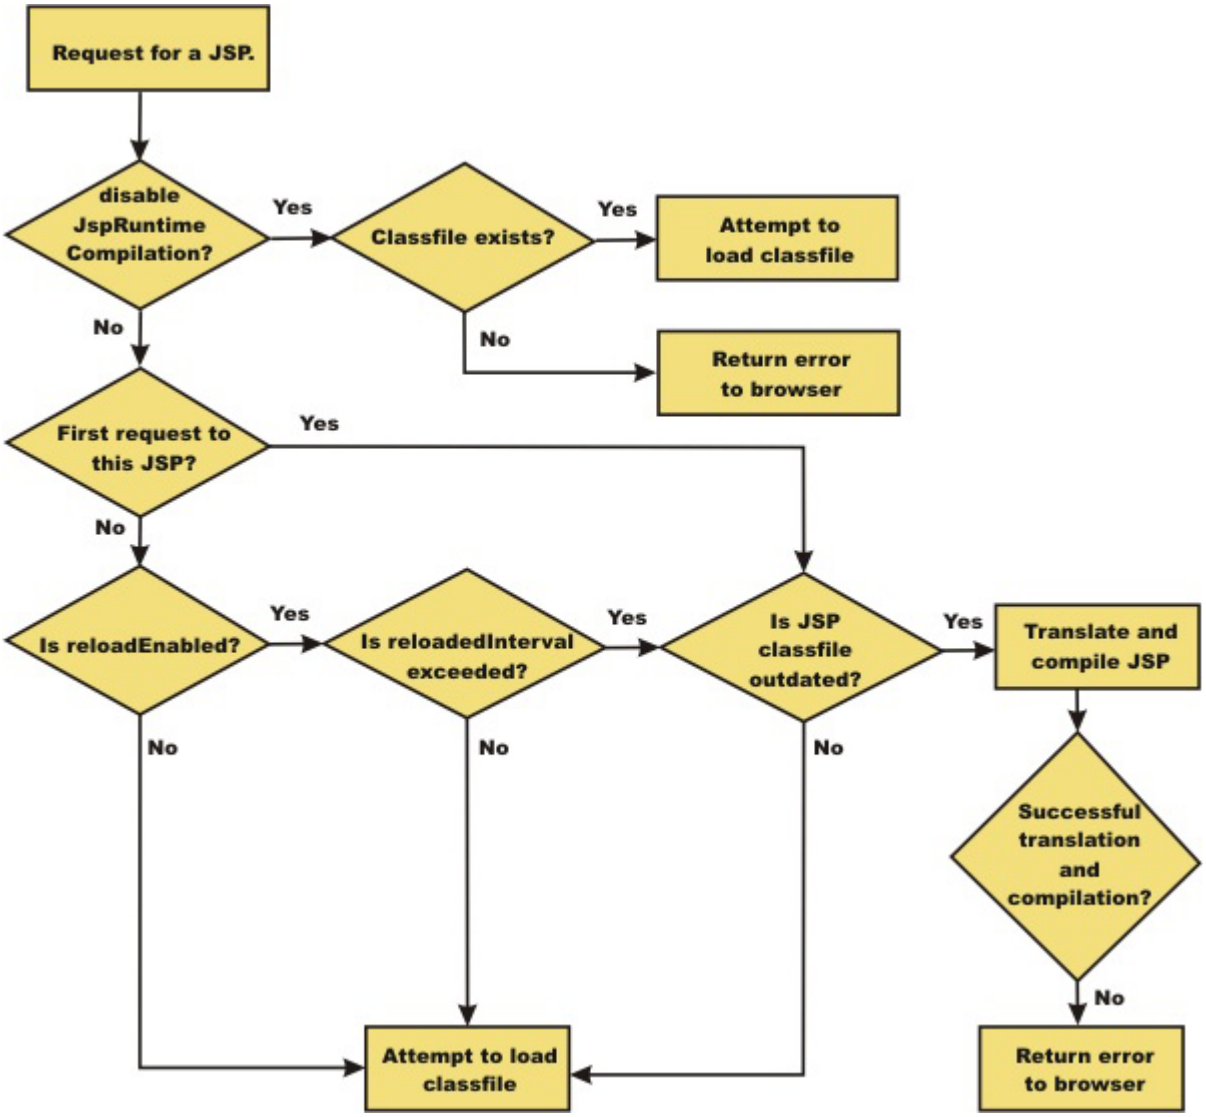

Figure 9. Reload processing sequence when trackDependencies is false.

When trackDependencies is true, the JSP engine does additional file system processing to determine if any of a JSP file's dependencies have changed since the JSP file was last translated and compiled. Figure 2 shows the additional processes that are performed on the 'No' path of flow chart labeled “is JSP class file outdated?”. You can see that the path taken when disableJspRuntimeCompilation is true is the most efficient path.

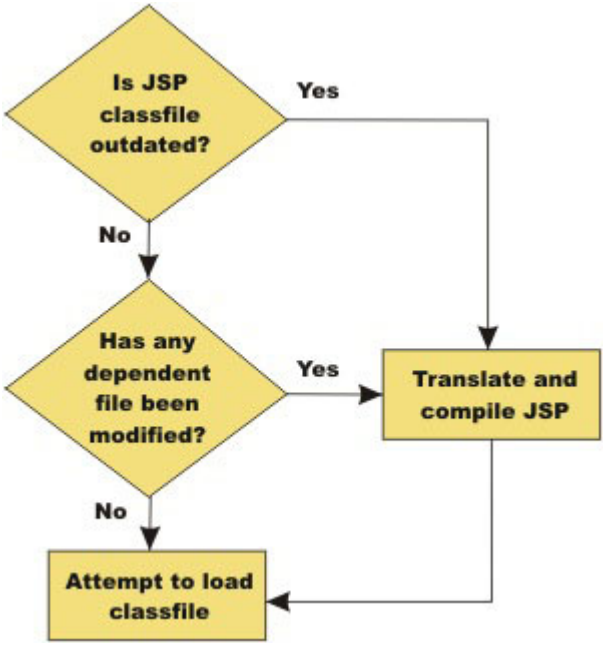

Figure 10. Additional reload processing performed when trackDependencies is true.

JSP and JSF option settings

Use this page to configure the class reloading of web modules such as JavaServer Pages (JSP) files and to select a JSF implementation to use with this application.

To view this administrative console page, click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name*** > **JSP and JSF options**. This page is the same as the **Provide JSP reloading options for web modules** page on the application installation and update wizards.

The following note applies to the files with an `.xmi` extension in this topic:

Note: For IBM extension and binding files, the .xmi or .xml file name extension is different depending on whether you are using a pre-Java EE 5 application or module or a Java EE 5 or later application or module. An IBM extension or binding file is named ibm-*-ext.xmi or ibm-*-bnd.xmi where * is the type of extension or binding file such as app, application, ejb-jar, or web. The following conditions apply:

- For an application or module that uses a Java EE version prior to version 5, the file extension must be .xmi.
- For an application or module that uses Java EE 5 or later, the file extension must be .xml. If .xmi files are included with the application or module, the product ignores the .xmi files.

However, a Java EE 5 or later module can exist within an application that includes pre-Java EE 5 files and uses the .xmi file name extension.

The `ibm-webservices-ext.xmi`, `ibm-webservices-bnd.xmi`, `ibm-webservicesclient-bnd.xmi`, `ibm-webservicesclient-ext.xmi`, and `ibm-portlet-ext.xmi` files continue to use the .xmi file extensions.

Web module

Specifies the name of a web module in the installed or deployed application.

URI
Specifies the location of the module that is relative to the root of the application (EAR file).

JSP enable class reloading
Specifies whether to enable class reloading when JSP files are updated.

A web container reloads JSP files only when the IBM extension reloadEnabled in the jspAttributes of the `ibm-web-ext.xmi` file is set to `true`.

Java Platform, Enterprise Edition 5 (Java EE 5) and later applications IBM extension files are in `.xml` file format. For applications versions earlier than Java EE 5, they are in the `.xmi` file format.

JSP reload interval in seconds
Specifies the number of seconds to scan the application file system for updated JSP files. The default is the value of the reloading interval attribute in the IBM extension (`META-INF/ibm-web-ext.xmi`) file of the web module.

To enable reloading, specify a value greater than zero (for example, 1 to 2147483647). The default reload interval is 5. To disable reloading, specify zero (0). The range is from 0 to 2147483647.

The reloading interval attribute takes effect only if class reloading is enabled.

Java EE 5 applications and later IBM extension files are in `.xml` file format. For applications versions earlier than Java EE 5, they are in the `.xmi` file format.

Sun Reference Implementation 1.2
Select this option to use the Sun Reference Implementation 1.2 JSF implementation.

If you change the JSF implementation that you are using for your application, you must delete any previously compiled JSP files. If you precompiled your application, you must recompile. If you did not precompile, but have already requested JSP files from this application, you must delete the JSP files from the temp directory of your profile.

You can set the JSF engine configuration parameter, com.ibm.ws.jsf.JSF_IMPL_CHECK, to true to automatically mark the JSP files to recompile at application startup.

MyFaces 2.0
Select this option to use the MyFaces JSF implementation. This is the default JSF implementation.

If you change the JSF implementation that you are using for your application, you must delete any previously compiled JSP files. If you precompiled your application, you must recompile. If you did not precompile, but have already requested JSP files from this application, you must delete the JSP files from the temp directory of your profile.

You can set the JSF engine configuration parameter, com.ibm.ws.jsf.JSF_IMPL_CHECK, to true to automatically mark the JSP files to recompile at application startup.

In a mixed-version cell, a Version 7 node uses MyFaces 1.2 if the MyFaces selection is toggled, while a Version 8 and later node uses MyFaces 2.0. For WebSphere Application Server versions before Version 7 (for example, Version 6.1 and earlier), this toggle is ineffective because JSF implementation switching was not supported before Version 7.

JSP run time compilation settings

By default, the JavaServer Pages (JSP) engine translates a requested JSP file, compiles the `.java` file, and loads the compiled servlet into the run time environment. You can change the JSP engine default behavior by indicating that a JSP file must not be translated or compiled at run time, even when a `.class` file does not exist.

If run time compilation is disabled, you must precompile the JSP files, which provides the following advantages:

- Reduces compilation related disk operations.
- Minimizes disk storage requirements necessary for handling temporary `.java` files generated during a run time compilation.
- Allows you to not include the JSP source files in the application.
- Allows verification that a JSP file compiled successfully before deploying and installing the application in the product

You can disable run time JSP file compilation on a global or an individual web application basis:

- To disable the translation and compilation of JSP files for all Web applications, in the administrative console, click **Servers > Server Types > WebSphere application servers >** *server_name*. Then, in the Container Settings section, click **Web container settings > Web container > Custom properties**.

  If the disableJspRuntimeCompilation property appears in the list of defined custom properties, but is set to `false`, click the property name, and then set the property to `true`.

  If this property is not included in the list of defined custom properties, click **New**, and then specify `disableJspRuntimeCompilation` in the **Name** field and `true` in the **Value** field.

  Valid settings for this property are `true` or `false`. When this property is set to `true`, translation and compilation of the JSP files is disabled at run time for all web applications.
- To disable the translation and compilation of JSP files for a specific web application, set the JSP engine initialization parameter disableJspRuntimeCompilation to `true`. This setting, if enabled, determines the run time behavior of the JSP engine and overrides the web container custom property setting.

  Set this parameter through the **JavaServer Pages attribute assembly settings** page when assembling applications.

  Valid values for this setting are `true` or `false`. If this parameter is set to `true`, then, for that specific web application, translation and compilation of the JSP files is disabled at run time, and the JSP engine only loads precompiled files.
- If neither the web container custom property nor the JSP parameter is set, the first request for a JSP file results in the translation and compilation of the JSP file when the `.class` file does not exist or is outdated. Subsequent requests for the file also result in translations and compilations, but only if the following conditions are met:
  - Translations are required because the `.class` file is outdated.
  - Reloading is enabled for the web module.
  - Reload interval is exceeded.

If you disable run time compilation and a request arrives for a JSP file that does not have a matching .class file, the JSP engine returns the following 404 error to the browser:

```
Error 404: SRVE0200E: Servlet [org.apache.jsp._jsp1]: Could not find required servlet class - _jsp1.class
```

In this case, an exception is written to the joblog (SYSPRINT) file if the ras_trace_outputLocation property in the was.env file is set to SYSPRINT, or to CTRACE if ras_trace_outputLocation is set to BUFFER.

If a JSP file has a matching .class file but that file is out of date, the JSP engine still loads the .class file into memory.

Provide options to compile JavaServer Pages settings

Use this page to specify options to be used by the JavaServer Pages (JSP) compiler.

This administrative console page is a step in the application installation and update wizards. To view this page, you must select **Precompile JavaServer Pages files** on the **Select installations options** page. Thus, to view this page, click **Applications** > **New Application** > **New Enterprise Application** > ***application_path*** > **Next** > **Detailed - Show me all installation options and parameters** > **Next** > **Next** or **Continue** > **Precompile JavaServer Pages files** > **Next** > **Step: Provide options to compile JSPs**.

You can specify the JSP compiler options on this page only when installing or updating an application that contains web modules. After the application is installed, you must edit the JSP engine configuration parameters of a web module `WEB-INF/ibm-web-ext.xmi` file to change its JSP compiler options.

Note: For IBM extension and binding files, the .xmi or .xml file name extension is different depending on whether you are using a pre-Java EE 5 application or module or a Java EE 5 or later application or module. An IBM extension or binding file is named ibm-*-ext.xmi or ibm-*-bnd.xmi where * is the type of extension or binding file such as app, application, ejb-jar, or web. The following conditions apply:

- For an application or module that uses a Java EE version prior to version 5, the file extension must be .xmi.
- For an application or module that uses Java EE 5 or later, the file extension must be .xml. If .xmi files are included with the application or module, the product ignores the .xmi files.

However, a Java EE 5 or later module can exist within an application that includes pre-Java EE 5 files and uses the .xmi file name extension.

The `ibm-webservices-ext.xmi`, `ibm-webservices-bnd.xmi`, `ibm-webservicesclient-bnd.xmi`, `ibm-webservicesclient-ext.xmi`, and `ibm-portlet-ext.xmi` files continue to use the .xmi file extensions.

Web module
Specifies the name of a module within the application.

URI
Specifies the location of the module relative to the root of the application (EAR file).

JSP class path
Specifies a temporary class path for the JSP compiler to use when compiling JSP files during application installation. This class path is not saved when the application installation is complete and is not used when the application is running. This class path is used only to identify resources outside of the application which are necessary for JSP compilation and which will be identified by other means (such as shared libraries) after the application is installed. In network deployment configurations, this class path is specific to the deployment manager machine.

To specify that multiple web modules use the same class path:
1. In the list of web modules, select the **Select** check box beside each web module that you want to use a particular class path.
2. Expand **Apply Multiple Mappings**.
3. Specify the desired class path.
4. Click **Apply**.

Use full package names
Specifies whether the JSP engine generates and loads JSP classes using full package names.

When full package names are used, precompiled JSP class files can be configured as servlets in the `web.xml` file, without having to use the `jsp-file` attribute. When full package names are not used, all JSP classes are generated in the same package, which has the benefit of smaller file-system paths.

When the options useFullPackageNames and disableJspRuntimeCompilation are both `true`, a single class loader is used to load all JSP classes, even if the JSP files are not configured as servlets in the `web.xml` file.

This option is the same as the useFullPackageNames JSP engine parameter.

JDK source level

Specifies the source level at which the Java compiler compiles JSP Java sources. Valid values are `13`, `14`, and `15`. The default value is `13` for pre-Java EE 5 web modules, which specifies source level 1.3 and `15` for Java EE 5 and later web modules.

Disable JSP runtime compilation

Specifies whether a JSP file should never be translated or compiled at run time, even when a `.class` file does not exist.

When this option is set to `true`, the JSP engine does not translate and compile JSP files at run time; the JSP engine loads only precompiled class files. JSP source files do not need to be present in order to load class files. You can install an application without JSP source, but the application must have precompiled class files.

For a single web application class loader to load all JSP classes, this compiler option and the **Use full package names** option both must be set to `true`.

This option is the same as the disableJspRuntimeCompilation JSP engine parameter.

Deploying web applications using RRD

Task overview: Assembling applications using remote request dispatcher

Remote request dispatcher (RRD) is a pluggable extension to the web container which allows application frameworks, servlets and JavaServer Pages (JSP) to include content from outside the currently executing resource's Java Virtual Machine (JVM) as part of the response sent to the client.

Before you begin

You must have WebSphere Application Server, Network Deployment installed to use remote request dispatcher function. You should also familiarize yourself the limitations of remote request dispatcher. See article, Remote request dispatcher considerations for details.

Procedure

1. Install enterprise application files with the console.
2. Configure the sending of include requests between the application and remote resources.
   - Configure web applications to dispatch remote includes.
   - Configure web applications to service remote includes.
3. Optional: Modify your application to locate resources located in two different contexts using the servlet programming model.

   The Servlet Programming Model for including resources remotely does not require you to use any non-Java Platform, Enterprise Edition (Java EE) Servlet Application Programming Interfaces (APIs). The remote request dispatcher (RRD) component follows the same rules to obtain a ServletContext and a remote resource. By using JavaServer Pages standard tag library (JSTL), your application is further removed from obtaining a ServletContext object or RequestDispatcher that is required in the framework example in the following step because the JSTL custom tag does this implicitly. Study the following example of a sample JavaServer Pages application to learn how to locate resources that are in two different contexts, investments and banking.

```
<HEAD>
<%@ page
language="java"
contentType="text/html; charset=ISO-8859-1"
pageEncoding="ISO-8059-1"
isELIgnored="false"
%>
<%@ taglib uri="http://java.sun.com/jsp/jstl/core" prefix="c" $>
</HEAD>
<BODY>

<%--

Programming example using JavaServer Pages and JavaSever Pages
Standard Tag Library (JSTL).
JSTL provides a custom tag to import contents (in servlet and JSP
terms include) in the scope of the same request from outside of
the current web module context by specifying a context parameter.

JSTL restriction: The web module that is imported
must run inside of the same JVM as the calling resource
if imported URL is not fully qualified.

RRD extends this functionality by permitting the web module to
be located within the scope of the current WebSphere Application Server
core group versus the scope of the JVM.
--%>

<hr size="5"/>
<%--  Include resource investmentSummary.jsp located in the
  web application with context root of /investments. --%>

<c:import url="investmentSummary.jsp" context="/investments"/>

<hr size="5"/>
<%--  Include resource accountSummary.jsp located in the
  web application with context root of /banking. --%>

<c:import url="accountSummary.jsp" context="/banking"/>

<hr size="5"/>

</BODY>
</HTML>
```

4. Optional: Modify your application to locate resources located in two different contexts using the framework programming model.

   The Framework Programming Model for including resources remotely does not require you to use any non- Java Platform, Enterprise Edition (Java EE) Servlet Application Programming Interfaces (APIs). When a request is initiated for a ServletContext name that is not presently running inside of the current web container, the remote request dispatcher (RRD) component returns a ServletContext object that can locate a resource that exists anywhere inside a WebSphere Application Sever WebSphere Application Server, Network Deployment environment provided that the resource exists and RRD is enabled for that ServletContext object. Study the following sample framework snippet that demonstrates how to locate resources located in two different contexts, investments and banking.

```
/*
Programming example using a generic framework.
Servlet Specification provides an API to obtain
a servlet context in the scope of the same request
different from the current web module context by
specifying a context parameter.

Servlet Specification restriction: The web module that obtain
must run inside of the same JVM as the calling resource.

RRD extends this functionality by permitting the web module to be located
within the scope of the current WebSphere Application Server core group
versus the scope of the JVM.

*/

protected void frameworkCall (ServletContext context, HttpServletRequest request, HttpServletResponse response)
       throws ServletException, IOException(

   PrintWriter writer = response.getWriter();

   writer.write("<HTML>");
   writer.write("<HEAD>");
   writer.write("</HEAD>");
   writer.write("<BODY>");
   writer.write("<hr size=\"5/">);

   //Include resource investmentSummary.jsp located in web application
```

```
   //with context root of /investments.
   RequestDispatcher rd = getRequestDispatcher ( context, "/investments", "/investmentSummary.jsp");
   rd.include(request, response);

   writer.write("<hr size=\"5/">);

   //Include resource accountSummary.jsp located in web application
   //with context root of /banking.
   rd = getRequestDispatcher ( context, "/banking", "/accountSummary.jsp");
   rd.include(request, response);

   writer.write("</BODY>");
   writer.write("</HTML>");
}
private RequestDispatcher getRequestDispatcher (ServletContext context, String contextName, String resource) {
   return context.getContext(contexName).getRequestDispatcher(resource);
}
```

Results

After enabling at least one enterprise application to dispatch remote includes and at least one enterprise application to service remote includes, RRD is now enabled.

What to do next

Restart the modified applications if already installed or start newly installed applications to enable RRD on each application.

Remote request dispatcher:

Remote Request Dispatcher (RRD) is a pluggable extension to the web container for application frameworks, servlets, and JavaServer Pages to include content from outside of the current Java virtual machine (JVM) for the resource, as part of the response sent to the client.

Remote request dispatcher is an extensible infrastructure for other components and stack products to add custom extensions like generators and handlers, to the RRD extension. The remote request dispatcher extension enhances the standard Java Platform, Enterprise Edition (Java EE) `javax.servlet.RequestDispatcher` implementation to be aware of locating remote resources using web services to communicate between machines within a WebSphere Application Server, Network Deployment (ND) core group. The remote request dispatcher extension reports any errors that occur on the remote server back to the originating server. It can also use SSL for secure communications and WS-Security security context propagation between servers. See the rrdSecurity.props file topic for more information.

RRD portlet support carries forward the remote request dispatcher concept to portlets and enhances the portlet container for invocation of portlets outside of the current JVM resource.

By using the RRD extension, you can share request load across multiple machines and JVMs by including remote servers within the cell. If RRD resource is memory or processor intensive, the calling resource is not affected as much as a standard RequestDispatcher running within the same JVM. RRD solves this problem by separating resources into a different JVM.

Capabilities

- Requests on remote server are treated as include requests. Filters and request listeners are started as if the dispatch type is INCLUDE.
- Serializable request attributes and query parameters are sent to remote server.
- Security context is sent to a remote server through LTPA tokens.
- Servlet parameters and OutputStream

  Request parameters are passed to remote server.
- Response headers that are set by the remotely included resource are ignored similar to includes on a local server. Internal headers such as Set-Cookie can still be set and are propagated back.
- All original request headers are passed to remote server

  - Similar to the plug-in for WebSphere Application Server.
  - Method calls return the state as if they are on local server. For example, getServer returns the local server name or isSecure returns whether the request to the ‘local' server has been secure.
- Cookies and sessions
  - Cookies are passed to the remote server as part of headers.
  - Sessions in local and remote servers use the same cookie or session ID for a given client which is similar to includes in the same server. If a session exists on a remote server, the session cookie contains the information for both the servers to maintain the affinity to the remote server.
- Exceptions
  - If there is an exception on the remote server, the server returns an RRD-specific web services fault which wraps the original exception created by the application.
  - Attempt to recreate the original exception on the local server if the exception class exists on both servers. If the original exception cannot be recreated, an RRD-specific ServletException is constructed and used instead.
  - The exception is recreated by the local server for error handling purposes.
- Dynamic cache

  When dynamic cache is enabled, caching is performed on the local and remote machine.
- Security

  You can use SSL to encrypt RRD messages between application servers. SSL is enabled by default, however, you must also pass security context needs through RRD to ensure that the security state is available in the remote machine. RRD uses WS-Security to pass this information, but this security context propagation is disabled by default. See the rrdSecurity.props file topic for additional information.

Chapter 48. Deploying web services

Deploying web services applications onto application servers

After assembling the artifacts required to enable the web module for web services into an enterprise archive (EAR) file, you can deploy the EAR file into the application server.

Before you begin

To deploy Java-based web services, you need an enterprise application, also known as an EAR file that is configured and enabled for web services.

A Java API for XML-Based Web Services (JAX-WS) application does not require additional bindings and deployment descriptors for deployment whereas a Java API for XML-based RPC (JAX-RPC) web services application requires you to add additional bindings and deployment descriptors for application deployment. JAX-WS is much more dynamic, and does not require any of the static data generated by the deployment step required for deploying JAX-RPC applications.

For JAX-WS web services, the use of the `webservices.xml` deployment descriptor is optional because you can use annotations to specify all of the information that is contained within the deployment descriptor file. You can use the deployment descriptor file to augment or override existing JAX-WS annotations. Any information that you define in the `webservices.xml` deployment descriptor overrides any corresponding information that is specified by annotations.

Note: In a mixed node cell, you can only target a JAX-WS enabled enterprise beans module to a server using WebSphere Application Server Version 7.0 and later. However, you can target a JAX-WS enabled web application archives (WAR) module to a server using either WebSphere Application Server Version 7.0 and later or WebSphere Application Server Version 6.1 Feature Pack for Web Services

You can use the **wsdeploy** command with JAX-RPC applications to add WebSphere product-specific deployment classes to a web services-compatible enterprise application enterprise archive (EAR) file or an application client Java archive (JAR) file.

To install or deploy a JAX-WS application, you only need to install the JAX-WS enabled EAR file. If your web services application contains only JAX-WS endpoints, you do not need to run the **wsdeploy** command, as this command is used to process only JAX-RPC endpoints.

Ensure that you have installed the HTTP or Java Message Service (JMS) router module that was generated with the **endptEnabler** command onto the same target as your web services enterprise bean JAR files. These HTTP or JMS router modules are included in your web services application and they need to use the runtime libraries of the application server.

About this task

This task is one of the steps in developing and implementing web services.

You can use either the administrative console or the **wsadmin** scripting tool to deploy an EAR file. If you are installing an application containing web services by using the **wsadmin** command, specify the `-deployws` option for JAX-RPC applications. If you are installing an application containing web services by using the administrative console, select **Deploy WebServices** in the Install New Application wizard. For more information about installing applications using the administrative console, see the installing enterprise application files with the console information.

If your JAX-RPC web services application was previously deployed with the **wsdeploy** command, it is not necessary to specify web services deployment during installation.

The following actions deploy the EAR file with the **wsadmin** command:

Procedure

1. Start *install_root*/bin/wsadmin from a command prompt.
2. Deploy the EAR file.
   - For JAX-WS web service applications, enter the `$AdminApp install` *EARfile* `"-usedefaultbindings"` command at the **wsadmin** prompt.
   - For JAX-RPC web service applications, enter the `$AdminApp install` *EARfile* `"-usedefaultbindings -deployws"` command at the **wsadmin** prompt.

Results

You have a web service installed onto your application server.

Note: While installing web services applications that contain a large number of enterprise beans onto the application server, you might receive out of memory errors. If you receive out of memory errors, increase the heap size of your Java Virtual Machine (JVM). If you are installing the application server in a network deployment environment, you might need to increase the heap size of the JVM in the application servers in which you are installing the application, and in the deployment manager profile, dmgr. Read about tuning the IBM virtual machine for Java documentation to learn more about tuning the application server environment.

What to do next

You can confirm that the web services application was deployed by entering the web service endpoint URL in a browser, then viewing an informative page. The information page contains the following information:

```
{http://webservice.pli.tc.wssvt.ibm.com}RetireWebServices
Hello! This is an Axis2 web service!
```

The first line of this information is variable, depending on your web service. The URI in the brackets is the namespace and the string that follows, in this example RetireWebServices, is the name of the port used to access the web service.

The next step you might want to consider is to apply security to your web service.

Provide options to perform the web services deployment settings

Use this page to specify options for web services deployment.

This administrative console page is a step in the application installation and update wizards.

To view this page, you must select **Deploy web services** on the **Select installation options** page.

To view this administrative console page, complete the following steps:

1. Click **Applications** > **New application** > ***application_path*** .
2. Select the option to **Show all installation options and parameters** .
3. Click **Next** to get to the **Step: Select installation options** page.
4. Select **Deploy web service**.
5. Click **Next** to get to the **Step: Provide options to perform the web services deployment** page.

You can specify the web services deployment options on this page only when installing or updating an application that uses web services.

The **wsdeploy** command is supported by Java API for XML-based RPC (JAX-RPC) applications. The Java API for XML-Based Web Services (JAX-WS) programming model that is implemented by the application server does not support the **wsdeploy** command. If your web services application contains only JAX-WS endpoints, you do not need to run the **wsdeploy** command, as this command is used to process only JAX-RPC endpoints.

The options that you specify set parameter values for the **wsdeploy** command. The **wsdeploy** command adds product-specific deployment classes to a web services-compatible enterprise archive (EAR) file or an application client Java archive (JAR) file. These classes include:
- Stubs
- Serializers and deserializers
- Implementations of service interfaces

The **wsdeploy** command is run during installation after you click **Finish** on the **Summary** page of the wizard.

Deploy web services option - Classpath
Specifies entries to add to the CLASSPATH when the generated classes are compiled.

To specify the class paths of multiple entries, you need to separate the entries with a semicolon on Windows platforms and on Linux, Unix, and z/OS platforms, you need to use a colon to separate the entries. This is the same separator that is used with the CLASSPATH environment variable.

This option is the same as the **wsdeploy** command parameter `-cp` *`class_path`*.

Information	Value
Data type	String
Default	null

Deploy web services option - Extension Directories
Specifies a directory that contains zipped or Java archive (JAR) files. All zipped and JAR files in this directory are added to the CLASSPATH used to compile the generated files.

This option is the same as the **wsdeploy** command parameter `-jardir` *`directory`*.

Information	Value
Data type	String
Default	null

wsdeploy command
Use the **wsdeploy** command to add WebSphere product-specific deployment classes to a web services-compatible enterprise application enterprise archive (EAR) file or an application client Java archive (JAR) file.

The **wsdeploy** command is supported by Java API for XML-based RPC (JAX-RPC) applications. The Java API for XML-Based Web Services (JAX-WS) programming model that is implemented by the application server does not support the **wsdeploy** command. If your web services application contains only JAX-WS endpoints, you do not need to run the **wsdeploy** command, as this command is used to process only JAX-RPC endpoints.

The deployment classes that are added by the **wsdeploy** tool to a web services-compatible EAR file or a JAR file include:
- Stubs
- Serializers and deserializers
- Implementations of service interfaces

This deployment step must be performed at least once, and can be performed more often. Deployment can be performed separately using the **wsdeploy** command, assembly tools, or when the application is installed. When using the **wsadmin** command for installation, specify the **-deployws** option.

The **wsdeploy** command operates as noted in the following list:
- Each module in the enterprise application or JAR file is examined.
- If the module contains web services implementations, indicated by the presence of the `webservices.xml` deployment descriptor, the associated Web Services Description Language (WSDL) files are located and the **WSDL2Java** command is run with the role deploy-server option.
- If the module contains web services clients, indicated by the presence of the client deployment descriptor, the associated WSDL files are located and the **WSDL2Java** command is run with the role deploy-client option.
- The files generated by the **WSDL2Java** command are compiled and repackaged.

See the **WSDL2Java** command for JAX-RPC applications command information to learn more about the files that are generated for deployment.

When the generated files are compiled, they can reference application-specific classes outside the EAR or JAR file, if the EAR or JAR file is not self-contained. In this case, use either the -jardir or -cp option to specify additional JAR or zip files to be added to CLASSPATH variable when the generated files are compiled.

wsdeploy command syntax

The command syntax is noted in the following example:

```
wsdeploy Input_filename Output_filename [options]
```

Required options:
- ***Input_filename***

  Specifies the path to the EAR or JAR file to deploy.
- ***Output_filename***

  Specifies the path of the deployed EAR or JAR file. If *output_filename* already exists, it is silently overwritten. The *output_filename* can be the same as the *input_filename*.

Other options:
- **-jardir** *directory*

  Specifies a directory that contains JAR or zip files. All JAR and zip files in this directory are added to the CLASSPATH used to compile the generated files. This option can be specified zero or more times.
- -**cp** *entries*

  Specifies entries to add to the CLASSPATH when the generated classes are compiled. Multiple entries are separated the same as they are in the CLASSPATH environment variable.
- **-codegen**

  Specifies to generate but not compile deployment code. This option implicitly specifies the -keep option.
- **-debug**

  Includes debugging information when compiling, that is, use javac -g to compile.
- **-help**

  Displays a help message and exit.
- **-ignoreerrors**

  Do not stop deployment if validation or compilation errors are encountered.

- **-keep**

  Do not delete working directories containing generated classes. A message is displayed indicating the name of the working directory that is retained.
- **-novalidate**

  Do not validate the web services deployment descriptors in the input file.
- **-trace**

  Displays processing information, including the names of the generated files.
- **-compliancelevel** *level*

  Sets the JDK level for compiler compliance. Valid values include: 1.4, 5.0, 6.0 (default) and 7.0. This flag is optional.

The following example illustrates how the options are used with the **wsdeploy** command:

```
wsdeploy x.ear x_deployed.ear -trace -keep
Processing web service module x_client.jar.
Keeping directory: f:\temp\Base53383.tmp for module: x_client.jar.
Parsing XML file:f:\temp\Base53383.tmp\WarDeploy.wsdl
Generating f:\temp\Base53383.tmp\generatedSource\com\test\WarDeploy.java
Generating f:\temp\Base53383.tmp\generatedSource\com\test\WarDeployLocator.java
Generating f:\temp\Base53383.tmp\generatedSource\com\test\HelloWsBindingStub.java
Compiling f:\temp\Base53383.tmp\generatedSource\com\test\WarDeploy.java.
Compiling f:\temp\Base53383.tmp\generatedSource\com\test\WarDeployLocator.java.
Compiling f:\temp\Base53383.tmp\generatedSource\com\test\HelloWsBindingStub.java.
Done processing module x_client.jar.
```

The following messages may be displayed:
- Flag *-f* is not valid.

  Option *f* was not recognized as a valid option.
- Flag *-c* is ambiguous.

  Options can be abbreviated, but the abbreviation must be unique. In this case, the **wsdeploy** command cannot determine which option was intended.
- Flag *-c* is missing parameter *-p*.

  A required parameter for an option is omitted.
- Missing *p* parameter.

  A required option is omitted.

JAX-WS application deployment model

The administration function of the product is enhanced to support installing and deploying Java Application Programming Interface (API) for XML Web Services (JAX-WS) applications like any other WebSphere Application Server applications.

A JAX-WS application is packaged as a web application archive (WAR) file or a WAR module within an Enterprise Archive (EAR) file. The JAX-WS application deployment model is similar to the Java API for XML Remote Protocol Call (JAX-RPC) web services application model. The main differences are JAX-RPC web services application requires you to add additional bindings and deployment descriptors for application deployment. A JAX-WS application does not require additional bindings and deployment descriptors for deployment. You can deploy your JAX-WS applications as you would deploy any other WebSphere Application Server application.

JAX-WS web services is a rewrite of JAX-RPC web services. The table compares the web services stack for both JAX-WS and JAX-RPC web services.

JAX-RPC web services	JAX-WS web services
Bindings are proprietary	Bindings are based on the open source Java API for XML Bindings (JAXB)
Parsing is proprietary	Parsing is based on the open source Java Specification Request (JSR) 173

JAX-RPC web services	JAX-WS web services
No Java annotations support	Support for Java annotations such as `@WebService`, `@WebMethod`, `@WebParam`, `@WebResult`, and `@SOAPBinding`
During deployment, some deployment descriptor files are created in a JAX-RPC based service and client. The following files are created on the services side, when it is an EJB based web service and EJB based module: • `webservices.xml` • <name_of_service>`_mapping.xml` • `ibm-webservices-bnd.xmi` • `ibm-webservices-ext.xmi` When the service is a JavaBeans-based or web module-based service, the following files and deployment descriptors are required: • `webservices.xml` • <name_of_service>`_mapping.xml` • In the `web.xml` file, there is no additional content • `ibm-webservices-bnd.xmi` • `ibm-webservices-ext.xmi` The `web.xml` exists in both EJB and JavaBeans based services. However, there is no additional content added to the file during deployment of a Web service application or module.	For JAX-WS web services, the use of the `webservices.xml` deployment descriptor is optional because you can use annotations to specify all of the information that is contained within the deployment descriptor file. You can use the deployment descriptor file to augment or override existing JAX-WS annotations. Any information that you define in the `webservices.xml` deployment descriptor overrides any corresponding information that is specified by annotations.

Starting with WebSphere Application Server Version 7.0 and later, Java EE 5 application modules (web application modules version 2.5 or above, or EJB modules version 3.0 or above) are scanned for annotations to identify JAX-WS services and clients. However, pre-Java EE 5 application modules (web application modules version 2.4 or before, or EJB modules version 2.1 or before) are not scanned for JAX-WS annotations, by default, for performance considerations. In the Version 6.1 Feature Pack for Web Services, the default behavior is to scan pre-Java EE 5 web application modules to identify JAX-WS services and to scan pre-Java EE 5 web application modules and EJB modules for service clients during application installation. Because the default behavior for WebSphere Application Server Version 7.0 and later is to not scan pre-Java EE 5 modules for annotations during application installation or server startup, to preserve backward compatability with the feature pack from previous releases, you must configure either the UseWSFEP61ScanPolicy property in the META-INF/MANIFEST.MF of a web application archive (WAR) file or EJB module or define the Java virtual machine custom property, com.ibm.websphere.webservices.UseWSFEP61ScanPolicy, on servers to request scanning during application installation and server startup. To learn more about annotations scanning, see the JAX-WS annotations information.

Using a third-party JAX-WS web services engine

In certain situations you might need to set up a third-party JAX-WS web services engine. For example, you must set up a third-party JAX-WS web services engine if you need to deploy applications that use a single runtime across various application servers such as WebSphere Application Server, JBoss, and WebLogic, or if you want to build JAX-WS web services applications using third party JAX-WS run-times such as CXF, Axis2, and Metro.

Before you begin

Use of a third-party JAX-WS runtime has limitations. It also requires mandatory configuration changes, and in some cases, it requires manual intervention to resolves issues that occur during deployment and when you run the application. These limitations and issues vary based on the third-party JAX-WS runtime you decide to use. You should understand the limitations for the third-party JAX-WS runtime you are preparing to use before you configure your system to use that implementation.

The following limitations exist regardless of which third-party JAX-WS implementation you use:

- The WebSphere Application Server runtime restricts usage of application modules that use both the JAX-WS implementation provided with WebSphere Application Server, and an external JAX-WS implementation in the same application EAR file. You must use either the JAX-WS implementation provided with WebSphere Application Server or the external implementation in a single application EAR file. This limitation ensures that the runtime WebSphere Application Server does not conflict with the external third-party JAX-WS implementation.
- You must remove any conflicting JAR files from your application library before you deploy an application that uses an external JAX-WS implementation. Most of the external third-party JAX-WS runtimes include some JAR file libraries that are already installed on WebSphere Application Server. This situation causes conflicts in your application library.
- After an application that uses a third-party JAX-WS runtime is deployed on WebSphere Application Server, it is not recognized as a service client or provider. Therefore, you cannot attach application level policy sets to these applications. You must rely on external runtimes support quality of service. Following is a list of WebSphere Application Server features that are not available if you decide to deploy and run application that uses third-party JAX-WS implementations:
  - WS-Security, WS-RM, and WS-Transactions policy sets
  - WSDM
  - JNDI lookup to retrieve JAX-WS Service or Port Instance.

gotcha: Even though IBM supports the enablement of third party JAX-WS runtimes to run on WebSphere Application Server, and ensures the successful deployment of applications that use such runtimes, IBM does not provide support for resolving JAR file conflict problems, or any problem that a stack trace indicates is in the third party code.

About this task

When you deploy an application EAR file with a third-party JAX-WS implementation on WebSphere Application Server, the WebSphere Application Server runtime must ensure the use of the third-party engine, and disable the use of the existing WebSphere Application Server JAX-WS web services engine.

WebSphere Application Server does not claim support for any of the third-party JAX-WS runtimes, but has tested the deployment and execution of applications that use such runtimes.

You must complete the following steps before you can use an external JAX-WS runtime in an application.

Procedure

1. Set the class loader policy to `Classes loaded with local class loader first (parent last)` at the module level.

   Changing the class loader policy to parent last ensures that the external third-party JAX-WS runtime and their dependent library JAR files are first in the class loader search path, thereby ensuring that the third-party implementation is used instead of the WebSphere Application Server.

   a. In the administrative console, click **Applications > Application Types > WebSphere enterprise applications >** *application_name* **> Class loading and update detection**.

   b. Under Class reloading options, select **Override class reloading settings for web and EJB modules** .

c. Under Class loader order, select **Class loader order** property to `Classes loaded with local class loader first (parent last)`.

a. Click **OK**, and then **Save** to save your changes.

2. Turn off web services annotation scanning.

   Annotation scanning can be turned off at the application level or at the server level.

   To turn off annotation scanning at the application level, set the DisableIBMJAXWSEngine property in the META-INF/MANIFEST.MF of a WAR file or EJB module to true. Example:

```
Manifest-Version: 1.0
DisableIBMJAXWSEngine: true
```

   To turn off web services annotation scanning at the server level:

   a. In the administrative console, go to the Custom properties page for the Java virtual machine.

      Click **Servers > Server Types > WebSphere application servers >** *server_name*, and then, in the Server Infrastructure section, click **Java and process management > Process definition > Control > Java virtual machine > Custom properties**

   b. Set the **com.ibm.websphere.webservices.DisableIBMJAXWSEngine** property to `true`

      If this property does not already exist for your configuration, click **New**, and add `com.ibm.websphere.webservices.DisableIBMJAXWSEngine` in the **Name** field and `true` in the **Value** field.

Results

What to do next

- Deploy and run an application EAR file with a third-party JAX-WS implementation on WebSphere Application Server.

Deploying web services client applications

After you have created an enterprise archive (EAR) file for the web services client application, you can deploy the web services client application into the Application Server.

Before you begin

To deploy a Java-based web services client, you need an enterprise application, also known as an enterprise archive (EAR) file that is configured and enabled for web services.

A Java API for XML-Based Web Services (JAX-WS) application is packaged as a web application archive (WAR) file or a WAR module within an Enterprise Archive (EAR) file. A JAX-WS application does not require additional bindings and deployment descriptors for deployment whereas a Java API for XML-based RPC (JAX-RPC) web services application requires you to add additional bindings and deployment descriptors for application deployment. JAX-WS is much more dynamic, and does not require any of the static data generated by the deployment step required for deploying JAX-RPC applications. For JAX-RPC web services clients, you must configure the client deployment descriptors.

About this task

You can use either the administrative console or the **wsadmin** scripting tool to deploy an EAR file. If you are installing an application containing web services by using the **wsadmin** command, specify the `-deployws` option for JAX-RPC applications.

Use the **wsdeploy** command only with JAX-RPC applications. The **wsdeploy** command is not applicable for JAX-WS applications.

If you are installing an application containing web services by using the administrative console, select **Deploy WebServices** in the Install New Application wizard. Read about installing a new application for more information on using the administrative console.

The following actions deploy the EAR file with the **wsadmin** command:

Procedure

1. Start *install_root*/bin/wsadmin from a command prompt.
2. Deploy the EAR file.
   - For JAX-WS web service applications, enter the `$AdminApp install` *EARfile* `"-usedefaultbindings"` command at the **wsadmin** prompt.
   - For JAX-RPC web service applications, enter the `$AdminApp install` *EARfile* `"-usedefaultbindings -deployws"` command at the **wsadmin** prompt.

Results

You have a deployed a web service client in the application server runtime environment.

What to do next

Test the web services client. You can now test a web services-enabled managed client EAR file or an unmanaged client JAR file.

Making deployed web services applications available to clients

You can publish WSDL files to the file system. If you are a client developer or a system administrator, you can use WSDL files to enable clients to connect to web services.

Before you begin

The publish WSDL administrative console panel supports both JAX-RPC and JAX-WS services. The publish WSDL panel generates a compression file that contains WSDL files for all modules in an application that contains JAX-WS or JAX-RPC web services. Read about providing the HTTP endpoint URL information to learn how the URL information affects the content of the published WSDL.

To publish a Web Services Description Language (WSDL) file you need an enterprise application, also known as an enterprise archive (EAR) file, that contains a Web services-enabled module and has been deployed into WebSphere Application Server. To learn how to deploy web services, see the deploying web services applications onto application servers information.

About this task

The purpose of publishing the WSDL file is to provide clients with a description of the web service, including the URL identifying the location of the service.

After installing a web services application, and optionally modifying the endpoint information, you might need WSDL files containing the updated endpoint informations to make deployed web services application to be available to clients.

Before you publish a WSDL file, you can configure web services to specify endpoint information in the form of URL fragments to enable full URL specification of WSDL ports. Refer to the tasks describing configuring endpoint URL information.

The WSDL files for each web services-enabled module are published to the file system location you specify. You can provide these WSDL files to clients that want to invoke your Web services.

You can specify endpoint information for HTTP ports, for Java Message Service (JMS) ports, or you can directly access enterprise beans that are acting as web services.

Procedure

1. Configure the web services client bindings.
2. Configure the URL endpoint information for HTTP bindings. Do one of the following depending on what kind of bindings you are using:
   - Configure the URL endpoint information for HTTP bindings.
   - Configure the URL endpoint information for JMS bindings.
   - Configure the URL endpoint information to directly access enterprise beans.
3. Externalize or publish the WSDL file out of the application. You can complete this task in the following ways:
   - Publish a WSDL file with the administrative console
   - Publish a WSDL file using a URL.
   - Publish a WSDL file with the wsadmin tool.

What to do next

Apply security to your web services. To learn more, see the securing web services applications using message level security information.

Configuring web services client bindings

When a web services application is deployed into WebSphere Application Server, an instance is created for each application or module. The instance contains deployment information for the web module or Enterprise JavaBeans (EJB) module, including client bindings.

Before you begin

Deploy a web service into your WebSphere Application Server instance. Read about deploying web services applications onto application servers.

You must know the topology of the URL endpoint address of the web services servers and which web service the client depends upon. You can view the deployment descriptors in the administrative console to find the topology information. To learn more, see the View web services server deployment descriptors information.

About this task

The client bindings define the Web Services Description Language (WSDL) file name and preferred ports. The relative path of a web service in a module is specified within a compatible WSDL file that contains the actual URL to be used for requests. The address is only needed if the original WSDL file did not contain a URL, or when a different address is needed. For a service endpoint with multiple ports, you need to define an alternative WSDL file name.

The following steps describe how to edit bindings for a web service after these bindings are deployed on a server. When one web service communicates with another web service, you must configure the client bindings to access the downstream web service.

You can also configure client bindings with the wsadmin tool. Read about configuring a web service client deployed WSDL file name with the wsadmin tool.

To configure client bindings through the administrative console:

Procedure

1. Open the administrative console.
2. Click **Applications** > **Enterprise Applications** > *application_instance* > **Manage Modules** > *module_instance* > **Web services client bindings**.
3. Find the web service you want to update.

   The web services are listed in the **Web Service** field.
4. Select the WSDL file name from the drop down box in the WSDL file name field.
5. Click **Edit** in the Preferred port mappings field to configure the default port to use.
   a. Specify the port type and the preferred ports in the Port type and Preferred ports fields.

      Configuring the preferred port enables you to select an optimal port implementation use non-SOAP protocols. See the RMI-IIOP web services using JAX-RPC information to learn more about using non-SOAP protocols.
   b. Click **Apply** and **OK**.
6. Click **Edit** in the Port information field to configure the request timeout, the overridden endpoint, and the overridden binding namespace for a port.

   Configuring the request timeout accommodates complex topologies that can have multiple cascaded Web services that involve multiple hops or long-running services.

   You can configure Timeout values based on observed behavior of the overall system as integration proceeds. For example, a web service client might time out because of changing network conditions or the performance of an external web service. When you have applications containing web services clients that timeout, you can change the request time out values for the clients.

   You can specify an endpoint URL to override the current endpoint. A client invoking a request on this port uses this endpoint instead of the endpoint specified in the WSDL file. You can specify the **Overridden endpoint URL** value for both Java API for XML-Based Web Services (JAX-WS) clients and Java API for XML-based RPC (JAX-RPC) clients.

   Note: The **Overridden endpoint URL** field is applicable for both JAX-WS and JAX-RPC clients. The other fields on this administrative console page are only applicable for JAX-RPC clients.
   a. Click **Apply** and **OK**.

Results

Your web service client bindings are configured.

What to do next

Now you can finish any other configurations, start or restart the application, and verify the expected behavior of the web service.

Web services client bindings

The client bindings define the Web Services Description Language (WSDL) file name, preferred ports and other port information. Use this page to specify the client bindings and the port mappings for the web services in a module.

A web service can specify the relative path within the module of a compatible WSDL file containing the actual URL to be used for requests. The relative path only needs to be specified if the original WSDL file does not contain a URL or when a different URL is needed. For a service endpoint with multiple ports defined, a preferred mapping specifies the default port to use for a port type.

To view this administrative console page, complete the following steps:

1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***resource_name*** .
2. Click **Manage Modules** > ***module_name*** > **Web services client bindings**.

This administrative console page applies only to Java API for XML-based RPC (JAX-RPC) applications.

Web service:

Identifies the name of this web service. A module can contain one or more web services.

EJB:

For EJB modules, identifies the name of the EJB.

WSDL file name:

Specifies the WSDL file name, which is relative to the module. Locate the WSDL file name in the drop down menu.

Preferred port mappings:

Specifies and manages the preferred port type mapping for a web service when a particular port type is requested.

Click **Edit** to edit the preferred port mapping information on the Preferred port mappings page.

Port information:

Specifies additional configuration information for the ports of this web service.

Click **Edit** to edit the port information on the Port information page. You can set a request timeout, override an endpoint and override a binding namespace for each client port.

Preferred port mappings:

Use this page to view and manage a preferred portType mapping for a web service.

This administrative console page applies only to Java API for XML-based RPC (JAX-RPC) applications.

When you have multiple ports that reference the same portType (service endpoint interface), a preferred port specifies the port to use when the `Service.getPort(Class SEI)` method is called with only the service endpoint interface.

To view this administrative console page, click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name*** > **Manage Modules** > ***module instance*** > **Web services client bindings** > **Edit** > ***preferred_port_instance***.

portType:

Specifies the portType.

The preferred port and the portType values are both of the type `java.xml.namespace.QName`.

Preferred port:

Specifies the preferred port to be associated with a particular portType. The `Service.getPort(Class)` method returns the preferred port associated with the specified service endpoint interface class (portType).

The preferred ports available are listed, as well as a value of `None`, which indicates no preferred port is selected.

Web services client port information:

Use this page to specify a request timeout, override an endpoint, and override a binding namespace for a web services client port.

A web service can have multiple ports. You can view and configure the port attributes for each defined web service port. The web services are listed on the web services client bindings page.

To view this administrative console page, complete the following steps:

1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***resource_name*** .
2. Click **Manage Modules** > ***module_name*** > **Web services client bindings**.
3. Click **Edit** under **Port Information**.

This administrative console page applies to both Java API for XML-Based Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) web services. The **Overridden endpoint URL** field is the only field supported for JAX-WS clients. The other fields are not applicable for JAX-WS clients.

Port:

Specifies the name of a port.

Request timeout:

Specifies the time, in seconds, that a web service client waits for a request to complete on this port. If a timeout is not specified, the default request timeout for the client to wait is `300` seconds. If the value is set at `0` (zero), the timeout used is the default value for the underlying transport mechanism. This field is supported only for JAX-RPC clients.

A typical use for this setting is to customize the client's behavior when it is configured to use a JMS transport to access a web service to make it wait longer for an expected completion. Depending upon network conditions, or the nature of a web service implementation, it might be necessary to tune the timeout.

Overridden endpoint URL:

Specifies the name of an endpoint that is used to override the current endpoint. A client invoking a request on this port uses this endpoint instead of the endpoint specified in the WSDL file. This field is supported for both JAX-WS and JAX-RPC clients.

If an assembled application contains a web service client that is statically bound, the client is locked into using the implementation (service end point) identified in the WSDL file used during development. Overriding the endpoint is an alternative to configuring the deployed WSDL attribute.

The overridden endpoint URI attribute is specified on a per port basis. It does not require an alternative WSDL file within the module. The overridden endpoint URI takes precedence over the deployed WSDL attribute. The client uses this value for the service end point URI or SOAP address, instead of the value in the static client bindings.

Note: You can edit this field if you have managed clients or a mixture of both managed and unmanaged clients. You cannot edit the field if you have unmanaged clients only.

If you do not want a request by an unmanaged JAX-WS client service to be sent to the endpoint URL that is specified in this field, you can specify the

com.ibm.ws.websvcs.unmanaged.client.dontUseOverriddenEndpointUri Java virtual machine (JVM) system property. For more information about this custom property, read about the Java virtual machine custom properties.

Overridden binding:

Specifies the WSDL file binding namespace URI to use with this port, instead of the namespace in the WSDL file. This binding does not need to exist in the WSDL file. A client invoking a request on this port uses this binding instead of the binding specified in the WSDL file. An overridden binding namespace cannot be specified unless an overridden endpoint is specified. This field is supported only for JAX-RPC clients.

Configuring endpoint URL information for HTTP bindings

Configuring a service endpoint is necessary to connect Java API for XML-Based Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) web services clients to any web services among the components being assembled or to any external web services.

Before you begin

You can develop an HTTP accessible Java API for XML-based remote procedure call (JAX-RPC) or Java API for XML Web Services (JAX-WS) web service when you have an existing JavaBeans object to enable as a web service. For additional information, see the using HTTP to transport web services requests information.

You can use either the administrative console or property files to configure and manage HTTP endpoint URL fragments. To learn about using property files to set and manage the URL fragments, see the information about working with web services endpoint URL fragment property files.

This task describes using the administrative console to configure endpoint URL information for HTTP bindings.

About this task

You can specify HTTP URL prefixes for web services that are accessed through HTTP by using the Provide HTTP endpoint URL information panel in the administrative console. The HTTP URL prefixes provide location specific information and are used to form complete endpoint URLs that are included within published WSDL files.

Note: The Provide HTTP panel in the administrative console displays modules that contain Java API for XML-Based Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) web services. You can use the Provide HTTP panel to provide URL information for both types of web services, however, the panel does not indicate which type of service that you are working with.

To configure these prefixes with the administrative console:

Procedure

1. Open the administrative console.
2. Click **Applications** > **Enterprise Applications** > *application_instance* > **Provide HTTP endpoint URL information**.
3. Specify the URL prefixes for the web service.

   In this step you specify the protocol (HTTP or HTTPS), as well as the *host_name* and *port_number* used in the endpoint URL. You can select a prefix from a predefined list, by selecting the default HTTP URL prefix, or you can use a custom HTTP URL prefix.

   a. Select **Default HTTP URL prefix** or **Custom HTTP URL Prefix**.

If you select the default HTTP URL prefix, a list provides you with a choice of endpoint URL prefixes. The list is a combination of two sets of ports in the module: the virtual host ports and the application server ports. Use a prefix from this list if the application server of the web service is accessed directly. Select a value and also select the check box of the modules to use the prefix.

If you want to use a custom HTTP URL prefix, type the value in the field. Select the check box to use in the prefix.

If you configure a custom HTTP URL prefix, , you must also configure the custom JVM property, `com.ibm.ws.webservices.enableHTTPPrefix` in the administrative console and set the value to `true`. You must restart the application server after this custom property has been defined so that this property is used by the system. Setting this custom JVM property is required so the custom HTTP endpoint prefix information is correctly displayed in the ?WSDL query that is returned from the browser and the URL field of the WSDL file that is returned to the client. If this custom property is not defined with the value of `true`, the custom HTTP URL prefix is not reflected in the WSDL file that the service returns to the client. To learn how to configure this custom JVM property, see the documentation on configuring additional HTTP transport properties using the JVM custom property panel in the administrative console.

Note: The `com.ibm.ws.webservices.enableHTTPPrefix` custom property applies to JAX-RPC web services applications only.

b. Click **Apply**.

The URL prefix, whether default or custom, is copied to the selected module HTTP URL prefix field.

c. Click **OK**. The URL information is saved to your workspace.

Results

You have specified the partial URL information that is used to form the target endpoint addresses in the WSDL files that are published using the Publish WSDL files panel.

What to do next

Configure any other URL endpoint information for Java Message Service (JMS) bindings and direct Enterprise JavaBeans (EJB) access. Then publish the WSDL files to make the deployed web services application available to clients.

Provide HTTP endpoint URL information

Use this page to specify endpoint URL prefix information for web services accessed by HTTP. Prefixes are used to form complete endpoint addresses included in published Web Services Description Language (WSDL) files.

To view this administrative console page, click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name*** > **Provide HTTP endpoint URL information**.

You can specify a portion of the endpoint URL to be used in each web service module. In a published WSDL file, the URL defining the target endpoint address is found in the location attribute of the port's `soap:address` element.

This administrative console page applies for Java API for XML-Based Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) web services.

In addition to the using the administrative console, you can use property files to configure and manage HTTP endpoint URL fragments. To learn about using property files to set and manage the URL fragments, see the information about working with web services endpoint URL fragment property files.

Specify endpoint URL prefixes for web services:

Specifies the *protocol* (either http or https), *host_name*, and *port_number* to be used in the endpoint URL.

You can select a prefix from a predefined list using the **HTTP URL prefix** or **Custom HTTP URL prefix** field.

The URL prefix format is *protocol://host_name:port_number*, for example, `http://myHost:9045`. The actual endpoint URL that is contained in a published WSDL file consists of the prefix followed by the module's context-root and the web service url-pattern, for example, `http://myHost:9045/services/myService`.

Select default HTTP URL prefix:

Specifies the drop down list associated with a default list of URL prefixes. This list is the intersection of the set of ports for the module's virtual host and the set of ports for the module's application server. Use items from this list if the web services application server is accessed directly.

To set an HTTP endpoint URL prefix, select **Select default HTTP URL prefix** and select a value from the drop down list. Select the check box of the modules that are to use the prefix and click **Apply**. When you click **Apply**, the entry in the **Select default HTTP URL prefix** or **Select custom HTTP URL prefix** fields, depending on which is selected, is copied into the **HTTP URL prefix** field of any module whose check box is selected.

Select custom HTTP URL prefix:

Specifies the *protocol*, *host*, and *port_number* of the intermediate service if the web services in a module are accessed through an intermediate node, for example the web services gateway or an IHS server.

To set a custom HTTP endpoint URL prefix, you must also configure the custom JVM property, `com.ibm.ws.webservices.enableHTTPPrefix` in the administrative console and set the value to `true`. Setting this custom JVM property is required so the custom HTTP URL is correctly populated in the URL field of the WSDL file that is returned to the client. If this custom JVM property is not configured, the custom HTTP URL prefix is not in the URL field in the copy of the WSDL file that the service returns to the client. To learn how to configure this custom JVM property, see the documentation on configuring additional HTTP transport properties using the JVM custom property panel in the administrative console. You must restart the application server after this custom property has been defined so that this property is used by the system.

After the `com.ibm.ws.webservices.enableHTTPPrefix` custom JVM property is configured, select **Select custom HTTP URL prefix** and enter a value. Select the check box of the modules that are to use the prefix and click **Apply**. When you click **Apply**, the entry in the **Select default HTTP URL prefix** or **Select custom HTTP URL prefix** fields, depending on which is selected, is copied into the **HTTP endpoint URL prefix** field of any module whose check box is selected.

Note: The `com.ibm.ws.webservices.enableHTTPPrefix` custom property applies to JAX-RPC web services applications only.

Configuring endpoint URL information for JMS bindings

WebSphere Application Server supports the use of the Java Message Service (JMS) API to transport web services requests, as an alternative to using HTTP.

Before you begin

The application server supports use of the Java Message Service (JMS) API to transport web services requests, as an alternative to HTTP transport. Read about using the Java Message Service (JMS) to transport web services requests to learn more about how web service clients and servers can communicate through JMS queues and topics instead of through HTTP connections.

You can use either the administrative console or property files to configure and manage JMS endpoint URL fragments. To learn about using property files to set and manage the URL fragments, see the information about working with web services endpoint URL fragment property files.

This task describes using the administrative console to configure endpoint URL information for JMS bindings.

About this task

Configuring a service endpoint is necessary to connect web service clients to any web services among the components being assembled or to any external web services. You can configure the endpoint URL information for JMS during application installation

In this task, enter the JMS endpoint URL prefix to use for each web service-enabled Enterprise JavaBeans (EJB) Java archive (JAR) file that belong to the application. The JMS endpoint URLs are included in the Web Services Description Language (WSDL) files published for clients to use.

You can specify HTTP URL prefixes for web services that are accessed through HTTP by using the Provide HTTP endpoint URL information panel in the administrative console. These prefixes are used to form complete endpoint addresses that are included in WSDL files when published.

You can specify JMS URL prefixes by using the Provide JMS and EJB endpoint URL information panel in the administrative console during or after application installation.

This task applies for Java API for XML-Based Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) web services.

To configure JMS URL prefixes:

Procedure

1. Open the administrative console.
2. Click **Applications** > **Enterprise Applications** > ***application_instance*** > **Provide JMS and EJB endpoint URL information**.
3. Locate the list of web services modules that are accessible through JMS transport.
4. Type the JMS URL fragment in the **URL fragment** field. Enter a URL fragment that is a prefix to the initial URL part that is obtained by examining the deployment information of the Web service. See the usage scenario following this task for more information.

   The value that you enter is used to define the location attribute of the port soap:address element within the WSDL file that is published using the *application_name*_ExtendedWSDLFiles.zip or the *application_name*_WSDLFiles.zip file on the Publish WSDL zip files panel.

Results

You have a web service that is accessible through the JMS transport and configured with JMS bindings.

Example

Suppose an application called StockQuoteService contains an EJB JAR file that is named StockQuoteEJB, which contains one or more web services that are accessible through the JMS transport.

See the using SOAP over Java Message Service to transport web services information to review the example that defines a queue with the Java Naming and Directory Interface (JNDI) name of jms/StockQuote_Q, and a connection factory with the JNDI name of jms/StockQuote_CF, for your application.

In this example, you specify the following string as the JMS URL prefix within the Provide JMS and EJB endpoint URL information panel:

```
jms:/queue?destination=jms/StockQuote_Q&connectionFactory=jms/StockQuote_CF
```

The WSDL publisher uses this partial URL string to produce the actual JMS URL for each port component that is defined in the module. The `targetService=<port_name>` string is added to the end of the JMS URL, for example:

```
jms:/queue?destination=jms/StockQuote_Q&connectionFactory=jms/StockQuote_CF&targetService=getQuote
```

The published WSDL file is used by clients to invoke the web service.

What to do next

Publish the WSDL files to make the deployed web services application available to clients.

Provide JMS and EJB endpoint URL information

Use this page to specify Java Message Service (JMS) and Enterprise JavaBeans (EJB) endpoint URL fragments for web services accessed through SOAP and Java Message Service (JMS) or directly as enterprise beans. Fragments are used to form complete endpoint addresses included in published Web Services Description Language (WSDL) files.

To view this administrative console page, click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name*** > **Provide JMS and EJB endpoint URL information**.

You can specify a fragment of the endpoint URL to be used in each web service module. In a published WSDL file, the URL defining the target endpoint address is found in the location attribute of the port's `soap:address` element.

If you are using web services modules that are configured to use JMS or configured to access enterprise beans directly, these modules are listed on this panel.

This administrative console page applies for Java API for XML-Based Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) web services.

In addition to the using the administrative console, you can use property files to configure and manage JMS and EJB endpoint URL fragments. To learn about using property files to set and manage the URL fragments, see the information about working with web services endpoint URL fragment property files.

URL fragment for JMS:

Specifies a URL fragment for web services accessed through a JMS transport. You can enter a value that is used to define the `soap:address` of a web service. When WSDL files are published, a URL is formed using this fragment and is contained in the WSDL files.

The URL fragment that is entered as a value is a prefix to which the targetService property is appended to form a complete JMS URL endpoint. The default value is obtained by examining the installed service's deployment information, for example, `jms:jndi:jms/MyQueue&jndiConnectionFactoryName=jms/MyCF`.

This information is obtained from the configured JMS endpoint for the web service, which is a Message Driven Bean (MDB) defined by the **endpointEnabler** command-line tool. You can modify the URL fragment, for example, by adding properties. The URL fragment is combined with the targetService property to form the complete URL, for example, `jms:jndi:jms/MyQueue&jndiConnectionFactoryName=jms/MyCF&priority=5&targetService=GetQuote`.

URL fragment for EJB:

Specifies a URL fragment for web services accessed through an EJB binding. You can enter a value used to define the location attribute of the port's `generic:address` element of a Web service. This port address is contained in the WSDL compression file when the compression file is published using the *application_name_ExtendedWSDLFiles*`.zip` field on the **Publish WSDL zip file** panel.

The URL fragment value entered is a suffix, which is appended to the initial part of the URL obtained by examining the web service's deployment information. For example, the following URL fragment can be obtained from the EJB's deployment information: `wsejb:/com.acme.sample.MyStockQuoteHome?jndiName=ejb/MyStockQuoteHome`.

In this case, you can enter the following information in the URL fragment field, `jndiProviderURL=corbaloc:iiop:myhost.mycompany.com:2809`, which results in this endpoint URL, `wsejb:/com.acme.sample.MyStockQuoteHome?jndiName=ejb/MyStockQuoteHome &jndiProviderURL=corbaloc:iiop:myhost.mycompany.com:2809`.

Configuring endpoint URL information to directly access enterprise beans

WebSphere Application Server supports directly accessing an enterprise bean as a web service, as an alternative to using HTTP or Java Message Service (JMS) to transport requests between the server and the client. The Enterprise JavaBeans (EJB) module that is used as a web service contains a Web Services Description Language (WSDL) file that contains EJB bindings.

Before you begin

To learn more about the process of directly accessing an enterprise bean as a web service, see the using WSDL EJB bindings to invoke an EJB from a JAX-RPC web services client.

You can use either the administrative console or property files to configure and manage EJB endpoint URL fragments. To learn about using property files to set and manage the URL fragments, see the information about working with web services endpoint URL fragment property files.

This task describes using the administrative console to configure endpoint URL information to directly access enterprise beans.

About this task

Configuring a service endpoint is necessary to connect web service clients to any web services among the components being assembled or to any external web services.

You can specify web address endpoints of the enterprise bean for web services that are accessed directly by EJB bindings using the Provide JMS and EJB endpoint web address information panel in the administrative console.

If you have modules that are configured for using direct EJB access, the modules are listed on the Provide JMS and EJB endpoint web address information panel in the administrative console. The EJB endpoint is only available in the WSDL that is found in the *application_name*`_ExtendedWSDLfiles.zip` file.

You can specify a fragment of the endpoint web address for the web services in each module.

To configure the web address endpoints of the enterprise bean with the administrative console:

Procedure

1. Open the administrative console.
2. Click **Applications** > **Enterprise Applications** > ***application_instance*** > **Provide JMS and EJB endpoint URL information**.

3. Locate the list of EJB modules.
4. Select the application module.
5. Type the web address fragment in the **URL fragment** field.

   Enter a web address fragment that is a suffix to the initial web address part that is obtained by examining the web service deployment information. See the example following this task for more information.

   The value that you enter is used to define the location attribute of the port generic:address element within the WSDL file that is published using the *application_name*_ExtendedWSDLFiles.zip file name link on the Publish WSDL zip files panel. The zip file names are listed as links on the panel.
6. Click **OK**.
7. Click **Save**.

Results

You have configured endpoints of the enterprise bean for Web services that are accessed directly by EJB bindings.

Example

The following example illustrates a web address fragment to enter in the URL fragment field.

The following web address information can be obtained from the deployment descriptor of an enterprise bean:

```
wsejb:/com.acme.sample.MyStockQuoteHome?jndiName=ejb/MyStockQuoteHome
```

Enter the following web address fragment in the URL fragment field:

```
jndiProviderURL=corbaloc:iiop:myhost.mycompany.com:2089
```

The results are shown in the following example:

```
wsejb:/com.acme.sample.MyStockQuoteHome?jndiName=ejb/MyStockQuoteHome&jndiProviderURL=
corbaloc:iiop:myhost.mycompany.com:2089
```

What to do next

Provide a description of the web service to the service requestor by publishing WSDL files. To learn more, read about making deployed web services applications available to clients.

Publishing WSDL files using the administrative console

You can publish a Web Services Description Language (WSDL) file using the WebSphere Application Server administrative console.

Before you begin

Before completing this task, you need to install or deploy the web service. After deployment, configure the URL endpoint tasks for your transport:

- Configure endpoint URL information for HTTP bindings
- Configure endpoint URL information for JMS bindings
- Configure endpoint URL information to directly access enterprise beans

About this task

By publishing a WSDL file, you are providing clients with a description of the web service, including the URL identifying the location of the service.

The WSDL files in each web services-enabled module are published to the file system location you specify. You can provide these WSDL files in the development and configuration process of the web service clients so they can invoke your web services.

This task applies for Java API for XML-Based Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) web services.

To learn about more ways to publish WSDL files, see the making deployed web services applications available to clients information.

To publish an application's WSDL file with the administrative console:

Procedure

1. Open the administrative console.
2. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
3. Under Web Services Properties, click **Publish WSDL files**. This takes you to the **Publish WSDL zip files** page.
4. Click the WSDL compression file to download. The compression file contains the application's published WSDL files. The compression file `ExtendedWDLFiles.zip` contains EJB binding information. It can also contain JMS or HTTP binding information. The compression file `WSDLFiles.zip` only contains JMS or HTTP binding information.

   The compression file `ExtendedWDLFiles.zip` can contain HTTP binding information. The compression file `WSDLFiles.zip` only contains HTTP binding information.

What to do next

Apply security to your web services. To learn more, see the securing web services applications using message level security information.

Publish WSDL compressed files settings

Use this page to publish Web Services Description Language (WSDL) files.

This administrative console page applies for Java API for XML-Based Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) web services.

The publish WSDL panel generates a compressed file that contains WSDL files for all modules in an application that contains a JAX-WS or JAX-RPC web service. Read about providing the HTTP endpoint URL information to learn how the URL information affects the content of the published WSDL.

To view this administrative console page, click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name*** > **Publish WSDL files**.

When you click **OK**, a panel showing one or several compressed file names displays. Each compressed file contains a WSDL file that represents the web services-enabled modules in the application. When you select a compressed file to publish, a dialogue displays from which you can choose where to create the compressed file. Within the published compressed files, the directory structure is *application_name*/*module_name*/[META-INF|WEB-INF]/wsdl/*wsdl_file_name*.

In a published WSDL file, the location attribute of a port's `soap:address` element contains the endpoint URL through which the web service is accessed. Using the **Provide HTTP endpoint URL information** and the **Provide JMS and EJB endpoint URL information** panels, configure the endpoint URLs to be used for the web services in each module.

*application_name*_***WSDLFiles.zip:***

Specifies the *application_name*_WSDLFiles.zip file containing the WSDL that describes web services that are accessible by standard SOAP-based ports.

*application_name*_***ExtendedWSDLFiles.zip:***

Specifies the *application_name*_ExtendedWSDLFiles.zip file containing the WSDL file that describes the web services available, including SOAP-based and non-SOAP based (for example, EJB) ports.

If there are no web services configured for direct EJB access, this compressed file name is not displayed. Do not use this compressed file if you want to produce a WSDL file compliant to standards.

Publishing WSDL files using a URL

You can publish a Web Services Description Language (WSDL) file using a URL.

Before you begin

Before you can publish a WSDL file using a URL, ensure the web services-enabled application is installed and running.

The files referenced by the <wsdl-file> element in the webservices.xml might import other WSDL or XML Schema Definition (XSD) files. Typically, all WSDL or XSD files are initially placed into the META-INF/wsdl directory when using Enterprise JavaBeans (EJB) or the WEB-INF/wsdl directory when using JavaBeans. If your WSDL or XSD files are not placed in one of these directories, the file referenced by the <wsdl-file> and its imported files are copied to the wsdl directory for publishing purposes.

There are two different forms of URL query strings. The first appends /wsdl to the service and returns only HTTP and JMS bindings. The second appends /extwsdl to the service and returns the extended WSDL file, including HTTP, JMS, and EJB bindings. If a WSDL file contains only EJB bindings and the /wsdl query is used, an error message displays in the browser saying there are no HTTP or JMS bindings in the WSDL file. The error message suggests using the /extwsdl query instead. Publishing a WSDL file using a URL requires that the application have a web module; either provided by the application or in the form of an HTTP router module. If an EJB application contains a WSDL file with only JMS or EJB Web service bindings, the **endptEnabler** command can be used to add an HTTP router module to the application.

Note: Only HTTP URLs are supported for publishing.

About this task

To publish a WSDL file using a URL:

Procedure

1. Retrieve the outer-most WSDL file. The outer-most WSDL file is the WSDL file defined by the <wsdl-file> element in the webservices.xml file.

   Each web service has an endpoint address, like http://example.com/services/stockquote. You can retrieve the outer-most WSDL file (defined by the <wsdl-file> element within the webservices.xml file) by appending the string "/wsdl" or "/wsdl/" to the endpoint address, for example, http://example.com/services/stockquote/wsdl.
2. Retrieve the imported WSDL files. When the outer-most WSDL file imports other WSDL or XSD files, these imported files can be retrieved by appending the relative path to the URL, which is used to retrieve the outer-most WSDL file. This is also true for WSDL files that import other files. This process is similar to the use of relative hyperlinks in HTML documents. If an HTML document contains a hyperlink to other documents, the relative path is appended to create the URL to access the hyperlinked documents.

Example

Suppose you have an application with the following directory structure:

```
<module-root>/
 WEB-INF/
  webservices.xml    /* the <wsdl-file> element points to "WEB-INF/wsdl/fooImpl.wsdl"*/
  web.xml
  ibm-webservices-bnd.xml

  wsdl/
   fooImpl.wsdl   /* imports foo.wsdl which is an interface wsdl */
   foo.wsdl       /* type definition for the interface */
```

If the SOAP address for the foo service is `http://examples.com:9080/services/foo`, the simple way to retrieve the foo service's outer-most WSDL is with the following form: `http://examples.com:9090/services/foo/wsdl` or `http://examples.com:9090/services/foo/wsdl/`. The URL is redirected to `http://examples.com:9090/services/foo/wsdl/fooImpl.wsdl`, where `fooImpl.wsdl` is the name of the outer-most WSDL file.

Since the `fooImpl.wsdl` file has the import `<import namespace="http://examples.com/foo" location="a/b/foo.wsdl>`, use the URL `http://examples.com:9090/services/foo/wsdl/a/b/foo.wsdl` to obtain the `foo.wsdl` file.

Running an unmanaged web services JAX-RPC client

WebSphere Application Server Version 8.5 and the Application Client for WebSphere Application Server Version 8.5 provides a thin Java Platform, Standard Edition 6 (Java SE 6) web services client runtime implementation that is based on the Java API for XML-based RPC (JAX-RPC) 1.1 specification. The Thin Client for JAX-RPC with WebSphere Application Server is a stand-alone Java SE 6 client environment that enables running unmanaged JAX-RPC web services client applications in a non-WebSphere environment to invoke web services that are hosted by the application server.

Before you begin

Note: You can use the Thin Client for JAX-RPC with WebSphere Application Server as a stand-alone client run time in a pure Java SE environment, or within an OSGi environment. The Thin Client for JAX-RPC is not supported when running within WebSphere Application Server or WebSphere Application Client environments. In this version of the application server, with the exception of the Administration Thin Client, other Thin Client run times provided with the application server can also reside in the CLASSPATH and coexist with the Thin Client for JAX-RPC.

Before you can set up a JAX-RPC unmanaged client environment you will need to obtain the Thin Client for JAX-RPC Java archive (JAR) file. To obtain the Thin Client for JAX-RPC, you must either install the application server or the application client.

The Thin Client for JAX-RPC JAR file, `com.ibm.ws.webservices.thinclient_8.5.0.jar`, is located in the *app_server_root*`\runtimes` directory. Refer to the license agreements to ensure correct usage and for limitations on copies of the Thin Client for JAX-RPC outside of the WebSphere environment.

The Thin Client for JAX-RPC is supported in the following environments:

- IBM Software Development Kits (SDKs) Version 6.0
- Sun Java Development Kit (JDK) Version 6.0 that are provided by IBM
- non-IBM SDKs Version 6.0 with this limitation:
  - Xerces limitation on non-IBM SDKs

    If you are using a non-IBM SDK, because of dependencies with the Xerces implementation, you will need to download Xerces-J version 2.6.2 and set it in the classpath before attempting to run the Thin Client for JAX-RPC.

– Equinox 3.6 OSGi runtime environments

About this task

Note: WS-Addressing is not supported for JAX-RPC web services in an unmanaged client environment. If you need to use WS-Addressing, or a web service standard that relies on WS-Addressing, such as WS-Notification, you must use the Thin Client for Java API for XML-based Web Services (JAX-WS) instead. To learn how to setup and run the Thin Client for JAX-WS, see the Thin Client for JAX-WS documentation.

Procedure

1. Configure the path. You can add the Java `bin` directories to your path by typing:

```
set PATH=<your_JDK_bin_directory>;%PATH%
```

2. Configure the classpath.

```
set CLASSPATH=.;<your_web_services_thin_client_install_directory>\com.ibm.ws.webservices.thinclient_8.5.0.jar;
<your_application_jars>;%CLASSPATH%
```

   - If you are using a non-IBM SDK, obtain a Xerces `xml-apis.jar` and `xercesImpl.jar` from the Xerces web site and configure the classpath definition.

```
set CLASSPATH=.;<your_Xerces_install_directory>\xml-apis.jar;<your_Xerces_install_directory>
\xercesImpl.jar;%CLASSPATH%
```

3. Configure SSL for the client.
   a. Add the following system properties to the Java command:

```
-Dcom.ibm.SSL.ConfigURL=file:///home/sample/ssl.client.props
```

      You can obtain the `ssl.client.props` file from the WebSphere Application Server installation and modify the file to suit your environment. You must, at a minimum, update the location of the `com.ibm.ssl.keyStore` and `com.ibm.ssl.trustStore` key files in the `ssl.client.props` file to the match location of your target environment. For example, use these SSL configuration settings when running the application with a Sun JRE:

```
com.ibm.ssl.protocol=SSL
com.ibm.ssl.trustManager=SunX509
com.ibm.ssl.keyManager=SunX509
com.ibm.ssl.contextProvider=SunJSSE

com.ibm.ssl.keyStoreType=JKS
com.ibm.ssl.keyStoreProvider=SUN
com.ibm.ssl.keyStore=/home/user1/etc/key.jks

com.ibm.ssl.trustStoreType=JKS
com.ibm.ssl.trustStoreProvider=SUN
com.ibm.ssl.trustStore=/home/user1/etc/trust.jks
```

      The key store file and trust store file must be created using the Java keytool utility before the application runs. The automatic key file generation is not supported with a non-IBM product JRE.

4. Enter the following command to run your client application:

```
%JAVA_HOME%/bin/java -Dcom.ibm.SSL.ConfigURL=file:///home/sample/ssl.client.props <your_client_application>
```

Results

You have set up an unmanaged JAX-RPC client runtime environment that can be used to invoke web services hosted on a WebSphere Application Server.

Running an unmanaged web services JAX-WS client

WebSphere Application Server provides a thin Java Platform, Standard Edition 6 (Java SE 6) web services client runtime implementation that is based on the Java API for XML-based Web Services (JAX-WS) 2.2 specification. The Thin Client for JAX-WS with WebSphere Application Server is a stand-alone Java SE 6 client environment that enables running unmanaged JAX-WS web services client applications in a non-WebSphere environment to invoke web services that are hosted by the application server.

Before you begin

Note: You can use the Thin Client for JAX-WS with WebSphere Application Server as a stand-alone client run time in a pure Java SE environment, or within an OSGi environment. The Thin Client for JAX-WS is not supported running within WebSphere Application Server or WebSphere Application Client environments. In this version of the application server, with the exception of the Administration Thin Client, other Thin Client run times provided with the application server can also reside in the CLASSPATH and coexist with the Thin Client for JAX-WS.

Before you set up a JAX-WS unmanaged client execution environment, obtain the Thin Client for JAX-WS Java archive (JAR) file. To obtain the Thin Client for JAX-WS, install WebSphere Application Server Version 8.5 or the Application Client for WebSphere Application Server Version 8.5. The Thin Client for JAX-WS JAR file, `com.ibm.jaxws.thinclient_8.5.0.jar`, is located in the *app_server_root*`\runtimes` directory.

Copy the Thin Client for JAX-WS, `com.ibm.jaxws.thinclient_8.5.0.jar` file and the `endorsed_apis_8.5.0.jar` files, to other machines to create a lightweight client environment that enables communications with the product. Copies of the Thin Client for JAX-WS are subject to the same terms and conditions of the license agreement for the WebSphere product where you obtained the Thin Client for JAX-WS. Refer to the license agreements for correct usage and other limitations.

The Thin Client for JAX-WS is supported in the following environments:

- IBM Software Development Kits (SDKs) Version 6.0
- non-IBM SDKs V6.0 with the following limitation:
  - Xerces limitation on non-IBM SDKs

    You must download Xerces-J Version 2.6.2, and add the file to the classpath when setting up the Thin Client for JAX-WS environment.
  - WS-SecurityKerberos on non-IBM SDKs

    WS-SecurityKerberos is not supported with the Sun JDK or other non-IBM SDKs. Applications running in a Thin Client for JAX-WS environment that make use of WS-Security message level protection and use Kerberos security tokens as described in the Web Services Security Kerberos Token Profile 1.1 specification, do not correctly work on non-IBM JDKs. This limitation exists because of a dependancy on the IBM JGSS provider that is only available within IBM SDKs.
- Equinox 3.6 OSGi runtime environments

About this task

Set up a Thin Client for JAX-WS environment by completing the following steps.

Procedure

1. Copy the Thin Client for JAX-WS JAR file, `com.ibm.jaxws.thinclient_8.5.0.jar`, to other machines to create a lightweight client environment.
2. Use the Java Endorsed Standards Override Mechanism to override APIs that are available in the JDK on your system.

   Because the Thin Client for JAX-WS with WebSphere Application ServerVersion 8.5 requires APIs that are more current than what is available in JDKs to support JAX-WS 2.2 and JAXB 2.2 implementations, you must override the default JDK APIs in use by your system by using the Java Endorsed Standards Override Mechanism.

   Copy the *app_server_root*`\runtimes\endorsed\endorsed_apis_8.5.0.jar` file into the default directory, `JAVA_JRE\lib\endorsed`. Alternatively, you can use the `java.endorsed.dirs` property to specify a directory of your choice. If you choose to use an alternative directory, it is a best practice to only include the `endorsed_apis` JAR file.
3. Configure the path. Enter the following command to add the Java `bin` directories to your path:

```
set PATH=<your_JDK_bin_directory>;%PATH%
```

4. Configure the classpath.
   - Add the Thin Client for JAX-WS JAR file to the classpath definition.

     Important: If the Thin Client is to use the Java Message Service (JMS), then **all** the JAR files that are required must be in the classpath for JMS and for the client so that entries exist for all the required files. Otherwise, required files will not be identified as installed and ready for use.

```
set CLASSPATH=.;<your_jax-ws_thin_client_install_directory>\com.ibm.jaxws.thinclient_8.5.0.jar;
<your_application_jars>;%CLASSPATH%
```

   - If you are using a non-IBM SDK, obtain a Xerces `xml-apis.jar` file and `xercesImpl.jar` file from the Xerces website, and configure the classpath definition.

```
set CLASSPATH=.;<your_Xerces_install_directory>\xml-apis.jar;<your_Xerces_install_directory>
\xercesImpl.jar;%CLASSPATH%
```

5. Optional: Implement policy sets for your client.
6. Configure SSL for the client.
   a. Add the following system properties to the Java command:

```
-Dcom.ibm.SSL.ConfigURL=file:///home/sample/ssl.client.props
```

   You can obtain the `ssl.client.props` file from the WebSphere Application Server installation and modify the file to suit your environment. You must, at a minimum, update the location of the `com.ibm.ssl.keyStore` and `com.ibm.ssl.trustStore` key files in the `ssl.client.props` file to the match location of your target environment. For example, use these SSL configuration settings when running the application with a Sun JRE:

```
com.ibm.ssl.protocol=SSL
com.ibm.ssl.trustManager=SunX509
com.ibm.ssl.keyManager=SunX509
com.ibm.ssl.contextProvider=SunJSSE

com.ibm.ssl.keyStoreType=JKS
com.ibm.ssl.keyStoreProvider=SUN
com.ibm.ssl.keyStore=/home/user1/etc/key.jks

com.ibm.ssl.trustStoreType=JKS
com.ibm.ssl.trustStoreProvider=SUN
com.ibm.ssl.trustStore=/home/user1/etc/trust.jks
```

   The key store file and trust store file must be created using the Java keytool utility before the application runs. The automatic key file generation is not supported with a non-IBM product JRE.

7. Run your client application:
   - Enter the following command if you have copied the `endorsed_apis_8.5.0.jar` file into the `JAVA_JRE\lib\endorsed` default directory; for example:

```
%JAVA_HOME%\bin\java -Dcom.ibm.SSL.ConfigURL=file:\\\home\sample\ssl.client.props <your_client_application>
```

   - Enter the following command if you have copied the `endorsed_apis_8.5.0.jar` file into a directory other than the default `JAVA_JRE\lib\endorsed` directory; for example:

```
%JAVA_HOME%\bin\java
-Djava.endorsed.dirs=<directory_that_includes_endorsed_apis_8.5.0.jar>
-Dcom.ibm.SSL.ConfigURL=file:\\\home\sample\ssl.client.props <your_client_application>
```

Results

You have set up an unmanaged JAX-WS client runtime environment to invoke web services hosted on a WebSphere Application Server.

Testing web services-enabled clients

Once you have developed, assembled, deployed and configured your web service, you can test to confirm your web service runs in the application server environment.

Before you begin

Before testing your web services Java client to confirm your web service runs in the WebSphere Application Server environment, verify that the server endpoint specified in the client Web Services Description Language (WSDL) file is running and available.

About this task

Tests are run differently depending on whether the client module is in a Java EE container or if the client is running in the Thin Client for Java API for XML-based RPC (JAX-RPC) with WebSphere Application Server application environment or the Thin Client for Java API for XML-Based Web Services (JAX-WS) with WebSphere Application Server application environment.

Procedure

1. Test an unmanaged client JAR file by running your application with the **java** command.

   For JAX-WS applications:

```
"$JAVA_HOME/bin/java"
-Djava.endorsed.dirs=<your_jax-ws_thin_client_install_directory>/endorsed_apis_8.5.0.jar
-classpath
"<your_JAX-WS_thin_client_install_directory>/runtimes/com.ibm.jaxws.thinclient_8.5.0.jar:
<list_of_your_application_jars_and_classes>"
<fully_qualified_class_name_to_run> <your_application_parameters>
```

   For JAX-RPC applications:

```
"$JAVA_HOME/bin/java"
-classpath
"<your_JAX-RPC_thin_client_install_directory>/runtimes/com.ibm.ws.webservices.thinclient_8.5.0.jar:
<list_of_your_application_jars_and_classes>"
<fully_qualified_class_name_to_run> <your_application_parameters>
```

   The unmanaged client application runs.

2. Test a managed JAX-RPC client EAR file or an unmanaged JAX-WS client EAR file.

   a. Run your client application with the **launchClient** command. The following example illustrates the use of this command:

```
launchClient clientEar
```

Results

You have a web services-enabled client that is tested. Now you can add security measures to the web service. Security measures are optional.

Chapter 49. Deploying web services - RESTful services

You can use Java API for RESTful Web Services (JAX-RS) to develop services that follow Representational State Transfer (REST) principles. RESTful services are based on manipulating resources. Resources can contain static or dynamically updated data. By identifying the resources in your application, you can make the service more useful and easier to develop.

Deploying JAX-RS web applications

After you assemble your Java API for RESTful Web Services (JAX-RS) web application, you can deploy the web application archive (WAR) package or the enterprise archive (EAR) package onto the application server.

Before you begin

To deploy a JAX-RS web application, you need a WAR package or EAR package that is configured and enabled for RESTful services.

About this task

Every web application must have a context root for the web application to deploy successfully. A context root for each Web module is defined in the application deployment descriptor during application assembly or during application deployment. The context root is combined with the defined servlet mapping from the WAR file to compose the full URL that users type to access the servlet. The context root for each deployed web application must be unique on the server. The context root can also be empty. For instance, if a Web application used a context root of `sample/application/`, the web application request URL begins with `http://<hostname>:<port>/sample/application/`.

The URL pattern of a servlet is appended to the context root of the Web application. For example, if the context root is `sample/application/` and the servlet URL mapping is `rest/api/*`, the base URI for the JAX-RS web application is `http://<hostname>:<port>/sample/application/rest/api`.

Procedure

Deploy the JAX-RS web application WAR package or EAR package onto the application server. Read about installing enterprise application files to learn more about deploying web applications.

Results

The JAX-RS web application is deployed and ready for your business use.

Deployment of a Java API for RESTful Web Services (JAX-RS) web application is successful if you can access the application by typing a Uniform Resource Locator (URL) in a browser or if you can access the application by following a link. If you cannot access your application, follow these steps to eliminate some common errors that can occur during deployment.

Note:

Use the following tips to resolve common errors during deployment of JAX-RS web applications.

An HTTP 404 Not Found error message is sent back to the client in the server response.

To resolve this problem, take the following actions:

- Verify that the root resource classes are annotated with a @javax.ws.rs.Path annotation and that value in the annotation is correct. Root resource classes without a @Path

annotation are not registered with the JAX-RS runtime. To learn more, see the defining the URI patterns for resources in RESTful applications information.

- Verify that the root resource class is added to the set of classes returned from the getClasses() method for the subclasses of the javax.ws.rs.core.Application class. Classes not registered in the subclasses of the javax.ws.rs.core.Application class are not recognized by the JAX-RS runtime environment. To learn more, see the defining the URI patterns for resources in RESTful applications information.
- Verify that the web.xml configuration is correct with the expected URL patterns. For additional details, see the configuring the web.xml file for JAX-RS servlets and filters information.
- Verify that the URL that is being used is correct and includes the context root. If you are using a servlet, the servlet URL pattern is a part of the final URL. Using a filter might be more suitable in your web application. For additional details, see the configuring the web.xml file for JAX-RS servlets and filters information.

An HTTP 406 Not Acceptable error message is automatically being sent back to the client in the server response.

To resolve this problem, take the following actions:

- Verify that the Accept HTTP request header in the incoming request is correct. To learn more, see the Implementing content negotiation based on HTTP headers information.
- Verify that the @javax.ws.rs.Produces value on the resource method or resource class is compatible with the incoming Accept HTTP request header. To learn more, see the defining media types for resources in RESTful applications.

An HTTP 415 Unsupported Media Type error message is automatically being sent back to the client in the server response.

To resolve this problem, take the following actions:

- Verify that that the Content-Type HTTP request header in the incoming request is correct and is being sent. To learn more, see the defining media types for resources in RESTful applications.
- Verify that the @javax.ws.rs.Consumes value on the resource method or resource class is compatible with the incoming Content-Type HTTP request header.

An HTTP 204 No Content response status is automatically being sent back to the client in the server response.

To resolve this problem, take the following action:

- If the object returned from a resource method is a null value, then a 204 No Content status response code is sent back from the server runtime automatically.

For information about known problems and their resolution, see the IBM Support page.

IBM Support has documents that can save you time gathering information needed to resolve this problem.

Chapter 50. Deploying web services - Security (WS-Security)

The Web Services Security specification defines core facilities for protecting the integrity and confidentiality of a message, and provides mechanisms for associating security-related claims with a message.

Deploying applications that use SAML

After SAML policy sets and bindings have been configured, and SAML tokens created, the SAML token information can be sent from the original login server to other servers using the SAML propagation feature. You can also extract SAML attributes from an existing SAML token and then create additional tokens using the extracted attributes.

About this task

Use the SAML propagation feature of WebSphere Application Server to send SAML token information based on the original login to other servers using a SAML token. Four propagation methods are provided. You can propagate the original SAML token, the SAML token identity and attributes, the WSCredential and WSPrincipal information, or a pre-existing SAML token inserted in the RequestContext.

When SAML is installed on a WebSphere server, you can create SAML attributes using the SAML runtime API. The SAML attributes are added to a CredentialConfig object, which is used to generate a SAML token. The API also provides a function that extracts SAML attributes from an existing SAML token and processes the attributes.

The following topics provide more information about deploying SAML applications.

Propagating SAML tokens

You can use various SAML token propagation methods to include SAML tokens in outbound web services messages.

About this task

A web services client can include two types of tokens in outbound web services messages:

- Original SAML tokens the client received from inbound web services messages.
- New self-issued SAML tokens.

New SAML tokens can be generated using attributes from the original SAML tokens, or using attributes from the WSPrincipal user name in the RunAs Subject. The web services policy configuration determines which SAML tokens will be propagated. You can override the policy configuration by programmatically inserting SAML tokens that you want to propagate into the Axis2 RequestContext object.

Four propagation methods are enabled. This table summarizes the propagation methods and the associated binding options:

Table 289. Propagation methods and associated binding options. Use propagation to include SAML tokens in web services messages.

SAML token propagation method	Binding option	Implementation details
Propagate the original SAML token.	The tokenRequest binding option is set to the value, `propagation`.	Sends the original SAML token from the server where the token was received to other servers using WS-Security.
Propagate the user security name, unique security name, group IDs, and security realm name.	The tokenRequest binding option is set to the value, `issueByWSCredential`.	Overrides the default system implementation. The self-issued SAML token contains user security name, user unique security name, group IDs, and security realm name that are specified by the WSCredential object in user security context.

Table 289. Propagation methods and associated binding options (continued). Use propagation to include SAML tokens in web services messages.

SAML token propagation method	Binding option	Implementation details
Propagate the SAML token identity and attributes.	No binding option is set.	Default system implementation. The server self-generates a new SAML token containing the original SAML attributes, Authentication method, and NameIdentifier or SAML NameID, and sends the new self-generated SAML token to downstream servers using WS-Security. The new SAML token issuer name, issuer signing certificate, and lifetime are determined by the SAML provider configuration properties.
Propagate the WSPrincipal.	The tokenRequest binding option is set to the value, `issueByWSPrincipal`.	Overrides the default system implementation. The self-issued SAML token contains WSPrincipal information in the RunAs subject. The information is stored as NameIdentity or NameID without copying anything from the original SAML token, even if the token exists in the subject.
Programmatically propagate a pre-existing SAML token.	Insert the SAML token that you want to propagate into the RequestContext using the property, `com.ibm.wsspi.wssecurity.core.token.config.WSSConstants.SAMLTOKEN_IN_MESSAGECONTEXT`.	Overrides all other existing binding options.

Procedure

1. Propagate the original SAML token by setting the tokenRequest binding option to the value, `propagation`, in the bindings.xml file, as shown in the steps. This method sends the original SAML token to other servers using WS-Security. In order for the propagation to succeed, there must be a valid SAML token in the RunAs subject. The server extracts the SAML token from the RunAs subject in the current security context and validates the following conditions. If any of these conditions are invalid, the WS-Security runtime environment does not propagate the SAML token, and the propagation request fails.
   - The SAML token has not expired, and the expiration time is within the time window of the notOnOrAfter value.
   - The ConfirmationMethod setting in the SAML token is the same as the confirmationMethod binding option defined in the token generator configuration.
   - The token ValueType in the SAML token matches the ValueType in the token generator configuration.

   Perform these steps to set the correct value for the tokenRequest binding option. This procedure assumes that a web services client application named JaxWSServicesSamples is deployed, and that the Saml Bearer Client sample binding is attached.
   a. Click **Applications > Application types > WebSphere enterprise Applications > *JaxWSServicesSamples* > Service client policy sets and bindings > *Saml Bearer Client sample* > WS-Security > Authentication and protection**.
   b. Click **gen_saml11token** in the Authentication tokens table.
   c. Click **Callback handler**.
   d. Add the custom property `tokenRequest` and set the property value to `propagation`.
2. To propagate the SAML token identity and attributes using a self-issuing SAML token, modify the outbound tokenGenerator in the bindings.xml file. This method sends the original SAML attributes, NameIdentifier or NameID, and authentication method from the original SAML token to other servers using WS-Security. If there is no SAML token in the subject, the server uses the WSPrincipal, stored as NameIdentifier or NameID, to create a self-issued SAML token. This propagation method is the default system implementation. In this method, the binding option is not set.

   The following limitations apply to the bindings.xml file when you are using this propagation method:
   - Do not set the tokenRequest binding option in the bindings.xml file.
   - Do not set the stsURI binding option in the bindings.xml file, or set the option to this value: `www.websphere.ibm.com/SAML/Issuer/Self`.

3. To propagate the WSPrincipal, modify the bindings.xml file as shown in the steps. Set the tokenRequest binding option to the value, `issueByPrincipal`, in the bindings.xml file. Using this method, the self-issued SAML token is always based on the WSPrincipal even if there is a SAML token in the subject. The new SAML token contains the WSPrincipal user name as the NameId or NameIdentifier. The token does not contain any other attributes in the WSPrincipal or WSCredential objects.

   The following limitation applies to the bindings.xml file when you are using this propagation method:

   - Do not set the stsURI binding option in the bindings.xml file, or set the option to the value, `www.websphere.ibm.com/SAML/Issuer/Self`.

   Perform these steps to set the correct value for the tokenRequest binding option. This procedure assumes that a web services client application named JaxWSServicesSamples is deployed, and that the Saml Bearer Client sample binding is attached.

   a. Click **Applications > Application types > WebSphere enterprise Applications > *JaxWSServicesSamples* > Service client policy sets and bindings > *Saml Bearer Client sample* > WS-Security > Authentication and protection**.

   b. Click **gen_saml11token** in the Authentication tokens table.

   c. Click **Callback handler**.

   d. Add the custom property `tokenRequest` and set the property value to `issueByPrincipal`.

4. To propagate a pre-existing SAML token by inserting SAMLToken in the RequestContext, follow these steps. Use this method to send a SAML token that you created to downstream servers using WS-Security. The propagation is automatically triggered if the WS-Security runtime detects a SAML token in the RequestContext. The pre-existing token overrides any other existing binding options. To use this propagation method, save the existing SAML token in the RequestContext by specifying `com.ibm.wsspi.wssecurity.core.token.config.WSSConstants.`*`SAMLTOKEN_IN_MESSAGECONTEXT`* as the key, as shown in the steps.

   a. Generate a SAML token using the method `SAMLToken samlToken = <token type>`, for example:

```
SAMLToken samlToken = samlFactory.newSAMLToken(cred, reqData, samlIssuerCfg);
```

   b. Save the SAMLToken to the RequestContext, for example:

```
Map requestContext = ((BindingProvider)port).getRequestContext();
   requestContext.put("com.ibm.wsspi.wssecurity.core.token.config.WSSConstants.SAMLTOKEN_IN_MESSAGECONTEXT", samlToken );
```

   This propagation option can co-exist with the other propagation methods, and overrides the other methods. If the SAML token in the RequestContext is expired, or the token expiration time is less than current time plus the cache cushion, the WS-Security runtime environment ignores the SAML token, and uses one of the other three propagation methods that is configured in the bindings.xml file. To avoid using the other three propagation methods, add the following binding option to the custom properties under callback handler in the TokenGenerator configuration: `failOverToTokenRequest = false`.

5. To propagate a user's group memberships, unique security name, and realm name contained in the `com.ibm.websphere.security.cred.WSCredential` object, modify the `bindings.xml` file as shown in the steps. Set the `tokenRequest` binding option to the value, `issueByWSCredential`, in the `bindings.xml` file. Using this method, the self-issued SAML token is always based on the `WSCredential` even if there is a SAML token in the subject.

   The new SAML 1.1 token contains the following assertions:

   - The `NameIdentifier` element contains the `SecurityName` value from `WSCredential` with the `NameQualifier` element set to the realm name from `WSCredential`. The `SecurityName` is obtained by calling the `WSCredential.getSecurityName()` method. The realm name is obtained by calling the `WSCredential.getRealmName()` method.
   - All attributes have an `AttributeNamespace` set to `com.ibm.websphere.security.cred.WSCredential` as the value.
   - The `GroupIds` attribute contains all group names that a user belongs to. The group names are obtained by calling the `WSCredential.getGroupIds()` method.

- The UniqueSecurityName attribute contains the unique security name, which is obtained by calling the WSCredential.getUniqueSecurityName() method.
- Optionally, you can assert the realm name from WSCredential by adding the includeRealmName=true custom property in the callback handler.

The new SAML 2.0 token contains the following assertions:

- The NameID element contains the SecurityName value from WSCredential with the NameQualifier element set to the realm name from WSCredential. The SecurityName is obtained by calling the WSCredential.getSecurityName() method. The realm name is obtained by calling the WSCredential.getRealmName() method.
- All attributes have a NameFormat set to com.ibm.websphere.security.cred.WSCredential as the value.
- The GroupIds attribute contains all group names that a user belongs to. The group names are obtained by calling the WSCredential.getGroupIds() method.
- The UniqueSecurityName attribute contains the unique security name, which is obtained by calling the WSCredential.getUniqueSecurityName() method.
- Optionally, you can assert the realm name from WSCredential by adding the includeRealmName=true custom property in the callback handler.

The following limitation applies to the bindings.xml file when you use the propagation method:

- Do not set the stsURI binding option in the bindings.xml file.

Perform these steps to set the correct value for the tokenRequest binding option. This procedure assumes that a Web services client application named JaxWSServicesSamples is deployed, and that the Saml Bearer Client sample binding is attached.

a. Click **Applications > Application types > WebSphere enterprise Applications > *JaxWSServicesSamples* > Service client policy sets and bindings > *Saml Bearer Client sample* > WS-Security > Authentication and protection.**
b. Click **gen_saml11token** in the Authentication tokens table.
c. Click **Callback handler**.
d. Add the tokenRequest custom property and set the property value to issueByWSCredential.

The following example illustrates the NameIdentifier and Attribute statement from a self-issued SAML 1.1 assertion based on WSCredential.

```
<saml:AttributeStatement>
    <saml:Subject>
        <saml:NameIdentifier NameQualifier="ldap.acme.com:9080">uid=alice,dc=acme,dc=com</saml:NameIdentifier>
        <saml:SubjectConfirmation>
            <saml:ConfirmationMethod>urn:oasis:names:tc:SAML:1.0:cm:bearer</saml:ConfirmationMethod>
        </saml:SubjectConfirmation>
    </saml:Subject>
    <saml:Attribute AttributeName="UniqueSecurityName" AttributeNamespace="com.ibm.websphere.security.cred.WSCredential">
        <saml:AttributeValue>uid=alice,dc=acme,dc=com</saml:AttributeValue>
    </saml:Attribute>
    <saml:Attribute AttributeName="GroupIds" AttributeNamespace="com.ibm.websphere.security.cred.WSCredential">
        <saml:AttributeValue>cn=development,dc=acme,dc=com</saml:AttributeValue>
        <saml:AttributeValue>cn=deployment,dc=acme,dc=com</saml:AttributeValue>
        <saml:AttributeValue>cn=test,dc=acme,dc=com</saml:AttributeValue>
    </saml:Attribute>
</saml:AttributeStatement>
```

The following example illustrates the NameID and Attribute statement from a self-issued SAML 2.0 assertion based on WSCredential.

```
<saml2:AttributeStatement>
    <saml2:Attribute Name="UniqueSecurityName"
           NameFormat="com.ibm.websphere.security.cred.WSCredential">
        <saml2:AttributeValue>uid=alice,dc=acme,dc=com</saml2:AttributeValue>
    <saml2:Attribute>
    <saml2:Attribute AttributeName="GroupIds"
           NameFormat="com.ibm.websphere.security.cred.WSCredential">
        <saml2:AttributeValue>cn=development,dc=acme,dc=com</saml2:AttributeValue>
```

```
        <saml2:AttributeValue>cn=deployment,dc=acme,dc=com</saml2:AttributeValue>
        <saml2:AttributeValue>cn=test,dc=acme,dc=com</saml2:AttributeValue>
    </saml2:Attribute>
</saml2:AttributeStatement>

<saml2:NameID NameQualifier="ldap.acme.com:9060">alice</saml2:NameID>
```

Creating SAML attributes in SAML tokens

Using the SAML runtime API, you can create SAML tokens containing SAML attributes. You can also extract the SAML attributes from an existing SAML token.

About this task

Using WebSphere Application Server, you can create SAML attributes using the SAML token library APIs. The SAML attributes are added to a CredentialConfig object, which is used to generate a SAML token. The API also provides a function that extracts SAML attributes from an existing SAML token and processes the attributes.

To create a SAML token containing SAML attributes, perform the following steps:

Procedure

1. Initialize a com.ibm.wsspi.wssecurity.saml.data.SAMLAttribute object. This creates a SAML attribute based on an address, for example:

```
SAMLAttribute sattribute =
         new SAMLAttribute("urn:oid:2.5.4.20", //Name
       new String[] {" any address"}, //Attribute Values
       null,  /*XML Attributes empty on this example*/
       "urn:oasis:names:tc:SAML:2.0:profiles:attribute:X500", //NameSpace
       "urn:oasis:names:tc:SAML:2.0:attrname-format:uri",  //format
       "Address");
```

2. Use the SAMLTokenFactory to create a CredentialConfig object containing a SAML attribute. This method requires the Java security permisson wssapi.SAMLTokenFactory.newCredentialConfig.
   a. Create a com.ibm.wsspi.wssecurity.saml.config.CredentialConfig object and set a valid principal name.
   b. Create a SAML attribute.
   c. Create a list of SAML attributes and add the SAML attribute to the list.
   d. Add the SAML attribute list to the CredentialConfig object.

   See the following example:

```
SAMLTokenFactory samlFactory =
  SAMLTokenFactory.getInstance("http://docs.oasis-open.org/wss/oasis-wss-saml-token-profile-1.1#SAMLV2.0");//samlTokenType

CredentialConfig credentialConfig = samlFactory.newCredentialConfig();
credentialConfig.setRequesterNameID("any name");

SAMLAttribute sattribute =
         new SAMLAttribute("urn:oid:2.5.4.20", //Name
       new String[] {" any address"}, //Attribute Values
       null,  /*XML Attributes empty on this example*/
       "urn:oasis:names:tc:SAML:2.0:profiles:attribute:X500", //NameSpace
       "urn:oasis:names:tc:SAML:2.0:attrname-format:uri",  //format
       "Address");

ArrayList<SAMLAttribute> al = new ArrayList<SAMLAttribute>();
al.add(sattribute);
credentialConfig.setSAMLAttributes(al);
```

3. Specifying the CredentialConfig as a parameter, use the com.ibm.websphere.wssecurity.wssapi.token.SAMLTokenFactory newSAMLToken method to create a SAML token containing the attributes. This step assumes that a RequesterConfig `reqData` object and a ProviderConfig `samlIssuerCfg` object have already been created. For more information on these objects, read about RequesterConfig and ProviderConfig.
   a. Obtain an instance of the SAMLTokenFactory.
   b. Create a SAML token using the newSAMLToken method from the SAMLTokenFactory, for example:

```
SAMLTokenFactory samlFactory =
  SAMLTokenFactory.getInstance("http://docs.oasis-open.org/wss/oasis-wss-saml-token-profile-1.1#SAMLV1.1");

SAMLToken aSamlToken = samlFactory.newSAMLToken(credentialConfig, reqData, samlIssuerCfg);
```

4. Optional: Extract SAML attributes from an existing SAML token. This step is useful to extract the SAML attributes from a received SAML token. You can use this step when a SAML assertion is received and the attributes contained in the assertion need to be processed.
   a. Invoke the getSAMLAttributes() method with the token as a parameter to obtain a list of the SAML attributes in the token. This method requires the Java security permission wssapi.SAMLToken.getSAMLAttributes.
   b. Apply an iterator to the list.
   c. Iterate through the list and perform any additional processing required for your application.

   See the following example:

```
List<SAMLAttribute> aList = aSAMLToken.getSAMLAttributes();
java.util.Iterator<SAMLAttribute> i = aList.iterator();

while(i.hasNext()){

   SAMLAttribute anAttribute = i.next();

   //do something with namespace
   String namespace = anAttribute.getAttributeNamespace();

   //do something with name
   String name = anAttribute.getName();

   //do something with friendly name
   String friendlyName = anAttribute.getFriendlyName();

   //process sring attribute values
   String[] stringAttributeValues = anAttribute.getStringAttributeValue();

   //process XML attribute values
   XMLStructure[] xmlAttributeValues = (XMLStructure[]) anAttribute.getXMLAttributeValue();

   }
```

SAML user attributes

A SAML assertion can contain user attributes relating to the principal of the SAML token. A SAML assertion can contain multiple user attributes.

You can include user attributes in the token to communicate the address of the person who is the SAML assertion principal. This example shows a SAML assertion containing a user attribute:

```
<saml:AttributeStatement>
  <saml:Attribute  xmlns:x500=
      "urn:oasis:names:tc:SAML:2.0:profiles:attribute:X500"
    NameFormat=
      "urn:oasis:names:tc:SAML:2.0:attrname-format:uri"
    Name="urn:oid:2.5.4.20"
    FriendlyName="Address">
          <saml:AttributeValue xsi:type="xs:string">
                      11111 Parker Lane, Austin, Texas, 78758
          </saml:AttributeValue>
  </saml:Attribute>
</saml:AttributeStatement>
```

This table describes the parameters used in the assertion:

Parameter	Description
NameFormat	Specifies how the attribute is interpreted.
Name	Indicates the formal name of the attribute.
FriendlyName	Provides a user-friendly name for an attribute when the Name parameter is cryptic.

Parameter	Description
AttributeValue	The value of the user attribute. The value can be a string, or a complex XML type.

Establishing security context for web services clients using SAML security tokens

WebSphere Application Server supports two policy set caller binding configuration options to establish client security context using SAML security tokens in web services SOAP request messages. The two configuration options are mapping SAML tokens to a user entry in a local user repository and, asserting SAML tokens based on a trust relationship.

Before you begin

This task assumes that you are familiar with WebSphere Application Server SAML technology.

About this task

This task describes setting the WebSphere Application Server policy set caller binding configuration option to establish client security context using SAML security tokens in web services SOAP request messages. You can either map SAML tokens to a user entry in a local user repository or assert SAML tokens based on a trust relationship. The second configuration option does not require accessing the local user repository. Instead, the WS-Security runtime environment populates the client security context entirely using the contents of SAML security tokens. This process is based on a trust relationship to the SAML token issuer. If a SAML tokens specifies the sender-vouches subject confirmation method. the process is based on a trust relationship to the message sender.

Procedure

1. Configure a policy set caller binding and select the SAML token type to represent a web services client request.
   a. Click **WebSphere enterprise applications** > ***application_name*** > **Service provider policy sets and bindings** > ***binding_name*** > **WS-Security** > **Callers**.
   b. Click **New** to create the caller configuration.
   c. Specify a **Name**, such as `caller`.
   d. Enter a value for the **Caller identity local part**. For example, `http://docs.oasis-open.org/wss/oasis-wss-saml-token-profile-1.1#SAMLV2.0`, which must match the local part of the `CustomToken` element in the attached WS-Security policy.
   e. Click **Apply** and **Save**.
2. Optional: Map SAML security tokens to a user entry in a local user repository. Mapping to a user entry is the default behavior when you configure a caller binding without specifying a configuration option. Alternatively and optionally, you can select this configuration option explicitly using the following steps:
   a. On the caller binding configuration page, add a Callback handler: `com.ibm.websphere.wssecurity.callbackhandler.SAMLIdAssertionCallbackHandler`.
   b. Add a Callback handler custom property, `crossDomainIdAssertion`, and set its value to `false`.
3. Optional: Assert SAML security tokens based on trust relationship.
   a. On the caller binding configuration page, add a Callback handler: `com.ibm.websphere.wssecurity.callbackhandler.SAMLIdAssertionCallbackHandler`.
   b. Add a Callback handler custom property, `crossDomainIdAssertion`, and set its value to `true`.

   In WebSphere Application Server Version 7.0 Fix Pack 7 and later releases, the WS-Security runtime environment takes a SAML token Issuer name to represent the foreign security realm name. WS-Security takes the `NameID` element in the case of SAML 2.0 security tokens or the `NameIdentifier`

element in the case of SAML 1.1 security tokens to represent user security name. Alternatively, you can explicitly specify which SAML token attribute to use to represent user security name. Moreover, you can also specify which SAML token attribute to use to represent user group membership. Read about SAML assertions across WebSphere Application Server security domains for a detailed discussion of the SAML token assertion trust model and binding configuration.

Version 8.x supports propagating select security context data in SAML tokens. You must set a `tokenRequest` custom property with an `issueByWSCredential` property value in the WS-Security binding configuration of the web services client. Read about propagating SAML tokens for a detailed description of this binding option. When the `crossDomainIdAssertion` property is set to `true` in Version 8.x, WS-Security checks whether a SAML token contains a SAML Attribute `UniqueSecurityName` with a `NameFormat` element with a value of `com.ibm.websphere.security.cred.WSCredential`. If found, WS-Security uses the `NameQualifier` attribute value of the `NameID` element or `NameIdentifier` element to represent the user security realm name. WS-Security also uses the `UniqueSecurityName` attribute value and the `GroupIds` attribute value to represent a unique user name and group membership. This default behavior is different between Version 7 and Version 8.x of the product. You can add a `CallbackHandler` property, `IssuerNameForRealm`, and set its value to `true` to configure Version 8.x to preserve the Version 7 behavior. Alternatively, you can add a `CallbackHandler` property, `NameQualifierForRealm`, and set its value to `true` to configure Version 8.x to always use the `NameQualifier` attribute to represent the user security realm name.

Results

You have configured a web service to establish a client security context using the SAML security token in the web services SOAP request messages.

Example

The following example illustrates the `NameIdentifier` and `Attribute` elements from a self-issued SAML 1.1 assertion based on `WSCredential`:

```
<saml:AttributeStatement>
    <saml:Subject>
        <saml:NameIdentifier NameQualifier="ldap.example.com:9080">uid=alice,dc=example,dc=com</saml:NameIdentifier>
        <saml:SubjectConfirmation>
            <saml:ConfirmationMethod>urn:oasis:names:tc:SAML:1.0:cm:bearer</saml:ConfirmationMethod>
        </saml:SubjectConfirmation>
    </saml:Subject>
    <saml:Attribute AttributeName="UniqueSecurityName" AttributeNamespace="com.ibm.websphere.security.cred.WSCredential">
        <saml:AttributeValue>uid=alice,dc=example,dc=com</saml:AttributeValue>
    </saml:Attribute>
    <saml:Attribute AttributeName="GroupIds" AttributeNamespace="com.ibm.websphere.security.cred.WSCredential">
        <saml:AttributeValue>cn=development,dc=example,dc=com</saml:AttributeValue>
        <saml:AttributeValue>cn=deployment,dc=example,dc=com</saml:AttributeValue>
        <saml:AttributeValue>cn=test,dc=example,dc=com</saml:AttributeValue>
    </saml:Attribute>
</saml:AttributeStatement>
```

The following example illustrates the `NameID` and `Attribute` elements from a self-issued SAML 2.0 assertion based on `WSCredential`:

```
<saml2:AttributeStatement>
    <saml2:Attribute Name="UniqueSecurityName" NameFormat="com.ibm.websphere.security.cred.WSCredential" />
    <saml2:AttributeValue>uid=alice,dc=example,dc=com</saml2:AttributeValue>
    <saml2:Attribute>
        <saml2:Attribute AttributeName="GroupIds" NameFormat="com.ibm.websphere.security.cred.WSCredential" />
        <saml2:AttributeValue>cn=development,dc=example,dc=com</saml2:AttributeValue>
        <saml2:AttributeValue>cn=deployment,dc=example,dc=com</saml2:AttributeValue>
        <saml2:AttributeValue>cn=test,dc=example,dc=com</saml2:AttributeValue>
    </saml2:Attribute>
<saml2:AttributeStatement>

<saml2:NameID NameQualifier="ldap.example.com:9060">alice</saml2:NameID>
```

Chapter 51. Deploying web services - Transports

Transport chains represent a network protocol stack that is used for I/O operations within an application server environment. Transport chains are part of the channel framework function that provides a common networking service for all components.

Invoking JAX-WS web services asynchronously using the HTTP transport

Using the JAX-WS asynchronous response servlet

Java API for XML-Based Web Services (JAX-WS) includes an asynchronous response servlet, which is used within the application server environment to receive responses for JAX-WS requests that are invoked asynchronously.

Before you begin

JAX-WS provides support for invoking web services using an asynchronous client invocation by using either a callback or polling model. Both the callback model and the polling model are available on the Dispatch client and the dynamic proxy client. When a JAX-WS client that is running within the application server environment uses an asynchronous client invocation, the responses are received by the asynchronous response servlet. To learn how to use the asynchronous client invocation model, read about invoking JAX-WS web services asynchronously.

About this task

The asynchronous response servlet is used within an application server to handle incoming asynchronous responses. The servlet uses the same secure and unsecure HTTP ports assigned to the application server. The servlet starts automatically when the application server starts. Because the asynchronous response servlet does not perform role-based authorization checks, only user authentication checks are performed.

The asynchronous response servlet supports both the HTTP and HTTPS protocols. Since the servlet inherits the SSL configuration of the application server, configuring the application server also configures the servlet. The asynchronous response servlet is not affected by the custom HTTP and SSL port properties used by the asynchronous response listener and only runs on the application ports for the application server.

Procedure

1. Determine if you want the JAX-WS client to use the HTTP or HTTPS transport mechanism.
2. Configure the web container transport chains to modify the SSL configuration of the application server. The servlet inherits these settings. Read about configuring transport chains to learn how to configure the web container transport chains.

Results

The asynchronous response servlet is configured to enable your JAX-WS clients to receive asynchronous responses on the HTTP or HTTPS transport protocol.

Note: When you add a new application server to your environment, the asynchronous response servlet is automatically restarted so the deployment.xml file can be updated for the new application server. If your application receives an incoming response when the asynchronous response servlet is restarting, the incoming response might fail with an HTTP 404 error.

Note: JAX-WS services do not successfully return asynchronous responses to clients that are installed in application security-enabled WebSphere Application Servers. Because the Asynchronous Response Servlet for WebSphere Application Server, which handles asynchronous web services responses, is protected when application security is enabled, you must supply a credential together with the JAX-WS service incoming response. Attach the HTTPTransport policy set binding to the JAX-WS service in the service attachment. Additionally, enter a valid basic authentication user ID and password, which are defined in the user registry of the client, into the Basic authentication for outbound asynchronous service responses field.

Using the JAX-WS asynchronous response listener

Java API for XML-Based Web Services (JAX-WS) includes an asynchronous response listener, which is used within the Thin Client for JAX-WS and application client environments to receive responses for requests that are invoked asynchronously.

Before you begin

JAX-WS provides support for invoking web services using an asynchronous client invocation by using either a callback or polling model. Both the callback model and the polling model are available on the Dispatch client and the dynamic proxy client. When the JAX-WS client uses an asynchronous client invocation, the responses are received by the asynchronous response listener. To learn how to use the asynchronous client invocation model, read about invoking JAX-WS web services asynchronously.

About this task

The asynchronous response listener is used within a Web services client to handle incoming asynchronous responses. You can use the listener in Thin Client for JAX-WS environments and application client environments. By default, the listener opens a random port to listen for asynchronous responses or you can optionally configure a specific port for the listener to use. The listener starts automatically in the JAX-WS run time when the JAX-WS client is configured to expect an asynchronous response.

There are two versions of the asynchronous response listener. The unsecure version of the asynchronous response listener supports the HTTP protocol, and the secure version of the asynchronous response listener supports the HTTPS protocol. The correct asynchronous response listener is automatically started based on the particular transport used by the JAX-WS client. To ensure that the correct Secure Sockets Layer (SSL) handshaking occurs between the asynchronous response listener and the application server, configure the SSL properties using the SSL transport policy or the Java system properties.

For web services clients running in the application server environment, use the asynchronous response servlet for receiving asynchronous responses.

Procedure

1. Determine if you want the JAX-WS client to use the HTTP or HTTPS transport mechanism.
2. Configure the asynchronous response listener for unsecure communication using HTTP.

   You can configure the HTTP port for the asynchronous response listener as a Java system property or as a custom property within the transport policy. Properties that are defined in the policy set binding files override any Java system property that might have been defined.

   a. Define the `com.ibm.websphere.webservices.http.listenerPort` property as a Java system property. If this property is set as a Java system property, then all asynchronous response listeners within that Java Virtual Machine (JVM) are affected.

   b. Define the `com.ibm.websphere.webservices.http.listenerPort` property within the `HTTPTransport` transport policy set bindings files. If this property is set as a custom property within a transport policy set binding, then only the services for which the policy set has been configured are affected.
3. Configure the asynchronous response listener for secure communication using HTTPS.

You can configure the HTTPS port for the asynchronous response listener as a Java system property or as a custom property within the transport policy.

a. Define the `com.ibm.websphere.webservices.https.listenerPort` property as a Java system property. If this property is set as a Java system property, thenall asynchronous response listeners within that JVM are affected.
b. Define the `com.ibm.websphere.webservices.https.listenerPort` property within the `SSLTransport` transport policy set bindings files. If this property is set as a custom property within a transport policy set binding, then only the services for which the policy set has been configured are affected.

Results

Your JAX-WS web services client is configured to use the asynchronous response listener to receive incoming asynchronous responses.

Example

The following examples demonstrate how to enable the asynchronous response listener when defining the custom port of 9999:

- Use the following Java command to configure the custom HTTP port for the asynchronous response listener in a thin client environment:
  - `java.exe` **`-Dcom.ibm.websphere.webservices.http.listenerPort=9999`** `com.ibm.websphere.my_program`
- Use the following launchClient command to configure the custom HTTP port for the asynchronous response listener in an application client container:
  - `launchClient.bat MyClient.ear` **`-CCDcom.ibm.websphere.webservices.http.listenerPort=9999`**
- The following is an excerpt from an HTTPTransport policy binding.xml file that includes the asynchronous response listener properties:

```
</wsp:Policy>
   </wsp:ExactlyOne>
 </wsp:All>
    <wshttp:outAsyncResponseProxy>
     <wshttp:connectInfo host="" port=""></wshttp:connectInfo>
                  <wshttp:basicAuth userid="" password=""></wshttp:basicAuth>
    </wshttp:outAsyncResponseProxy>
    <wshttp:properties>
  <wshttp:customProperty name="com.ibm.websphere.webservices.http.listenerPort" value="9999" />
   </wshttp:properties>
 </wsp:All>
   </wsp:ExactlyOne>
</wsp:Policy>
```

What to do next

Run the JAX-WS client with the specified asynchronous response listener options.

Invoking JAX-WS web services asynchronously using the SOAP over JMS transport

Using the JAX-WS JMS asynchronous response message listener

Java API for XML-Based Web Services (JAX-WS) includes a Java Message Service (JMS) asynchronous response message listener, which is used to receive responses to asynchronous JAX-WS requests that use the JMS transport. The JMS asynchronous response message listener is used in the application server and application client environments.

Before you begin

JAX-WS provides support for invoking web service operations asynchronously by using either a callback or a polling model. When the JAX-WS client uses the JMS transport to invoke asynchronous operations, the

responses are received by the asynchronous response message listener. To learn how to use the JAX-WS asynchronous client invocation model, read about invoking JAX-WS web services asynchronously.

About this task

The JMS asynchronous response message listener is used within the web services client environment to receive incoming asynchronous responses when the client application is using the JMS Transport. The listener requires a connection factory and a queue to function correctly. Begin by configuring the connection factory and queue, and then specify the JNDI names of the connection factory and queue to the listener by setting Java system properties. The environment in which the client is running determines how the system properties are set.

The JMS asynchronous response message listener is started automatically by the web services client runtime environment when the client invokes the first asynchronous JAX-WS operation using the JMS transport.

The connection factory and the queue configured with the asynchronous response message listener is used for all requests that are invoked within a particular Java process such as for the application server or an application client container. You can share the connection factory among different Java processes. However, you cannot share a queue among Java processes.

Procedure

1. Determine if you want the JAX-WS client to use the JMS transport mechanism.
2. For each Java process that will use JMS as a transport for asynchronous JAX-WS requests, configure the connection factory and queue that are used by the JMS asynchronous response listener for that process. You can share a connection factory among multiple Java processes, but you cannot share a queue among Java processes.
3. For each Java process, set the com.ibm.websphere.webservices.jms.AsyncReplyQueueName and com.ibm.websphere.webservices.jms.AsyncReplyCFName Java system properties to specify the JNDI names of the queue and connection factory that are used by the JMS asynchronous response message listener for that process.

   If the JNDI name of the queue is the default value, jms/DefaultAsyncReplyQueue, then you do not need to set the AsyncReplyQueueName property. Likewise, if the JNDI name of the connection factory is the default value, `jms/DefaultAsyncReplyCF`, then you do not need to set the AsyncReplyCFName property as well.

   If your client runs within the application server environment, then set the properties as application server system properties by using the administrative console or the **wsadmin** command.

   If your client runs within the application client container environment, then you should set the properties by using the `–CCD` option on the **launchClient** command line.

Results

Your JAX-WS web services client is configured to use the JMS asynchronous response message listener to receive asynchronous response messages when using the JMS transport.

Example

Suppose that you have a JAX-WS web services client that runs in the application client container environment and uses the JMS transport to communicate with the server. Suppose also that the client invokes asynchronous JAX-WS operations. You can create a connection factory with the JNDI name, `jms/MyAppCF`, and a queue with the JNDI name, `jms/MyAppAsyncReplyQueue`. When you invoke the client with the **launchClient** command, specify the JNDI names of the queue and connection factory as illustrated in the following command:

```
launchClient MyAppClient.ear \
   -CCDcom.ibm.websphere.webservices.jms.AsyncReplyQueueName=jms/MyAppReplyQueue \
   -CCDcom.ibm.websphere.webservices.jms.AsyncReplyCFName=jms/MyAppCF \
   <application arguments>
```
