How to send your comments

Your feedback is important in helping to provide the most accurate and highest quality information.

- To send comments on articles in the WebSphere Application Server Information Center
  1. Display the article in your Web browser and scroll to the end of the article.
  2. Click on the **Feedback** link at the bottom of the article, and a separate window containing an email form appears.
  3. Fill out the email form as instructed, and submit your feedback.
- To send comments on PDF books, you can email your comments to: **wasdoc@us.ibm.com**.

  Your comment should pertain to specific errors or omissions, accuracy, organization, subject matter, or completeness of this book. Be sure to include the document name and number, the WebSphere Application Server version you are using, and, if applicable, the specific page, table, or figure number on which you are commenting.

For technical questions and information about products and prices, please contact your IBM branch office, your IBM business partner, or your authorized remarketer. When you send comments to IBM, you grant IBM a nonexclusive right to use or distribute your comments in any way it believes appropriate without incurring any obligation to you. IBM or any other organizations will only use the personal information that you supply to contact you about your comments.

Using this PDF

Links

Because the content within this PDF is designed for an online information center deliverable, you might experience broken links. You can expect the following link behavior within this PDF:

- Links to Web addresses beginning with http:// work.
- Links that refer to specific page numbers within the same PDF book work.
- The remaining links will *not* work. You receive an error message when you click them.

Print sections directly from the information center navigation

PDF books are provided as a convenience format for easy printing, reading, and offline use. The information center is the official delivery format for IBM WebSphere Application Server documentation. If you use the PDF books primarily for convenient printing, it is now easier to print various parts of the information center as needed, quickly and directly from the information center navigation tree.

To print a section of the information center navigation:

1. Hover your cursor over an entry in the information center navigation until the **Open Quick Menu** icon is displayed beside the entry.
2. Right-click the icon to display a menu for printing or searching your selected section of the navigation tree.
3. If you select **Print this topic and subtopics** from the menu, the selected section is launched in a separate browser window as one HTML file. The HTML file includes each of the topics in the section, with a table of contents at the top.
4. Print the HTML file.

For performance reasons, the number of topics you can print at one time is limited. You are notified if your selection contains too many topics. If the current limit is too restrictive, use the feedback link to suggest a preferable limit. The feedback link is available at the end of most information center pages.

Chapter 1. Developing ActivitySessions

This page provides a starting point for finding information about ActivitySessions, a WebSphere extension for reducing the complexity of commitment rules and limitations that are associated with one-phase commit resources.

Use ActivitySessions to extend the scope and group multiple local transactions. With this capability, you can commit these transactions based on either deployment criteria or through explicit program logic.

Developing an enterprise application to use ActivitySessions

This topic provides an overview of the high-level tasks for using ActivitySessions in enterprise applications.

About this task

Before you use ActivitySessions in enterprise applications, consider the following points:

- An application that is accessed under an ActivitySession context can receive a javax.transaction.InvalidTransactionException RemoteException, thrown by the Enterprise JavaBeans (EJB) container when servicing any application method. This exception occurs when an instance of an enterprise bean that has an ActivitySession-based activation policy becomes involved with concurrent global and local transactions.
- To enable an enterprise bean to participate in an ActivitySession context and support ActivitySession-based operations, it must be configured with an ActivationPolicy of ACTIVITY_SESSION. A bean configured with ActivationPolicy of either TRANSACTION or ONCE cannot participate in an ActivitySession context.
- A session bean can either use container-managed ActivitySessions or implement bean-managed ActivitySessions; entity beans can use only container-managed ActivitySessions. A bean is deployed to be bean-managed or container-managed with respect to ActivitySession management by setting its transaction type deployment attribute to be bean-managed or container-managed when you deploy the enterprise bean. A bean that uses bean-managed transactions can use bean-managed ActivitySessions; a bean that uses container-managed transactions can use container-managed ActivitySessions.
- If you want a session bean or an enterprise application client to manage its own ActivitySessions, you must write the code that explicitly demarcates the boundaries of an ActivitySession, as described in Developing an enterprise bean or J2EE client to manage ActivitySessions.

The following high level tasks illustrate how to use an ActivitySession in an enterprise application:

Procedure

- Develop an enterprise application that uses one or more enterprise beans that are persisted to non-transactional data stores. Use this approach for an application that needs to coordinate multiple one-phase resource managers, for example, for two or more entity enterprise beans whose persistence is delegated to LocalTransaction resource adapters.

  In this scenario, the enterprise beans that the application uses have an Activation policy of ActivitySession and a local transaction containment policy with a boundary of ActivitySession and resolution-control of ContainerAtBoundary. The container synchronizes the EJB state data with the one-phase resource managers at ActivitySession completion, and no application code needs to be aware of ActivitySession support.
- Develop an enterprise application in which an enterprise bean accesses a resource manager multiple times in different business methods. Use this approach for an application that needs to extend a resource manager local transaction (RMLT) over several business methods of an enterprise bean instance.

  In this scenario, the enterprise beans that the application uses have an Activation policy of ActivitySession and a local transaction containment policy with a boundary of ActivitySession and resolution-control of Application. The application logic starts and ends the RMLTs, for example, using the

javax.resource.cci.LocalTransaction interface offered by a LocalTransaction Connector, but is not constrained to start and commit the LocalTransaction in the same method.

- Develop an enterprise client application to use an ActivitySession to scope EJB activation and load-balancing. Use this approach for an application client that needs to access an entity bean instance several times in the same client session, either without needing to run under a transaction context, or with the need to run under a number of distinct and serially-executed transactions.

  In this scenario, the enterprise beans that the application uses have an Activation policy of ActivitySession and a local transaction containment policy appropriate to the function of the enterprise bean. The enterprise client application can represent a period of user activity, for example a signon period, during which a number of interactions occur with one or more enterprise beans. If the enterprise client application begins an ActivitySession and invokes the enterprise beans within the scope of the unit of work (UOW) that the ActivitySession represents, the container on the ActivitySession boundary activates the enterprise bean instances. The instances remain in the active state until the container passivates them at the end of the ActivitySession. Workload affinity management based on the ActivitySession is a platform quality of service. Global transactions can begin and end within the ActivitySession, if they are wholly encapsulated by the ActivitySession and run serially. EJB instances that are activated at the ActivitySession boundary remain active across the serial global transactions.
- Develop a Web application client to participate in an ActivitySession context. A Web application that runs in the WebSphere® Web container can participate in an ActivitySession context. Web applications can use the UserActivitySession interface to begin and end an ActivitySession context. Also, the ActivitySession can be associated with an HttpSession, thereby extending access to the ActivitySession over multiple HTTP invocations and supporting EJB activation periods that can be determined by the lifecycle of the Web HTTP client.

  The Web container manages ActivitySessions based on deployment descriptor attributes associated with the Web application module.

Example

For examples of using ActivitySessions in enterprise applications, see the topic about ActivitySessions samples.

Developing an enterprise bean or enterprise application client to manage ActivitySessions

Use this task to write the code needed by a session EJB or enterprise application client to manage an ActivitySession, based on the example code extract provided.

About this task

In most situations, an enterprise bean can depend on the EJB container to manage ActivitySessions within the bean. In these situations, all you need to do is set the appropriate ActivitySession attributes in the EJB module deployment descriptor, as described in the topic about configuring EJB module ActivitySession deployment attributes.. Further, in general, it is practical to design your enterprise beans so that all ActivitySession management is handled at the enterprise bean level.

However, in some cases you may need to have a session bean or enterprise application client participate directly in ActivitySessions. You then need to write the code needed by the session bean or enterprise application client to manage its own ActivitySessions.

Note: Session beans that use BMT and have an **Activate at** setting of `Activity session` can manage ActivitySessions. Entity beans cannot manage ActivitySessions; the EJB container always manages ActivitySessions within entity beans.

When preparing to write code needed by a session bean or enterprise application client to manage ActivitySessions, consider the points described in the topic about ActivitySession and transaction contexts.

To write the code needed by a session EJB or enterprise application client to manage an ActivitySession, complete the following steps, based on the following example code extract.

Procedure

1. Get an initial context for the ActivitySession.
2. Get an implementation of the UserActivitySession interface, by a JNDI lookup of the URL java:comp/websphere/UserActivitySession. The UserActivitySession interface is used to begin and end ActivitySessions and to query various attributes of the active ActivitySession associated with the thread.
3. Set the timeout, in seconds, after which any subsequently started ActivitySessions are automatically completed by the ActivitySession service. If the session bean or enterprise application client does not specifically set this value, the default timeout (300 seconds) is used.

   The default timeout can also be overridden for each application server, on the ***server*-> Activity Session Service** panel of the administrative console.
4. Start the ActivitySession, by calling the beginSession() method of the UserActivitySession.
5. Within the ActivitySession, call business methods to do the work needed. You can also call other methods of UserActivitySession to manage the ActivitySession; for example, to get the status of the ActivitySession or to checkpoint all the ActivitySession resources involved in the ActivitySession.
6. End the ActivitySession, by calling the endSession() method of the UserActivitySession.

Example

The following code extract provides a basic example of using the UserActivitySession interface:

```
// Get initial context
  InitialContext ic = new InitialContext();
// Lookup UserActivitySession
  UserActivitySession uas =
 (UserActivitySession)ic.lookup("java:comp/websphere/UserActivitySession");

// Set the ActivitySession timeout to 60 seconds
  uas.setSessionTimeout(60);
// Start a new ActivitySession context
  uas.beginSession();
// Do some work under this context
  MyBeanA beanA.doSomething();
  ...
  MyBeanB beanB.doSomethingElse();
// End the context
  uas.endSession(EndModeCheckpoint);
```

ActivitySession service application programming interfaces

The ActivitySession service provides an application programming interface that is available to Web applications, session Enterprise JavaBeans (EJBs), and Java platform for enterprise applications client applications for application-managed demarcation of ActivitySession context.

Applications use the UserActivitySession interface, which provides demarcation scope methods.

ActivitySession API

The ActivitySession service provides the UserActivitySession interface for use by EJB Session beans using bean-managed context demarcation, Web application components that are configured with the **ActivitySession control** attribute set to `Web Application`, and Java platform for enterprise applications client applications. This UserActivitySession interface defines the set of ActivitySession operations that are available to an application component. To obtain an implementation of this interface, use a Java Naming and Directory Interface (JNDI) lookup of the URL `java:comp/websphere/UserActivitySession`. The UserActivitySession interface is used to begin and end ActivitySessions and to query various attributes of the active ActivitySession that is associated with the thread.

For more information about the ActivitySession API, see the application programming interface (API) reference information.

The ActivitySession API and the implementation of its interfaces is contained in the com.ibm.websphere.ActivitySession package.

Programming Examples

The following code extract provides a basic example of using the UserActivitySession interface:

```
// Get initial context
  InitialContext ic = new InitialContext();
// Lookup UserActivitySession
  UserActivitySession uas =
  (UserActivitySession)ic.lookup("java:comp/websphere/UserActivitySession");

// Set the ActivitySession timeout to 60 seconds
  uas.setSessionTimeout(60);
// Start a new ActivitySession context
  uas.beginSession();
// Do some work under this context
  MyBeanA beanA.doSomething();
  ...
  MyBeanB beanB.doSomethingElse();
// End the context
  uas.endSession(EndModeCheckpoint);
```

Assembling applications that use ActivitySessions

You can set the ActivitySession deployment attributes for an enterprise bean or a Web application.

About this task

For an enterprise bean, you can set the ActivitySession deployment attributes so that the bean can participate in an ActivitySession context and support ActivitySession-based operations.

For a Web application, you can set the ActivitySession deployment attributes so that the application can start UserActivitySessions and perform work scoped within ActivitySessions.

Procedure

- Set EJB module ActivitySession deployment attributes.
- Set Web module ActivitySession deployment attributes.

Setting EJB module ActivitySession deployment attributes

Use this task to set the ActivitySession deployment attributes for an enterprise bean to enable the bean to participate in an ActivitySession context and support ActivitySession-based operations.

Before you begin

This task description assumes that you have an Enterprise Archive (EAR) file, which contains an application enterprise bean that can be deployed in WebSphere Application Server. For more details, see the topic about assembling applications.

About this task

You configure the deployment attributes of an application by using an assembly tool. This topic describes the use of Rational® Application Developer to configure the ActivitySession deployment attributes. These attributes are in addition to other deployment attributes, for example, “Load at”, which specifies when the bean loads its state from the database. For details about the fields in the assembly tool, and for associated task help, refer to the Rational Application Developer information.

To set the ActivitySession deployment attributes for an enterprise bean, complete the following steps:

Procedure

1. Start the assembly tool. For more information, refer to the Rational Application Developer information.
2. Create or edit the application EAR file.

   Note: Ensure that you set the target server as WebSphere Application Server Version 7.0.

   For example, to change attributes of an existing application, use the Import wizard to import the EAR file into the assembly tool. To start the Import wizard:

   a. Click **File** > **Import** > **EAR file**.

   b. Click **Next**, then select the EAR file.

   c. In the Target server field, select `WebSphere Application Server v7.0`.

   d. Click **Finish**.
3. In the Project Explorer view of the Java EE perspective, right-click the EJB module for the enterprise bean instance, then click **Open With** > **Deployment Descriptor Editor**. A property dialog notebook for the enterprise bean instance is displayed in the property pane.
4. In the property pane, select the Beans tab.
5. Select the bean that you want to change.
6. In the WebSphere Extensions section, under **Bean Cache**, set the **Activate at** attribute to **ActivitySession**:

   An enterprise bean with this activation policy is activated and passivated as follows:
   - On an ActivitySession boundary, if an ActivitySession context is present on activation.
   - On a transaction boundary, if a transaction context, but no ActivitySession context, is present on activation.
   - Otherwise, on an invocation boundary.
7. In the Local Transactions group box, set the **Boundary** attribute to **ActivitySession**: When this setting is used, the local transaction must be resolved within the scope of any ActivitySession in which it was started or, if no ActivitySession context is present, within the same bean method in which it was started.

   A setting of ActivitySession does not apply to any EJB home methods, for example, create or finder methods. EJB home methods cannot participate in an ActivitySession because this situation might cause deadlocks.
8. For entity beans, or session beans, set the ActivitySession properties for each EJB method.

   a. In the property pane, select the ActivitySession tab.

   b. In the **Configure ActivitySession policies** field, click **Add** or **Edit** to set the **ActivitySession kind** attribute for methods of the enterprise bean. This specifies how the container must manage the ActivitySession boundaries when delegating a method invocation to an enterprise bean's business method:

      Never The container invokes bean methods without an ActivitySession context.
      - If the client invokes a bean method from within an ActivitySession context, the container throws an InvalidActivityException exception, which is a javax.rmi.RemoteException.
      - If the client invokes a bean method from outside an ActivitySession context, the container behaves in the same way as if the **Not Supported** value was set. The client must call the method without an ActivitySession context.

      Mandatory
      The container always invokes the bean method within the ActivitySession context associated with the client. If the client attempts to invoke the bean method without an ActivitySession context, the container throws an ActivityRequiredException exception to the client. The ActivitySession context is passed to any EJB object or resource accessed by an enterprise bean method.

The ActivityRequiredException exception is javax.rmi.RemoteException.

Requires new

The container always invokes the bean method within a new ActivitySession context, regardless of whether the client invokes the method within or outside an ActivitySession context. The new ActivitySession context is passed to any enterprise bean objects or resources that are used by this bean method.

Any received ActivitySession context is suspended for the duration of the method and resumed after the method ends. The container starts a new ActivitySession before method dispatch and completes it after the method ends.

Required

The container invokes the bean method within an ActivitySession context. If a client invokes a bean method from within an ActivitySession context, the container invokes the bean method within the client ActivitySession context. If a client invokes a bean method outside an ActivitySession context, the container creates a new ActivitySession context and invokes the bean method from within that context. The ActivitySession context is passed to any enterprise bean objects or resources that are used by this bean method.

Not supported

The container invokes bean methods without an ActivitySession context. If a client invokes a bean method from within an ActivitySession context, the container suspends the association between the ActivitySession and the current thread before invoking the method on the enterprise bean instance. The container then resumes the suspended association when the method invocation returns. The suspended ActivitySession context is not passed to any enterprise bean objects or resources that are used by this bean method.

Supports

If the client invokes the bean method within an ActivitySession, the container invokes the bean method within an ActivitySession context. If the client invokes the bean method without a ActivitySession context, the container invokes the bean method without an ActivitySession context. The ActivitySession context is passed to any enterprise bean objects or resources that are used by this bean method.

c. Click **Next**.

d. Select the methods to which the ActivitySession kind policy is to be applied.

e. Click **Finish**.

How the container manages the ActivitySession boundaries when delegating a method invocation depends on both the **ActivitySession kind** set here, and the **Container transaction type**, as described in the topic about configuring transactional deployment attributes. For more detail about the relationship between these two properties, see the topic about ActivitySession and transaction container policies in combination.

9. Save your changes to the deployment descriptor.
   a. Close the Deployment Descriptor Editor.
   b. When prompted, click **Yes** to save changes to the deployment descriptor.
10. Verify the archive files. For more information about verifying files using Rational Application Developer, refer to the Rational Application Developer information.
11. From the popup menu of the project, click **Deploy** to generate EJB deployment code.
12. Optional: Test your completed module on a WebSphere Application Server installation. Right-click a module, click **Run on Server**, and follow the instructions in the displayed wizard.

    Important: Use **Run On Server** for unit testing only. The assembly tool controls the WebSphere Application Server installation and, when an application is published remotely, the assembly tool overwrites the server configuration file for that server. Do not use the **Run On Server** option on production servers.

What to do next

After assembling your application, use a systems management tool to deploy the EAR file onto the application server that is to run the application. For example, to use the administrative console, see the topic about deploying and administering enterprise applications.

Setting Web module ActivitySession deployment attributes

Use this task to set the ActivitySession deployment attributes for a Web application to start UserActivitySessions and perform work scoped within ActivitySessions.

Before you begin

This task assumes that you have an Enterprise Archive (EAR) file that contains an application enterprise bean that can be deployed in WebSphere Application Server. For more details, see the topic about assembling applications.

About this task

You can configure the deployment attributes of an application by using an assembly tool. This topic describes the use of Rational Application Developer to configure the deployment attributes.

To set the ActivitySession deployment attributes for a Web application, complete the following steps:

Procedure

1. Start the assembly tool. For more information, refer to the Rational Application Developer information.
2. Create or edit the Web module. For example, to change attributes of an existing module, click **File** > **Open**, then select the archive file for the module. For example, to change attributes of an existing module, use the Import wizard to import the EAR or WAR file into the assembly tool. To start the Import wizard:
   a. Click **File** > **Import**.
   b. Expand the Web folder, click **WAR file**, then click **Next**.
   c. Select the WAR file, then click **Finish**.
3. In the Project Explorer view of the Java EE perspective, right-click the component instance, right-click **Deployment Descriptor Editor**, then click **Open With** . A property dialog notebook for the Web module is displayed in the property pane.
4. In the property pane, select the Extended services tab.
5. Select the servlet that you want to change.
6. In the ActivitySession section, set the **ActivitySession control kind** attribute to Application, Container, or None.
   Application
   The Web application is responsible for starting and ending ActivitySessions, as follows:
   - If an HttpSession is active when an application begins an ActivitySession, the container associates the ActivitySession with the HttpSession.
   - If an ActivitySession is started in the absence of an HttpSession, the application must ensure it is completed before the dispatched method completes; otherwise, an exception results.
   - If an HttpSession is associated with a request dispatched to an application with this ActivitySession control value, and if that HttpSession has an ActivitySession associated with it, the container dispatches the request in the context of that ActivitySession. For example, the container resumes the ActivitySession context onto the thread before the dispatch.

- A Web application can use both transactions and ActivitySessions. Any transactions started within the scope of an ActivitySession must be ended by the Web component that started them and within the same request dispatch.

Container
A servlet has no access to UserActivitySessions. Any HttpSession started by the servlet has an ActivitySession automatically associated with it by the container, and this ActivitySession is put onto the thread of execution. If such a servlet is dispatched by a request that has an HttpSession containing no ActivitySession, then the container starts an ActivitySession and associates it with the HttpSession and the thread.

A Web application can use both transactions and ActivitySessions. Any transactions started within the scope of an ActivitySession must be ended by the Web component that started them and within the same request dispatch.

None A servlet has no access to UserActivitySession. An HttpSession started by the servlet does not have an ActivitySession automatically associated with it by the container. If such a servlet is dispatched by a request that has an HttpSession containing an ActivitySession, then the container dispatches the request in the context of that ActivitySession. For example, the container resumes the ActivitySession context onto the thread before the dispatch.

7. To apply the changes and close the assembly tool, click **OK**. Otherwise, to apply the values but keep the property dialog open for additional edits, click **Apply**.
8. Save your changes to the deployment descriptor.
   a. Close the deployment descriptor editor.
   b. When prompted, click **Yes** to save changes to the deployment descriptor.
9. Verify the archive files. For more information about verifying files using Rational Application Developer, refer to the Rational Application Developer information.
10. From the popup menu of the project, click **Deploy** to generate EJB deployment code.
11. Optional: Test your completed module on a WebSphere Application Server installation. Right-click a module, click **Run on Server**, and follow the instructions in the displayed wizard.

Important: Use **Run On Server** for unit testing only. The assembly tool controls the WebSphere Application Server installation and, when an application is published remotely, the assembly tool overwrites the server configuration file for that server. Do not use the **Run On Server** option on production servers.

What to do next

After assembling your application, use a systems management tool to deploy the WAR file. For example, to use the administrative console, see the topic about deploying and administering enterprise applications.

Chapter 2. Developing Application profiling

This page provides a starting point for finding information about application profiling, a WebSphere extension for defining strategies to dynamically control concurrency, prefetch, and read-ahead.

Application profiling and access intent provide a flexible method to fine-tune application performance for enterprise beans without impacting source code. Different enterprise beans, and even different methods in one enterprise bean, can have their own intent to access resources. Profiling the components based on their access intent increases performance in the application server run time.

Using the TaskNameManager interface

Using the TaskNameManager interface, you can programmatically set the current task name. It enables both overriding of the current task associated with the thread of execution and resetting of the current task with the original task.

About this task

Except for J2EE 1.3 applications that are running on a server where the 5.x Compatibility Mode attribute is selected, this interface cannot be used within Enterprise JavaBeans that are configured for container-managed transactions or container-managed ActivitySessions because units of work can only be associated with a task at the exact time that the unit of work is initiated. The call to set the task name must therefore be invoked before the unit of work is begun. Units of work cannot be named after they are begun. Calls on this interface during the execution of a container-managed unit of work are simply ignored.

Application profiling does not support queries of the task that is in operation at run time. Instead, applications interact with logical task names that are declaratively configured as application managed tasks. Logical references enable the actual task name to be changed without having to recompile applications.

Wherever possible, avoid setting tasks programmatically. The declarative method results in more portable function that can be easily adjusted without requiring redevelopment and recompilation.

Note: If you select the 5.x Compatibility Mode attribute on the Application Profile Service's console page, then tasks configured on J2EE 1.3 applications are not necessarily associated with units of work and can arbitrarily be applied and overridden. This is not a recommended mode of operation and can lead to unexpected deadlocks during database access. Tasks are not communicated on requests between applications that are running under the Application Profiling 5.x Compatibility Mode and applications that are not running under the compatibility mode.

For a Version 6.0 client to interact with applications run under the Application Profiling 5.x Compatibility Mode, you must set the *appprofileCompatibility* system property to *true* in the client process. You can do this by specifying the *-CCDappprofileCompatibility=true* option when invoking the launchClient command.

Procedure

1. Configure application-managed tasks. Application profiling requires that a task name reference be declared for any task that is to be set programmatically. Task name references introduce a level of indirection so that the actual task set at run time can be adjusted by reassembly without requiring recoding or recompilation. Any attempt to set a task name that is undeclared as a task reference results in the raising of an exception. If a unit of work has already begun when a task name is set, then that existing unit of work is not associated with the task name. Only units of work that are begun after the task name is set are associated with the task.

Configure application-managed tasks as described in the following topics. To complete these tasks see the assembly tool information center:

- Configure application managed tasks for web components.
- Configure application managed tasks for application clients.
- Configure application managed tasks for Enterprise JavaBeans.

2. Perform a Java Naming and Directory Interface (JNDI) lookup on the TaskNameManager interface:

```
InitialContext ic = new InitialContext();
TaskNameManager tnManager = ic.lookup
("java:comp/websphere/AppProfile/TaskNameManager");
```

The *TaskNameManager* interface is not bound into the namespace if the application profiling service is disabled.

3. Set the task name:

```
try {
tnManager.setTaskName("updateAccount");
}
catch (IllegalTaskNameException e) {
// task name reference not configured. Handle error.
}
// . . .
//
```

The name passed to the setTaskName() method ("updateAccount" in this example) is actually a task name reference that you configured in step one.

4. Begin a UserTransaction

Note: If you are using a J2EE 1.3 application with the 5.x Compatibility mode set, the task name set in step 3 is now the active task name and you can disregard this step.

If you are using a J2EE application and the compatibility mode is not set, or if you are using a J2EE 1.4 application, you must begin a transaction for the task name to become active. A task name can only be associated with a transaction. Furthermore, it is associated with a transaction when that transaction is begun, and that task name is associated with the transaction for the life of the transaction. Therefore, the task name set above is not active at this point. You must begin a UserTransaction as the following code snippet illustrates:

```
try{
    InitialContext initCtx = new InitialContext();
    userTran = (UserTransaction) initCtx.lookup("java:comp/UserTransaction");
    userTran.begin();
}
catch(Exception e){
}
// . . .
//
```

Notice the resetTaskName() method on the TaskNameManager interface. Resetting the task name has no effect unless called by a J2EE 1.3 application running on a server for which the 5.x Compatibility Mode attribute is selected on the Application Profile Service's console page. This is not a recommended mode of operation and can lead to unexpected deadlocks during database access. A call to resetTask( ) should only be used by J2EE 1.3 applications when the 5.x Compatibility mode is set to undo the effects of any setTaskName() method operations and reestablish whatever task name was current when the component began execution. If the setTaskName() method has not been called, the resetTaskName() method has no effect.

TaskNameManager interface

The TaskNameManager is the programmatic interface to the application profiling function. Because on rare occasions it may be necessary to programmatically set the current task name, the TaskNameManager interface enables both overriding of the current task associated with the thread of execution and resetting of the current task with the original task.

Application profiling enables you to identify particular units of work to the WebSphere Application Server runtime environment. The run time can tailor its support to the exact requirements of that unit of work. Access intent is currently the only runtime component that makes use of the application profiling functionality. For example, you can configure one transaction to load an entity bean with strong update locks and configure another transaction to load the same entity bean without locks.

Application profiling introduces two concepts in order to achieve this function: tasks and profiles.

A *task* is a configurable name for a unit of work. *Unit of work* in this case means either a transaction or an ActivitySession.

A *profile* is simply a mapping of a task to a set of access intent policies that are configured on entity beans. When an invocation on a bean (whether by a finder method, a container managed relationship (CMR) getter, or a dynamic query) requires data to be retrieved from the back end system, the task of the active unit of work associated with the request is used to determine the exact requirement of the transaction. The same bean loads and behaves differently in the context of the task-to-profile mapping. Each profile provides the developer an opportunity to reconfigure the application's access intent.

Except for J2EE 1.3 applications that are executing on a server where the *5.x Compatibility Mode* attribute is selected, this interface cannot be used within Enterprise JavaBeans that are configured for container-managed transactions or container-managed ActivitySessions because units of work can only be associated with a task at the exact time that the unit of work is initiated. The call to set the task name must therefore be started before the unit of work is begun. Units of work cannot be named after they are begun. Calls on this interface during the execution of a container-managed unit of work are simply ignored.

The TaskNameManager interface is available to all J2EE components using the following Java Naming and Directory Interface (JNDI) lookup:

```
java:comp/websphere/AppProfile/TaskNameManager
```

```
package com.ibm.websphere.appprofile;

/**
* The TaskNameManager is the programmatic interface
* to the application profiling function. Using this interface,
* programmers can set the current task name on the
* thread of execution. The task name must have been
* configured in the deployment descriptors as a task
* reference associated with a task. The set task
* name's scope is the duration of the method
* invocation in the EJB and Web components and for
* the duration of the client process, or until the
* resetTaskName() method is invoked.
*/
public interface TaskNameManager {

/**
* Set the thread's current task name to the specified
* parameter. The task name must have been configured as
* a task reference with a corresponding task or the
* IllegalTaskName exception is thrown.
*/
public void setTaskName(String taskName) throws IllegalTaskNameException;

/**

```
* Sets the thread's task name to the value that was set
* at, or imported into, the beginning of the method
* invocation (for EJB and Web components) or process
* (for J2EE clients).
*/
public void resetTaskName();

}
```

Assembling applications for application profiling

To enable application profiling, you must configure tasks, create an application profile, and declaratively configure a unit of work on necessary methods.

Before you begin

Application profiling enables multiple access intent policies to be configured on the same entity bean, each specified for a particular unit of work. You can use the one of the default policies or create your own. To create your own access intent policy, see the topic, Creating a custom access intent policy, in the assembly tool information center.

Procedure

1. Configure tasks. Declaratively configure tasks as described in the following topics that are located in the assembly tool information center:
   - Configuring container-managed tasks for Enterprise Java Beans.
   - Configuring container-managed tasks for web components.
   - Configuring container-managed tasks for application clients.

   On rare occasions, you might find it necessary to configure tasks *programmatically*. Application profiling supports this requirement with a simple interface that enables a task name to be set before a unit of work is programmatically initiated. Setting a task name and then initiating a transaction or ActivitySession causes the task to be associated with the new unit of work. This interface cannot be used within Enterprise JavaBeans that are configured for container-managed transactions or container-managed ActivitySessions because units of work can only be associated with a task at the exact time that the unit of work is initiated. The call to set the task name must therefore be invoked before the unit of work is begun. Units of work cannot be named after they are begun. See the topic, Using the TaskNameManager interface.

   Note: If you select the 5.x Compatibility Mode attribute on the Application Profile Service's console page, then tasks configured on J2EE 1.3 applications are not necessarily associated with units of work and can arbitrarily be applied and overridden. This is not a recommended mode of operation and can lead to unexpected deadlocks during database access. Tasks are not communicated on requests between applications that are running under the Application Profiling 5.x Compatibility Mode and applications that are not running under the compatibility mode.

   For a Version 6.0 client to interact with applications run under the Application Profiling 5.x Compatibility Mode, you must set the *appprofileCompatibility* system property to *true* in the client process. You can do this by specifying the *-CCDappprofileCompatibility=true* option when invoking the launchClient command.
2. Create an application profile. See the assembly tool information center to complete this task.
3. Declaratively configure a unit of work on necessary methods. In step one of this article, you defined a task on a method. The task defined on a method only becomes active when a unit of work is begun on that method's behalf. The method must begin a new unit of work for the configured task to be applied. If the method runs under an imported unit of work, then the configured task on the method is ignored and the task (if any) associated with the imported unit of work is used. If the container begins a new unit of work when the method executes, then it is associated with the configured task name. Therefore, the last step in assembling applications for application profiling is to define a unit of work on any

method that has a task name (and eventually an Application Profile) associated with it. A unit of work can either be a transaction or an ActivitySession. See the topic, Defining container transactions for EJB modules, for a description on how to configure a transaction on an EJB module. The topic, Configuring transactional deployment attributes, describes how to define other transaction attributes. The topic, Using the ActivitySession service, describes how to use and create an ActivitySession unit of work. For more information about the relationships between tasks and units of work, see the topic, Tasks and units of work considerations.

What to do next

To complete the following tasks using assembly tools see the assembly tool documentation. The following tasks can be done using assembly tools:

- Automatic configuration of application profiling

  The assembly tool includes a static analysis engine that can assist you in configuring application profiling. The tool examines the compiled classes and the deployment descriptor of a Java EE application to determine the entry point of transactions, calculate the set of entities enlisted in each transaction, and determine whether the entities are read or updated during the course of each identified transaction.
- Automatically configure application profiles and tasks.

  Automatically configure application profiling for an application through static analysis.
- Apply profile-scoped access intent policies to entity beans.

  Configure entities with access intent for an application profile.
- Create a custom access intent policy.

  Define a custom access intent policy, which can be configured for Enterprise JavaBeans (EJB) 2.x and 3.0 entity beans.
- Create an application profile.

  An application profile contains a set of access intent policies applied to an application's entity beans. The access intent policies are only applied for requests that are associated with tasks configured on the application profile.
- Configure container-managed tasks for application clients.

  For application clients that programmatically begin either a transaction or ActivitySession only, you must configure an application client's container-managed task to associate requests from the client with an application profile.
- Configure container-managed tasks for Web components.

  For Web components that programmatically set the configured task and then programmatically begin either a transaction or ActivitySession only, you can configure Web components application-managed tasks to associate requests from a servlet or JavaServer Pages (JSP) file with application profiles.
- Configure container-managed tasks for Enterprise JavaBeans.

  For methods that cause a new transaction or ActivitySession to be started either by the container or programmatically by the EJB developer, you can configure an enterprise bean's container-managed tasks to associate requests from the bean with application profiles.
- Configure container-managed tasks for application clients.

  For application clients that programmatically begin either a transaction or ActivitySession only, you must configure an application client's container-managed task to associate requests from the client with an application profile.
- Configure application-managed tasks for Web components.

  For Web components that programmatically begin either a transaction or ActivitySession only, you can configure a Web component's container-managed task to associate requests from a servlet or JSP file with an application profile.
- Configure application-managed tasks for Enterprise JavaBeans.

For Enterprise JavaBeans that programmatically set the configured task and then programmatically begin either a transaction or ActivitySession only, you can configure EJB application-managed tasks to associate requests from the bean with application profiles.

Chapter 3. Developing Asynchronous beans

This page provides a starting point for finding information about asynchronous beans.

Asynchronous beans and asynchronous scheduling facilities offer performance enhancements for resource-intensive tasks by enabling single tasks to run as multiple tasks.

Developing work objects, event listeners, and asynchronous scopes

Developing work objects to run code in parallel

You can run work objects in parallel, or in a different Java Platform, Enterprise Edition (Java EE) context, by wrapping the code in a work object.

Before you begin

Your administrator must have configured at least one work manager using the administrative console.

About this task

To run code in parallel, wrap the code in a work object.

Procedure

1. Create a work object.

   A work object implements the com.ibm.websphere.asynchbeans.Work interface. For example, you can create a work object that dynamically subscribes to a topic and any component that has access to the event source can add an event on demand:

```
class SampleWork implements Work
{
 boolean released;
 Topic targetTopic;
 EventSource es;
 TopicConnectionFactory tcf;

 public SampleWork(TopicConnectionFactory tcf, EventSource es, Topic targetTopic)
 {
  released = false;
  this.targetTopic = targetTopic;
  this.es = es;
  this.tcf = tcf;
 }

 synchronized boolean getReleased()
 {
  return released;
 }

 public void run()
 {
  try
  {
   // setup our JMS stuff.
   TopicConnection tc = tcf.createConnection();
   TopicSession sess = tc.createSession(false, Session.AUTOACK);
   tc.start();

   MessageListener proxy = es.getEventTrigger(MessageListener.class, false);
   while(!getReleased())
   {
```

```
    // block for up to 5 seconds.
    Message msg = sess.receiveMessage(5000);
    if(msg != null)
    {
     // fire an event when we get a message
     proxy.onMessage(msg);
    }
   }
   tc.close();
  }
  catch (JMSException ex)
  {
   // handle the exception here
   throw ex;
  }
  finally
  {
   if (tc != null)
   {
    try
    {
     tc.close();
    }
    catch (JMSExceptin ex1)
    {
     // handle exception
    }
   }
  }
 }

 // called when we want to stop the Work object.
 public synchronized void release()
 {
  released = true;
 }
}
```

As a result, any component that has access to the event source can add an event on demand, which allows components to subscribe to a topic in a more scalable way than by simply giving each client subscriber its own thread. The previous example is fully explored in the WebSphere Trader Sample. Refer to the Samples section of the Information Center for details.

2. Determine the number of work managers needed by this application component.
3. Look up the work manager or managers using the work manager resource reference (or logical name) in the java:comp namespace. (For more information on resource references, refer to the References topic.)

   ```
   InitialContext ic = new InitialContext();
   WorkManager wm = (WorkManager)ic.lookup("java:comp/env/wm/myWorkManager");
   ```

   The resource reference for the work manager (in this case, `wm/myWorkManager`) must be declared as a resource reference in the application deployment descriptor.
4. Call the WorkManager.startWork() method using the work object as a parameter. For example:

   ```
   Work w = new MyWork(...);
   WorkItem wi = wm.startWork(w);
   ```

   The startWork() method can take a startTimeout parameter. This specifies a hard time limit for the Work object to be started. The startWork() method returns a work item object. This object is a handle that provides a link from the component to the now running work object.
5. [Optional] If your application component needs to wait for one or more of its running work objects to complete, call the WorkManager.join() method. For example:

```
WorkItem wiA = wm.start(workA);
WorkItem wiB = wm.start(workB);
ArrayList l = new ArrayList();
l.add(wiA);
l.add(wiB);
if(wm.join(l, wm.JOIN_AND, 5000)) // block for up to 5 seconds
{

// both wiA and wiB finished
}
else
{

// timeout

// we can check wiA.getStatus or wiB.getStatus to see which, if any, finished.
}
```

This method takes an array list of work items which your component wants to wait on and a flag that indicates whether the component will wait for one or all of the work objects to complete. You also can specify a timeout value.

6. Use the release() method to signal the unit of work to stop running. The unit of work then attempts to stop running as soon as possible. Typically, this action is completed by toggling a flag using a thread-safe approach like the following example:

```
public synchronized void release()
{
 released = true;
}
```

The Work.run() method can periodically examine this variable to check whether the loop exits or not.

Work objects

A work object is a type of asynchronous bean used by application components to run code in parallel or in a different Java Platform, Enterprise Edition (Java EE) context.

A work object implements the com.ibm.websphere.asynchbeans.Work interface. A work object is essentially a java.lang.Runnable object that is serializable and provides additional methods. For details, refer to the Interface Work in the generated API documentation.

A component wanting to run work in parallel, or in a different Java EE context, locates a work manager in Java™ Naming and Directory Interface (JNDI), then calls the WorkManager.startWork() method using the work object as a parameter.

The startWork() method returns a work item object. This object is a handle that provides a link from the component to the now running work object. The work item object is typically used when the component needs to wait for one or more of its running work objects to complete. The WorkManager.join() method takes an array list of work items that the component wants to wait on, and a flag indicating whether the component will wait for all or one of the work objects to complete. A timeout can be specified, which prevents the component from waiting indefinitely.

The application does not create Java SE Development Kit 6 (JDK 6) threads because they are not managed threads. Plus, these threads are not affiliated with the Java EE environment, which makes them useless inside an application server. In addition, these threads have no Java EE context (for example, a java:comp) and are not authenticated when they fire. Work object threads are fully supported by the application server and have the same properties as other asynchronous beans.

Example: Creating work objects

You can create a work object that dynamically subscribes to a topic and any component that has access to the event source can add an event on demand.

The following is an example of a work object that dynamically subscribes to a topic:

```
class SampleWork implements Work
{
 boolean released;
 Topic targetTopic;
 EventSource es;
 TopicConnectionFactory tcf;

 public SampleWork(TopicConnectionFactory tcf, EventSource es, Topic targetTopic)
 {
  released = false;
  this.targetTopic = targetTopic;
  this.es = es;
  this.tcf = tcf;
 }

 synchronized boolean getReleased()
 {
  return released;
 }

 public void run()
 {
  try
  {
   // setup our JMS stuff.
   TopicConnection tc = tcf.createConnection();
   TopicSession sess = tc.createSession(false, Session.AUTOACK);
   tc.start();

   MessageListener proxy = es.getEventTrigger(MessageListener.class, false);
   while(!getReleased())
   {
    // block for up to 5 seconds.
    Message msg = sess.receiveMessage(5000);
    if(msg != null)
    {
     // fire an event when we get a message
     proxy.onMessage(msg);
    }
   }
   tc.close();
  }
  catch (JMSException ex)
  {
   // handle the exception here
   throw ex;
  }
  finally
  {
   if (tc != null)
   {
    try
    {
     tc.close();
    }
    catch (JMSExceptin ex1)
    {
     // handle exception
    }
   }
  }
 }

 // called when we want to stop the Work object.
 public synchronized void release()
```

```
 {
  released = true;
 }
}
```

As a result, any component that has access to the event source can add an event on demand, which allows components to subscribe to a topic in a more scalable way than by simply giving each client subscriber its own thread. The previous example is fully explored in the WebSphere Trader Sample. See the Samples section of the Information Center for details.

Developing event listeners

Application components that listen for events can use the EventSource.addListener() method to register an event listener object (a type of asynchronous bean) with the event source to which the events will be published. An event source also can fire events in a type-safe manner using any interface.

About this task

Notifications between components within a single EAR file are handled by a special event source. See the Using the application notification service topic for more information about notifications.

Procedure

1. Create an event listener object, which can be any type. For example, see the following interface code:

```
interface SampleEventGroup
{
  void finished(String message);
}

class myListener implements SampleEventGroup
{
  public void finished(String message)
  {
  // This will be called when we 'finish'.
  }
}
```

2. Register the event listener object with the event source. For example, see the following code:

```
InitialContext ic = ...;
EventSource es = (EventSource)ic.lookup("java:comp/websphere/ApplicationNotificationService");
myListener l = new myListener();
es.addListener(l);
```

   This enables the myListener.finished() method to be called whenever the event is fired. The following code example shows how this event might be fired:

```
InitialContext ic = ...;
EventSource es = (EventSource)ic.lookup("java:comp/websphere/ApplicationNotificationService");
myListener proxy = es.getEventTrigger(myListener.class);
// fire the 'event' by calling the method
// representing the event on the proxy
proxy.finished("done");
```

Example

You can fire a listenerCountChanged event that produces a proxy for the interface on which the method fires. Calling the method corresponding to the event on the proxy implements the EventSourceEvents interface. The same proxy can be used to send multiple events simultaneously.

The following code example demonstrates how to fire a listenerCountChanged event:

```
// Imagine this snippet inside an EJB or servlet method.
// Make an inner class implementing the required event interfaces.
EventSourceEvents listener = new Object() implements EventSourceEvents.class
{
 void listenerCountChanged(EventSource es, int old, int newCount)
```

```
 {
  try
  {
     InitialContext ic = new InitialContext();
   // Here, the asynchronous bean can access an environment variable of
   // the component which created it.
    int i = (Integer)ic.lookup("java:comp/env/countValue").intValue());
   if(newCount == i)
   {
    // do something interesting
   }
   // call this event when the following code executes:
  }
  catch(NamingException e)
  {
  }
 }
 void listenerExceptionThrown( EventSource es, Object listener,
       String methodName, Throwable exception)
 {
 }
 void unexpectedException(EventSource es, Object runnable, Throwable exception)
 {
 }
}
// register it.
es.addListener(listener);

...

// now fire an event which the previous listener receives.
EventSourceEvents proxy = (EventSourceEvents)
   es.getEventTrigger(EventSourceEvents.class, false);

proxy.listenerCountChanged(es, 0, 1);

// now, fire another event, you can call any of the methods.
proxy.listenerCountChanged(es, 4, 5);
```

The output in this example is a proxy for the interface on which the method fires. Then, call the method corresponding to the event on the proxy. This action causes the same method with the same parameters to be called on any event listeners that implement the EventSourceEvents interface and that were previously registered with the EventSource "es". The same proxy can be used to send multiple events simultaneously.

The boolean parameter on the getEventTrigger() method is `sameTransaction`. When the `sameTransaction` parameter is `false`, a new transaction is started for each event listener invoked and these event listeners can be called in parallel to the caller. However, the event() method is blocked until all of the event listeners are notified. If the `sameTransaction` parameter is `true`, then the current transaction (if any) on the thread is used for all of the event listeners. The event listeners share the transaction of the method that fired the event. For that reason, all event listeners must run serially in an undetermined order. The order that listeners are called is undefined, and the order in which listeners are registered does not act as a guide for the order used at run time. The method on the proxy does not return until all of the event listeners are called, which means that this action is a synchronous operation.

The parameters that references and listeners pass do not interfere with the function of these references, unless you configure the method to do so. For example, event listeners can be used as collaborators and add data to a map, which was a parameter. Each event listener runs on its own transaction, independent of any transaction that is active on the thread. Extreme care must be taken when the `sameTransaction` parameter is `false` because the parameters can be accessed by multiple threads.

Using the application notification service

During the application lifetime, individual J2EE components (servlets or enterprise beans) within a single EAR file might need to signal each other. There is an event source in the java:comp namespace that is bound into all components within an EAR file that can be used for notification.

About this task

The JNDI name for this event source, in the java:comp namespace that is bound into all components within an EAR file, is:

```
java:comp/websphere/ApplicationNotificationService
```

Components within the same application can fire asynchronous events and register event listeners using this application notification service. Startup beans can be used to register these event listeners at application startup or they can be registered dynamically at run time.

Procedure

To have your enterprise bean or servlet use the application notification service, write code similar to the following example:

```
InitialContext ic = new InitialContext();
EventSource appES = (EventSource)
  ic.lookup("java:comp/websphere/ApplicationNotificationService");
// now, the application can add a listener using the EventSource.addListener method.
// MyEventType is an interface.
MyEventType myListener = ...;
AppES.addListener(myListener);

// later another component can fire events as follows
InitialContext ic = new InitialContext();
EventSource appES = (EventSource)
ic.lookup("java:comp/websphere/ApplicationNotificationService");

// This highlights a constant string on the EventSource interface which
// specifies the 'java:comp/websphere/ApplicationNotificationService' string.
ic.lookup(appES.APPLICATION_NOTIFICATION_EVENT_SOURCE)
// now, the application can add a listener using the EventSource.addListener method.
MyEventType proxy = appES.getEventTrigger(MyEventType.class, false);
proxy.someEvent(someArguments);
```

Example

Example: Firing a listenerCountChanged event

You can fire a listenerCountChanged event that produces a proxy for the interface on which the method fires. Calling the method corresponding to the event on the proxy implements the EventSourceEvents interface. The same proxy can be used to send multiple events simultaneously.

The following code example demonstrates how to fire a listenerCountChanged event:

```
// imagine this snippet inside an EJB or servlet method.
// Make an inner class implementing the required event interfaces.
EventSourceEvents listener = new Object() implements EventSourceEvents.class
{
 void listenerCountChanged(EventSource es, int old, int newCount)
 {
  try
  {
     InitialContext ic = new InitialContext();
   // Here, the asynchronous bean can access an environment variable of
   // the component which created it.
    int i = (Integer)ic.lookup("java:comp/env/countValue").intValue());
   if(newCount == i)
   {
```

```
    // do something interesting
   }
   // call this event when the following code executes:
  }
  catch(NamingException e)
  {
  }
 }
 void listenerExceptionThrown( EventSource es, Object listener,
       String methodName, Throwable exception)
 {
 }
 void unexpectedException(EventSource es, Object runnable, Throwable exception)
 {
 }
}
// register it.
es.addListener(listener);

...

// now fire an event which the previous listener receives.
EventSourceEvents proxy = (EventSourceEvents)
   es.getEventTrigger(EventSourceEvents.class, false);

proxy.listenerCountChanged(es, 0, 1);

// now, fire another event, you can call any of the methods.
proxy.listenerCountChanged(es, 4, 5);
```

The output in this example is a proxy for the interface on which the method fires. Then, call the method corresponding to the event on the proxy. This action causes the same method with the same parameters to be called on any event listeners that implement the EventSourceEvents interface and that were previously registered with the EventSource "es". The same proxy can be used to send multiple events simultaneously.

The boolean parameter on the getEventTrigger() method is `sameTransaction`. When the `sameTransaction` parameter is `false`, a new transaction is started for each event listener invoked and these event listeners can be called in parallel to the caller. However, the event() method is blocked until all of the event listeners are notified. If the `sameTransaction` parameter is `true`, then the current transaction (if any) on the thread is used for all of the event listeners. The event listeners share the transaction of the method that fired the event. For that reason, all event listeners must run serially in an undetermined order. The order that listeners are called is undefined, and the order in which listeners are registered does not act as a guide for the order used at run time. The method on the proxy does not return until all of the event listeners are called, which means that this action is a synchronous operation.

The parameters that references and listeners pass do not interfere with the function of these references, unless you configure the method to do so. For example, event listeners can be used as collaborators and add data to a map, which was a parameter. Each event listener runs on its own transaction, independent of any transaction that is active on the thread. Extreme care must be taken when the sameTransaction parameter is `false` because the parameters can be accessed by multiple threads.

Developing asynchronous scopes

`Asynchronous scopes` are units of scoping that comprise a set of alarms, subsystem monitors, and child asynchronous scopes. You can create asynchronous scopes, starting with the parent.

About this task

Using asynchronous scopes can involve some or all of the following steps:

Procedure

1. Create asynchronous scopes. Create the parent asynchronous scope object by using a unique parameter name that calls the AsynchScopeManager.createAsynchScope() method. You can store properties in an asynchronous scope object. This storage provides Java 2 Enterprise Edition (J2EE) applications with a way to store a non-serializable state that otherwise cannot be stored in a session bean. You also can create child asynchronous scopes, which is useful for scoping data beneath the parent.
2. Listen for alarm notifications
   a. Create a listener object by implementing the AlarmListener interface. For more information, refer to the AlarmListener interface in the generated API documentation.
   b. Supply this object to the AlarmManager.create() method, as the target for the alarm. The create() method takes the following parameters:
      Target for the alarm
      The target on which the fired() method is called when the alarm is fired.
      Context
      The context object for the alarm. This object is useful for supplying alarm-specific data to the listener and supports a single listener for multiple alarms.
      Interval
      The number of milliseconds before the alarm fires.

      After the specified interval, the alarm fires and the fired() method of the listener is called with the firing alarm as a parameter. The alarm object is returned. By calling methods on this object, you can cancel or reschedule the alarm.
3. Monitor remote systems.
   a. Implement a mechanism for detecting messages sent from the remote system. For example, publish and subscribe messaging.
   b. Create a subsystem manager object by calling the SubsystemMonitorManager.create() method with the following parameters:
      Name Each subsystem monitor must have a unique name.
      Heartbeat interval
      The expected interval, in milliseconds, between heartbeats.
      Missed heart beats until stale or suspect
      The number of heartbeats that can be missed before the subsystem is marked as stale.
      Missed heart beats until dead
      The number of heartbeats that can be missed before the system is marked as dead.
   c. Create an object that implements the SubsystemMonitorEvents interface. For more information, see the SubsystemMonitorEvents in the generated API documentation.
   d. Add an instance of this object to the subsystem monitor using the SubsystemMonitor.addListener() method.
   e. Whenever a heartbeat message arrives from the remote system, call the SubsystemMonitor ping() method.

   The subsystem monitor configures alarms to track the heartbeat status of the remote system. When the ping() method is called, the alarms are reset. If an alarm fires, the ping() method is not called; that is, the application did not receive a heartbeat from the monitored subsystem.

Example

Asynchronous scopes are useful in stateful server applications. An application can have a startup bean that creates an asynchronous scope on a named work manager. The application also might create subsystem monitors to monitor the health of any remote systems on which the application is dependent.

When a client attaches to the server, the application creates a child asynchronous scope that is owned by the application asynchronous scope for the client and named using the client ID. A subsystem monitor for

monitoring the client might be created on the client asynchronous scope. If the client times out, a callback can clean up the client state on the server. Callbacks can be attached to the application subsystem monitors, on behalf of the client. When a remote system becomes unavailable, the client code in the server is notified and an event is sent to the client to warn that a critical remote system has failed. For example, the failure might be a data feed in an electronic trading application.

Asynchronous scopes

An asynchronous scope (AsynchScope object) is a unit of scoping provided for use with asynchronous beans.

Asynchronous scopes are collections of alarms, subsystem monitors, and child asynchronous scopes that enable a relationship to form. Each asynchronous scope uses a single work manager.

Each AsynchScope object owns and controls the life cycle of the following objects:

Child asynchronous scopes
: Each AsynchScope object extends the AsynchScopeManager interface, which is a factory for AsynchScope objects. (For more information on the AsynchScopeManager interface, refer to the generated API documentation). Any asynchronous scope can therefore create named asynchronous scopes (children). Child asynchronous scopes can be useful for scoping data underneath the parent. All of the child asynchronous scopes must be uniquely named. These children are destroyed if the parent asynchronous scope is destroyed.

Alarms
: Each asynchronous scope has an associated alarm manager. All of the alarms created by the alarm manager are automatically cancelled if the associated asynchronous scope is destroyed.

Subsystem monitors
: Each asynchronous scope has a subsystem monitor manager, which manages a set of subsystem monitors associated with the asynchronous scope. When the asynchronous scope is destroyed, all of the associated subsystem monitors also are destroyed.

In summary, asynchronous scopes can be organized into an acyclic tree. The life cycle of each asynchronous scope is directly coupled to that of its parent asynchronous scope. Each asynchronous scope is associated with a set of alarms and subsystem monitors, and an optional set of child asynchronous scopes. These objects are cancelled and destroyed when the asynchronous scope is destroyed.

Asynchronous scope state

Each asynchronous scope has an associated map, in which applications can store their state in the form of name and value pairs.

Asynchronous scope events

Each asynchronous scope is also an event source. Applications can therefore register event listeners against the asynchronous scope. The event listeners can receive notification if, for example, the AsynchScope object is about to be destroyed.

Applications also can use this event source to fire events only to listeners of this asynchronous scope. For example, an AsynchScope object created for a client session might be used to fire asynchronous events to parties interested in that client.

Alarms

An alarm runs Java Platform, Enterprise Edition (Java EE) context-aware code at a given time interval. Alarm objects are fine-grained, nonpersistent, transient, and can fire at millisecond intervals.

Alarms are run using a thread pool associated with the work manager that owns the associated asynchronous scope. You must create a work manager instance to create an alarm. Refer to the Configuring work managers topic for more information.

The AlarmManager.createAlarm() method takes an application-written object that implements the AlarmListener interface. For more information on the AlarmListener interface, refer to the generated API documentation. The fired method is called when the alarm expires. The createAlarm() method returns a non-serializable handle, which can be used to cancel or reset the alarm. All of the pending alarms are cancelled when its associated AsynchScope object is destroyed.

best-practices: The Java SE Development Kit 6 (JDK6)already has a timer mechanism, so why create a new one? The JDK 6 is a Java Platform, Standard Edition (Java SE) feature that knows nothing about the Java EE environment. Timers fired by the Java SE feature do not run on a managed thread and are therefore unusable inside an application server. These timers also lack a Java EE context (that is, a java:comp value) and are not authenticated when they fire. The asynchronous scope alarms are fully supported by the product and have the same properties as any other asynchronous bean.

Alarm performance

The alarm subsystem is designed to handle a large number of alarms. However, do not expect alarms to process heavy loads when they are firing because this activity slows the processing of later alarms. If an alarm needs to process a heavy load, design a work object that is activated by a work manager. This procedure moves the heavy processing to a different thread and enables the alarm threads to process alarms unhampered. All of the alarms owned by asynchronous scopes that are owned by a single work manager share a common thread pool. The properties of this thread pool can be tuned at the work manager level using the administrative console.

Subsystem monitors

A subsystem monitor is an object that monitors the health of a remote system. It uses an event source to inform all registered listeners of the health of the system.

AdvancedJava Platform, Enterprise Edition (Java EE) applications often rely on remote, non-managed, non-Java EE systems. These remote systems can periodically send clients a message to indicate that they are working. A subsystem monitor is a set of alarms that tracks indicator messages or heart beats from a remote system.

An application creates a subsystem monitor by calling the SubsystemMonitorManager.create() method with the following parameters:

Name Each subsystem monitor must be uniquely named.

Heart beat interval
The time period, in milliseconds, between arriving heart beat messages.

Missed heart beats until stale or suspect
The number of heart beats that can be missed before the subsystem is marked as stale. This designation indicates that the subsystem might be having problems.

Missed heart beats until dead
The number of heart beats that can be missed before the system is considered down. The system then is marked as dead.

The subsystem monitor configures alarms to track the heart beat status. Whenever the ping() method is called, the alarms are reset. If an alarm fires, the ping() method has not been called; that is, the application did not receive a heart beat from the monitored subsystem. When the number of **Missed heart beats until stale** value has elapsed without a ping, a stale event is fired. Later, if the number of **Missed heart beats until dead** value elapses without a ping, a dead event is fired. If a ping is received after a stale or dead notification, a fresh event is sent, which indicates that the subsystem is alive again.

Make the **Missed heart beats until dead** value greater or equal to the **Missed heart beats until stale** value. If **Missed heart beats until stale** value equals the **Missed heart beats until dead** value, then a stale event is not published. Only a dead event is published.

You can register a listener that implements the SubsystemMonitorEvents interface for applications that require notification of events. For more information on the SybsystemMonitorEvents interface, refer to the generated API documentation.

Heart beat messages can be transmitted using a variety of mechanisms. The application must call the SubsystemMonitor ping() method whenever a heart beat message arrives from a remote system, but the method used to detect these messages is up to the application. For example, you might use a Java Message Service (JMS) publish or subscribe implementation or even a third-party Java messaging product that does not implement JMS.

Asynchronous scopes: Dynamic message bean scenario

Java Platform, Enterprise Edition (Java EE) now supports message-driven beans, but the beans are static. This scenario provides information about how to set up the environment to enable the dynamic message bean.

All of the message sources must be known in advance and bound at deployment time. This action is not always viable, especially in fluid messaging environments such as those found in brokerages. Some environments have publish-subscribe topic spaces that are continually changing and clients need servers that can subscribe on demand to an arbitrary topic.

An asynchronous bean application can create a work object that performs a blocking receive on a Java Message Service (JMS) topic and then publishes the message as an event on an application-defined event source. Clients requiring a subscription to that message can add an event listener to the event source. The event source can inform the work object when there are no listeners. Then, the event source can shut down and make the JMS and thread resources available. The work object registers a listener with its own event source. When the count is one again, the work object knows that it is the only listener and it is time to shut down the work object. The WebSphere Trader Sample uses this pattern to dynamically subscribe to JMS topics at run time to gather stock prices. For more information, see the overview of the samples.

How does the server catch clients that disconnect or crash? It creates a subsystem monitor to watch the client and adds an event listener to catch dead events. When a dead event occurs, the server application can clean up the client server state. For example, the server application can remove the client event listener from the dynamic message bean, thereby allowing the server to subscribe to a dynamic topic only when it is needed.

Assembling timer and work managers

Assembling applications that use work managers and timer managers

The work manager and timer manager objects are both supported for assembling applications that implement the asynchronous bean technology. You can assemble either work managers or time managers.

Before you begin

Configure at least one work manager or timer manager using the administrative console.

About this task

Complete the steps to either assemble work managers or time managers.

Procedure

1. Assemble applications that use asynchronous beans work managers.
2. Assemble applications that use CommonJ work managers.
3. Assemble applications that use CommonJ timer managers.

Assembling applications that use a CommonJ WorkManager

When a work manager has been configured, if it references a logical work manager it must be bound to a physical work manager using an assembly tool. Then resources can be created and bound to a physical work manager.

Before you begin

Your administrator needs to configure at least one work manager using the administrative console.

About this task

If your application references one or more logical work managers, the logical work managers must be bound to one or more physical work managers using an assembly tool, such as Rational Web Developer.

Procedure

1. Declare a resource reference for each work manager (required action by the application developer). This forms an EAR file. (For more information on resource references, refer to the References. topic)
2. Bind each resource reference to a physical work manager, using an assembly tool, such as Rational Web Developer.
3. Add a resource reference with the type commonj.work.WorkManager to the application deployment descriptor. The application can look up this work manager using its resource reference name in java:comp. Now, you can use an assembly tool or Rational Application Developer to specify which resource references are bound to the physical commonj.work.WorkManager.

   Attention: The previous steps outline the same process used for data sources.

Assembling applications that use timer managers

When a work manager has been configured, if it references a logical work manager it must be bound to a physical work manager using an assembly tool. Then resources can be created and bound to a physical timer.

Before you begin

Your administrator needs to configure at least one timer manager using the administrative console.

About this task

If your application references one or more logical timer managers, the logical timer managers must be bound to one or more physical timer managers using an assembly tool, such as the Rational Application Developer.

Procedure

1. Declare a resource reference for each timer manager (required action by the application developer). This forms an EAR file. (For more information on resource references, refer to the References topic.)
2. Bind each resource reference to a physical timer manager, using an assembly tool.
3. Add a resource reference with the type commonj.timers.TimerManager to the application deployment descriptor. The application then can look up this timer manager using its resource reference name in java:comp. The assembly tool can specify which resource references are bound to a physical timer manager.

Attention: The previous steps outline the same process used for data sources.

Assembling applications that use asynchronous beans work managers

When a work manager has been configured, if it references a logical work manager it must be bound to a physical work manager using an assembly tool. Then resources can be created and bound to a physical work managers.

Before you begin

Your administrator needs to configure at least one work manager using the administrative console.

About this task

If your application references one or more logical work managers, the logical work managers must be bound to one or more physical work managers using an assembly tool.

The CommonJ 1.1 interfaces are supported. Both asynchronous beans and CommonJ interfaces can use one configuration work manager object. The type of interface implemented is resolved during the JNDI lookup time. The type of interface used is determined by the one specified in the resource-reference, instead of the one specified in the configuration object. So, there can be one resource-reference for each interface, per configuration object. Each resource-reference lookup returns the appropriate type of instance. For example, there are two resource-references defined for the `wm/MyWorkManager:` `wm/ABWorkMgr` and `wm/CommonJWorkMgr`. The WebSphere Application Server run time returns the correct interface for each resource-reference lookup.

Procedure

1. Declare a resource reference for each work manager (required action by the application developer). This action results in an EAR file. For more information on resource references, refer to the References topic.
2. Use an assembly tool to bind each resource reference to a physical work manager.
3. Add a resource reference with the type com.ibm.websphere.asynchbeans.WorkManager to the application deployment descriptor. The application then can look up this work manager using its resource reference name in java:comp. The assembly tool or Rational Application Developer then can specify which resource references are bound to a physical work manager.

   Attention: Use the same previous steps to configure data sources.

Chapter 4. Developing applications that use the Bean Validation API

The Bean Validation API is introduced with the Java Enterprise Edition 6 platform as a standard mechanism to validate Enterprise JavaBeans in all layers of an application, including, presentation, business and data access. Before the Bean Validation specification, the JavaBeans were validated in each layer. To prevent the reimplementation of validations at each layer, developers bundled validations directly into their classes or copied validation code, which was often cluttered. Having one implementation that is common to all layers of the application simplifies the developers work and saves time.

Bean Validation

The Bean Validation API is introduced with the Java Enterprise Edition 6 platform as a standard mechanism to validate JavaBeans in all layers of an application, including presentation, business, and data access.

Before the Bean Validation specification, JavaBeans were validated in each layer. To prevent the re-implementation of validations at each layer, developers bundled validations directly into their classes or copied validation code, which was often cluttered. Having one implementation that is common to all layers of the application simplifies the developers work and saves time.

The Bean Validation specification defines a metadata model and an API that are used to validate JavaBeans for data integrity. The metadata source is the constraint annotations defined that can be overridden and extended using XML validation descriptors. The set of APIs provides an ease of use programming model allowing any application layer to use the same set of validation constraints. Validation constraints are used to check the value of annotated fields, methods, and types to ensure that they adhere to the defined constraint.

Constraints can be built in or user-defined. Several built-in annotations are available in the javax.validation.constraints package. They are used to define regular constraint definitions and for composing constraints. For a list of built-in constraints, see the topic, “Bean validation built-in constraints” on page 32. For more details about the Bean Validation metadata model and APIs see the JSR 303 Bean Validation specification document.

The following example is a simple Enterprise JavaBeans (EJB) class that is decorated with built-in constraint annotations.

```
public class Home  {
   @Size(Max=20)
    String builder;
    @NotNull @Size(Max=20)
    String address;

    public String getAddress() {
         return address;
    }

    public String getBuilder() {
         return address;
    }
    public String setAddress(String newAddress) {
         return address = newAddress;
    }

    public String setBuilder(String newBuilder) {
         return builder = newBuilder;
    }
}
```

The @Size annotations on builder and address specify that the string value assigned should not be greater 20 characters. The @NotNull annotation on address indicates that it cannot be null. When the Home object is validated, the builder and address values are passed to the validator class defined for the @Size annotation. The address value is also be passed to the @NotNull validator class. The validator classes handle checking the values for the proper constraints and if any constraint fails validation, a ConstraintViolation object is created, and is returned in a set to the caller validating the Home object.

Validation APIs

The javax.validation package contains the bean validation APIs that describe how to programmatically validate JavaBeans.

ConstraintViolation is the class describing a single constraint failure. A set of ConstraintViolation classes is returned for an object validation. The constraint violation also exposes a human readable message describing the violation.

ValidationException are raised if a failure happens during validation.

The Validator interface is the main validation API and a Validator instance is the object that is able to validate the values of the Java object fields, methods, and types. The bootstrapping API is the mechanism used to get access to a ValidatorFactory that is used to create a Validator instance. For applications deployed on the product, bootstrapping is done automatically. There are two ways for applications to get the validator or the ValidatorFactory. One way is injection, for example, using the @Resource annotation, and the other way is the java: lookup.

The following example uses injection to obtain a ValidatorFactory and a Validator:

```
@Resource ValidatorFactory _validatorFactory;
@Resource Validator _validator;
```

Attention: When using @Resource to obtain a Validator or ValidatorFactory, the authenticationType and shareable elements must not be specified.

The following example uses JNDI to obtain a ValidatorFactory and a Validator:

```
ValidatorFactory validatorFactory = (ValidatorFactory)context.lookup("java:comp/ValidatorFactory");
Validator validator = (Validator)context.lookup("java:comp/Validator");
```

Constraint metadata request APIs

The metadata APIs support tool providers, provides integration with other frameworks, libraries, and Java Platform, Enterprise Edition technologies. The metadata repository of object constraints is accessed through the Validator instance of a given class.

XML deployment descriptors

Besides declaring constraints in annotations, support exists for using XML to declare your constraints.

The validation XML description is composed of two kinds of xml files. The META-INF/validation.xml file describes the bean validation configuration for the module. The other XML file type describes constraints declarations and closely matches the annotations declaration method. By default, all constraint declarations expressed through annotations are ignored for classes described in XML. It is possible to force validation to use both the annotations and the XML constraint declarations by using the ignore-annotation="false" setting on the bean. The product ensures that application modules deployed containing a validation.xml file and constraints defined in XML files are isolated from other module validation.xml and constraint files by creating validator instances specific to the module containing the XML descriptors.

Advanced bean validation concepts

The Bean Validation API provides a set of built-in constraints and an interface that enables you to declare custom constraints. This is accomplished by creating constraint annotations and declaring an annotation on a bean type, field, or property. Composing constraints is also done by declaring the constant on another constraint definition.

The following example shows creating a CommentChecker constraint that is defined to ensure a comment string field is not null. The comment text is enclosed by brackets, such as [*text*].

```
package com.my.company;
import java.lang.annotation.Documented;
import java.lang.annotation.Retention;
import java.lang.annotation.Target;
import static java.lang.annotation.ElementType.METHOD;
import static java.lang.annotation.ElementType.FIELD;
import static java.lang.annotation.RetentionPolicy.RUNTIME;
import javax.validation.Constraint;
import javax.validation.Payload;

@Documented
@Constraint(validatedBy = CommentValidator.class)
@Target({ METHOD, FIELD })
@Retention(RUNTIME)
public @interface CommentChecker {
       String message() default "The comment is not valid.";
       Class<?>[] groups() default {};
       Class<? extends Payload>[] payload() default {};
      ...}
```

The next example shows the constraint validator that handles validating elements with the @CommentChecker annotation. The constraint validator implements the ConstraintValidator interface provided by the Bean Validation API.

```
package com.my.company;
import javax.validation.ConstraintValidator;
import javax.validation.ConstraintValidatorContext;
public class CommentValidator implements ConstraintValidator<CommentChecker, String> {
    public void initialize(CommentChecker arg0) {
    }
    public boolean isValid(String comment, ConstraintValidatorContext context) {
        if (comment == null) {
            // Null comment is not allowed, fail the constraint.
            return false;
        }
        if (!comment.contains("[") && !comment.contains("]")) {
            // Can't find any open or close brackets, fail the constraint
            return false;
        }
        // Ignore leading and trailing spaces
        String trimmedComment = comment.trim();
        return // validate '[' prefix condition
               trimmedComment.charAt(0) == '[' &&
               // validate ']' suffix condition
               trimmedComment.charAt(trimmedComment.length()!-1) == ']';
    }
}
```

After the @CommentChecker is defined, it can be used to ensure that the comment string field is a valid comment based on the CommentValidator isValid() implementation. The following example shows the use of the @CommentChecker constraint. When the myChecker bean is validated, the comment string is validated by the CommentValidator class to ensure the constraints defined are met.

```
package com.my.company;
public myChecker {

    @CommentChecker
    String comment = null;
    ...
}
```

The product provides a specific bean validation provider, but it might be necessary for an application to use or require another provider.

This method can be accomplished by using the validator methods to set the provider programmatically and create a validation factory. Or, by using the validation.xml default-provider element. The specific provider that is defined and used to create the validation factory and not the default provider provided by the application server in the default implementation. If you want to ensure that the user-provided implementation does not conflict with the default implementation, the server or application class loading parameter, the class loader order should be set to be loaded with local class loader first (parent last). See additional information in the class loading documentation on how to set this setting.

The Bean Validation specification indicates that if more than one validation.xml file is found in the class path, a ValidationException occurs. However, WebSphere Application Server supports an environment where multiple teams develop modules that are assembled and deployed into the Application Server together. In this environment, all EJB modules within an application are loaded with the same class loader and it is possible to configure the application class loaders so that all EJB and web archive (WAR) modules are loaded by a single class loader. Because of this, the product provides support for multiple validation.xml files in the same class path.

When an application using bean validation and XML descriptors contains multiple EJB modules and web modules, each validation.xml file is associated with a validation factory that is specific to that module. In this environment, any constraint-mapping elements that are defined are only looked up in the module where the validation.xml file is defined. For example, if an EJB module building.jar contains a META-INF/validation.xml file and the validation.xml file defined the following constraints, both the META-INF/constraints-house.xml and META-INF/constraints-rooms.xml files must also be located in the building.jar file:

```
<constraint-mapping>META-INF/constraints-house.xml</constaint-mapping>
<constraint-mapping>META-INF/constraints-rooms.xml</constraint-mapping>
```

The exception to this behavior is when all bean validation constraints classes and configuration are visible to all application modules. In a case where a single validation.xml file is defined in an EAR file, and no other validation.xml files are visible in a module's class path, any module that creates a validator factory or validator will use the validation.xml file that is defined in the EAR file. This makes it possible for other modules to create a validator factory that uses the validation.xml file of another module, if the class path has been configured so that both modules are visible on the same class path and only one validation.xml file is visible to those modules.

For a more detailed understanding about the Bean Validation APIs and metadata see the JSR 303 Bean Validation specification document.

Bean validation built-in constraints

Use this information to look up information about Bean Validation API built-in constraints.

The Bean Validation API is supported by constraints that are primarily expressed through annotations. The constraints are added to a class, field, or method of an Enterprise JavaBeans (EJB) component. The annotated element value is checked by the constraint.

Constraints can be built in or user defined. Several built-in annotations are available in the javax.validation.constraints package. They are used to define regular constraint definitions and for composing constraints.

The following table is a list of constraints and usage.

Table 1. Bean validation built-in constraints. Use of bean validation built-in constraints

Constraint	Usage
@Null	Specifies that the configuration property decorated with this annotation must have a null value. This constraint accepts any type.
@NotNull	Specifies that the configuration property decorated with this annotation must not have a null value. That is, the property is required. This constraint accepts any type.
@AssertTrue	Specifies that the configuration property decorated with this annotation must be true. Supported value types are boolean and Boolean. Null elements are considered valid.
@AssertFalse	Specifies that the configuration property decorated with this annotation must be false. Supported value types are boolean and Boolean. Null elements are considered valid.
@Min	Specifies that the configuration property decorated with this annotation must have a value greater than or equal to the specified minimum. Supported value types are BigDecimal, BigInteger, byte, short, int, long and their respective wrappers. Null elements are considered valid.
@Max	Specifies that the configuration property decorated with this annotation must have a value less than or equal to the specified maximum. Supported value types are BigDecimal, BigInteger, byte, short, int, long and their respective wrappers. Null elements are considered valid.
@DecimalMin	Specifies that the configuration property decorated with this annotation must have a value higher or equal to the specified minimum. Supported value types are BigDecimal, BigInteger, String, byte, short, int, long and their respective wrappers. Null elements are considered valid.
@DecimalMax	Specifies that the configuration property decorated with this annotation must have a value lower or equal to the specified maximum. Supported value types are BigDecimal, BigInteger, String, byte, short, int, long and their respective wrappers. Null elements are considered valid.
@Size	Specifies that the configuration property decorated with this annotation must have a value between the specified boundaries (included). Supported value types are String (string length is evaluated), Collection (collection size is evaluated), Map (map size is evaluated), Array (array length is evaluated). Null elements are considered valid.
@Digits	Specifies that the configuration property decorated with this annotation must have a value within accepted range. Supported value types are BigDecimal, BigInteger, String, byte, short, int, long and their respective wrappers. Null elements are considered valid.
@Past	Specifies that the configuration property decorated with this annotation must have a date in the past. Now is defined as the current time according to the virtual machine. The calendar is used if the compared type is of type Calendar and the calendar is based on the current timezone and the current locale. Supported value types are java.util.Date, java.util.Calendar. Null elements are considered valid.
@Future	Specifies that the configuration property decorated with this annotation must have a date in the future. Now is defined as the current time according to the virtual machine. The calendar is used if the compared type is of type Calendar and the calendar is based on the current timezone and the current locale. Supported value types are java.util.Date, java.util.Calendar. Null elements are considered valid.
@Pattern	Specifies that the configuration property decorated with this annotation must match the following regular expression. The regular expression follows the Java regular expression conventions java.util.regex.Pattern. Supported type value is String. Null elements are considered valid.

Using bean validation in the product

The Java Enterprise Edition (Java EE) 6 specification includes the Bean Validation API that is a standard mechanism for validating JavaBeans in all layers of an application.

About this task

Before the Bean Validation specification, JavaBeans were validated in each layer. To prevent the reimplementation of validations at each layer, developers bundled validations directly into their classes or copied validation code, which was often cluttered. Having one implementation that is common to all layers of the application simplifies the developers work and saves time.

Bean validation is common to all layers of an application. Specifically, web applications have the following layers:

- Presentation

This layer represents how the user interacts with the application and might be built on a thin client or rich client.

- Business

  This layer coordinates the application, processes commands, makes logical decisions and evaluations and performs calculations. It also moves and processes data between the two other layers. The EJB contains business logic in WebSphere Application Server.

- Data access

  Your data is stored and retrieved from a database or file system at this layer. The business layer processes the data and sends it in usable form to the user interface. WebSphere Application Server supports several databases and methods of retrieving data. This layer also defines persistence.

For WebSphere Application Server, these layers are built and administered with several components in the product that are necessary for developing and deploying applications.

The product provides support for the Bean Validation API in the Java Platform, Enterprise Edition (Java EE) environment by providing a bean validation service in multiple Java EE technologies including Java Servlets, Enterprise JavaBeans, Java Persistence API (JPA) 2.0, Java EE Connector API (JCA) 1.6 and Java ServerFaces (JSF) 2.0. Bean validation provides these technologies a way to maintain data integrity in an integrated and standard environment.

Enterprise application development involves multiple teams developing numerous applications and modules that are assembled and deployed in an application server environment. The product ensures that each application and module data is validated independently. Validation is performed using only the constraints defined for the application and module.

What to do next

- Data access resources:

  Bean validation in RAR modules.

  The product validates resource adapter archive (RAR) Enterprise JavaBeans (EJB) constraints in compliance with the JCA version 1.6 specification. Resource adapters can use the built-in bean validation constraint annotations or provide a bean validation XML configuration to specify the validation requirements of resource adapter configuration properties to the application server.

- Using bean validation in JPA

  A new feature defined by the JPA 2.0 specification is the ability to seamlessly integrate with the Bean Validation API. With minimal effort, JPA 2.0 can be coupled with the validation provider for runtime data validation. By combining these two technologies, you get a standardized persistence solution with the added ability to perform standardized data validation.

- Using bean validation with JSF

  JSF previously was able do bean validation, but now it provides built-in support of the Bean Validation specification.

- Using bean validation in web container

  The web container provides an instance of ValidatorFactory and makes it available to JSF implementations by storing it in a servlet context attribute named javax.faces.validator.beanValidator.ValidatorFactory.

- Using bean validation with the embeddable container.

  To use bean validation with the embeddable EJB container, the javax.validation classes must exist in the class path. That can be done in one of two ways:

  – Include the JPA thin client that is located in the directory `${WAS_INSTALL_ROOT}\runtimes\com.ibm.ws.jpa.thinclient_8.0.0.jar` in the class path. See the topic, Running an embeddable container, and the information about JPA, for more information.

  – Include a third party bean validation provider Java archive (JAR) file in the class path of the embeddable EJB container run time.

Bean validation in RAR modules

WebSphere Application Server validates resource adapter archive (RAR) JavaBeans constraints in compliance with the Java Connector Architecture (JCA) version 1.6 specification.

Resource adapters can specify the validation requirements of configuration properties to the Application Server through annotations in the source code of the resource adapter, constraint specifications in a resource adapter validation descriptor, or a mixture of both. In specifying these constraints, resource adapters can use the built-in bean validation constraints supplied with the Application Server, custom bean validation constraints supplied either by the application developer or a third party, or a mixture of both. Resource adapter developers can apply constraints to the fields and JavaBeans-compliant properties of the following JCA types:

- ResourceAdapter
- ManagedConnectionFactory
- ActivationSpec
- AdministeredObject

At run time, the application server creates instances of bean types declared by the resource adapter. Each instance is validated immediately upon setting its configuration properties, before placing the instance into service.

When validating a RAR bean, the Application Server creates an instance of a validator factory according to the bean validation deployment descriptor discovered by the Application Server. A validator instance is then obtained from the factory and used to validate the bean instance.

If validation fails, the Application Server throws a constraint violation exception and reports all violations to the system log. The effects of the exception for each RAR bean type and problem determination information are documented in the topic, Troubleshooting bean validation in RAR modules.

Note: The Bean Validation specification requires that no more than one `validation.xml` is visible on the class path. This requirement is violated whenever two or more stand-alone RARs provide a validation descriptor. See the section, “RAR bean validation descriptor” in this topic, for more information. When more than one `validation.xml` is visible to the Application Server class loaders, the Application Server or application modules might fail to acquire the default ValidatorFactory and subsequently cannot perform bean validation. For example, the server cannot validate beans of a RAR embedded in an application whenever the embedded RAR lacks a validation configuration, and two or more stand-alone RARs provide configurations. To avoid trouble, install stand-alone RARs that provide a bean validation descriptor as isolated whenever possible.

Built-in constraint annotations

Note: Use built-in constraint annotations to specify the range and mandatory attributes of configuration properties rather than provide custom annotations for the same purpose. The following constraints are useful, but you can use all bean validation built-in constraints. See the topic Bean validation built-in constraints for a complete list of the constraints.

- @Min

  Specifies the minimum value of the configuration property decorated with this annotation. The value must be greater than or equal to the specified minimum.
- @Max

  Specifies the maximum value of the configuration property decorated with this annotation. The value must less than or equal to the specified maximum.
- @Size

Specifies the range of values of the configuration property decorated with this annotation. The value must be greater than or equal to the specified minimum and be less than or equal to the specified maximum.

- @NotNull

  Specifies the value of the configuration property decorated with this annotation must not be null. That is, the property is required.

The following example is a RAR bean class that is decorated with built-in constraint annotations.

The value of the serverName configuration property must not be null, and the value of the instanceCount property must be at least 1 when the Application Server creates and configures an instance of the MyConnector class. Otherwise, a constraint validation exception occurs and, in the case of ResourceAdapter bean, the resource adapter fails to start. See the topic Troubleshooting bean validation in RAR modules for more information.

```
package com.my.company;

@Connector(...)
public class MyConnector implements ResourceAdapter, Serializable
{
 @ConfigProperty(type=java.lang.String.class,defaultValue="WAS")
 private String serverName;

 @NotNull()
 public String getServerName() {return serverName;}

 private Integer instanceCount = 0;

 @Min(value=1)
 public Integer getInstanceCount() {return instanceCount;}
 ...
```

RAR bean validation descriptor

Bean validation constraints can be declared through an XML descriptor supplied by a RAR module. In the simplest case, a RAR validation descriptor consists of the validation configuration declared in the validation.xml file and zero or more XML files that declare RAR bean validation constraints. Files containing constraint declarations are specified in the constraint-mapping elements of the validation configuration (validation.xml).

You must package the validation descriptor in the META-INF directory of a RAR module. Any custom constraint annotation classes that are declared in the validation descriptor must also be packaged in the RAR module.

The following example is a simple RAR validation descriptor that declares constraint metadata like the code shown in the section, “Built-in constraint annotations.”

```
<?xml version="1.0" encoding="UTF-8"?>
<validation-config
  xmlns=http://jboss.org/xml/ns/javax/validation/configuration
   xmlns:xsi=http://www.w3.org/2001/XMLSchema-instance
   xsi:schemaLocation=http://jboss.org/xml/ns/javax/validation/configuration validation-configuration-1.0.xsd>
<constraint-mapping>META-INF/constraints.xml</constraint-mapping>
</validation-config>
```

The constraints XML file is also located in the META-INF directory and looks like the following:

```
<constraint-mappings
 xmlns=http://jboss.org/xml/ns/javax/validation/mapping
 xmlns:xsi=http://www.w3.org/2001/XMLSchema-instance
 xsi:schemaLocation=http://jboss.org/xml/ns/javax/validation/mapping validation-mapping-1.0.xsd>
<default-package>com.my.company</default-package>
<bean class="MyConnector" ignore-annotations="true">
 <field name="serverName">
  <valid/>
  <!-- @NotNull() -->
  <constraint annotation="javax.validation.constraints.NotNull">
   <message>Value is not null</message>
  </constraint>
 </field>
 <field name="instanceCount">
  <valid/>
```

```
  <!-- @Min(1) -->
  <constraint annotation="javax.validation.constraints.Min">
    <message>Minimum possible value is 1</message>
    <element name="value">1</element>
   </constraint>
  </field>
 </bean>
<constraint-mapping>
```

The packaged RAR module, `MyResourceAdapter.rar`, looks like the following:

```
my/
  company/
    MyConnector.class
. . .
META-INF
  /validation.xml
  /constraints.xml
```

Third-party bean validation

WebSphere Application Server supports using different bean validation implementations. If a resource adapter requires a bean validation implementation different from the implementation that is provided by the product, and the RAR provides the bean validation implementation, you must package the JAR file that contains the bean validation implementation in the RAR module root directory.

The RAR module must also contain a single validation configuration descriptor (`validation.xml`), which can be packaged in the META-INF directory of the RAR module, or in the `META-INF/services` directory of the bean validation JAR file, but not both.

RAR bean validation configuration discovery

When validating RAR beans, the Application Server bootstraps the bean validation configuration, specific to the RAR, according to the bean validation descriptor supplied in the RAR META-INF directory. If the descriptor does not exist, the server bootstraps the configuration using the first validation descriptor discovered in the RAR class loading context, such as that supplied in a third-party bean validation that is packaged in the RAR. Finally, the server uses the default validation configuration provided by the product.

The server then creates a validator factory specific to the discovered bean validation configuration and uses this factory to create validator instances for validating the RAR bean instances. When you deploy a RAR that supplies a bean validation descriptor, you must take additional steps to ensure that the class loader that loads the RAR loads the bean validation descriptor and classes packaged in the RAR.

For an embedded RAR, after you have deployed the application that embeds the RAR, you must set the delegation mode of the application class loader to Parent-Last (Child-First). See the topic Configuring application class loaders for more information.

For a stand-alone RAR, you must install the RAR as an isolated resource provider. See the topic Resource Adapter settings for more information.

Bean validation in JPA

Data validation is a common task that occurs in all layers of an application, including persistence. The Java Persistence API (JPA) 2.0 provides support for the Bean Validation API so that data validation can be done at run time. This topic includes a usage scenario where bean validation is used in the JPA environment of a sample digital image gallery application.

The Bean Validation API provides seamless validation across technologies on Java Enterprise Edition 6 (Java EE 6) and Java Platform, Standard Edition (JSE) environments. In addition to JPA 2.0, these technologies include JavaServer Faces (JSF) 2.0 and Java EE Connector Architecture (JCA) 1.6. You can read more about bean validation in the topic, Bean Validation API.

There are three core concepts of bean validation: constraints, constraint violation handling, and the validator. If you are running applications in an integrated environment like JPA, there is no need to interface directly with the validator.

Validation constraints are annotations or XML code that are added to a class, field, or method of a JavaBeans component. Constraints can be built in or user-defined. They are used to define regular constraint definitions and for composing constraints. The built-in constraints are defined by the bean validation specification and are available with every validation provider. For a list of built-in constraints, see the topic, Bean validation built-in constraints. If you need a constraint different from the built-in constraints, you can build your own user-defined constraint.

Constraints and JPA

The following usage scenario illustrates how a built-in constraint is used in the JPA architecture of a sample digital image gallery application.

In the first code example, a built-in constraint is added to a simple entity of the JPA model called *image*. An image has an ID, image type, file name, and image data. The image type must be specified and the image file name must include a valid JPEG or GIF extension. The code shows the annotated image entity with some built-in bean validation constraints applied.

```
package org.apache.openjpa.example.gallery.model;

import javax.persistence.Entity;
import javax.persistence.EnumType;
import javax.persistence.Enumerated;
import javax.persistence.GeneratedValue;
import javax.persistence.Id;
import javax.validation.constraints.NotNull;
import javax.validation.constraints.Pattern;

@Entity
public class Image {

    private long id;
    private ImageType type;
    private String fileName;
    private byte[] data;

    @Id
    @GeneratedValue
    public long getId() {
        return id;
    }

    public void setId(long id) {
        this.id = id;
    }

    @NotNull(message="Image type must be specified.")
    @Enumerated(EnumType.STRING)
    public ImageType getType() {
        return type;
    }

    public void setType(ImageType type) {
        this.type = type;
    }

    @Pattern(regexp = ".*\\.jpg|.*\\.jpeg|.*\\.gif",
        message="Only images of type JPEG or GIF are supported.")
    public String getFileName() {
        return fileName;
    }
```

```
    public void setFileName(String fileName) {
        this.fileName = fileName;
    }

    public byte[] getData() {
        return data;
    }

    public void setData(byte[] data) {
        this.data = data;
    }
}
```

The Image class uses two built-in constraints, @NotNull and @Pattern. The @NotNull constraint ensures that an ImageType element is specified and the @Pattern constraint uses regular expression pattern matching to ensure that the image file name is suffixed with a supported image format. Each constraint has corresponding validation logic that gets started at run time when the image entity is validated. If either constraint is not met, the JPA provider throws a ConstraintViolationException with the defined message. The JSR-303 specification also makes provisions for the use of a variable within the message attribute. The variable references a keyed message in a resource bundle. The resource bundle supports environment-specific messages and globalization, translation, and multicultural support of messages.

You can create your own custom validator and constraints. In the previous example, the Image entity used the @Pattern constraint to validate the file name of the image. However, it did not check constraints on the actual image data itself. You can use a pattern-based constraint; however, you do not have the flexibility that you would if you created a constraint specifically for checking constraints on the data. In this case you can build a custom method-level constraint annotation. The following is a custom or user-defined constraint called ImageContent.

```
package org.apache.openjpa.example.gallery.constraint;

import java.lang.annotation.Documented;
import java.lang.annotation.Retention;
import java.lang.annotation.Target;
import static java.lang.annotation.ElementType.METHOD;
import static java.lang.annotation.ElementType.FIELD;
import static java.lang.annotation.RetentionPolicy.RUNTIME;

import javax.validation.Constraint;
import javax.validation.Payload;

import org.apache.openjpa.example.gallery.model.ImageType;

@Documented
@Constraint(validatedBy = ImageContentValidator.class)
@Target({ METHOD, FIELD })
@Retention(RUNTIME)
public @interface ImageContent {
     String message() default "Image data is not a supported format.";
     Class<?>[] groups() default {};
  Class<? extends Payload>[] payload() default {};
  ImageType[] value() default { ImageType.GIF, ImageType.JPEG };
}
```

Next, you must create the validator class, ImageContentValidator. The logic within this validator gets implemented by the validation provider when the constraint is validated. The validator class is bound to the constraint annotation through the validatedBy attribute on the @Constraint annotation as shown in the following code:

```
package org.apache.openjpa.example.gallery.constraint;
import java.util.Arrays;
import java.util.List;
import javax.validation.ConstraintValidator;
```

```
import javax.validation.ConstraintValidatorContext;
import org.apache.openjpa.example.gallery.model.ImageType;
/**
 * Simple check that file format is of a supported type
 */
public class ImageContentValidator implements ConstraintValidator<ImageContent, byte[]> {
    private List<ImageType> allowedTypes = null;
    /**
     * Configure the constraint validator based on the image
     * types it should support.
     * @param constraint the constraint definition
     */
    public void initialize(ImageContent constraint) {
        allowedTypes = Arrays.asList(constraint.value());
    }
    /**
     *Validate a specified value.
     */
    public boolean isValid(byte[] value, ConstraintValidatorContext context) {
        if (value == null) {
            return false;
        }
        // Verify the GIF header is either GIF87 or GIF89
        if (allowedTypes.contains(ImageType.GIF)) {
            String gifHeader = new String(value, 0, 6);
            if (value.length >= 6 &&
                (gifHeader.equalsIgnoreCase("GIF87a") ||
                 gifHeader.equalsIgnoreCase("GIF89a"))) {
                return true;
            }
        }
        // Verify the JPEG begins with SOI and ends with EOI
        if (allowedTypes.contains(ImageType.JPEG)) {
            if (value.length >= 4 &&
                value[0] == 0xff && value[1] == 0xd8 &&
                value[value.length - 2] == 0xff && value[value.length -1] == 0xd9) {
                return true;
            }
        }
        // Unknown file format
        return false;
    }
}
```

Apply this new constraint to the getData() method on the Image class; for example:

```
@ImageContent
    public byte[] getData() {
        return data;
    }
```

When validation of the data attribute occurs, the isValid() method in the ImageContentValidator is started. This method contains logic for performing simple validation of the format of the binary image data. A potentially overlooked feature in the ImageContentValidator is that it can also validate for a specific image type. By definition, it accepts JPEG or GIF formats, but it can also validate for a specific format. For example, by changing the annotation to the following code example, the validator is instructed to only permit image data with valid JPEG content:

```
@ImageContent(ImageType.JPEG)
    public byte[] getData() {
        return data;
    }
```

Type-level constraints are also a consideration because you might need to validate combinations of attributes on an entity. In the previous examples validation constraints were used on individual attributes. Type-level constraints make it possible to provide collective validation. For example, the constraints

applied to the image entity validate that an image type is set (not null), the extension on the image file name is of a supported type, and the data format is correct for the indicated type. But, for example, it does not collectively validate that a file named `img0.gif` is of type GIF and the format of the data is for a valid GIF file image. For more information about type-level constraints, see the white paper, OpenJPA Bean Validation Primer, and the section "Type-level constraints."

Validation groups

Bean validation uses validation groups to determine what type of validation and when validation occurs.

There are no special interfaces to implement or annotations to apply to create a validation group. A validation group is denoted by a class definition.

Note: When using groups, use simple interfaces. Using a simple interface makes validation groups more usable in multiple environments. Whereas, if a class or entity definition is used as a validation group, it might pollute the object model of another application by bringing in domain classes and logic that do no make sense for the application. By default, if a validation group or multiple groups is not specified on an individual constraint, it is validated using the javax.validation.groups.Default group. Creating a custom group is as simple as creating a new interface definition.

For more information about validation groups, read the white paper, OpenJPA Bean Validation Primer, and the section "Validation groups."

JPA domain model

In addition to the Image entity are Album, Creator and Location persistent types. An Album entity contains a reference to collection of its Image entities. The Creator entity contains a reference to the album entities that the image Creator contributed to and a reference to the Image entities created. This provides full navigational capabilities to and from each of the entities in the domain. An embeddable location, has been added to image to support storing location information with the image.

The Album and Creator entities have standard built-in constraints. The embeddable location is more unique in that it demonstrates the use of the @Valid annotation to validate embedded objects. To embed location into an image, a new field and corresponding persistent properties are added to the Image class; for example:

```
private Location location;

    @Valid
    @Embedded
    public Location getLocation() {
        return location;
    }

    public void setLocation(Location location) {
        this.location = location;
    }
```

The @Valid annotation provides chained validation of embeddable objects within a JPA environment. Therefore, when image is validated, any constraints on the location it references are also validated. If @Valid is not specified, the location is not validated. In a JPA environment, chained validation through @Valid is only available for embeddable objects. Referenced entities and collections of entities are validated separately to prevent circular validation.

Bean validation and the JPA environment

The JPA 2.0 specification makes integration with the Bean Validation API simple. In a JSE environment, bean validation is enabled by default when you provide the Bean Validation API and a bean validation

provider on your runtime class path. In a Java EE 6 environment, the application server includes a bean validation provider so there is no need to bundle one with your application. In both environments, you must use a Version 2.0 `persistence.xml` file.

A Version 1.0 `persistence.xml` provides no means to configure bean validation. Requiring a Version 2.0 `persistence.xml` prevents a pure JPA 1.0 application from incurring the validation startup and runtime costs. This is important given that there is no standard means for a 1.0-based application to disable validation. In a Java EE 6 environment, enable validation in an existing 1.0 application by modifying the root element of your `persistence.xml` file. The following example represents the `persistence.xml` file:

```
<?xml version="1.0" encoding="UTF-8"?>
<persistence xmlns="http://java.sun.com/xml/ns/persistence"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://java.sun.com/xml/ns/persistence
    http://java.sun.com/xml/ns/persistence/persistence_2_0.xsd"
    version="2.0" >
...
</persistence>
```

Bean validation provides three modes of operation within the JPA environment:

- Auto

  Enables bean validation if a validation provider is available within the class path. Auto is the default.
- Callback

  When callback mode is specified, a bean validation provider must be available for use by the JPA provider. If not, the JPA provider throws an exception upon instantiation of a new JPA entity manager factory.
- None

  Disables bean validation for a particular persistence unit.

Auto mode simplifies deployment, but can lead to problems if validation does not take place because of a configuration problem.

Note: Use either none or callback mode explicitly for consistent behavior.
Also, if none is specified, JPA optimizes at startup and does not attempt to perform unexpected validation. Explicitly disabling validation is especially important in a Java EE 6 environment where the container is mandated to provide a validation provider. Therefore, unless specified, a JPA 2.0 application started in a container has validation enabled. This process adds additional processing during life cycle events.

There are two ways to configure validation modes in JPA 2.0. The simplest way is to add a validation-mode element to the `persistence.xml` with the wanted validation mode as shown in the following example:

```
 <persistence-unit name="auto-validation">
          ...
    <!-- Validation modes: AUTO, CALLBACK, NONE -->
    <validation-mode>AUTO</validation-mode>
    ...
  </persistence-unit>
```

The other way is to configure the validation mode programmatically by specifying the javax.persistence.validation.mode property with value auto, callback, or none when creating a new JPA entity manager factory as shown in the following example:

```
Map<String, String> props = new HashMap<String, String>();
  props.put("javax.persistence.validation.mode", "callback");
        EntityManagerFactory emf =
            Persistence.createEntityManagerFactory("validation", props);
```

Bean validation within JPA occurs during JPA life cycle event processing. If enabled, validation occurs at the final stage of the PrePersist, PreUpdate, and PreRemove life cycle events. Validation occurs only after

all user-defined life cycle events, since some of those events can modify the entity that is being validated. By default, JPA enables validation for the default validation group for PrePersist and PreUpdate life cycle events. If you must validate other validation groups or enable validation for the PreRemove event, you can specify the validation groups to validate each life cycle event in the `persistence.xml` as shown in the following example:

```
<persistence-unit name="non-default-validation-groups">
  <class>my.Entity</class>
  <validation-mode>CALLBACK</validation-mode>
  <properties>
   <property name="javax.persistence.validation.group.pre-persist"
       value="org.apache.openjpa.example.gallery.constraint.SequencedImageGroup"/>
   <property name="javax.persistence.validation.group.pre-update"
       value="org.apache.openjpa.example.gallery.constraint.SequencedImageGroup"/>
   <property name="javax.persistence.validation.group.pre-remove"
       value="javax.validation.groups.Default"/>
  </property>
 </persistence-unit>
```

The following example shows various stages of the JPA life cycle, including persist, update, and remove:

```
EntityManagerFactory emf =
            Persistence.createEntityManagerFactory("BeanValidation");
        EntityManager em = emf.createEntityManager();

        Location loc = new Location();
        loc.setCity("Rochester");
        loc.setState("MN");
        loc.setZipCode("55901");
        loc.setCountry("USA");

        // Create an Image with non-matching type and file extension
        Image img = new Image();
        img.setType(ImageType.JPEG);
        img.setFileName("Winter_01.gif");
        loadImage(img);
        img.setLocation(loc);

        // *** PERSIST ***
        try {
            em.getTransaction().begin();
            // Persist the entity with non-matching extension and type
            em.persist(img);
        } catch (ConstraintViolationException cve) {
            // Transaction was marked for rollback, roll it back and
            // start a new one
            em.getTransaction().rollback();
            em.getTransaction().begin();
            // Fix the file type and re-try the persist.
            img.setType(ImageType.GIF);
            em.persist(img);
            em.getTransaction().commit();
        }

        // *** UPDATE ***
        try {
            em.getTransaction().begin();
            // Modify the file name to a non-matching file name
            // and commit to trigger an update
            img.setFileName("Winter_01.jpg");
            em.getTransaction().commit();
        }  catch (ConstraintViolationException cve) {
            // Handle the exception.  The commit failed so the transaction
            // was already rolled back.
            handleConstraintViolation(cve);
        }
        // The update failure caused img to be detached. It must be merged back
```

```
        // into the persistence context.
        img = em.merge(img);

        // *** REMOVE ***
        em.getTransaction().begin();
        try {
            // Remove the type and commit to trigger removal
            img.setType(ImageType.GIF);
            em.remove(img);
        }  catch (ConstraintViolationException cve) {
            // Rollback the active transaction and handle the exception
            em.getTransaction().rollback();
            handleConstraintViolation(cve);
        }
        em.close();
        emf.close();
```

Exceptions

Validation errors can occur in any part of JPA life cycle.

If one or more constraints fail to validate during a life cycle event, a ConstraintViolationException is thrown by the JPA provider. The ConstraintViolationException thrown by the JPA provider includes a set of ConstraintViolations that occurred. Individual constraint violations contain information regarding the constraint, including: a message, the root bean or JPA entity, the leaf bean which is useful when validating JPA embeddable objects, the attribute which failed to validate, and the value that caused the failure. The following is a sample exception handling routine:

```
private void handleConstraintViolation(ConstraintViolationException cve) {
      Set<ConstraintViolation<?>> cvs = cve.getConstraintViolations();
   for (ConstraintViolation<?> cv : cvs) {
     System.out.println("------------------------------------------------");
           System.out.println("Violation: " + cv.getMessage());
           System.out.println("Entity: " + cv.getRootBeanClass().getSimpleName());
           // The violation occurred on a leaf bean (embeddable)
           if (cv.getLeafBean() != null && cv.getRootBean() != cv.getLeafBean()) {
              System.out.println("Embeddable: " +
cv.getLeafBean().getClass().getSimpleName());
           }
           System.out.println("Attribute: " + cv.getPropertyPath());
           System.out.println("Invalid value: " + cv.getInvalidValue());
      }
    }
```

Constraint violation processing is typically simple when using attribute-level constraints. If you are using a type-level validator with type-level constraints, it can be more difficult to determine which attribute or combination of attributes failed to validate. Also, the entire object is returned as the invalid value instead of an individual attribute. In cases where specific failure information is required, use of an attribute-level constraint or a custom constraint violation might be provided as described in the Bean Validation specification.

Sample

The JPA model and image gallery application usage scenario provided in this topic can be implemented through a sample that is provided in the white paper, *OpenJPA Bean Validation primer*.

Chapter 5. Developing Client applications

This page provides a starting point for finding information about application clients and client applications. Application clients provide a framework on which application code runs, so that your client applications can access information on the application server.

For example, an insurance company can use application clients to help offload work on the server and to perform specific tasks. Suppose an insurance agent wants to access and compile daily reports. The reports are based on insurance rates that are located on the server. The agent can use application clients to access the application server where the insurance rates are located. More introduction...

Developing client applications

A *client application* performs business logic and makes use of the framework provided by an underlying *client*. Developing the code for a client application depends on the objects and functions you want to exploit, and the programming model that you want to use.

Before you begin

Install the software development resources needed to develop client applications for use with WebSphere Application Server. During code development, you do not need access to the WebSphere Application Server. However, to assemble some types of client applications you need to install files for the client that provides the framework for the client application. Instead of installing WebSphere Application Server you can install the Application Client feature, which provides the same resources and clients to aid development of client applications.

About this task

To use a client application to access a remote object on an application server, develop your client application code as described in the following steps and the related topics. These topics only describe the client-specific considerations; they do not describe general client programming models, which you should already be familiar with. Samples for different types of client applications are provided with the Application Client.

Procedure

1. Choose the type of client that you want to use as a framework for your client application. Decision factors for choosing a client include whether you want to run a client application on Java EE or J2SE; whether you want ease of use with a small installation footprint or full-function with medium-large footprint; and whether you need licence to copy or redistribute the client. For more information about choosing the type of client, see “Choosing a type of client” on page 46.
2. Develop the client application code. The following substeps are a high-level general procedure. Information specific to a type of client is given in the related tasks.
   a. Create an instance of the object that you want to access on the remote server. You can use full Java Naming and Directory Interface (JNDI) support to get a suitable reference to administered objects from the server's JNDI namespace. Alternatively, you can get suitable references to objects programmatically without using JNDI.

      Using the javax.naming.InitialContext class, the client application program uses the lookup operation to access the Java Naming and Directory Interface (JNDI) namespace. The InitialContext class provides the lookup method to locate resources.

      You can compare the use of JNDI and programmatic techniques by looking at the samples provided for the Java EE client and Java thin client in an Application Client installation (for example, in `C:\wac70\samples\src\`):

- Java EE client use of JNDI for BasicCalculatorHome: `TechnologySamplesJ2EEClient\BasicCalculator\com\ibm\websphere\samples\technologysamples\basiccalcclient\BasicCalculatorClientJ2EE.java`
- Java thin client programmatic retrieval of BasicCalculatorHome: `TechnologySamplesThinClient\BasicCalculator\com\ibm\websphere\samples\technologysamples\basiccalcthinclient\BasicCalculatorClientThin.java`

b. Create a connection to the server. If the server runs with security enabled, you can configure secure connections.

c. Work with the objects to perform your business requirements. For example, send and receive JMS messages, update database entries, handle error conditions, and close resources used.

3. Compile or assemble the client application. This creates the JAR or EAR file that you can deploy to make the client application available for use.

   To compile your client application, include the JAR files needed in the CLASSPATH setting for the **javac** command; for example, any extra JAR files for the client application's own classes, JAR files for IBM® Thin clients used, and JAR files for JDBC provider classes.

   Attention: IBM-provided clients are not packaged with JDBC provider classes. For example, the WebSphere Application Server Version 7.0 Java Thin application client is not packaged with Apache Derby 10.2 classes. If your client application needs to use a database class (such as through the JNDI lookup of a datasource), you must obtain the class files from the database provider and make them available when compiling and running the client application.

What to do next

After you develop a client application, deploy it into the environment you want it to run.

Choosing a type of client

A *client* provides the framework for client applications that run separately from your application server.

About this task

Decision factors for choosing a client include whether you want to run a client application on Java Platform, Enterprise Edition (Java EE) or Java Platform, Standard Edition (J2SE) ; whether you want ease of use with a small installation footprint or full-function with medium to large footprint; and whether you need licence to copy or redistribute the client.

A usual first decision to make is do you want a client application that runs on Java EE or J2SE?. This leads you to choose from the main types of clients, as described in this topic. Otherwise, if you want to run an ActiveX program, or a Java applet, to interact with enterprise beans on WebSphere Application Server, your decision is only for one of those types of client.

Procedure

- J2SE

  If you want to run a lightweight client application, without the resource and processing cost of the Java EE platform for WebSphere Application Server on the client machine, then choose either the Java thin client or the stand-alone thin clients to run on J2SE.

  – If you want a client with a small installation footprint, that you can embed into your application, and that runs under an IBM, Sun, or HP-UX JRE, choose the stand-alone clients. Each client is an embeddable single jar with small footprint; for example, the Thin Client for JMS with WebSphere Application Server, `com.ibm.ws.sib.client.thin.jms_7.0.0.jar` needs about 2 MB of disk space. For notable restrictions of stand-alone clients, see the client comparison table in Client applications.

  – If you want a full-function client with medium to large footprint, that runs under the IBM JRE supplied, choose the Java thin client.

- If you run your client application to use the installed files of Application Client for WebSphere Application Server, you need about 400 MB of disk space (as part of the Application Client installation). Choose this option if you intend to copy and redistribute the Java thin client, within your licensing agreement.
- If you run your client application to use the installed files of the WebSphere Application Server, you need about 1 GB of disk space (as part of the Application Server installation). Choose this option if you do not mind the larger footprint, and you want maintenance support for the Java thin client.

However, the thin clients running on J2SE do not support a Java EE container that provides easy access to system services for object resolution, security, Reliability Availability and Servicability (RAS), and other services. Also, thin clients running on J2SE do not initialize any of the services that the client application might require.

- Java EE

  If you want to run a Java client application that makes full use of the Java EE platform features of WebSphere Application Server, then choose the Java EE client.

  – If you run your client application to use the installed files of Application Client for WebSphere Application Server, you need about 400 MB of disk space (as part of the Application Client installation). Choose this option if you intend to copy and redistribute the Java EE client, within your licensing agreement.
  – If you run your client application to use the installed files of the WebSphere Application Server, you need about 1 GB of disk space (as part of the Application Server installation). Choose this option if you do not mind the larger footprint, and you want maintenance support for the Java EE client.

  The Java EE client provides a container that client applications can use to access system services. The Java EE client also initializes the runtime environment for client applications.
- ActiveX to Enterprise JavaBeans (EJB) Bridge

  If you want ActiveX programs to access enterprise beans on WebSphere Application Server, choose this client.
- Applet client

  If you want a browser-based Java client application program that provides a richer and more robust environment than the one offered by the Applet > Servlet > enterprise bean model, choose this client.

What to do next

Develop your client application to use the type of client that you have chosen.

Developing stand-alone thin client applications

Develop the application code, then assemble the code into a client application that you can deploy on a client machine.

Procedure

- Get server objects and resources.

  A stand-alone client application can get suitable server objects and resources (like connection factories, JMS queues, and data sources) programmatically without using JNDI. Alternatively, a client application can use full JNDI support provided by the Thin Client for EJB.
- Compile stand-alone thin client applications. To compile your client application, include the JAR files needed in the CLASSPATH setting for the **javac** command; for example, any extra JAR files for the client application's own classes, JAR files for IBM Thin clients used, and JAR files for JDBC provider classes.

  For the stand-alone thin clients, the following JAR files are provided in the `/runtimes/` directory of either an Application Client installation or Application Server installation:

Table 2. JAR files for stand-alone thin clients. The product provides JAR files for stand-alone thin clients descriptions.

JAR file	Description
com.ibm.jaxws.thinclient_8.5.0.jar	IBM Thin Client for Java API for XML-based Web Services (JAX-WS). This file enables a Java SE client application to use the JAX-WS programming model to invoke web services that are hosted by the application server. You must use the endorsed APIs JAR file when starting Java because the Thin Client for JAX-WS requires APIs that are more current than what is available in JDKs to support JAX-WS 2.2 and JAXB 2.2 implementations.
com.ibm.ws.ejb.thinclient_8.5.0.jar	Thin Client for Enterprise Java Beans (EJB) . This file enables a Java SE client application to access remote Enterprise Java Beans on a server through Java Naming and Directory Interface (JNDI) look up. If this file is running with a non-IBM product JRE on a non-IBM product platform, the IBM ORB implementation library, com.ibm.ws.orb_8.5.0.jar, is also needed.
com.ibm.ws.jpa.thinclient_8.5.0.jar	IBM Thin Client for Java Persistence API (JPA). This file allows a Java SE client application to use the Java Persistence API (JPA) to store and retrieve persistent data without the use of an application server.
com.ibm.ws.messagingClient.jar	With the com.ibm.ws.ejb.thinclient_8.5.0.jar file, this file enables a Java SE client application to use WebSphere MQ messaging provider JMS resources from the WebSphere Application Server JNDI namespace. WebSphere MQ client jar files are also needed, and must be obtained from the WebSphere MQ product.
com.ibm.ws.orb_8.5.0.jar	The IBM ORB implementation library. This file is needed if the IBM Thin Client for EJB is running with a non-IBM product JRE on a non-IBM product platform.
com.ibm.ws.sib.client.thin.jms_8.5.0.jar	IBM Thin Client for Java Messaging Service (JMS). This file enables a Java SE client application to use JMS resources of the default messaging provider. For languages other than US English, you also need the additional language files from sibc.nls.zip, which provides language-specific resource bundles.
com.ibm.ws.sib.client_ExpeditorDRE_8.5.0.jar	The JMS Client packaged for Lotus® Expeditor.
com.ibm.ws.webservices.thinclient_8.5.0.jar	IBM Thin Client for Java API for XML-based RPC (JAX-RPC). This file enable a Java SE client application to use the JAX-RPC programming model to invoke web services that are hosted by the application server.

If you are running two or more of these stand-alone thin clients together, you must obtain all the clients that you are using from the same installation of Application Client for WebSphere Application Server, the same installation of the WebSphere Application Server product, or the same service refresh.

What to do next

After developing and compiling a stand-alone thin client application, you can deploy and run the client application.

Using JMS resources

If you are using JMS resources with the Thin Client for JMS with WebSphere Application Server, you can choose either to obtain these resources programmatically or using the Java Naming and Directory Interface (JNDI). Stand-alone Java SE JMS thin client applications that connect to an external WebSphere MQ queue manager can get administratively-created WebSphere MQ messaging provider JMS resources from the WebSphere Application Server Java Naming and Directory Interface (JNDI) namespace.

About this task

If you are using the Thin Client for JMS with WebSphere Application Server, you can obtain suitable JMS connection factories and references to JMS queues or topics programmatically without using JNDI. Alternatively, full JNDI support might be obtained from the Thin Client for EJB with WebSphere Application Server. For further information, refer to the Using JMS resources with the Thin Client for JMS with WebSphere Application Server topic.

If you are using a stand-alone Java SE JMS thin client application that connects to an external WebSphere MQ queue manager and want to obtain administratively-created WebSphere MQ messaging provider JMS resources from the WebSphere Application Server JNDI namespace, refer to the Obtaining WebSphere MQ JMS resources in the thin client environment topic.

Developing a Java EE client application

This topic provides the steps that are required to develop code for a Java Platform, Enterprise Edition (Java EE) client application.

About this task

Procedure

1. Write the client application program. Write the Java EE client application on any development machine. At this stage, you do not require access to the WebSphere Application Server.

   Rules: If you are writing a client application program that will run on z/OS®, the following rules apply:
   - Client programs may start their own transactions but cannot join in or start transactions in the WebSphere Application Server for z/OS run-time.
   - Client application code must contain a main method.
   - All input and output files for the client application must be in ASCII, because the client run-time runs in an ASCII JVM.

2. Assemble the client application JAR file using an assembly tool.

   The JNDI namespace knows what to return on a lookup because of the information assembled by the assembly tool.

   Assemble the client application on any development machine with the assembly tool installed.

   When you assemble your client application, provide the required information to initialize the runtime environment for your client application. For information about how to provide the required information, see the documentation for the assembly tool.

   When you configure resources for use by your client application, consider the following items:
   - Resource environment references are different than resource references. Resource environment references enables your client application to use a logical name to look up a resource bound into the server JNDI namespace. A resource reference enables your application to use a logical name to look up a local Java EE resource. The Java EE specification does not specify a particular implementation of a resource. The following table contains supported resource types and identifies the resources to which the WebSphere Application Server provides a client implementation.

Table 3. Supported resource types and resource identifiers. Supported resource types

Resource Type	Client Configuration Notes®	Client implementation provided by WebSphere Application Server
javax.sql.DataSource	Supports specification of any data source implementation class	No
java.net.URL	Supports specification of custom protocol handlers	Provided by Java Runtime Environment files
javax.mail.Session	Supports custom protocol configuration	Yes - POP3/POP3S, SMTP/SMTPS, IMAP/IMAPS
javax.jms.QueueConnectionFactory, javax.jms.TopicConnectionFactory, javax.jms.Queue, javax.jms.Topic	Supports configuration of WebSphere embedded messaging, IBM MQ Series and other JMS providers	Yes - WebSphere embedded messaging

3. Assemble the Enterprise Archive (EAR) file.

   The application is contained in an enterprise archive (EAR file). The EAR file is composed of:
   - Enterprise bean, application client, and user-defined modules or JAR files
   - Web applications or WAR files
   - Metadata describing the applications or application XML files

What to do next

After developing the Java EE client application code, deploy the application onto the client machines where the client application is to run.

Java EE client application class loading

When you run your Java Platform, Enterprise Edition (Java EE) application client, a hierarchy of class loaders is created to load classes used by your application.

The following list describes the hierarchy of class loaders:

- The Application Client for WebSphere Application Server (Application Client) run time sets this value to the `WAS_LOGGING` environment variable.
- The extensions class loader is a child to the bootstrap class loader. This class loader contains JAR files in the `java/jre/lib/ext` directory or those JAR files defined by the `-Djava.ext.dirs` parameter on the Java command. The Application Client client run time does not set `-Djava.ext.dirs` parameters. So it uses the JAR files in the `java/jre/lib/ext` directory.
- The system class loader contains JAR files and classes that are defined by the `-classpath` parameter on the Java command. The Application Client run time sets this parameter to the `WAS_CLASSPATH` environment variable.
- The WebSphere class loader loads the Application Client run time and any classes placed in the Application Client user directories. The directories used by this class loader are defined by the `WAS_EXT_DIRS` environment variable. The `WAS_BOOTCLASSPATH`, `WAS_CLASSPATH`, and the `WAS_EXT_DIRS` environment variables are set in the *app_server_root*`/bin/setupCmdLine` script for WebSphere Application Server installations, or in the *app_server_root*`/bin/setupClient` script for client installations.

As the Java EE application client run time initializes, additional class loaders are created as children of the WebSphere class loader. If your client application uses resources such as Java DataBase Connectivity (JDBC) API, Java Message Service (JMS) API, or Uniform Resource Locator (URL), a different class loader is created to load each of those resources. Finally, the Application Client run time sets the WebSphere class loader to load classes within the EAR file by processing the client JAR manifest repeatedly. The system class path, defined by the CLASSPATH environment variable is never used and is not part of the hierarchy of class loaders.

To package your client application correctly, you must understand which class loader loads your classes. When the Java code loads a class, the class loader used to load that class is assigned to it. Any classes subsequently loaded by that class will use that class loader or any of its parents, but it will not use children class loaders.

In some cases the Application Client run time can detect when your client application class is loaded by a different class loader from the one created for it by the Application Client run time. When this detection occurs, you see the following message:

```
WSCL0205W: The incorrect class loader was used to load [0]
```

This message occurs when your client application class is loaded by one of the parent class loaders in the hierarchy. This situation is typically caused by having the same classes in the EAR file and on the hard drive. If one of the parent class loaders locates a class, that class loader loads it before the Application Client run time class loader. In some cases, your client application still functions correctly. In most cases, however, you receive “class not found” exceptions.

Configuring the classpath fields

When packaging your Java EE client application, you must configure various class path fields. Ideally, you should package everything required by your application into your EAR file. This is the easiest way to distribute your Java EE client application to your clients. However, you should not package such resources as JDBC APIs, JMS APIs, or URLs. In the case of these resources, use class path references to access those classes on the hard drive. You might also have other classes installed on your client machines that

you do not need to redistribute. In this case, you also want to use classpath references to access the classes on the hard drive, as described later in this topic.

Referencing classes within the EAR file

WebSphere product Java EE applications do not use the system class path. Use the MANIFEST Class path entry to refer to other JAR files within the EAR file. Configure these values using an assembly tool. For example, if your client application needs to access the path of the EJB JAR file, add the deployed enterprise bean module name to your application client class path. The format of the Class path field for each of the different modules (Application Client, EJB, Web) is the same:

- The values must refer to JAR and class files that are contained within the EAR file.
- The values must be relative to the root of the EAR file.
- The values cannot refer to absolute paths in the file systems.
- Multiple values must be separated by spaces, not colons or semicolons.

Attention: This is the Java method for allowing applications to function platform independent.

Typically, you add modules (JAR files) to the root of the EAR file. In this case, you only need to specify the name of the module (JAR file) in the Class path field. If you choose to add a module with a path, you need to specify the path relative to the root of the EAR file.

For referencing class files, you must specify the directory relative to the root of the EAR file. With an assembly tool, you can add individual class files to the EAR file. It is recommended that these additional class files are packaged in a JAR file. Add this JAR file to the module Class path fields. If you add class files to the root of the EAR file, add `./` to the module Class path fields.

Consider the following example directory structure in which the file myapp.ear contains an application client JAR file named `myclient.jar` and a `mybeans.jar` EJB module. Additional classes reside in `class1.jar` and `utility/class2.zip` files. A class file named `xyz.class` is not packaged in a JAR file but is in the root of the EAR file. Specify `./ mybeans.jar utility/class2.zip class1.jar` as the value of the Classpath property. The search order is: `myapp.ear/myclient.jar myapp.ear/xyz.class myapp.ear/mybeans.jar myapp.ear/utility/class2.zip myapp.ear/class1.jar`

Referencing classes that are not in the EAR file

Use the launchClient `-CCclasspath` parameter. This parameter is specified at run time and takes platform-specific class path values, which means multiple values are separated by semi-colons or colons. The client and the server are similar in this respect.

Resource class paths

When you configure resources used by your client application using the Application Client Resource Configuration Tool (ACRCT), or the z/OS ACRCT scripting tool, you can specify class paths that are required by the resource. For example, if your application is using a JDBC to a DB2® database, add `db2java.zip` to the class path field of the database provider. These class path values are platform-specific and require semi-colons or colons to separate multiple values.

On WebSphere Application Server for i5/OS®, if you use the IBM Developer Kit for Java JDBC provider to access DB2/400, you do not have to add the `db2_classes.jar` file to the class path. However, if you use the IBM Toolbox for Java JDBC provider, specify the location of the `jt400.jar` file.

Using the launchClient API

If you use the **`launchClient`** command, the WebSphere class loader hierarchy is created for you. However, if you use the launchClient API, you must perform this setup yourself. Copy the `launchClient` shell command in defining the Java system properties.

Assembling Java EE client applications

Application client projects contain programs that run on networked client systems. An application client project is deployed as a Java archive (JAR) file.

About this task

Assemble a client module to contain client application code. Group enterprise beans, web components, and resource adapter code in separate modules.

Use an assembly tool to assemble an application client module in any of the following ways:
- Import an existing application client JAR file.
- Create a new application client module.

Procedure

1. Start an assembly tool.
2. If you have not done so already, configure the assembly tool for work on Java Platform, Enterprise Edition (Java EE) modules. Ensure that Java EE capability is enabled.
3. Migrate application client JAR files created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to an assembly tool. To migrate files, import your application client JAR files to the assembly tool.
4. Create a new client application.
5. Verify the contents of the new client application in either of the following ways:
   - In the Project Explorer view, expand **Application Client Projects** and view the new module.
   - Click **Window > Show View > Navigator** to see the associated files for the application client module in a Navigator view.

What to do next

After you finish assembling all of your application's modules, you are ready to deploy your application.

Developing a Java thin client application

Develop the application code, then assemble the code into a client application that you can deploy on a client machine.

About this task

To develop a Java thin client application, you developing the application code, generate the client bindings needed for the enterprise bean and CORBA objects, and package these pieces together to install on the client machine.

With the Java thin client, the client application must code explicitly the fully-qualified location for each resource that it uses. For example, a Java thin client application that looks up an enterprise bean Home contains the following code:

```
java.lang.Object ejbHome =
  initialContext.lookup("the/fully/qualified/path/to/actual/home/in/namespace/MyEJBHome");
MyEJBHome = (MyEJBHome)javax.rmi.PortableRemoteObject.narrow(ejbHome,  MyEJBHome.class);
```

The Java thin client application must know the fully-qualified physical location of the enterprise bean Home in the namespace. If this location changes, the thin client application must also change the value placed on the lookup() statement.

To compile a Java thin client application, include the client jars file needed by the application in the CLASSPATH setting for the javac command.

Developing ActiveX client application code

This topic provides an outline for developing an ActiveX Windows program, such as Visual Basic, VBScript, and Active Server Pages, to use the WebSphere ActiveX to EJB bridge to access enterprise beans.

Before you begin

Important: This topic assumes that you are familiar with ActiveX programming and developing on the Windows platform. For information about the programming concepts of ActiveX application clients and the ActiveX to EJB bridge, refer to the ActiveX to Enterprise JavaBeans™ (EJB) Bridge topic, and related topics.

Consider the information given in ActiveX to EJB bridge as good programming guidelines.

About this task

To use the ActiveX to EJB bridge to access a Java class, develop your ActiveX program to complete the following steps:

Procedure

1. Create an instance of the XJB.JClassFactory object.
2. Create Java virtual machine (JVM) code within the ActiveX program process, by calling the XJBInit() method of the XJB.JClassFactory object. After the ActiveX program has created an XJB.JClassFactory object and called the XJBInit() method, the JVM code is initialized and ready for use.
3. Create a proxy object for the Java class, by using the XJB.JClassFactory FindClass() and NewInstance() methods. The ActiveX program can use the proxy object to access the Java class, object fields, and methods.
4. Call methods on the Java class, using the Java method invocation syntax, and access Java fields as required.
5. Use the helper functions to do the conversion in cases where automatic conversion is not possible. You can convert between the following data types:
   - Java Byte and Visual Basic Byte
   - Visual Basic Currency types and Java 64-bit
6. Implement methods to handle any errors returned from the Java class. In Visual Basic or VBScript, use the Err.Number and Err.Description fields to determine the actual Java error.

Example

- Viewing a System.out message
- ActiveX client application using helper methods for data type conversion

Viewing a System.out message: The ActiveX to Enterprise JavaBeans (EJB) bridge does not have a console available to view Java System.out messages. To view these messages when running a stand-alone client program (such as Visual Basic), redirect the output to a file.

The following example illustrates how to redirect output to a file:

```
launchClientXJB.bat MyProgram.exe > output.txt
```

- To view the System.out messages when running a Service program such as Active Server Pages, override the Java System.out OutputStream object to FileOutputStream. For example, in VBScript:

```
'Redirect system.out to a file
' Assume that oXJB is an initialized XJB.JClassFactory object
 Dim clsSystem
 Dim oOS
 Dim oPS
 Dim oArgs
```

```
' Get the System class
  Set clsSystem = oXJB.FindClass("java.lang.System")

' Create a FileOutputStream object
' Create a PrintStream object and assign to it our FileOutputStream
  Set oArgs = oXJB.GetArgsContainer  oArgs.AddObject "java.io.OutputStream", oOS
  Set oPS = oXJB.NewInstance(oXJB.FindClass("java.io.PrintStream"), oArgs)

' Set our System OutputStream to our file
  clsSystem.setOut oPS
```

ActiveX client application using helper methods for data type conversion. Generally, data type conversion between ActiveX (Visual Basic and VBScript) and Java methods occurs automatically, as described in ActiveX to EJB bridge, converting data types. However, the byte helper function and currency helper function are provided for cases where automatic conversion is not possible.

- Byte helper function

  Because the Java Byte data type is signed (-127 through 128) and the Visual Basic Byte data type is unsigned (0 through 255), convert unsigned Bytes to a Visual Basic Integers, which look like the Java signed byte. To make this conversion, you can use the following helper function:

```
Private Function GetIntFromJavaByte(Byte jByte) as Integer
      GetIntFromJavaByte = (CInt(jByte) + 128) Mod 256 - 128
End Function
```

- Currency helper function

  Visual Basic 6.0 cannot properly handle 64-bit integers like Java methods can (as the Long data type). Therefore, Visual Basic uses the Currency type, which is intrinsically a 64-bit data type. The only side effect of using the Currency type (the Variant type VT_CY) is that a decimal point is inserted into the type. To extract and manipulate the 64-bit Long value in Visual Basic, use code like the following example. For more details on this technique for converting Currency data types, see Q189862, “HOWTO: Do 64-bit Arithmetic in VBA”, on the Microsoft Knowledge Base.

```
' Currency Helper Types
Private Type MungeCurr
    Value As Currency
End Type
Private Type Munge2Long
    LoValue As Long
    HiValue As Long
End Type

' Currency Helper Functions
Private Function CurrToText(ByVal Value As Currency) As String
    Dim Temp As String, L As Long
    Temp = Format$(Value, "#.0000")
    L = Len(Temp)
    Temp = Left$(Temp, L - 5) & Right$(Temp, 4)
    Do While Len(Temp) > 1 And Left$(Temp, 1) = "0"
        Temp = Mid$(Temp, 2)
    Loop
    Do While Len(Temp) > 2 And Left$(Temp, 2) = "-0"
        Temp = "-" & Mid$(Temp, 3)
    Loop
    CurrToText = Temp
End Function

Private Function TextToCurr(ByVal Value As String) As Currency
    Dim L As Long, Negative As Boolean
    Value = Trim$(Value)
    If Left$(Value, 1) = "-" Then
        Negative = True
        Value = Mid$(Value, 2)
    End If
```

```
    L = Len(Value)
    If L < 4 Then
        TextToCurr = CCur(IIf(Negative, "-0.", "0.") & _
                          Right$("0000" & Value, 4))
    Else
        TextToCurr = CCur(IIf(Negative, "-", "") & _
                          Left$(Value, L - 4) & "." & Right$(Value, 4))
    End If
End Function

' Java Long as Currency Usage Example
Dim LC As MungeCurr
Dim L2 As Munge2Long

' Assign a Currency Value (really a Java Long)
' to the MungeCurr type variable
LC.Value = cyTestIn

' Coerce the value to the Munge2Long type variable
LSet L2 = LC

' Perform some operation on the value, now that we
' have it available in two 32-bit chunks
L2.LoValue = L2.LoValue + 1

' Coerce the Munge value back into a currency value
LSet LC = L2
cyTestIn = LC.Value
```

What to do next

After you develop the ActiveX client application code, deploy and run the ActiveX application.

Example: Using an ActiveX client application to access a Java class or object

This reference topic provides an example of using Java proxy objects with the ActiveX to Enterprise JavaBeans (EJB) bridge.

To use Java proxy objects with the ActiveX to Enterprise JavaBeans (EJB) bridge:

- After an ActiveX client program (Visual Basic, VBScript, or Active Server Pages (ASP)) has initialized the XJB.JClassFactory object and thereby, the Java virtual machine (JVM), the client program can access Java classes and initialize Java objects. To complete this action, the client program uses the XJB.JClassFactory FindClass() and NewInstance() methods.
- In Java programming, two ways exists to access Java classes: direct invocation through the Java compiler and through the Java Reflection interface. Because the ActiveX to Java bridge needs no compilation and is a complete run-time interface to the Java code, the bridge depends on the latter Reflection interface to access its classes, objects, methods and fields. The XJB.JClassFactory FindClass() and NewInstance() methods behave very similarly to the Java Class.forName() and the Method.invoke() and Field.invoke() methods.
- XJB.JClassFactory.FindClass() takes the fully qualified class name as its only parameter and returns a Proxy Object (JClassProxy). You can use the returned Proxy object like a normal Java Class object and call static methods and access static fields. You can also create a Class Instance (or object), as described later in this section. For example, the following Visual Basic code extract returns a Proxy object for the java.lang.Integer Java class:

  ```
  ...
  Dim clsMyString as Object
  Set clsMyString = oXJB.FindClass("java.lang.Integer")
  ```

- After the proxy is created, you can access its static information directly. For example, you can use the following code extract to convert a decimal integer to its hexadecimal representation:

```
...
Dim strHexValue as String
strHexValue = clsMyString.toHexString(CLng(255))
```

- The equivalent Java syntax is: `static String toHexString(int i)`. Because ints units in Java programming are really 32-bit (which translates to Long in Visual Basic), the CLng() function converts the value from the default int to a long. Also, even though the toHexString() function returns a java.lang.String, the code extract does not return an Object proxy. Instead, the returned java.lang.String is automatically converted to a native Visual Basic string.

  To create an object from a class, you use the JClassFactory.NewInstance() method. This method creates an Object instance and takes whatever parameters your class constructor needs. Once the object is created, you have access to all of its public instance methods and fields. For example, you can use the following Visual Basic code extract to create an instance of the java.lang.Integer string:

```
...
Dim oMyInteger as Object
set oMyInteger = oXJB.NewInstance(CLng(255))

Dim strMyInteger as String
strMyInteger = oMyInteger.toString
```

Example: ActiveX client application calling Java methods

In the ActiveX to Enterprise Java Beans (EJB) bridge, methods are called using the native language method invocation syntax.

The following differences between Java invocation and ActiveX Automation invocation exist:

- Unlike Java methods, ActiveX does not support method (and constructor) polymorphism; that is, you cannot have two methods in the same class with the same name.
- Java methods are case-sensitive, but ActiveX Automation is not case-sensitive.
- To compensate for Java polymorphic behavior, give the exact parameter types to the method call. The parameter types determine the correct method to invoke. For a listing of correct types to use, see ActiveX to EJB bridge, converting data types.
- For example, the following Visual Basic code fails if the CLng() method was not present or the toHexString syntax was incorrectly typed as ToHexString:

```
...
Dim strHexValue as String
strHexValue = clsMyString.toHexString(CLng(255))
```

- Sometimes it is difficult to force some development environments to leave the case of your method calls unchanged. For example, in Visual Basic if you want to call a method close() (lowercase), the Visual Basic code capitalizes it “Close()”. In Visual Basic, the only way to effectively work around this behavior is to use the CallByName() method. For example:

```
o.Close(123)                                'Incorrect...
CallByName(o, "close", vbMethod, 123)       'Correct...
```

  or in VBScript, use the Eval function:

```
o.Close(123)                                 'Incorrect...
Eval("o.Close(123)")                         'Correct...
```

- The return value of a function is always converted dynamically to the correct type. However, you must take care to use the set keyword in Visual Basic. If you expect a non-primitive data type to return, you must use set. (If you expect a primitive data type to return, you do not need to use set.) See the following example for more explanation:

```
Set oMyObject = o.getObject
iMyInt = o.getInt
```

- In some cases, you might not know the type of object returning from a method call, because wrapper classes are converted automatically to primitives (for example, java.lang.Integer returns an ActiveX Automation Long). In such cases, you might need to use your language built-in exception handling techniques to try to coerce the returned type (for example, On Error and Err.Number in Visual Basic).
- Methods with character arguments

Because ActiveX Automation does not natively support character types supported by Java methods, the ActiveX to EJB bridge uses strings (byte or VT_I1 do not work because characters have multiple bytes in Java code). If you try to call a method that takes a char or java.lang.Character type you must use the JMethodArgs argument container to pass character values to methods or constructors. For more information about how this argument container is used, see Methods with “Object” Type as Argument and Abstract Arguments.

- Methods with “Object” Type as Argument and Abstract Arguments

  Because of the polymorphic nature of Java programming, the ActiveX to Java bridge uses direct argument type mapping to find a method. This method works well in most cases, but sometimes methods are declared with a Parent or Abstract class as an argument type (for example, java.lang.Object). You need the ability to send an object of arbitrary type to a method. To acquire this ability, you must use the XJB.JMethodArgs object to coerce your parameters to match the parameters on your method. You can get a JMethodArgs instance by using the JClassFactory.GetArgsContainer() method.

  The JMethodArgs object is a container for method parameters or arguments. This container enables you to add parameters to it one-by-one and then you can send the JMethodArgs object to your method call. The JClassProxy and JObjectProxy objects recognize the JMethodArgs object and attempt to find the correct method and let the Java language coerce your parameters appropriately.

  For example, to add an element to a Hashtable object the method syntax is `Object put(Object key, Object value)`. In Visual Basic, the method usage looks like the following example code:

```
Dim oMyHashtable as Object
Set oMyHashtable = _
    oXJB.NewInstance(oXJB.FindClass("java.utility.Hashtable"))

' This line will not work. The ActiveX to EJB bridge cannot find a method
' called "put" that has a short and String as a parameter:
oMyHashtable.put 100, "Dogs"
oMyHashtable.put 200, "Cats"

' You must use a XJB.JMethodArgs object instead:
Dim oMyHashtableArgs as Object
Set oMyHashtableArgs = oXJB.GetArgsContainer
oMyHashtableArgs.AddObject("java.lang.Object", 100)
oMyHashtableArgs.AddObject("java.lang.Object", "Dogs")

oMyHashtable.put oMyHashTableArgs
' Reuse the same JMethodArgs object by clearing it.
oMyHashtableArgs.Clear
oMyHashtableArgs.AddObject("java.lang.Object", 200)
oMyHashtableArgs.AddObject("java.lang.Object", "Cats")

oMyHashtable.put oMyHashTableArgs
```

ActiveX client programming best practices

The best way to access Java components is to use the Java language. It is recommended that you do as much programming as possible in the Java language and use a small simple interface between your COM Automation container (for example, Visual Basic) and the Java code. This interface avoids any overhead and performance problems that can occur when moving across the interface.

best-practices: The following topics are covered:

- Visual Basic guidelines
- CScript and Windows Scripting Host
- Active Server Pages guidelines
- J2EE guidelines

Visual Basic guidelines

The following guidelines are intended to help optimize your use of the ActiveX to EJB bridge with Visual Basic:

- Launch the Visual Basic replication through the `launchClientXJB.bat` file. If you want to run your Visual Basic application through the Visual Basic debugger, run the Visual Basic integrated development environment (IDE) within the ActiveX to EJB bridge environment. After you create your Visual Basic project, you can launch it from a command line; for example, `launchClientXJB MyApplication.vbp`. You can also launch the Visual Basic application alone in the ActiveX to EJB environment, by changing the Visual Basic shortcut on the Windows Start menu so that the `launchClientXJB.bat` file precedes the call to the `VB6.EXE` file.
- Exit the Visual Basic IDE before debugging programs.

  Because the Java virtual machine (JVM) code attaches to the running process, you must exit the Visual Basic editor before debugging your program. If you run the process, then exit your program within the Visual Basic IDE, the JVM code continues to run and you reattach the same JVM code when XJBInit() is called by the debugger. This causes problems if you try to update XJBInit() arguments (for example, classpath) because the changes are not be applied until you restart the Visual Basic program.
- Store the XJB.JClassFactory object globally.

  Because you cannot unload or reinitialize the JVM code, cache the resulting XJB.JClassFactory object as a global variable. The overhead of treating this object as a global variable or passing a single reference around is much less than recreating a new XJB.JClassFactory object and calling the XJBInit() argument more than once.

CScript and Windows Scripting Host

The following guidelines intend to help optimize your use of the ActiveX to EJB bridge with CScript and Windows Scripting Host (WSH):

- Launch in ActiveX to EJB environment.

  Launch the VBScript files in the ActiveX to EJB bridge environment, to run VBScript files in `.vbs` files. Two common ways exist to launch your script:
  - `launchClientXJB MyScript.vbs`
  - `launchClientXJB cscript MyScript.vbs`

Active Server Pages guidelines

The following guidelines intend to help optimize your use of the ActiveX to EJB bridge with Active Server Pages software:

- Use the ActiveX to EJB Helper functions from the Active Server Pages Application.

  Because Active Server Pages (ASP) code typically use VBScript, you can use the included helper functions in any VBScript environment with minor changes. For more information about these helper functions, see Helper functions for data type conversion. To run outside of the ASP environment, remove or change all references to the Server, Request, Response, Application and Session objects; for example, change `Server.CreateObject` to `CreateObject`.
- Set JRE path globally in system.

  The XJB.JClassFactory object must be able to find the Java run time dynamic link library (DLL) when initializing. In Internet Information Server, you cannot specify a path for its processes independently; you must set the process paths in the system PATH variable. You can only have a single JVM version available on a machine using the ASP application. Also, remember that after you change the system PATH variable you must reboot the Internet Information Server machine so that the Internet Information Server can see the change.
- Set the system TEMP environment variable.

  If the system TEMP environment variable is not set, Internet Information Server stores all temporary files in the `WINNT` directory, which is usually not desired.
- Use high isolation or an isolated process.

When using the ActiveX to Java bridge with Active Server Pages software, creating your web application in its own process is recommended. You can only load one JVM instruction in a single process and if you want to have more than one application running with different JVM environment options (for example, different classpaths), then you need to have separate processes.

- Use the Application Unload option.

  When debugging your application, use `Unload` when viewing your ASP application properties in the Internet Information Server administration console to unload the process from memory and thereby unload the JVM code.
- Run one process per application.

  Use only one ASP application per J2EE application or JVM environment, in your ASP environment. If you need separate class paths or JVM settings, you need separate ASP applications (virtual directories with high isolation or an isolated process).
- Store the XJB.JClassFactory object in application scope.

  Because of the one-to-one relationship required between a JVM instruction and a process, and because the JVM code can never detach or shut down from a process independently, cache the XJB.JClassFactory object at application scope and call the XJBInit() method only once.

  Because the ActiveX to EJB bridge employs a free-threaded marshaler, take advantage of the multi-threaded nature of Internet Information Server and the ASP environment. If you choose to reinitialize the XJB.JClassFactory object at Page scope (local variables), then the XJBInit() method can only initialize your local XJB.JClassFactory variable. It is more efficient to use the XJBInit() method once.
- Use VBScript conversion functions.

  Because VBScript code only supports variant data types, use the CStr(), CByte(), CBool(), CCur(), CInt(), Clng(), CSng() and CDbl() functions to tell the activeX to EJB bridge which data type you are using; for example oMyObject.Foo(CDbl(1.234)).

J2EE guidelines

The following guidelines are intended to help optimize your use of the ActiveX to EJB bridge with the J2EE environment;

- Store client container objects globally.

  Because you can only have one JVM instruction per process, and a single J2EE client container (com.ibm.websphere.client.applicationclient.launchClient) per JVM instruction, initialize your J2EE client container only once and reuse it. For ASP applications, store the J2EE client container in an application level variable and initialize it only once (either on the Application_OnStart() event in the `global.asa` file or by checking to see if it IsEmpty()).

  A side effect to storing the client container object globally is that you cannot change the client container parameters without destroying the object and creating a new one. These parameters include the EAR file, BootstrapHost, class path, and so on. If you run a Visual Basic application and want to change the client container parameters, you must end the application and restart it. If you run an Active Server Pages application, you must first unload the application from Internet Information Server (see “Use the Application Unload Button” under Active Server Pages guidelines). Then load the Active Server Pages application with the different client container parameters. The parameters set the first time the Active Server Pages application loads. Since the client container is stored on the Internet Information Server, all the browser clients share the parameters using the Active Server Pages application. This behavior is normal for Active Server Pages code, but can be confusing when you try to run to different WebSphere Application Servers using the same Active Server Pages application, which is not supported.
- Reuse custom temporary directory for EAR file extraction.

  By default, the client container launches and extracts the application `.ear` file to your `temp` directory and then sets up the thread class loader to use the extracted EAR file directory and the JAR files included in the client JAR manifest. This process is time consuming and because of some limitations with JVM shutdown through Java Native Interface (JNI) and file locking, these files are never cleaned up.

  Specifically, each time the client container launch() method is called, it extracts the EAR file to a random directory name in your temporary directory on your hard drive. The current Java thread class loader is

then changed to point to this extracted directory which in turn locks the files within. In a normal J2EE Java client, these files automatically clean up after the application exits. This cleanup occurs when the client container shutdown hook is called (which never happens in the ActiveX to EJB bridge), which leaves the temporary directory there.

To avoid these problems, you can specify a directory to extract the EAR file by setting the com.ibm.websphere.client.applicationclient.archivedir Java system property before calling the client container launch() method. If the directory does not exist or is empty, you extract the EAR file normally. If the EAR file was previously extracted, the directory is reused. This feature is particularly important for server processes (for example, ASP), which can stop and restart, potentially calling the launchClient() method several times.

If you need to update your EAR file, delete the temporary directory first. The next time you create the client container object, it extracts the new EAR file to the temporary directory. If you do not delete the temporary directory or change the system property value to point to a different temporary directory, the client container reuses the currently extracted EAR file, and does not use your changed EAR file.

Note: When specifying the com.ibm.websphere.client.applicationclient.archivedir property, ensure that the directory you specify is unique for each EAR file you use. For example, do not point `MyEar1.ear` and `MyEar2.ear` files to the same directory.

If you choose not to use this system property, go regularly to your Windows `temp` directory and delete the WSTMP* subdirectories. Over a relatively short period of time, these subdirectories can waste a significant amount of space on the hard drive.

ActiveX client programming, tips for passing arrays

Arrays are very similar between Java and Automation containers like Visual Basic and VBScript. This topic provides some important points to consider when passing arrays back and forth between these containers.

Here are some important points to consider when passing arrays back and forth between these containers:

- Java arrays cannot mix types. All Java arrays contain a single type, so when passing arrays of variants to a Java array, you must make sure that all of the elements in the variant array are of the same base type. For example, in Visual Basic code:

```
...
Dim VariantArray(1) as Variant
VariantArray(0) = CLng(123)
VariantArray(1) = CDbl(123.4)
oMyJavaObject.foo(VariantArray) '     Illegal!

VariantArray(0) = CLng(123)
VariantArray(1) = CLng(1234)
oMyJavaObject.foo(VariantArray) '     This works
```

- Arrays of primitive types are converted using the rules defined in primitive data type conversion.
- Arrays of Java objects are handled through arrays of JObjectProxy objects.
- Arrays of JObjectProxy objects must be fully initialized and of the correct associated Java type. When initializing an array in Visual Basic (for example, Dim oJavaObjects(1) as Object), you must set each object to a JObjectProxy object before you send the array to a Java object. The bridge is unable to determine the type of null or empty object values.
- When receiving an array from a Java method, the lower-bound is always zero. Java methods only support zero-based arrays.
- Nested or multidimensional arrays are treated as zero-based multidimensional arrays in Visual Basic and VBScript containers.
- Uninitialized arrays or Array Types are unsupported. When calling a Java method that takes an array of objects as a parameter, you must fully initialize the array of JObjectProxy objects.

ActiveX client programming, Java field programming tips

Using the ActiveX to Enterprise JavaBeans (EJB) bridge to access Java fields has the same case sensitivity issue that it has when invoking methods. Field names must use the same case as the Java field syntax.

Visual Basic code has the same problem with unsolicited case changing on fields as it does with methods. (For more information about this problem, see ActiveX to EJB bridge, calling Java methods). You might use the CallByName() function to set a field in the same way that you call a method in some cases. For fields, use VBLet for primitive types and VBSet for objects. For example:

```
o.MyField = 123                          'Incorrect...
CallByName(o, "MyField", vbLet, 123)     'Correct...
```

or in VBScript:

```
o.MyField = 123                           'Incorrect...
Eval("o.myField = 123")                   'Correct...
```

ActiveX client programming, JClassProxy and JObjectProxy classes

The majority of tasks for accessing your Java classes and objects are handled with the JClassProxy and JObjectProxy objects. This topic provides reference information about the object classes of the ActiveX to Enterprise Java Beans (EJB) bridge.

JClassFactory is the object used to access the majority of Java Virtual Machine (JVM) features. This object handles JVM initialization, accesses classes and creates class instances (objects). Use the JClassProxy and JObjectProxy objects to access the majority of your Java classes and objects:

- XJBInit(String astrJavaParameterArray())

  Initializes the JVM environment using an array of strings that represent the command line parameters you normally send to the `java.exe` file.

  If you have invalid parameters in the XJBInit() string array, the following error is displayed:

  ```
  Error: 0x6002 "XJBJNI::Init() Failed to create VM" when calling XJBInit()
  ```

  If you have C++ logging enabled, the activity log displays the invalid parameter.
- JClassProxy FindClass(String strClassName)

  Uses the current thread class loader to load the specified fully qualified class name and returns a JClassProxy object representing the Java Class object.
- JObjectProxy NewInstance()

  Creates a Class instance for the specified JClassProxy object using the parameters supplied to call the Class constructor. For more information about using the JMethodArgs method, see ActiveX to EJB bridge, calling Java methods.

```
JObjectProxy NewInstance(JClassFactory obj, Variant vArg1, Variant vArg2, Variant vArg3, ...)
JObjectProxy NewInstance(JClassFactory obj, JMethodArgs args)
```

- JMethodArgs GetArgsContainer()

  Returns a JMethodArgs object (Class instance).

  You can create a JClassProxy object from the JClassFactory.FindClass() method and from any Java method call that normally return a Java Class object. You can use this object as if you had direct access to the Java Class object. All of the class static methods and fields are accessible as are the java.lang.Class methods. In case of a clash between static method names of the reflected user class and those of the java.lang.Class (for example, getName()), the reflected static methods would execute first.

  For example, the following is a static method called getName(). The java.lang.Class object also has a method called getName():

  – In Java:

  ```
  class foo{
   foo(){};
   public static String getName(){return "abcdef";}
   public static String getName2(){return "ghijkl";}
   public String toString2(){return "xyz";}
  }
  ```

  – In Visual Basic:

```
...
Dim clsFoo as Object
set clsFoo = oXJB.FindClass("foo")
clsFoo.getName()  ' Returns "abcdef" from the static foo class
clsFoo.getName2() ' Returns "ghijkl" from the static foo class
clsFoo.toString() ' Returns "class foo" from the java.lang.Class object.
oFoo = oXJB.NewInstance(clsFoo)
oFoo.toString() ' Returns some text from the java.lang.Object's
                ' toString() method which foo inherits from.
oFoo.toString2() ' Returns "xyz" from the foo class instance
```

You can create a JObjectProxy object from the JClassFactory.NewInstance() method, and can be created from any Java method call that normally returns a Class instance object. You can use this object as if you had direct access to the Java object and can access all the static methods and fields of the object. All of object instance methods and fields are accessible (including those accessible through inheritance).

The JMethodArgs object is created from the JClassFactory.GetArgsContainer() method. Use this object as a container for method and constructor arguments. You must use this object when overriding the object type when calling a method (for example, when sending a java.lang.String JProxyObject type to a constructor that normally takes a java.lang.Object type).

You can use two groups of methods to add arguments to the collection: Add and Set. You can use Add to add arguments in the order that they are declared. Alternatively, you can use Set to set an argument based on its position in the argument list (where the first argument is in position 1).

For example, if you had a Java Object Foo that took a constructor of Foo (int, String, Object), you could use a JMethodArgs object as shown in the following code extract:

```
...
Dim oArgs as Object
set oArgs = oXJB.GetArgsContainer()

oArgs.AddInt(CLng(12345))
oArgs.AddString("Apples")
oArgs.AddObject("java.lang.Object", oSomeJObjectProxy)

Dim clsFoo as Object
Dim oFoo as Object
set clsFoo = oXJB.FindClass("com.mypackage.foo")
set oFoo = oXJB.NewInstance(clsFoo, oArgs)

' To reuse the oArgs object, just clear it and use the add method
' again, or alternatively, use the Set method to reset the parameters
' Here, we will use Set
oArgs.SetInt(1, CLng(22222))
oArgs.SetString(2, "Bananas")
oArgs.SetObject(3, "java.lang.Object", oSomeOtherJObjectProxy)

Dim oFoo2 as Object
set oFoo2 = oXJB.NewInstance(clsFoo, oArgs)
```

- AddObject (String strObjectTypeName, Object oArg)

  Adds an arbitrary object to the argument container in the next available position, casting the object to the class name specified in the first parameter. Arrays are specified using the traditional [] syntax; for example:

  ```
  AddObject("java.lang.Object[][]", oMy2DArrayOfFooObjects)
  ```

  or

  ```
  AddObject("int[]", oMyArrayOfInts)
  ```

- AddByte (Byte byteArg)

  Adds a primitive byte value to the argument container in the next available position.

- AddBoolean (Boolean bArg)

  Adds a primitive boolean value to the argument container in the next available position.

- AddShort (Integer iArg)

  Adds a primitive short value to the argument container in the next available position.
- AddInt (Long lArg)

  Adds a primitive int value to the argument container in the next available position.
- AddLong (Currency cyArg)

  Adds a primitive long value to the argument container in the next available position.
- AddFloat (Single fArg)

  Adds a primitive float value to the argument container in the next available position.
- AddDouble (Double dArg)

  Adds a primitive double value to the argument container in the next available position.
- AddChar (String strArg)

  Adds a primitive char value to the argument container in the next available position.
- AddString (String strArg)

  Adds the argument in string form to the argument container in the next available position.
- SetObject (Integer iArgPosition, String strObjectTypeName, Object oArg)

  Adds an arbitrary object to the argument container in the specified position casting it to the class name or primitive type name specified in the second parameter. Arrays are specified using the traditional [] syntax; for example:

  ```
  SetObject(1, "java.lang.Object[][]", oMy2DArrayOfFooObjects)
  ```

  or

  ```
  SetObject(2, "int[]", MyArrayOfInts)
  ```
- SetByte (Integer iArgPosition, Byte byteArg)

  Sets a primitive byte value to the argument container in the position specified.
- SetBoolean (Integer iArgPosition, Boolean bArg)

  Sets a primitive boolean value to the argument container in the position specified.
- SetShort (Integer iArgPosition, Integer iArg)

  Sets a primitive short value to the argument container in the position specified.
- SetInt (Integer iArgPosition, Long lArg)

  Sets a primitive int value to the argument container in the position specified.
- SetLong (Integer iArgPosition, Currency cyArg)

  Sets a primitive long value to the argument container in the position specified.
- SetFloat (Integer iArgPosition, Single fArg)

  Sets a primitive float value to the argument container in the position specified.
- SetDouble (Integer iArgPosition, Double dArg)

  Sets a primitive double value to the argument container in the position specified.
- SetChar (Integer iArgPosition, String strArg)

  Sets a primitive char value to the argument container in the position specified.
- SetString (Integer iArgPosition, String strArg)

  Sets a java.lang.String value to the argument container in the position specified.
- Object Item(Integer iArgPosition)

  Returns the value of an argument at a specific argument position.
- Clear()

  Removes all arguments from the container and resets the next available position to one.
- Long Count()

  Returns the number of arguments in the container.

ActiveX client programming, Java virtual machine initialization tips

Initialize the Java virtual machine (JVM) code with the ActiveX to Enterprise Java Beans (EJB) bridge. For an ActiveX client program (Visual Basic, VBScript, or ASP) to access Java classes or objects, the first step that the program must do is to create Java virtual machine (JVM) code within its process.

To create JVM code, the ActiveX program calls the XJBInit() method of the XJB.JClassFactory object. When an XJB.JClassFactory object is created and the XJBInit() method called, the JVM is initialized and ready to use.

- To enable the XJB.JClassFactory to find the Java run-time description definition language (DLL) when initializing, the Java Runtime Environment (JRE) bin and `bin\classic` directories must exist in the system path environment variable.
- The XJBInit() method accepts only one parameter: an array of strings. Each string in the array represents a command line argument that for a Java program you would normally specify on the Java.exe command line. This string interface is used to set the class path, stack size, heap size and debug settings. You can get a listing of these parameters by typing `java -?` from the command line.
- If you set a parameter incorrectly, you receive a 0x6002 “Failed to initialize VM” error message.
- Due to the current limitations of Java Native Interface (JNI), you cannot unload or reinitialize the JVM code after it has loaded. Therefore, after the XJBInit() method has been called once, subsequent calls have no effect other than to create a duplicate JClassFactory object for you to access. It is best to store your XJB.JClassFactory object globally and continue to reuse that object.
- The following Visual Basic extract shows an example of initializing JVM code:

```
Dim oXJB as Object
set oXJB = CreateObject("XJB.JClassFactory")
Dim astrJavaInitProps(0) as String
astrJavaInitProps(0) = _
     "-Djava.class.path=.;c:\myjavaclasses;c:\myjars\myjar.jar"
oXJB.XJBInit(astrJavaInitProps)
```

ActiveX to Java primitive data type conversion values

All primitive Java data types are automatically converted to native ActiveX Automation types. However, not all Automation data types are converted to Java types (for example, VT_DATE). Variant data types are used for data conversion.

Variant data types are a requirement of any Automation interface, and are used automatically by Visual Basic and VBScript. The following tables provide details about how primitive data types are converted between Automation types and Java types.

Table 4. ActiveX to Java primitive data type conversion. Conversion details for primitive data types

Visual Basic Type	Variant Type	Java Type	Notes
Byte	VT_I1	byte	Byte in Visual Basic is unsigned, but is signed in Java data type.
Boolean	VT_BOOL	boolean	
Integer	VT_I2	short	
Long	VT_I4	int	
Currency	VT_CY	long	
Single	VT_R4	float	
Double	VT_R8	double	
String	VT_BSTR	java.lang.String	
String	VT_BSTR	char	
Date	VT_DATE	n/a	

Example: ActiveX client application using helper methods for data type conversion:

Generally, data type conversion between ActiveX (Visual Basic and VBScript) and Java methods occurs automatically, as described in ActiveX to EJB bridge, converting data types. However, the byte helper function and currency helper function are provided for cases where automatic conversion is not possible:

- Byte helper function

Because the Java Byte data type is signed (-127 through 128) and the Visual Basic Byte data type is unsigned (0 through 255), convert unsigned Bytes to a Visual Basic Integers, which look like the Java signed byte. To make this conversion, you can use the following helper function:

```
Private Function GetIntFromJavaByte(Byte jByte) as Integer
      GetIntFromJavaByte = (CInt(jByte) + 128) Mod 256 - 128
End Function
```

- Currency helper function

  Visual Basic 6.0 cannot properly handle 64-bit integers like Java methods can (as the Long data type). Therefore, Visual Basic uses the Currency type, which is intrinsically a 64-bit data type. The only side effect of using the Currency type (the Variant type VT_CY) is that a decimal point is inserted into the type. To extract and manipulate the 64-bit Long value in Visual Basic, use code like the following example. For more details on this technique for converting Currency data types, see “Q189862, HOWTO: Do 64-bit Arithmetic in VBA”, on the Microsoft Knowledge Base.

```
' Currency Helper Types
Private Type MungeCurr
    Value As Currency
End Type
Private Type Munge2Long
    LoValue As Long
    HiValue As Long
End Type

' Currency Helper Functions
Private Function CurrToText(ByVal Value As Currency) As String
    Dim Temp As String, L As Long
    Temp = Format$(Value, "#.0000")
    L = Len(Temp)
    Temp = Left$(Temp, L - 5) & Right$(Temp, 4)
    Do While Len(Temp) > 1 And Left$(Temp, 1) = "0"
        Temp = Mid$(Temp, 2)
    Loop
    Do While Len(Temp) > 2 And Left$(Temp, 2) = "-0"
        Temp = "-" & Mid$(Temp, 3)
    Loop
    CurrToText = Temp
End Function

Private Function TextToCurr(ByVal Value As String) As Currency
    Dim L As Long, Negative As Boolean
    Value = Trim$(Value)
    If Left$(Value, 1) = "-" Then
        Negative = True
        Value = Mid$(Value, 2)
    End If
    L = Len(Value)
    If L < 4 Then
        TextToCurr = CCur(IIf(Negative, "-0.", "0.") & _
                          Right$("0000" & Value, 4))
    Else
        TextToCurr = CCur(IIf(Negative, "-", "") & _
                          Left$(Value, L - 4) & "." & Right$(Value, 4))
    End If
End Function

' Java Long as Currency Usage Example
Dim LC As MungeCurr
Dim L2 As Munge2Long

' Assign a Currency Value (really a Java Long)
' to the MungeCurr type variable
LC.Value = cyTestIn
```

```
' Coerce the value to the Munge2Long type variable
LSet L2 = LC

' Perform some operation on the value, now that we
' have it available in two 32-bit chunks
L2.LoValue = L2.LoValue + 1

' Coerce the Munge value back into a currency value
LSet LC = L2
cyTestIn = LC.Value
```

ActiveX client programming, handling error codes

All exceptions thrown in Java code are encapsulated and thrown again as a COM error through the ISupportErrorInfo interface and the EXCEPINFO structure of IDispatch::Invoke(), the Err object in Visual Basic and VBScript. Because there are no error numbers associated with Java exceptions, whenever a Java exception is thrown, the entire stack trace is stored in the error description text and the error number assigned is 0x6003.

In Visual Basic or VBScript, you need to use the Err.Number and Err.Description fields to determine the actual Java error. Non-Java errors are thrown as you would expect via the IDispatch interface; for example, if a method cannot be found, then error 438 “Object doesn't support this property or method” is thrown.

Table 5. Error numbers and descriptions.. Error numbers and descriptions in VBScript

Error number	Description
0x6001	Java Native Interface (JNI) error
0x6002	Initialization error
0x6003	Java exception. Error description is the Java Stack Trace.
0x6FFF	General Internal Failure

ActiveX client programming, threading tips

The ActiveX to Enterprise JavaBeans (EJB) bridge supports both free-threaded and apartment-threaded access and implements the Free Threaded Marshaler to work in a hybrid environment such as Active Server Pages (ASP). Each thread created in the ActiveX process is mirrored in the Java environment when the thread communicates through the ActiveX to EJB bridge.

When all references to Java objects (there are no JObjectProxy or JClassProxy objects) are loaded in an ActiveX thread, the ActiveX to EJB bridge detaches the thread from the Java virtual machine (JVM) code. Therefore, you must be careful that any Java code that you access from a multithreaded Windows application is thread safe. Visual Basic code and VBScript applications are both essentially single threaded. Therefore, Visual Basic and VBScript applications do not have threading issues in the Java programs they access. Active Server Pages and multithreaded C and C++ programs can have issues.

Consider the following scenario:

1. A multithreaded Windows Automation Container (our ActiveX Process) starts. It exists on Thread A.
2. The ActiveX Process initializes the ActiveX to EJB bridge, which starts the JVM code. The JVM attaches to the same thread and internally calls it Thread 1.
3. The ActiveX Process starts two threads: B and C.
4. Thread B in the ActiveX Process uses the ActiveX to EJB bridge to access an object that was created in Thread A. The JVM attaches to thread B and calls it Thread 2.
5. Thread C in the ActiveX Process never talks to the JVM code, so the JVM never needs to attach to it. This is a case where the JVM code does not have a one-to-one relationship between ActiveX threads and Java threads.
6. Thread B later releases all of the JObjectProxy and JClassProxy objects that it used. The Java Thread 2 is detached.

7. Thread B again uses the ActiveX to EJB bridge to access an object that was created in Thread A. The JVM code attaches again to the thread and calls it Thread 3.

Table 6. Thread scenario.. Thread scenario

ActiveX process	JVM access by ActiveX process
Thread A - Created in 1	Thread 1 - Attached in 2
Thread B - Created in 4	Thread 2 - Attached in 4, detached in 6 Thread 3 - Attached in 7
Thread C - Created in 4	

Threads and Active Server Pages

Active Server Pages (ASP) in Microsoft Internet Information Server is a multithreaded environment. When you create the XJB.JClassFactory object, you can store it in the Application collection as an Application-global object. All threads within your ASP environment can now access the same ActiveX to EJB bridge object. Active Server Pages by default creates 10 Apartment Threads per ASP process per CPU. This means that when your ActiveX to EJB bridge object is initialized any of the 10 threads can call this object, not just the thread that created it.

If you need to simulate single-apartment behavior, you can create a Single-Apartment Threaded ActiveX dynamic link library (DLL) in Visual Basic code and encapsulate the ActiveX to the EJB bridge object. This encapsulation guarantees that all access to the JVM object is on the same thread. You need to use the <OBJECT> tag to assign the XJB.JClassFactory to an Application object and must be aware of the consequences of introducing single-threaded behavior to a web application.

The Microsoft KnowlegeBase has several articles about ASP and threads, including:
- Q243543 INFO: Do Not Store STA Objects in Session or Application
- Q243544 INFO: Component Threading Model Summary Under Active Server Pages
- Q243548 INFO: Design Guidelines for VB Components Under ASP

Example: Enabling logging and tracing for activeX client applications

The ActiveX to EJB bridge provides two logging and tracing formats: Windows Application Event Log and Java Trace Log.

- Windows Event Log

  The Windows Application Event Log shows JNI errors, Java console error messages, and XJB initialization messages. This log is most useful for determining XJBInit() errors and any unusual exceptions that do not come from the Java environment. By default, critical error logging will be enabled and debug and event logging is disabled.

  To enable or disable logging of certain event types to the Windows Event Log, specify one or more parameters to XJBInit(). If more than one parameter is set, they will be processed in the order in which they appear in the input string array to the XJBInit() method. Once the XJBInit() method is initialized, these parameters can no longer be set/reset for the life of the process. Using Java java.lang.System.setProperty() to set these values also has no effect.
  - -Dcom.ibm.ws.client.xjb.native.logging.debug=enabled|disabled

    Enables or disables debug level messages from displaying in the Windows operating system event log. This level of logging is most useful and shows most internal errors, user programming issues or configuration problems.
  - -Dcom.ibm.ws.client.xjb.native.logging.event=enabled|disabled

    Enables or disables event level messages from appearing in the Windows operating system event log.
  - -Dcom.ibm.ws.client.xjb.native.logging.*=enabled|disabled

Enables or disables both event and debug level messages from appearing in the Windows operating system event log. It is not possible to disable some critical error messages from being displayed in the error log. Only debug and event level messages can be disabled.

To view the Windows application event log with the Event Viewer, complete the following steps:

1. Click **Start** > **Control Panel**.
2. Double-click **Administrative Tools**.
3. Double-click **Event Viewer**.

All ActiveX to EJB bridge events display the text `WebSphere XJB` in the source column and in the application log.

When using the Event Viewer, you can get help information by clicking the menu choice **Action** > **Help**.

- Java trace log

  The Java trace log displays information that you can use to debug method calls, class lookups, and argument coercion problems. Because the Java portion of the bridge mirrors the function of the COM IDispatch interface, the information in the trace log is similar to what you have come to expect from an IDispatch interface. To understand the trace log, you need a fundamental understanding of IDispatch.

  To enable user-logging, add the following parameters to the XJBInit() input string array:

```
"-DtraceString=com.ibm.ws.client.xjb.*=event=enabled"
"-DtraceFile=C:\MyTrace.txt"
```

Example: Viewing a System.out message

The ActiveX to Enterprise JavaBeans (EJB) bridge does not have a console available to view Java System.out messages. To view these messages when running a stand-alone client program (such as Visual Basic), redirect the output to a file.

This example redirects output to a file:

```
launchClientXJB.bat MyProgram.exe > output.txt
```

- To view the System.out messages when running a Service program such as Active Server Pages, you need to override the Java System.out OutputStream object to FileOutputStream. For example, in VBScript:

```
'Redirect system.out to a file
' Assume that oXJB is an initialized XJB.JClassFactory object
 Dim clsSystem
 Dim oOS
 Dim oPS
 Dim oArgs

' Get the System class
  Set clsSystem = oXJB.FindClass("java.lang.System")

' Create a FileOutputStream object
' Create a PrintStream object and assign to it our FileOutputStream
  Set oArgs = oXJB.GetArgsContainer  oArgs.AddObject "java.io.OutputStream", oOS
  Set oPS = oXJB.NewInstance(oXJB.FindClass("java.io.PrintStream"), oArgs)

' Set our System OutputStream to our file
  clsSystem.setOut oPS
```

Developing applet client code

Applet clients are capable of communicating over the HTTP protocol and the RMI-IIOP protocol.

About this task

Unlike typical applets that reside on either web servers or WebSphere Application Servers and can only communicate using the HTTP protocol, applet clients are capable of communicating over the HTTP protocol and the RMI-IIOP protocol. This additional capability gives the applet direct access to enterprise beans.

Standard applets require the HTML <APPLET> tag to identify the applet to the browser. If you replace the <OBJECT> and <EMBED> tags, make sure that you specify appropriate values for <OBJECT> and <EMBED> tags, especially the <OBJECT classid and <EMBED type values.

In the code for your applet client, when you initialize an instance of the InitialContext class, you must set properties to specify the computer name, domain, and port, and to identify this program (the client) as an applet.

Example

- Applet client tag requirements
- Applet client code requirements

Applet client tag requirements: Standard applets require the HTML <APPLET> tag to identify the applet to the browser. The <APPLET> tag invokes the Java virtual machine (JVM) of the browser. It can also be replaced by <OBJECT> and <EMBED> tags. The following code example illustrates the applet code using the <APPLET> tag:

```
<APPLET code="MyAppletClass.class" archive="Applet.jar, EJB.jar" width="600" height="500" >
</APPLET>
```

The following code example illustrates the applet code using the <OBJECT> and <EMBED> tags.

```
<OBJECT classid="clsid: 8AD9C840-044E-11D1-B3E9-00805F499D93"
width="600" height="500">
<PARAM NAME=CODE VALUE=MyAppletClass.class>
<PARAM NAME="archive" VALUE='Applet.jar, EJB.jar'>
<PARAM TYPE="application/x-java-applet;version=1.5.0">
<PARAM NAME="scriptable" VALUE="false">
<PARAM NAME="cache-option" VALUE="Plugin">
<PARAM NAME="cache-archive" VALUE="Applet.jar, EJB.jar">
<COMMENT>
<EMBED type="application/x-java-applet;version=1.5.0" CODE=MyAppletClass.class
ARCHIVE="Applet.jar, EJB.jar" WIDTH="600" HEIGHT="500"
scriptable="false">
<NOEMBED>
</COMMENT>
</NOEMBED>WebSphere Java Application/Applet Thin Client for
Windows is required.
</EMBED>
</OBJECT>
```

Attention: To successfully invoke the applet client in WebSphere Application Server version 6.1 or later, the <OBJECT classid and <EMBED type values need to be those shown in the preceding example.

For more information about the <APPLET> tag, see the article, Using applet, object and embed Tags.

Applet client code requirements: The code used by an applet to talk to an enterprise bean is the same as that used by a stand-alone Java program or a servlet, except for one additional property called java.naming.applet. This property informs the InitialContext and the Object Request Broker (ORB) that this client is an applet rather than a stand-alone Java application or servlet. The following code example illustrates the applet code using the <APPLET> tag:

When you initialize an instance of the InitialContext class, the first two lines in this code snippet illustrate what both a stand-alone Java program and a servlet issue to specify the computer name, domain, and port. In this example, <yourserver.yourdomain.com> is the computer name and domain where WebSphere Application Server resides, and 900 is the configured port. After the bootstrap values (<yourserver.yourdomain.com>:900) are defined, the client to server communications occur within the underlying infrastructure. In addition to the first two lines for applets, you must add the third line to your code, which identifies this program as an applet, for example:

```
prop.put(Context.INITIAL_CONTEXT_FACTORY, "com.ibm.websphere.naming.WsnInitialContextFactory");
prop.put(Context.PROVIDER_URL, "iiop://<yourserver.yourdomain.com>:900)
prop.put(Context.APPLET, this);
```

Example: Applet client tag requirements

Standard applets require the HTML <APPLET> tag to identify the applet to the browser. The <APPLET> tag invokes the Java virtual machine (JVM) of the browser. It can also be replaced by <OBJECT> and <EMBED> tags.

The following code example illustrates the applet code using the <APPLET> tag.

```
<APPLET code="MyAppletClass.class" archive="Applet.jar, EJB.jar" width="600" height="500" >
</APPLET>
```

The following code example illustrates the applet code using the <OBJECT> and <EMBED> tags.

```
<OBJECT classid="clsid: 8AD9C840-044E-11D1-B3E9-00805F499D93"
width="600" height="500">
<PARAM NAME=CODE VALUE=MyAppletClass.class>
<PARAM NAME="archive" VALUE='Applet.jar, EJB.jar'>
<PARAM TYPE="application/x-java-applet;version=1.5.0">
<PARAM NAME="scriptable" VALUE="false">
<PARAM NAME="cache-option" VALUE="Plugin">
<PARAM NAME="cache-archive" VALUE="Applet.jar, EJB.jar">
<COMMENT>
<EMBED type="application/x-java-applet;version=1.5.0" CODE=MyAppletClass.class
ARCHIVE="Applet.jar, EJB.jar" WIDTH="600" HEIGHT="500"
scriptable="false">
<NOEMBED>
</COMMENT>
</NOEMBED>WebSphere Java Application/Applet Thin Client for
Windows is required.
</EMBED>
</OBJECT>
```

Attention: To successfully invoke the applet client in WebSphere Application Server version 6.1 or later, the <OBJECT classid and <EMBED type values need to be those shown in the preceding example.

For more information about the <APPLET> tag, see Using applet, object and embed Tags.

Example: Applet client code requirements

The code used by an applet to talk to an enterprise bean is the same as that used by a stand-alone Java program or a servlet, except for one additional property called java.naming.applet. This property informs the InitialContext and the Object Request Broker (ORB) that this client is an applet rather than a stand-alone Java application or servlet.

When you initialize an instance of the InitialContext class, the first two lines in this code snippet illustrate what both a stand-alone Java program and a servlet issue to specify the computer name, domain, and port. In this example, <yourserver.yourdomain.com> is the computer name and domain where WebSphere Application Server resides, and 900 is the configured port. After the bootstrap values (<yourserver.yourdomain.com>:900) are defined, the client to server communications occur within the underlying infrastructure. In addition to the first two lines for applets, you must add the third line to your code, which identifies this program as an applet, for example:

```
prop.put(Context.INITIAL_CONTEXT_FACTORY, "com.ibm.websphere.naming.WsnInitialContextFactory");
prop.put(Context.PROVIDER_URL, "iiop://<yourserver.yourdomain.com>:900)
prop.put(Context.APPLET, this);
```

Example: Enabling logging and tracing for application clients

The ActiveX to EJB bridge provides two logging and tracing formats: Windows Application Event Log and Java Trace Log.

- Windows Event Log

The Windows Application Event Log shows JNI errors, Java console error messages, and XJB initialization messages. This log is most useful for determining XJBInit() errors and any unusual exceptions that do not come from the Java environment. By default, critical error logging will be enabled and debug and event logging is disabled.

To enable or disable logging of certain event types to the Windows Event Log, specify one or more parameters to XJBInit(). If more than one parameter is set, they will be processed in the order in which they appear in the input string array to the XJBInit() method. Once the XJBInit() method is initialized, these parameters can no longer be set/reset for the life of the process. Using Java `java.lang.System.setProperty()` to set these values also has no effect.

- `-Dcom.ibm.ws.client.xjb.native.logging.debug=enabled|disabled`

  Enables or disables debug level messages from displaying in the Windows operating system event log. This level of logging is most useful and shows most internal errors, user programming issues or configuration problems.
- `-Dcom.ibm.ws.client.xjb.native.logging.event=enabled|disabled`

  Enables or disables event level messages from appearing in the Windows operating system event log.
- `-Dcom.ibm.ws.client.xjb.native.logging.*=enabled|disabled`

  Enables or disables both event and debug level messages from appearing in the Windows operating system event log. It is not possible to disable some critical error messages from being displayed in the error log. Only debug and event level messages can be disabled.

Viewing the Windows application event log with the event viewer:

To open the event viewer in the Windows operating system:

1. Click **Start** > **Settings** > **Control Panel**.
2. Double-click Administrative Tools.
3. Double-click Event Viewer.

All ActiveX to EJB bridge events display the text WebSphere XJB in the source column and in the application log. For information about using Event Viewer, click the **Action** menu in Event Viewer, and then click **Help**.

To open the even viewer in the Windows operating system, click **Start** > **Programs** > **Administrative Tools** > **Event Viewer**. All ActiveX to EJB bridge events have the text WebSphere XJB in the source column and display in the application log. For information about using Event Viewer, click the **Help** menu in Event Viewer.

- Java trace log

  The Java trace log displays information that you can use to debug method calls, class lookups, and argument coercion problems. Since the Java portion of the bridge mirrors the function of the COM IDispatch interface, the information in the trace log is similar to what you have come to expect from an IDispatch interface. To understand the trace log, you need a fundamental understanding of IDispatch.

  To enable user-logging, add the following parameters to the XJBInit() input string array:

```
"-DtraceString=com.ibm.ws.client.xjb.*=event=enabled"
"-DtraceFile=C:\MyTrace.txt"
```

Chapter 6. Developing Communications Enabled Applications

Communications Enabled Applications (CEA) is a functionality that provides the ability to add dynamic web communications to any application or business process. The product provides a suite of integrated telephony and collaborative web services that extends the interactivity of enterprise and web commerce applications. With the CEA capability, enterprise solution architects and developers can use a single core application to enable multiple modes of communication. Enterprise developers do not need to have extensive knowledge of telephony or Session Initiation Protocol (SIP) to implement CEA. The CEA capability delivers call control, notifications, and interactivity and provides the platform for more complex communications.

Developing communications enabled applications

Developing SIP communications applications

Before you begin

Note: Failover for SIP applications is supported on the z/OS platform.

Procedure

- Use the Session Initiation Protocol (SIP) application router to select the order in which SIP applications are triggered.

  When configuring a SIP application router, you can either use the default application router or create a custom application router.
- Use the Asynchronous Invocation API to transfer events that require processing in the context of a Session Initiation Protocol (SIP) application session to any server in a cluster based on the related application session ID.

  The Asynchronous Invocation API transfers the event task to the correct server.
- Use the Domain Resolver API to perform DNS lookups of SIP URIs using the RFC 3263 protocol.

  The Domain Resolver API provides an interface that enables an application to perform DNS queries for SIP URIs.
- Create a SIP servlet request that includes proprietary header fields.

  SIP proprietary header fields enable certain SIP settings to be implemented on a per message basis. SIP settings set at the SIP container level apply to all SIP messages handled by that SIP container.

Domain Resolver API

Use the Domain Resolver API to perform DNS lookups of SIP URIs using the RFC 3263 protocol. These lookups can be performed synchronously if you want to avoid having to preserve state in order to handle an asynchronous callback. They can also be performed asynchronously if you need a better performing interface.

The Domain Resolver API provides an interface that enables an application to perform DNS queries for SIP URIs. When the Domain Resolver API is used asynchronously, a listener is called after the DNS query completes. You can use one of the following methods in your application code to access the Domain Resolver API:

- Get an attribute from the ServletContext using com.ibm.ws.sip.container.domain.resolver as a key.

  ```
  getServletContext().getAttribute("com.ibm.ws.sip.container.domain.resolver")
  ```
- Use @resource injection.

  ```
  @resource
  DomainResolver resolver
  ```

Use one of the following methods to perform the URI lookup:

- Use the SIPURI method if a synchronous API which will return the result of the URI resolve request response.

```
DomainResolver
locate(SIPURI)
```

- locate(SIPURI, Listener) – an asynchronous API which will signal the listener once it is finished. When the result is cached the listener will be triggered on the same caller thread.

```
DomainResolver
locate(SIPURI, Listener)
```

For more information about this API, expand the **Reference > Programming interfaces > APIs - Application Programming Interfaces** section in the Feature Pack for Communications Enabled Applications Information Center navigation. Then scroll down to the com.ibm.ws.sip.container.domain.resolver API.

For more information about DNS servers, see the topic *Using DNS procedures to locate SIP servers*

SIP proprietary header fields

You can create a SIP servlet request that includes proprietary header fields. SIP proprietary header fields enable certain SIP settings to be implemented on a per message basis. SIP settings set at the SIP container level apply to all SIP messages handled by that SIP container.

To include one or more proprietary header fields in a message, set up your SIP servlet request such that it includes one or more SipServletMessage.setHeader(*string_name*, *string value*) methods. When the application calls SipServletRequest.send() to send the request, the message object that is passed to the SIP stack for transmission includes the propriety header information. The SIP stack then creates a client transaction to send out the request, and adjusts the SIP configuration settings for this specific request based on any proprietary header fields that are included in the message object. The stack removes the proprietary header fields before the message is sent out to the network.

Proprietary header fields used to specify timer values

The following proprietary header fields are available for specifying timer values for a specific message. The application can set multiple timer values in one message instance, but cannot specify multiple values for the same proprietary header field.

IBM-TransactionTimeout
Use this header field to specify, in milliseconds, the length of the client transaction timeout. This header is equivalent to specifying a value for timer B in INVITE client transactions, and timer F in non-INVITE client transactions.

IBM-RetransmissionInterval
Use this header field to specify, in milliseconds, the length of the request retransmission interval. This header is equivalent to specifying a value for timer A in INVITE client transactions, and timer E in non-INVITE client transactions.

IBM-RetransmissionMaxInterval
Use this header field to specify, in milliseconds, the maximum retransmission interval. This header is equivalent to specifying a value for timer T2 in non-INVITE client transactions, and timer B in INVITE client transactions.

Chapter 7. Developing data access resources

This page provides a starting point for finding information about data access. Various enterprise information systems (EIS) use different methods for storing data. These backend data stores might be relational databases, procedural transaction programs, or object-oriented databases.

The flexible IBM WebSphere Application Server provides several options for accessing an information system backend data store:

- Programming directly to the database through the JDBC 4.0 API, JDBC 3.0 API, or JDBC 2.0 optional package API.
- Programming to the procedural backend transaction through various J2EE Connector Architecture (JCA) 1.0 or 1.5 compliant connectors.
- Programming in the bean-managed persistence (BMP) bean or servlets indirectly accessing the backend store through either the JDBC API or JCA-compliant connectors.
- Using container-managed persistence (CMP) beans.
- Using the IBM data access beans, which also use the JDBC API, but give you a rich set of features and function that hide much of the complexity associated with accessing relational databases.

Service Data Objects (SDO) simplify the programmer experience with a universal abstraction for messages and data, whether the programmer thinks of data in terms of XML documents or Java objects. For programmers, SDOs eliminate the complexity of the underlying data access technology such as, JDBC, RMI/IIOP, JAX-RPC, and JMS, and message transport technology such as, java.io.Serializable, DOM Objects, SOAP, and JMS.

Developing data access applications

Developing data access applications

You can use data access applications to manipulate data from outside sources for use within your application serving environment.

About this task

You can access data in various ways:

- using standard or extended APIs
- using container-managed persistence beans
- using bean-managed persistence beans, session beans, or web components.
- using Service Data Objects (SDO)

Procedure

1. Decide how to implement data access.

   The Enterprise JavaBeans (EJB) programming model provides several distinct server-side component types: entity, session, and message-driven beans, and servlets. Of these types, entity beans are typically used to model business components in an application. Entity beans have both *state* and *behavior*.

   The state of entity beans is persistent and is stored in a database. As changes are made to an entity bean, its state is kept in synchronization with the database record representing the bean. There are two types of entity beans provided by the EJB model and these two types differ in the mechanism used to provide persistence. These two types of entity beans are *container-managed persistence* (CMP) beans and *bean-managed persistence* (BMP) beans.

   - With BMP beans, the developer manually produces code to manage the persistent state of the bean.

- With CMP beans, the EJB container manages the persistent state of the bean. Persistent state management is a complex and difficult task; using CMP beans allows the developer to concentrate on business logic by delegating persistence behavior to the container.

  Typical examples of CMP beans are *Customer*, *Account*, and so on. Because CMP beans are objects, their data (state) is accessed using field accessors. For example, a *Customer* entity bean is likely to have fields such as *name* and *phoneNumber*. These pieces of data are accessed using the accessor methods *getName()/setName()* and *getPhoneNumber()/setPhoneNumber()*. As a developer, you are not concerned with how this data is eventually stored and retrieved from the backend database and can assume that the integrity of the data is maintained by the container.

See the topic, Developing enterprise beans for information on developing entity beans.

Tips:

- To maximize the efficiency of application requests to relational databases, consider using Structured Query Language in Java (SQLJ) when developing BMP and CMP beans. This option is available for applications that use the DB2 JDBC Universal Driver to access DB2 databases.

  The only exception to this driver requirement applies to SQLJ-backed BMP beans that access DB2 for z/OS; this schema requires the DB2 for z/OS Legacy Driver (required for the DB2 for z/OS Local JDBC Provider RRS).
- Also consider using cursor holdability for potential performance gains; see the topic, JDBC application cursor holdability support, for details.

An alternative to developing entity beans is using the Service Data Objects (SDO) framework, which is a unified framework for data application development. With SDO, you do not need to be familiar with a technology-specific API in order to access and utilize data. You need to know only one API, the SDO API, which lets you work with data from multiple sources, including relational databases, entity EJB components, XML pages, web services, the Java Connector Architecture, JavaServer Pages, and more.

2. Look up a data source or connection factory using a resource reference. See the topic, Looking up data sources with resource references for relational access for more information. *Do not perform this step if you work with CMP beans. The EJB container handles this process for CMP beans.*

   To run applications on WebSphere Application Server, your code must use resource references to logically named data sources or connection factories. Mapping the resource references to actual resources is usually done at assembly time. The Application Server administrator configures those resources.

   - For relational database access, administrators configure a JDBC provider and associated data sources, which work with the embedded WebSphere Relational Resource Adapter.
   - For non-relational database access, administrators install a Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) resource adapter onto an application server and configure associated connection factories.

   Generic work context implementation provides a mechanism for a resource adapter to control the contexts in which instances of work submitted by the resource adapter to the product work manager for execution are executed. By submitting a work instance that implements the WorkContextProvider interface, the resource adapter can propagate various types of context to the WebSphere Application Server. The application server then, if it supports the propagated context type, sets the provided context as the execution context of the work instance during its execution.
3. Get a connection to a data source or a connection factory. See the "Getting connections" section of the topic, Connection life cycle for details.) *Do not perform this step if you work with CMP beans. The EJB container handles this process for CMP beans.*

   The connection management architecture for both relational and procedural access to enterprise information systems (EIS) is based on the Java EE Connector Architecture (JCA) specification. The Connection Manager (CM), which pools and manages connections within an application server, is capable of managing connections obtained through both resource adapters (RAs) defined by the JCA specification, and data sources defined by the JDBC Extensions Specification.

4. Use thread identity to assign an owner to the connection. See the topic, Using thread identity, support for more information.

Using Bean Validation in RAR modules

WebSphere Application Server validates resource archive (RAR) JavaBeans constraints in compliance with the Java Connector Architecture (JCA) version 1.6 specification.

Bean validation in RAR modules:

WebSphere Application Server validates resource adapter archive (RAR) JavaBeans constraints in compliance with the Java Connector Architecture (JCA) version 1.6 specification.

Resource adapters can specify the validation requirements of configuration properties to the Application Server through annotations in the source code of the resource adapter, constraint specifications in a resource adapter validation descriptor, or a mixture of both. In specifying these constraints, resource adapters can use the built-in bean validation constraints supplied with the Application Server, custom bean validation constraints supplied either by the application developer or a third party, or a mixture of both. Resource adapter developers can apply constraints to the fields and JavaBeans-compliant properties of the following JCA types:

- ResourceAdapter
- ManagedConnectionFactory
- ActivationSpec
- AdministeredObject

At run time, the application server creates instances of bean types declared by the resource adapter. Each instance is validated immediately upon setting its configuration properties, before placing the instance into service.

When validating a RAR bean, the Application Server creates an instance of a validator factory according to the bean validation deployment descriptor discovered by the Application Server. A validator instance is then obtained from the factory and used to validate the bean instance.

If validation fails, the Application Server throws a constraint violation exception and reports all violations to the system log. The effects of the exception for each RAR bean type and problem determination information are documented in the topic, Troubleshooting bean validation in RAR modules.

Note: The Bean Validation specification requires that no more than one `validation.xml` is visible on the class path. This requirement is violated whenever two or more stand-alone RARs provide a validation descriptor. See the section, “RAR bean validation descriptor” in this topic, for more information. When more than one `validation.xml` is visible to the Application Server class loaders, the Application Server or application modules might fail to acquire the default ValidatorFactory and subsequently cannot perform bean validation. For example, the server cannot validate beans of a RAR embedded in an application whenever the embedded RAR lacks a validation configuration, and two or more stand-alone RARs provide configurations. To avoid trouble, install stand-alone RARs that provide a bean validation descriptor as isolated whenever possible.

Built-in constraint annotations

Note: Use built-in constraint annotations to specify the range and mandatory attributes of configuration properties rather than provide custom annotations for the same purpose. The following constraints are useful, but you can use all bean validation built-in constraints. See the topic Bean validation built-in constraints for a complete list of the constraints.

- @Min

  Specifies the minimum value of the configuration property decorated with this annotation. The value must be greater than or equal to the specified minimum.

- @Max

  Specifies the maximum value of the configuration property decorated with this annotation. The value must less than or equal to the specified maximum.
- @Size

  Specifies the range of values of the configuration property decorated with this annotation. The value must be greater than or equal to the specified minimum and be less than or equal to the specified maximum.
- @NotNull

  Specifies the value of the configuration property decorated with this annotation must not be null. That is, the property is required.

The following example is a RAR bean class that is decorated with built-in constraint annotations.

The value of the serverName configuration property must not be null, and the value of the instanceCount property must be at least 1 when the Application Server creates and configures an instance of the MyConnector class. Otherwise, a constraint validation exception occurs and, in the case of ResourceAdapter bean, the resource adapter fails to start. See the topic Troubleshooting bean validation in RAR modules for more information.

```
package com.my.company;

@Connector(...)
public class MyConnector implements ResourceAdapter, Serializable
{
 @ConfigProperty(type=java.lang.String.class,defaultValue="WAS")
 private String serverName;

 @NotNull()
 public String getServerName() {return serverName;}

 private Integer instanceCount = 0;

 @Min(value=1)
 public Integer getInstanceCount() {return instanceCount;}
 ...
```

RAR bean validation descriptor

Bean validation constraints can be declared through an XML descriptor supplied by a RAR module. In the simplest case, a RAR validation descriptor consists of the validation configuration declared in the validation.xml file and zero or more XML files that declare RAR bean validation constraints. Files containing constraint declarations are specified in the constraint-mapping elements of the validation configuration (validation.xml).

You must package the validation descriptor in the META-INF directory of a RAR module. Any custom constraint annotation classes that are declared in the validation descriptor must also be packaged in the RAR module.

The following example is a simple RAR validation descriptor that declares constraint metadata like the code shown in the section, “Built-in constraint annotations.”

```
<?xml version="1.0" encoding="UTF-8"?>
<validation-config
  xmlns=http://jboss.org/xml/ns/javax/validation/configuration
   xmlns:xsi=http://www.w3.org/2001/XMLSchema-instance
   xsi:schemaLocation=http://jboss.org/xml/ns/javax/validation/configuration validation-configuration-1.0.xsd>
<constraint-mapping>META-INF/constraints.xml</constraint-mapping>
</validation-config>
```

The constraints XML file is also located in the META-INF directory and looks like the following:

```
<constraint-mappings
 xmlns=http://jboss.org/xml/ns/javax/validation/mapping
 xmlns:xsi=http://www.w3.org/2001/XMLSchema-instance
 xsi:schemaLocation=http://jboss.org/xml/ns/javax/validation/mapping validation-mapping-1.0.xsd>
<default-package>com.my.company</default-package>
<bean class="MyConnector" ignore-annotations="true">
 <field name="serverName">
```

```
  <valid/>
  <!-- @NotNull() -->
  <constraint annotation="javax.validation.constraints.NotNull">
   <message>Value is not null</message>
  </constraint>
 </field>
 <field name="instanceCount">
  <valid/>
  <!-- @Min(1) -->
  <constraint annotation="javax.validation.constraints.Min">
    <message>Minimum possible value is 1</message>
    <element name="value">1</element>
   </constraint>
  </field>
 </bean>
<constraint-mapping>
```

The packaged RAR module, `MyResourceAdapter.rar`, looks like the following:

```
my/
  company/
    MyConnector.class
. . .
META-INF
  /validation.xml
  /constraints.xml
```

Third-party bean validation

WebSphere Application Server supports using different bean validation implementations. If a resource adapter requires a bean validation implementation different from the implementation that is provided by the product, and the RAR provides the bean validation implementation, you must package the JAR file that contains the bean validation implementation in the RAR module root directory.

The RAR module must also contain a single validation configuration descriptor (`validation.xml`), which can be packaged in the META-INF directory of the RAR module, or in the `META-INF/services` directory of the bean validation JAR file, but not both.

RAR bean validation configuration discovery

When validating RAR beans, the Application Server bootstraps the bean validation configuration, specific to the RAR, according to the bean validation descriptor supplied in the RAR META-INF directory. If the descriptor does not exist, the server bootstraps the configuration using the first validation descriptor discovered in the RAR class loading context, such as that supplied in a third-party bean validation that is packaged in the RAR. Finally, the server uses the default validation configuration provided by the product.

The server then creates a validator factory specific to the discovered bean validation configuration and uses this factory to create validator instances for validating the RAR bean instances. When you deploy a RAR that supplies a bean validation descriptor, you must take additional steps to ensure that the class loader that loads the RAR loads the bean validation descriptor and classes packaged in the RAR.

For an embedded RAR, after you have deployed the application that embeds the RAR, you must set the delegation mode of the application class loader to Parent-Last (Child-First). See the topic Configuring application class loaders for more information.

For a stand-alone RAR, you must install the RAR as an isolated resource provider. See the topic Resource Adapter settings for more information.

Troubleshooting bean validation in RAR modules:

RAR beans that fail validation are not placed into service. When constraint violations occur, applications encounter resource connectivity issues that are different according to the bean type and how the RAR is deployed. This topic explains how to understand, service, and prevent these known issues.

RAR bean constraint violations

WebSphere Application Server displays a constraint violation exception and reports all constraint violations to the system log when it validates RAR bean instances that violate one or more constraints. The cause of all constraint violation must be determined and resolved to restore full connectivity to the affected resource.

Problem determination starts with consulting the RAR provider documentation for the valid values of the configuration properties that are indicated in the violations. If the property values are invalid, you must reconfigure them according to the documentation and restart the resource adapter. If the adapter is embedded in an application, then restart the application to restart the adapter; if the adapter is stand-alone, then restart the application server.

If a valid configuration property value is indicated in a violation, then the constraint might be incorrectly specified for the bean, or the bean is incorrectly computing the property value. In these cases, the RAR vendor must correct the problem.

If the problem is caused by a faulty constraint definition (implementation), then the bean validation provider must correct the problem. In these cases, if the RAR is provided by IBM, or the RAR uses the bean validation implementation supplied by the Application Server, then contact IBM support to continue problem determination.

ResourceAdapter beans

ResourceAdapter beans are validated when the server starts a Java 2 Connector (J2C) resource adapter. When validation fails, the server rejects the ResourceAdapter instance and the resulting constraint violation exception causes the J2C resource adapter to fail. Applications cannot establish outbound connections to the resource, and the resource cannot deliver messages to applications. For an embedded adapter, the application that embeds the adapter fails to start. In-doubt transactions that involve the resource cannot be recovered.

The following example is a ResourceAdapter bean, MyConnector, at heap address 7efa7efa. Two validation constraints are violated. The constraint violation exception causes J2CResourceAdapter_1285109360562 to fail:

```
[9/29/10 10:51:24:125 CDT] 00000000 BeanValidatio E
 J2CA0238E: JavaBean com.my.company.adapter.MyConnector@7efa7efa failed Bean Validation due to one or more invalid
 configuration settings indicated in the following list of constraint violations:

 ConstraintViolationImpl{interpolatedMessage='The minimum size is 2', propertyPath=dataBaseName, rootBeanClass=class
    com.my.company.adapter.MyConnector, messageTemplate='The minimum size is 2'}
 ConstraintViolationImpl{interpolatedMessage='must be greater than or equal to 10', propertyPath=idleTimeout, rootBeanClass=class
    com.my.company.adapter.MyConnector, messageTemplate='{javax.validation.constraints.Min.message}'}
...

. . .
```

ManagedConnectionFactory beans

ManagedConnectionFactory JavaBeans are validated during the initial Java Naming and Directory Interface (JNDI) lookup of a J2C connection factory.

When validation fails, the Application Server rejects the ManagedConnectionFactory instance and displays a naming exception to the application that performs the lookup. This exception indicates the causal constraint violation exception (javax.validation.ConstraintValidationException).

Applications cannot establish outbound connections to the resource. In-doubt transactions started over connections to the resource that were created by the connection factory cannot be recovered.

The following example is a ManagedConnectionFactory bean, MyMcf, at heap address 7dd07dd0, Two validation constraints are violated. The constraint violation exception causes the application to not obtain a connection factory that is required to create a connection to the resource, MyConnector:

```
[9/30/10 7:58:58:734 CDT] 00000023 BeanValidatio E
 J2CA0238E: JavaBean com.my.company.adapter.MyMcf@7dd07dd0 failed Bean Validation due to one or more invalid

. . .
```

ActivationSpec bean violations

ActivationSpec beans are validated when the applications starts. This is when the Application Server initially activates message endpoints bound to J2C activation specifications. These activation specifications name the bean class in their configuration. When validation fails, the endpoint fails to activate and the resulting constraint violation exception causes the application hosting the endpoint to fail.

Because the J2C resource adapter that contains the activation specification is started, applications can still establish connections to the resource. The resource can deliver messages to endpoints that have successfully activated. If the activation specification is defined within an embedded resource adapter, the server stops the adapter in the course of stopping the application. Failed transactional messages delivered by previous instances of the resource adapter that contains the activation specification cannot be recovered.

The following example is an ActivationSpec bean, MyActSpec, at heap address 51625162. Two validation constraints are violated. The log shows the constraint violation exception that causes the application, my_company_app, to fail:

```
[9/29/10 10:52:05:125 CDT] 00000009 BeanValidatio E
 J2CA0238E: JavaBean com.my.company.adapter.MyActSpec@51625162 failed Bean Validation due to one or more invalid

AdministeredObject beans

AdministeredObject beans are validated when the server starts a J2C resource adapter that contains the administered object in its configuration. When validation fails, the server rejects the AdministeredObject instance and the resulting constraint violation exception causes the resource adapter to fail.

The following example is an AdministeredObject beans, MyAdminObj, at heap address 3a803a80. Two validation constraints are violated. The log shows the constraint violation exception that causes resource adapter to fail:

```
[9/29/10 10:51:25:125 CDT] 00000000 BeanValidatio E

JCA 1.6 support for annotations in RAR modules

The Java Connector Architecture (JCA) Version 1.6 specification adds support for Java annotations in resource archive (RAR) modules. Annotations are a means of specifying metadata, or configuration data, for a RAR module in the class files that make up the module.

Before JCA 1.6, this metadata was specified only in the deployment descriptor, but now you can specify this metadata using either a deployment descriptor or annotations. Metadata that is specified in annotations is merged into the deployment descriptor of a RAR module when it is updated, if the module is not marked metadata-complete in the deployment descriptor and if the module version is 1.6 or later.

The metadata-complete element defines whether the deployment descriptor for the resource adapter module is complete or whether the class files that are available to the module and packaged with the resource adapter should be examined for annotations that specify deployment information. If the metadata-complete is set to *true*, the application server deployment tool must ignore any annotations that specify deployment information, which might be present in the class files of the application. If metadata-complete is not specified, or is set to *false*, the deployment tool must examine the class files of the application for annotations, as specified by the JCA 1.6 Specification. If the deployment descriptor is not included, or is included but not marked metadata-complete, the deployment tool processes annotations.

Application servers must assume that metadata-complete is *true* for resource adapter modules with deployment descriptors that meet the requirements of JCA specification 1.5 and earlier. For a complete list of the supported annotations and their usage, consult the JCA specification.

The JCA Version 1.6 specification also adds support for Bean Validation constraint annotations in RAR modules. You can specify Bean Validation constraint metadata for RAR JavaBeans by decorating your classes with Bean Validation constraint annotations or by supplying XML validation descriptors. The Application Server validates the constraints of all JCA 1.6 RAR JavaBeans instances before placing them into service at run time.

Extensions to data access APIs

If a single data access API does not provide a complete solution for your applications, use WebSphere Application Server extensions to achieve interoperability between both the JCA and JDBC APIs.

Applications that draw from diverse and complex resource management configurations might require use of both the Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) API and the Java Database Connectivity (JDBC) API. However, in some cases the JDBC programming model does not completely integrate with the JCA (even though full integration is a foundation of the JCA specification). These inconsistencies can limit data access options for an application that uses both APIs. WebSphere Application Server provides API extensions to resolve the compatibility issues.

For example:

Without the benefit of an extension, applications using both APIs cannot modify the properties of a shareable connection after making the connection request, if other handles exist for that connection. (If no other handles are associated with the connection, then the connection properties can be altered.) This limitation stems from an incompatibility between the connection-configuration policies of the APIs:

The Connector Architecture (JCA) specification supports relaying to the resource adapter the specific properties settings at the time you request the connection (using the getConnection() method) by passing in a `ConnectionSpec` object. The ConnectionSpec object contains the necessary connection properties used to get a connection. After you obtain a connection from this environment, your application does not need to alter the properties. The JDBC programming model, however, does not have the same interface to specify the connection properties. Instead, it gets the connection first, then sets the properties on the connection.

WebSphere Application Server provides the following extensions to fill in such gaps between the JDBC and JCA specifications:

- WSDataSource interface - this interface extends the javax.sql.DataSource class, and enables a component or an application to specify the connection properties through the WebSphere Application Server JDBCConnectionSpec class to get a connection.
  - getConnection(JDBCConnectionSpec) - this method returns a connection with the properties specified in the JDBCConnectionSpec class.
  - For more information see the `WSDataSource` API documentation topic (as listed in the API documentation index).
- JDBCConnectionSpec interface - this interface extends the `com.ibm.websphere.rsadapter.WSConnectionSpec` class, which extends the javax.resources.cci.ConnectionSpec class. The standard ConnectionSpec interface provides only the interface marker without any get() and set() methods. The WSConnectionSpec and the JDBCConnectionSpec interfaces define a set of get() and set() methods used by the WebSphere Application Server run time. This interface enables the application to specify all the essential connection properties in order to get an appropriate connection. You can create this class from the WebSphere WSRRAFactory class. For more information see the `JDBCConnection` API documentation topic (as listed in the API documentation index).
- WSRRAFactory class - this is a factory class for the WebSphere Relational Resource Adapter, which allows the user to create a JDBCConnectionSpec object or other resource adapter related object. For more information see the `WSRRAFactory` API documentation topic (as listed in the API documentation index).
- WSConnection interface - this is an interface that allows users to call WebSphere proprietary methods on SQL connections; those methods are:
  - setClientInformation(Properties props) - See the topic, Example: Setting the client information with the setClientInformation(Properties) API, for more information and examples of setting client information.
  - Properties getClientInformation() - This method returns the properties object that is set using `setClientInformation(Properties)`. Note that the properties object returned is not affected by implicit settings of client information.
  - WSSystemMonitor getSystemMonitor() - This method returns the SystemMonitor object from the backend database connection if the database supports System Monitors. The backend database will provide some connection statistics in the SystemMonitor object. The SystemMonitor object returned is wrapped in a WebSphere object (`com.ibm.websphere.rsadapter.WSSystemMonitor`) to shield applications from dependency on any database vendor code. See `com.ibm.websphere.rsadapter.WSSystemMonitor` Java documentation for more information. The following code is an example of using the `WSSystemMonitor` class:

```
import com.ibm.websphere.rsadapter.WSConnection;
...
try{
 InitialContext ctx=new InitialContext();
 // Perform a naming service lookup to get the DataSource object.
 DataSource ds=(javax.sql.DataSource]ctx.lookup("java:comp/jdbc/myDS");
} catch (Exception e) {;}
```

```
WSConnection conn=(WSConnection)ds.getConnection();
WSSystemMonitor sysMon=conn.getSystemMonitor();
if (sysMon!=null) // indicates that system monitoring is supported on the current backend database
 {
  sysMon.enable(true);
  sysMon.start(WSSystemMonitor.RESET_TIMES);
  // interact with the database
  sysMon.stop();
  // collect data from the sysMon object
 }
conn.close();
```

The WSConnection interface is part of the `plugins_root/com.ibm.ws.runtime.jar` file.

Example: Using IBM extended APIs for database connections.

Using the WSDataSource extended API, you can code your JDBC application to define connection properties through an object prior to obtaining a connection. This behavior increases the chances that the application can share a connection with another component, such as a CMP.

If your application runs with a shareable connection that might be shared with other container-managed persistence (CMP) beans within a transaction, it is recommended that you use the WebSphere Application Server extended APIs to get the connection. When you use these APIs, you cannot port your application to other application servers.

You can code with the extended API directly in your JDBC application; instead of using the DataSource interface to get a connection, use the WSDataSource interface. The following code segment illustrates WSDataSource:

```
import com.ibm.websphere.rsadapter.*;

...

// Create a JDBCConnectionSpec and set connection properties. If this connection is shared with
the CMP bean, make sure that the isolation level is the same as the isolation level that is mapped by
 the Access Intent defined on the CMP bean.

JDBCConnectionSpec connSpec = WSRRAFactory.createJDBCConnectionSpec();

connSpec.setTransactionIsolation(CONNECTION.TRANSACTION_REPEATABLE_READ);

connSpec.setCatalog("DEPT407");

//Use WSDataSource to get the connection

Connection conn = ((WSDataSource)datasource).getConnection(connSpec);
```

Example: Using IBM extended APIs to share connections between CMP beans and BMP beans.

Within an application component that accesses data through JDBC objects (such as a bean-managed persistence (BMP) bean), you can use a WebSphere extended API to define connection properties through an object prior to obtaining a connection. This behavior increases the chances that the BMP bean can share a connection with a container-managed persistence (CMP) bean.

If your BMP bean runs with a shareable connection that might be shared with other container-managed persistence (CMP) beans within a transaction, it is recommended that you use the WebSphere Application Server extended APIs to get the connection. When you use these APIs, you cannot port your application to other application servers.

In this case, use the extended API WSDataSource interface rather than the DataSource interface. To ensure that both the CMP and bean-managed persistence (BMP) beans are sharing the same physical connection, define the same access intent profile on both the CMP and BMP beans. Inside your BMP method, you can get the right isolation level from the relational resource adapter helper class.

```

Recreating database tables from the exported table data definition language

When the WebSphere Application Server deployment tooling deploys an EJB jar file containing container-managed persistence (CMP) enterprise beans, it selects the target database and creates a corresponding *Table*.ddl file. This file contains the SQL statement necessary to generate the database table for your CMP beans.

About this task

The following steps demonstrate the process for creating tables in DB2.

Procedure

1. Extract the *Table*.ddl file from your CMP enterprise bean JAR file and save it on your database server.
   - Save the file to a temporary directory on your work station. Transfer the file to a data set on your DB2 for z/OS system.
2. Run the *Table*.ddl file.
   - Specify the data set as the input data set to SPUFI, and run the program.

Results

The database tables are created.

Container managed persistence bean associated technologies

WebSphere Application Server delivers container-managed persistence (CMP) services beyond the standards set by the Enterprise JavaBeans (EJB) specification.

According to the specification, the EJB container synchronizes the state of CMP beans with the underlying database, and manages the relationships (container-managed relationships, or CMR's) among entity beans. Thus the EJB specification relieves bean developers from writing any database-specific code; instead, they can focus on writing business logic. WebSphere Application Server offers the following additional CMP functions to increase development efficiency even more, as well as optimize the run-time performance of business logic:

Entity bean inheritance

Inheritance is a key aspect of object-oriented software development and is a capability currently missing from the EJB specification.

The use of inheritance enables a developer to define fields, relationships, and business logic in a superclass entity bean that are inherited by all subclasses. See the section *EJB inheritance* of the Rational Application Developer documentation for details on using inheritance with WebSphere Application Server and entity beans.

Access Intent Policies

Access intent policies provide Java Platform, Enterprise Edition (Java EE) application developers the mechanism by which they can indicate the intent of an application's interaction with the essential state for entity beans in order that the persistence mechanisms can make appropriate optimizations. For example, if it is known that an entity is not updated during the course of a transaction, then the persistence management is able to ease up on the concurrency control and still maintain data integrity by disallowing update operations on that bean for the duration of the transaction.

Caching data across transactions

Data caching across transactions is a configurable option set by the bean deployer that can greatly improve performance. Essentially, this is for data that changes infrequently. The option is known as *LifetimeInCache*. The data for an entity configured for lifetime in cache is stored in a cache until its specified lifetime expires. Requests on the entity during that configured lifetime use the cached data, and do not result in the execution of queries against the underlying data store. Lifetime can be expressed as time elapsed since the data was retrieved from the data store or until a specific time of day or week. The *LifetimeInCache* value can be one of the following:

Off The LifetimeInCache setting is ignored. Beans of this type are only cached in a transaction scoped cache. The cached data for this instance is not valid when the transaction is completed.

ElapsedTime

The value in the LifetimeInCache setting is added to the current time when the transaction

(in which the bean instance is retrieved) is completed. The cached data for this instance is not valid after this time. The value of the LifetimeInCache setting can add up to minutes, hours, days, and so on.

ClockTime

The value of LifetimeInCache represents a particular time of day. The value is added to the immediately preceding or following midnight to calculate a future time value, which is then treated as for Elapsed Time. Using this setting enables you to specify that all instances of this bean type have their cached data invalidated at a specific time no matter when the data were retrieved.

The use of preceding or following midnight to calculate a future time value depends on the value of LifetimeInCache. If LifetimeInCache plus preceding midnight is earlier than the current time, then the following midnight is used.

When you use the ClockTime setting, the value of LifetimeInCache must not represent more than 24 hours. If it does, the cache manager subtracts increments of 24 hours from it until a value less than or equal to 24 hours is achieved. To invalidate data at 12 midnight, you set LifetimeInCache to zero (0).

WeekTime

This setting is similar to ClockTime, except the value of LifetimeInCache is added to the preceding or following Sunday midnight (actually, 11:59 PM on Saturday plus 1 minute). In this case, the LifetimeInCache value can represent more than 24 hours, but not more than 7 days.

See the *LifetimeInCache* help sections of the assembly tool for more details.

Note:

Because the data used by an entity bean can be loaded by previous transactions, if you configure the bean as LifeTimeInCache, the isolation level and update lock (access intent policies) for the bean are lost for the current transaction. This can cause data integrity problems if your application has logic to calculate information from read-only data, and then save the result in another bean. This makes it important to perform read-read consistency checking to ensure the data get locked properly if loading the data from in-memory cache; otherwise, data is updated to the database without knowing the underlining data is changed, causing previous changes to be lost. For more information, see the topic Configuring read-read consistency checking with an assembly tool.

Read-only entity beans

Declaring entity beans as read-only potentially increases the performance enhancement offered by caching. Both features operate on the same principle: to minimize the overhead incurred by frequent reloading of entity beans from data in persistent storage. When you designate entity beans as read-only, you can specify the reload requirements and frequency, according to the needs of your application.

To use this function, you declare the bean type as read-only by selecting a particular set of bean caching options, through a selection list within the assembly tooling. See Configuring read-read consistency checking with an assembly tool for details.

Container-managed persistence restrictions and exceptions:

Some external software that directly impact your applications can limit container-managed persistence (CMP) features. However, you can work around these limitations.

In each case, only very specific behaviors of the software place restrictions on your CMP beans. The following tips help you prevent these behaviors.

CMP deployment and Sybase IMAGE type restriction

When deploying enterprise beans with container managed persistence (CMP) types that are non-primitive and do not have a natural JDBC mapping, the deployment tool maps the CMP type to a binary type in the database, where it is stored as a serialized instance. For Sybase, the tool uses the JDBC type *LONG VARBINARY*. The Sybase driver maps *LONG VARBINARY* to the native type *IMAGE*.

Although the type *VARBINARY* has fewer restrictions than *IMAGE* in Sybase, you cannot use it because it is limited to a size of 255 bytes, which is too small for typical serialized Java objects.

The specific restrictions on the IMAGE type are:

- You cannot use the *IMAGE* type in the *WHERE* clause of an SQL query. You can encounter this restriction whenever an enterprise bean contains an EJB-QL query that has a CMP type in the *WHERE* clause, which maps to the *IMAGE* type in the Sybase relational database.
- You cannot use *IMAGE* type in select queries marked *DISTINCT*. This situation arises in these user scenarios:
  - When the *DISTINCT* key word is specified in an EJB-QL select query having a Java type mapping to IMAGE.
  - When Enterprise beans have finder and ejbSelect() methods returning java.util. Set and have CMP types mapping to *IMAGE*.

To work around this restriction, edit the EJB mappings in the Rational Application Developer toolset and do either of the following:

- If you are **sure** that the serialized instance of the CMP type is **never** larger than 255 bytes, you can change the CMP type mapping from *IMAGE* or *LONG VARBINARY* to *VARBINARY*.
- Map the CMP type to multiple RDB fields through a composer. For example, if the CMP type is a Java object X with an int field and a string field, then map X to two RDB fields *INTEGER* and *VARCHAR*, using a composer. Refer to the Rational Application Developer documentation for more information about using composers.

A ClassCastException exception occurs when running CMP 1.1 beans

If you created your Enterprise JavaBeans (EJB) application using Rational Application Developer or WebSphere Studio Application Developer Integration Edition, Version 4.0.x , and the application contains container managed persistence (CMP) 1.1 beans with associations (relationships), you might receive a *java.lang.ClassCastException* exception when you run your application on WebSphere Application Server.

Note: Business processes modeled with WebSphere Studio Application Developer Integration Edition Version 5.0 or earlier are deprecated.

The cast operation generated by Rational Application Developer or WebSphere Studio Application Developer Integration Edition, Version 4.0.x, does not use the *javax.rmi.PortableRemoteObject.narrow(...)* object to convert the remote object to the remote interface of CMP beans in the *XToYLink.java* (or *YToXLink.java*) class where X and Y are CMP 1.1 beans.

Recommended response:

1. Locate the following methods in all link classes, for example, XToYLink.java and YToXLink.java where X and Y are CMP 1.1 beans:

   ```
   public void secondaryAddElementCounterLinkOf(javax.ejb.EJBObject anEJB)
   public void secondaryRemoveElementCounterLinkOf(javax.ejb.EJBObject anEJB)
   public void secondarySetCounterLinkOf(javax.ejb.EJBObject anEJB)
   ```

2. Add the javax.rmi.PortableRemoteObject.narrow(...) object to convert the remote object to the remote interface of CMP beans.

For example, change the following original method:

```
public void secondaryAddElementCounterLinkOf(javax.ejb.EJBObject anEJB) throws java.rmi.RemoteException {
        if (anEJB != null)
               ((X) anEJB).secondaryAddY((Y) getEntityContext().getEJBObject());
```

to:

```
public void secondaryAddElementCounterLinkOf(javax.ejb.EJBObject anEJB) throws java.rmi.RemoteException {
        if (anEJB != null)
             ((X) anEJB).secondaryAddY((Y)
javax.rmi.PortableRemoteObject.narrow(getEntityContext().getEJBObject(), Y.class));
```

Application performance and entity bean behavior:

WebSphere Application Server allows you to override two behaviors that are required by the Enterprise JavaBeans (EJB) specification, because your application might benefit from handling these aspects of bean data management in a slightly different manner.

Application-managed persistent store synchronization for findBy methods

Sections 10.5.3 and 12.1.4.2 of the EJB 2.0 and 2.1 specifications require that prior to running a query as part of any findBy method (except for findByPrimaryKey), the EJB container writes out to persistent storage the state of any entity beans of the type that are enlisted in the current transaction. Stated another way, the container performs the following actions:

1. Creates a list of beans that are both enlisted in the current transaction and are of the same type that the findby method is returning
2. Stores the state of these enterprise beans to persistent storage before running the query

If the state of an EJB instance is not altered in the current transaction, the store operation is skipped for that instance. This practice ensures that the query is performed on the most current state of all the persistent data, reducing the chance of data integrity issues.

However, there are scenarios where it is inefficient and wasteful for the EJB container to automatically perform this action on every findBy method. Examples of this would be where the application itself ensures that the most current data is used on findBy queries, or where the application can tolerate some non-current data as part of the query results.

WebSphere Application Server allows you to initiate the synchronization process under application control, and to disable the container-managed synchronization for specific EJB types within your application. Careful use of these functions can improve the performance of your application without sacrificing data integrity. Refer to the topic Manipulating the synchronization of entity beans and datastores.

Avoiding ejbStore invocations on non-modified entity bean instances

The EJB specification requires that the EJB container invoke the user-provided ejbStore method on all entity beans within a transaction when that transaction is committed. For container-managed persistence (CMP) beans (as opposed to bean-managed persistence beans) this operation is usually unnecessary, because this method on CMP beans is often empty. Even in cases where the method is not empty, the application might only require the method to be called if the bean's persistent state is modified during the current transaction.

WebSphere Application Server provides a mechanism for you to indicate if you want this behavior for specific EJB types within the application. See the topic Avoiding ejbStore invocations on non-modified EntityBean instances.

Manipulating synchronization of entity beans and datastores

You can indicate that a particular Enterprise JavaBeans (EJB) type should not synchronize its state to persistent storage prior to each findBy invocation by using environment variables or a marker interface.

About this task

There are two options available for indicating that a particular EJB type should not synchronize its state to persistent storage prior to each findBy invocation:

- Set an EJB environment variable within the bean's deployment descriptor
- Have the bean implementation class implement a marker interface. This second technique is especially useful if you have a number of bean implementations that all extend a single root class; in this case you can have the root class implement the marker interface, causing all beans that extend this class to inherit the behavior as well.

Procedure

- **To use the EJB environment variable technique**, edit the EJB deployment descriptor using any standard Java Platform, Enterprise Edition (Java EE) development tool. For information on your tool options, see the topic, Assembly tools.
  1. Start the tool.
  2. Select the EJB deployment descriptor of the bean with which you want to work.
  3. Create an EJB environment variable with the name **com/ibm/websphere/ejbcontainer/disableFlushBeforeFind**.
  4. Set the type of this variable to **java.lang.Boolean**.
  5. Set the value to True to prevent the pre-find synchronization, or False to enable the default behavior.
  6. Save your changes.
- **To use a marker interface**, code your bean implementation class to implement the **com.ibm.websphere.ejbcontainer.disableFlushBeforeFind** interface. The bean implementation class need not directly implement the interface; any parent class can implement the interface. See the **com.ibm.websphere.ejbcontainer** package in the **Reference** > **Developer** > **API documentation** section of the information center.

  Ensuring data integrity for queries performed during a transaction

  If you choose to disable the automatic pre-find synchronization for certain bean types, it is very important that your application use other means to ensure that queries performed during the transaction are not performed on data that might no longer be valid. You can use the flushCache method on the com.ibm.websphere.ejbcontainer.EJBContextExtension class (an extension of javax.ejb.EJBContext) to perform a manual synchronization to persistent storage at times that are defined by the application. For more information on EJBContextExtension and its related classes SessionContextExtension, EntityContextExtension and MessageDrivenContextExtension, see the **com.ibm.websphere.ejbcontainer** package in the **Reference** > **Developer** > **API documentation** section of the information center.

Avoiding ejbStore invocations on non-modified EntityBean instances

You can configure your EntityBean instances to bypass an invocation of the ejbStore method if they have not been modified during the current transaction.

About this task

There are two options available for indicating that a particular Enterprise JavaBeans (EJB) type should only have its ejbStore method invoked if the bean has been modified during the current transaction:

- Set an EJB environment variable within the bean's deployment descriptor
- Have the bean implementation class implement a marker interface. This second technique is especially useful if you have a number of bean implementations that all extend a single root class; in this case you may have the root class implement the marker interface, causing all beans that extend this class to inherit the behavior as well.

Procedure

- **To use the EJB environment variable technique**, edit the EJB deployment descriptor using any standard Java Platform, Enterprise Edition (Java EE) development tool. Use the following steps as a guide. For information on your tool options, see the topic, Assembly tools.
  1. Start the tool.
  2. Select the EJB deployment descriptor of the bean you want to work with.
  3. Create an EJB environment variable with the name **com/ibm/websphere/ejbcontainer/ disableEJBStoreForNonDirtyBeans**.
  4. Set the type of this variable to **java.lang.Boolean.**
  5. Set the value to True to avoid the ejbStore invocation, or False to enable the default behavior.
  6. Save your changes.
- **To use a marker interface**, code your bean implementation class to implement the **com.ibm.websphere.ejbcontainer.DisableEJBStoreForNonDirtyBeans** interface. The bean implementation class need not directly implement the interface; any parent class can implement the interface. See the **com.ibm.websphere.ejbcontainer** package in the **Reference** > **Developer** > **API documentation** section of the information center.

Resource reference benefits

WebSphere Application Server requires your code to reference application server resources (such as data sources or J2C connection factories) through logical names, rather than access the resources directly in the Java Naming and Directory Interface (JNDI) name space. These logical names are called *resource references*.

Application Server requires use of resource references for the following reasons:

- If application code looks up a data source directly in the JNDI naming space, every connection that is maintained by that data source inherits the properties that are defined in the application. Consequently, you create the potential for numerous exceptions if you configure the data source to maintain shared connections among multiple applications. For example, an application that requires a different connection configuration might attempt to access that particular data source, resulting in application failure.
- It relieves the programmer from having to know the name of the actual data source or connection factory at the target application server.
- You can set the default isolation level for a data source through resource references. With no resource reference you get the default for the JDBC driver you use.

The following example of using a resource reference invokes a data source by creating a place holder for it through the lookup method. Using the logical name *jdbc/Section*, the code stores the place holder in the JNDI subcontext *java:comp/env/*; hence *jdbc/Section* becomes a resource reference. (The subcontext *java:comp/env/* is the name space that WebSphere Application Server provides exclusively for object references within application code.)

```
javax.sql.DataSource specificDataSource  =
   (javax.sql.DataSource) (new InitialContext()).lookup("java:comp/env/jdbc/Section");
//The method InitialContext()).lookup creates the logical name, or resource reference, jdbc/Section.
```

Generally, an actual data source is configured later as an administrative task.

The logical name *jdbc/Section* is officially declared as a resource reference in the application deployment descriptor. You can then associate the resource reference with the JNDI name of the actual data source in several ways:

- If you know the data source JNDI name at the point of application assembly, specify the name on the resource references Bindings page.
- Specify the data source JNDI name during application deployment.

- Map the resource reference to the data source JNDI name when you configure the application after deployment.

This act of association is called *binding* the resource reference to the data source.

See the article, Application bindings, for information on all types of required resource bindings.

Requirements for setting data access isolation levels:

This article discusses the criteria and effects of setting isolation levels for data access components that comprise Enterprise JavaBeans (EJB) 2.x and later modules.

In an EJB 1.1 module, you can set the isolation level at the method level or bean level. This capability also applies to container-managed persistence (CMP) 1.1 beans that you assemble into *EJB 2.x modules*. WebSphere Application Server permits the deployment descriptor of a CMP bean to declare the version level of 1.1, regardless of the overall module version.

However, the ability to set isolation level at the method or bean level does **not** apply to other enterprise beans within an EJB 2.x module, including *CMP 2.x beans*. WebSphere Application Server Version 5.0 removed this capability from EJB 2.0 modules to deliver an architecture that ultimately provides more efficient connection use.

Consequently, later versions of the product enforce the following restrictions on declaring isolation level for CMP 2.x beans—as well as session beans, message-driven beans, and bean managed persistence (BMP) beans that you assemble into EJB 2.x modules:

- You cannot specify isolation level on the EJB method level or bean level.
- If you configure a JDBC application, a bean-managed persistence (BMP) bean, or a servlet to participate in global transactions, any connection that is shared cannot accept a user-specified isolation level. WebSphere Application Server can only set a user-specified isolation level on a connection that is not shared within a global transaction. *Generally, you want to refrain from specifying isolation levels on shareable connections.*

The configuration for the isolation level is determined by the type of bean that is used by the component:

Isolation level on connections used by 2.x CMP beans

In a EJB 2.x module, when a CMP 2.x bean uses a new data source to access a backend database, the isolation level is determined by the WebSphere Application Server run time, based on the type of access intent assigned to the bean or the calling method. Other non-CMP connection users can access this same data source and also use the access intent and application profile support to manage their concurrency control.

Connections used by other 2.x enterprise beans and other non-CMP components

For all other JDBC connection instances (connections other than those used by CMP beans), you can specify an isolation level on the data source resource reference. For shareable connections that run in global transactions, this method is the only way to set the *isolationLevel* for connections. Trying to directly set the isolation level through the *setTransactionIsolation()* method on a shareable connection that runs in a global transaction is not allowed. To use a different isolation level on connections, you must provide a different resource reference. Set these defaults through your assembly tool.

Each resource reference associates with one isolation level. When your application uses this resource reference Java Naming and Directory Interface (JNDI) name to look up a data source, every connection returned from this data source using this resource reference has the same isolation level.

Components needing to use shareable connections with multiple isolation levels can create multiple resource references, giving them different JNDI names, and have their code look up the

appropriate data source for the isolation level they need. In this way, you use separate connections with the different isolation levels enabled on them.

It is possible to map these multiple resource references to the same configured data source. The connections still come from the same underlying pool, however; the connection manager does not allow sharing of connections requested by resource references with different isolation levels. Consider the following scenario:

- A data source is bound to two resource references: *jdbc/RRResRef* and *jdbc/RCResRef*.
- RRResRef has the *RepeatableRead* isolation level defined. RCResRef has the *ReadCommitted* isolation level defined.

If your application wants to update the tables or a BMP bean updates some attributes, it can use the *jdbc/RRResRef* JNDI name to look up the data source instance. All connections returned from the data source instance have a RepeatableRead isolation level. If the application wants to perform a query for read only, then it is better to use the *jdbc/RCResRef* JNDI name to look up the data source.

The product does not require you to set the isolation level on a data source resource reference for a non-CMP application module. If you do not specify isolation level on the resource reference, or if you specify TRANSACTION_NONE, the WebSphere Application Server run time uses a default isolation level for the data source. Application Server uses a default setting based on the JDBC driver.

For most drivers, WebSphere Application Server uses an isolation level default of TRANSACTION_REPEATABLE_READ. For Oracle drivers, however, Application Server uses an isolation level of TRANSACTION_READ_COMMITTED. Use the following table for quick reference:

Database:	**Default isolation level:**
DB2	RR
Oracle	RC
Sybase	RR
Informix®	RR
Apache Derby	RR
SQL Server	RR

Note: These same default isolation levels are used in cases of direct JNDI lookups of a data source.

- RR = JDBC Repeatable read (TRANSACTION_REPEATABLE_READ)
- RC = JDBC Read committed (TRANSACTION_READ_COMMITTED)

To customize the default isolation level, you can use the webSphereDefaultIsolationLevel custom property for the data source. In most cases you should define the isolation level in the deployment descriptor when you package the EAR file, but in certain situations you might need to customize the default isolation level. This property will have no effect if any of the previous options are used, and this custom property is provided for those situations in which there is no other means of setting the isolation level.

Use the following values for webSphereDefaultIsolationLevel custom property:

Possible values	**JDBC isolation level**	**DB2 isolation level**
8	TRANSACTION_SERIALIZABLE	Repeatable Read (RR)
4 (default)	TRANSACTION_REPEATABLE_READ	Read Stability (RS)
2	TRANSACTION_READ_COMMITTED	Cursor Stability (CS)

Possible values	JDBC isolation level	DB2 isolation level
1	TRANSACTION_READ_UNCOMMITTED	Uncommitted Read (UR)

To define this custom property for a data source:

1. Click **Resources** > **JDBC provider** > ***JDBC_provider***.
2. Click **Data sources** in the Additional Properties section.
3. Click the name of the data source.
4. Click **Custom properties**.
5. Create the webSphereDefaultIsolationLevel custom property.
   a. Click **New**.
   b. Enter webSphereDefaultIsolationLevel for the name field.
   c. Enter one of the possible values in the value field.

Application Server sets the isolation level by prioritizing the available settings. Application Server will set the isolation level based on the values for the following, in this order:

1. Resource reference isolation level
2. Isolation level that is specified by the access intent policy
3. Custom property that configures an isolation level
4. Application Server's default setting.

Data source lookups for enterprise beans and web modules:

During either application assembly or deployment, you must bind the resource reference to the Java Naming and Directory Interface (JNDI) name of the actual resource in the runtime environment. You can take this action in the assembly tool or as one of the steps during installation of the application enterprise archive (EAR) file.

Bean-managed persistence bean: When developing your bean-managed persistence (BMP) bean you generally lack knowledge about the name of the data source on the target application server. In your code, do not look up the data source directly. Instead, you look up the resource reference from the *java:comp/env namespace* file. Let us assume that you look up the resource reference named *ref/ds*, for example:

```
javax.sql.DataSource dSource = (javax.sql.DataSource)((new InitialContext()).lookup("java:comp/env/ref/ds"));
```

In the assembly tool, you specify the name **ref/ds** in the Resource Reference page on the General Tab. If you know the name of the data source you can specify it in this Resource References page on the Bindings Tab. Note that if you do not specify it here , you must provide this JNDI name when you install the application EAR file.

Container-managed persistence bean: The data source binding process for the container-managed persistence (CMP) bean is the same process that you perform for bean-managed persistence (BMP) beans. Use the data source JNDI name as a WebSphere binding property for each bean during application assembly.

Servlets and JavaServer Pages Files: In a servlet application, you look up the data source exactly as you look it up in the BMP bean case.

Direct and indirect JNDI lookup methods for data sources:

You can use a direct or indirect method for the Java Naming and Directory Interface (JNDI) name (such as jdbc/DataSource) to look up a data source.

Direct

When you use a JNDI name such as jdbc/myDatasource, the application server assigns default values to the resource reference data. An informational message resembling the following is logged to document the default values:

```
[10/5/07 11:40:38:468 CDT] 0000002e ConnectionFac W
 J2CA0294W: Direct JNDI lookup of resource jdbc/myDatasource.
   The following default values are used:

[Resource-ref CMConfigData key items]
res-auth:                 1 (APPLICATION)
res-isolation-level:      0 (TRANSACTION_NONE)
res-sharing-scope:        true (SHAREABLE)
loginConfigurationName:   null
loginConfigProperties:    null

[Resource-ref non-key items]
isCMP1_x:                 false (not CMP1.x)
isJMS:                    false (not JMS)
commitPriority            0
Java EE Name:                not set
Resource ref name:        not set
isCMP:                    false (not set)
```

The first of these attributes, *res-auth*, dictates what type of authentication is done. This default setting says that the component-managed authentication alias is used if you do not specify an activation specification or you do not specify the username and password on the getConnection call. It says that the container-managed alias is not used.

The second of these settings, *res-isolation-level*, says that the isolation level is set to the "default" settings. For an enterprise bean, you can set this in the Enterprise JavaBeans (EJB) bean itself. For a servlet getting a connection, this results in the isolation level being Repeatable_Read. This is a fairly restrictive isolation level. This can lead to lowered performance, because application requests will lock more rows than with a less restrictive isolation level.

Finally, the *res-sharing-scope* is set to **Shareable**, meaning a Shareable connection is used. For some applications, a Shareable connection is fine. For others, in particular those servlets that get multiple connections within a single service() method, it is not.

To avoid any surprises that might accompany these settings, you should change your application to use an indirect JNDI name instead of the direct JNDI name, and you should create a resource reference.

Indirect

To use values that are different from the defaults, use an assembly tool to define your resource reference. The resource reference can also be created in the EJB Deployment Descriptor (ejb-jar.xml), Web Deployment Descriptor (web.xml), or Application Client Deployment Descriptor (application-client.xml) editors using an assembly tool. After you define the resource reference, you can do an indirect JNDI lookup (using the java:comp/env context). Then the values for the resource reference properties that are defined in the resource reference are used and the J2CA0122I message no longer appears. Read the topic on creating a resource reference for more information.

Access intent service:

The access intent service enables developers to precisely tune the management of application persistence.

Access intent enables developers to configure applications so that the Enterprise JavaBeans (EJB) container and its agents can make performance optimizations for entity bean access. Entity beans and entity bean methods are configured with access intent policies. A policy is acted upon by either the

combination of the WebSphere EJB container and Persistence Manager (for container-managed persistence (CMP) entities) or by bean-managed persistence (BMP) entities directly. Note that access intent policies apply to entity beans only.

Predefined access intent policies

Seven predefined access intent policies are available. The policies are composed of different attributes. The *access type* is of primary interest and controls the isolation level, lock type, and duration of locks obtained when bean data is read from the database.

A pessimistic access type indicates to hold locks for the duration of the transaction under which the data loads. An optimistic type indicates to drop locks immediately after the data is read from the backend. A *read* type indicates that the run time must not allow updates to the data; any attempt to do so on data read under a *read* type results in an exception. *Update* types permit you to change data.

Though a pessimistic update policy is designed to hold update locks on data records, it does not block threads with other policies that try to access the same data records. When two threads that run pessimistic update policies access a given record, they serialize (but not block) other threads that run pessimistic read or optimistic policies and try to access the same record.

The seven access intent policies and their attribute definitions follow:

wsPessimisticUpdate
- Access type = Pessimistic update
- Collection scope = Transaction
- Collection increment = 1
- Resource manager prefetch increment = 0
- Read ahead hint = null

wsOptimisticUpdate
- Access type = Optimistic update
- Collection scope = Transaction
- Collection increment = 25
- Resource manager prefetch increment = 0
- Read ahead hint = null

wsOptimisticRead
- Access type = Optimistic read
- Collection scope = Transaction
- Collection increment = 25
- Resource manager prefetch increment = 0
- Read ahead hint = null

wsPessimisticRead
- Access type = Pessimistic read
- Collection scope = Transaction
- Collection increment = 25
- Resource manager prefetch increment = 0
- Read ahead hint = null

wsPessimisticUpdate-Exclusive
- Access type = Pessimistic update
- Exclusive = true
- Collection scope = Transaction
- Collection increment = 1
- Resource manager prefetch increment = 0
- Read ahead hint = null

wsPessimisticUpdate-NoCollision
- Access type = Pessimistic update
- No collision = true
- Collection scope = Transaction

- Collection increment = 25
- Resource manager prefetch increment = 0
- Read ahead hint = null

wsPessimisticUpdateWeakestLockAtLoad

- ***default policy**
- Access type = Pessimistic Update
- Promote = true
- Collection scope = transaction
- Collection increment = 25
- Resource manager prefetch increment = 0
- Read ahead hint = null

To support connection sharing, you must ensure that all data loaded in the same transaction is under the same isolation level. Verify that all participating methods that drive loads are configured with either a pessimistic access type or an optimistic access type.

Access intent -- isolation levels and update locks:

WebSphere Application Server access intent policies provide a consistent way of defining the isolation level for CMP bean data across the different relational databases in your environment.

Within a deployed application, the combination of an access intent policy *concurrency definition* and *access type* signifies the isolation level value that Application Server sets on a database connection. See the articles, Concurrency control, and Access intent and isolation, for more information on concurrency and access type. This combination of properties also signifies the update lock flag that Application Server passes to the database through a JDBC prepared statement.

Databases do not provide as many isolation level definitions as WebSphere Application Server. Databases define an isolation level as one of only three types. Furthermore, only one parameter indicates the type of isolation level that the databases set on incoming connections. Each of the three types can be represented by a *different* parameter value, as determined by each database vendor. For example, one database might define an isolation level as RR (JDBC Repeatable read), whereas a different database might define the same isolation level as RC (JDBC Read committed).

Because of this inconsistency, WebSphere Application Server does not map access intent policies to the parameter values. Instead, Application Server maps access intent policies to the types of isolation level that are common across all database vendors.

Table 7. Access intent policies relationship to database isolation levels and update lock settings. The following matrix shows how access intent policies correspond to different database isolation levels and update lock settings.

Access Intent profile	Isolation level						Update lock implementation
	DB2	Oracle*	SyBase	Informix	Apache Derby	SQL Server	
wsPessimisticUpdate-Weakest LockAtLoad (Default policy)	RR	RC	RR	RR	RR	RR	No (*Oracle, Yes)
wsPessimisticUpdate	RR	RC	RR	RR	RR	RR	Yes
wsPessimisticRead	RR	RC	RR	RR	RR	RR	No
wsOptimisticUpdate	RC	RC	RC	RC	RC	RC	No
wsOptimisticRead	RC	RC	RC	RC	RC	RC	No
wsPessimisticUpdate No-Collisions	RC	RC	RC	RC	RC	RC	No
wsPessimisticUpdate-Exclusive	S	S	S	S	S	S	Yes

- RC = JDBC Read Committed
- RR = JDBC Repeatable Read
- S = JDBC Serializable

- * Oracle does not support JDBC Repeatable Read (RR). Therefore, wsPessimisticUpdate-weakestLockAtLoad and wsPessimisticUpdate behave the same way on Oracle as do wsPessismisticRead and wsOptimisticRead. Because of an Oracle restriction, the OracleXADataSource JDBC class cannot run with an S transaction isolation level. Therefore, you cannot use this class to run an application containing enterprise beans with access intent policies that are configured to cause the bean to load with S isolation.
- Setting access intent policies per EJB method support is deprecated for Version 6.0. It is recommended that you set access intent only for the entire bean.

New for MS SQL Server 2005: MS SQL Server 2005 offers a new option for the Read Committed isolation level and a new option for the Serializable isolation level:

- Read Committed with Snapshots
- Transaction Snapshot (for Serializable)

Both options use optimistic locking. To use Read Committed with Snapshots instead of Read Committed, enable the READ_COMMITTED_SNAPSHOT setting for the database according to the MS SQL Server 2005 documentation. To use Transaction Snapshot instead of Serializable, configure the custom data source property, snapshotSerializable, to "true" and enable the ALLOW_SNAPSHOT_ISOLATION setting for the database according to the MS SQL Server 2005 documentation.

Structured Query Language (SQL) keywords and restrictions

Table 8. SQL keywords and restrictions. The following table shows which SQL keywords are used during update intent locking, as well as any restrictions imposed on the SQL.

Database	SQL syntax used for locking update	join restrictions	order by restrictions	subselect restrictions	aggregation restrictions
DB2	FOR UPDATE OF	not allowed	not allowed	not allowed	not allowed
DB2 UDB for iSeries® (V5R3 and earlier)	FOR UPDATE OF	not allowed	allowed with limitations*	allowed with limitations*	not allowed
DB2 UDB for iSeries (V5R4 and later)	WITH RS/RR USE AND KEEP EXCLUSIVE LOCKS	not allowed	allowed with limitations*	allowed with limitations*	not allowed
DB2 on z/OS V8.x	WITH RS/RR USE AND KEEP UPDATE LOCKS	none	none	none	none
DB2 UDB workstation V8.2	WITH RS/RR USE AND KEEP UPDATE LOCKS	none	none	none	none
Oracle	FOR UPDATE	none	none	none	none
Apache Derby	FOR UPDATE OF	not allowed	not allowed	not allowed	not allowed
Informix	FOR UPDATE	not allowed	not allowed	not allowed	not allowed
Sybase	FOR UPDATE	not allowed	not allowed	not allowed	not allowed
Sqlserver	UPDLOCK	not allowed	not allowed	not allowed	not allowed

Note: For details on the limitations for these permitted SQL restrictions, refer to the DB2 Universal Database™ for iSeries SQL Reference. You can find this document in the iSeries Information Center, Version 5 Release 4. In the Contents navigation area, click **Database** > **Reference** > **SQL Reference**.

Custom finder SQL dynamic enhancement:

To ensure data integrity for applications using custom finders defined on Enterprise JavaBeans (EJB) version 1.1 home interfaces, WebSphere Application Server Version 6.x uses custom finder Structured Query Language (SQL) dynamic enhancement to maintain correct SQL locking semantics.

WebSphere Application Server uses SQL clauses applied to the custom finder SQL statements for those custom finders defined with the *Update* attribute and certain method-level isolation level settings. These dynamic enhancements are applied only if the backend data store supports these clauses.

This support takes affect at run time when the run time attempts to execute container-managed persistence (CMP) persistence operations associated with the custom finders. To ensure that the SQL dynamic enhancements occur correctly for custom finders defined on an EJB version 1.1 home interface accessing a backend data store that requires the special SQL locking clauses, WebSphere Application Server provides new Java Virtual Machine (JVM) and bean (module) properties. These properties enable you to indicate which custom finders should be enhanced, provided the backend store supports the SQL clauses. For more information about these properties, Custom finder SQL dynamic enhancement properties.

There are several important items to consider when using this functionality:

- This support **only** applies to EJB version 1.1 CMP Custom Finder methods
- Option A CMP beans and CMP beans involved in an inheritance relationship are not supported
- Applications using this capability in WebSphere Application Server for z/OS Version 4.x continue to function, but you must address some compatibility issues:
  - The default behavior of WebSphere Application Server Version 5.x and above is the opposite of the Version 4.x product, that is, the default for 5.x and above is **not** to enhance custom finder SQL statements unless directed to by specific settings. If your WebSphere Application Server for z/OS installation relies on the automatic dynamic enhancement of all custom finders in all applications installed, you must set the *com.ibm.websphere.ejbcontainer.customfinder.honorAccessIntent* indicator to **all**.
  - If an application contains a bean which has the *com.ibm.websphere.persistence.bean.managed.custom.finder.access.intent* indicator set into its env-var settings, that indicator continues to be used, provided the dynamic SQL enhancement features of the product at Version 5.x and above are enabled. For more information, see the topic Custom finder SQL dynamic enhancement properties.

Custom finder SQL dynamic enhancement properties:

Use this page to modify custom finder SQL dynamic enhancement properties settings.

To ensure that the Structured Query Language (SQL) dynamic enhancements occur correctly for custom finders defined on an EJB 1.1 Home interface that uses a backend data store that requires the special SQL locking clauses, the following Java virtual machine (JVM) and bean (module) properties are provided. These properties enable you to indicate which custom finders to enhance, assuming the backend data store supports the SQL clauses.

For z/OS, to view this administrative console page, click **Servers > Server Types > WebSphere application servers >** *server_name* **> Control** (to define the property in the Control) or **Servant** (to define the property in the Servant) **> Java and process management > Process definition > Java virtual machine > Custom properties**.

com.ibm.websphere.ejbcontainer.customfinder.honorAccessIntent:

Used to indicate which enterprise beans should have custom finder SQL dynamic enhancement enabled at runtime.

This property takes effect at the server level. Any EJB 1.1 home interface-defined custom finder (prefix named *find*) that has *Update* as an access intent is a candidate for custom finder SQL dynamic enhancement based on its specified isolation level. If the backend data store requires special SQL semantics, they are applied. The particular SQL used varies according to the isolation level you choose for beans in the application, as well the backend data base being used. If set to **all**, custom finder SQL

dynamic enhancement is enabled for all custom finders defined in any beans that are installed into the container. If set to **J2EENAME[:J2EENAME]**, where *J2EENAME* is a fully qualified package or bean name, custom finder SQL dynamic enhancement is enabled for only the custom finders defined in the beans that are installed into the container and represented by the bean names denoted.

Information	Value
Data type	String
Range	Valid values are **all** or **J2EENAME[:J2EENAME]**
Default	Enhancement behavior not active

Note: Some of your applications might use custom finders that have been manually coded and already contain the SQL locking clauses, or keywords *ORDER BY* and *DISTINCT* on the *SELECT* operation. In these instances, if the run time attempts SQL dynamic enhancement, the possibility exists of introducing malformed SQL statements to the underlying backend data store. If an application contains these custom finders, then you must be careful when specifying the value for the JVM property *com.ibm.websphere.ejbcontainer.customfinder.honorAccessIntent*. A value of **all** causes custom finder SQL dynamic enhancement to occur for every custom finder method defined with an access intent of *Update* found in all beans that are installed in the application server, thus introducing malformed SQL for that subset of custom finders.

To prevent this from happening, ***do not*** set the server-wide setting to **all**. Instead, use the bean method level property, *com.ibm.websphere.ejbcontainer.customfinder.honorAccessIntent.methodLevel* to indicate on a per bean basis only those custom finder methods that should have the custom finder SQL dynamic enhancement executed on them at run time.

com.ibm.websphere.ejbcontainer.customfinder.honorAccessIntent.methodLevel:

Used to indicate custom finder SQL dynamic enhancement be enabled at the method level on a particular bean.

When a bean is defined with this property set to a list of one or more custom finder methods, any custom finder (prefix named *find*) defined on the home interface that has a matching method name and parameter signature has SQL locking semantics applied at run time. This occurs only if the custom finder method has an access intent of *Update* specified and the backend data store supports the SQL clauses. The particular SQL used varies according to the isolation level chosen for the application as well as the backend data store being used.

Information	Value
Data type	String
Range	Valid value is a string of this form: **method1(parm1,parm2,..parmn):method2(parm1,parm2,..parmn):methodn(...)**

com.ibm.websphere.persistence.bean.managed.custom.finder.access.intent:

Used by WebSphere Application Server for z/OS Version 4.x users to indicate that the SQL enhancement capability should **not be** applied to applications installed in the WebSphere Application Server for z/OS product.

The default behavior of the WebSphere Application Server for z/OS Version 4.x product is to perform the dynamic SQL enhancements. For those z/OS users choosing not to participate in dynamic SQL enhancement of custom finders in the Version 4.x product, this attribute is used to make this indication at both the bean and the server level.

At the bean level, a name/value pair consisting of this attribute name and a value of **true** disables the SQL enhancement of any custom finder defined on the given bean's home interface.

At the server level, an entry into the WebSphere Application Server for z/OS server property file with a value of **true** disables the SQL enhancement of all beans installed in the given server.

This custom finder enhancement attribute continues to be supported by the runtime at the bean level in the product. Its use as a server wide indicator has been deprecated by the fact that the default behavior of earlier versions is to ***not*** dynamically enhance custom finder SQL.

Note: If your WebSphere Application Server for z/OS installation relies on the automatic dynamic enhancement of all custom finders in all applications installed, you should set the *com.ibm.websphere.ejbcontainer.customfinder.honorAccessIntent* indicator to **all**. If an application contains a bean that has the *com.ibm.websphere.persistence.bean.managed.custom.finder.access.intent* indicator set into its *env-var* settings, that indicator continues to be used, provided the dynamic SQL enhancement features of the product are enabled as described above.

Information	**Value**
Data type	String
Range	Valid values are **true** and **false**

Some notes about precedence:

- The *com.ibm.websphere.ejbcontainer.customfinder.honorAccessIntent.methodLevel* attribute overrides any server-wide or bean level attribute setting
- Any bean listed through a *J2EE Name* in the *com.ibm.websphere.ejbcontainer.customfinder.honorAccessIntent* indicator causes dynamic enhancement to occur for custom finders defined for that bean, even if the default behavior is in effect for the server in question.
- The *com.ibm.websphere.persistence.bean.managed.custom.finder.access.intent* attribute disables a particular bean's use of this feature if the server-wide setting or bean setting is enabled and no method level settings are specified.

Accessing data using Java EE Connector Architecture connectors

To access data from a Java EE Connector Architecture (JCA) compliant application in WebSphere Application Server, you configure and use resource adapters and connection factories.

About this task

An application component uses a connection factory to access a connection instance, which the component then uses to connect to the underlying enterprise information system (EIS). Examples of connections include database connections, Java Message Service connections, and SAP R/3 connections.

As indicated in the Java EE Connector Architecture (JCA) Specification, each enterprise information system (EIS) needs a resource adapter and a connection factory. This connection factory is then accessed through the following programming model. If you use Rational Application Development tools, most of the following deployment descriptors and code are generated for you. This example shows the manual method of accessing an EIS resource.

Procedure

1. Declare a connection factory resource reference in your application component deployment descriptors, as described in this example:

```
<resource-ref>
   <description>description</description>
   <res-ref-name>eis/myConnection</res-ref-name>
   <res-type>javax.resource.cci.ConnectionFactory</res-type>
   <res-auth>Application</res-auth>
</resource-ref>
```

2. During the deployment process, configure each resource adapter and associated connection factory through the console. See the topics on installing a resource adapter and configuring a connection factory for more information.
3. Locate the corresponding connection factory for the EIS resource adapter using Java Naming and Directory Interface (JNDI) lookup in your application component, during run time.
4. Get the connection to the EIS from the connection factory.
5. Create an interaction from the connection object.
6. Create an *InteractionSpec* object. Set the function to execute in the InteractionSpec object.
7. Create a record instance for the input and output data used by function.
8. Execute the function through the Interaction object.
9. Process the record data from the function.
10. Close the connection.

Example

The following code segment shows how an application component might create an interaction and implement it on the EIS:

```
javax.resource.cci.ConnectionFactory connectionFactory = null;
javax.resource.cci.Connection connection = null;
javax.resource.cci.Interaction interaction = null;
javax.resource.cci.InteractionSpec interactionSpec = null;
javax.resource.cci.Record inRec = null;
javax.resource.cci.Record outRec = null;

try {
// Locate the application component and perform a JNDI lookup
   javax.naming.InitialContext ctx = new javax.naming.InitialContext();
   connectionFactory = (javax.resource.cci.ConnectionFactory)
ctx.lookup("java:comp/env/eis/myConnection");

// create a connection
   connection = connectionFactory.getConnection();

// Create Interaction and an InteractionSpec
   interaction = connection.createInteraction();
   interactionSpec = new InteractionSpec();
   interactionSpec.setFunctionName("GET");

// Create input record
   inRec = new javax.resource.cci.Record();

// Execute an interaction
   interaction.execute(interactionSpec, inRec, outRec);

// Process the output...

} catch (Exception e) {
   // Exception Handling
}
finally {
    if (interaction != null) {
         try {
              interaction.close();
         }
         catch (Exception e) {/* ignore the exception*/}
```

```
    }
    if (connection != null) {
         try {
              connection.close();
         }
         catch (Exception e) {/* ignore the exception */}
    }
}
```

JDBC application development tips

By using best practices to help maximize the efficiency of JDBC queries, you can potentially increase application performance.

Most of the following recommendations assume that you use DB2 on z/OS.

- Program according to the most current JDBC specifications.
- Use prepared statements to allow dynamic statement cache of DB2 on z/OS.
- Do not include literals in the prepared statements; use a parameter marker "?" to allow dynamic statement cache of DB2 on z/OS.
- Use the right getXxx method by each data type of DB2.
- Turn auto commit off when just read-only operations are performed.
- Use explicit connection context objects.
- When coding an iterator, you have a choice of named or positioned. Positioned iterators have the better performance potential.
- Close prepared statements before reusing the statement handle to prepare a different SQL statement within the same connection.
- As a bean developer, you have the choice of using JDBC or Structured Query language in Java (SQLJ) queries. JDBC makes use of dynamic SQL whereas SQLJ generally is static and uses pre-prepared plans. SQLJ requires an extra step to create and bind the plan whereas JDBC does not. SQLJ, as a general rule, is faster than JDBC.
- With JDBC and SQLJ, you are better off writing specific calls that retrieve just what you want rather than generic calls that retrieve the entire row. There is a high per-field cost.

JDBC application cursor holdability support

The cursor holdability feature can reduce the overhead of JDBC interaction with your relational database, thereby helping to increase application performance.

By activating cursor holdability, you keep a result set available across transaction boundaries for use by multiple JDBC calls. The holdability setting triggers a database cursor to keep newly updated rows active beyond the commit of the transaction that generated the new values, or result set. Hence the cursor makes the result set available for use by statements in a subsequent transaction.

Setting cursor holdability

Use one of the following techniques to set cursor holdability. For more details, see the JDBC 3.0 specification, available at the Oracle website at http://www.oracle.com/technetwork/java/index.html.

- Specify the ResultSet.HOLD_CURSORS_OVER_COMMIT parameter when creating or preparing a statement using the createStatement, prepareStatement, or prepareCall methods.
- Invoke the setHoldability method on the Connection object. The cursor holdability value that you set with this method becomes the default. If you specify cursor holdability on the Statement object, that value overrides the value that you specified on the connection.

  You cannot specify cursor holdability on a shareable connection after that connection is referenced by a second handle. Invoking the holdability method at this point generates an exception. If you want to set cursor holdability on a shareable connection, invoke the method before the connection is enlisted. Otherwise a shareable connection retains the same holdability value that applied in the previous enlistment.

- Check your database documentation to see if the product supports cursor holdability as a data source property. DB2, for example, responds to the holdability trigger if you set it as a data source custom property. See the topic, Custom property settings, for more information.

The impact of connection and transaction behaviors on cursor holdability

Setting cursor holdability in WebSphere Application Server results in the following behavior for different transaction events:

- When a connection is closed, all statements and result sets are closed even if you have set cursor holdability.
- When a transaction is rolled back, all result sets are closed even if you have set cursor holdability.
- When a local transaction is committed, both shareable and unshareable connections can have an open result set across a transaction boundary.
- When a global transaction is committed, unshareable connections can have an open result set across a transaction boundary. For shareable connections, the statements and result sets are closed even if you have set cursor holdability; the holdability value does not impact shareable connections participating in global transactions.
- When a local transaction scope ends, either at the method level or the activity session level, all statements and result sets for shareable connections are closed. Statements and result sets for unshareable connections remain open until the close method is called on the connection.

Note: For a global transaction with an unshareable connection, the backend database has responsibility for supporting cursor holdability.

Data access bean types

For easy data access programming, WebSphere Application Server provides a special class library that implements many methods of the Java Database Connectivity (JDBC) API for you. The library is essentially a set of Service Data Objects (SDO).

To make things clearer, you can refer to the classes by the name of the Java archive (JAR) file that contains them:

`databeans.jar` - This JAR file ships with WebSphere Application Server. This file contains classes that enable you to access the database using the JDBC API.

`ivjdab.jar` - This JAR file ships with Visual Age for Java. This file contains all of the classes in the `databeans.jar` file and classes that support easy use of the data access beans from the Visual Age for Java Visual Composition Editor.

`dbbeans.jar` - This JAR file ships with Rational Application Developer. This file contains a set of data access beans to more closely conform to the JDBC 2.0 RowSet standard.

The `com.ibm.db` package is provided to support existing applications that use data access beans.

IBM strongly suggests that any new applications using data access beans be developed using the `com.ibm.db.beans` package that is provided with Rational Application Developer.

Example: Using data access beans. Data access beans are essentially a class library that makes it easier to access a database. The library contains a set of beans with methods that access the database through the Java Database Connectivity (JDBC) API. This example shows using data access beans in WebSphere Application Server Version 5 and later to create new applications that use the com.ibm.db.beans package.

```
package example;
import com.ibm.db.beans.*;
import java.sql.SQLException;
```

```
public class DBSelectExample {

 public static void main(String[] args) {

  DBSelect select = null;

  select = new DBSelect();
  try {

   // Set database connection information
   select.setDriverName("COM.ibm.db2.jdbc.app.DB2Driver");
   select.setUrl("jdbc:db2:SAMPLE");
   select.setUsername("userid");
   select.setPassword("password");

   // Specify the SQL statement to be executed
   select.setCommand("SELECT * FROM DEPARTMENT");

   // Execute the statement and retrieve the result set into the cache
   select.execute();

   // If result set is not empty
   if (select.onRow()) {
    do {
     // display first column of result set
     System.out.println(select.getColumnAsString(1));
     System.out.println(select.getColumnAsString(2));
    } while (select.next());
   }

   // Release the JDBC resources and close the connection
   select.close();

  } catch (SQLException ex) {
   ex.printStackTrace();
  }
 }
}
```

Accessing data from application clients

To access a database directly from a Java Platform, Enterprise Edition (Java EE) application client, you retrieve a *javax.sql.DataSource* object from a resource reference configured in the client deployment descriptor. This resource reference is configured as part of the deployment descriptor for the client application, and provides a reference to a pre-configured data source object.

About this task

Note that data access from an application client uses the JDBC driver connection functionality directly from the client side. It does not take advantage of the additional pooling support available in the application server run time. For this reason, your client application should utilize an enterprise bean running on the server side to perform data access. This enterprise bean can then take advantage of the connection reuse and additional added functionality provided by the product run time.

Procedure

1. Import the appropriate JDBC API and naming packages:
   ```
   import java.sql.*;
   import javax.sql.*;
   import javax.naming.*;
   ```
2. Create the initial naming context:
   ```
   InitialContext ctx = new InitialContext();
   ```
3. Use the *InitialContext* object to look up a data source object from a resource reference.

```
javax.sql.DataSource ds = (DataSource)ctx.lookup("java:comp/env/jdbc/myDS");
//where jdbc/myDS is the name of the resource reference
```

4. Get a *java.sql.Connection* from the data source.
   - If no user ID and password are required for the connection, or if you are going to use the *defaultUser* and *defaultPassword* that are specified when the data source is created in the Application Client Resource Configuration tool (ACRCT) in a future step, use this approach:

     ```
     java.sql.Connection conn = ds.getConnection();
     ```
   - Otherwise, you should make the connection with a specific user ID and password:

     ```
     java.sql.Connection conn = ds.getConnection("user", "password");
     //where user and password are the user id and password for the connection
     ```
5. Run a database query using the *java.sql.Statement*, *java.sql.PreparedStatement*, or *java.sql.CallableStatement* interfaces as appropriate.

   ```
   Statement stmt = conn.createStatement();
   String query = "Select FirstNme from " + owner.toUpperCase() + ".Employee where LASTNAME = '" + searchName + "'";
   ResultSet rs = stmt.executeQuery(query);
   while (rs.next()) { firstNameList.addElement(rs.getString(1));
   }
   ```
6. Close the database objects used in the previous step, including any *ResultSet*, *Statement*, *PreparedStatement*, or *CallableStatement* objects.
7. Close the connection. Ideally, you should close the connection in a *finally* block of the *try...catch* statement wrapped around the database operation. This action ensures that the connection gets closed, even in the case of an exception.

   ```
   conn.close();
   ```

Service Data Objects version 2.1.1

Service Data Objects (SDO) is a framework for data application development that provides an architecture and application programming interfaces (API). The product includes an implementation of SDO 2.1.1 interfaces. After the product is installed and SDO is enabled, SDO 2.1.1 becomes the default SDO implementation when programming with SCA or SDO interfaces.

transition: For backwards compatibility, deprecated functions like JDBMediator continue to use previous SDO implementations described in “Data access with Service DataObjects, API versions 1.0 and 2.01”. Otherwise, SDO clients are bound to the SDO 2.1.1 implementation.

SDO 2.1.1 is a Java standard approved by the Java Community Process (JSR 235). For details on SDO 2.1.1, refer to the JSR 235 specification.

The product implementation complies with JSR 235, and provides some implementation-specific extensions. These extensions align with the latest direction of the SDO 3.0 specification under development at OASIS. Although there is no guarantee, these 3.0 API extensions will likely be officially standardized in future versions of SDO. Table 1 lists the 3.0 API extensions included in the product.

Table 9. SDO 3.0 API extensions included in the product. The SDO 3.0 API extensions might be standardized in future specifications.

SDO interface or class name	Method or constant	SDO 3.0 extension change
interface commonj.sdo.Type;	getHelperContext()	New SDO 3.0 method
interface commonj.sdo.helper.TypeHelper:	SDO_URI	New SDO 3.0 constant
	SDO_JAVA_URI	New SDO 3.0 constant
	SDO_XML_URI	New SDO 3.0 constant
interface commonj.sdo.Sequence:	add(String)	Removed deprecated method
	add(int, String)	Removed deprecated method
interface commonj.sdo.helper.HelperContext:	getIdentifier()	New SDO 3.0 method
class commonj.sdo.helper.HelperProvider:		Replaced SPI with SDO 3.0 version

Table 9. SDO 3.0 API extensions included in the product (continued). The SDO 3.0 API extensions might be standardized in future specifications.

SDO interface or class name	Method or constant	SDO 3.0 extension change
class commonj.sdo.helper.SDO		New API in SDO 3.0
interface commonj.sdo.helper.HelperContextFactory		New API in SDO 3.0
class commonj.sdo.impl.Environment		New SPI in SDO 3.0
class commonj.sdo.impl.Resolvable		New SPI in SDO 3.0

For information on SDO HelperContext, see “Creating and accessing SDO HelperContext”.

Creating and accessing SDO HelperContext objects:

The Service Component Architecture (SCA) implementation complies with Service Data Objects (SDO) 2.1.1 (JSR 235), and provides some implementation-specific extensions. These extensions align with the latest direction of the OASIS SDO 3.0 specification under development. One of the extensions introduces an API for creating and managing HelperContext objects, which are in the SDO class and HelperContextFactory interface.

About this task

This topic describes how to create and access SDO HelperContext in non-SCA applications.

In versions of SDO previous to 3.0, including SDO 2.1.1, there is no standard way to create HelperContext objects. SDO helper classes are accessible from the default HelperContext and are typically accessed using their corresponding INSTANCE fields, for example, TypeHelper.INSTANCE. The use of INSTANCE fields is discouraged in SDO 2.1.1, and will likely be deprecated in SDO 3.0. Instead of using INSTANCE fields, code your applications to access helpers using their corresponding accessor method on the HelperContext interface, for example, helperContext.getTypeHelper(). In SDO 2.1.1, the only HelperContext available through standard APIs is the default helper context: HelperProvider.getDefaultContext().

The proposed SDO 3.0 scoping solution, which is available in the product, is more flexible and is described in this topic.

A HelperContext represents a metadata scope in SDO. In SDO 3.0 available in the product, a HelperContext is created using a HelperContextFactory. The HelperContextFactory interface is as follows:

```
public interface HelperContextFactory {

  /**
  * Create a new HelperContext in this implementation.  Once created the HelperContext
  * can be looked up as follows (Note if the identifier is null or "" it is not registered):
  * SDO.getHelperContext(identifier);
  * @param identifier - A unique identifier that can be used to access the HelperContext.
  * @param properties - Properties required to initialize the HelperContext.
  * @return a HelperContext object
  * @throws IllegalArgumentException If a different HelperContext is already
  * registered with the specified identifier.
  */
  public HelperContext createHelperContext(String identifier, Map<String, Object> properties)
       throws IllegalArgumentException;
    /**
    * Create a new HelperContext in this implementation.  Once created the HelperContext
    * can be looked up as follows (Note if the identifier is null or "" it is not registered):
    * SDO.getHelperContext(identifier);
    * @param identifier - A unique identifier that can be used to access the HelperContext.
    * @param classLoader - The class loader for the generated static classes (if any).
    * @param properties - Properties required to initialize the HelperContext.
    * @return a HelperContext object
```

```
    * @throws IllegalArgumentException If a different HelperContext is already
    * registered with the specified identifier.
    */
  public HelperContext createHelperContext(String identifier, ClassLoader classLoader,
      Map<String, Object> properties) throws IllegalArgumentException;
}
```

There can be more than one HelperContextFactory available in an SDO environment, but one is the default. The default HelperContextFactory is accessible through the interface commonj.sdo.helper.SDO.

Procedure

1. Using the default factory, create a HelperContext object in your code.

   The following example uses the default factory to create the HelperContext `hc`:

   ```
   HelperContext hc =
   SDO.getHelperContextFactory().createHelperContext("ScopeManagerTestID", options);
   ```

   The identifier string, `"ScopeManagerTestID"`, must be unique within a Java virtual machine (JVM). If you are not concerned with the actual value, generate a guaranteed unique one using the Java UUID class, for example:

   ```
   hc = SDO.getHelperContextFactory().createHelperContext(
       UUID.randomUUID().toString(), options);
   ```

2. Access the HelperContext object in your code.

   The SDO run time manages HelperContext objects. Access an existing HelperContext object using the SDO.getHelperContext(identifier) method:

   ```
   hc = SDO.getHelperContext("ScopeManagerTestID");
   ```

   The identifier of a HelperContext can be accessed using the getIdentifier() method:

   ```
   String id = hc.getIdentifier();
   ```

Results

A HelperContext object is defined and accessible.

What to do next

Use SDO in an SCA application. When SDO is used in an SCA application, the SCA run time typically creates the HelperContext objects and identifiers. Refer to topics on using SDO 2.1.1 in SCA applications.

Because the SCA run time manages the HelperContext objects and identifiers when using SDO in SCA applications, the method used to create and access SDO HelperContext in SCA applications is different than that used in non-SCA applications. An SCA application can access SDO HelperContext using a DefaultHelperContext annotation; for example:

```
import com.ibm.websphere.soa.sca.sdo.DefaultHelperContext;

@DefaultHelperContext
public HelperContext defaultHelperContext;
```

Using SDO 2.1.1 in SCA applications:

The Service Component Architecture (SCA) implementation complies with Service Data Objects (SDO) 2.1.1 (JSR 235). You can use SDO 2.1.1 in your SCA applications.

Before you begin

Read SDO data binding for SCA applications to better understand how to work with SDO in SCA Java clients and implementations. For more information, read about using business exceptions with SCA interfaces.

Consider installing a Rational Application Developer product with SCA Development Tools that you can use to assemble service-oriented application components based on open SCA specifications. See the Rational Application Developer documentation.

About this task

SDO is supported in both the OSOA and OASIS applications. Unless otherwise specified, the information in this topic pertains to applications for both the OSOA and OASIS specifications.

To use SDO 2.1.1 in an SCA application, access the default HelperContext programmatically in a Java or Java Platform, Enterprise Edition (Java EE) component implementation type and then develop one or more SCA composites that use SDO following a bottom-up or top-down approach.

Procedure

1. Develop one or more SCA components that use SDO.
   a. Decide whether you are going to use a top-down or bottom-up approach to developing your SCA component implementations.

      The section on top-down and bottom-up development in SDO data binding for SCA applications describes the approaches. The top-down approach is typically preferred in SCA service architecture and development.
   b. Use a top-down approach (starting from WSDL and XSD files) or a bottom-up approach (starting from Java files) to develop SCA composites that use SDO.
      - Use a top-down approach to develop SCA composites.
      - Use a bottom-up approach to develop SCA composites.
   c. Access the default HelperContext programmatically.

      You can access the default HelperContext programmatically in a Java or Java EE component implementation type. You cannot access the default HelperContext programmatically in a Spring component implementation type.

   Restriction: You cannot use array types for Java parameters. You cannot map from schema elements declared with the attribute, `maxOccurs="unbounded"` to array types. Instead, map the element to a List, such as a `List<DataObject>` or `List<String>`.
2. If you are using a top-down development approach, package your WSDL and XSD files in an SCA contribution.

   Packaging WSDL and XSD files in an appropriate contribution enables your component to access the schema definitions. The section on schema registration in SDO data binding for SCA applications describes the registration.

   Consider packaging your WSDL and XSD files so that they can be accessed across various parts of your application from a shared in-memory instance. For details, see Implementing shared scopes in SCA applications that use SDO.
3. Deploy your SCA composites that use SDO in an SCA business-level application.

   See topics on SCA contributions and shared scopes for information on how to establish a shared SDO scope. Otherwise, there are no special deployment considerations for applications using the SDO data binding.

Results

You have developed and deployed an SCA composite that uses SDO in a business-level application.

What to do next

Test the deployed SCA composites.

SDO data binding for SCA applications:

Service Data Objects (SDO) is a framework for data application development that provides an architecture and application programming interfaces (API). Product support for Service Component Architecture (SCA) includes an implementation of SDO 2.1.1 interfaces. To work with SDO in SCA Java clients and implementations, it is helpful to understand SDO data binding concepts.

The product supports SDO for both OSOA and OASIS specifications, unless otherwise stated in this topic.

The SDO data binding support consists of the following concepts:
- Scope management
- Wire format serialization or deserialization
- Top-down and bottom-up development
- Schema registration
- Shared scopes
- JAX-WS based programming model

Scope management

In SDO, a scope typically corresponds to a commonj.sdo.helper.HelperContext instance. This scope sets visibility boundaries for SDO types. In the product runtime environment, the SCA layer defines HelperContext objects on SCA application boundaries, which are meaningful boundaries from an SCA perspective. Together, SCA and SDO define a default HelperContext for a given application and enable the SCA application to access the HelperContext programmatically.

In the product runtime environment, the primary SCA application scope is tied to the deployable composite. There is a 1-1 relationship between a deployable composite and an SCA default HelperContext that is managed in the runtime environment. To determine the default HelperContext of an SCA component, you must identify the deployable composite which defines this component to the SCA domain.

Wire format serialization or deserialization

An important use of SDO is to serialize or deserialize application data to and from the data format “on the wire” (the “wire format”) for the various binding configurations. The SCA runtime environment uses the default HelperContext with its registered schema definitions to perform this serialization or deserialization. This process is relevant for serializing or deserializing input argument values and return values of SCA service interfaces when the client or implementation uses the SDO data binding.

Top-down and bottom-up development

Both top-down (starting from WSDL and XSD files) and bottom-up (starting from Java files) approaches can be used with SDO in SCA applications. This section briefly explains three different usage patterns. You can combine aspects of all three patterns in a single application.

- Top-down, strongly typed

  In this usage pattern, start with a composite definition file that uses the `<interface.wsdl>` element in describing a component service interface; for example:

  ```
  <service ...>
    <interface.wsdl ...> Refers to WSDL with updateAccount
  ```

  The doc-lit-wrapped WSDL and XSD definition uses a specific type, and not `xsd:anyType`:

```
<element name="updateAccount">
  <complexType>
    <sequence>
      <element name="person" type="p:Person"/>
```

This definition maps to a Java method; for example:

```
void updateAccount(DataObject person)
```

With this usage pattern, you can write your Java code so that is reusable, even later with types other than `p:Person`. You can potentially reuse the same dynamically typed Java code with multiple strongly typed interfaces, without having to regenerate any Java code.

You can also write your Java code so that the SDO usage is tightly coupled with a specific XSD type. Further, you can mix the tightly coupled and dynamically typed programming styles in the same SCA Java application.

- Top-down, weakly typed

  In this usage pattern, start with a composite definition file that uses the `<interface.wsdl>` element; for example:

  ```
  <service ...>
    <interface.wsdl ...> Refers to WSDL with updateAccount
  ```

  The doc-lit-wrapped WSDL and XSD definition uses `xsd:anyType`:

  ```
  <element name="updateAccount">
    <complexType>
      <sequence>
        <element name="arg0" type="xsd:anyType"/>
  ```

  This definition maps to a Java method; for example:

  ```
  void updateAccount(DataObject arg0)
  ```

  This usage pattern is like top-down, strongly-typed. With the top-down, weakly typed usage pattern both WSDL and XSD files map to equivalent Java code. However, you might write your Java code to enable it to handle any type of data, as opposed to the top-down, strongly-typed usage pattern where you expect a specific type, even though you work with it through the dynamic SDO APIs.

- Bottom-up

  In this usage pattern, you start with a Java interface method such as:

  ```
  void updateAccount(DataObject arg0)
  ```

  The method maps to a WSDL or XSD definition such as:

  ```
  <element name="updateAccount">
    <complexType>
      <sequence>
        <element name="arg0" type="xsd:anyType"/>
  ```

  Depending on the bindings, you might view or work directly with the WSDL and XSD files to which the Java object maps. When mapping from Java to XSD, the SCA runtime environment maps `commonj.sdo.DataObject` to `xsd:anyType`.

  You cannot use `java.lang.Object` as a dynamic, generic interface method parameter or return type, instead of `commonj.sdo.DataObject`. The SCA runtime environment relies on introspection of the method type to signal that it uses SDO, and not JAXB, to work with this type; for example, to construct the argument values upon deserializing data on the wire.

In each of the usage patterns, you can mix styles within a single operation. For example, suppose you have the following doc-lit-wrapped WSDL definition:

```
<element name="updateAccount">
  <complexType>
    <sequence>
      <element name="arg0" type="xsd:anyType"/>
      <element name="id" type="xsd:string"/>
```

The WSDL definition maps to the following Java method:

```
void updateAccount(DataObject arg0, String id)
```

The `arg0` field is dynamically typed by DataObject, while the `id` field is statically typed by String.

Schema registration

The SCA runtime environment provides mechanisms to register schema definitions from your SCA application (for example, in WSDL and XSD files packaged with your application) to the default HelperContext of your SCA application. All schema definitions packaged within the same contribution Java archive (JAR) file as the one your deployable composite is contributed within are registered with the default HelperContext of that deployable composite.

Schema registration is important because it affects the exact details of your application SDO programming model. For example, the `DataFactory.create()` methods can be used to create DataObject instances of the corresponding schema definitions that are registered in the runtime environment, without having to reference or load the XSD files containing these schema definitions in application code.

Some styles of interface definition and programming result in DataObject instances of unknown type. Within the SDO type system, the XSD type of such an object is the SDO-equivalent of `xsd:anyType`. Methods might return different values depending on whether the instance is of a known, specific type or the `anyType`-equivalent.

For example, SDO API calls such as the following might return different results depending on whether the object instances are recognized in the SDO type system as instances of a registered XSD type. For the following call, `get(int propertyIndex)` returns a List for `xsd:anyType`:

```
dataObjectInstance.get(1);
```

The following call returns an empty List for `xsd:anyType`:

```
dataObjectInstance.getType().getDeclaredProperties();
```

Shared scopes

Shared scopes are only supported for applications based on OSOA specifications.

SCA contribution support enables convenient packaging of WSDL and XSD definition files used by multiple SCA application composites using the contribution import and export mechanism. The common WSDL and XSD files can be packaged into a single contribution JAR file, which is like a shared library.

The SDO data binding function further uses the SCA contribution support by enabling you to establish a shared scope (HelperContext) for your SDO types. This reduces the memory footprint involved in loading schema definitions from large WSDL and XSD files used across your application and in constructing the corresponding SDO Type definitions from them.

The shared scope is maintained at the level of a business-level application. For any business-level application, all references to an SDO Type that correspond to a schema definition from an XSD or WSDL file imported from a shared contribution resolve to a single SDO Type instance in a single scope (HelperContext).

For shared scopes, there are two restrictions:

- A contribution that exports schema definitions cannot, in turn, import other schema definitions from another contribution.
- You cannot divide namespaces across more than one contribution. That is, you cannot package schema definitions in a given target namespace in one contribution and then import others in that same target namespace from a second contribution.

JAX-WS based programming model

In the product, the mapping between a WSDL operation and Java method is defined by JAX-WS. Within that operation-level mapping, it is the mapping between specific XSD types and the corresponding Java parameter types that is defined by the particular data binding (SDO in this case, rather than JAXB). Other than the type mapping, the programming model is independent of the choice of data binding.

One consequence of this capability is that the JAX-WS annotations such as @RequestWrapper, @ResponseWrapper, @WebParam, @WebResult are significant in SCA applications using SDO.

Another important consequence is that the product uses JAX-WS to define the mapping between a Java exception that occurs in Java clients and implementations, and the fault bean that is serialized on the wire. Thus, the fault bean can be an SDO (of type commonj.sdo.DataObject). In which case, SDO is used to serialize or deserialize the fault bean to or from the wire format.

Using a top-down approach to develop SCA components that use SDO:

You can use a top-down approach that starts from Web Services Description Language (WSDL) or XML definition files to develop Service Component Architecture (SCA) component implementations that use Service Data Objects (SDO) 2.1.1 (JSR 235).

Before you begin

Consider installing a Rational Application Developer product with SCA Development Tools that you can use to assemble service-oriented application components based on open SCA specifications. See the Rational Application Developer documentation.

Access the default HelperContext programmatically in a Java or Java Platform, Enterprise Edition (Java EE) component implementation type. Complete step 1 of Using SDO 2.1.1 in SCA applications.

About this task

This topic describes how to develop SCA composites that use SDO following a top-down approach.

Unless otherwise specified, this topic describes how to develop both OSOA and OASIS SCA composites that use SDO.

Procedure

1. Describe the service interface in your WSDL and XSD definition files.

   The following example WSDL and XSD files describe a service interface.

   Example WSDL file, test.wsdl

```
<?xml version="1.0" encoding="UTF-8"?>

<wsdl:definitions targetNamespace="http://test" xmlns:tns="http://test"
        xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"
        xmlns:wsdlsoap="http://schemas.xmlsoap.org/wsdl/soap/"
        xmlns:xsd="http://www.w3.org/2001/XMLSchema" name="Test">

  <wsdl:types>
    <schema targetNamespace="http://test" xmlns="http://www.w3.org/2001/XMLSchema" xmlns:p="http://person">
      <import namespace="http://person" schemaLocation="person.xsd"/>

      <element name="updateAccount">
        <complexType>
          <sequence>
            <element name="person" type="p:Person"/>
            <element name="code" type="xsd:string"/>
          </sequence>
        </complexType>
      </element>
```

```
      <element name="updateAccountResponse">
        <complexType>
          <sequence>
            <element name="response" type="p:Status"/>
          </sequence>
        </complexType>
      </element>
    </schema>
  </wsdl:types>

  <wsdl:message name="PersonRequestMessage">
    <wsdl:part element="tns:updateAccount" name="parameters"/>
  </wsdl:message>

  <wsdl:message name="PersonResponseMessage">
    <wsdl:part element="tns:updateAccountResponse" name="parameters"/>
  </wsdl:message>

  <wsdl:portType name="Test">
    <wsdl:operation name="updateAccount">
      <wsdl:input message="tns:PersonRequestMessage" name="ReqMsgName"/>
      <wsdl:output message="tns:PersonResponseMessage" name="RespMsgName"/>
    </wsdl:operation>
  </wsdl:portType>

  <wsdl:binding name="TestSoapBinding" type="tns:Test">
    <wsdlsoap:binding style="document" transport="http://schemas.xmlsoap.org/soap/http"/>
    <wsdl:operation name="updateAccount">
      <wsdlsoap:operation soapAction="urn:updateAccount"/>
      <wsdl:input name="ReqMsgName">
        <wsdlsoap:body use="literal"/>
      </wsdl:input>
      <wsdl:output name="RespMsgName">
        <wsdlsoap:body use="literal"/>
      </wsdl:output>
    </wsdl:operation>
  </wsdl:binding>

  <wsdl:service name="TestService">
    <wsdl:port binding="tns:TestSoapBinding" name="TestSoapPort">
      <wsdlsoap:address location=""/>
    </wsdl:port>
  </wsdl:service>

</wsdl:definitions>
```

Example XSD file, person.xsd, that test.wsdl imports

```
<?xml version="1.0" encoding="UTF-8"?>

  <schema targetNamespace="http://person"  xmlns="http://www.w3.org/2001/XMLSchema">
    <complexType name="Person">
      <sequence>
        <element name="firstName" type="string"/>
        <element name="lastName" type="string"/>
      </sequence>
    </complexType>

    <complexType name="Status">
      <sequence>
        <element name="statusCode" type="int"/>
        <element name="message" type="string"/>
      </sequence>
    </complexType>
  </schema>
```

2. Produce a corresponding Java interface.

   If you are using an IBM Rational tool that supports SCA, you do not need to complete this step. The tool generates the code for you. Proceed to step 3.

   If you are not using a Rational tool that supports SCA, you can manually produce a Java interface from a WSDL file by completing this step 2, which provides an example that modifies generated code. There is not an automated tool to produce a Java interface from a command-line interface.

   a. Identify the WSDL and XSD files from which you want to produce Java interfaces.

      This example uses the `test.wsdl` and `person.xsd` files in step 1.

   b. Run the **wsimport** command with the `-s` option to save source files.

      ```
      wsimport.bat -s . test.wsdl
      ```

c. Among the generated Java files, identify the SEI.

   The SEI is a Java interface, and not a class file, with a class-level @WebService annotation, javax.jws.WebService.

   In this example, the Java interface is the `test/Test.java` file. Running the **wsimport** command produces the following output:

```
//
// Generated By:JAX-WS RI, IBM 2.1.1 in JDK 6 (JAXB RI, IBM JAXB 2.1.3 in JDK 1.6)
//

package test;

import javax.jws.WebMethod;
import javax.jws.WebParam;
import javax.jws.WebResult;
import javax.jws.WebService;
import javax.xml.bind.annotation.XmlSeeAlso;
import javax.xml.ws.RequestWrapper;
import javax.xml.ws.ResponseWrapper;
import person.Person;
import person.Status;

@WebService(name = "Test", targetNamespace = "http://test")
@XmlSeeAlso({
    person.ObjectFactory.class,
    test.ObjectFactory.class
})
public interface Test {

    /**
     *
     * @param person
     * @param code
     * @return
     *     returns person.Status
     */
    @WebMethod(action = "urn:updateAccount")
    @WebResult(name = "response", targetNamespace = "")
    @RequestWrapper(localName = "updateAccount", targetNamespace =
            "http://test", className = "test.UpdateAccount")
    @ResponseWrapper(localName = "updateAccountResponse", targetNamespace =
            "http://test", className = "test.UpdateAccountResponse")
    public Status updateAccount(
        @WebParam(name = "person", targetNamespace = "")
        Person person,
        @WebParam(name = "code", targetNamespace = "")
        String code);
}
```

d. Modify the SEI.

   1) For all parameter and return values of generated (JAXB) types, change the Java type to `commonj.sdo.DataObject`. All complex schema types must map to `commonj.sdo.DataObject` Java types. Also, remove all imports of these generated JAXB types.

   2) For each @RequestWrapper and @ResponseWrapper annotation, change the value of the `className` element to `commonj.sdo.DataObject`. Otherwise, leave the JAX-WS annotations because they are significant.

   3) Remove or comment out the @XmlSeeAlso block.

Completing these steps results in the following Java interface:

```
//
// Generated By:JAX-WS RI, IBM 2.1.1 in JDK 6 (JAXB RI, IBM JAXB 2.1.3 in JDK 1.6)
//

package test;

import javax.jws.WebMethod;
import javax.jws.WebParam;
import javax.jws.WebResult;
import javax.jws.WebService;
import javax.xml.bind.annotation.XmlSeeAlso;
import javax.xml.ws.RequestWrapper;
```

```
import javax.xml.ws.ResponseWrapper;
import commonj.sdo.DataObject;

@WebService(name = "Test", targetNamespace = "http://test")

public interface Test {

    /**
     *
     * @param person
     * @param code
     * @return
     *     returns person.Status
     */
    @WebMethod(action = "urn:updateAccount")
    @WebResult(name = "response", targetNamespace = "")
    @RequestWrapper(localName = "updateAccount", targetNamespace =
            "http://test", className = "commonj.sdo.DataObject")
    @ResponseWrapper(localName = "updateAccountResponse", targetNamespace =
            "http://test", className = "commonj.sdo.DataObject")
    public DataObject updateAccount(
        @WebParam(name = "person", targetNamespace = "")
        DataObject person,
        @WebParam(name = "code", targetNamespace = "")
        String code);
}
```

The following example shows the resulting code with JAX-WS annotations removed for readability only. Do not remove the annotations before compiling to use the example code.

```
package test;
import commonj.sdo.DataObject;
public interface Test {
    public DataObject updateAccount(DataObject person, String code);
}
```

3. Write your SCA Java client or component implementation using the dynamic SDO programming model.

   The following example code shows a service implementation in Java. Read the source comments carefully to see the differences between OSOA and OASIS.

```
package test.impl;

import test.Test;

// FOR OSOA
import org.osoa.sca.annotations.Service;
// FOR OASIS, commented out
// import org.oasisopen.sca.annotation.Service;

import commonj.sdo.DataObject;
import commonj.sdo.helper.DataFactory;
import commonj.sdo.helper.HelperContext;

import com.ibm.websphere.soa.sca.sdo.DefaultHelperContext;

@Service(Test.class)
public class TestImpl implements Test {

    @DefaultHelperContext
    protected HelperContext myDefaultHC;

    public DataObject updateAccount(DataObject person, String code) {
        String error_msg = null;
        if (code.equals("ERROR_STRING_IN_FIELD1")) {
            error_msg = "ERROR firstName: " +  person.getString("firstName"0);
            HelperContext defaultHC = ContextHelper.getCurrentHelperContext();
            DataFactory dataFactory = myDefaultHCdefaultHC.getDataFactory();
            DataObject returnDO = dataFactory.create("http://person","Status");
            returnDO.setInt("statusCode", -1);
            returnDO.setString("message", error_msg);
            return returnDO;
        } else {
            // process(person);
```

```
            ...
        }
    }
}
```

The input `person` DataObject is of type `{http://person}Person`. The returned output DataObject is of type `{http://person}Status`. Both the input and output are registered in the SCA application default HelperContext that is accessed using the `myDefaultHC` object.

4. In a composite definition, declare your component reference or component service interface with an `<interface.wsdl>` element that refers to the original `portType` value.

   Example accountTest.composite file for OSOA

```
<composite xmlns="http://www.osoa.org/xmlns/sca/1.0"
    targetNamespace="http://www.ibm.com/test/soa/sca/sdo/"
    name="AccountTestComposite">
  <component name="AccountTestComponent">
    <implementation.java class="test.impl.TestImpl"/>
    <service name="Test">
      <interface.wsdl interface="http://test#wsdl.interface(Test)"/>
    </service>
  ...
  </component>
</composite>
```

   Example accountTest.composite file for OASIS

```
<composite xmlns="http://docs.oasis-open.org/ns/opencsa/sca/200912"
    targetNamespace="http://www.ibm.com/test/soa/sca/sdo/"
    name="AccountTestComposite">
  <component name="AccountTestComponent">
    <implementation.java class="test.impl.TestImpl"/>
    <service name="Test">
      <interface.wsdl interface="http://test#wsdl.interface(Test)"/>
    </service>
  ...
  </component>
</composite>
```

5. Package the composite and deploy the component with the authored implementation along with the WSDL or XSD files into a single contribution JAR file.

   Suppose the example files are packaged into a single file, `MyAccountTestContribution.jar`. A listing of the JAR file contents from the command line is as follows:

```
$ jar tf MyAccountTestContribution.jar

wsdl/test.wsdl
wsdl/person.xsd
test/Test.class
test/impl/TestImpl.class
META-INF/accountTest.composite
META-INF/sca-contribution.xml
```

Results

You have developed an SCA composite that uses SDO following a top-down approach.

What to do next

Optionally, implement shared scopes. See the topic on using SDO 2.1.1 in SCA applications.

Deploy your files that use SDO in an SCA business-level application.

Using a bottom-up approach to develop SCA components that use SDO:

You can use a bottom-up approach that starts from Java files to develop Service Component Architecture (SCA) component implementations that use Service Data Objects (SDO) 2.1.1 (JSR 235).

Before you begin

Consider installing a Rational Application Developer product with SCA Development Tools that you can use to assemble service-oriented application components based on open SCA specifications. See the Rational Application Developer documentation.

Access the default HelperContext programmatically in a Java or Java Platform, Enterprise Edition (Java EE) component implementation type. Complete step 1 of Using SDO 2.1.1 in SCA applications.

About this task

This topic describes how to develop SCA composites that use SDO following a bottom-up approach.

Procedure

1. Start from a Java interface or implementation using type commonj.sdo.DataObject for one or more parameters or return types.

   The following example Java file provides an interface.

   Logger.java (interface):

   ```
   package logger;
   import commonj.sdo.DataObject;
   public interface Logger {
       public String logDataObjectProperties (DataObject input);
   }
   ```

2. Write your SCA Java client or component implementation using the dynamic SDO programming model.

   The following example Java file provides a component implementation.

   LoggerImpl.java (component implementation):

   ```
   package logger.impl;

   import logger.Logger;
   import org.osoa.sca.annotations.Service;

   import commonj.sdo.DataObject;
   import commonj.sdo.helper.DataFactory;
   import commonj.sdo.helper.HelperContext;

   @Service(Logger.class)
   public class LoggerImpl implements Logger {

       public String logDataObjectProperties (DataObject input) {
           String logMsg =  "==========\n";
           List props = input.getInstanceProperties();
           for (int i=0; i < props.size(); i++){
               Property prop = (Property)props.get(i);
               logMsg += "  prop[" + i + "], name = " + prop.getName() + ", val = " +
                   input.get(prop).toString() + "\n";
           }
           logMsg += "==========\n";
           return logMsg;
       }
   }
   ```

   The SDO application programming interfaces used are generic in that they do not depend on any particular schema definitions. This behavior fits the bottom-up approach because, without a WSDL interface describing this service, the runtime environment cannot associate the input object that is built during deserialization with a specific XSD or SDO type.

Results

You have developed an SCA composite that uses SDO following a bottom-up approach.

What to do next

Optionally, implement shared scopes. See the topic on using SDO 2.1.1 in SCA applications.

Deploy your files that use SDO in an SCA business-level application.

Accessing default HelperContext objects in SCA applications:

A Service Component Architecture (SCA) application can access a Service Data Objects (SDO) 2.1.1 HelperContext object. This object either uses DefaultHelperContext annotation or implements a application programming interface (API) that uses the commonj.sdo.helper.SDO class.

Before you begin

Read SDO data binding for SCA applications to better understand how to work with SDO in SCA Java clients and implementations.

Develop one or more SCA composites that use SDO following a top-down or bottom-up approach.

About this task

This topic describes how to create and access SDO HelperContext in SCA applications. For information about accessing SDO HelperContext in non-SCA applications, see Creating and accessing SDO HelperContext objects.

You can create and access SDO HelperContext in both OSOA and OASIS SCA applications.

Because the SCA run time manages the HelperContext objects and identifiers when using SDO in SCA applications, the method used to create and access SDO HelperContext in SCA applications is different from that used in non-SCA applications. An SCA application can access SDO HelperContext using a DefaultHelperContext annotation, `@DefaultHelperContext`.

Alternatively, an SCA application can implement an API that uses the commonj.sdo.helper.SDO class, to obtain the same SCA-managed HelperContext instance. This approach is an alternative to the annotation. To use this approach, pass the String ID of the SCA-managed HelperContext, which is `sca-default`, into the SDO.getHelperContext method.

You can access the default HelperContext programmatically in a Java or Java Platform, Enterprise Edition (Java EE) component implementation type using either annotation injection or an API. You cannot access the default HelperContext programmatically in a Spring component implementation type. When you use an OSGI application as an implementation of an SCA component, you can access the default HelpContext instance using the API mechanism. However, you cannot access the instance using the annotation injection mechanism.

Procedure

1. Add a public or protected field or setter method of the `commonj.sdo.helper.HelperContext` type to your Java implementation class.

   The method can either be a Java component implementation, such as `<implementation.java>`, or a Java EE implementation class, such as an EJB implementation class.
2. Annotate the field or setter method with `@com.ibm.websphere.soa.sca.sdo.DefaultHelperContext`.

   The following example shows a field annotation:

   ```
   @DefaultHelperContext
   protected HelperContext myDefaultHC;
   ```

   The following example shows an annotation of a setter method:

```
private HelperContext helperContext;

@DefaultHelperContext
public void setHelperContext(HelperContext hc) {
   this.helperContext = hc;
}
```

Alternative step: The following example uses the API rather than annotation:

```
import commonj.sdo.helper.SDO;
import com.ibm.websphere.sdox.SDOUtil;

HelperContext helperContext = SDO.getHelperContext("sca-default")
// Or the following line is equivalent to using the string value directly
HelperContext helperContext = SDO.getHelperContext(SDOUtil.SCA_DEFAULT_SCOPE);
```

3. Use the injected HelperContext in your implementation logic.

   When your component starts, the container will inject this field, or call this setter, with the default HelperContext instance for this component so you can use it in your implementation.

```
import com.ibm.websphere.soa.sca.sdo.DefaultHelperContext;
import commonj.sdo.helper.HelperContext;

// FOR OSOA
import org.osoa.sca.annotations.Service;
// FOR OASIS, commented out
// import org.oasisopen.sca.annotation.Service;
...

// This is a Java implementation of an SCA component
@Service(AccountService.class)
public class AccountServiceImpl implements AccountService {

    private HelperContext helperContext;

    @DefaultHelperContext
    public void setHelperContext(HelperContext hc) {
        this.helperContext = hc;
    }

    @Override
    public DataObject accountMethod(DataObject account, String name) {
        // ....

        // Get dataFactory to create return object
        DataFactory dataFactory = this.helperContext.getDataFactory();
        DataObject retVal = dataFactory.create("http://myns", "Response");

        retVal.set(..)    // ... Set properties on return object

        return retVal;
    }
```

Results

You have written code that accesses the default HelperContext.

What to do next

Develop one or more SCA composites that use SDO following a bottom-up or top-down approach.

Implementing shared scopes in SCA applications that use SDO:

You can package your WSDL and XSD files so they can be accessed across various parts of a Service Component Architecture (SCA) application that uses Service Data Objects (SDO) 2.1.1.

Before you begin

Develop one or more SCA composites that use SDO following a top-down approach.

If you are using a top-down development approach, you must package WSDL and XSD files in an appropriate SCA contribution so the component can access the schema definitions. Read the section on schema registration in SDO data binding for SCA applications for details.

About this task

This topic discusses how to package WSDL and XSD files so that they can be accessed across various parts of your application from a shared in-memory instance. The packaging establishes a shared SDO scope. Shared SDO scope is only supported for applications developed on OSOA specifications.

Procedure

1. Package the WSDL and XSD files that have schema definitions which you want to share into a shared contribution JAR file.
2. In the `META-INF/sca-contribution.xml` file within the shared contribution JAR file, export the namespaces for which you want to share schema definitions within SDO scopes.

   To export the namespaces, use the `<export namespace="...">` statement.

   The examples in this topic continue the example scenario described in the topic on using SDO 2.1.1 in SCA applications.

   Example META-INF/sca-contribution.xml for mySharedDefs.jar:

   ```
   <?xml version="1.0" encoding="UTF-8"?>
   <contribution xmlns="http://www.osoa.org/xmlns/sca/1.0"
       targetNamespace="http://www.ibm.com/test/soa/sca/sdo/scope/">
     <export namespace="http://www.ibm.com/test/soa/sca"/>
     <export namespace="http://www.ibm.com/test/soa/sca/person"/>
     <export namespace="http://www.ibm.com/test/soa/sca/address"/>
     ...
   </contribution>
   ```

3. For composite applications that reference the shared WSDL and XSD schema definitions, import the desired namespaces from the appropriate `META-INF/sca-contribution.xml` file.

   Import namespaces from the `sca-contribution.xml` file of the contribution JAR that contributes the deployable composite which deploys the application components that reference the shared schema definitions as SDO definitions. To import the namespaces, use the `<import namespace="...">` statement.

   Example META-INF/sca-contribution.xml for myImportingComposite1.jar:

   ```
   <?xml version="1.0" encoding="UTF-8"?>
   <contribution xmlns="http://www.osoa.org/xmlns/sca/1.0"
       targetNamespace="http://www.ibm.com/test/soa/sca/sdo/scope/"
       xmlns:sdoscope="http://www.ibm.com/test/soa/sca/sdo/scope/">

     <deployable composite="sdoscope:MyShippingComposite"/>

     <import namespace="http://www.ibm.com/test/soa/sca"/>
     <import namespace="http://www.ibm.com/test/soa/sca/person"/>
     <import namespace="http://www.ibm.com/test/soa/sca/address"/>
     ...
   </contribution>
   ```

   Example META-INF/sca-contribution.xml for myImportingComposite2.jar:

   ```
   <?xml version="1.0" encoding="UTF-8"?>
   <contribution xmlns="http://www.osoa.org/xmlns/sca/1.0"
       targetNamespace="http://www.ibm.com/test/soa/sca/sdo/scope/"
       xmlns:sdoscope="http://www.ibm.com/test/soa/sca/sdo/scope/">

     <deployable composite="sdoscope:MyLoggingComposite"/>

     <import namespace="http://www.ibm.com/test/soa/sca"/>
     <import namespace="http://www.ibm.com/test/soa/sca/person"/>
     <import namespace="http://www.ibm.com/test/soa/sca/address"/>
     ...
   </contribution>
   ```

Results

The packaging establishes a shared SDO scope.

Assuming the composites `MyShippingComposite` and `MyLoggingComposite` are deployed using the same business-level application, then all SDO references to schema definitions in the namespaces exported from the `mySharedDefs.jar` file (and imported from the respective JAR files contributing these two composites) are scoped to a common, shared scope associated with the `mySharedDefs.jar` file. If sharing has not been established through this mechanism, the schema definitions are created separately in each of the two separate scopes associated with the each of the deployable composites.

What to do next

Deploy your files that use SDO in an SCA business-level application.

Data access with Service DataObjects, API versions 1.0 and 2.01

The Service Data Objects (SDO) framework is a data-centric, disconnected, XML-integrated, data access mechanism that provides a source-independent result set.

- SDO is data-centric because it eliminates the need for client applications to work with special formats of data, such as the object representations of the Enterprise JavaBeans (EJB) API. Instead, clients work with easily traversable graphs of DataObjects.
- SDO is disconnected because the retrieved result is independent of any back-end data store connections or transactions.
- SDO is XML-integrated in that it provides services to easily convert retrieved data to and from XML format.

Put simply, SDO is a framework for data application development, which includes an architecture and API. SDO does the following:

- Simplifies the Java Platform, Enterprise Edition (Java EE) data programming model.
- Abstracts data in a service-oriented architecture (SOA).
- Unifies data application development.
- Supports and integrates XML.
- Incorporates Java EE patterns and best practices.

The Service Data Objects framework provides a unified framework for data application development. With SDO, you do not need to be familiar with a technology-specific API in order to access and use data. You need to know only one API, the SDO API, which lets you work with data from multiple data sources, including relational databases, entity EJB components, XML pages, web services, the Java Connector Architecture, JavaServer Pages, and more.

Unlike some of the other data integration models, SDO does not stop at data abstraction. The SDO framework also incorporates a good number of Java EE patterns and best practices, making it easy to incorporate proven architecture and designs into your applications. For example, most web applications today are not (and cannot) be connected to backend systems 100 percent of the time; so SDO supports a disconnected programming model. Likewise, many applications tend to be remarkably complex, comprising many layers of concern. How will data be stored? Sent? Presented to users in a GUI framework? The SDO programming model prescribes patterns of usage that allow clean separation of each of these concerns.

SDO components

An architectural overview of SDO describes each of the components that make up the framework and explains how they work together. The first three components listed are “conceptual” features of SDO: They do not have a corresponding interface in the API.

SDO clients

SDO clients use the SDO framework to work with data. Instead of using technology-specific APIs and frameworks, they use the SDO programming model and API. SDO clients work on SDO DataObjects and do not need to know how the data they are working with is persisted or serialized.

Data mediator services

Data mediators services (DMS) are responsible for creating a DataGraph from data sources, and updating data sources based on changes made to a DataGraph. (A DataGraph is an envelope object that contains service data objects.)

The DMS provides the mechanism to move data between a client and a data source. It is created with back end specific metadata. The metadata defines the structure of the DataGraph that is produced by the DMS as well as the query to be used against the back end. When the DMS is requested to produce a DataGraph, it queries its targeted back end and transforms the native result set into the DataGraph format. Once the DataGraph is returned, the DMS no longer has any reference to it, making it stateless with respect to the DataGraph. When the DMS is requested to flush modifications of an existing DataGraph to the back end, it extracts the changes made from the original state of the DataGraph and flushes those changes to the back end. A DMS typically employs some form of optimistic concurrency control strategy to detect update collisions.

WebSphere Application Server provides functionality for two separate Data Mediator Services. If you simply need to retrieve data from a relational data source and return a DataGraph, using the Java Database Data Mediator Service is a good choice. However, if you have business logic, then you probably want an object-oriented (OO) rendering of the data into entity beans. One could consider SDO as an object rendering of data like entity beans. But entity beans have better Object-Relational (OR) mapping tools, and the EJB container and persistence manager for entity beans offer more sophisticated caching policies. Your best choice then is the EJB Data Mediator Service. The EJB mediator can work with these caches. Also, the entity bean programming model is a single level store model. You can navigate from entity to entity and the container and persistence manager either prefetches or lazily fetches in data as needed. On update, the programmer commits the transaction and the container and persistence manager do the work of tracking updated beans and writing them back to the data store and in memory cache.

Data sources

Data sources are not restricted to backend data sources (for example, persistence databases). A data source contains data in its own format. As to the SDO 1.0 API, only the DMS accesses data sources; SDO applications do not. The applications only work with SDO 1.0 DataGraphs.

Each of the following components corresponds to a Java interface in the SDO programming model.

DataObjects

As the fundamental components of SDO, DataObjects provide a common view of structured data for SDO clients. DataObjects can hold multiple different attributes of any serializable type (such as string or integer); more complex DataObjects can also contain simpler DataObjects. DataObjects hold all of their data in properties.

SDO version 1.0 DataObjects are always linked together and contained in DataGraphs. The version 1.0 DataObject interface provides simple creation and deletion methods (createDataObject() with various signatures and delete()), and reflective methods to get their types (instance class, name, properties, and namespaces). The interface also supports static object types that you create from external code generators. See the article “Dynamic and static object types for the JDBC DMS” for more information.

DataGraphs

A DataGraph is a structured result returned in response to a service request. The DMS transforms the native backend query results into the DataGraph, which is independent of the originating backend data store. This makes the DataGraph easily transferable between different data sources. The DataGraph is composed of interconnected nodes, each of which is an SDO DataObject. It is

independent of connections and transactions of the originating data source. The DataGraph tracks changes made to it from its original source. This change history can be used by the DMS to reflect changes back to the original data source. DataGraphs can easily be converted to and from XML documents enabling them to be transferred between layers within a multi-tiered system architecture. A DataGraph can be accessed in either breadth-first or depth-first manner, and it provides a disconnected data cache that can be serialized for web services

The DataGraph returned by the mediator can contain either dynamic or generated static DataObjects. Use of generated classes gives type safe interfaces for easier programming and better runtime performance. The EMF generated classes must be consistent in name and type with the schema that would be created for dynamic DataObjects except that additional attributes and references can be defined. Only those attributes and references specified in the query are filled in with data. Remaining attributes and references are not set.

Change summary

SDO 1.0 change summaries are contained by DataGraphs and are used to represent the changes that have been made to a DataGraph returned by the DMS. They are initially empty (when the DataGraph is returned to a client) and populated as the DataGraph is modified. Change summaries are used by the DMS at backend update time to apply the changes back to the data source. They enable the DMS to efficiently and incrementally update data sources by providing lists of the changed properties (along with their old values) and the created and deleted DataObjects in the DataGraph. Information is added to the change summary of a DataGraph only when the change summary's logging is activated. Change summaries provide methods for DMS to turn logging on and off.

Note: The SDO 1.0 change summary is not a client API; it is used only by the DMS.

Properties, types, and sequences

DataObjects hold their contents in a series of properties. Each property has a type, which is either an attribute type such as a primitive (for example, int) or a commonly used data type (for example, Date) or, if a reference, the type of another DataObject. Each DataObject provides read and write access methods (getters and setters) for its properties. Several overloaded versions of these accessors are provided, allowing the properties to be accessed by passing the property name (String), number (int), or property metaobject itself. The String accessor also supports an XPath-like syntax for accessing properties. For example, you can call get(“department[number=123]”) on a company DataObject to get its first department whose number is 123. Sequences are more advanced. They allow order to be preserved across heterogeneous lists of property-value pairs.

For more introductory information

For a good introduction to SDO 1.0 that also includes a small sample application, refer to the IBM developerWorks® paper “Introduction to Service DataObjects.”

Note: To fully understand the EJB data mediator service you need a good understanding of the EJB programming model. For more information refer to the articles “Task overview: Using enterprise beans in applications” and “Service Data Objects: Resources for learning.”

Java DataBase Connectivity Mediator Service:

The Java Database Connectivity (JDBC) Data Mediator Service (DMS) is the Service Data Objects (SDO) component that connects to any database that supports JDBC connectivity. It provides the mechanism to move data between a DataGraph and a database.

A regular JDBC call returns a result set in a tabular format. This format does not directly correspond to the object-oriented data model of Java, and can complicate navigation and update operations. When a client sends a query for data through the JDBC DMS, the JDBC result set of tabular data is transformed into a

DataGraph composed of related DataObjects. This enables clients to navigate through a graph to locate relevant data rather than iterating through rows of a JDBC result set. Once you have altered the DataGraph, all of the changes can be committed together and propagated back to the database by the JDBC DMS. Between the processes of being populated and committed, the DataGraph is disconnected from the database, and there are no locks held on the data accessed. Once disconnected allows multiple changes to be made to the graph without making additional round trips to the database, improving performance.

The JDBC DMS is created with server-specific metadata. The metadata defines the structure of the DataGraph that is produced by the DMS, as well as the query to be used against the server.

Metadata for Data Mediator Service:

A Data Mediator Service (DMS) is the Service Data Object (SDO) component that connects to the back end database. It is created with back end specific metadata. The metadata defines the structure of the DataGraph that is produced by the DMS as well as the query to be used against the back end.

Metadata is composed of the following components:

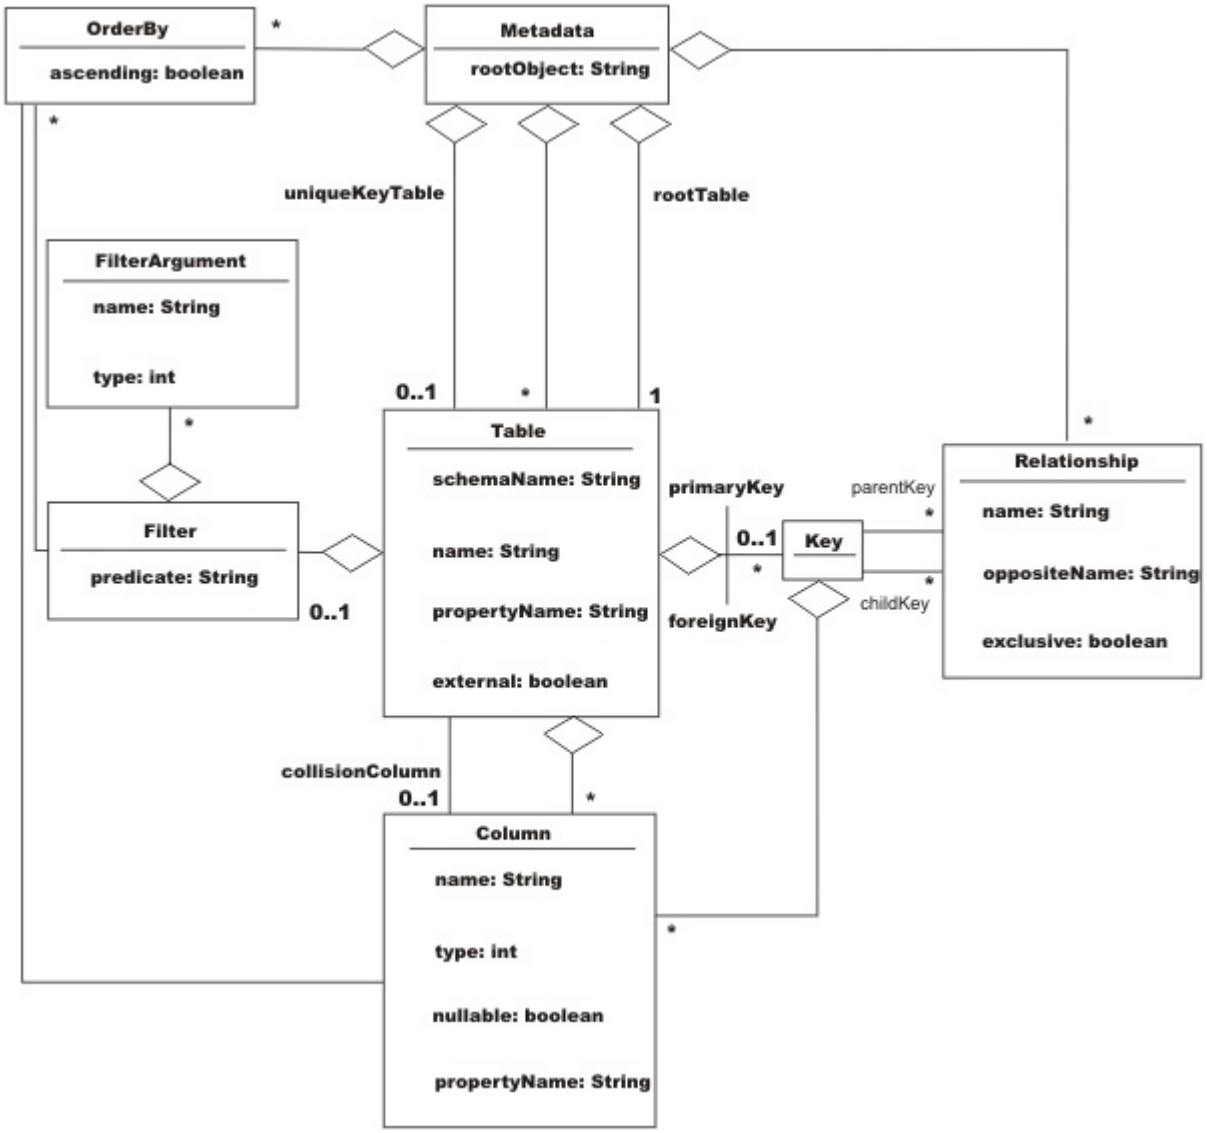

Table This represents a table within the target database and is composed of the following items:

Name This is the database table name. A table might also have a property name that can be

used to specify the name of the DataObject that corresponds to this table. By default, the property name is the same as the table name.

Columns
The subset of database table columns to return from the database. A column has a type that corresponds to a JDBC type and it can prohibit null entries. A column has a name that corresponds to the name in the database and an optional property name that identifies the column name in the DataObject. By default, the property name is the same as the column name in the database.

Primary Key
The column (or columns) used to uniquely identify a row within the table.

Note: Keys may be composed of multiple columns. The following example illustrates creation of a compound primary key :

```
Key pk = MetadataFactory.eINSTANCE.createKey();
pk.getColumns().add(xColumn);
pk.getColumns().add(yColumn);
coordinateTable.setPrimaryKey(pk);
```

If a table is related to this one and is the child table, it uses the same method to create the foreign key to point to this coordinate table.

Foreign Key
The column (or columns) used to relate the table to another table in the metadata. There is an assumed positional mapping between compound primary keys and foreign keys. For example, if a parent table has a primary key such as (x,y) with respective types (integer, string), then it is expected that any pointing foreign key is also (x', y') with respective types (integer, string).

Note: Keys may be composed of multiple columns. The following example illustrates the creation of a compound foreign key :

```
Key fk = MetadataFactory.eINSTANCE.createKey();
fk.getColumns().add(xColumn);
fk.getColumns().add(yColumn);
coordinateTable.getForeignKeys().add(fk);
```

If a table is related to this one and is the child table, it uses the same method to create the foreign key to point to this coordinate table.

Filter A structured query language (SQL) WHERE clause predicate that can be given with or without parameters to fill in later. This is added to the DataGraph SELECT statement WHERE clause. It is not parsed or interpreted in any way; it is used as is. If given with parameters to fill in later, these parameters become arguments passed into the JDBC DMS when getting the DataGraph. Filters are used with generated queries only. If a supplied query is given, the metadata filters are ignored.

Relationship
Relates two tables through the primary key of the parent table and the foreign key of the child table. Relationships are composed of the following items:

Name This is the name given to the relationship, usually associated with how the two tables are related. If *Customers* is the parent table and *Orders* is the child table, then the default name of the relationship is Customers_Orders.

Opposite Name
This is the name used to navigate from the child DataObject to the parent DataObject.

Parent Key
The primary key of the parent table.

Child Key
The foreign key of the child table that points to the parent key.

Exclusive
By default, a Relationship causes the generated query to use an inner join operation on the two tables involved in the relationship. This means that it only returns the parent entries that have children, that is, child entries pointing to them. If the value of the Exclusive attribute is set to false, the query uses a left outer join operation instead and returns all parent entries, even those without children.

Ordering
Columns used for ordering the tables. Can be either ascending or descending. When specified, this causes generated queries to contain an ORDER BY clause.

Dynamic and static object types for the JDBC DMS:

DataObjects of the Service Data Object (SDO) 1.0 Specification can use static types as well as dynamic types. If you know that a particular dataGraph schema meets all of your application query requirements, you can generate static SDO code for potential runtime benefits.

With dynamic types, the information that defines the shape of a DataGraph is constructed at runtime. The DataGraph schema is created by the JDBC data mediator service (DMS) from the metadata provided upon creation. The JDBC DMS only requires the metadata and a connection to a data source to produce the DataGraph with dynamic typing. This is the default method for creating the JDBC DMS.

If you know the shape of the DataGraph at development time, you can use a code generator to create strongly typed interfaces (static data API code) that simplify DataGraph navigation, provide better compile-time checking for errors, and improve performance. For more information about the metamodels from which you can generate static SDO code, consult the introduction of the SDO 1.0 Specification. The introduction contains a list of the specification scope requirements, where you can find a brief discussion on support for static data API. Note that the dynamic API is still available when you use strongly typed DataObjects.

With the code generator you create classes for each DataObject type in the DataGraph. Each class contains `getter()` and `setter()` methods for each property in the DataObject. This enables a client to call type-safe methods rather than passing in the name of a property. For example, instead of calling the property `DataObject.get("CUSTFIRSTNAME")`, the generated types can contain a DataObject.getCustFirstName() method. If you are accessing a related DataObject, an accessor returns a strongly-typed DataObject rather than a regular DataObject. For example, `DataObject.get("Customers_Orders")` returns a DataObject, but `DataObject.getOrders()` returns an object of type Order.

To use static typing with the JDBC DMS, the metadata, a connection to the data source, and the DataGraph schema need to be provided to the JDBCMediatorFactory class `create` methods. In this case, the JDBC DMS metadata does not determine the shape of the DataGraph, but does give the DMS information about the backend data source and the way it maps to a DataGraph.

When using strongly typed DataObjects, it is important to make sure that the query matches the DataGraph schema. The query is not required to fill all of the data objects and properties in the schema, but a query cannot return data objects or properties that are not defined in the DataGraph schema. For example, a DataGraph schema might define `Customer` and `Order` DataObjects, but a query might only return Customer objects. Also, the Customer object might define properties for `ID`, `Name`, and `Address`, but the query might not return an address. In this case, the value of the address property is null, and the value is not updated in the database when the `applyChanges()` method is called. In this example, the query could not return a `Phone` property because it has not been defined as a property on the Customer object. When a query attempts this, the DMS returns an invalid metadata exception.

JDBC mediator supplied query:

An SDO client can supply the JDBC Data Mediator Service (DMS) with a SELECT statement to replace the statement that is generated from the DMS metadata.

When the SDO client instantiates a DMS, the DMS uses the defining metadata to generate a basic SELECT statement. Substituting that query gives you the ability to specify parameter markers; therefore you have more control over the client data that populates a dataGraph. Use a standard SQL SELECT string for a client-supplied query.

With both supplied queries and generated queries, UPDATE, INSERT, and DELETE statements are automatically generated for each DataObject. They are applied when the mediator commits the changes made to the DataGraph back to the database.

Parameter DataObjects for supplied queries

Clients can use a parameter DataObject to supply arguments to an SQL SELECT query. A parameter DataObject is a DataObject, but is not part of any DataGraph. It is constructed by the JDBC DMS when requested by the client. The ParameterDataObject for supplied queries is created based on the query given to the mediator. Every parameter in the query is given a name like *arg0, arg1, ..., argX*.

Because a parameter DataObject is a DataObject, you can set its properties using either the property name or an index value. The properties can be referenced by their argX name, or by the number associated with that parameter, 0, 1, ... , X. For example, your query is “SELECT CUSTFIRSTNAME WHERE CUSTSTATE = ? AND CUSTZIP = ?”. This supplied query contains two parameters. The first parameter corresponds with CUSTSTATE and can be set using the string “arg0” or the index 0. The second parameter corresponds with CUSTZIP and can be set using the string “arg1” or the index 1. Here is sample code of how they are set. This code assumes that you have already set up the metadata and mediator with the metadata and the aforementioned supplied query. Using the index value method, you code:

```
DataObject parameters = mediator.getParameterDataObject();
parameter.setString(0, "NY");
parameter.setInt(1, 12345);
DataObject graph = mediator.getGraph(parameters);
```

Using the property name method, you code:

```
DataObject parameters = mediator.getParameterDataObject();
parameters.setString("arg0", "NY");
parameters.setInt("arg1", 12345);
DataObject graph = mediator.getGraph(parameters);
```

The results are the same for both cases.

Limitations

The JDBC DMS generated SQL SELECT query is not fully supported on Oracle or Informix. This is because the mediator takes advantage of the ResultSetMetaData interface in JDBC 2.0 and requires it to be fully implemented. Oracle, Informix, DB2/390, and older supported versions of Sybase do not implement the ResultSetMetaData interface completely. The supplied select approach can still be used with these databases with one limitation: **column names in the Metadata must be unique across all tables.** An InvalidMetadataException occurs if the select statement returns a column with a name that appears multiple times in the metadata. For instance, if the Customer and the Order tables both contain a column named “ID”, this would be invalid and cause problems. The way to fix this is to change the name of at least one of the matching columns in the database to better distinguish the two columns from each other. For the Customer table, the column name could be changed to “CUSTID,” as it is in the examples. The Order column name could be changed to “ORDERID”. If you change the Customer column name, you do not have to change the Order column name, but for consistency it may be a good idea.

JDBC mediator generated query:

If you do not provide a structured query language (SQL) SELECT statement, then the data mediator service (DMS) generates one using the metadata provided at instance creation.

The internal query engine uses information in the metadata about tables, columns, relationships, filters, and order-bys to construct a query. As with the supplied queries, UPDATE, DELETE, and INSERT statements are automatically generated for each DataObject to be applied when the mediator commits the changes made to the DataGraph back to the database.

Filters

Filters define an SQL WHERE clause that might contain parameter markers. These are added to the DataGraph SELECT statement WHERE clause. Filters are used as is; they are not parsed or interpreted in any way so there is no error checking. If you use the wrong name, predicate, or function, it is not detected and the generated query is not valid. If a Filter WHERE clause contains parameter markers, then the corresponding parameter name and type are defined using Filter arguments. Parameter DataObjects fill in these parameters before the graph is retrieved. An example of the Filters and Parameter DataObjects for generated queries follows.

Limitation: Because of the tree-like nature of the DataGraph, any table at a branch appears in more than one subquery in the final union with the root table appearing in all paths. This means that it is not possible to filter on a table that appears in more than one path independent of all other paths. All filters defined on a particular table are joined by a boolean AND, and used everywhere that table appears.

Parameter DataObjects for generated queries

Clients use a Parameter DataObject to supply arguments that are applied to the filters provided in the DMS metadata. A Parameter DataObject is a DataObject, but is not part of any DataGraph. It is constructed by the JDBC DMS when requested by the client. The Parameter DataObject for generated queries is created based on the mediator's metadata. Every argument of every filter of every table is put into the Parameter DataObject. Unlike the supplied query Parameter DataObject, the parameters have the name assigned to them by the Filter arguments. The Parameter DataObject uses this name to map to the parameter to be filled in. The following sample code illustrates how a filter is created for a table in the mediator metadata. It also demonstrates the use of a Parameter DataObject to pass filter parameter values to a mediator instance. The sample assumes that the Customer table has already been defined:

```
// The factory is a MetadataFactory object
Filter filter = factory.createFilter();
filter.setPredicate("CUSTSTATE = ? AND CUSTZIP = ?");

FilterArgument arg0 = factory.createFilterArgument();
arg0.setName("customerState");
arg0.setType(Column.String);
queryInfo.getFilterArguments().add(arg0);

FilterArgument arg1 = factory.createFilterArgument();
arg1.setName("customerZipCode");
arg1.setType(Column.Integer);
queryInfo.getFilterArguments().add(arg1);

// custTable is the Customer Table object
custTable.setFilter(filter);

..... // setting up mediator

DataObject parameters = mediator.getParameterDataObject();
```

```
// Notice the first parameter is the name given to the
// argument by the FilterArgument.
parameter.setString("customerState", "NY");
parameter.setInt("customerZipCode", 12345);
DataObject graph = mediator.getGraph(parameters);
```

Order-by

Ordering of query results is specified using OrderBy objects that identify a column from a table to sort the results. This ordering can be either ascending or descending. The OrderBy objects are part of the metadata and are automatically applied to generated queries. An example of this for a customer table results to be sorted by first names is as follows:

```
// This example assumes that the custTable, a table in
// the metadata, and factory, the MetaDataFactory
// object, have already been created.
Column firstName = ((TableImpl)custTable).getColumn("CUSTFIRSTNAME");
OrderBy orderBy = factory.createOrderBy();
orderBy.setColumn(firstName);
orderBy.setAscending(true);
metadata.getOrderBys().add(orderBy);
```

Limitation: Even though Order-bys are defined on each table in the metadata, the RDBMS model requires them to be applied to the final query. This has many implications. For example, you cannot order a table and then use that in a join to another table and propagate the ordering in the first table. Because a result set is a union of all the tables in the DataGraph, the nature of the single result set requires that it be padded with nulls, which can affect the order-bys, particularly in the non-root tables. This can give unexpected results.

External Tables

An external table is a table defined in the metadata that is not needed in the DataGraph returned by the JDBC DMS. This might be appropriate when you want to filter the result set based on data from a table but that table's data is not needed in the result set. An example of this with the Customers and Orders relationship would be to filter the results to return all customers who ordered items with an order date of the first of the year. In this case, you do not want any order information returned, but you do need to filter on the order information. Making the Orders table external excludes the orders information from the DataGraph and therefore reduces the DataGraph's size, improving efficiency. To designate a table as external, you call the setExternal(true) method from a table object in the JDBC DMS metadata. If the client tries to access an external table from the DataGraph, an illegal argument exception occurs.

Limitation: Many RDBMSs require that an orderby column appear in the final result set; the columns from an external table cannot in general be used to order a result set. Order-bys are actually applied to the result set (the word “set” is key here), and not to intermediate query results.

General limitations of generated queries

In understanding the limitations of the query generation feature in the JDBC DMS, there are two things to keep in mind. The first is that the DataGraph imposes a model that is a directed, connected graph with no cycles (that is, a model that is a tree) on a relational model that is a non-directed, potentially disconnected graph with cycles. `Directed` means that the developer chooses the orientation of the graph by picking a root table. `Connected` means that all tables that are a member of the DataGraph are reachable from the root. Any tables that are not reachable from the root cannot be included in the DataGraph. In order for a table to be reachable from the root, there must be at least one foreign key relationship defined between each pair of tables in the DataGraph. `No cycles` means that there is only one foreign key relationship between a pair of tables in the DataGraph. The tree nature of the DataGraph determines how the queries are built, and what data is returned from a query.

The second item to keep in mind is the following high level description of how query generation produces read queries for a DataGraph:

1. The JDBC DMS creates a single result set (that is, a DataGraph) whether the DataGraph is composed from a single table or from multiple tables.
2. Each path through the foreign key relationships in DMS Metadata from root to leaves represents a separate path. The data for that path is retrieved by using joins across the foreign keys defined between the tables in the path. The joins are by default inner joins.
3. All the paths in a DataGraph are unioned together in order to create a single result set by the query that is generated by the mediator, and are thus treated independently of one another.
4. Any user-defined filtering is done first on the tables. Then the result is joined to the rest of the path.
5. Relational databases generally require order-bys to be applied to the entire final result set and not on intermediate results.

JDBC mediator performance considerations and limitations:

Use these tips to help you determine if a JDBC Data Mediator Service suits the requirements of your application serving environment.

Miscellaneous database limitations

- Sybase before Version 12.5.1 does not support in-line queries in the “from” clause, and therefore does not support multiple table DataGraphs with filters. To use the Service Data Object in WebSphere Application Server use Sybase Version 12.5.1.
- The Informix Dynamic Server does not support sub-selects, which are needed for multiple table graphs. Use Informix Extended Parallel Server.
- Oracle 8i does not support the ANSI join syntax. The mediator in multiple table cases requires Oracle 9i or 10g.

General performance recommendations

- Evaluate if your target projects are well suited to these technologies. In general, projects that are read-intensive and require disconnected data are good candidates.
- Limit the number of tables in the metadata. One or two is best because relationships, with respect to filters, become ambiguous when graphs have many branches.
- Work with small data sets as often as possible to avoid consuming excessive amounts of memory within your applications. You can limit the amount of data returned to the SDO by specifying filters in the metadata objects or by using paging.
- For web applications, if the DataGraph is not too large and is to be reused later, store it in the user session.

JDBC mediator transactions:

You can specify that the JDBC mediator either act as transaction manager, or refrain from such activities in the case of external transaction management (performed by the SDO client).

Mediator managed transactions

A JDBC connection is wrapped in a connection wrapper and passed to the Data Mediator Service (DMS) during the instance creation. The ConnectionWrapper object contains the connection that is used by the JDBC DMS and indicates whether the mediator manages the current transaction. When the JDBC DMS manages the transaction, it performs commit and rollback operations as required. However, the DMS does not perform any transaction management activities if the wrapped connection is currently engaged in another transaction.

Using the createConnectionWrapper method for active transaction management is the general practice.

Non-mediator managed transactions

When a *passive* connection wrapper is passed to the DMS, the DMS takes no managerial action; a passive wrapper is generally intended for an existing transaction that is under external management. Commit or rollback operations are not performed by the connection wrapper in this case.

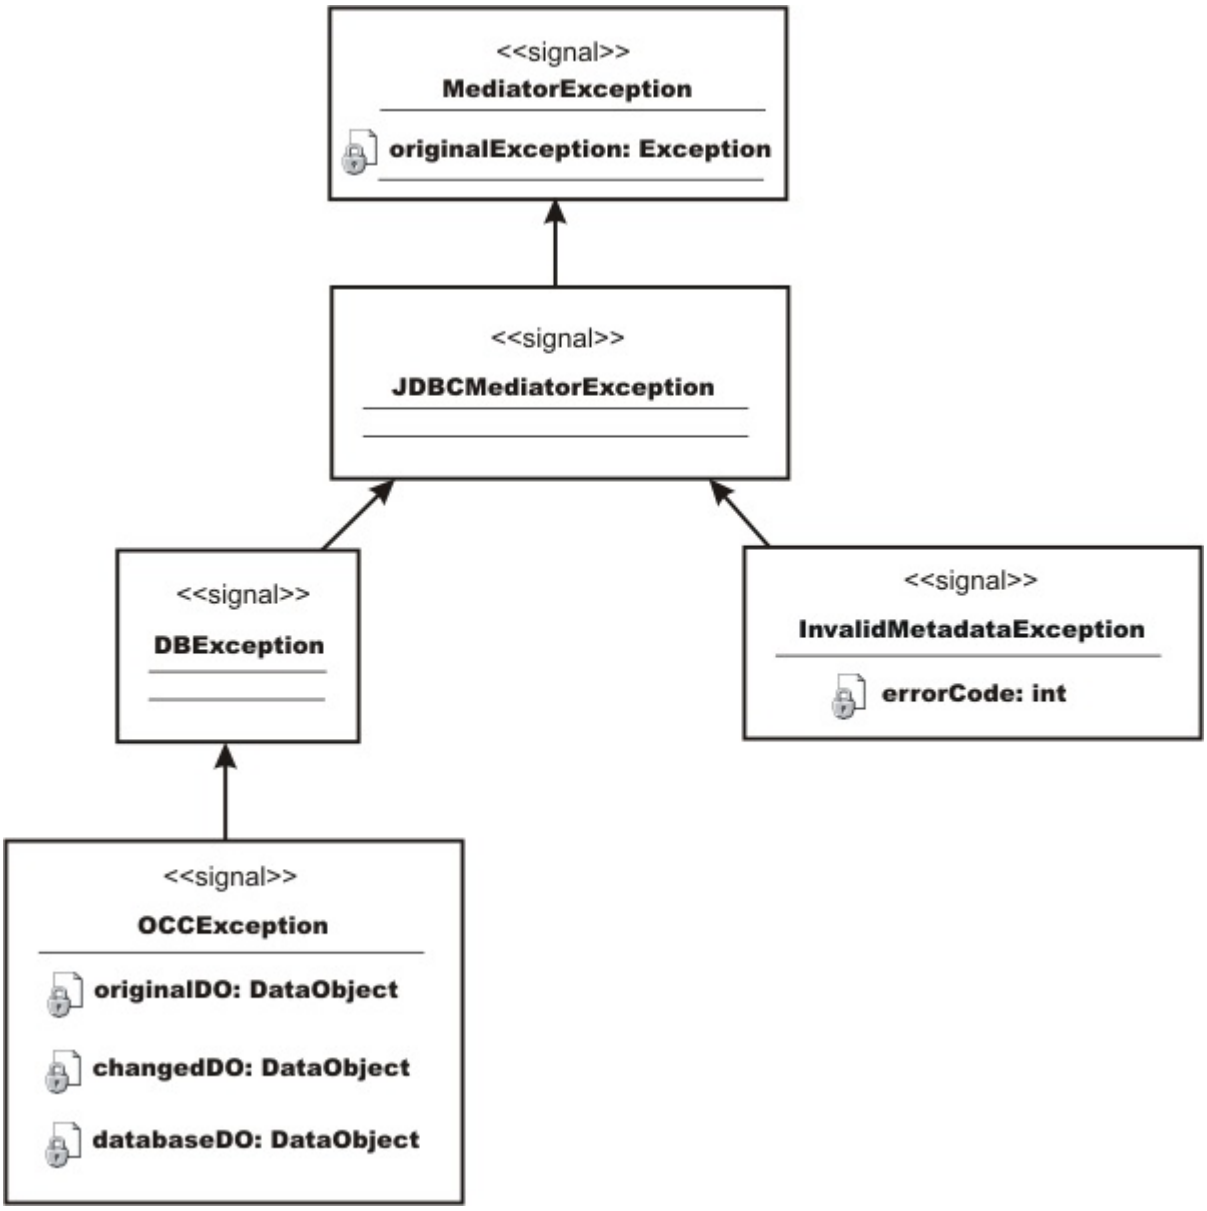
Use the createPassiveConnectionWrapper method.

Protection against referential integrity (RI) violations

The JDBC Data Mediator Service safeguards data transactions from incurring RI violations and other database logic violations. When the JDBC DMS applies the updates of a data graph to a back end, it automatically orders the change operations so that they do not violate database RI policy. Similarly, the DMS filters counter operations (such as INSERT and DELETE) so that opposing client requests can perform updates in a logical order. The client deletes one object, and then creates an entirely separate object with the same primary key. The DMS transforms these two operations into an update operation that modifies the existing database object.

JDBC mediator exceptions:

JDBC mediator exceptions either surface errors reported by the database, or indicate use of non-valid metadata in the attempt to instantiate the DMS.



The `Mediator` exception is the root exception of all the data mediator services, and the `JDBCMediator` exception is the root exception for the JDBC DMS in particular.

The `DB` exception occurs when an error is reported by the database. This can occur several ways:
- when the connection being used has the AutoCommit property set to *true*, but the JDBC DMS is controlling the transaction and needs it to be set to false
- when an unsupported database is trying to be used
- when other backend database errors occur during commit or rollback.

An optimistic concurrency control (OCC) exception occurs when the applyChanges() operation results in an data collision. When this occurs, the exception contains the original row values, current row values, and the attempted row values. These values are used to help recover from the error.

An `InvalidMetadata` exception occurs for invalid metadata supplied to the JDBC DMS upon creation. This can happen when a query requires tables or columns that are not defined in the metadata, or when there are identical column names for different tables for the Oracle, Informix, and older supported versions of Sybase databases.

Example: Forcing OCC data collisions and JDBC mediator exceptions, The following example forces a collision to demonstrate detection and shows the exception that occurs as a result.

```
// This example assumes that a mediator has already
// been created and the first name in the list is Sam.
// It also assumes that the Customer table has an OCC
// column and the metadata has set this column to be
// the collision column.

DataObject graph1 = mediator.getGraph();
DataObject graph2 = mediator.getGraph();

DataObject customer1 = (DataObject)graph1.getList("CUSTOMER").get(0);
customer1.set("CUSTFIRSTNAME", "Bubba");

DataObject customer2 = (DataObject)graph2.getList("CUSTOMER").get(0);
customer2.set("BOWLERFIRSTNAME", "Slim");

mediator.applyChanges(graph2);

try
{
 mediator.applyChanges(graph1);
}
catch (OCCException e)
{
// Since graph1 was obtained before graph2 and
// graph2 has already been submitted, trying to
// apply the same changes to graph1 causes
// this OCC Exception.

assertEquals("Sam", e.getOriginalDO(). getString("CUSTFIRSTNAME"));
assertEquals("Bubba", e.getChangedDO(). getString("CUSTFIRSTNAME"));
assertEquals("Slim", e.getDatabaseDO(). getString("CUSTFIRSTNAME"));
}
```

Defining optimistic concurrency control for JDBC Mediator:

Implement an optimistic concurrency control (OCC) strategy for the JDBC DMS to diagnose transaction problems that are caused by update collisions.

About this task

An *update collision* occurs when client data that populates a data graph is changed in the database before the data graph can submit the modifications of the client. If you configure the JDBC DMS for OCC, the DMS issues an OCC-specific exception when such a data collision happens. The OCC exception contains collision details such as the original row values, current row values, and the attempted row values. The client application uses these values to determine how to recover from the collision. For example, the application can reread the data and restart the transaction.

Be aware, however, that when one exception occurs, there is no way of knowing whether more exceptions exist deeper in the data graph schema and therefore are not displayed.

To activate OCC for the data mediator service, you must incorporate OCC columns into your database tables.

Add an *OCC Integer* column to a given table, and specify that this column is to be used for OCC in the metadata. The defined OCC collision column is reserved for the exclusive use of the mediator. If there is no OCC column defined for a table, the DMS does not monitor and notify you of update collisions. The following generic code segments create this setup.

Procedure

1. Create the OCC column
   ```
   Column collisionColumn = table.addIntegerColumn("OCC_COUNT");
   ```
2. Ensure that it does not allow null values
   ```
   collisionColumn.setNullable(false);
   ```
3. Designate the column as the table collision column
   ```
   table.setCollisionColumn(collisionColumn);
   ```
   For a fully-fledged code example that forces a collision to demonstrate the OCC exception, see the topic Example: Forcing OCC data collisions and JDBC mediator exceptions.

JDBC mediator integration with presentation layer:

The JDBC Data Mediator Service (DMS) can be used in conjunction with web application presentation layer technologies such as JavaServer Pages Standard Tag Library (JSTL) and JavaServer Faces (JSF).

This discussion assumes a general understanding of both of the JavaServer Pages Standard Tag Library (JSTL) and JavaServer Faces (JSF) technologies. In particular for JSF, the UIData component and the general file structure of a JSF dynamic web application should be known. For a brief overview of both JSF and JSTL refer to the topics under Service Data Objects.

The JDBC DMS and JSTL work well together because the JSTL access code is equivalent to the code necessary to access attributes and lists inside of a DataObject. For example, in relation to a root Customer DataObject, the JSTL expression:

```
${rootDO.CUSTOMER[index].CUSTNAME}
```

is equivalent to the Java code for a DataObject of:

```
rootDO.getList("CUSTOMER").get(index).get("CUSTNAME")
```

The reason for this is the dot notation in the JSTL expression language correlates to a *getter()* method in Java code, and the bracket notation allows you to access elements inside a list.

The JDBC DMS and JSF fit well together because the DataGraph produced by the JDBC DMS is able to populate a JSF UIData component without having to be transformed. The UIData component uses a *dataTable* tag that takes a list as its input to populate the table. This works out well with the DataGraph because all you need to pass into the dataTable is the root list of the DataGraph. The most common way to lay out the DataGraph in the dataTable is to display each attribute of the DataObject from the list retrieved from the root in its own column, and to embed each additional relationship to the DataObject in a new dataTable contained within the parent DataObject's row. Using this method instead of a traditional ResultSet table eliminates duplicate information and makes it easier to see the separation of the parent object's children. An example of how the Customer and Order scenario is laid out in a dataTable is shown in the topic Example: Using JavaServer Faces and JDBC Mediator dataTables.

Example: Using JavaServer Faces and JDBC Mediator dataTables.

This example shows code that would be located inside of a Faces JSP page. It demonstrates how to use JavaServer Faces and JDBC Mediator dataTables in an application.

It contains the UIData component dataTable tag with all of the customer's information, along with their orders. Each Customer attribute has its own column. The Customer Orders are embedded in another

dataTable containing each of the Order attributes in separate columns. This embedded dataTable of Orders is like any other Customer attribute, having its own column inside each Customer row.

```
<h:dataTable id="table1" value="">{pc_Customers.customer}" var=
"varcustomer" styleClass="dataTable">

       id="text28"></h:outputText>
   </f:facet>
   <h:outputText id="text29"
       value=">{varCUSTOMERS_ORDERS.EMPLOYEEID}" styleClass="outputText">
     <f:convertNumber />
   </h:outputText>
 </h:column>

    </h:dataTable>
  </h:column>
</h:dataTable>
```

JDBC mediator paging:

Paging can be useful for moving through large data sets because it can limit the amount of data pulled into memory at any given time. The JDBC DMS API provides two interfaces that implement paging.

If the metadata provided to the data mediator service (DMS) defines customers and the page size is set to ten, then the first page is a DataGraph containing the first ten customer DataObjects. The next page is another DataGraph with the next ten Customers, and so forth.

One thing to note is that the JDBC DMS provides paging at the root of the graph. That is, there is no restriction on the number of related DataObjects returned. For example, if the metadata provided to the DMS defines customers and related orders, it is the customers that are paged. If the page size is set to ten, then the first page is a graph with the first 10 customers and all related orders for each customer.

There are two interfaces provided by the DMS that you can take advantage of, the **Pager** and the **CountingPager**. The Pager interface provides a cursor-like *next()* method capability. The next() function returns a graph representing the next page of data from the entire data set specified by the mediator metadata. There is also a *previous()* function available with the same capabilities, only going backward. The CountingPager interface enables you to retrieve a specific page number. The following example illustrates paging through a large set of customer instances using a CountingPager interface with a maximum of 5 DataObjects from the root table per page.

```
CountingPager pager = PagerFactory.soleInstance.createCountingPager(5);
int count = pager.pageCount(mediator);
for (int i = 1, i <= count, i++) {
DataObject graph = pager.page(i, mediator);
// Iterate through all returned customers in the
// current page.
Iterator iter = graph.getList("CUSTOMER").iterator();
 while (iter.hasNext()) {
  DataObject cust = (DataObject) iter.next();
System.out.println(cust.getString("CUSTFIRS NAME"));
 }
}
```

If you try to move before the first page or after the last available page, a JDBC mediator exception occurs.

JDBC mediator serialization:

The DataGraph produced by the JDBC DMS can be serialized and written out to a file, or sent across a network.

The following example illustrates serialization and de-serialization of a graph:

```
// This example assumes the creation of the Customer
// metadata and the JDBC DMS.

DataObject object = mediator.getGraph();
DataGraph origGraph = object.getDataGraph();

FileOutputStream out = new FileOutputStream("test.datagraph");
ObjectOutputStream oos = new ObjectOutputStream(out);
oos.writeObject(origGraph);
out.close();

FileInputStream in = new FileInputStream("test.datagraph");
ObjectInputStream oin = new ObjectInputStream(in);
DataGraph graph = (DataGraph) oin.readObject();
DataObject obj = (DataObject) graph.getRootObject();

// Now, the DataObject retrieved from the input stream
// obj is equal to the original variable object put
// through the output stream.
```

Enterprise JavaBeans Data Mediator Service:

The Enterprise JavaBeans (EJB) Data Mediator Service (DMS) is the Service Data Objects (SDO) Java interface that, given a request in the form of EJB queries, returns data as a DataGraph containing DataObjects of various types.

This is different from a typical EJB finder or ejbSelect method, which also takes an EJB query but returns a collection of EJB objects that are all of the same type or a collection of container managed persistence (CMP) values.

The EJB DMS enables you to specify an EJB query that returns a data graph (the DataGraph) of data objects (DataObjects). The query can be expressed as a compound EJB query that is contained in a string array of EJB query statements. One advantage of using a DataGraph is that much of the code written in an EJB facade session bean that creates, populates, and updates copy helper objects can be replaced with a DataGraph and a DMS.

Important: The EJB DMS has support for EJB2.x container managed persistence (CMP) entity beans only. It does not support EJB 3.x modules.

You can obtain a DataGraph using the getGraph call, either from EJB instances cached in the container, or the query request can be compiled into SQL and executed directly against the data source.

Updated DataObjects can be written back to the data store by using the applyChanges method in one of two ways. The updates can be translated into SQL and applied directly to the data store or can be written back through EJB accessor methods. Writing back directly to the data store can improve performance because it avoids EJB activation. However, if business logic or EJB container function is required by the application, writing back through EJB is the preferred approach. When writing back through EJB, you can specify a user-defined MediatorAdapter method to ensure customized handling of changed DataObjects. This customization can include application-specific optimistic concurrency control, invoking business methods on the EJB to perform updates, update of computed values in the DataObject, and calling application-specific create methods on EJBHome.

Update processing is not dependent on how the DataGraph was originally retrieved. In other words, it is possible to retrieve a DataGraph directly from the data source, but have the deferred updates applied through the enterprise bean or the other way around.

Regardless of which update approach you use, an optimistic concurrency control algorithm is used. Fields designated as consistency fields are read during the update to ensure that the current value is equal to the old value DataObject field.

Runtime processing

An EJB mediator request is a compound EJB query, which consists of an ordered list of regular EJB queries. Each query in the compound query defines an SDO. The SELECT clause of the query specifies the CMP fields or expressions to return in the DataObject. The WHERE clause specifies the filtering conditions. The first query in the list is considered to be the ROOT node in the DataGraph. The FROM clause of a query, other than the first, specifies an EJB relationship that is used to create references between DataObjects. More details about how the DataGraph schema is derived from the query can be found in the topic DataGraph schema.

EJB data mediator service programming considerations:

When you begin writing your applications to take advantage of the Enterprise JavaBeans (EJB) data mediator service (DMS) provided in the product, consider the following items.

EJB programming model

Only a subset of the EJB programming model is supported by the EJB data mediator service.

- When using EJB collection parameters to retrieve data from EJB instances, or when using applyChanges to update EJB instances:
  - The EJB DMS uses local interfaces for enterprise beans. `Getter` and `setter` calls for container-managed persistence (CMP) fields must be promoted to the local interface, as well as any EJB methods used in query expressions.
  - For the mediator to create an EJB, there must be a create method using the primary key class as the only argument method defined on the EJB home. If no such method exists, you must supply an adapter that handles the create operation. Also, the EJBLocalHome interface defined for the EJB must include (in addition to the create method) the following method:

    ```
    findByPrimaryKey(<key class>)
    remove (java.lang.Object)
    create (<key class>)
    ```
- When invoking the applyChanges method directly to the database, the following occur:
  - you bypass container update. You should force a refresh as soon as possible by transaction termination and using appropriate container cache options.
  - you bypass EJB container-managed relationship (CMR) maintenance. You must rely on database RI to maintain those relationships not retrieved into the DataGraph.
- CMP fields must be the allowed types. See “EJB mediator query syntax” on page 146 for a list of those types.
- CMP fields of user-defined types that use EJB converters/composer are not supported.

The following table shows limitations in the EJB programming model that are not supported by the EJB DMS.

Table 10. EJB programming model limitations with EJB DMS. The following table shows limitations in the EJB programming model that are not supported by the EJB DMS.

	retrieve direct from db	**retrieve from EJB Container**	**update direct to db**	**update through EJB**
EJB persistence inheritance	No	No	No	No
EJB cmp field with converter	No	Yes	No	Yes

Transactional

- All mediator calls, including create, must be done within a transaction scope – either a user transaction or a container transaction. The various mediator calls including, create, getGraph, and applyChanges, do not have to be called within the same transaction. In fact, most often the calls are done in separate transactions.

Access intent

- When the mediator query references an EJB using its abstract schema name (ASN), data is retrieved directly from the database. The access intent and isolation level used on the data source connection is the access intent specified in the application profile for EJB dynamic query access intent. It is recommended that you define an optimistic access intent for your application because a DataGraph is intended to be used in a disconnected programming model.
- When the mediator is retrieving data using an EJB collection, the access intent specified in the application profile is used if the EJB requires activation.
- During applyChanges, optimistic concurrency control is used to verify certain fields in the DataObject before applying changes to the database. Updates are typically processed under a different transaction from the retrieval. Therefore, to avoid lost updates it is necessary to verify that another transaction has not updated the data. When defining the EJB to RDB mapping you can specify one or more EJB fields as optimistic Predicates. The fields are used for verification by comparing the current database value to the old value from the DataGraph change log. If the verification succeeds, then the current value of the fields is written to the database. If the comparison returns false and the update fails, an exception occurs. All of this is accomplished in a single update statement with extra predicates added, such as in the following example. The optimisticPredicate field is `myColumn1`.

  ```
  update  myTable set  myColumn1 = "new value1", myColumn2="new value2"
  where myKey= "key value" and myColumn1 ="old value1"
  ```

- When applyChanges is done through the EJB container, the current values of the enterprise beans are compared with the old values of the optimistic predicates fields. If the values are unequal an exception occurs.
- Provided that you have defined one or more EJB fields as optimisticPredicates, then for the SDO to be updateable, at least one of the optmisticPredicate fields must be retrieved into the data object. Otherwise, applyChanges returns an exception. The field should be updated either by the caller or a database trigger – the mediator does not automatically increment or set the field.
- Not all fields are verified, only those fields marked as optimisticPredicate in the EJB-RDB mapping.
- Note that the EJB mapping tool allows for the possibility of no optimisticPredicate fields. In this case the mediator will perform updates without any verification.
- Creation and deletion operations do not make use of the optimistic predicate fields.
- When applying changes through EJB instances, the EJB might have to be activated first. In this case, the appropriate access intent associated with the EJB methods apply. It is recommended that you run applyChanges in a profile that has pessimistic access intent, otherwise the optimistic concurrency logic is invoked twice – once when copying data object values to the EJB, and a second time when the persistence manager compares the old values of the EJB field values against the database record.
- The access intent used by the mediator when retrieving directly from the database is the default access intent defined for the EJB named in the first query statement.

Best practices

- You can call getGraph on one mediator instance, update the returned DataGraph, and then call applyChanges on a different mediator instance. However, while they do not need the same mediator instance, they do need the same `query shape`. The query shape is the number and order of query statements, the fields and relationships specified in the SELECT and FROM clauses, and so on.
- Avoid repeated calls to createMediator if possible. Use parameterized queries and use getGraph to pass in different parameter values.

EJB data mediator service data retrieval:

An Enterprise JavaBeans (EJB) mediator request is a compound EJB query. You can obtain a DataGraph using the *getGraph* call.

Directly from the data source

To retrieve data directly from the data source, specify your first EJB query to reference the Abstract Schema Name (ASN) of the enterprise bean.

From the EJB container

To retrieve data through the EJB container, specify your first query to use an input parameter in the FROM clause referring to the EJB collection desired.

You should use this method when there is high likelihood that your EJB instances will be cached in the container. This way you avoid container flush and then read from the database to retrieve data.

For an example, see the topic Using the EJB data mediator service for data access.

EJB data mediator service data update:

An Enterprise JavaBeans (EJB) mediator request is a compound EJB query. You can write an updated DataGraph back to the data source by using the applyChanges method.

The update can be applied directly to the data source or through EJB instances.

When applying changes through EJB instances an optional adapter class can be specified on the applyChanges method. Each changed data object is first passed to the adapter applyChange method. The adapter can process the change itself and return **true**, or have the EJB Mediator process the change by returning **false**.

The adapter can be used to customize the optimistic concurrency (OCC) logic, or process changes to read only DataGraph attributes, or process changes that require business logic.

There are two forms of the applyChanges method. The first, *applyChanges(DataObject)* takes the updated DataGraph and runs structured query language (SQL) insert, update, and delete statements directly against the database, bypassing the EJB container. The second form, *applyChanges(DataObject, MediatorAdapter)* processes updates using EJB instances and accessors. A null value for the MediatorAdapter is supported.

When to use an adapter with applyChanges

- Use when there are create methods other than create(PrimaryKey)
- Use when business methods must be called instead of container-managed persistence (CMP) *setter* methods
- Use when special optimistic caching logic is needed

How the adapter works

Three passes are made over the DataGraph log, passing changed DataObject to the adapter:

1. New DataObjects are passed. The adapter can create the object and set the CMP fields. Container-managed relationships (CMR) that reference enterprise beans not yet created are deferred until pass 2.
2. New and updated DataObjects are passed. CMRs deferred from pass 1 can be set at this time.
3. Deleted DataObjects are passed.

EJB mediator query syntax:

When you begin writing your applications to take advantage of the Enterprise JavaBeans (EJB) data mediator service (DMS) provided in the product, consider the following items.

- The EJB DMS takes as an input argument a compound EJB query which consists of an array containing EJB query language (QL) statements and an optional XREL command. The XREL command is a list of EJB relationships and must appear last in the array.
- Each EJB QL query returns data in the form of a Service DataObjects (SDO) instance. All of the SDO instances are merged into a DataGraph. The SELECT clause of each query specifies the container-managed persistence (CMP) fields or expressions to return in the SDO. The WHERE clause specifies the filtering conditions and you can define an ORDER BY clause. If two or more SELECTs return the same SDO type, each SELECT must project the same CMP fields and expressions. For updatability, the primary key fields of the EJB must be projected. JOINs, UNIONs, and aggregation are not supported except in subqueries.
- A query in the array can refer to a prior query in the FROM clause by using the identification variable defined in the prior query and a relationship name. This relationship can be single or collection valued.
- Relationships are constructed between data object instances in the graph when a relationship is used in either the FROM clause or in the XREL command.
- Collection valued input arguments are supported in FROM clause If ?1 refers to a collection of Dept EJBs then the following query is valid for the mediator. The cast syntax is required to tell the query compiler the collection element type.

  ```
  select d.deptno from (Dept) ?1 as d
  ```

- The collection input argument is useful when it is desired to build a DataGraph from EJB instances that are cached in the EJB Container or persistence manager data cache.
- The SELECT clause can specify a list of CMP fields to retrieve (the wildcard * notation can be used to retrieve all CMP fields) or valid EJB query language expressions. CMP fields and expressions must be one of the following types:
  - Primitive types: boolean, byte, short, integer, long, float, double, char
  - Object wrapper types for the primitive types
  - Java.lang.String
  - Java.math.BigDecimal
  - java.math.BigInteger
  - byte [ ]
  - Java.sql.Date
  - java.sql.Time
  - java.sql.Timestamp
  - java.util.Date
  - java.util.Calendar
- All primary key CMP fields must be retrieved in order for the Service Data Objects (SDO) to be updateable; otherwise, applyChanges returns an exception.
- SDO attributes that come from EJB query language expressions such as *e.salary + e.bonus AS TOTAL_PAY* cannot be updated. If you try to make an update, applyChanges returns a QueryException.
- Aggregate expressions such as *SUM(e.salary)* are not allowed even though they are part of the EJB query language. Aggregate expressions can be used in subselects in the WHERE clause.

XREL keyword:

The XREL keyword is used to build relationships independent of how the data was retrieved. XREL is valid only in Enterprise JavaBeans (EJB) Mediator queries.

XREL does not retrieve additional data, it only builds relationships from data already retrieved by the select statements. The relationships can be one-to-one, one-to-many, many-to-one, or many-to-many. The

relationships can be unidirectional or bidirectional. If you specify a bidirectional relationship in an XREL, the inverse relationship is also established in addition to the specified relationship.

```
xrel := XREL identification_variable . { single_valued_cmr_field | collection_valued_cmr_field }
            [ , identification_variable . { single_valued_cmr_field | collection_valued_cmr_field } ]*
```

Examples: XREL keyword

This example retrieves all employees and all departments, and establishes the *emps* and *mgr* relationships.

```
select e.name from EmpBean e
  select  d.name from DeptBean d
  xrel  d.emps, d.mgr
```

Notice that the employees are retrieved through d.emps relationship, xrel d.mgr is to establish the *mgr* relationship for those employees who are also a manager.

```
 select  d.name from DeptBean d
   select e.name from in(d.emps) e
   xrel  d.mgr
```

DataGraph schema:

DataGraph schema created by the EJB mediator

The schema created by the mediator for a query consists of an Eclass for each query statement. The name of the Eclass is the Abstract Schema Name (ASN) of the Enterprise JavaBeans (EJB). The Eattributes of the Eclass correspond to the container-managed persistence (CMP) fields or expressions returned by the query statement.

For static DataObjects, the Eclass name can be different provided that the Map argument is used on the createMediator call.

Each EJB relationship specified in the FROM or XREL clause adds an Ereference into the schema. EJB relationships can be unidirectional or bidirectional. However, all Ereferences are defined as bidirectional as this is needed to efficiently navigate the DataGraph on update. An inverse relationship name is generated in the case of a unidirectional EJB relationship. A generated name is of the format <ASName_source><ASName_target>. For example, if the ASNames are EmpBean and DeptBean, and the unidirectional relationship is *dept* going from EmpBean to DeptBean, the generated inverse name is **DeptBeanEmpBean**.

If no ECLass argument is used on createMediator, then the mediator creates a DataGraph schema with the following characteristics:

- the DataObject Eclass names are the corresponding EJB Abstract Schema Names (ASN)
- the DataObject attributes names and types are the expression names and types in the query SELECT clauses
- the DataObject reference names and types come from the EJB relationships referenced in the FROM clauses.

A *dummy* DataObject with the Eclass name of *DataGraphRoot* is also created and has containment reference to all the DataObjects. The reference is multivalued, using the EJB ASN name.

```
DataObject root =  m.getGraph( parms );
root.getType().getName();   // this would return the string "DataGraphRoot"

List depts = (List) root.get("DeptBean");
// the list of all DeptBean SDOs in the DataGraph

List emps = (List) root.get("EmpBean");
// the list of all EmpBean SDOs in the DataGraph
```

DataGraph containment patterns

References between Service Data Objects (SDO) can be defined as containment references, in which case when an SDO is deleted the delete is cascaded to all of the contained SDO. Also, when the DataGraph is serialized as an XML document, the contained SDO are nested within the parent SDO. Noncontained references are expressed as path expressions in the XML document.

Containment must be defined in the DataGraph schema. When the mediator defines the schema, the root SDO (named *DataGraphRoot*) contains all other SDO. EJB relationships are defined as noncontained SDO references.

When the caller defines the DataGraph schema, there are three patterns.

ROOT_CONTAINS_ALL
: In this pattern there is a dummy SDO that is the root. It is a dummy in the sense that it does not correspond to any EJB. Its purpose is to contain all other SDOs. If the mediator generates the graph schema, the dummy root has a class name of DataGraphRoot and it will have containing references whose names are the EJB ASN names. If the caller uses static schema, the root can have any name. The Eclass of the root is passed on the createMediator call.

ROOT_CONTAINS_SOME
: This pattern is applicable only for static schema. There is still a dummy SDO that is the graph root. Other SDO must either be contained by the Ereference that corresponds to the EJB relationship used in the query statement or the SDO must be contained by the dummy root.

NO_DUMMY ROOT
: This pattern is applicable only for static schema. There is no dummy root. The root SDO corresponds to the first query statement which must return only a single instance. Non-root SDOs must be contained by the Ereference corresponding to the EJB relationship used in the query statement.

Using the Java Database Connectivity data mediator service for data access

The following steps demonstrate how to create the metadata for a Java Database Connectivity (JDBC) data mediator service (DMS), as well as how to instantiate the DMS dataGraph.

Procedure

1. Create the metadata factory. This can be used for creating metadata, tables, columns, filters, filter arguments, database constraints, keys, order-by objects, and relationships.

   ```
   MetadataFactory factory = MetadataFactory.eINSTANCE;
   Metadata metadata = factory.createMetadata();
   ```

2. Create the table for the metadata. You can do this two ways. Either the metadata factory can create the table and then the table can add itself to the already created metadata, or the metadata can add a new table in which case a new table is created. Because it involves fewer steps, this example uses the second option to create a table called CUSTOMER.

   ```
   Table custTable = metadata.addTable("CUSTOMER");
   ```

3. Set the root table for the metadata. Again, you can do this in two ways. Either the table can declare itself to be the root or the metadata can set its own root table. For the first option, code:

   ```
   custTable.beRoot();
   ```

   If you want to use the second option, you code:

   ```
   metadata.setRootTable(custTable)
   ```

4. Set up the columns in the table. The example table is called CUSTOMER. Each column is created using its type. The column types in the metadata can only be the types supported by the JDBC driver being used. If you have questions on which types the JDBC driver being used supports, consult the JDBC driver documentation.

```
Column custID = custTable.addIntegerColumn("CUSTID");
custID.setNullable(false);
```

This example creates a column object for this column, but does not for the remainder. The reason is because this column is the primary key, and is used to set the table's primary key after the rest of the columns are added. A primary key cannot be null; therefore custID.setNullable(false) prohibits this from happening. Adding the rest of the columns:

```
custTable.addStringColumn("CUSTFIRSTNAME");
custTable.addStringColumn("CUSTLASTNAME");
custTable.addStringColumn("CUSTSTREETADDRESS");
custTable.addStringColumn("CUSTCITY");
custTable.addStringColumn("CUSTSTATE");
custTable.addStringColumn("CUSTZIPCODE");
custTable.addIntegerColumn("CUSTAREACODE");
custTable.addStringColumn("CUSTPHONENUMBER");

custTable.setPrimaryKey(custID);
```

5. Create other tables as needed. For this example, create the Orders table. Each order is made by one Customer.

```
Table orderTable = metadata.addTable("ORDER");

Column orderNumber = orderTable.addIntegerColumn("ORDERNUMBER");
orderNumber.setNullable(false);

orderTable.addDateColumn("ORDERDATE");
orderTable.addDateColumn("SHIPDATE");
Column custFKColumn = orderTable.addIntegerColumn("CUSTOMERID");

orderTable.setPrimaryKey(orderNumber);
```

6. Create foreign keys for the tables that need relationships. In this example, orders have a foreign key that points to the customer who made the order. In order to create a relationship between the two tables, you must first make a foreign key for the Orders table.

```
Key custFK = factory.createKey();
custFK.getColumns().add(custFKColumn);

orderTable.getForeignKeys().add(custFK);
```

The relationship takes two keys, the parent key and the child key. Because no specific name is given, the default concatenation of CUSTOMER_ORDER is the name used for this relationship.

```
metadata.addRelationship(custTable.getPrimaryKey(), custFK);
```

The default relationship includes all customers who have orders. To get all customers, even if they do not have orders, you need this line as well:

```
metadata.getRelationship("CUSTOMER_ORDER")
                            .setExclusive(false);
```

Now that the two tables are related to one another you can add a filter to the Customer table to find customers with specific characteristics.

7. Specify any filters needed. In this example, set filters to the Customer table to find all the customers in a particular state, with a certain last name, who have made orders.

```
Filter filter = factory.createFilter();
filter.setPredicate("CUSTOMER.CUSTSTATE = ? AND CUSTOMER.CUSTLASTNAME = ?");

FilterArgument arg1 = factory.createFilterArgument();
arg1.setName("CUSTSTATE");
arg1.setType(Column.STRING);
filter.getFilterArguments().add(arg1);

FilterArgument arg2 = factory.createFilterArgument();
arg2.setName("CUSTLASTNAME");
```

```
arg2.setType(Column.STRING);
filter.getFilterArguments().add(arg2);

custTable.setFilter(filter);
```

8. Add any order by objects needed. In this example, set the order by object to sort by the customer's first name.

```
Column firstName = ((TableImpl)custTable).getColumn("CUSTFIRSTNAME");
OrderBy orderBy = factory.createOrderBy();
orderBy.setColumn(firstName);
orderBy.setAscending(true);
metadata.getOrderBys().add(orderBy);
```

This completes the creation of the metadata for this JDBC DMS.

9. Create a connection to the database. This example does not show the creation of the connection to the database; it assumes that the SDO client calls the method connect() that does that. See the topic,
10. Instantiate and initialize the JDBC DMS object (dataGraph). The SDO client performs these actions. For this example:

```
ConnectionWrapperFactory factory = ConnectionWrapperFactory.soleInstance;
connectionWrapper = factory.createConnectionWrapper(connect());
JDBCMediatorFactory mFactory = JDBCMediatorFactory.soleInstance;
JDBCMediator mediator = mFactory.createMediator(metadata, connectionWrapper);
DataObject parameters = mediator.getParameterDataObject();
parameters.setString("CUSTSTATE", "NY");
parameters.setString('CUSTLASTNAME', 'Smith');
DataObject graph = mediator.getGraph(parameters);
```

Now that you have the dataGraph, you can manipulate the information. The example below contains basic manipulation of data in a DataGraph object.

Example: Manipulating data in a DataGraph object

Using the simple DataGraph that was created during the task Using the Java Database Connectivity data meditaor service for data access, some typical data manipulation follows.

First get the list of customers, then for each customer get every order, then print out the customer's first name and order date. (For this example, assume that you already know the last name is Smith).

```
List customersList = graph.getList("CUSTOMER");
Iterator i = customersList.iterator();
while (i.hasNext())
{
 DataObject customer = (DataObject)i.next();
List ordersList = customer.getList("CUSTOMER_ORDER");
Iterator j = ordersList.iterator();
while (j.hasNext())
{
DataObject order = (DataObject)j.next();
System.out.print( customer.get("CUSTFIRSTNAME") + " ");
System.out.println( order.get("ORDERDATE"));
 }
}
```

Now change every customer with the name Will to be Matt.

```
i = customersList.iterator();
while (i.hasNext())
{
 DataObject customer = (DataObject)i.next();
 if (customer.get("CUSTFIRSTNAME").equals("Will"))
 {
  customer.set("CUSTFIRSTNAME", "Matt");
 }
}
```

Delete the first Customer entry.

```
((DataObject) customersList.get(0)).delete();
```

Add a new DataObject to the graph

```
DataObject newCust = graph.createDataObject("CUSTOMER");
newCust.setInt("CUSTID", 12345);
newCust.set("CUSTFIRSTNAME", "Will");
newCust.set("CUSTLASTNAME", "Smith");
newCust.set("CUSTSTREETADDRESS", "123 Main St.");
newCust.set("CUSTCITY", "New York");
newCust.set("CUSTSTATE", "NY");
newCust.set("CUSTZIPCODE", "12345");
newCust.setInt("CUSTAREACODE", 555);
newCust.set("CUSTPHONENUMBER", "555-5555");

graph.getList("CUSTOMER").add(newCust);
```

Submit the changes.

```
mediator.applyChanges(graph);
```

11. Submit the changed information to the DMS for updating the database.

Using the EJB data mediator service for data access

The following steps use code samples to describe a simple instance of how to create the Enterprise JavaBeans (EJB) data mediator service (DMS) metadata.

Procedure

1. A mediator instance is created using one of the create methods on the mediator factory (com.ibm.websphere.sdo.mediator.ejb.MediatorFactory) as in the following example

```
import com.ibm.websphere.sdo.mediator.ejb.Mediator;
import com.ibm.websphere.sdo.mediator.ejb.MediatorFactory;
import com.ibm.webpshere.ejbquery.QueryException;
import commonj.sdo.DataObject;

try{
 String[] query =  { "select d.deptno,d.name from DeptBean as d" };
 Mediator m = MediatorFactory.getInstance().createMediator( query, null);
 DataObject root = m.getGraph();
} catch (QueryException e) { ... }
```

2. There are 3 different forms of the createMediator method. The arguments are explained as follows:

```
createMediator( query, parms)
createMediator( query, parms, schema )
createMediator( query, parms, schema,  typeMap,  pattern)
```

Table 11. createMediator method arguments. The arguments are explained in the following table:

Type	Argument	Description
String	query	array of EJB query statements
Object	parms	values for input parameters of the query statements
Eclass*	schema	the EClass of the root DataObject
Map*	typeMap	a java.util.Map that maps EJB Abstract Schema Names from the query statement into Eclass names
int*	pattern	the pattern used for containment
* used only when using caller provided schema		

Example

Using query arguments with EJB mediator.

The following examples show how you can fine-tune your Enterprise JavaBeans (EJB) mediator query arguments.

A simple example

This query returns a DataGraph containing multiple instances of DataObjects of type (Eclass name) *Emp*. The data object attributes are *empid* and *name* and their data types correspond to the container-managed persistence (CMP) field types.

```
select  e.empid, e.name
from Emp as e
where e.salary > 100
```

The returned DataGraph serialized in its XML format looks like this:

```
  <?xml version="1.0" encoding="ASCII"?>
<datagraph:DataGraphSchema xmlns:datagraph="datagraph.ecore">
<root>
<Emp empid="1003" name="Eric" />
<Emp empid="1004" name="Dave" />
</root>
</datagraph:DataGraphSchema>
```

Query parameters

This example shows how parameter markers can be used. Recall that the syntax for parameter markers in an EJB query is a question mark followed by a number (?n). When calling the getGraph ( ) method on the EJBMediator, you can optionally pass an array of values. ?n refers to the value of parm[n-1]. The array of values can also be passed on the factory call to create the EJBMediator. Parameters passed on the getGraph( ) override any parameters passed on the create call.

```
select  e.empid, e.name
from Emp as e
where e.salary > ?1
```

Returning expressions and methods

This example illustrates that the data object attributes can be the return values of query expressions. EJB query expressions include arithmetic, date-time, path expressions, and methods. Input arguments and return values from methods are restricted to the list of supported data types see the topic EJB mediator query syntax. A data object containing an updated attribute derived from an expression causes an exception to occur during the applyChanges process unless the user has provided a MediatorAdapter to handle the change.

```
select  e.empid as employeeId,
  e.bonus+e.salary as totalPay,
  e.dept.mgr.name as managerNam,
  e.computePension( ) as pension
from Emp as e
where e.salary > 100
```

Data object attribute names are derived from the CMP field names but can be overridden by using the *AS* keyword in the query. When specifying an expression, the *AS* keyword should always be used to give a name to the expression.

The * syntax

The notation *e.** is a short cut for specifying all the CMP fields (but not container-managed relationships) for an EJB. The following query means the same thing as *e.empid, e.name e.salary, e.bonus*.

```
select e.* from Emp as e
```

No primary key in select clause

This example shows a query that does not return the primary key field. However, unless the data object contains all the primary key fields for an EJB, updates to the DataGraph cannot be processed by the mediator. This is because the primary key is required to translate the changes into structured query language (SQL), or to convert DataObject references to EJB references. An exception when applyChanges tries to run.

```
select e.name, e.salary from Emp as e
```

Order by

DataObjects can be ordered.

```
select d.* from Dept d  order by d.name
 select e.* from in(d.emps) e order by e.empid desc
```

This results in the *Dept* objects being ordered by name and the *Emp* objects within each *Dept* being order by *empid* in descending order.

Navigating a multi-valued relationship

This compound query returns a DataGraph with DataObject classes *Dept* and *Emp*. The shape of the DataGraph reflects the path expressions used in the FROM clauses.

```
select d.deptno, d.name, d.budget from Dept d
   where d.deptno < 10
select e.empid, e.name, e.salary  from in(d.emps) e
   where e.salary > 10
```

In this case *Dept* is the root node in the DataGraph and there is a multivalued reference from *Dept* to *Emp* as shown:

```
<?xml version="1.0" encoding="ASCII" ?>
<datagraph:DataGraphSchema xmlns:datagraph="datagraph.ecore">
<root>
<Dept deptno="1" name="WAS_Sales" budget="500.0"
   emps="//@root/@Emp.1 //@root/@Emp.0" />
<Dept deptno="2" name="WBI_Sales" budget="450.0"
   emps="//@root/@Emp.3 //@root/@Emp.2" />
<Emp empid="1001" name="Rob" salary="100.0" EmpDept="//@root/@Dept.0" />
<Emp empid="1002" name="Jason" salary="100.0" EmpDept="//@root/@Dept.0" />
<Emp empid="1003" name="Eric" salary="200.0" EmpDept="//@root/@Dept.1" />
<Emp empid="1004" name="Dave" salary="500.0" EmpDept="//@root/@Dept.1" />
</root>
</datagraph:DataGraphSchema>
```

More on query parameters

Search conditions can be specified on any query. Input arguments are global to the query and can be referenced by number anywhere in the compound query. In the example above, the query arguments passed on the create or getGraph call should be in order { deptno value, salary value, deptno value }.

```
select d.* from Dept as d
   where d.deptno between ?1 and ?3
select e.* from in(d.emps) e
   where e.salary < ?2
```

Navigating a path with multiple relationships

The following query navigates the path composed of EJB relationships Dept.projs and Project.tasks and returns DataObjects for Dept, Emp and Project containing selected CMP fields.

```
select d.deptno, d.name from Dept as d
select p.projid  from in(d.projects) p
select t.taskid, t.cost from  in (p.tasks) t
```

The resulting data graph in XML format is shown here.

```
<?xml version="1.0" encoding="ASCII" ?>
<datagraph:DataGraphSchema xmlns:datagraph="datagraph.ecore">
<root>
<Dept deptno="1" name="WAS_Sales" projects="//@root/@Project.0" />
<Dept deptno="2" name="WBI_Sales" projects="//@root/@Project.1" />
<Project projid="1" ProjectDept="//@root/@Dept.0"
      tasks="//@root/@Task.0   //@root/@Task.2 //@root/@Task.1" />
<Project projid="2" ProjectDept="//@root/@Dept.1"
      tasks="//@root/@Task.3" />
<Task taskid="1" cost="50.0" TaskProject="//@root/@Project.0" />
<Task taskid="2" cost="60.0" TaskProject="//@root/@Project.0" />
<Task taskid="3" cost="900.0" TaskProject="//@root/@Project.0" />
<Task taskid="7" cost="20.0" TaskProject="//@root/@Project.1" />
</root>
</datagraph:DataGraphSchema>
```

Navigating multiple paths

Here is a mediator query returning a DataGraph with DataObjects for Dept with related employees and a second path that retrieves related projects and tasks.

```
select d.deptno, d.name from Dept d
select e.empid, e.name  from in(d.emps) e
select p.projid from in(d.projects) p
select t.taskid, t.cost from in(p.tasks) where t.cost > 10
```

The returned DataGraph looks like this:

```
<?xml version="1.0" encoding="ASCII" ?>
    <datagraph:DataGraphSchema xmlns:datagraph="datagraph.ecore">
    <root>
        <Dept deptno="1" name="WAS_Sales" projects="//@root/@Project.0"
 emps="//@root/@Emp.1 //@root/@Emp.0" />
        <Dept deptno="2" name="WBI_Sales" projects="//@root/@Project.1"
     emps="//@root/@Emp.3 //@root/@Emp.2" />
        <Project projid="1" ProjectDept = "//@root/@Dept.0"
     tasks="//@root/@Task.0 //@root/@Task.2 //@root/@Task.1" />
        <Project projid="2" ProjectDept="//@root/@Dept.1" tasks="//@root/@Task.3" />
      <Task taskid="1" cost="50.0" TaskProject="//@root/@Project.0" />
        <Task taskid="2" cost="60.0" TaskProject="//@root/@Project.0" />
        <Task taskid="3" cost="900.0" TaskProject="//@root/@Project.0" />
        <Task taskid="7" cost="20.0" TaskProject="//@root/@Project.1" />
        <Emp empid="1001" name="Rob" EmpDept="//@root/@Dept.0" />
        <Emp empid="1002" name="Jason" EmpDept="//@root/@Dept.0" />
         <Emp empid="1003" name="Eric" EmpDept="//@root/@Dept.1" />
         <Emp empid="1004" name="Dave" EmpDept="//@root/@Dept.1" />
  </root>
  </datagraph:DataGraphSchema>
```

Navigating a single valued relationship

The important thing to point out here is that even though Emp is the root data object in the graph, multiple Emp data objects will be related to the same Dept data object. So unlike the previous examples, the data graph does not have a tree shape when you look at the data object instances – there are multiple root Emp objects related to the same Dept object. But then after all it is a data graph, not a data tree. Note that mediator queries allow single valued path expressions in the FROM clause. This is a change from the standard EJB query syntax.

```
select e.empid, e.name  from Emp e
select d.deptno, d.name  from in(e.dept) d
```

And the DataGraph in XML format looks like:

```
<?xml version="1.0" encoding="ASCII" ?>
   <datagraph:DataGraphSchema xmlns:datagraph="datagraph.ecore">
   <root>
   <Emp empid="1001" name="Rob" dept="//@root/@Dept.0" />
```

```
   <Emp empid="1002" name="Jason" dept="//@root/@Dept.0" />
   <Emp empid="1003" name="Eric" dept="//@root/@Dept.1" />
   <Emp empid="1004" name="Dave" dept="//@root/@Dept.1" />
   <Dept deptno="1" name="WAS_Sales"
DeptEmp="//@root/@Emp.1 //@root/@Emp.0" />
   <Dept deptno="2" name="WBI_Sales"
 DeptEmp="//@root/@Emp.3 //@root/@Emp.2" />
 </root>
 </datagraph:DataGraphSchema>
```

Path expressions in the SELECT clause

This query is similar to the preceding one (both queries return employee data along with department number and name) but note the data graph contains only one data object type in this query (vs. two in the previous query). The fields deptno and name field are read only because they are result of a path expression in the SELECT clause and are not CMP fields of the Emp EJB.

```
select  e.empid as EmplId , e.name as EmpName ,
   e.dept.deptno as DeptNo , e.dept.name as DeptName
from Emp as e
```

Navigating a many: many relationship

The Emp to Task relationship is deemed a *many:many* relationship. The following query retrieves employees, tasks, and projects. There is only a single occurrence of any particular task DataObject in the DataGraph, even though it can be related to many employees.

```
select e.empid, e.name from Emp as e
select t.taskid, t.description from in(e.tasks) as t
select p.projid, p.cost from in(t.proj) as p
```

Multiple links between data objects

The EJB mediator enables you to retrieve data based on relationships and use the XREL command to construct one or more additional relationships based on data already retrieved. The mediator also enables retrieval of data based on ASNname and then construction of one or more relationships based on the data retrieved using the XREL command. The following query retrieves departments, employees that work in the departments, and the employees that manage the departments.

```
select d.deptno, d.name from Dept d where d.name like '%Dev%'
select e.empid, e.name from in (d.emps) as e
select m.empid, m.name from in(d.manager) as m
```

The second and third *select* clauses both return instances of Emp DataObject. It is possible that the same Emp instance is retrieved through the d.emps relationship and the d.manager relationship. The EJB mediator creates one Emp instance, but creates both relationships.

The following query is processed as follows. Dept DataObjects are created from the data in the first query. Emp DataObjects are created from the data in the second query. Relationships in the graph are then constructed for any relationship used in either the FROM clause or an XREL keyword. During relationship construction, no additional data is retrieved. In this example, an employee who works in a department named *Dev* appears in the DataGraph. If this employee manages a department called *Sales*, the *manages* reference is empty. The Dev department was retrieved in the first query, not the Sales department.

```
select d.deptno, d.name from Dept d where d.name like '%Dev%'
select e.empid, e.name from in (d.emps) as e
xrel d.manager
```

The emps and manager relationship are constructed based on the DataObject instances created from the queries. An employee whose name is ‘Dev' but works in department ‘Sales' will have a null dept relationship in the graph.

```
select d.deptno, d.name from Dept d where d.name like '%Dev%'
select e.empid, e.name from Emp e where e.name like 'Dev%'
xrel d.emps, d.manager
```

The next example shows the retrieval of data objects for all the employees, projects, and tasks for a given department, and the linkage of employees with tasks.

```
select d.deptno from Dept d where d.deptno = 42
select e.empid from in(d.emps) e
select p.projid from in(d.projs) p
select t.* from in(p.tasks) t
  xrel e.tasks
```

If a task is assigned to an employee in department 42 then that link appears in the data graph. If the task is assigned to an employee not in department 42, then that link does not appear in the data graph because the data object was filtered out by the query. An XREL keyword can be followed by one or more EJB relationships. Bidirectional relationships can refer to either role name. Both source and target of the relationship must be retrieved by one or more queries.

Retrieving unrelated objects

The following query retrieves Dept and Task.

```
select d.deptno, d.name from Dept d where d.name like '%Dev%'
select t.taskid, t.startDate from Task t where t.startDate > '2005'
```

The following query retrieves Dept and Emps. Even though there are relationships between Dept and Emp (namely mgr and emps), neither relationship is used in FROM or XREL and so the resulting graph does not contain the relationship values.

```
select d.deptno, d.name from Dept d where d.name like '%Dev%'
select e.empid, e.name from Emp e where e.dept.name like '%Dev%'
```

Retrieving null or empty relationships

This query returns departments that have no employees and employees with no department. Presumably the application wants to assign the employees to one of the departments. The purpose of xrel is to define the e.dept relationship (and the inverse role d.emps) into the graph schema.

```
select d.deptno, d.name from Dept d where d.emps is empty
select e.empid, e.name from Emp e where e.dept is null
xrel e.dept
```

Collection Input parameter

A collection of enterprise beans can be passed as an input argument to the ejb mediator and referenced in the FROM clause. Using a collection parameter satisfies the requirement to construct a data graph from a user collection of already activated enterprise beans.

```
select d.deptno, d.name from ((Dept) ?1) as d
select e.empid, e.name from in(d.emps) as e where e.salary > 10
```

The above query iterates through the collection of Dept beans and related Emp beans applying the query predicates and constructing the data graph. Values will be obtained from current values of the beans. An example of a program using an ejb collection parameter.

```
// this method runs in an EJB context and within a transaction scope
public DataGraph myServiceMethod() {
      InitialContext ic = new InitialContext();
      DeptLocalHome deptHome = ic.lookup("java:comp/env/ejb/Dept");
      Integer deptKey = new Integer(10);
```

```
      DeptEJB dept = deptHome.findByPrimaryKey( deptKey));
      Iterator i = dept.getEmps().iterator();
      while (i.hasNext()) {
       EmpEJB e = (EmpEJB)i.next();
       e.setSalary( e.getSalary() * 1.10); // give everyone a 10% raise
      }

      // create the query collection parameter
      Collection c = new LinkedList();
      c.add(dept);
      Object[] parms = new Object[] { c};  // put ejb collection in parm array.

      // collection containing the dept EJB is passed to EJB Mediator

      String[] query = new String[]
          { "select d.deptno, d.name from ((Dept)?1 ) as d",
             "select e.empid, e.name, e.salary " +
                 " from in (d.employees) as e",
            "select p.projno, p.name from in (d.projects) as p" };

      Mediator m = EJBMediatorFactory.getInstance().createMediator(
 query, parms);
      DataGraph dg = m.getGraph();
      return dg;
      // the DataGraph contains the updated and as yet uncommitted
//  salary information.  Dept and Emp data
      // is fetched through EJB instances active in the EJBContainer.
      //  Project data is retrieved from database using
      //   container managed relationships.
   }
```

Using MediatorAdapter

In this example, the adapter processes CREATE events for an EMP data object. The name and salary attributes are extracted from the data object and passed to the create method on the EmpLocalHome.

The create method returns an instance of Emp EJB and the primary key value is copied back to the DataObject. The caller can then obtain the generated key value. After processing, the adapter returns a value of **true**. All other changes are ignored by the adapter and processed by the EJB Mediator.

```
package com.example;
import com.ibm.websphere.sdo.mediator.ejb.*;
import javax.naming.InitialContext;
import commonj.sdo.ChangeSummary;
import commonj.sdo.DataObject;
import commonj.sdo.DataGraph;
import commonj.sdo.ChangeSummary;

// example of Adapter class calling a EJB create method.

public class SalaryAdapter implements MediatorAdapter{

 ChangeSummary log = null;
      EmpLocalHome empHome = null;

 public boolean applyChange(DataObject object,  int phase){

  if (object.getType().getName().equals("Emp")
       && phase == MediatorAdapter.CREATE){
   try{
    String name = object.getString("name");
    double salary = object.getDouble("salary");
    EmpLocal emp = empHome.create(name, salary);
    object.set("empid", emp.getPrimaryKey() ); // set primary key in SDO
    return true;
```

```
  } catch(Exception e){ // error handling code goes here
                  }
 }
 return true;
}

public void init (ChangeSummary log){
        try {
 this.log = log;
 InitialContext ic = new InitialContext();
 empHome = (EmpLocalHome)ic.lookup( "java:comp/env/ejb/Emp");
        } catch (Exception e) { // error handling code goes here
        }
}

public void end(){}
}
```

Developing a custom DataStoreHelper class

Apply the WebSphere extension, GenericDataStoreHelper class, to create your own data store helper for data sources that the application server does not support. With this helper class, your JDBC configuration can use database-specific functions during transactions.

Before you begin

If you are using a configuration with a data source that is not supported by the application server, you might want to create a custom data store helper. This helper will allow you to leverage the database to perform functions during a transaction that would not otherwise be available. You will need to create a user-defined DataStoreHelper class, and there is information for creating a new exception handler to catch any exceptions that might be created with the use of your custom data handler.

About this task

Note: The CUSTOM_HELPER constant field in the com.ibm.websphere.rsadapter.DataStoreHelper class API is deprecated. If you create your own DataStoreHelper implementation class, do not invoke setHelperType(DataStoreHelper.CUSTOM_HELPER). Instead, let the HelperType value be set by the implementation class from which it inherits.

Procedure

1. Create a class that extends the existing data store helpers. Use the following code as an example; this type of data source is based on a user-defined JDBC provider:

```
package com.ibm.websphere.examples.adapter;

import java.sql.SQLException;
import javax.resource.ResourceException;

import com.ibm.websphere.appprofile.accessintent.AccessIntent;
import com.ibm.websphere.ce.cm.*;
import com.ibm.websphere.rsadapter.WSInteractionSpec;

/**
* Example DataStoreHelper class, demonstrating how to create a user-defined DataStoreHelper.
* The implementation for each method is provided only as an example.  More detail is probably
* required for any custom DataStoreHelper that is created for use by a real application.
* In this example, we will override the doStatementCleanup(),getIsolationLevel(), and set userDefined
* exception map.
*/
public class ExampleDataStoreHelper extends com.ibm.websphere.rsadapter.GenericDataStoreHelper
{

    public ExampleDataStoreHelper(java.util.Properties props)
    {
        super(props);

        // Update the DataStoreHelperMetaData values for this helper.
        getMetaData().setGetTypeMapSupport(false);

        // Update the exception mappings for this helper.
        java.util.Map xMap = new java.util.HashMap();
```

```
        // Add an Error Code mapping to StaleConnectionException.
        xMap.put(new Integer(2310),  StaleConnectionException.class);
        // Add an Error Code mapping to DuplicateKeyException.
        xMap.put(new Integer(1062),  DuplicateKeyException.class);
        // Add a SQL State mapping to the user-defined ColumnNotFoundException
        xMap.put("S0022",            ColumnNotFoundException.class);
        // Undo an inherited StaleConnection SQL State mapping.
        xMap.put("S1000",            Void.class);

        setUserDefinedMap(xMap);

        // If you are extending a helper class, it is
        // normally not necessary to issue 'getMetaData().setHelperType(...)'
        // because your custom helper will inherit the helper type from its
        //  parent class.

         }

    public void doStatementCleanup(java.sql.PreparedStatement stmt) throws SQLException
    {
        // Clean up the statement so it may be cached and reused.

        stmt.setCursorName("");
        stmt.setEscapeProcessing(true);
        stmt.setFetchDirection(java.sql.ResultSet.FETCH_FORWARD);
        stmt.setMaxFieldSize(0);
        stmt.setMaxRows(0);
        stmt.setQueryTimeout(0);
    }

    public int getIsolationLevel(AccessIntent intent) throws ResourceException
    {
        // Determine an isolation level based on the AccessIntent.

        // set WebSphere default isolation level to TRANSACTION_SERIALIZABLE.
        if (intent == null) return java.sql.Connection.TRANSACTION_SERIALIZABLE;

        return intent.getConcurrencyControl() == AccessIntent.CONCURRENCY_CONTROL_OPTIMISTIC ?
               java.sql.Connection.TRANSACTION_READ_COMMITTED :
               java.sql.Connection.TRANSACTION_REPEATABLE_READ;
    }
        public int getLockType(AccessIntent intent) {
           if ( intent.getConcurrencyControl() == AccessIntent.CONCURRENCY_CONTROL_PESSIMISTIC) {
              if ( intent.getAccessType() == AccessIntent.ACCESS_TYPE_READ ) {
                  return WSInteractionSpec.LOCKTYPE_SELECT;
              }
              else {
                  return WSInteractionSpec.LOCKTYPE_SELECT_FOR_UPDATE;
               }
           }
           return WSInteractionSpec.LOCKTYPE_SELECT;
        }
}
```

2. Optional: Create your own exception handler class. Use the following code as a guide:

```
package com.ibm.websphere.examples.adapter;

import java.sql.SQLException;
import com.ibm.websphere.ce.cm.PortableSQLException;

/**
* Example PortableSQLException subclass, which demonstrates how to create a user-defined
* exception for exception mapping.
*/
public class ColumnNotFoundException extends PortableSQLException
{
    public ColumnNotFoundException(SQLException sqlX)
    {
        super(sqlX);
    }
}
```

3. Compile the newly created DataStoreHelper class or classes. You will need the following JAR files in your classpath to compile them:
   - *app_server_root*/dev/JavaEE/j2ee.jar
   - *app_server_root*/dev/was_public.jar

     Note: was_public.jar contains classes from *app_server_root*/lib/rsahelpers.jar that are needed to compile a custom DataStoreHelper class.
   - *app_server_root*/plugins/com.ibm.ws.runtime.jar

- If you are using a development environment, such as Eclipse, you need to set the above JAR files in your classpath to be able to compile. Then, create a JAR file of the project after you have finished editing your files (see the help documentation for your development environment for specific instructions).
- If you do not have development environment, and you are using the javac compiler:
  a. Create your .java file that extends the GenericDataStoreHelper or any other data store helper, as shown in Step 1.
  b. Change to your home directory after you are done editing your file or files in the command line utility.
  c. Set the classpath using this command:
  d. Compile your class or classes. For example, on Windows operating systems enter the following command (this will compile all the .java files in the directory that you specify):

     ```
     C:\javac your_directory\*.java
     ```

  e. From the `Java` directory, create a JAR file of all the compiled class files in your directory. For example, enter the following command on Windows operating systems (change *myFile* to the name you want for your JAR file):

     ```
     C:\Java> jar cf myFile.jar *.class
     ```

     For more information on using the javac compiler go to the Oracle website for the Java compiler.

4. Place your compiled JAR files in a directory, and update the class path for the JDBC provider to include that location. For example, if your JAR file is `c:\myFile.jar`, then make sure to modify the JDBC class path to include c:\myFile.jar.
   a. Click **Resources** > **JDBC** > **JDBC Providers** > ***JDBC_provider***.
   b. In the **Class path** field, add the location of the JAR files that you compiled. For example, press ENTER in the field and add a new line:

      ```
      c:\myFile.jar
      ```

5. Configure the application server to use your new custom DataStoreHelper class.
   a. From the administrative console select **Resources** > **JDBC** > **Data Sources**.
   b. Select the data source that you want to configure with your custom DataStoreHelper class.
   c. In the section labeled **Data store helper class name**, select **Specify a user-defined data store helper**.
   d. Enter the class name for the data store helper that you created.
   e. Apply your changes and select **OK**.

Example: Setting client information with the setClientInformation(Properties) API

You can set WebSphere Application Server client information on connections to pass that information to your database with this API.

The following example code calls setClientInformation(Properties) on the com.ibm.websphere.rsadapter.WSConnection object.

```
import com.ibm.websphere.rsadapter.WSConnection;
.....
try {
   InitialContext ctx = new InitialContext();
   //Perform a naming service lookup to get the DataSource object.
   DataSource ds = (javax.sql.DataSource)ctx.lookup("java:comp/jdbc/myDS");
  }catch (Exception e) {System.out.println("got an exception during lookup:"  + e);}

  WSConnection conn = (WSConnection) ds.getConnection();
  Properties props = new properties();
  props.setProperty(WSConnection.CLIENT_ID, "user123");
  props.setProperty(WSConnection.CLIENT_LOCATION, "127.0.0.1");
```

```
props.setProperty(WSConnection.CLIENT_ACCOUNTING_INFO, "accounting");
props.setProperty(WSConnection.CLIENT_APPLICATION_NAME, "appname");
props.setProperty(WSConnection.CLIENT_OTHER_INFO, "cool stuff");
conn.setClientInformation(props);
conn.close()
```

Parameters

props contains the client information to be passed. Possible values are:

- WSConnection.CLIENT_ACCOUNTING_INFO
- WSConnection.CLIENT_LOCATION
- WSConnection.CLIENT_ID
- WSConnection.CLIENT_APPLICATION_NAME
- WSConnection.CLIENT_OTHER_INFO
- WSConnection.OTHER_CLIENT_TYPE

Refer to the WSConnection documentation for more details on which client information is passed to the backend database. To reset the client information, call the method with a null parameter.

Exceptions

This API creates an SQL exception if the database issues an exception when setting the data.

Passing client info to a db cdat_clientinfo

Changing the error detection model to use the Exception Checking Model

The error detection model has been expanded and the data source has a configuration option that you can use to select the exception mapping model or the exception checking model for error detection. This configuration option allows the Error Detection Model to comply with Java Database Connectivity (JDBC) 4.0.

About this task

By default, the exception mapping Error Detection Model configuration is selected. The exception mapping Error Detection Model replaces some exceptions raised by the JDBC driver. Exception checking does not do this. If you want to use this configuration, no changes are needed. If you want to use the exception checking model, you need to configure the error detection model in the application server. If you previously changed the **Error Detection Model**, you can also use these steps to change the configuration back to using to the exception mapping model.

Procedure

1. Open the administrative console.
2. Go to the **WebSphere Application Server Data Source properties** panel for the data source.
   a. Select **Resources** > **JDBC** > **Data Sources** > ***data_source***
   b. Select **WebSphere Application Server Data Source properties**.
3. In the **Error Detection Model** section, click **Use the WebSphere Application Server Exception Checking Model**.

Exceptions pertaining to data access

All enterprise bean container-managed persistence (CMP) beans under the Enterprise JavaBeans (EJB) 2.x specification receive a standard EJB exception when an operation fails. Java Database Connectivity

(JDBC) applications receive a standard SQL exception if any JDBC operation fails. The product provides special exceptions for its relational resource adapter (RRA), to indicate that the connection currently held is no longer valid.

- The connection wait timeout exception indicates that the application has waited for the number of seconds specified by the connection timeout setting and has not received a connection. This situation can occur when the pool is at maximum size and all of the connections are in use by other applications for the duration of the wait. In addition, there are no connections currently in use that the application can share because either the connection properties do not match, or the connection is in a different transaction.

  For a Version 4.0 data source, the ConnectionWaitTimeout object creates an exception that is instantiated from the com.ibm.ejs.cm.pool.ConnectionWaitTimeoutException class.

  For Java 2 Connector (J2C) connection factories, the ConnectionWaitTimeout object generates a resource exception of the com.ibm.websphere.ce.j2c.ConnectionWaitTimeoutException class.

  When the error detection model is configured to exception mapping, later versions of data sources issue an SQL exception of the com.ibm.websphere.ce.cm.ConnectionWaitTimeoutException subclass. When the error detection model is configured to exception checking, later versions of data sources issue an SQL exception of the java.sql.SQLTransientConnectionException class with a chained exception of the com.ibm.websphere.ce.cm.ConnectionWaitTimeoutException class.
- When the error detection model is configured to exception mapping, the stale connection exception indicates that the connection is no longer valid. When the error detection model is configured to exception checking, the JDBC driver raises a JDBC 4.0 exception, such as java.sql.SQLRecoverableException or java.sql.SQLNonTransientConnectionException, or the JDBC driver specifies an appropriate SQLState to indicate that the connection is no longer valid. Read the topic Stale connections for more information about this type of exception.

Note: The userDefinedErrorMap custom property overlays existing entries in the error map by starting the DataStoreHelper.setUserDefinedMap method. You can use the custom property to add, change, or remove entries from the error map.

- Entries are delimited by a ; (semicolon).
- Each entry consists of a key and value, where the key is an error code (numeric value) or SQLState, which is text enclosed in quotation marks.
- Keys and values are separated by the = (equals sign).

For example, to remove the mapping of SQLState S1000, add a mapping of error code 1062 to duplicate key, and add a mapping of SQLState 08004 to stale connection, you can specify the following value for userDefinedErrorMap:

```
"S1000"=;1062=com.ibm.websphere.ce.cm.DuplicateKeyException;"08004"=
com.ibm.websphere.ce.cm.StaleConnectionException
```

userDefinedErrorMap can be located in the administrative console by selecting the data source and configuring the custom properties.

- Database deadlock and foreign key conflicts

Stale Connections

The product provides a special subclass of the java.sql.SQLException class for using connection pooling to access a relational database. This com.ibm.websphere.ce.cm.StaleConnectionException subclass exists in both a WebSphere 4.0 data source and in the most recent version data source that use the relational resource adapter. This class serves to indicate that the connection currently held is no longer valid.

This situation can occur for many reasons, including the following:
- The application tries to get a connection and fails, as when the database is not started.
- A connection is no longer usable because of a database failure. When an application tries to use a previously obtained connection, the connection is no longer valid. In this case, all connections currently in use by the application can get this error when they try to use the connection.
- The connection is orphaned (because the application had not used it in at most two times the value of the unused timeout setting) and the application tries to use the orphaned connection. This case applies only to Version 4.0 data sources.
- The application tries to use a JDBC resource, such as a statement, obtained on a stale connection.
- A connection is closed by the Version 4.0 data source auto connection cleanup feature and is no longer usable. Auto connection cleanup is the standard mode in which connection management operates. This mode indicates that at the end of a transaction, the transaction manager closes all connections enlisted in that transaction. This enables the transaction manager to ensure that connections are not held for excessive periods of time and that the pool does not reach its maximum number of connections prematurely.

  A negative ramification does ensue, however, when the transaction manager closes the connections and returns the connection to the free pool after a transaction ends. An application cannot obtain a connection in one transaction and try to use it in another transaction. If the application tries this connection, a stale connection exception occurs because the connection is already closed.

If you are trying to use an orphaned connection or a connection that is made unavailable by auto connection cleanup, a stale connection exception indicates that the application has attempted to use a connection that is already returned to the connection pool. It does not indicate an actual problem with the connection. However, other cases of a stale connection exception indicate that the connection to the database has gone bad, or stale. Once a connection has gone stale, you cannot recover it, and you must completely close the connection rather than returning it to the pool.

Detecting stale connections

When a connection to the database becomes stale, operations on that connection result in an SQL exception from the JDBC driver. Because an SQL exception is a rather generic exception, it contains state and error code values that you can use to determine the meaning of the exception. However, the meanings of these states and error codes vary depending on the database vendor. The connection pooling run time maintains a mapping of which SQL state and error codes indicate a stale connection exception for each database vendor supported. When the connection pooling run time catches an SQL exception, it checks to see if this SQL exception is considered a stale connection exception for the database server in use.

Recovering from stale connections

An application can catch a stale connection exception, depending on the type of error detection model that is configured on the data source:

- When the error detection model is configured to exception mapping, the application server replaces the exception that is raised by the JDBC driver with StaleConnectionException. In this case, the application might trap for a stale connection exception.
- When the error detection model is configured to exception checking, the application server still consults the error map in order to manage the connection pool, but it does not replace the exception. In this case, the application should not trap for a stale connection exception.

Because of the differences between error detection models, the application server provides an API that applications can use with either case to identify stale connections. The API is com.ibm.websphere.rsadapter.WSCallHelper.getDataStoreHelper(datasource).isConnectionError(sqlexception).

Applications are not required to explicitly identify a stale connection exception. Applications are already required to catch the java.sql.SQLException, and the stale connection exception or the exception that is raised by the JDBC driver, always inherits data from the java.sql.SQLException. The stale connection exception, which can result from any method that is declared to raise SQLException, is caught automatically in the general catch-block. However, explicitly identifying a stale connection exception makes it possible for an application to recover from bad connections. When application code identifies a stale connection exception, it should take explicit steps to recover, such as retrying the operation under a new transaction and new connection.

Example: Handling data access exception - stale connection

These code samples demonstrate how to programmatically address stale connection exceptions for different types of data access clients in different transaction scenarios.

When an application receives a stale connection exception on a database operation, it indicates that the connection currently held is no longer valid. Although it is possible to get an exception for a stale connection on any database operation, the most common time to see a stale connection exception issued is after the first time the connection is retrieved. Because connections are pooled, a database failure is not detected until the operation immediately following its retrieval from the pool, which is the first time communication to the database is attempted. It is only when a failure is detected that the connection is marked stale. The stale connection exception occurs less often if each method that accesses the database gets a new connection from the pool.

Many stale connection exceptions are caused by intermittent problems with the network of the database server. Obtaining a new connection and retrying the operation can result in successful completion without exceptions. In some cases it is advantageous to add a small wait time between the retries to give the database server more time to recover. However, applications should not retry operations indefinitely, in case the database is down for an extended time.

Note: If you are developing applications for the Application Server with an integrated development environment (IDE) like Eclipse, you might must import the *app_server_root*/`plugins/com.ibm.ws.runtime.jar` file into the development environment to take advantage of code that is provided.

Before the application can obtain a new connection for a retry of the operation, roll back the transaction in which the original connection was involved and begin a new transaction. You can break down details on this action into the following two categories:

Objects operating in a bean-managed global transaction context begun in the same method as the database access

A servlet or session bean with bean-managed transactions (BMT) can start a global transaction explicitly by calling `begin()` on a `javax.transaction.UserTransaction` object, which you can retrieve from naming or from the bean `EJBContext` object. To commit a bean-managed transaction, the application calls `commit()` on the `UserTransaction` object. To roll back the transaction, the application calls `rollback()`. Entity beans and non-BMT session beans cannot explicitly begin global transactions.

If an object that explicitly started a bean-managed transaction receives a stale connection exception on a database operation, close the connection and roll back the transaction. At this point, the application developer can decide to begin a new transaction, get a new connection, and retry the operation.

The following code fragment shows an example of handling stale connection exceptions in this scenario:

```
//get a userTransaction
javax.transaction.UserTransaction tran = getSessionContext().getUserTransaction();
//retry indicates whether to retry or not
//numOfRetries states how many retries have
// been attempted
boolean retry = false;
int numOfRetries = 0;
java.sql.Connection conn = null;
java.sql.Statement stmt = null;
do {
  try {
    //begin a transaction
    tran.begin();
    //Assumes that a datasource has already been obtained
    //from JNDI
    conn = ds.getConnection();
    conn.setAutoCommit(false);
    stmt = conn.createStatement();
    stmt.execute("INSERT INTO EMPLOYEES VALUES
              (0101, 'Bill', 'R', 'Smith')");
    tran.commit();
    retry = false;
  } catch(java.sql.SQLException sqlX)
  {
    // If the error indicates the connection is stale, then
    // rollback and retry the action
    if (com.ibm.websphere.rsadapter.WSCallHelper
        .getDataStoreHelper(ds)
        .isConnectionError(sqlX))
    {
      try {
        tran.rollback();
      } catch (java.lang.Exception e) {
        //deal with exception
        //in most cases, this can be ignored
      }
      if (numOfRetries < 2) {
        retry = true;
        numOfRetries++;
      } else {
        retry = false;
      }
    }
    else
    {
      //deal with other database exception
      retry = false
    }
  } finally {
    //always cleanup JDBC resources
    try {
      if(stmt != null) stmt.close();
    } catch (java.sql.SQLException sqle) {
      //usually can ignore
    }
    try {
      if(conn != null) conn.close();
    } catch (java.sql.SQLException sqle) {
      //usually can ignore
    }
  }
} while (retry) ;
```

Objects operating in a global transaction context and transaction not begun in the same method as the database access.

When the object which receives the stale connection exception does not have direct control over the transaction, such as in a container-managed transaction case, the object must mark the

transaction for rollback, and then indicate to its caller to retry the transaction. In most cases, you can do this by creating an application exception that indicates to retry that operation. However this action is not always allowed, and often a method is defined only to create a particular exception. This is the case with the ejbLoad() and ejbStore() methods on an enterprise bean. The next two examples explain each of these scenarios.

Example 1: Database access method creates an application exception

When the method that accesses the database is free to create whatever exception is required, the best practice is to catch the stale connection exception and create some application exception that you can interpret to retry the method. The following example shows an EJB client calling a method on an entity bean with transaction demarcation TX_REQUIRED, which means that the container begins a global transaction when *insertValue()* is called:

```
public class MyEJBClient
{
  //... other methods here ...

  public void myEJBClientMethod()
  {
    MyEJB myEJB = myEJBHome.findByPrimaryKey("myEJB");
    boolean retry = false;
    do
    {
      try
      {
        retry = false;
        myEJB.insertValue();
      }
      catch(RetryableConnectionException retryable)
      {
        retry = true;
      }
      catch(Exception e) { /* handle some other problem */ }
    }
    while (retry);
  }
}  //end MyEJBClient

public class MyEJB implements javax.ejb.EntityBean
{
  //... other methods here ...
  public void insertValue() throws RetryableConnectionException,
         java.rmi.EJBException
  {
    try
    {
      conn = ds.getConnection();
      stmt = conn.createStatement();
      stmt.execute("INSERT INTO my_table VALUES (1)");
    }
    catch(java.sql.SQLException sqlX)
    {
      // Find out if the error indicates the connection is stale
      if (com.ibm.websphere.rsadapter.WSCallHelper
          .getDataStoreHelper(ds)
          .isConnectionError(sqlX))
      {
        getSessionContext().setRollbackOnly();
        throw new RetryableConnectionException();
      }
      else
      {
        //handle other database problem
      }
    }
    finally
    {
      //always cleanup JDBC resources
      try
      {
        if(stmt != null) stmt.close();
      }
      catch (java.sql.SQLException sqle)
      {
        //usually can ignore
      }
      try
      {
        if(conn != null) conn.close();
```

```
      }
      catch (java.sql.SQLException sqle)
      {
        //usually can ignore
      }
    }
  }
}  //end MyEJB
```

`MyEJBClient` first gets a `MyEJB` bean from the home interface, assumed to have been previously retrieved from the Java Naming and Directory Interface (JNDI). It then calls `insertValue()` on the bean. The method on the bean gets a connection and tries to insert a value into a table. If one of the methods fails with a stale connection exception, it marks the transaction for `rollbackOnly` (which forces the caller to roll back this transaction) and creates a new `retryable connection` exception, cleaning up the resources before the exception is thrown. The retryable connection exception is simply an application-defined exception that tells the caller to retry the method. The caller monitors the retryable connection exception and, if it is caught, retries the method. In this example, because the container is beginning and ending the transaction; no transaction management is needed in the client or the server. Of course, the client could start a bean-managed transaction and the behavior would still be the same, provided that the client also committed or rolled back the transaction.

Example 2: Database access method creates an onlyRemote exception or an EJB exception

Not all methods are allowed to throw exceptions defined by the application. If you use bean-managed persistence (BMP), use the `ejbLoad()` and `ejbStore()` methods to store the bean state. The only exceptions issued from these methods are the java.rmi.Remote exception or the javax.ejb.EJB exception, so you cannot use something similar to the previous example.

If you use container-managed persistence (CMP), the container manages the bean persistence, and it is the container that sees the stale connection exception. If a stale connection is detected, by the time the exception is returned to the client it is simply a remote exception, and so a simple catch-block does not suffice. There is a way to determine if the root cause of a remote exception is a stale connection exception. When a remote exception is created to wrap another exception, the original exception is usually retained. All remote exception instances have a detail property, which is of type `java.lang.Throwable`. With this detail, you can trace back to the original exception and, if it is a stale connection exception, retry the transaction. In reality, when one of these remote exceptions flows from one Java Virtual Machine API to the next, the detail is lost, so it is better to start a transaction in the same server as the database access occurs. For this reason, the following example shows an entity bean accessed by a session bean with bean-managed transaction demarcation.

```
public class MySessionBean extends javax.ejb.SessionBean
{
  ... other methods here ...
  public void mySessionBMTMethod() throws
    java.rmi.EJBException
  {
    javax.transaction.UserTransaction tran =
    getSessionContext().getUserTransaction();
    boolean retry = false;
    do
    {
      try
      {
        retry = false;
        tran.begin();
        // causes ejbLoad() to be invoked
        myBMPBean.myMethod();
        // causes ejbStore() to be invoked
        tran.commit();
      }
      catch(java.rmi.EJBException re)
      {
        try
        {
```

```
          tran.rollback();
        }
        catch(Exception e)
        {
          //can ignore
        }
        if (causedByStaleConnection(re))
          retry = true;
        else
          throw re;
      }
      catch(Exception e)
      {
        // handle some other problem
      }
      finally
      {
        //always cleanup JDBC resources
        try
        {
          if(stmt != null) stmt.close();
        }
        catch (java.sql.SQLException sqle)
        {
          //usually can ignore
        }
        try
        {
          if(conn != null) conn.close();
        }
        catch (java.sql.SQLException sqle)
        {
          //usually can ignore
        }
      }
    }
    while (retry);
  }

  public boolean causedByStaleConnection(java.rmi.EJBException re)
  {
    // Search the exception chain for errors
    // indicating a stale connection
    for (Throwable t = re; t != null; t = t.getCause())
      if (t instanceof RetryableConnectionException)
        return true;

    // Not found to be stale
    return false;
  }
}

public class MyEntityBean extends javax.ejb.EntityBean
{
  ... other methods here ...
  public void ejbStore() throws java.rmi.EJBException
  {
    try
    {
      conn = ds.getConnection();
      stmt = conn.createStatement();
      stmt.execute("UPDATE my_table SET value=1 WHERE
      primaryKey=" + myPrimaryKey);
    }
    catch(java.sql.SQLException sqlX)
    {
      // Find out if the error indicates the connection is stale
      if (com.ibm.websphere.rsadapter.WSCallHelper
          .getDataStoreHelper(ds)
          .isConnectionError(sqlX))
      {
        // rollback the tran when method returns
        getEntityContext().setRollbackOnly();
        throw new java.rmi.EJBException(
          "Exception occurred in ejbStore",
          new RetryableConnectionException(sqlX));
      }
      else
      {
        // handle some other problem
      }
    }
    finally
    {
```

```
      //always cleanup JDBC resources
      try
      {
        if(stmt != null) stmt.close();
      }
      catch (java.sql.SQLException sqle)
      {
        //usually can ignore
      }
      try
      {
        if(conn != null) conn.close();
      }
      catch (java.sql.SQLException sqle)
      {
        //usually can ignore
      }
    }
  }
}
```

In *mySessionBMTMethod()* of the previous example:

- The session bean first retrieves a *UserTransaction* object from the session context and then begins a global transaction.
- Next, it calls a method on the entity bean, which calls the *ejbLoad()* method. If *ejbLoad()* runs successfully, the client then commits the transaction, causing the *ejbStore()* method to be called.
- In *ejbStore()*, the entity bean gets a connection and writes its state to the database; if the connection retrieved is stale, the transaction is marked *rollbackOnly* and a new *EJBException* that wraps the *RetryableConnectionException* is thrown. That exception is then caught by the client, which cleans up the JDBC resources, rolls back the transaction, and calls *causedByStaleConnection()*, which determines if a stale connection exception is buried somewhere in the exception.
- If the method returns true, the retry flag is set and the transaction is retried; otherwise, the exception is re-issued to the caller.
- The *causedByStaleConnection()* method looks through the chain of detail attributes to find the original exception. Multiple wrapping of exceptions can occur by the time the exception finally gets back to the client, so the method keeps searching until it encounters stale connection exception and `true` is returned; otherwise, there is no stale connection exception in the list and `false` is returned.
- If you are talking to a CMP bean instead of to a BMP bean, the session bean is the same. The CMP bean *ejbStore()* method would most likely be empty, and the container after calling it would persist the bean with generated code.
- If a stale connection exception occurs during persistence, it is wrapped with a remote exception and returned to the caller. The *causedByStaleConnection()* method would again look through the exception chain and find the root exception, which would be stale connection exception.

Objects operating in a local transaction context

When a database operation occurs outside of a global transaction context, a local transaction is implicitly begun by the container. This includes servlets or JSPs that do not begin transactions with the *UserTransaction* interface, as well as enterprise beans running in unspecified transaction contexts. As with global transactions, you must roll back the local transaction before the operation is retried. In these cases, the local transaction containment usually ends when the business method ends. The one exception is if you are using activity sessions. In this case the activity session must end before attempting to get a new connection.

When the local transaction occurs in an enterprise bean running in an unspecified transaction context, the enterprise bean client object, outside of the local transaction containment, could use the method described in the previous bullet to retry the transaction. However, when the local transaction containment takes place as part of a servlet or JSP file, there is no client object available to retry the operation. For this reason, it is recommended to avoid database operations in servlets and JSP files unless they are a part of a user transaction.

Stale Connection on Linux systems

You might must set a loopback to access DB2 databases from the application server on a Linux platform.

A Linux semaphore issue can interfere with JDBC access to your DB2 database in either of these configurations:

- Using the DB2 Universal JDBC Type 2 driver to connect to a local DB2 database
- Using the DB2 Universal JDBC Type 2 driver to access DB2 for z/OS through a DB2 Connect™ installation on the same machine as the application server. The problem occurs only if DB2 Connect restricts local clients from running within an agent. (That is, if the DB2_IN_APP_PROCESS setting is not the default value, or if the setting is `Yes`. Set the value to `No` to fix the problem and avoid performing the following procedure.)

The issue often triggers the JVM logs to display the DB2 stale connection exception `SQL1224`. Because the SQL exception code can vary, however, check the DB2 trace log when you encounter a stale connection. If you see the following error data, the Linux semaphore behavior is the problem:

```
'71' -SQLCC_ERR_CONN_CLOSED_BY_PARTNER and SQLCODE -XXXX
```

To work around the problem, set the loopback for your database. For example, if your database name is `WAS`, host name is `LHOST`, and database service port number is `50000`, issue the following commands from the DB2 command-line window:

```
db2 catalog TCPIP node RHOST remote LHOST server 50000
db2 uncatalog db WAS
db2 catalog db WAS as WASAlias at node loop authentication server
//If you connect to WASAlias, it is connect through loopback;
//If you connect to WAS, it is "normal" connect.
db2 catalog db WASAlias as WAS at node RHOST
```

Example: Handling servlet JDBC connection exceptions

The following code sample demonstrates how to set transaction management and connection management properties, such as operation retries, to address stale connection exceptions within a servlet JDBC transaction.

This example code performs the following actions:

- initializes a servlet
- looks up a data source
- specifies error messages, connection retries, and transaction rollback requirements

Example: Handling connection exceptions for BMP beans in container-managed database transactions

The following code sample demonstrates how to roll back transactions and issue exceptions to the bean client in cases of stale connection exceptions.

          // Always close the connection in a finally statement to ensure
          // proper closure in all cases. Closing the connection does not
          // close an actual connection, but releases it back to the pool
          // for reuse.
          if (rs != null)
          {
             try
             {
                rs.close();
             }
             catch (Exception e)
             {
                System.out.println("Close Resultset Exception:" + e.getMessage());
             }
          }
          if (ps != null)
          {
             try
             {
                ps.close();
             }
             catch (Exception e)
             {
                System.out.println("Close Statement Exception:" + e.getMessage());
             }
          }
          if (conn != null)
          {
             try
             {
                conn.close();
             }
             catch (Exception e)
             {
                System.out.println("Close connection exception:" + e.getMessage());
             }
          }
        }
}

Example: Handling data access exception - ConnectionWaitTimeoutException (for the JDBC API)

This code sample demonstrates how you specify the conditions under which the application server issues the ConnectionWaitTimeoutException for a JDBC application.

In all cases in which the ConnectionWaitTimeoutException is caught, there is little that can be done to recover.

```
public void test1() {
      java.sql.Connection conn = null;
      java.sql.Statement stmt = null;
      java.sql.ResultSet rs = null;

      try {
         // Look for datasource
         java.util.Properties props = new java.util.Properties();
         props.put(
            javax.naming.Context.INITIAL_CONTEXT_FACTORY,
            com.ibm.websphere.naming.WsnInitialContextFactory);
         ic = new javax.naming.InitialContext(props);
         javax.sql.DataSource ds1 = (javax.sql.DataSource) ic.lookup(jndiString);

         // Get Connection.
         conn = ds1.getConnection();
         stmt = conn.createStatement();
         rs = stmt.executeQuery("select * from mytable where this = 54");
      }
      catch (java.sql.SQLException sqlX) {
     if (sqlX instanceof com.ibm.websphere.ce.cm.ConnectionWaitTimeoutException
      || sqlX instanceof java.sql.SQLTransientConnectionException
         && sqlX.getCause() instanceof com.ibm.websphere.ce.cm.ConnectionWaitTimeoutException)
     {
         //notify the user that the system could not provide a
         //connection to the database.  This usually happens when the
         //connection pool is full and there is no connection
         //available for to share.
      }
     else
     {
         // handle other database problems.
     }
      }
      finally {
         if (rs != null)
            try {
               rs.close();
            }
            catch (java.sql.SQLException sqle1) {
            }
         if (stmt != null)
            try {
               stmt.close();
            }
            catch (java.sql.SQLException sqle1) {
            }
         if (conn != null)
            try {
               conn.close();
            }
            catch (java.sql.SQLException sqle1) {
            }
      }
   }
```

Example: Handling data access exception - ConnectionWaitTimeoutException for Java EE Connector Architecture

This code sample demonstrates how you specify the conditions under which WebSphere Application Server issues the ConnectionWaitTimeout exception for a JCA application.

In all cases in which the `ConnectionWaitTimeout` exception is caught, there is little to do for recovery.

The following code fragment shows how to use this exception in Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA):

```
/**
 * This method does a simple Connection test.
 */
public void testConnection()
   throws javax.naming.NamingException, javax.resource.ResourceException,
       com.ibm.websphere.ce.j2c.ConnectionWaitTimeoutException {
   javax.resource.cci.ConnectionFactory factory = null;
   javax.resource.cci.Connection conn = null;
   javax.resource.cci.ConnectionMetaData metaData = null;
   try {
      // lookup the connection factory
      if (verbose) System.out.println("Look up the connection factory...");
try {
factory =
  (javax.resource.cci.ConnectionFactory) (new InitialContext()).lookup("java:comp/env/eis/Sample");
  }
   catch (javax.naming.NamingException ne) {
      // Connection factory cannot be looked up.
      throw ne;
   }
    // Get connection
      if (verbose) System.out.println("Get the connection...");
      conn = factory.getConnection();
      // Get ConnectionMetaData
      metaData = conn.getMetaData();
      // Print out the metadata Information.
      System.out.println("EISProductName" is + metaData.getEISProductName());
   }
   catch (com.ibm.websphere.ce.j2c.ConnectionWaitTimeoutException cwtoe) {
      // Connection Wait Timeout
      throw cwtoe;
   }
   catch (javax.resource.ResourceException re) {
      // Something wrong with connections.
      throw re;
   }
   finally {
      if (conn != null) {
         try {
            conn.close();
         }
         catch (javax.resource.ResourceException re) {
         }
      }
   }
}
```

Example: Handling data access exception - error mapping in DataStoreHelper

The application server provides a DataStoreHelper interface for mapping different database SQL error codes to the appropriate exceptions in the application server.

Error mapping is necessary because various database vendors can provide different SQL errors and codes that represent that same issue. For example, the stale connection exception has different codes in

different databases. The DB2 SQLCODEs of 1015, 1034, 1036 , and so on indicate that the connection is no longer available because of a temporary database problem. The Oracle SQLCODEs of 28, 3113, 3114, and so on, indicate the same situation.

Mapping these error codes to standard exceptions provides the consistency that makes applications portable across different installations of the application server. The following code segment illustrates how to add two error codes into the error map:

```
public class NewDSHelper extends GenericDataStoreHelper
{
  public NewDSHelper(java.util.Properties dataStoreHelperProperties)
  {
    super(dataStoreHelperProperties);
    java.util.Hashtable myErrorMap = null;
    myErrorMap = new java.util.Hashtable();
    myErrorMap.put(new Integer(-803), myDuplicateKeyException.class);
    myErrorMap.put(new Integer(-1015), myStaleConnectionException.class);
    myErrorMap.put("S1000", MyTableNotFoundException.class);
    setUserDefinedMap(myErrorMap);
    ...
  }
}
```

A configuration option known as the Error Detection Model controls how the error map is used. At V6 and earlier, Exception Mapping was the only option available for the Error Detection Model. At V7 and later, another option called Exception Checking is also available. Under the Exception Mapping model, the application server consults the error map and replaces exceptions with the corresponding exception type listed in the error map. Under the Exception Checking model, the application server still consults the error map for its own purposes but does not replace exceptions. If you want to continue to use Exception Mapping, you do not need to change anything. Exception Mapping is the default Error Detection Model. If you want to use the Exception Checking Model, see the topic “Changing the Error Detection Model to use the Exception Checking Model” in the related links.

Database deadlock and foreign key conflicts

Repetition of certain SQL error messages indicates problems, such as database referential integrity violations, that you can prevent by using the container managed persistence (CMP) sequence grouping feature.

Exceptions resulting from foreign key conflicts due to violations of database referential integrity

A database referential integrity (RI) policy prescribes rules for how data is written to and deleted from the database tables to maintain relational consistency. Runtime requirements for managing bean persistence, however, can cause an enterprise JavaBeans (EJB) application to violate RI rules, which can cause database exceptions.

Your EJB application is violating database RI if you see an exception message in your WebSphere Application Server trace or log file that is similar to one of the following messages (which were produced in an environment running DB2):

```
The insert or update value of the FOREIGN KEY table1.name_of_foreign_key_constraint
is not equal to any value of the parent key of the parent table.
```

or

```
A parent row cannot be deleted because the relationship table1.name_of_foreign_key_constraint
is not equal to any value of the parent key of the parent table.
```

To prevent these exceptions, you must designate the order in which entity beans update relational database tables by defining sequence groups for the beans.

Exceptions resulting from deadlock caused by optimistic concurrency control schemes

Additionally, sequence grouping can minimize transaction rollback exceptions for entity beans that are configured for optimistic concurrency control. Optimistic concurrency control dictates that database locks be held for minimal amounts of time, so that a maximum number of transactions consistently have access to the data. In such a highly available database, concurrent transactions can attempt to lock the same table row and create deadlock. The resulting exceptions can generate messages similar to the following (which was produced in an environment running DB2):

```
Unsuccessful execution caused by deadlock or timeout.
```

Use the sequence grouping feature to order bean persistence so that database deadlock is less likely to occur.

Directory conventions

References in product information to *app_server_root*, *profile_root*, and other directories imply specific default directory locations. This article describes the conventions in use for WebSphere Application Server.

Default product locations - z/OS

app_server_root
: Refers to the top directory for a WebSphere Application Server node.

  The node may be of any type—application server, deployment manager, or unmanaged for example. Each node has its own *app_server_root*. Corresponding product variables are *was.install.root* and *WAS_HOME*.

  The default varies based on node type. Common defaults are *configuration_root*/AppServer and *configuration_root*/DeploymentManager.

configuration_root
: Refers to the mount point for the configuration file system (formerly, the configuration HFS) in WebSphere Application Server for z/OS.

  The *configuration_root* contains the various *app_server_root* directories and certain symbolic links associated with them. Each different node type under the *configuration_root* requires its own cataloged procedures under z/OS.

  The default is /wasv8config/*cell_name*/*node_name*.

plug-ins_root
: Refers to the installation root directory for Web Server Plug-ins.

profile_root
: Refers to the home directory for a particular instantiated WebSphere Application Server profile.

  Corresponding product variables are *server.root* and *user.install.root.*

  In general, this is the same as *app_server_root*/profiles/*profile_name*. On z/OS, this will always be *app_server_root*/profiles/default because only the profile name "default" is used in WebSphere Application Server for z/OS.

smpe_root
: Refers to the root directory for product code installed with SMP/E or IBM Installation Manager.

  The corresponding product variable is *smpe.install.root*.

  The default is /usr/lpp/zWebSphere/V8R5.

Assembling data access applications

When you assemble enterprise bean code into files that can be deployed onto an application server, you configure properties that define how the application accesses an enterprise information system (EIS), such as a database.

Before you begin

This topic assumes that you have created an enterprise application containing an EJB module that must transact with a database.

About this task

A data access application uses resources, such as data sources or connection factories, to connect with a database.

An application component uses a *connection factory* to access a connection instance, which the component then uses to connect to the underlying enterprise information system (EIS). Examples of connections include database connections, Java Message Service connections, and SAP R/3 connections.

During application assembly you perform activities that enable the application to use these resources. The process typically requires an assembly tool.

Procedure

1. Identify the logical names that are used by the EJB module to reference application resources. These logical names are called *resource references*.

   For further explanation, read the topic, The benefits of using resource references.
2. Start an assembly tool.
3. If you have not done so already, configure the assembly tool for work on Java Platform, Enterprise Edition (Java EE) modules. Ensure that **Java EE** capability is enabled.
4. Define mapping and security properties for the resource references. This process includes the following activities:
   a. Bind the resource references to the application resources that provide database connectivity.

      See the topic, Data source lookups for enterprise beans and web modules, for more information on the concept of binding. At deployment time you can alter your bindings if necessary.
   b. For each resource define an authentication type, which is the security configuration through which database connections are granted. There are two authentication types:

      Component-managed
      The enterprise bean code performs EIS signon for data source or connection factory connections.

      Container-managed
      The product performs EIS signon.

      See the topic, J2EE connector security, for detailed reference on resource authentication.
5. Configure access intent policy settings for your enterprise beans.
   a. Right-click your EJB module in a Project Explorer view and click **Open With > Deployment Descriptor Editor**.
   b. In an EJB Deployment Descriptor editor, select the **Access** tab.
   c. Under **Isolation Level**, click **Add**.
   d. Select the isolation level, enterprise beans, and method elements. For information on isolation levels, press **F1**.
   e. Click **Finish**.
6. Map enterprise beans to database tables.

Results

Files for the updated application are shown in the Project Explorer view.

What to do next

After testing your application, you are ready to deploy your application to an application server.

Creating or changing a resource reference

A resource reference supports application access to a resource (such as a data source, URL, or mail provider) using a logical name rather than the actual name in the runtime environment. This capability eliminates the necessity to alter application code when you change the resource runtime configurations.

Before you begin

This topic guides you through updating the resource references of an enterprise application that you assembled previously. The topic, Assembling applications, details the assembly procedure.

About this task

Resource references are declared in the deployment descriptor by the application provider. At some point in the application deployment process, you must bind the resource reference to the actual name of the resource in the run time environment. When you create a connection factory or data source in the application server, the application server provides a JNDI name that a component can use to access that connection factory or data source. The application server uses an indirect name with the java:comp/env prefix. For example:

- When you create a data source, the default JNDI name is set to jdbc/*data_source_name*.
- When you create a connection factory, its default name is eis/*j2c_connection_factory_name*.

If you override these values by specifying your own, retain the java:comp/env prefix. An indirect JNDI name allows the connection management infrastructure to access to any data from the resource reference that is associated with the application. This allows you to better manage resources based on the settings for authentication, isolation level, sharing scope, and resolution control.

This topic describes how to update the resource references of an enterprise application using an assembly tool. After you define the resource reference, you can perform an indirect JNDI lookup using the java:comp/env context.

Procedure

1. Start an assembly tool.
2. If you have not done so already, configure the assembly tool for work on Java Platform, Enterprise Edition (Java EE) modules.
3. Import the enterprise application (EAR file) that you want to change into the EJB project.
4. Display the resource references for the type of module:
   - If an enterprise bean uses the resource reference:
     a. Expand the name of the EAR file.
     b. Expand **EJB Modules**.
     c. Expand the EJB module wanted.
     d. Expand the section for the appropriate type of enterprise bean (**Session Beans** or **Entity Beans**).
     e. Expand the enterprise bean.
   - If a servlet uses the resource reference:
     a. Expand the name of the EAR file.
     b. Expand **Web Modules**.
     c. Expand the web module wanted.
   - If an application client uses the resource reference:
     a. Expand the name of the EAR file.

b. Expand **Application Clients**.
c. Expand the application client module wanted.

5. Right-click the module whose resource references you want to change and click **Open With > Deployment Descriptor Editor**.
6. For servlets and application clients, click **Add**. For EJB modules, select the particular bean and click **Add**.
7. Select the resource reference option and click **Next**.
8. Specify the settings for the resource reference, and click **Finish**.
9. Optional: Select the **References** tab and, under **WebSphere Extensions**, select an isolation level. If you choose to forego this step, the isolation level defaults to TRANSACTION_NONE.
10. Optional: Under **WebSphere Bindings**, specify a JNDI name. If you choose to forego this step you can set (or override) the binding when the application is deployed.
11. Close the deployment descriptor editor and save your changes.

Results

Files for the updated module are shown in the Project Explorer view.

What to do next

Verify the contents of the updated enterprise application in the Project Explorer view. Then, deploy your enterprise application.

You can generate EJB deployment code and deploy an EJB module to a target server in one step. In the Project Explorer view, right-click on the EJB project and click **Deploy**. See also the topic, Deploying EJB modules.

Assembling resource adapter (connector) modules

A resource adapter archive (RAR) file contains code that implements a library for connecting with a backend Enterprise Information System (EIS).

Before you begin

This topic assumes that you have created and unit tested a resource adapter RAR file that you want to assemble in an enterprise application and deploy onto an application server.

A Resource Adapter Archive (RAR) file is a Java archive (JAR) file used to package a resource adapter for the Java 2 Connector (J2C) Architecture for the product.

A RAR file can contain the following:
- Enterprise information system (EIS) supplied resource adapter implementation code in the form of JAR files or other runnable components, such as dynamic link lists.
- Utility classes.
- Static documents, such as HTML files, images, and sound files.

The standard file extension of a RAR file is *.rar*.

About this task

In an assembly tool, RAR files are called *connectors* and assembled resource adapters are called *connector modules*.

A *connector* is a Java Platform, Enterprise Edition (Java EE) component that provides access to Enterprise Information Systems (EIS), and must comply with the Java EE Connector Architecture (JCA). An example of an EIS is a transaction manager such as the Customer Information Control System (CICS®).

You might see the terms resource adapter *modules*, resource adapter *connectors* and resource adapter *archive files* used interchangeably.

Use an assembly tool to assemble a *connector* in either of the following ways:
- Import an existing RAR file.
- Create a new connector module.

For information on assembling connectors, refer to the online documentation or the information center for your assembly tool.

Procedure

1. Start an assembly tool.
2. If you have not done so already, configure the assembly tool for work on J2EE modules. Ensure that **Java EE** and **EJB** capabilities are enabled.
3. Migrate RAR files created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to an assembly tool. To migrate files, import your RAR files to the assembly tool.
4. Create a new connector module.

Results

A connector project is migrated or created. Files for the connector project are shown in the Project Explorer view under **Enterprise Applications** and **Connector Projects**.

What to do next

After creating a connector project, you can edit the connector deployment descriptor if default properties are not sufficient. In the Connector Deployment Descriptor editor, you can view and edit source code.

After assembling the connector project, deploy the module or its application onto a server. After deployment, to ensure that the connector module finds the classes and resources that it needs, check the **Classpath** setting for the RAR on the console Resource adapter settings page.

Planning to use optimized local adapters for z/OS

Use this high-level task when you are planning to implement the optimized local adapters for z/OS in your environment.

Before you begin

For CICS Transaction Server for z/OS to communicate with optimized local adapters, the minimum required version of CICS Transaction Server for z/OS is version 3.1. If you want to use two-phase commit or resource manager local transactions (RMLT) support for outbound calls from WebSphere Application Server to CICS, you must use CICS Transaction Server for z/OS Version 4.1.

About this task

Optimized local adapters and the supporting native API callable services provide a different path for enterprise architecture and application development on the z/OS platform. Optimized local adapters can be used to make inbound calls from an external address space to Enterprise JavaBeans (EJB) applications that are deployed on a local WebSphere Application Server for z/OS server, and make outbound calls from

an application running under WebSphere Application Server for z/OS to a server program that is running in an external address space.

Procedure

1. Review existing business and middleware applications in your environment to determine which processes would benefit from using optimized local adapters. Using optimized local adapters provides applications that are written in native languages like Cobol, PL/I, C/C+, and high-level assembler, and are running under environments such as z/OS batch, Customer Information Control System (CICS) and UNIX System Services (USS), a different way to call Java applications that are implemented as EJB applications on WebSphere Application Server for z/OS.

   You can read about several different types of scenarios where optimized local adapters are used with existing business and middleware applications in the topic, Optimized local adapters for z/OS usage scenarios.
2. Make sure that you are running WebSphere Application Server in 64-bit mode. When you create an application server, it is automatically configured to run in 64-bit mode. If you find that your application server is configured to run in 31-bit mode, you can convert your application server to run in 64-bit mode. To learn how to do this conversion, see the topic, Running servers in 31-bit mode, and the section “Converting a migrated server to run in 64-bit mode”.
3. Make sure that WebSphere Application Server is using a SAF-based user registry if you plan to propagate a SAF user ID from WebSphere Application Server for z/OS to the enterprise information system (EIS).

   Optimized local adapters can be used to connect with CICS and Information Management Systems (IMS™), over OTMA support.
4. Review the optimized local adapters samples. There are several examples that are included when you install WebSphere Application Server for z/OS. See the topic Optimized local adapters Samples on how to locate and use the samples.
5. Decide how to use optimized local adapters. You can use the optimized local adapters to make inbound or outbound calls.
   a. Use the optimized local adapters for inbound support.

      You can use the optimized local adapters support to call inbound to WebSphere Application Server for z/OS EJB applications. The following image shows the flow of an inbound CICS call to a WebSphere Application Server EJB application.

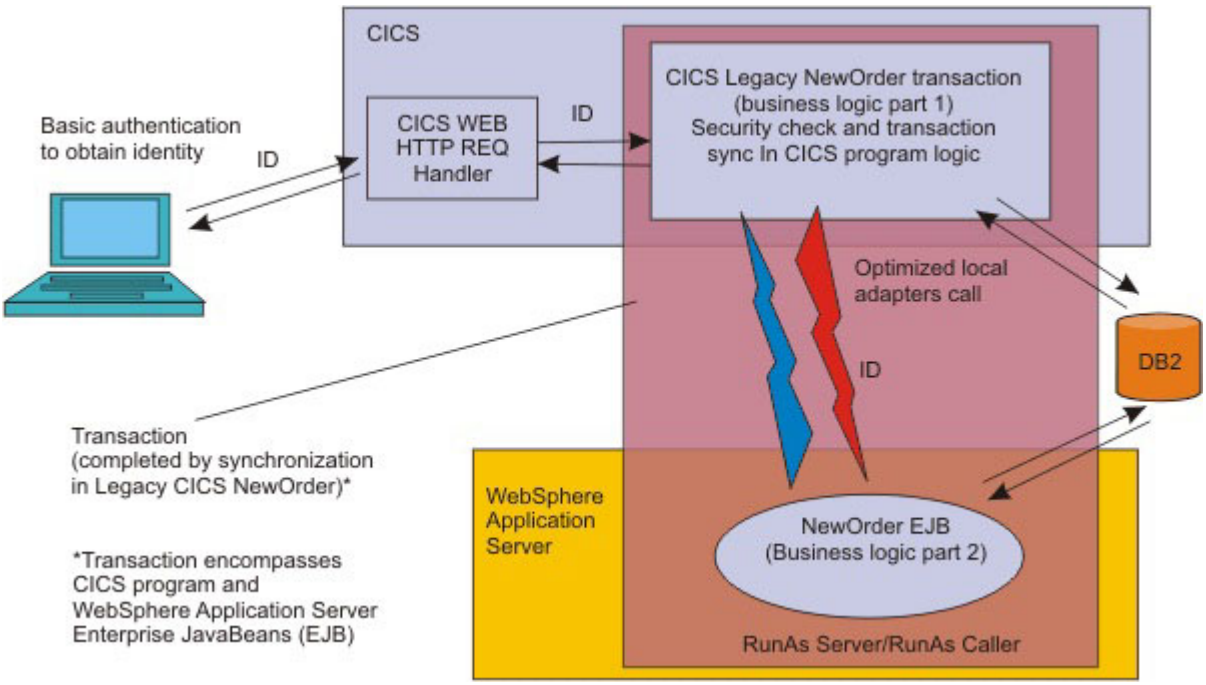

Figure 1. Using CICS

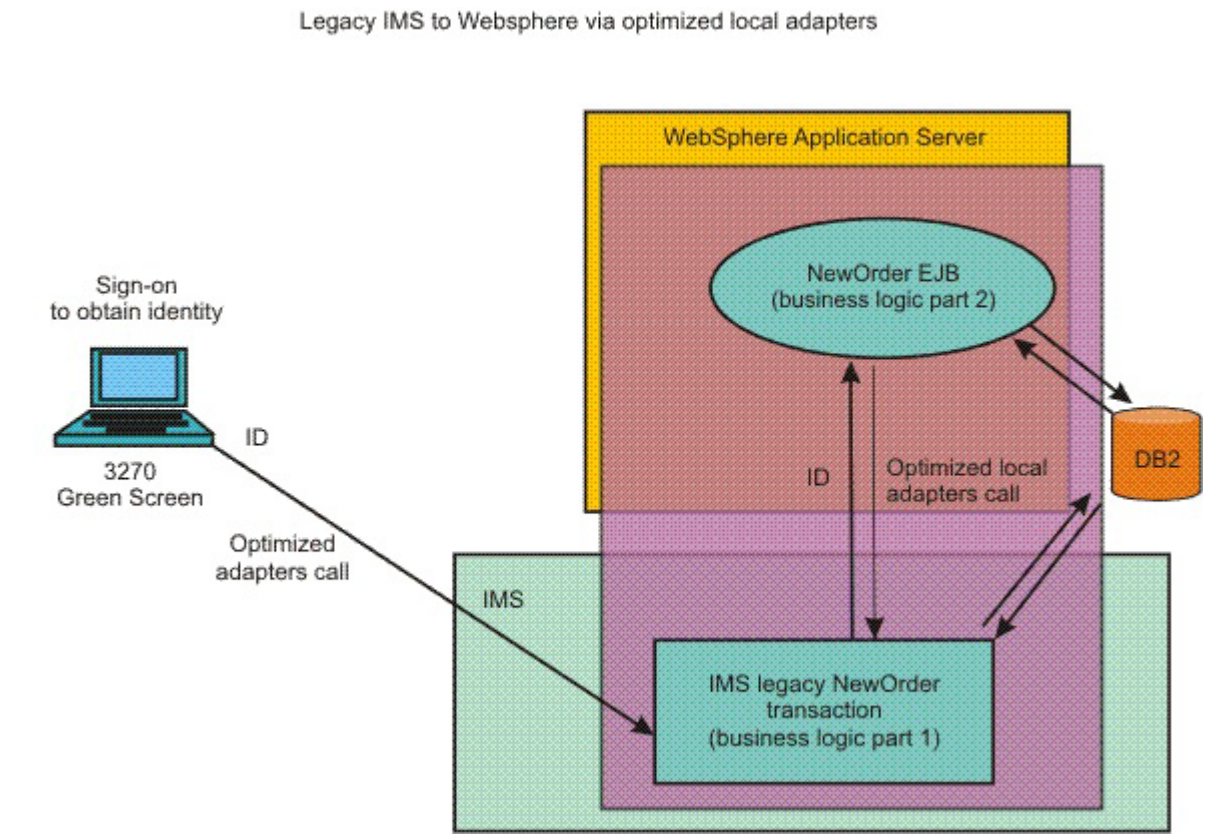

Figure 2. Using IMS

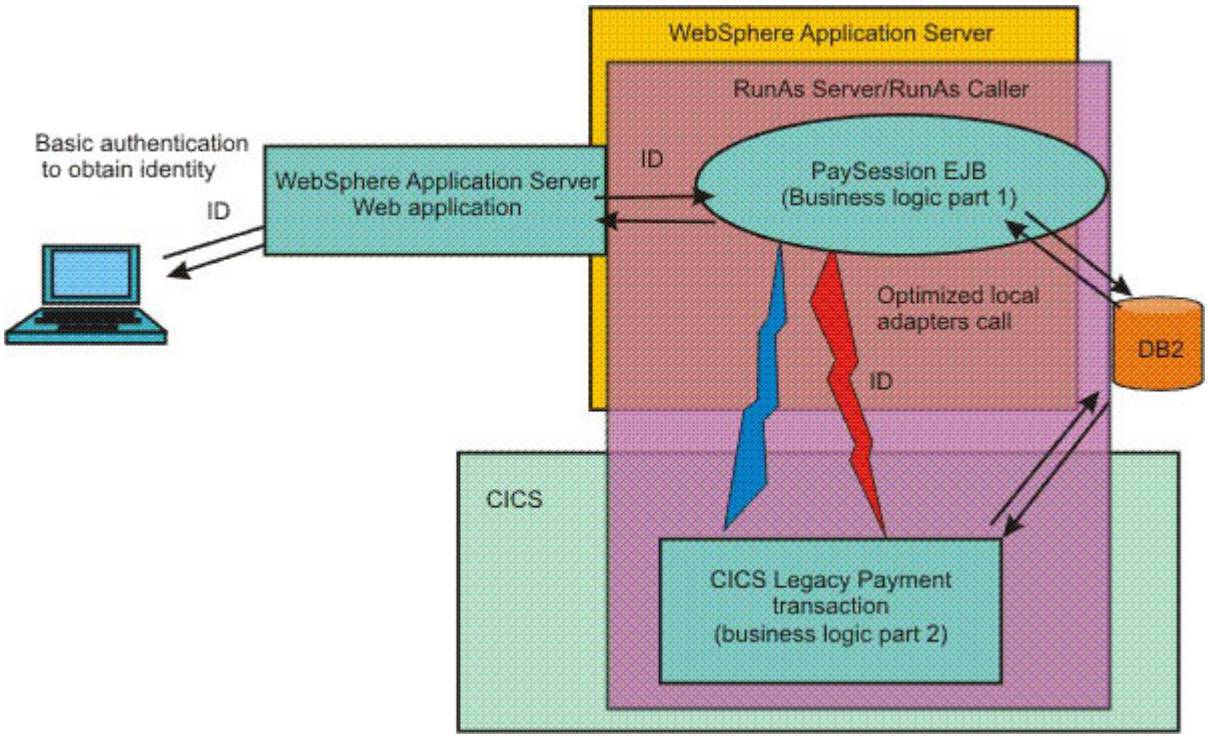
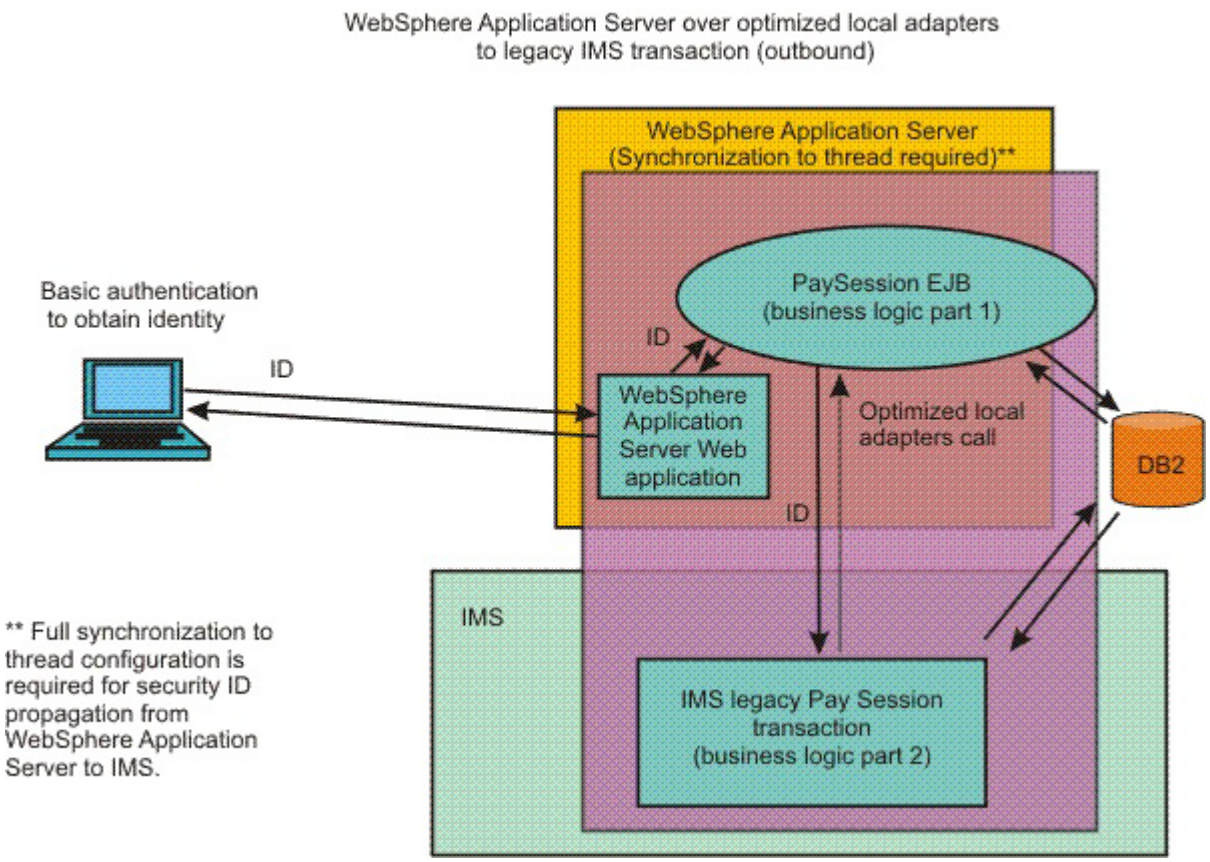
b. Use the optimized local adapters for outbound support.

You can use the optimized local adapters support to call programs in external address spaces from WebSphere Application Server for z/OS applications.

The following illustration shows the flow of an outbound WebSphere Application Server call to a CICS transaction.



The following illustration shows the flow of an outbound WebSphere Application Server call to a IMS transaction.



Optimized local adapters on WebSphere Application Server for z/OS

Optimized local adapters support on WebSphere Application Serverfor z/OS consists of a set of callable services and a Java EE Connector Architecture (JCA) 1.5 resource adapter. The services and adapter work together to provide high performance calling between native language applications on z/OS and business logic in a WebSphere Application Server for z/OS environment.

The optimized local adapters can be used to make inbound calls to applications that are deployed on WebSphere Application Server from an external address space. They are also used to make outbound calls from WebSphere Application Server applications to applications that are running in an external address space on the same z/OS system.

With this support, existing z/OS applications that are written in Cobol, PL/I, C, C++, and assembler can achieve high performance and efficient integration with Java applications that are deployed under WebSphere Application Server on the same z/OS system.

Optimized local adapters also provide close integration of qualities of service (QoS), including support for fast thread-level security propagation and assertion between the API-exploiting external address spaces and WebSphere Application Server for z/OS. Support is provided for using the adapters APIs in the following environments: Customer Information Control System (CICS), Information Management System (IMS), UNIX System Services (USS), and batch processing.

Two paths for the adapters exist: Support for inbound Enterprise JavaBeans (EJB) calls to WebSphere Application Server for z/OS and support for outbound communication with locally running external server programs from WebSphere Application Serverfor z/OS.

A task-related user exit (TRUE) program is provided to support the optimized local adapters under CICS.

Optimized local adapters support is provided for applications running in IMS-dependent region environments using the IMS External Subsystem Attach Facility (ESAF). With this ESAF, WebSphere optimized local adapters are implemented as an IMS subsystem.

Benefits to using optimized local adapters

There are several benefits to using the optimized local adapters, including:

- **Performance improvement**

  Significant performance characteristics can be achieved when using the optimized local adapters APIs to call into applications that are deployed on a WebSphere server from a local batch, USS, IMS, and CICS applications. The ability to pass parameter data using binary techniques provides a large part of the performance improvement. The transport-level support that the adapters provide uses z/OS cross-memory services to optimize the performance of calls to applications that are deployed on a locally accessible WebSphere Application Server for z/OS server.

- **Identity context propagation**

  For inbound requests to WebSphere Application Server using the optimized local adapters APIs, the user ID on the existing z/OS thread is always propagated and asserted in theWebSphere Application Server EJB container. For calls from CICS, this can be extended with a registration option which indicates that the identity of the CICS task level user is propagated and asserted. For calls from applications deployed on WebSphere Application Server, identity can be propagated and asserted under CICS using the optimized local adapters CICS Link server. Selection of this behavior is also controlled with a flag on the registration API.

  When using optimized local adapters over IMS Open Transaction Manager Access (OTMA) support, the identity of the WebSphere Application Server application user on the current thread can be propagated and asserted in the target IMS-dependent region (Fast Path or Message Processing Region).

- **Global transactions**

  Global, two-phase commit transactions are supported with the optimized local adapters for inbound calls from CICS to WebSphere Application Server, and outbound calls from WebSphere Application Serverto CICS.

  Resource manager local transactions (RMLT) are supported with the optimized local adapters for outbound calls from WebSphere Application Server for z/OS to CICS when using the supplied link server.

  Attention: Two-phase commit and RMLT support for outbound calls from WebSphere Application Server to CICS requires the use of CICS Transaction Server for z/OS, Version 4.1 or later.

- **Workload balancing and availability**

  The workload balancing framework in the optimized local adapter support is designed so that the inbound call requests are passed into the target server control region, where the requests are queued using z/OS workload management (WLM) to an eligible servant region for execution.

- **Local binding support**

  Optimized local adapters can provide a high performance local binding for existing applications, middleware, and subsystems on z/OS platforms. These local bindings are used with current programming interfaces when it is determined there is a local WebSphere Application Server available.

- **Providing a gateway or proxy for legacy assets on z/OS systems**

  Built-in optimized local adapters provide the basis for you to begin to use the WebSphere Application Server for z/OS stack as an easily accessible set of capabilities. These capabilities extend the life of application assets that might be difficult to replace. When you use an enterprise bean as a proxy, any Cobol, assembler, or C/C+ application that is deployed on a z/OS system can easily become a Web services client or a Web 2.0 application requestor that reaches a set of Web applications that are within reach of your locally running application server.

  Using the WebSphere Application Server outbound APIs, any Cobol, assembler, or C/C+ application can be presented to WebSphere Application Server as a callable service. A provider Web services application can then be deployed in the local WebSphere server that accepts requests as a gateway for

this backend service. In this scenario, the JCA 1.5 programming model is used to send requests to the application, received responses from it and send back responses to the Web-based caller.

Optimized local adapter Samples

Optimized local adapters Samples

The product provides sample files that support optimized local adapters for z/OS.

The following sample files are located in the WebSphere Application Server product directory, `<Prod_FS_root>/util/zos/OLASamples`:

- `.jclsamp` files
- `olarar.py` and `olararupdate.py` files
- Header files, `bboaapi.h` and `bboaapip.include`
- EAR sample files

The `ola_apis.jar` file is located in the product directory, `/lib`.

Sample descriptions

A directory of the sample names and what they do is available in a directory in the @@README member of the native set of files. The samples include:

- CSDUPDAT - Customer Information Control System (CICS) DFHCSDUP utility job that defines all the resource definitions needed for optimized local adapters under CICS. Group BBOACSD contains CICS definitions for the optimized local adapters; group BBOASAMP contains definitions for the adapter samples.
- DFHPLTOL - Job Control Language (JCL) source for assembling a sample PLT with the optimized local adapters. Enable the Task Related User Exit (TRUE) program, BBOACPLT, and the optimized local adapters BBOC command processor PLT, BBOACPL2.
- OLABATCH - JCL to run one of the samples in batch. Ensure that this runs on the same LPAR that WebSphere Application Server for z/OS is running.
- OLACB01 - JCL source for CICS link to sample Cobol program that uses a commarea. This is a sample target program when using the optimized local adapters CICS Link server. It echoes back the sent message.
- OLACB02 - JCL source for CICS link to sample Cobol program that uses a container. This is a sample target program when using the optimized local adapters CICS Link server. It echoes back the sent message.
- OLACB03 - JCL source for CICS sample Cobol program that demonstrates how to make a CICS task into an optimized local adapters server using the Host Service API.
- OLACB04 - JCL source for CICS sample Cobol program that demonstrates how to make a CICS task into an optimized local adapters server using the Receive Request and Get Data APIs
- OLACB05 - JCL source for CICS sample Cobol program that demonstrates how to use the APIs to Register, Get a Connection, call an Enterprise JavaBeans (EJB) with Send Request, get the response with Get Data, and release the connection with Connection Release and Unregister.
- OLACB06 - JCL source for CICS sample Cobol program that demonstrates how to use the APIs to Register, call an EJB application with Invoke and Unregister.
- OLACC01 - JCL source for a C program that does Register, Invoke, and Unregister. This can be run under batch, UNIX System Services (USS) and CICS.
- OLACC02 - JCL source for a C program that does Host Service, Send Request, Send Response, and Get Data API calls. This program invokes itself, calling in to an enterprise bean that then calls back to this program. This can be run under batch, USS and CICS.
- OLAMAP - JCL source for a CICS BMS screen map definition. This is a 3270 test driving screen for passing requests to and from CICS to WebSphere Application Server.

- OLAUTIL - JCL source for Cobol CICS test application utility. You can test Register, Invoke, Host Service, Send Response APIs from this panel and update the daemon group (cell short name), server and node names, as well as the service name, to run with. This utility can be used for testing calls in both directions. Code from here can be used as samples for using these APIs.
- OLAPL01 - JCL source for a PL/I program that runs as an IMS Fast Path program and is called by the sample WebSphere Application Server application using the optimized local adapter over OTMA support. It in turn does an optimized local adapter Register, Invoke, and Unregister - calling the target EJB in the OLASample2 application.
- OLAPL02 - .JCL source for a PL/I program that runs as an Information Management System (IMS) Message Processing Program (MPP) and is called by the sample WebSphere Application Server application using optimized local adapters over OTMA support. It in turn does an optimized local adapter Register, Invoke, and Unregister - calling the target EJB in the OLASample2 application.
- PSBOLA2 - Sample JCL/source to show how the IMS processor-side bus (PSB) generates the samples OLAPL01 and OLAPL02.
- OTMAINIT - Sample JCL to show how to start the IMS OTMA callable interface SVCs on your system.
- STAGE1 - Sample source for IMS STAGE1 for the samples, OLAPL01 and OLAPL02

Samples installation

1. Allocate a Partitioned data set (PDS) or Partitioned data set extended (PDSE) to hold the JCL source. In the sample JCL, this data set is named BOSS.OLA.SAMPLES.SRC.

   This data set is allocated as RECFM=FB, DSORG=PO, LRECL=80, BLKSIZE=9040, TRKS=40. Copy, for example OGET, the files with file type “jclsamp” from the `<Prod_FS_root>/util/zos/OLASamples` directory to this data set. The header file `bboaapi.h` is also put in this data set as BBOAAPI.
2. There is an enterprise archive (EAR) file that can be installed immediately after you have set up your resource adapter, ola.rar, and defined a connection factory with the Java Naming and Directory Interface (JNDI) name of eis/ola.

   The EAR file is located in the directory, `<Prod_FS_root>/util/zos/OLASamples`.

   Attention: If you are using V8.0 use the `OLASample2.ear` file.
3. Allocate another PDS or PDSE to be used to hold the COBOL COPYBOOK created by the Customer Information Control System (CICS) BMS map build job OLAMAP.

   This data set is allocated as RECFM=FB, DSORG=PO, LRECL=80, BLKSIZE=9040, TRKS=15. In the sample JCL, this data set is named BOSS.OLA.SAMPLES.COPYBOOK.
4. Allocate or select a load module library to contain the optimized local adapter samples load modules.

   It must be allocated as a LIBRARY rather than a PDS.
5. Use the following steps to build and run the z/OS batch samples.

   For all the members you update during these steps, you must change the JCLLIB statement to point at your procedure libraries (for C compiles in this case). Someone familiar with where this information is located on your system should be involved in doing this. Also, the test case source has the daemon group (cell short name), the node short name, and the server short name embedded and you must change these before compiling, in order for these to function on your system.
   a. Edit member OLACC*nn* (where *nn*=test case number) and update the JCL to match your site data set naming conventions for your C compiler and set the SYSLMOD data set where the output load module is placed.
   b. In member OLACC*nn*, update the daemon group name (cell short name), the node name and the server name and submit the job to build the test case load module.
   c. Ensure that the target application server is started with optimized local adapters support enabled. You enable the optimized local adapters support by setting the WAS_DAEMON_ONLY_enable_adapter to `true`. Also, make sure that the `ola.rar` file is installed and a connection factory is created with the JNDI name, eis/ola.
   d. Ensure that the OLA sample EAR file is installed in the target application server.

Attention: If you are using V8.0, use the `OLASample2.ear` file.

e. Use OLABATCH as a template for running the OLACC*nn* batch samples.

Some sample jobs refer to a data set named BOSS.OLA90902.SBBOLOAD. This represents the data set into which you copied the online adapter modules using the **copyZOS.sh** script.

6. The z/OS batch samples can also be run under CICS. Follow the steps in the topic, Enabling optimized local adapters support in CICS, and add the samples load modules library from step 4 to the CICS DFHRPL DD concatenation.
7. Use the following steps to build and run the optimized local adapters CICS sample test utility panel. For all the members that you update during this process, you need to change the JCLLIB statement to point at your procedure libraries (for COBOL compilers and for CICS translation in this case). Someone familiar with where this information is located on your system needs to be involved in doing this process.
   a. Edit member OLAMAP and update the JCL to match your site data set name conventions for HLASM applications.

      You need to change the MAPLIB and DSCTLIB parameters to your own data set names. The MAPLIB should point to the samples load module library that you allocated in step 4. The DSCTLIB should point to the COPYBOOK data set that you allocated in step 3.

      Note: You can change the default register name on this panel from CICSTEST to something else. You can also set the default daemon group name (cell short name), node name and server name. The values you enter here display on the panel when you run the OLAU transaction under CICS.

   b. Submit the OLAMAP job to build the CICS map set module.
   c. Edit member OLAUTIL and review the content.

      This is a sample Cobol application that demonstrates a number of the optimized local adapters APIs from Cobol. It sends and receives the CICS BMS map, OLAMAP, and can send a message to any target enterprise bean in any locally attached application server. It can also be used to demonstrate how to make your CICS task into an optimized local adapters target service using the BBOA1SRV API. After updating the JCL to conform to your local data set name conventions, submit the job and the OLAUTIL load module is saved in the data set pointed to by the PROGLIB symbol.
   d. Ensure that the optimized local adapters load module library, and the optimized local adapters samples load module library, are in the CICS DFHRPL DD concatenation of your CICS cataloged procedure.
   e. Ensure that the sample job CSDUPDAT has run and the steps to install optimized local adapters under CICS are complete.
   f. Ensure that the target application server is started with the optimized local adapters support enabled. You enable optimized local adapters by setting the WAS_DAEMON_ONLY_enable_adapter to `true`. Also, make sure that the `ola.rar` file is installed and a connection factory is created with the JNDI name eis/ola. You can read more about these procedures in the topic, Enabling the server environment to use optimized local adapters.
   g. Ensure that the OLA sample EAR file is installed in the target application server.

      Attention: If you are using V8.0, use the `OLASample2.ear` file.

   h. Start CICS.

      Make sure that optimized local adapters support is enabled, logon to CICS with a user ID that is authorized to run the BBOC and OLAU transactions, and clear the screen. Enter BBOC START_TRUE to start the optimized local adapters CICS task-related user exit (TRUE). A message displays about the exit starting successfully. If you do not get this message, you should get a message indicating the kind of error that occurred. For more detailed messages, refer to the CICS job output and look in file BBOOUT. If you want to use the optimized local adapters Program List Table for Post Initialization (PLTPI) program to start the optimized local adapters TRUE during CICS startup, refer to the following section that describes this process.

i. Clear the screen again and enter OLAU to start the test panel.

   If everything is working properly, the panel displays with the heading, * Optimized Local Adapters WAS z/OS Testing *. The Run parameters are listed on the panel, with Register first with a value of `Y`, Register name with a value of `CICSTEST` and Service name with a value of `ejb/com/ibm/ola/olasample1_echoHome`. The Number of Tests to run field has a value of `00001`.

j. In the Send message data field, enter a message to send to the service in WebSphere Application Server.

k. Enter the WebSphere Application Server server short name, WebSphere Application Server node short name, andWebSphere Application Server cell short name (daemon group name) for the server that you want to call an enterprise bean into.

l. The remaining fields can remain as they are. The service name displayed above is the JNDI home name of a sample target enterprise bean in the OLA sample EAR file.

   Attention: If you are using V8.0, use the `OLASample2.ear` file.

m. Click **PF4** to send the message to the EJB, olasample1_echoHome. The message returns in the Received message data field.

n. You have now demonstrated a call from a CICS Cobol program to a WebSphere Application Server EJB application.

   The panel display has now changed. The Register First? field changed from `Y` to `N`. Rerunning requests with this Register name does not require a register call first, so this changes to the value, `N`. If you get a return code 8 (RC8) and reason code 8 (RSN8) on Register, this means that you are already registered and do not need to register again. After leaving OLAU and coming back in later, that registration is still active, so you do not need to register again with that name and should set that to the value, `N`.

o. To test a call from WebSphere Application Server to CICS, you can use this same panel.

   You must update the service name field to whatever name you want to identify as your target service name and click **PF5**. This puts the screen into an x-wait since OLAUTIL calls the BBOA1SRV API with the service name and registration name that you requested. The panel shows a registration called CICSTEST and service name called myserv. Other parameters that show values on the panel are WAS server short name, WAS node short name, WAS cell short name (daemon group name), Number of Tests to run, and Number of Tests Completed.

p. When OLAU is in the wait for the service name that you requested, start the sample Web application in your browser.

   Use the following URL (updating the IP/port# for your site): http://nn.nn.nn.nn:nnnn/OLA_Sample1_Web/ - change the *nnnn* port number to your non-SSL WebSphere Application Server application port.

q. A web page displays with the following fields listed: Data to send to external address space, Response back from external address space, OLA Register Name, OLA Service Name, CICS Link server-specific data, CICS Link Request Container ID, CICS Link Response Container ID, and CICS Link Transaction ID. Enter the message that you want to send, register name and service name as you did on the OLAU panel and click **Run WAS->External address space test**.

r. You now see the message you entered on the browser display on your CICS 3270 panel in the Received message data field.

s. Type in a response message in the Send message data field and click **PF6** to send the response back to WebSphere Application Server. This should come up on the browser.

t. You have now demonstrated a call from a WebSphere Application Server servlet to a CICS Cobol program.

8. Use the following steps to demonstrate calling from a WebSphere Application Server application to a CICS Cobol program using the optimized local adapters CICS Link server.

   a. Edit member OLACB01 and review the contents.

      This is a sample Cobol application that is the target of an EXEC CICS LINK with a COMMAREA. It writes the passed COMMAREA message data to the default Cobol standard out (CEEMSG) and

echoes back the message. Update the JCL to point to your local data sets and submit it. The load library that this module is saved in must be in the CICS DFHRPL concatenation.

b. Edit member OLACB02 and review the contents.

   This is a sample Cobol application that is the target of an EXEC CICS LINK with a CONTAINER. It reads the CONTAINER contents and writes it back to the same container. Update the JCL to point to your local data sets and submit it. The load library that this module is saved in must be in the CICS DFHRPL concatenation.

c. Ensure that the sample job CSDUPDAT has run and the steps to install optimized local adapters under CICS are complete.

d. Start CICS.

   Logon to CICS with a user ID that is authorized to run the BBOC, BBO# and BBO$ transactions, and clear the screen.

   Enter BBOC START_TRUE to start the optimized local adapters CICS TRUE.

   A message displays about the exit starting successfully. If you do not get this message, you should get a message indicating what kind of error occurred. For more detailed messages, refer to the CICS job output and look in file BBOOUT. If you want to use the optimized local adapters PLTPI program to start the optimized local adapters TRUE during CICS startup, refer to the section in this topic that describes this process.

e. Clear the screen again and enter the following to start an optimized local adapters CICS Link server task: `bboc start_srvr rgn=olaserver svn=<serverName> dgn=<cellName> ndn=<nodeName> mnc=1 mxc=5 sec=n svc=*`

   This results in a BBO$ task starting with the register name OLASERVER, connecting the specified application server. Make sure to specify the server short name, cell short name and node short name for the server.

f. You are now ready to send a request to link to an existing CICS program. Start the test web page (http://nn.nn.nn.nn:nnnn/OLA_Sample1_Web/). Enter OLASERVER as the register name and OLACB01 as the service name.

g. Click **Run WAS** > **External address space test**. You should get a page back with the same message that was sent to CICS returned. If you look in the CICS CEEMSG DD (in the running CICS job), the message data in UTF-8 displayed.

h. You have now demonstrated a call from a servlet in WebSphere Application Server to a CICS Cobol program OLACB01 passing and returning data in a COMMAREA.

i. Display the browser panel again and change the service name to OLACB02 and click the Use Containers check box.

   Important: You must check the Use Containers check box.

j. Click **Run WAS** > **External address space test**. You should get a page back with the input message echoed back.

k. You have now demonstrated a call from a servlet in WebSphere Application Server to CICS Cobol program OLACB02 passing data using a CONTAINER.

l. If you want to track what is happening more closely, you can stop the link server and restart it with tracing set. By setting TRC=2, you can view the trace messages in the CICS job BBOOUT file. To stop the link server type the following: `bboc stop_srvr rgn=olaserver`. To restart the link server with tracing, type the following: `bboc start_srvr rgn=olaServer svn=<serverName> dgn=<cellName> ndn=<nodeName>` mnc=1 mxc=5 sec=*n* svc=* trc=2

9. Use the following steps if you want to set up CICS to automatically start the optimized local adapters TRUE during CICS start up.

   a. You can code BBOC START_TRUE\ in a CICS sequential terminal (TYPE=SDSCI) to start the optimized local adapters TRUE, or

   b. You can create a CICS region Program List Table for Post Initialization (PLTPI) and have it invoked during CICS region startup.

The sample job DFHPLTOL creates a PLTPI with suffix OL. Run this sample, placing the resulting module DFHPLTOL in a load modules library in the DFHRPL concatenation, and add OL to the SIT PLTPI specified for the CICS region, for example, PLTPI=OL.

Refer to the samples file DFHPLTOL for an example of this. When you run the PLTPI, you should see the following messages on your CICS job log if the optimized local adapters TRUE started properly:

```
+BBOA9920I WAS z/OS OLA CICS PLT init start.
+BBOA9921I WAS z/OS OLA CICS TRUE enabled.
+BBOA9925I WAS z/OS OLA CICS PLT init ending.
```

Optimized local adapters for z/OS usage scenarios

Optimized local adapters and the supporting native API callable services provide an alternative path for enterprise architecture and application development on the z/OS platform.

Using optimized local adapters provides existing business and middleware applications that are written in native languages like Cobol, PL/I, C/C+, and high-level assembler, and running under environments such as z/OS batch, Customer Information Control System (CICS), Information Management System (IMS), and UNIX System Services (USS), an alternative way to call Java applications that are implemented as Enterprise JavaBeans (EJB) applications on WebSphere Application Server for z/OS.

Optimized local adapters support is also provided for calling from applications that are running on WebSphere Application Server to an external server program running locally or on the same logical partition (LPAR), using the Java EE Connect Architecture (JCA) programming model Version 1.5. The target external server programs might be business or middleware applications that are developed using Cobol, PL/I, C/C+, or high-level assembly languages.

A scenario where the optimized local adapters can provide increased performance is CICS or IMS support for the use of server and client Web services. The targeted backend applications can call business logic that is located elsewhere in a more efficient manner when using the optimized local adapters instead of XML and SOAP messaging technology. Web services is a scenario where you can improve efficiency by using optimized local adapters. The following hypothetical real-world scenarios describe how the optimized local adapters are useful in various business goals.

Financial services company scenario

An IBM z/OS financial services customer that is running business applications under CICS must decide about purchasing a financial processing application, which provides new support for stock trade real-time reporting to the exchanges. The ability to do this style of real-time reporting can result in increasing revenue for the customer.

The application that does real-time reporting is developed as a Java Enterprise Edition (Java EE)-based application and deployed on WebSphere Application Server on a Windows XP platform. The application offers a set of enterprise beans and associated Web services interfaces that can be called for various kinds of interactions.

A test scenario is developed and successfully implemented to call the Java EE application from a CICS Cobol program. Therefore, the customer decides to move forward and do more rigorous testing. Further testing shows that when this mechanism is pressed by more than 50-100 requests per second, it begins to slow to the point where the response times do not meet the customer requirements. The effort is abandoned until a more realistic approach is available for exchanging information in real time between the CICS business application and the new vendor application.

The optimized local adapters can provide this CICS customer with an option to deploy WebSphere Application Server for z/OS and update the CICS application to use the optimized local adapters Invoke or Send Request API. These APIs provide a way to call EJB applications that are deployed on a local WebSphere Application Server for z/OS server, which calls the business logic for the Web service.

Insurance company scenario

An IBM z/OS insurance industry customer that is running a business application under CICS wants to provide customers with the ability to retrieve and update policy information in real time. This information must be gathered in various ways and from several places, including:

- Information directly gathered from DB2
- Information gathered by calling a program in CICS
- Information gathered by starting a Web service to communicate with a remote service provided by another company

The customer chooses to use a Java application for several reasons, but most importantly because most of their programming skills are Java-based. When the new application is tested, the customer experiences long response times when retrieving information. The slow response time is a result of WebSphere Application Server running on a distributed server and the latency involved with communicating remotely with DB2 while calling CICS using Web services and SOAP messages.

To fix the problem, the customer deploys multiple WebSphere Application Server in the same configuration to reduce the number of requests per second on any one of the servers and to spread the requests across separate network paths.

Using optimized local adapters gives the customer an alternative other than deploying multiple servers. The customer could install WebSphere Application Server for z/OS and install the new application on a server on z/OS, closer to the DB2 and CICS environments. For the calls to CICS from WebSphere Application Server, using the optimized local adapters APIs provides a significant boost over the Web services and SOAP solution. Consolidating like this on z/OS platforms reduces the need for more distributed servers that consume floor space, power, and resources to maintain. In this scenario, since the location of the data and applications is the gating factor, increasing the size of the remote server to the most robust one available does not necessarily solve the problem.

Migrating business logic to WebSphere Application Server for z/OS

A customer has years of application logic with Cobol running inside of CICS. They want to migrate some of these applications to WebSphere Application Server to take advantage of Java and Java EE technologies, and use other capabilities in the WebSphere stack.

One of the applications is too large to migrate in one piece, and they would like to gradually move portions of it to WebSphere Application Server. The transactional and security qualities of service provided by CICS must be maintained during the transition, and the performance impact of the transition must be minimal. Using optimized local adapters, portions of the application can be migrated to WebSphere Application Server and wrapped in a stateless session bean. The application logic written in Cobol can be modified to use the optimized local adapter to call the stateless session beans. These calls to WebSphere Application Server run under the same transaction and security contexts used by the Cobol programs running in the CICS region. There is a significant performance gain when compared to making similar calls using a Web service. The customer can continue to relocate portions of the application to WebSphere Application Server until the application is migrated.

Optimized local adapters performance considerations

When using the WebSphere Application Server for z/OS optimized local adapters APIs, there are several areas that need to be considered regarding performance.

The optimized local adapter APIs are designed to provide optimal performance for calling between an external address space and applications on WebSphere Application Server for z/OS, and are expected to establish new kinds of application patterns which supports fine-grained interactions between applications in these environments. The following information describes issues to be aware of regarding optimized local adapters and performance. This content is designed to help you understand the configuration options for using the optimized local adapters in order to achieve the best performance. Benchmark results comparing optimized local adapters to other technologies for synchronous calling between WebSphere Application Server and external address spaces on the same system, like SOAP over HTTP, are not documented here. For this information, read the WebSphere Application Server for z/OS Performance Report.

Selection of Connection Minimum and Maximum Connection values for Register API call

Selecting a value that is too high for the minimum number of connections parameter on the Register API call is not recommended and can degrade performance. This results in a call from the external address space to the WebSphere Application Server control region to establish each connection and add it to the optimized local adapters connection pool during the Register API call. When these connections are established with a server, the connections remain until an Unregister API call is received, at which time WOLA disconnects the connections from the server and removes them from the available connection pool. Setting a minimum value too high results in more memory consumed and adds path length cost to the Register and Unregister APIs. Select a minimum connections value that is best for your need. If the

expectation is that there is a potential for hundreds of simultaneous threads sharing a registration, then it might make sense to pay for the cost of the connections during registration. If the expected number of concurrent threads sharing a registration is lower, then it is recommended that the minimum connections value is set lower.

The maximum connections Register API parameter provides a boundary for the number of connections in the optimized local adapters connection pool for a registration. This is not extendable for the life of the registration. Once the number of concurrent Connection Get requests exceeds this value, the calling thread waits the specified number of seconds set on the Wait Time parameter for Connection Get, Invoke, Receive Request Any, or Host Service APIs for a connection to become available. Once this time expires, a return and reason code are passed back indicating a connection handle cannot be acquired for the request before the wait time expired. There is a maximum size for the connection pool for any single registration which can be set. This value is derived by the cell-wide environment variable, WAS_DAEMON_ONLY_adapter_max_conn. The shipped default value for this variable is 100. The value can be changed using the administrative console. You must restart of the daemon after the setting is changed.

Effect of Connection Minimum and Maximum settings on the optimized local adapters CICS Link server

When starting a Link server task under Customer Information Control System (CICS) (using BBOC START_SRVR), if the minimum connections (MNC) and maximum connections (MXC) parameters are not passed, the MNC register setting defaults to `1` and the MXC defaults to `10`. This means that the number of Link invocation tasks (BBO# tasks) that can be started and run concurrently by the starting Link server (BBO$) task is 10. This translates to the number of concurrent threads from WebSphere Application Server that can run and start CICS target programs. The setting for MXC Link server parameter must reflect the expected duration of the typical target CICS programs that are expected to be started under this instance of the Link server. If the target CICS programs are mostly long-running, then a larger MXC value is appropriate to keep requests flowing efficiently from WebSphere Application Server into CICS. If the target programs are short-lived, then a lower MXC setting is more efficient.

Determining the correct MXC setting should also take into account how many WebSphere Application Server servant regions are communicating with a Link server under a specific registration name. If there is a single servant region and it is running with the threading option set to `ISOLATE` then only a single thread can be sending to CICS in that servant at once, so the MXC value would be set to the number of servants times 1 to ensure that there are no bottlenecks. If running with threading set to `LONGWAIT`, where up to 40 threads can be active per servant, depending on the expected number of requests and types of CICS programs being called, long-running or short-lived, the MXC should be set according to the expected number of concurrent requests across the servants to the Link server running for a specific registration name. It might take some experimentation to determine the optimum MXC setting. Start with a lower number and raise it gradually and settle where the throughput is determined to be best.

Shared 64-bit memory

The optimized local adapters support requires that the WebSphere Application Server for z/OS server runs in 64-bit mode. When the daemon group starts the first time with the WAS_DAEMON_ONLY_enable_adapter value set to `true` or `1`, WebSphere Application Server allocates a shared memory buffer in 64-bit above the bar storage and initializes it. The default size of this area is 32MB. This is where the optimized local adapters shared control structures all reside. It is not where message data is cached. Message and context data is flowed between external address spaces and WebSphere Application Server servant regions using WebSphere Application Server for z/OS local communications inter-address space technology, which stages message data in the server address space. For large messages, this is in 64-bit above the bar storage. Currently, WebSphere Application Server local communication supports a maximum message size of 2GB and in the initial optimized local adapters support, this is the largest supported size for single message.

If a misbehaved application continues to call the Register API and loop without calling Unregister and without terminating (where these are automatically cleaned up), it can overflow the optimized local adapters shared memory buffer for the daemon group. If this occurs, API calls are returned with out of memory reason codes. To diagnose this situation, issue the following command on one of the WebSphere Application Server servers in the effected daemon group:

```
F <server_name>,DISPLAY,ADAPTER,REGISTRATIONS
```

From the display output you should be able to determine what job is consuming and not releasing the registrations and rectify the problem by restarting it.

If, after analysis, the default 32MB is determined to be too small to meet the needs of the daemon group, this value can be changed using the WAS_DAEMON_ONLY_adapter_max_shrmem cell-wide environment variable. Changing this value should only be done after careful consideration. It requires a recreate of the optimized local adapters shared above the bar memory buffer, which can only be done with an IPL of the system.

You can get a rough estimate of the amount of memory needed. Each client registration consumes 392 bytes of shared memory, plus 112 bytes of shared memory for each connection. A registration with a maximum of 100 connections consumes about 12 KB of shared memory. Each client thread, which must wait for a connection to become available, (all connections are in use) consumes an additional 80 bytes. Each service being hosted by the registration consumes an additional 336 bytes.

For example, suppose you have 200 registrations in your daemon group. Each registration contains 200 connections, and will have a maximum of 1000 threads waiting for a connection at any time. The total memory consumed by this configuration is about 20 MB. This leaves enough shared memory to host about 38,000 services concurrently or 190 concurrent services per registration.

```
200 Registrations x 392 bytes=78,400 bytes
200 Registrations x 200 connections x 112 bytes=4,480,000 bytes
200 Registrations x 1000 waiters x 80 bytes= + 16,000,000 bytes
--------------------------------
20,558,400 bytes

33,554,432 bytes – 20,558,400 bytes=12,996,032 bytes remaining
/      336 bytes per service
---------------------------------
38,678 Services
```

When increasing or decreasing the size of the shared memory, remember that above-the-bar shared memory is allocated in 1MB sections. WebSphere Application Server rounds the value you specify upwards to the nearest MB.

Controlling the maximum number of concurrent outbound calls from WebSphere Application Server

There is a daemon-wide default setting that controls the maximum number of concurrent outbound from WebSphere Application Server calls for a single registration that is supported with optimized local adapters. The variable for controlling this is WAS_DAEMON_ONLY_adapter_max_serv. The default value is `100`. This means that there can be no more than 100 different target services running under a single registration (concurrent Host Service, Receive Request Any, or Receive Request Specific API calls). If this value is changed, a restart of the daemon is required.

With the default value of `100`, attempts to set up a thread as a 101st server for a specific registration name using one of the three APIs for this purpose results in a non-zero return and reason code indicating the adapter_max_serv was reached. If an application in WebSphere Application Server looks for this service and it is unavailable immediately, the application waits for a default value of `30` seconds before receiving an exception indicating a timeout occurred waiting for the requested service. In theWebSphere Application

Server servant log this appears as a C9C24C15 minor code. The default 30 seconds for this timeout can be modified by the application using the setConnectionWaitTimeout() method on the Java EE Connector Architecture (JCA) ConnectionSpecImpl.

Optimized local adapters CICS Link server performance considerations

The optimized local adapters support for the CICS Link server can be used to provide a simple means for invoking existing CICS application programs from applications running on WebSphere Application Server for z/OS. When you start the Link server using the BBOC transaction, or the CICS PLTPI program BBOACPL2, the optimized local adapters Link server task (BBO$) starts and receives program link requests from WebSphere Application Server. The Program Link task (BBO#) is then initiated, which in turn issues an EXEC CICS LINK to the target program, receives the response, and sends it back to the WebSphere Application Server caller. Part of this support involves propagating and asserting the WebSphere Application Server application thread-level identity onto the target CICS task. The propagation and assertion of the identity is requested using the SEC=Y parameter on the BBOC START_SRVR command.

Running a Link server with SEC=N and using the identity of the user ID that initiated the Link server yields the better performance, but might not be aligned with the security and auditing requirements of your organization.

If it is determined that the Link server can run with SEC=N, the best performance is achieved by also running with the REU=Y BBOC START_SRVR parameter. REU=Y results in the Link server reusing the program Link invocation tasks (BBO# transactions) between program invocation requests.

Important: If you run the Link server in this configuration, the support in the optimized local adapters JCA for passing a separate LINK transaction ID for individual requests is disabled and a request for this results in a ResourceException thrown back to the application. Also, if you attempt to select REU=Y and SEC=Y, the reuse option is forced to No as the Link server must start a new Program Link task for each request with the identity that was propagated asserted.

Running with the REU=Y option means that the Program Link tasks (BBO#s) remain active, once started, until a BBOC STOP_SRVR or BBOC UNREGISTER is entered for the registration. If you are running with a high MXC value on BBOC START_SRVR and a large number of requests arrive concurrently, the number of BBO# tasks can get high and these do not terminate until the Link server is stopped. This is another issue to consider when determining whether to use REU=Y and what is an appropriate MXC value.

If the goal is to achieve the fastest performance for calling into an application under CICS from WebSphere Application Server, consider coding the Host Service (BBOA1SRV), Receive Request Any (BBOA1RCA), or Receive Request Specific (BBOA1RCS) APIs directly in your application program. With this, there is no built-in support for identity propagation as the Link server provides, but if this is not required and performance is a high enough priority, then direct use of the APIs might be the best option.

JCA considerations

When using the optimized local adapters JCA resource adapter, keep in mind that there is additional overhead with each connection that is obtained from the ConnectionFactory object. If your application must make several calls to an external address space or CICS in the same application method, using the same connection for each interaction performs better than obtaining a different connection for each interaction. In addition, a JCA interaction object can be used repeatedly within the same application method.

When creating the JCA ConnectionFactory for optimized local adapters, it is possible to modify the minimum and maximum size of the JCA connection pool for that ConnectionFactory. This connection pool represents logical connections, which are bound to physical connections (those specified on your BBOA1REG register call) during an interaction. For optimal performance, the size of the JCA connection

pool should be the same size of the physical connection pool set during BBOA1REG. If your JCA connection pool is set too small, your application might have to wait for a JCA connection object, even though there are physical connections available. Your physical connection pool is shared by all servant regions, so if you have multiple servant regions, you might want to decrease the size of the JCA connection pool for each servant region to keep the total number of JCA connections across all servant regions in line with the size of the physical connection pool.

Developing applications that use optimized local adapters

Using the optimized local adapters native APIs to invoke an EJB application from an external address space

Use this task when you want to use the optimized local adapters native APIs to connect an external address space to WebSphere Application Server for z/OS and invoke an Enterprise JavaBeans (EJB) application that is deployed on the application server.

Before you begin

The WebSphere Application Server daemon group must be active on the same z/OS image that the register request originates from.

When running under Customer Information Control System (CICS), the optimized local adapters task related user exit (TRUE) program must be activated before a connection is made between CICS and WebSphere Application Server. To read about how the TRUE program is activated by the transactions, see the topic, Installing the BBOC, BBO$ and BBO# transactions on the client environment, and the topic, WebSphere Application Server transactions BBOC, BBO$, BBO#. For programs running in z/OS batch and UNIX Systems Services (USS), activating the TRUE program is not required. Ensure that the current address space has already registered and bound to the target WebSphere Application Server daemon group with a call to the Register, BBOA1REG API.

About this task

The adapter APIs invoke a stateless session bean is from an external native language program and retrieves the response. This is designed for exploiters wanting more flexibility and where the response area maximum length is not known before-hand.

Procedure

1. The client address space native language application, such as Cobol, PL/I, C/C++, assembler program, calls the BBOA1CNG Connection Get API and passes the register name it used for the register call. A connection handle is returned that must be used for all future API calls.
2. The client application gathers its parameters and designates the target service name as the Java Naming and Directory Interface (JNDI) home interface path name for the enterprise bean that it wants to invoke and calls the BBOA1SRQ Send Request API. This results in a connection to the WebSphere Application Server control region and then to a Workload Manager (WLM)-derived servant region where the passed JNDI home interface executes its create method. The preset method, execute, is located and invoked with the byte array parameters. Control returns immediately back to the caller if the asynchronous parameter is specified and set to `1`. When the asynchronous parameter is set to `0` (zero), the API returns the length of the response in the ResponseLength parameter, as well as the return value.
3. In the WebSphere Application Server servant, the execute method of the target bean invokes business logic. The execute method of a target bean can now invoke the business logic it requires before returning the response data as a serialized byte array back to the native language caller.
4. A 0 (zero) return code and reason code indicates that the Client API Send_Request was queued successfully. With the asynchronous parameter set to `0` (zero), the response length is provided in the

ResponseLength parameter, as well as the return value. With the asynchronous parameter set to 1, the response might not be ready and a call to the BBOA1RCL Receive_RespLen API is required to determine if the response arrived and the length response.

5. For asynchronous Send_Request calls, the client application calls the BBOA1RCL Receive_RespLen API with either asynchronous 0|1 call. The asynchronous 0 (zero) call indicates that the adapter API must block the thread until a response is received. The asynchronous 1 call indicates that the adapter API returns immediately whether the response has arrived or not.
6. A 0 (zero) return code and reason code indicate that the Receive_RespLen client API call successfully completed. With the asynchronous parameter set to 1, a ResponseLength and return value of all 0xFFs indicates there is no response received yet on the passed connection. This provides the client application with more control over the way it sends requests and receives responses. The client can group send requests and send them in sequence over a group of connections and then periodically poll these connections for responses. A connection that is processing a Send_Request with the asynchronous 1 call, cannot be passed another Send_Request for the same connection until the related Receive_RespLen and Get_Data API calls are processed.

   Important: Using these APIs asynchronously with the asynchronous parameter set to 1, grouping send requests, and processing them simultaneously, can only be done on connections that are configured as non-transactional. For example, when using CICS, you want to align a unit of work with an RRS unit of recovery, and a syncpoint under CICS must be propagated to WebSphere Application Server, there can only be a single connection to a specific WebSphere server in the current CICS task. That request receives a warning return code, which indicates that the adapter does not propagate the commit across more than one connection to the same server in the same CICS task.
7. Client applications use the response length that is returned by Receive_RespLen API to ensure it has an area large enough to hold the response data and uses the BBOA1GET Get Data API call to copy the response data into its buffer.
8. Client applications repeat this using the same connection handle until it is ready to release the connection. When the connection is released, the BBOA1CNR Connection_Release is called. Connection handles must be released before they can be retained on a Connection Get API call and used again.

Results

The client invoked a stateless session bean from WebSphere Application Server using the optimized local adapter APIs.

Using the Invoke API to call an enterprise bean from an external address space

Use this task when you want to use the Invoke API to call a stateless session bean from an external address space that is in an application that is deployed on a locally attached WebSphere Application Server for z/OS.

Before you begin

The WebSphere Application Server daemon group must be active on the same z/OS image that the register request originates from. Ensure that the current address space has already registered and is bound to the target WebSphere Application Server cell using the Register API.

About this task

This method is designed for high-level exploiters looking for a simplified path where the response area length is known beforehand.

Procedure

1. Set up the client address space native language application, such as Cobol, PL/I, C/C++, or assembler program, to gather its parameters and designate the target service name as the Java Naming and Directory Interface (JNDI) home interface path name for the stateless session bean that it wants to start.
2. Call the Invoke (BBOA1INV) API. In the target Enterprise JavaBeans (EJB) application, the execute method runs and then starts any business logic that is required before returning the response data as a serialized byte array back to the native language caller.
3. Review the response data. A `0` return code and reason code indicates that the client Invoke API completed successfully and the response data and response data length are saved in the areas designated by the caller.
4. The client application repeats these steps using the same register name call, calling as many stateless session beans as needed, and as often as needed.

   Attention: With this API, the three primitive functions, Send_Request, Receive_RespLen, and Get_Data are all completed using the Invoke API. The calling thread is blocked until the response data is received and copied to the response area.

Results

The client started a stateless session bean from WebSphere Application Server using the optimized local adapter Invoke API.

Calling an enterprise bean from an external address space within a client-initiated transaction

Use this task when you call an Enterprise JavaBeans (EJB) application that is deployed on WebSphere Application Server for z/OS from an external address space within a client-initiated transaction. The Customer Information Control System (CICS) environment is the only environment where transactional support is supported.

Before you begin

The client process must be running on a z/OS operating system, and the client environment must support transactional semantics. The connection between the client and the WebSphere Application Server server is configured to support transactions. Also, the client must have called the Register API with the TRANSACTIONAL flag set to the value of `1`.

About this task

This process starts when you begin a transaction in a client environment. The client calls an EJB application that is running on WebSphere Application Server for z/OS and propagates the new transaction to the application server. The semantics for starting a transaction in the client environment varies based on the client environment. Refer to the CICS documentation for information about the semantics for starting a transaction in a CICS client environment.

Procedure

1. Deploy an EJB application on WebSphere Application Server. Use a transaction attribute, such as required, support or mandatory, on the execute method.
2. Start a transaction on the client application using the transactional semantics. The client application performs transactional work that is required in the client environment.
3. Use the Invoke (BBOA1INV) API or the Send Request (BBOA1SRQ) API to make a remote call with the client program to the EJB application that is deployed on WebSphere Application Server. The transaction context propagates to the WebSphere Application Server server and the EJB application runs under the transaction context.

4. Use the transactional semantics of the client environment to commit or end the transaction independent of the outcome of the WebSphere Application Server server transaction.

Results

The new transaction is propagated to the WebSphere Application Server for z/OS server. The client commits the transaction and a single two-phase commit completes the transaction across the two address spaces.

Calling an enterprise bean from an external address space while ignoring the client transaction context

Use this task when you want to call an Enterprise JavaBeans (EJB) application that is deployed on WebSphere Application Server for z/OS from an external address space while ignoring the client transaction context. The only environment where transactional semantics are supported is Customer Information Control System (CICS).

Before you begin

The client process must be running on a z/OS operating system and the client environment must support transactional semantics. The connection between the client and the WebSphere Application Server is configured to support transactions. Also, the client must have called the Register API with the TRANSACTIONAL flag set to the value of 1.

About this task

The semantics for starting a transaction in the client environment varies based on the client environment. Refer to the CICS documentation for information about the semantics for starting a transaction in a CICS client environment.

Procedure

1. Deploy an EJB application on WebSphere Application Server using a transaction attribute of not supported, never or requires new on the execute method.
2. Start the client program transaction using the transactional semantics and perform transactional work that is required in the client environment.
3. Use the Invoke (BBOA1INV) API or the Send Request (BBOA1SRQ) API to make a remote call to the EJB application that is deployed on WebSphere Application Server for z/OS. The transaction context propagates to the WebSphere Application Server server, but the EJB application creates a new local or global transaction context, depending on the transaction attribute used by the EJB application.
4. The WebSphere Application Server server transaction is committed at the end of the execute method.
5. Use the transactional semantics of the client environment to commit or end the transaction independent of the outcome of the WebSphere Application Server server transaction.

Results

The new transaction is propagated to the WebSphere Application Server for z/OS. The server ignores the transaction context and drives the EJB call inside its own unit of work, which commits independent of the client's unit of work when the EJB call returns.

Using optimized local adapters to connect to an application in an external address space from a WebSphere application

Use this task when you want to use the outbound APIs to connect to an application in an external address space from an application that is deployed on WebSphere Application Server for z/OS.

Before you begin

The daemon group, address space, and external address space must be set up to use the optimized local adapters APIs. The external address space must be registered in the daemon group by calling the BBOA1REG API.

The application that is running in the external address space must have established itself as an optimized local adapters server task using one of the APIs, including BBOA1SRV, BBOA1RCA or BBOA1RCS.

The optimized local adapters resource adapter archive (RAR) file, ola.rar, is deployed and configured using the WebSphere Application Server administrative console or the `olaRar.py` script.

Procedure

1. Locate the application deployment descriptor in the application that makes the external call. This is the application that is deployed on WebSphere Application Server for which you want to make an outbound call from.
2. Create a resource reference that points to the optimized local adapter connection factory. The optimized local adapter connection factory is created when the `ola.rar` file is installed on WebSphere Application Server.
3. Locate the connection factory for the optimized local adapter. You can find the connection factory by looking up the resource reference in the Java Naming Directory Interface (JNDI), for example:

   ```
   Context ctx = new InitialContext();
   ConnectionFactory cf = ctx.lookup("java:comp/env/ola");
   ```
4. Create a ConnectionSpecImpl method call and provide the register name to connect to. You can either use the Register name as an attribute on the managed connection factory or use the ConnectionSpecImpl method, setRegisterName, to provide the registration name for the application that is running in the external address space or subsystem that you want to connect to. This must be the same registration name that was provided by the application in the external address space or subsystem using one of the server optimized local adapters APIs, BBOA1SRV, BBOA1RCA, or BBOA1RCS. For example,

   ```
   ConnectionSpecImpl csi = new ConnectionSpecImpl();
   csi.setRegisterName ("MyRES1");
   ```

   Attention: Setting the register name on the ConnectionSpecImpl object is not necessary if the register name was specified using the RegisterName custom property on the ConnectionFactory object.

   Attention: If you want to use the resource adapter high availability feature, you must ensure that your application does not use the setRegisterName method and instead you must configure the target Register name in the managed connection's connection factory attributes. Refer to the topic, Enabling resource adapter high availability support, for more information on how to configure high availability.
5. Optional: If you are calling an Information Management System (IMS) transaction that does not use the optimized local adapter server APIs, BBOA1SRV, BBOA1RCA, or BBOA1RCS, use this step to set the IMS Open Transaction Manager Access (OTMA) parameters. You can either set the IMS OTMA server name, XCF group ID and transaction level as attributes on the managed connection factory, or use the corresponding ConnectionSpecImpl setter methods, setOTMAServerName, setOTMAGroupID, and setOTMATranLevel, to provide this information for the application that is running in the external address space or subsystem that you want to connect to.

   Attention: When you use optimized local adapters over OTMA, the registration name does not have a counterpart on the IMS transaction side. The registration name can be set, but it is not used for optimized local adapter calls over OTMA. For more information, see the topic Calling existing IMS transactions with optimized local adapters over OTMA.
6. Use the connection factory to create a connection, for example:

```
Connection con = cf.getConnection(csi);
```

Results

Your application that is deployed on WebSphere Application Server is connected to an external address space and ready to call the services that are hosted on the external address space.

Using the outbound APIs with the external address space or subsystem

Use this task to create an interaction between the outbound APIs and the external address space or subsystem.

Before you begin

Establish a connection with an external address space or subsystem as described in the topic, Using the optimized local adapters to call an external address space or subsystem from a WebSphere Application Server on z/OS application.

Procedure

1. Optional: Start a resource manager local transaction (RMLT) if you are using a Customer Information Control System (CICS) server task that supports transactions. To use a CICS server task that supports transactions, the keyword TXN=Y is used when starting the server task. You can start an RMLT to encapsulate several interactions in a single unit of work. Your Java Enterprise Edition (Java EE) application component must not be running on a global transaction and must have a LocalTransaction boundary set to Application in its application deployment descriptor. The following example shows how to start the local transaction using the LocalTransaction object, after the deployment descriptor has been changed:

   ```
   LocalTransaction lt = con.getLocalTransaction();
   lt.begin();
   ```

   For more information about how to change the LocalTransaction setting on an application deployment descriptor, see the topic, Configuring transactional deployment attributes.

   If your Java EE application component is configured to use the LocalTransaction boundary,`ContainerAtBoundary`, the connection is automatically enlisted in an RMLT when the connection is obtained. The work that is done when using that connection is automatically completed when the Java EE application component ends.

   If your Java EE application component is starting in a global transaction, the connector is automatically enlisted in the global transaction when the connection is obtained. The work done when using that connection is automatically completed when the Java EE application component ends. The ConnectionFactory object that is used to obtain your connection must have the RegisterName custom property set to participate in a global transaction.
2. Create an interaction using the connection object, for example:

   ```
   Interaction int = con.createInteraction();
   ```
3. Create an InteractionSpecImpl object and set the service name into the interaction spec. The service name describes the name of the method or function that you want to call on the remote system. The service name was provided when the remote system called the host or one of the Receive Request APIs, or when using the Customer Information Control System (CICS) server task is the program name to start inside CICS, for example:

   ```
   InteractionSpecImpl isi = new InteractionSpecImpl();
   isi.setServiceName("MYSERVICE");
   ```

   Attention: When you use optimized local adapters over OTMA, the service name is not defined and the target IMS transaction is specified in the message stream. The service name can be set, but it is not used for optimized local adapters over OTMA. For more information, see the topic, Calling existing IMS transactions with optimized local adapters over OTMA.

4. Run the interaction using the created interaction spec, for example:
   ```
   int.execute(isi, null);
   ```
5. If your application used an RMLT, commit or back out the work after you are finished with your last interaction. Use the commit or rollback methods on the LocalTransaction object, for example:
   ```
   lt.commit();
   ```

Results

The interaction with the external address space or subsystem is complete.

Attention: When using an RMLT or global transaction, if the CICS application issues a sync point during the RMLT or global transaction, the server task issues a BBOX abend during the sync point. This causes the sync point to fail and an ASPx abend is generated by CICS. The CICS application should wait for WebSphere Application Server to issue the sync point operation by calling the commit or rollback method on the LocalTransaction object, or by letting the Java EE application component finish.

Attention: If you want to define the maximum time that a CICS transaction can run when a global transaction context or RMLT is imported into CICS from WebSphere, modify the OTSTIMEOUT parameter value on the transaction definition that is used to start the CICS link server link task. By default, the transaction name is BBO#. If the CICS transaction run time exceeds the time that is specified by the OTSTIMEOUT parameter, the CICS task that is running the CICS transaction abends, causing the entire global transaction or RMLT to roll back. For information about how to code the OTSTIMEOUT parameter on the transaction definition, see the CICS Transaction Server for z/OS Resource Definition Guide.

If your Java EE application component is participating in an RMLT or global transaction, and the application is communicating with a batch program or a CICS link server started with keyword TXN=N, the optimized local adapter connection is not able to establish a connection to the target program. The target program is not able to provide the transaction capabilities required by the Java EE application. An exception displays with minor code 0xC9C24C3B. This code indicates that the target registration name is found but is not enabled for transactions. Only CICS link servers enabled with keyword TXN=Y can support propagating transactions from WebSphere Application Server for z/OS.

Example

The following method shows how to start an interaction with input and output data as a byte array (byte[]):

```
public byte[] driveInteraction(javax.resource.cci.ConnectionFactory cf,
javax.resource.cci.Connection con,byte[] inputDataBytes),throws javax.resource.ResourceException
 {
 // Create an interaction using the optimized local adapter connection
   javax.resource.cci.Interaction i = con.createInteraction();
 // The InteractionSpec describes the service we want to call
   com.ibm.websphere.ola.InteractionSpecImpl isi = new com.ibm.websphere.ola.InteractionSpecImpl();
   isi.setServiceName("MYSERVICE");
 // The input data is specified using an IndexedRecord.  The first
 // slot in the indexed record contains the input data bytes.
   javax.resource.cci.RecordFactory rf = cf.getRecordFactory();
   javax.resource.cci.IndexedRecord ir = rf.createIndexedRecord(null);
   ir.add(inputDataBytes);

 // The interaction returns another IndexedRecord, whose first
 // slot contains the output data bytes.
   javax.resource.cci.Record or = i.execute(isi, ir);
   byte[] outputDataBytes = null;

   if (or != null)
   {
      outputDataBytes = (byte[])((javax.resource.cci.IndexedRecord)or).get(0);
   }
```

```
// Return the output data to the caller
  return outputDataBytes;
  }
```

The following method shows how to start an interaction using a Rational Application Developer generated copybook Record object:

```
/**
* An example of driving an optimized local adapter interaction, using a Rational
 * Application Developer copybook mapping class as input (inputRecord) and receiving
 * a Rational Application Developer copybook mapping as output.
*/
  public javax.resource.cci.Record driveInteraction(
   javax.resource.cci.Connection con,
   javax.resource.cci.Record inputRecord)
   throws javax.resource.ResourceException
  {
// Create an interaction using the OLA connection
   javax.resource.cci.Interaction i = con.createInteraction();
// The InteractionSpec describes the service we want to call com.ibm.websphere.ola.InteractionSpecImpl isi =
  new com.ibm.websphere.ola.InteractionSpecImpl();
  isi.setServiceName("MYSERVICE");
// The Rational Application Developer generated copybook implements
// javax.resource.cci.Record and can be passed directly to the interaction.
// The interaction returns an IndexedRecord, whose first slot contains
 // the output data bytes.
   javax.resource.cci.Record or = i.execute(isi, inputRecord);
   javax.resource.cci.Record outputRecord = null;
   if (or != null)
  {
// In this example, RADGeneratedOutputType is the name of the Rational Application Developer
 // generated copybook mapping class.
   outputRecord = new RADGeneratedOutputType();
// The output bytes are stored in the output record returned on the
// interaction, which is an IndexedRecord.
  byte[] outputDataBytes =
    (byte[])((javax.resource.cci.IndexedRecord)or).get(0);

// To convert the output bytes to another Rational Application Developer generated copybook,
// call the setBytes(byte[]) method of that class.  The class will
// implement the  com.ibm.etools.marshall.RecordBytes interface.
  ((com.ibm.etools.marshall.RecordBytes)outputRecord)
       .setBytes(outputDataBytes);
  }

// Return the output data to the caller
     return outputRecord;
  }
```

Optimized local adapters for z/OS APIs

WebSphere Application Server for z/OS optimized local adapters are supported by a set of z/OS native language callable services, or application programming interfaces (APIs), and the Java EE Connector Architecture (JCA).

These callable services can be used from the following native programming languages:

- Cobol
- C/C++
- PL/I
- High Level Assembler

Each callable service has a 31-bit and a 64-bit version. The naming convention is BBOA1- for 31-bit API stubs and BBGA1- for 64-bit API callers.

A caller running in AMODE 64 can use the AMODE 31 versions of the APIs, provided the parameter list is below the bar and it passes parameter using 31-bit conventions (each parameter's pointer is a 31 bit address). Callers running in 64-bit must be in either C, C++, or assembler, and execute in 64-bit addressing mode. When using the BBGA1* 64-bit APIs from assembler applications, a format 4, or F4SA, 64-bit save area is required, which is used by the optimized local adapters stubs to save and restore the caller's registers. When calling from C or C++, the sample header in *<Prod_FS_root>*/util/zos/OLASamples/bboaapi.h defines the 64-bit APIs as external OS_NOSTACK, which ensures that they are called with the proper linkage and save area conventions.

When the term *local connection* is used in this API documentation, a reference is being made to a cross-memory link that is created for communication between an external address space on the z/OS system and the WebSphere Application Server on the same z/OS system. The client address space must be running on the same z/OS image. The adapter API manages these local connections in pools that are associated with each uniquely registered caller. The 12-character registration name can be used for one set only of connection pools per address space. There is no limit to the number of unique registrations in a single address space. It is limited only by the amount of available storage.

The API services are listed according to user goal, for example, the first section listed is Register. This section explains the APIs that are used in the task of registering an optimized local adapter so that it can be used in a call.

- Register - BBOA1REG/BBGA1REG
- Unregister - BBOA1URG/BBGA1URG
- Connection Get - BBOA1CNG/BBGA1CNG
- Connection Release - BBOA1CNR/BBGA1CNR
- Send Request - BBOA1SRQ/BBGA1SRQ
- Send Response - BBOA1SRP/BBGA1SRP
- Send Response Exception - BBOA1SRX/BBGA1SRX
- Receive Request Any - BBOA1RCA/BBGA1RCA
- Receive Request Specific - BBOA1RCS/BBGA1RCS
- Receive Response Length - BBOA1RCL/BBGA1RCL
- Get Message Data - BBOA1GET/BBGA1GET
- Invoke - BBOA1INV/BBGA1INV
- Host Service - BBOA1SRV/BBGA1SRV
- JCA Adapter APIs

Register

Using the BBOA1REG (for 31-bit callers) and BBGA1REG (for 64-bit callers) APIs, you can register with a local WebSphere Application Server for z/OS daemon group and server. The BBOA1REG and BBGA1REG APIs request that a group of optimized connections to a local WebSphere Application Server daemon group and server be allocated and registered under the specified "registername."

Table 12. BBOA1REG (31-bit caller) and BBGA1REG (64-bit caller) APIs syntax. The syntax is explained in the Parameters section.

API	Syntax

BBOA1REG or BBGA1REG	`BBOA1REG ( daemongroupname , nodename, servername , registername , minconn , maxconn , registerflags, rc, rsn )`
	
	`BBGA1REG ( daemongroupname, nodename , servername , registername , minconn , maxconn , registerflags , rc, rsn )`

Parameters

daemongroupname (input)

An entry variable or entry constant containing the name of the WebSphere Application Server for z/OS daemon group to be joined. The entry variable or constant must be passed by reference. The WebSphere Application Server z/OS daemon must be running and initialized on the local system. This must be a null-terminated string of exactly 8 characters.

nodename (input)

An entry variable or entry constant containing the name of the WebSphere Application Server for z/OS node (short name) to be joined. The entry variable or constant must be passed by reference. The WebSphere Application Server z/OS Server must be running and initialized on the local system. This must be a blank padded string of exactly 8 characters.

servername (input)

An entry variable or entry constant containing the name of the WebSphere Application Server for z/OS Server (short name) to be joined. The entry variable or constant must be passed by reference. The WebSphere Application Server z/OS server must be running and initialized on the local system. This must be a blank padded string of exactly 8 characters.

registername (input)

An entry variable or entry constant containing the name to be used to register a set of local connections. Later calls require this name to identify the pool of connections to use. This must be a blank padded string of exactly 12 characters and cannot be used in the current address space.

minconn (input)

An integer containing the initial minimum number of connections to allocate for this registration. The adapter attempts to reserve this number of connections with the associated server during registration.

Important: At minimum, one connection is allocated to bind with the target server, even if MINCONN is specified as zero (0). Specifying 0 is the same as 1.

maxconn (input)

An integer containing the maximum number of connections to allocate for this registration. The adapter attempts to extend the local connection pool up to this number during a Connection Get request when the minimum number of connections are all in use.

registerflags (input)

A 32 - bit flag word containing registration flags.

- **reg_flag_trans** - bit 30

  Contains a 1 if the transactional recovery is to be supported over connections under this registration and a 0 (zero) if the transactional recovery is not to be supported. When the transactional parameter is enabled, the adapter API attempts to register with the z/OS Resource Recovery Services (RRS) and a global transaction supporting two-phase commit is created between WebSphere Application Server and the API exploiter's environment.
- **reg_flag_W2Cprop** - bit 31 or bit 64

  The reg_flag_W2Cprop controls WebSphere Application Server to CICS outbound transaction security propagation.
- **reg_flag_C2Wprop** - bit 29

Propagates the identity on the calling task from CICS to WebSphere Application Server. For transactions that are inbound from CICS to WebSphere Application Server, registration flag reg_flag_C2Wprop controls how the identity is determined. When this bit is turned *on*, the CICS application task identity is used in the WebSphere Application Server server authorization process. When this bit is turned *off*, the CICS region identity is used.

Attention: You must enable WebSphere Application Server for CICS application level security to be requested. Set the WebSphere environment variable, ola_cicsuser_identity_propagate, to `1` through the administrative console to set this type of security propagation.

- **reg_flag_trcmod** - bit 0

  Set reg_flag_trcmod if you want to modify the optimized local adapter trace settings for the requested registration. If you do not set this flag, no change to the trace setting is made, and the system defaults or predefined trace settings that apply to the registration name or job name are used.

- **reg_flag_trcmore** - bit 1 and **reg_flag_trcsome** - bit 2

  With reg_flag_trcmod set to 1, set either reg_flag_trcmore or reg_flag_trcsome to specify a trace setting if you want detailed tracing or coarse level tracing for the registration. Leaving both of them set to "off" with reg_flag_trcmod set to `1` forces no tracing for the registration no matter what pre-definitions or defaults are set.

`rc` (output)

An integer return code indicating success or failure of this call.

`rsn` (output)

An integer reason code describing the reason for a failure on this call.

Usage notes:

- Ensure that the WebSphere Application Server for z/OS daemon group and server specified on this call are started and the support for local adapters is enabled.
- The minimum connections requested is validated against the server maximum connections, which is configurable using the WebSphere Application Server administrative console. A minimum connection (minconn) value of `3` means that three connections are reserved during the register call. If more than three connections are requested at a given time, the connection pool can increase to the maximum connection (maxconn) value. When the number of all connections to a server reaches the maximum that is permitted, all subsequent Connection Get API requests for that server are rejected, even if the maxconn value is not yet reached.

  Important: Use caution in setting the minimum connections value. Except in specific instances, a large setting is not advised as resources in the WebSphere Application Server control region are reserved for each connection.
- Multiple calls to the Register API can be made under the same address space, thread, or Customer Information Control System (CICS) task, however, they cannot share the same register name. The register name must be a unique name.
- Setting the transactional parameter to `1` results in all connections for this registration running with transactionality. This means that RRS is attached from the current address space. See the section on Propagating Transactions for more details on the requirements and set up for this. Transactionality is only supported between WebSphere Application Server and CICS. Requests for `transactional(1)` from other environments results in a warning during the register call, the flag is ignored, and processing continues.
- Use the Unregister API call to remove this registration and release the connection pool associated with it.

- When the address space that makes a register call terminates, the registration is automatically terminated and the connections are released.

Return and reason codes:

Table 13. BBOA1REG and BBGA1REG APIs return and reason codes. The following table also recommends appropriate actions.

Return Code	Reason Code	Description	Action
0	-	Success	
4	-	Warning - see reason code	
	4	The transactional register flag was set to 1 in an environment where the adapter does not support global transactions.	This setting is ignored and processing continues.
8	-	Error - see reason code	
	8	The registration name token already exists.	You must unregister this name before calling the Register API for it.
	10	The maximum connections parameter exceeds the maximum number of connections permitted for any single registration.	The Register API request is rejected. Ensure that the target server maximum optimized local adapter value is large enough to accommodate this and all other requests. For more information about the WAS_DAEMON_ONLY_adapter_max_conn environment variable see the topic, Optimized local adapters custom properties, and the topic, Enabling the server environment to use optimized local adapters.
	12	The specified minimum connections parameter is larger than the maximum.	Ensure that the minimum connections setting is less than, or equal to, the maximum setting.
	14	Out of shared memory while trying to create registration.	Increase the shared memory allocation for the optimized local adapter or issue unregister calls to reduce resource consumption.
	21	An error occurred while attempting to contact with the local WebSphere Application Server.	If you set the reg_flag_C2Wprop bit (bit 29) to 1, ensure that the WebSphere environment variable, ola_cicsuser_identity_propagate, is set to 1.
	25	The transaction manager cannot be initiated.	Call IBM Support for assistance.
	70	Out of shared memory while trying to create a connection.	Increase the shared memory allocation for the optimized local adapter.
	74	Input register name contains a null.	Blank pad the register name before starting the Register API.
12	4	An error occurred while locating the BBOACALL module.	Ensure that the data set that contains the WebSphere Application Server BBOACALL module is available in the STEPLIB, LNKLST.
	10	Unable to locate the selectedWebSphere Application Server daemon group.	Ensure that the WebSphere Application Server daemon and target server are started, verify that the optimized local adapters support is active and try again.
	14	The user ID is not authorized for the requested WebSphere Application Server.	Ensure that the user ID is authorized to the CBIND SAF class for the requested WebSphere Application Server.
	16	The node name or server name is not found.	Ensure that the node name and server name parameters that are being passed are valid and that the server is active.
	23	An error occurred while naming the token.	Call IBM Support for assistance.
	24	An error occurred while establishing the initial WebSphere Application Server local communication connection.	Refer to the WebSphere Application Server region logs for details on the local communication connect call.
	28	The registration identified with this name is not valid.	The specified register name is already registered, but the RGE is missing. Contact IBM support and report the error. A workaround is to call the Unregister API and attempt to call the Register API again.
	30	The daemon group is not running with WAS_DAEMON_ONLY_enable_adapter property set to 1.	Add the variable:WAS_DAEMON_ONLY_enable_adapter=1 through the WebSphere Application Server administrative console.
	34	A 64-bit API stub was used in an IMS environment.	The 64-bit APIs are not supported under IMS.
	38	A 64-bit API stub was used in a CICS environment.	The 64 bit APIs are not supported under CICS.
	68	An attachment to shared memory failed.	Call IBM Support for assistance.
	86	WebSphere Application Server for z/OS master BGVT could not be located	WebSphere has not been started yet on the current z/OS system image. Ensure the daemon and a node/server are started before starting any WebSphere Application Server optimized local adapters client processes.

Table 13. BBOA1REG and BBGA1REG APIs return and reason codes (continued). The following table also recommends appropriate actions.

Return Code	Reason Code	Description	Action
	88	WebSphere Application Server for z/OS master client stub table could not be located.	A WebSphere Application Server has been started on the current z/OS system image, but is not running at the level where the optimized local adapters client stub table is supported. You are possibly running with a WebSphere Application Server Version 8.0.0.1 optimized local adapters stub interface that is not compatible with the maintenance level of the application server. To use the V8.0.0.1 optimized local adapters stubs, the application server must also be running at the WebSphere Application Server Version 8.0.0. level. Ensure your application is running with the level of the optimized local adapters stubs that are compatible with WebSphere Application Server on this z/OS system.
	90	WebSphere Application Server for z/OS optimized local adapters master client stub table slot could not be located.	A WebSphere Application Server has been started on the current z/OS system image, but is not running at the level where the optimized local adapters client stub table is supported. You are possibly running with a WebSphere Application Server Version 8.0.0.1 optimized local adapters stub interface that is not compatible with the maintenance level of the application server. To use the V8.0.0.1 optimized local adapters stubs, the application server must also be running at the WebSphere Application Server Version 8.0.0. level. Ensure your application is running with the level of the optimized local adapters stubs that are compatible with WebSphere Application Server on this z/OS system.

Unregister

Unregister from the local WebSphere Application Server for z/OS daemon group and server using the BBOA1URG (for 31-bit callers) and BBGA1URG (for 64-bit callers) APIs.

Table 14. BB0A1URG API (31-bit caller) and BBGA1URG (64-bit caller) syntax. This API requests that a group of optimized connections to a local WebSphere Application Server daemon group and server be released using the specified register name.

API	Syntax

BBOA1URG or BBGA1URG	`BBOA1URG (registername, unregflags, rc, rsn)`
	
	`BBGA1URG (registername, unregflags, rc, rsn)`

Parameters:

registername (input)

An entry variable or entry constant containing the name to be used to unregister a set of local connections. This must be exactly 12 characters, blank padded, and the same name used on BBOA1REG.

unregisterflags (input)

A 32 - bit flag word that contains unregistration flags.

- Reserved - bit 0-30
- Force (0|1) - bit 31 or bit 64

  Contains a 1 if the unregister request should be forced. By default, an unregister request is complete if all the connections have been returned to the connection pool. If all the connections are not returned to the pool, a warning is returned to the caller. The unregister process is complete when the last connection has been returned to the pool. A second unregister request can be made with the force bit set to 1, which forces the unregister process to complete and all remaining connection handles for that registration are invalidated.

rc (output)

An integer return code indicating success or failure of this call.

rsn (output)

An integer reason code describing the reason for a failure on this call.

Usage notes:

- Ensure that the WebSphere Application Server for z/OS daemon group and server specified on this call are started and the support for local adapters is enabled .
- If the Unregister API is not called, and the address space that made a register call terminates, an unregister call is done automatically and the connections are released.
- Any connection handles for this registration that are active when the unregister call occurs might continue to be valid until they are returned to the connection pool using the BBOA1CNR API. To force the connection handles to be cleaned up, a second unregister call must be made, specifying the force flag. This invalidates all outstanding connection handles.

Return and reason codes:

Table 15. BBOA1URG and BBGA1URG APIs return and reason codes. The following table also recommends appropriate actions.

Return Code	Reason Code	Description	Action
0	-	Success	
4	-	Warning - see reason code	
	66	The unregister call is delayed until all the connections are returned to the pool.	Unregistration completes when the last connection is returned to the free pool.
8	-	Error - see reason code	
	8	Registration token name does not exist.	You must register this name before calling the Unregister API for it.
	64	The *force* option cannot be specified until a normal unregister is issued.	Call the Unregister API without specifying the *force* option.
	76	An attempt to communicate with the server failed because the server is no longer running.	Start the server and try the communication again.
	82	An attempt has already been made to unregister this registration.	Wait for the previous unregister request to complete or reissue this unregister with the *force* option.
12	34	A 64-bit API stub was used in an IMS environment.	The 64-bit APIs are not supported under IMS.
	38	A 64-bit API stub was used in a CICS environment.	The 64 bit APIs are not supported under CICS.
	86	WebSphere Application Server for z/OS master BGVT could not be located	WebSphere has not been started yet on the current z/OS system image. Ensure the daemon and a node/server are started before starting any WebSphere Application Server optimized local adapters client processes.
	88	WebSphere Application Server for z/OS master client stub table could not be located.	A WebSphere Application Server has been started on the current z/OS system image, but is not running at the level where the optimized local adapters client stub table is supported. You are possibly running with a WebSphere Application Server Version 8.0.0.1 optimized local adapters stub interface that is not compatible with the maintenance level of the application server. To use the V8.0.0.1 optimized local adapters stubs, the application server must also be running at the WebSphere Application Server Version 8.0.0. level. Ensure your application is running with the level of the optimized local adapters stubs that are compatible with WebSphere Application Server on this z/OS system.
	90	WebSphere Application Server for z/OS optimized local adapters master client stub table slot could not be located.	A WebSphere Application Server has been started on the current z/OS system image, but is not running at the level where the optimized local adapters client stub table is supported. You are possibly running with a WebSphere Application Server Version 8.0.0.1 optimized local adapters stub interface that is not compatible with the maintenance level of the application server. To use the V8.0.0.1 optimized local adapters stubs, the application server must also be running at the WebSphere Application Server Version 8.0.0. level. Ensure your application is running with the level of the optimized local adapters stubs that are compatible with WebSphere Application Server on this z/OS system.

Connection Get

This API requests that an available connection from the pool created with the selected registration name is returned.

Table 16. BBOA1CNG (31 bit caller) and BBGA1CNG (64-bit caller) APIs syntax. The syntax is explained in the Parameters section.

API	Syntax

BBOA1CNG or BBGA1CNG	`BBOA1CNG ( registername, connectionhandle, waittime, rc, rsn )`
	
	`BBGA1CNG ( registername, connectionhandle, waittime, rc, rsn )`

Parameters:

registername (input)

An entry variable or entry constant that contains the name to be used to locate the connection pool from which to retrieve a connection. This must be a blank padded string of exactly 12 characters.

connectionhandle (output)

A 12 - byte connection handle that must be passed on later requests for actions on this connection.

waittime (input)

An integer containing the number of seconds to wait for the connection to complete before returning a connection unavailable reason code. A value of `0` implies there is no wait time and the API waits indefinitely.

rc (output)

An integer return code indicating success or failure of this call.

rsn (output)

An integer reason code describing the reason for a failure on this call.

Usage notes:

- Ensure that the WebSphere Application Server for z/OS daemon group and server specified on this call are started and the support for local adapters is enabled .
- Ensure that a successful register (BBOA1REG) call was completed in the current address space with a matching name before using the Connection Get API.

Return and reason codes:

Table 17. BBOA1CNG and BBGA1CNG APIs return and reason codes. The following table also recommends appropriate actions.

Return Code	Reason Code	Description	Action
0	-	Success	
4	-	Warning - see reason code	
8	-	Error - see reason code	
	8	The registration name token does not exist.	Ensure that you have registered this name before you try to call the name with the Connection Get API.

Table 17. BBOA1CNG and BBGA1CNG APIs return and reason codes (continued). The following table also recommends appropriate actions.

Return Code	Reason Code	Description	Action
	10	The connection is unavailable. The wait time expired before the connection request could be obtained.	The application behavior varies. Wait and try again, or abend this connection. Another option is to increase the maximum connections setting on the Register API call.
	24	After a successful register call, an error occurred when getting a connection from the pool.	Verify that the server is started. If it is not working, restart the server and try the API request again.
	28	Registration is found, but is inactive.	
12	10	Unable to locate the WebSphere Application Server daemon group or server.	Ensure that the WebSphere Application Server daemon and server are started and the local connections support is active and try again.
	34	A 64-bit API stub was used in an IMS environment.	The 64-bit APIs are not supported under IMS.
	38	A 64-bit API stub was used in a CICS environment.	The 64 bit APIs are not supported under CICS.
	86	WebSphere Application Server for z/OS master BGVT could not be located	WebSphere has not been started yet on the current z/OS system image. Ensure the daemon and a node/server are started before starting any WebSphere Application Server optimized local adapters client processes.
	88	WebSphere Application Server for z/OS master client stub table could not be located.	A WebSphere Application Server has been started on the current z/OS system image, but is not running at the level where the optimized local adapters client stub table is supported. You are possibly running with a WebSphere Application Server Version 8.0.0.1 optimized local adapters stub interface that is not compatible with the maintenance level of the application server. To use the V8.0.0.1 optimized local adapters stubs, the application server must also be running at the WebSphere Application Server Version 8.0.0. level. Ensure your application is running with the level of the optimized local adapters stubs that are compatible with WebSphere Application Server on this z/OS system.
	90	WebSphere Application Server for z/OS optimized local adapters master client stub table slot could not be located.	A WebSphere Application Server has been started on the current z/OS system image, but is not running at the level where the optimized local adapters client stub table is supported. You are possibly running with a WebSphere Application Server Version 8.0.0.1 optimized local adapters stub interface that is not compatible with the maintenance level of the application server. To use the V8.0.0.1 optimized local adapters stubs, the application server must also be running at the WebSphere Application Server Version 8.0.0. level. Ensure your application is running with the level of the optimized local adapters stubs that are compatible with WebSphere Application Server on this z/OS system.

Connection Release

The Connection Release API requests that a connection is returned to the pool that it was retrieved from and is made available for another requestor.

Table 18. BBOA1CNR (31-bit caller) and BBGA1CNR (64-bit caller) APIs syntax. The syntax is explained in the Parameters section.

API	Syntax

BBOA1CNR or BBGA1CNR	`BBOA1CNR ( connectionhandle, rc, rsn )`
	
	`BBGA1CNR ( connectionhandle, rc, rsn )`

Parameters:

`connectionhandle` (input)

A 12 - byte connection handle indicating the previously obtained connection that is to be released back into the connection pool.

`rc` (output)

An integer return code that indicates the success or failure of this call.

rsn (output)

An integer reason code that describes the reason that the call failed.

Usage notes

- Ensure that the WebSphere Application Server for z/OS daemon group and server that are specified on this call are started and the support for the local adapters is enabled.
- Before using the Connection Release API, ensure that a successful register (BBOA1REG or BBGA1REG API) call is completed in the current address space with a matching name, and a successful Connection Get (BBOA1CNG or BBGA1CNG) call completed to obtain the connection that is now to be released.

Table 19. BBOA1CNR and BBGA1CNR APIs return and reason codes. The following table also recommends appropriate actions.

Return Code	Reason Code	Description	Action
0	-	Success	
4	-	Unable to locate the WebSphere Application Server daemon group and server. Any resources that are related to this connection have been cleared.	None
8	-	Error-see reason code	
	36	The connection state is not valid.	The connection handle that is used for this request is in the wrong state. Refer to the API documentation for the rules on connection states.
	38	The client connection handle is not valid.	The client connection handle that is used for this request is not valid. Refer to the API documentation for information about client connection handles.
12	14	The API calling vector using the provided connection handle cannot be located or verified.	The connection handle is not valid or an unregister call (BBOA1URG API) might have invalidated the connection pool.
	34	A 64-bit API stub was used in an IMS environment.	The 64-bit APIs are not supported under IMS.
	38	A 64-bit API stub was used in a CICS environment.	The 64 bit APIs are not supported under CICS.
	86	WebSphere Application Server for z/OS master BGVT could not be located	WebSphere has not been started yet on the current z/OS system image. Ensure the daemon and a node/server are started before starting any WebSphere Application Server optimized local adapters client processes.
	88	WebSphere Application Server for z/OS master client stub table could not be located.	A WebSphere Application Server has been started on the current z/OS system image, but is not running at the level where the optimized local adapters client stub table is supported. You are possibly running with a WebSphere Application Server Version 8.0.0.1 optimized local adapters stub interface that is not compatible with the maintenance level of the application server. To use the V8.0.0.1 optimized local adapters stubs, the application server must also be running at the WebSphere Application Server Version 8.0.0. level. Ensure your application is running with the level of the optimized local adapters stubs that are compatible with WebSphere Application Server on this z/OS system.
	90	WebSphere Application Server for z/OS optimized local adapters master client stub table slot could not be located.	A WebSphere Application Server has been started on the current z/OS system image, but is not running at the level where the optimized local adapters client stub table is supported. You are possibly running with a WebSphere Application Server Version 8.0.0.1 optimized local adapters stub interface that is not compatible with the maintenance level of the application server. To use the V8.0.0.1 optimized local adapters stubs, the application server must also be running at the WebSphere Application Server Version 8.0.0. level. Ensure your application is running with the level of the optimized local adapters stubs that are compatible with WebSphere Application Server on this z/OS system.

Send Request

These APIs send a request into the local WebSphere Application Server for processing.

Table 20. BBOA1SRQ API (31-bit caller) and BBGA1SRQ (64-bit caller) APIs syntax. The syntax is explained in the Parameters section.

API	Syntax

BBOA1SRQ or BBGA1SRQ	`BBOA1SRQ ( connectionhandle, requesttype, requestservicename, requestservicenamel, requestdata, requestdatalen, async(0|1), responsedatalen, rc, rsn )`
	
	`BBGA1SRQ ( connectionhandle, requesttype, requestservicename, requestservicenamel, requestdata, requestdatalen, async(0|1), responsedatalen, rc, rsn )`

Parameters:

connectionhandle (input)

A 12 - byte connection handle that is to be used for this request.

requesttype (input)

An integer containing the request type that indicates the type of work request to process. Supported type values: 1 = local EJB work requests, 2 = Remote EJB work requests.

requestservicename (input)

An EBCDIC character string up to 256 bytes in length containing the name of the service to invoke. For Type=1, EJB, this is the JNDI Home name for the local target EJB. For Type=2, EJB, this is the JNDI Home name for the remote target EJB.

requestservicenamel (input)

An integer containing the length of the service name to start or `0` (zero) if the service name is null terminated.

requestdata (input)

A 31-bit or 64-bit pointer to the address of the start of the request data to send.

requestdatalen (input)

A 32-bit unsigned value in 31-bit mode or a 64-bit unsigned value in 64-bit mode containing the length of the data to send.

async(0|1) (input)

An integer value that when set to 1 indicates that the caller wants control returned immediately, even though the response length might not yet be known. For async(0), the current thread is requesting to wait for the response to be returned from the WebSphere Application Server and the response length is returned in the **responsedatalen** output argument.

responsedatalen (output)

A 32-bit unsigned value in 31-bit mode or a 64-bit unsigned value in 64-bit mode that contains the length of the response. This length can then be used by the caller to acquire storage before calling the Get Data API to copy it in. When async is set to 1, indicating the caller wants control back immediately, this is set to all 0xFFs if the response is not yet received.

rc (output)

An integer return code indicating success or failure of this call.

rsn (output)

An integer reason code describing the reason for a failure on this call.

Usage notes:

- Ensure that theWebSphere Application Server for z/OS daemon group and server specified on this call are started and the support for local adapters is enabled.
- Ensure that a successful register (BBOA1REG) call was completed in the current address space with a matching name before using the Send Request API.

Return and reason codes:

Table 21. BBOA1SRQ and BBGA1SRQ APIs return and reason codes. The following table also recommends appropriate actions.

Return Code	Reason Code	Description	Action
0	-	Success	
4	-	Warning - see reason code	
8	-	Error - see reason code	
	8	Register name token already exists.	Ensure that the register name passed is valid.
	14	An out of memory condition occurred while saving the message.	There is not enough memory available for Send Request to process the message. The current address space is out of private storage.
	16	The request service name length is not valid.	Correct the program and try again.
	18	The request length exceeds the system limits.	The message size is larger than the WebSphere Application Server size can support. Verify that the size is valid. If the size is valid, ensure that the WebSphere Application Server size is large enough to accommodate the message size.
	26	Global transaction could not begin.	
	32	The API call request type is not valid.	The request type is not valid. Correct the program and try the call again.
	34	The target service is not found.	Ensure that the application that contains the target enterprise bean is installed and started in the target server for WebSphere Application Server.
	36	The connection state is not valid.	The connection handle that is used for the request is in the wrong state. Refer to the API documentation for the rules on connection states.
	38	The client connection handle is not valid.	The client connection handle that is used for the request is not valid. Refer to the API documentation for information about client connection handles.
	40	A local communication error occurred.	Check the WebSphere Application Server server log for any local communication error messages.
	44	An exception or unexpected condition occurred in the target enterprise bean.	Refer to the WebSphere Application Server logs to review the exception data.
	46	An error occurred in the local communication send request call.	Check the WebSphere Application Server logs to determine the error.
12	10	Unable to locate theWebSphere Application Server daemon group or server.	Ensure that the WebSphere Application Server daemon and server are started and the local connections support is active. Retry to locate theWebSphere Application Server daemon group and server.
	14	The API calling vector using the provided connections handle cannot be located or verified.	The connection handle is not valid or an unregister call (BBOA1URG API) might have invalidated the connection pool.

Table 21. BBOA1SRQ and BBGA1SRQ APIs return and reason codes (continued). The following table also recommends appropriate actions.

Return Code	Reason Code	Description	Action
	34	A 64-bit API stub was used in an IMS environment.	The 64-bit APIs are not supported under IMS.
	38	A 64-bit API stub was used in a CICS environment.	The 64 bit APIs are not supported under CICS.
	86	WebSphere Application Server for z/OS master BGVT could not be located	WebSphere has not been started yet on the current z/OS system image. Ensure the daemon and a node/server are started before starting any WebSphere Application Server optimized local adapters client processes.
	88	WebSphere Application Server for z/OS master client stub table could not be located.	A WebSphere Application Server has been started on the current z/OS system image, but is not running at the level where the optimized local adapters client stub table is supported. You are possibly running with a WebSphere Application Server Version 8.0.0.1 optimized local adapters stub interface that is not compatible with the maintenance level of the application server. To use the V8.0.0.1 optimized local adapters stubs, the application server must also be running at the WebSphere Application Server Version 8.0.0. level. Ensure your application is running with the level of the optimized local adapters stubs that are compatible with WebSphere Application Server on this z/OS system.
	90	WebSphere Application Server for z/OS optimized local adapters master client stub table slot could not be located.	A WebSphere Application Server has been started on the current z/OS system image, but is not running at the level where the optimized local adapters client stub table is supported. You are possibly running with a WebSphere Application Server Version 8.0.0.1 optimized local adapters stub interface that is not compatible with the maintenance level of the application server. To use the V8.0.0.1 optimized local adapters stubs, the application server must also be running at the WebSphere Application Server Version 8.0.0. level. Ensure your application is running with the level of the optimized local adapters stubs that are compatible with WebSphere Application Server on this z/OS system.

Send Response

This API sends a response to a request back to the local WebSphere Application Server.

Table 22. BBOA1SRP API (31-bit caller) and BBGA1SRP (64-bit caller) syntax. The syntax is explained in the Parameters section.

API	Syntax

BBOA1SRP or BBGA1SRP	`BBOA1SRP ( connectionhandle, responsedata, responsedatalen, rc, rsn )`
	
	`BBGA1SRP ( connectionhandle, responsedata, responsedatalen, rc, rsn )`

Parameters:

`connectionhandle` (input)

A 12 - byte connection handle that is to be used for this response.

`responsedata` (input)

A 31-bit or 64-bit pointer to the address of the start of the response data to send.

`responsedatalen` (input)

A 32-bit unsigned value in 31-bit mode or a 64-bit unsigned value in 64 bit mode containing the length of the data to send.

`rc` (output)

An integer return code indicating success or failure of this call.

rsn (output)

An integer reason code describing the reason for a failure on this call.

Usage notes:

- Ensure that theWebSphere Application Server for z/OS daemon group and server specified on this call are started and the support for local adapters is enabled .
- Ensure that a successful register (BBOA1REG or BBGA1REG API) call was completed in the current address space with a matching name before using the Send Response API.
- Ensure that a successful connection get (BBOA1CNG or BBGA1CNG) call completed and the handle is provided as input on this call.
- Ensure that a successful receive Request Any, Receive Request Specific, or Host API call was issued and returned with request data for the connection handle. The connection must be in a state where the Send Response API is valid.

Return and reason codes:

Table 23. BBOA1SRP and BBGA1SRP APIs return and reason codes. The following table also recommends appropriate actions.

Return Code	Reason Code	Description	Action
0	-	Success	
4	-	Warning - see reason code	
8	-	Error - see reason code	
	8	Register name token already exists.	Ensure that the register name passed is valid.
	14	An out of memory condition occurred while saving the message.	There is not enough memory available for Send Response to process the message. The current address space is out of private storage.
	18	The response length exceeds the system limits.	The message size is larger than the WebSphere Application Server size can support. Verify that the size is valid. If the size is valid, ensure that the WebSphere Application Server size is large enough to accommodate the message size.
	34	The target service is not found.	Ensure that the application containing the target EJB is installed and started in the target WebSphere Application Server.
	36	The connection state is not valid.	The connection handle used for this request is in the wrong state. Refer to the API documentation for the rules on connection states.
	38	The client connection handle is not valid.	The client connection handle used for this request is not valid. Refer to the API documentation for information about client connection handles.
	40	A local communication error occurred.	Check the WebSphere Application Server server log for any local communication error messages.
	46	An error occurred in the local communication send request call.	Check the WebSphere Application Server logs to determine the error.
12	10	Unable to locate to WebSphere Application Server daemon group or server.	Ensure that the WebSphere Application Server daemon and server are started and local connections support is active and try the call again.
	14	The API calling vector using the provided connection handle cannot be located or verified.	The connection handle is not valid or an unregister call (BBOA1URG) might have invalidated the connection pool.
	34	A 64-bit API stub was used in an IMS environment.	The 64-bit APIs are not supported under IMS.
	38	A 64-bit API stub was used in a CICS environment.	The 64 bit APIs are not supported under CICS.
	86	WebSphere Application Server for z/OS master BGVT could not be located	WebSphere has not been started yet on the current z/OS system image. Ensure the daemon and a node/server are started before starting any WebSphere Application Server optimized local adapters client processes.

Table 23. BBOA1SRP and BBGA1SRP APIs return and reason codes (continued). The following table also recommends appropriate actions.

Return Code	Reason Code	Description	Action
	88	WebSphere Application Server for z/OS master client stub table could not be located.	A WebSphere Application Server has been started on the current z/OS system image, but is not running at the level where the optimized local adapters client stub table is supported. You are possibly running with a WebSphere Application Server Version 8.0.0.1 optimized local adapters stub interface that is not compatible with the maintenance level of the application server. To use the V8.0.0.1 optimized local adapters stubs, the application server must also be running at the WebSphere Application Server Version 8.0.0. level. Ensure your application is running with the level of the optimized local adapters stubs that are compatible with WebSphere Application Server on this z/OS system.
	90	WebSphere Application Server for z/OS optimized local adapters master client stub table slot could not be located.	A WebSphere Application Server has been started on the current z/OS system image, but is not running at the level where the optimized local adapters client stub table is supported. You are possibly running with a WebSphere Application Server Version 8.0.0.1 optimized local adapters stub interface that is not compatible with the maintenance level of the application server. To use the V8.0.0.1 optimized local adapters stubs, the application server must also be running at the WebSphere Application Server Version 8.0.0. level. Ensure your application is running with the level of the optimized local adapters stubs that are compatible with WebSphere Application Server on this z/OS system.

Send Response Exception

This API sends an exception response data back to the JCA caller in the local WebSphere Application Server. The response is a ResourceAdapterException with the specified exception response data returned.

Table 24. BBOA1SRX (31-bit caller) and BBGA1SRX (64-bit caller) APIs syntax. The syntax is explained in the Parameters section.

API	Syntax

BBOA1SRX or BBGA1SRX	`BBOA1SRX ( connectionhandle, excresponsedata, exresponsedatalen, rc, rsn )`
	
	`BBGA1SRX ( connectionhandle, excresponsedata, exresponsedatalen, rc, rsn )`

Parameters:

`connectionhandle` (input)

A 12 - byte connection handle that is used for the response.

`excresponsedata` (input)

Specifies a 31-bit or 64-bit pointer to the address of the start of the exception response data to send.

`excresponsedatalen` (input)

Specifies a 32-bit unsigned value in 31-bit mode or a 64-bit unsigned value in 64-bit mode of the length of the exception response data to send. Exception response data is an EBCDIC string describing the error.

`rc` (output)

An integer return code indicating success or failure of this call.

`rsn` (output)

An integer reason code describing the reason for a failure on this call.

Usage notes:

- Ensure that the WebSphere Application Server for z/OS daemon group and server that are specified on this call are started and the support for local adapters is enabled.
- Ensure that a successful register (BBOA1REG or BBGAREG API) call completed in the current address space with a matching name before using the send response call.
- Ensure that a successful connection get (BBOA1CNG or BBGA1CNG API) call completed and the handle for this is provided as input on this call.
- Ensure that a successful Receive Request Any or Receive Request Specific or Host API call was issued and returned with request data for the connection handle. The connection must be in a state where the Send Response and Send Response Exception APIs are valid.

Return and reason codes:

Table 25. BBOA1SRX and BBGA1SRX APIs return and reason codes. The following table also recommends appropriate actions.

Return Code	Reason Code	Description	Action
0	-	Success	
4	-	Warning - see reason code	
8	-	Error - see reason code	
	8	Register name token already exists.	Ensure that the register name passed is valid.
	10	The connection handle is in a released or not valid state.	Ensure that a valid connection handle was passed.
	14	An out of memory condition occurred while saving the message.	There is not enough memory available for Send Response Exception to process the message. The current address space is out of private storage.
	16	One or more parameters are not valid.	Verify that all the parameters are valid and try the call again.
	18	The response length exceeds the system limits.	The message size is larger than the WebSphere Application Server size can support. Verify that the size is valid. If the size is valid, ensure that the WebSphere Application Server size is large enough to accommodate the message size.
	20	One or more parameters are not valid.	Verify that all the parameters are valid and try the call again.
	28	The registration that the connection handle was associated with is no longer active.	Call register with the registration name again before making the connection get and send request calls.
	36	The connection state is not valid.	The connection handle used for this request is in the wrong state. Refer to the API documentation for the rules on connection states.
	38	The client connection handle is not valid.	The client connection handle used for this request is not valid. Refer to the API documentation for information about client connection handles.
	40	A local communication error occurred.	Check the WebSphere Application Server server log for any local communication error messages.
	46	An error occurred in the local communication send request call.	Check the WebSphere Application Server logs to determine the error.
12	10	Unable to locate to WebSphere Application Server daemon group or server.	Ensure that the WebSphere Application Server daemon and server are started and local connections support is active and try the call again.
	14	The API calling vector using the provided connection handle cannot be located or verified.	The connection handle is not valid or an unregister call (BBOA1URG API) might have invalidated the connection pool.
	34	A 64-bit API stub was used in an IMS environment.	The 64-bit APIs are not supported under IMS.
	38	A 64-bit API stub was used in a CICS environment.	The 64 bit APIs are not supported under CICS.
	86	WebSphere Application Server for z/OS master BGVT could not be located	WebSphere has not been started yet on the current z/OS system image. Ensure the daemon and a node/server are started before starting any WebSphere Application Server optimized local adapters client processes.

Table 25. BBOA1SRX and BBGA1SRX APIs return and reason codes (continued). The following table also recommends appropriate actions.

Return Code	Reason Code	Description	Action
	88	WebSphere Application Server for z/OS master client stub table could not be located.	A WebSphere Application Server has been started on the current z/OS system image, but is not running at the level where the optimized local adapters client stub table is supported. You are possibly running with a WebSphere Application Server Version 8.0.0.1 optimized local adapters stub interface that is not compatible with the maintenance level of the application server. To use the V8.0.0.1 optimized local adapters stubs, the application server must also be running at the WebSphere Application Server Version 8.0.0. level. Ensure your application is running with the level of the optimized local adapters stubs that are compatible with WebSphere Application Server on this z/OS system.
	90	WebSphere Application Server for z/OS optimized local adapters master client stub table slot could not be located.	A WebSphere Application Server has been started on the current z/OS system image, but is not running at the level where the optimized local adapters client stub table is supported. You are possibly running with a WebSphere Application Server Version 8.0.0.1 optimized local adapters stub interface that is not compatible with the maintenance level of the application server. To use the V8.0.0.1 optimized local adapters stubs, the application server must also be running at the WebSphere Application Server Version 8.0.0. level. Ensure your application is running with the level of the optimized local adapters stubs that are compatible with WebSphere Application Server on this z/OS system.

Receive Request Any

Receive a request from a local WebSphere Application Server on any connection. Receive a request and related data on any available connection in the pool for the passed register name. Returns request data length as an output parameter. A connection handle is also an output parameter returned to the caller. A Get Data API call with the returned connection handle returns the received message data.

Table 26. BBOA1RCA API (31-bit caller) and BBGA1RCA (64-bit caller) APIs syntax. The syntax is explained in the Parameters section.

API	Syntax

BBOA1RCA or BBGA1RCA	`BBOA1RCA ( registername, connectionhandle, requestservicename, requestservicenamel, requestdatalen, waittime, rc, rsn )`
	
	`BBGA1RCA ( registername, connectionhandle, requestservicename, requestservicenamel, requestdatalen, waittime, rc, rsn )`

Parameters:

registername (input)

An entry variable or entry constant that contains the name to be used to locate the connection pool from which to retrieve a connection. This must be a blank padded string of exactly 12 characters.

connectionhandle (output)

A 12 - byte connection handle that is returned and must be passed on later requests for actions on this connection.

requestservicename (input/output)

An EBCDIC character string up to 256 bytes containing the name of the service. This is the name of the target service specified on the InteractionSpec by the WebSphere Application Server application. A value of * indicates a receive request for all service names arriving under the current register name.

requestservicenamel (input/output)

An integer containing the length of the service name to start or 0 if the service name is null terminated.

requestdatalen (output)

A 32-bit unsigned value in 31-bit mode or a 64-bit unsigned value in 64-bit mode is returned containing the length of the data to receive.

waittime (input)

An integer that contains the number of seconds to wait for the connection to complete before returning a connection unavailable reason code. A value of `0` indicates that there is no wait time and that the API waits indefinitely.

rc (output)

An integer return code indicating success or failure of this call.

rsn (output)

An integer reason code describing the reason for a failure on this call.

Usage notes:

- Ensure that the WebSphere Application Server for z/OS daemon group and server specified on this call are started and the support for local adapters is enabled .
- Ensure that a successful register (BBOA1REG or BBGA1REG API) call was completed in the current address space with a matching name before using this API.

Return and reason codes:

Table 27. BBOA1RCA and BBGA1RCA APIs return and reason codes. The following table also recommends appropriate actions.

Return Code	Reason Code	Description	Action
0	-	Success	
4	-	Warning - see reason code	
8	-	Error - see reason code	
	8	Register name token already exists.	Ensure that the register name passed is valid.
	11	Bad data was sent from WebSphere Application Server	
	16	The request service name length is not valid.	Correct the program and try the call again.
	19	Local communication existing data failure	
	21	Local communication preview data failure	
	38	The client connection handle is not valid.	The client connection handle used for this request was determined to be not valid. Refer to the API documentation for information about client connection handles.
	40	A local communication error occurred.	Check the WebSphere Application Server server log for any local communication error messages.
	46	An error occurred in the local communication send request call.	Check the WebSphere Application Server logs to determine the error.
	76	An attempt to communicate with the server failed because the server is no longer running.	Start the server and try the communication again.
12	10	WebSphere Application Server daemon group or server cannot be located.	Ensure that theWebSphere Application Server daemon and server are started and that the local connections support is active and try the call again.

Table 27. BBOA1RCA and BBGA1RCA APIs return and reason codes (continued). The following table also recommends appropriate actions.

Return Code	Reason Code	Description	Action
	24	After a successful registration call, an error occurred when getting a connection from the pool.	Verify that the server is started. If the server is not started, restart the server and try the API request again.
	34	A 64-bit API stub was used in an IMS environment.	The 64-bit APIs are not supported under IMS.
	38	A 64-bit API stub was used in a CICS environment.	The 64 bit APIs are not supported under CICS.
	44	Bad CP build for service call	
	46	Bad CP get for service cell	
	48	Bad CP free for service cell	
	60	Unable to get SRVQ lock	
	62	Unable to unlock SRVQ lock	
	86	WebSphere Application Server for z/OS master BGVT could not be located	WebSphere has not been started yet on the current z/OS system image. Ensure the daemon and a node/server are started before starting any WebSphere Application Server optimized local adapters client processes.
	88	WebSphere Application Server for z/OS master client stub table could not be located.	A WebSphere Application Server has been started on the current z/OS system image, but is not running at the level where the optimized local adapters client stub table is supported. You are possibly running with a WebSphere Application Server Version 8.0.0.1 optimized local adapters stub interface that is not compatible with the maintenance level of the application server. To use the V8.0.0.1 optimized local adapters stubs, the application server must also be running at the WebSphere Application Server Version 8.0.0. level. Ensure your application is running with the level of the optimized local adapters stubs that are compatible with WebSphere Application Server on this z/OS system.
	90	WebSphere Application Server for z/OS optimized local adapters master client stub table slot could not be located.	A WebSphere Application Server has been started on the current z/OS system image, but is not running at the level where the optimized local adapters client stub table is supported. You are possibly running with a WebSphere Application Server Version 8.0.0.1 optimized local adapters stub interface that is not compatible with the maintenance level of the application server. To use the V8.0.0.1 optimized local adapters stubs, the application server must also be running at the WebSphere Application Server Version 8.0.0. level. Ensure your application is running with the level of the optimized local adapters stubs that are compatible with WebSphere Application Server on this z/OS system.

Receive Request Specific

Receive a request from a local WebSphere Application Server on a specific connection. Receive a request and related data for the supplied input connection handle. Returns request data length. A Get Data API call with the returned connection handle returns the received message data.

Table 28. BBOA1RCS (31-bit caller) and BBGA1RCS (64-bit caller) APIs syntax. The syntax is explained in the Parameters section.

API	Syntax

BBOA1RCS or BBGA1RCS	`BBOA1RCS ( connectionhandle, requestservicename, requestservicenamel, requestdatalen, async(0|1), rc, rsn )`
	
	`BBGA1RCS ( connectionhandle, requestservicename, requestservicenamel, requestdatalen, async(0|1), rc, rsn )`

Parameters:

`connectionhandle` (input)

A 12 - byte connection handle that is to be used for the receive request.

`requestservicename` (input/output)

An EBCDIC character string up to 256 bytes containing the name of the service. This is the name of the target service specified on the InteractionSpec by the WebSphere Application Server application. A value of * indicates that set up as a server for all service names arriving under the current register name.

requestservicenamel (input/output)

An integer containing the length of the service name to start or 0 if the service name is null terminated.

requestdatalen (output)

A 32-bit unsigned value in 31-bit mode or a 64-bit unsigned value in 64-bit mode is returned that contains the length of the request data received. This length can then be used by the caller to acquire storage before calling the Get Data API to copy it in. When async is set to 1, indicating the caller wants control back immediately, this is set to all 0xFFs if the request data has not yet been received. In this case, the API must be called again to retrieve an inbound request.

async(0|1) (input)

An integer value that when set to 1 indicates the caller wants control returned immediately, even though the request length may not yet be known. When async is set to 0, this call waits for a request from the WebSphere Application Server to be received.

rc (output)

An integer return code indicating success or failure of this call.

rsn (output)

An integer reason code describing the reason for a failure on this call.

Usage notes:

- Ensure that theWebSphere Application Server for z/OS daemon group and server specified on this call are started and the support for local adapters is enabled.
- Ensure that a successful register (BBOA1REG API) call was completed in the current address space with a matching name before using this API.

Return and reason codes:

Table 29. BBOA1RCS and BBGA1RCS APIs return and reason codes. The following table also recommends appropriate actions.

Return Code	Reason Code	Description	Action
0	-	Success	
4	-	Warning - see reason code	
8	-	Error - see reason code	
	8	Register name token already exists.	Ensure that the register name passed is valid.
	10	The connection handle is in a released state improper state.	Ensure that a valid connection handle passed.
	11	Bad data was sent from the WebSphere Application Server	
	16	The request service name length is not valid.	Correct the program and try the call again.
	19	Local communication existing data failure	
	21	Local communication preview data failure	

Table 29. BBOA1RCS and BBGA1RCS APIs return and reason codes (continued). The following table also recommends appropriate actions.

Return Code	Reason Code	Description	Action
	28	The registration that the connection handle was associated with is no longer active.	Call the registration name again before calling connection get and receive request specific.
	36	The connection state is not valid.	The connection handle used for this request is in the wrong state. Refer to the API documentation for the rules on connection states.
	38	The client connection handle is not valid.	The client connection handle used for this request is not valid. Refer to the API documentation for information about client connection handles.
	40	A local communication error occurred.	Check the WebSphere Application Server server log for any local communication error messages.
	46	An error occurred in the local communication send request call.	Check the WebSphere Application Server logs to determine the error.
	76	An attempt to communicate with the server failed because the server is no longer running.	Start the server and try the communication again.
	78	An internal error occurred that caused the connection to select a request that was not a part of the transaction being processed by this connection.	Return the connection to the connection pool. If the problem persists, contact IBM Support.
	80	The transaction that is active on this connection has timed out and the connection state could not be reset so that another request is processed.	Return the connection to the connection pool. If the problem persists, contact IBM Support.
12	10	The WebSphere Application Server daemon group or server cannot be located.	Ensure that WebSphere Application Server daemon and server are started and local connections support is active and try the call again.
	14	The API calling vector using the provided connection handle cannot be located or verified.	The connection handle is not valid or an unregister call (BBOA1URG API) might have invalidated the connection pool.
	34	A 64-bit API stub was used in an IMS environment.	The 64-bit APIs are not supported under IMS.
	38	A 64-bit API stub was used in a CICS environment.	The 64 bit APIs are not supported under CICS.
	44	Bad CP build for service cell	
	46	Bad CP get for service call	
	48	Bad CP free for service cell	
	60	Unable to get SRVQ lock	
	62	Unable to unlock SRVQ lock	
	86	WebSphere Application Server for z/OS master BGVT could not be located	WebSphere has not been started yet on the current z/OS system image. Ensure the daemon and a node/server are started before starting any WebSphere Application Server optimized local adapters client processes.
	88	WebSphere Application Server for z/OS master client stub table could not be located.	A WebSphere Application Server has been started on the current z/OS system image, but is not running at the level where the optimized local adapters client stub table is supported. You are possibly running with a WebSphere Application Server Version 8.0.0.1 optimized local adapters stub interface that is not compatible with the maintenance level of the application server. To use the V8.0.0.1 optimized local adapters stubs, the application server must also be running at the WebSphere Application Server Version 8.0.0. level. Ensure your application is running with the level of the optimized local adapters stubs that are compatible with WebSphere Application Server on this z/OS system.
	90	WebSphere Application Server for z/OS optimized local adapters master client stub table slot could not be located.	A WebSphere Application Server has been started on the current z/OS system image, but is not running at the level where the optimized local adapters client stub table is supported. You are possibly running with a WebSphere Application Server Version 8.0.0.1 optimized local adapters stub interface that is not compatible with the maintenance level of the application server. To use the V8.0.0.1 optimized local adapters stubs, the application server must also be running at the WebSphere Application Server Version 8.0.0. level. Ensure your application is running with the level of the optimized local adapters stubs that are compatible with WebSphere Application Server on this z/OS system.

Receive Response Length

Receive response length is used to retrieve the length of the response data from a prior send request call.

Table 30. BBOA1RCL API (31-bit caller) and BBGA1RCL (64-bit caller) APIs syntax. The syntax is explained in the Parameters section.

API	Syntax

BBOA1RCL or BBGA1RCL	`BBOA1RCL ( connectionhandle, async(0|1), responsedatalen, rc, rsn )`
	
	`BBGA1RCL ( connectionhandle, async(0|1), responsedatalen, rc, rsn )`

Parameters:

connectionhandle (input)

A 12 - byte connection handle that is to be used for this request.

async (input)

An integer value that when set to `1` indicates the caller wants control returned immediately, even though the response length might not be known. When async is set to `0`, this call waits for the response to be returned from the WebSphere Application Server and supply the response length in the **responsedatalen** parameter value.

responsedatalen (output)

A 32-bit unsigned value in 31-bit mode and a 64-bit unsigned value in 64-bit mode containing the length of the data received is returned. This length can be used by the caller to acquire storage before calling the Get Data API to copy it in. If async is `1`, this might be returned as all FFs if the response data is not yet received

rc (output)

An integer return code indicating success or failure of this call.

rsn (output)

An integer reason code describing the reason for a failure on this call.

Usage notes:

- Ensure that the WebSphere Application Server for z/OS daemon group and server specified on this call are started and the support for local adapters is enabled .
- Ensure that a successful register (BBOA1REG or BBGA1REG API) call was completed in the current address space with a matching name before using this API.
- Ensure that a successful Connection Get (BBOA1CNG or BBGA1CNG API) call completed and the handle is provided as input on this call.
- Ensure that a successful Send Request (BBOA1SRQ or BBGA1SRQ API) call was completed before making this call.

Return and reason codes:

Table 31. BBOA1RCL and BBGA1RCL APIs return and reason codes. The following table also recommends appropriate actions.

Return Code	Reason Code	Description	Action
0	-	Success	
4	-	Warning - see reason code	
8	-	Error - see reason code	
	8	Register name token already exists.	Ensure that the register name passed is valid.
	11	Bad data was sent from the WebSphere Application Server.	
	19	Local communication existing data failure	
	21	Local communication preview data failure	
	36	The connection state is not valid.	The connection handle used for this request was determined to be in the wrong state. Refer to the API documentation for the rules on connection states.
	38	The client connection handle is not valid.	The client connection handle used for this request was determined to be not valid. Refer to the API documentation for information about client connection handles.
	40	A local communication error occurred.	Check the WebSphere Application Server server log for any local communication error messages.
12	10	The WebSphere Application Server daemon group or server cannot be located.	Ensure that the WebSphere Application Serverdaemon and server are started and local connections support is active and try the call again.
	14	The API calling vector using the provided connection handle cannot be located or verified.	The connection handle is not valid or an unregister call (BBOA1URG API) might have invalidated the connection pool.
	34	A 64-bit API stub was used in an IMS environment.	The 64-bit APIs are not supported under IMS.
	38	A 64-bit API stub was used in a CICS environment.	The 64 bit APIs are not supported under CICS.
	86	WebSphere Application Server for z/OS master BGVT could not be located	WebSphere has not been started yet on the current z/OS system image. Ensure the daemon and a node/server are started before starting any WebSphere Application Server optimized local adapters client processes.
	88	WebSphere Application Server for z/OS master client stub table could not be located.	A WebSphere Application Server has been started on the current z/OS system image, but is not running at the level where the optimized local adapters client stub table is supported. You are possibly running with a WebSphere Application Server Version 8.0.0.1 optimized local adapters stub interface that is not compatible with the maintenance level of the application server. To use the V8.0.0.1 optimized local adapters stubs, the application server must also be running at the WebSphere Application Server Version 8.0.0. level. Ensure your application is running with the level of the optimized local adapters stubs that are compatible with WebSphere Application Server on this z/OS system.
	90	WebSphere Application Server for z/OS optimized local adapters master client stub table slot could not be located.	A WebSphere Application Server has been started on the current z/OS system image, but is not running at the level where the optimized local adapters client stub table is supported. You are possibly running with a WebSphere Application Server Version 8.0.0.1 optimized local adapters stub interface that is not compatible with the maintenance level of the application server. To use the V8.0.0.1 optimized local adapters stubs, the application server must also be running at the WebSphere Application Server Version 8.0.0. level. Ensure your application is running with the level of the optimized local adapters stubs that are compatible with WebSphere Application Server on this z/OS system.

Get Message Data

This API is used to copy the received message data. On return from this call, the message is removed from the adapter message cache.

Table 32. BBOA1GET (31-bit caller) and BBGA1GET (64-bit caller) APIs syntax. The syntax is explained in the Parameters section.

API	Syntax

BBOA1GET or BBGA1GET	`BBOA1GET ( connectionhandle, msgdata, msgdatalen, rc, rsn, rv )`
	
	`BBGA1GET ( connectionhandle, msgdata, msgdatalen, rc, rsn, rv )`

Parameters:

connectionhandle (input)

A 12 - byte connection handle that is to be used for this request.

msgdata (input)

A 31-bit or 64-bit pointer to the address of the start of the data area to copy into. The storage this points to must be in a key that is writable by the caller.

msgdatalen (input)

A 32-bit unsigned value in 31-bit mode or a 64-bit unsigned value in 64-bit mode containing the length of the data to be copied.

rc (output)

An integer return code indicating success or failure of this call.

rsn (output)

An integer reason code describing the reason for a failure on this call.

rv (output)

A 32 - bit integer return value containing the size of the context buffer for this request.

Usage notes:

- Ensure that the WebSphere Application Server for z/OS daemon group and server specified on this call are started and the support for local adapters is enabled.
- Ensure that a successful register (BBOA1REG or BBGA1REG API) call was completed in the current address space with a matching name before using the Send Request API.
- Ensure that a successful connection get (BBOA1CNG or BBGA1CNG API) call completed and the handle is provided as input on this call.
- If the API caller input **msgdatalen** parameter is larger than the actual message response, the return code contains a `0` and the actual message length is provided to the return value.
-

  Important: Once the get message data call returns to the caller, the message data does not persist and the connection is returned to a state where it can be used for another send or receive request call. A subsequent call to get message data or receive response length is returned in error.

Return and reason codes:

Table 33. BBOA1GET and BBGA1GET APIs return and reason codes. The following table also recommends appropriate actions.

Return Code	Reason Code	Description	Action
0	-	Success	
4	-	Warning - see reason code	
8	-	Error - see reason code	
	8	Register name token already exists.	Ensure that the register name passed is valid.
	36	The connection state is not valid.	The connection handle used for this request was determined to be in the wrong state. Refer to the API documentation for the rules on connection states.
	38	The client connection handle is not valid.	The client connection handle used for this request was determined to be not valid. Refer to the API documentation for information about client connection handles.
	40	A local communication error occurred.	Check the WebSphere Application Server server log for any local communication error messages.
	48	An error occurred in the local communication read request.	Check the WebSphere Application Server logs to determine the error.
	50	The connection with the WebSphere Application Server is terminated.	Check the WebSphere Application Server logs to determine the error.
	72	Response length input parameter is not large enough to contain the response message.	Only a portion of the message is returned. The remainder is discarded. Refer to the return value for the size of the message response.
12	10	The WebSphere Application Server daemon group or server cannot be located.	Ensure that the WebSphere Application Server daemon and server are started and the local connections support is active and try the call again.
	14	The API calling vector using the provided connection handle cannot be located or verified.	The connection handle is not valid or an unregister call (BBOA1URG API) might have invalidated the connection pool.
	34	A 64-bit API stub was used in an IMS environment.	The 64-bit APIs are not supported under IMS.
	38	A 64-bit API stub was used in a CICS environment.	The 64 bit APIs are not supported under CICS.
	86	WebSphere Application Server for z/OS master BGVT could not be located	WebSphere has not been started yet on the current z/OS system image. Ensure the daemon and a node/server are started before starting any WebSphere Application Server optimized local adapters client processes.
	88	WebSphere Application Server for z/OS master client stub table could not be located.	A WebSphere Application Server has been started on the current z/OS system image, but is not running at the level where the optimized local adapters client stub table is supported. You are possibly running with a WebSphere Application Server Version 8.0.0.1 optimized local adapters stub interface that is not compatible with the maintenance level of the application server. To use the V8.0.0.1 optimized local adapters stubs, the application server must also be running at the WebSphere Application Server Version 8.0.0. level. Ensure your application is running with the level of the optimized local adapters stubs that are compatible with WebSphere Application Server on this z/OS system.
	90	WebSphere Application Server for z/OS optimized local adapters master client stub table slot could not be located.	A WebSphere Application Server has been started on the current z/OS system image, but is not running at the level where the optimized local adapters client stub table is supported. You are possibly running with a WebSphere Application Server Version 8.0.0.1 optimized local adapters stub interface that is not compatible with the maintenance level of the application server. To use the V8.0.0.1 optimized local adapters stubs, the application server must also be running at the WebSphere Application Server Version 8.0.0. level. Ensure your application is running with the level of the optimized local adapters stubs that are compatible with WebSphere Application Server on this z/OS system.

Invoke

This API uses other underlying primitive API functions to call a method in a local WebSphere Application Server. It is designed to be used in situations where the response output area maximum size is known in advance.

Table 34. BBOA1INV (31-bit caller) and BBGA1INV (64-bit caller) APIs syntax. The syntax is explained in the Parameters section.

API	Syntax

BBOA1INV or BBGA1INV	`BBOA1INV ( registername, requesttype, requestservicename, requestservicenamel, requestdata, requestdatalen, responsedata, responsedatalen, waittime, rc, rsn, rv )`
	
	`BBGA1INV ( registername, requesttype, requestservicename, requestservicenamel, requestdata, requestdatalen, responsedata, responsedatalen, waittime, rc, rsn, rv )`

Parameters:

registername (input)

An entry variable or entry constant containing the name to be used to locate the connection pool to retrieve a connection for this invocation. This must be a blank padded string of exactly 12 characters.

requesttype (input)

An integer containing the request type that indicates the type of work request to process. Supported type values: 1 = local EJB work requests, 2 = Remote EJB work requests.

requestservicename (input)

An EBCDIC character string up to 256 bytes in length containing the name of the service to invoke. For Type=1, EJB, this is the JNDI Home name for the target.

requestservicenamel (input)

An integer containing the length of the service name to start or `0` if the service name is null terminated.

requestdata (input)

A 31-bit or 64-bit pointer to the address of the start of the request data to send.

requestdatalen (input)

A 32-bit unsigned value in 31-bit mode or a 64-bit unsigned value in 64-bit mode containing the length of the data to send.

responsedata (input)

A 31-bit or 64-bit pointer to the address of the start of the response data area to copy into. The storage this points to must be in a key that is writable by the caller.

responsedatalen (input)

A 32-bit unsigned value in 31-bit mode or a 64-bit unsigned value in 64-bit mode containing the length of the data to send.

waittime (input)

An integer that contains the number of seconds to wait for the connection to complete before returning a connection unavailable reason code. A value of 0 (zero) indicates that there is no timeout and that this API waits indefinitely.

rc (output)

An integer return code indicating success or failure of this call.

rsn (output)

An integer reason code describing the reason for a failure on this call.

rv (output)

A 32 - bit integer return value containing the size of the message data that was received and copied into the caller response area.

Usage notes:

- Ensure that the WebSphere Application Server for z/OS daemon group and server specified on this call are started and the support for local adapters is enabled .
- Ensure that a successful register (BBOA1REG or BBGA1REG API) call was completed in the current address space with a matching name before using the Send Request API.
- If the API caller input **responsedatalen** parameter is larger than the actual message response, the return code contains a 0 (zero) and the actual message length is provided in the return value.

Return and reason codes:

Table 35. BBOA1INV and BBGA1INV API return and reason codes. The following table also recommends appropriate actions.

Return Code	Reason Code	Description	Action
0	-	Success	
4	-	Warning - see reason code	
8	-	Error - see reason code	
	8	Register name token already exists.	Ensure that the register name passed is valid.
	10	The connection is unavailable. The wait time expired before the connection request is obtained.	The application behavior varies. Wait and retry, or accept this failed Invoke API call. Another option is to increase the maximum connections setting on the Register API call.
	11	Bad data was sent from the WebSphere Application Server.	
	14	An out of memory condition occurred while saving the message.	There is not enough memory available for the invoke to process the message. The current address space is out of private storage.
	16	The request service name length is not valid.	Correct the program and try the call again.
	18	The response length exceeded the system limits.	The message size is larger than the WebSphere Application Server size can support. Verify that the size is valid. If the size is valid, ensure that the WebSphere Application Server size is large enough to accommodate the message size.
	19	Local communication existing data failure.	
	21	Local communication preview data failure.	
	24	After a successful register call, an error occurred when getting a connection from the pool.	Verify that the server is started. If it is not working, restart the server and try the API request again.
	26	Global transaction could not begin.	
	28	Registration is found, but is inactive.	
	32	The request type on the API call is not valid.	The request type parameter is not valid. Correct the program and try the call again.
	34	The target service not found.	Ensure the application containing the target enterprise bean is installed and started in the target WebSphere Application Server.

Table 35. BBOA1INV and BBGA1INV API return and reason codes (continued). The following table also recommends appropriate actions.

Return Code	Reason Code	Description	Action
	36	The connection state is not valid.	The connection handle used for this request was determined to be in the wrong state. Refer to the API documentation for the rules on connection states.
	38	The client connection handle is not valid.	The client connection handle used for this request was determined to be not valid. Refer to the API documentation for information about client connection handles.
	40	A local communication error occurred.	Check the WebSphere Application Server server log for any local communication error messages.
	44	An exception or unexpected condition occurred in the target enterprise bean.	Refer to the WebSphere Application Server logs to review the exception data.
	46	An error occurred in the local communication send request.	Refer to the WebSphere Application Server logs to determine the error.
	48	An error occurred in the local communication read request.	Check the WebSphere Application Server logs to determine the error.
	50	The connection with theWebSphere Application Server is terminated.	Check the WebSphere Application Server to determine the error.
	72	Response length input parameter is not large enough to contain the response message.	Only a portion of the message is returned. The remainder is discarded. Refer to the return value for the size of the message response.
12	10	The WebSphere Application Server daemon group or server cannot be located.	Ensure that the WebSphere Application Server daemon and server are started and local connections support is active and try the call again.
	14	The API calling vector using the provided connection handle cannot be located or verified.	The connection handle is not valid or an unregister call (BBOA1URG API) might have invalidated the connection pool.
	24	After a successful register call, an error occurred while getting a connection from the connection pool.	Verify that the server is started. If it is not started, restart the server and try the API request again.
	34	A 64-bit API stub was used in an IMS environment.	The 64-bit APIs are not supported under IMS.
	38	A 64-bit API stub was used in a CICS environment.	The 64 bit APIs are not supported under CICS.
	86	WebSphere Application Server for z/OS master BGVT could not be located	WebSphere has not been started yet on the current z/OS system image. Ensure the daemon and a node/server are started before starting any WebSphere Application Server optimized local adapters client processes.
	88	WebSphere Application Server for z/OS master client stub table could not be located.	A WebSphere Application Server has been started on the current z/OS system image, but is not running at the level where the optimized local adapters client stub table is supported. You are possibly running with a WebSphere Application Server Version 8.0.0.1 optimized local adapters stub interface that is not compatible with the maintenance level of the application server. To use the V8.0.0.1 optimized local adapters stubs, the application server must also be running at the WebSphere Application Server Version 8.0.0. level. Ensure your application is running with the level of the optimized local adapters stubs that are compatible with WebSphere Application Server on this z/OS system.
	90	WebSphere Application Server for z/OS optimized local adapters master client stub table slot could not be located.	A WebSphere Application Server has been started on the current z/OS system image, but is not running at the level where the optimized local adapters client stub table is supported. You are possibly running with a WebSphere Application Server Version 8.0.0.1 optimized local adapters stub interface that is not compatible with the maintenance level of the application server. To use the V8.0.0.1 optimized local adapters stubs, the application server must also be running at the WebSphere Application Server Version 8.0.0. level. Ensure your application is running with the level of the optimized local adapters stubs that are compatible with WebSphere Application Server on this z/OS system.

Host Service

Host Service for a local WebSphere Application Server. This API uses other underlying primitive API functions to set up a native language z/OS program as a server and target for optimized local adapter calls from a localWebSphere Application Server. It is designed to be used in situations where the request area maximum size is known in advance.

Table 36. BBOA1SRV (31-bit caller) and BBGA1SRV API (64-bit caller) APIs syntax. The syntax is explained in the Parameters section.

API	Syntax

BBOA1SRV or BBGA1SRV	`BBOA1SRV ( registername, requestservicename, requestservicenamel, requestdata, requestdatalen, connectionhandle, waittime, rc, rsn, rv )`
	
	`BBGA1SRV ( registername, requestservicename, requestservicenamel, requestdata, requestdatalen, connectionhandle, waittime, rc, rsn, rv )`

Parameters:

registername (input)

An entry variable or entry constant containing the name to be used to locate the connection pool to retrieve a connection from for this call. This must be a blank padded string of exactly 12 characters.

requestservicename (input/output)

An EBCDIC character string up to 256 bytes containing the name of the service. This is the name of the target service specified on the InteractionSpec by the WebSphere Application Server application. A value of * indicates set up as a server for all service names arriving under the current register name.

requestservicenamel (input/output)

An integer containing the length of the service name to start or 0 if the service name is null terminated.

requestdata (input)

A 31-bit or 64-bit pointer to the address of the start of the request data received. The storage this points to must be in a key that is writable by the caller.

requestdatalen (input)

A 32-bit unsigned value in 31-bit mode or a 64-bit unsigned value in 64-bit mode containing the length of the data area to receive the message into.

connectionhandle (output)

A 12-byte connection handle that is returned to the caller and used for sending a response for this request.

waittime (input)

An integer that contains the number of seconds to wait for the connection to complete before returning a connection unavailable reason code. A value of 0 (zero) implies that there is no timeout and that the API waits indefinitely.

rc (output)

An integer return code indicating success or failure of this call.

rsn (output)

An integer reason code describing the reason for a failure on this call.

rv (output)

A 32-bit integer return value containing the size of the message request data that was received and copied into the caller area.

Usage notes

- Ensure that the WebSphere Application Server for z/OS daemon group and server specified on this call are started and the support for local adapters is enabled.
- Ensure that a successful register (BBOA1REG or BBGA1REG API) call was completed in the current address space with a matching name before using this API.
- If the API caller input **requestdatalen** parameter is larger than the actual message response, the return code contains a 0 (zero) and the actual message length is provided in the return value.
- The returned connection handle must be supplied on any response for this Host call using the BBOA1SRP or BBGA1SRP API. A subsequent BBOA1SRV or BBGA1SRVAPI call reuses the same connection handle. If so, the API assumes that there is no response for the earlier request.
-

Important: Once the Host Service call returns to the caller, the message data is not persisted and the connection is returned to a state where it can be used for another API request.

Return and reason codes:

Table 37. BBOA1SRV and BBGA1SRV APIs return and reason codes. The following table also recommends appropriate actions.

Return Code	Reason Code	Description	Action
0	-	Success	
4	-	Warning - see reason code	
8	-	Error - see reason code	
	8	Register name token already exists.	Ensure that the register name passed is valid.
	10	The connection handle is in a released state.	Ensure that a right connection handle passed.
	12	The connection handle is not in the connection that is in the registration name.	Correct to program and try the call again.
	16	The request service name length is not valid.	Correct the program and try the call again.
	18	The response length exceeds the system limits.	The message size is larger than the WebSphere Application Server size can support. Verify that the size is valid. If the size is valid, ensure that the WebSphere Application Server size is large enough to accommodate the message size.
	40	A local communication error occurred.	Check the WebSphere Application Server server log for any local communication error messages.
	46	An error occurred in the local communication send request call.	Check the WebSphere Application Server logs to determine the error.
	48	An error occurred in the local communication read request.	Check the WebSphere Application Server logs to determine the error.
	50	The connection with the WebSphere Application Server is terminated.	Check theWebSphere Application Server logs to determine the error.
	72	Response length input parameter is not large enough to contain the response message.	Only a portion of the message is returned. The remainder is discarded. Refer to the return value for the size of the message response.

Table 37. BBOA1SRV and BBGA1SRV APIs return and reason codes (continued). The following table also recommends appropriate actions.

Return Code	Reason Code	Description	Action
	76	An attempt to communicate with the server failed because the server is no longer running.	Start the server and try the communication again.
12	10	The WebSphere Application Server daemon group or server cannot be located.	Ensure WebSphere Application Server daemon and server are started and local connections support is active and try again.
	14	The API calling vector using the provided connection handle cannot be located or verified.	The connection handle is not valid or an unregister call (BBOA1URG or BBGA1URG API) might have invalidated the connection pool.
	34	A 64-bit API stub was used in an IMS environment.	The 64-bit APIs are not supported under IMS.
	38	A 64-bit API stub was used in a CICS environment.	The 64 bit APIs are not supported under CICS.
	44	Bad CP build for service cell.	
	46	Bad CP get for service cell.	
	48	Bad CP free for service cell.	
	60	Unable to get SRVQ lock.	
	62	Unable to unlock SRVQ lock.	
	86	WebSphere Application Server for z/OS master BGVT could not be located	WebSphere has not been started yet on the current z/OS system image. Ensure the daemon and a node/server are started before starting any WebSphere Application Server optimized local adapters client processes.
	88	WebSphere Application Server for z/OS master client stub table could not be located.	A WebSphere Application Server has been started on the current z/OS system image, but is not running at the level where the optimized local adapters client stub table is supported. You are possibly running with a WebSphere Application Server Version 8.0.0.1 optimized local adapters stub interface that is not compatible with the maintenance level of the application server. To use the V8.0.0.1 optimized local adapters stubs, the application server must also be running at the WebSphere Application Server Version 8.0.0. level. Ensure your application is running with the level of the optimized local adapters stubs that are compatible with WebSphere Application Server on this z/OS system.
	90	WebSphere Application Server for z/OS optimized local adapters master client stub table slot could not be located.	A WebSphere Application Server has been started on the current z/OS system image, but is not running at the level where the optimized local adapters client stub table is supported. You are possibly running with a WebSphere Application Server Version 8.0.0.1 optimized local adapters stub interface that is not compatible with the maintenance level of the application server. To use the V8.0.0.1 optimized local adapters stubs, the application server must also be running at the WebSphere Application Server Version 8.0.0. level. Ensure your application is running with the level of the optimized local adapters stubs that are compatible with WebSphere Application Server on this z/OS system.

JCA adapters APIs

For calls from WebSphere Application Server into a batch program or subsystem, the WebSphere Application Server application uses the standard JCA APIs. The objects that are customized for this adapter are as follows:

- ConnectionSpec
- InteractionSpec
- Record I/O

See the related links for additional information about these standard JCA APIs in the information center.

The ConnectionSpec API is used to indicate which register name to communicate with. The register name is created when the Register API is used. This also identifies which subsystem to connect to. A subsystem can have more than one register name.

The name of the Program Link transaction ID can be passed fromWebSphere Application Server to CICS, and is used to run the Program Link invocation task. This must be 4 characters and defined in the CICS

region. You must set it up with the same attributes and program name as the BBO# transaction (program: BBOACLNK). When this transaction ID is passed using the setLinkTaskTranid method, it overrides the BBO# API and any transaction ID that was specified using BBOC with the LTX=*xxx* parameter.

A setUseCICSContainer method is provided on the ConnectionSpecImpl. When this is set to 1, the name and type of a message request CICS container can be passed to CICS using the methods, setLinkTaskReqContid() and setLinkTaskReqContType(0|1), where 0=CHAR and 1=BIT. When this is passed, the target program has its own input data passed in the named container, which is created with the selected type of BIT or CHAR.

The name and type of a message response CICS container can be passed to CICS using the methods, setLinkTaskRspContid() and setLinkTaskRspContType(bit|char). When this is passed, the target program response is expected to come from the named container with the selected type of BIT or CHAR.

For IMS application transactions, use the setOTMAMaxRecvSize(*nnn*) method on the Connection Specification to set the Maximum Message Receive size. To set the Maximum Segments connection level value use the setOTMAMaxSegments(*nnn*) method on the Connection Specification. For more information about using optimized local adapters with IMS over OTMA, see the topic Calling existing IMS transactions with optimized local adapters over OTMA.

InteractionSpec

The InteractionSpec API is used to specify which service is to be started by the target. This is dependent on what subsystem or batch process is started. The process can choose to receive requests for a specific service, or for any service. For CICS, the service name is the name of the program to start in CICS.

Record I/O

Applications can pass data to and receive data from the adapter using the JCA record interface. This adapter API proposes to use the indexed record interface to allow the caller to pass one or more data structures, including Cobol copybooks and C structures, to the external address space. Each index in the list is taken as a separate copybook and passed to the target in that order.

When used to accept return parameters from a function call, the IndexedRecordImpl can be predefined to accept a particular number of parameters, and the class names generated by the assembly tools for the individual copybooks and structures can be provided. The IndexedRecordImpl inflates the serialized copybooks and structures and sets them into the IndexedRecordImpl so that they can be retrieved and used without dealing with the serialized byte[] representations.

To give a general idea of how this API works, only selected methods are shown. All of the methods on the interface are implemented.

Optimized local adapters client-side code relocated to common storage

With WebSphere Application Server Version 8.0.0.1, the amount of optimized local adapters code that needs to be loaded in the external client address space on behalf of the optimized local adapters APIs is reduced significantly.

Prior to WebSphere Application Server Version 8.0.0.1, the optimized local adapters OLAMODS dataset, which contains the optimized local adapters API calling vector modules, had to be present in a job's STEPLIB DD or in the z/OS system link list concatenation. With optimized local adapters in WebSphere Application Server Version 8.0.0.1, this is no longer required. The optimized local adapters BBOA1* and BBGA1* API calling stubs have been enhanced to locate the optimized local adapters calling vector in z/OS common storage, which is located off the WebSphere Application Server global BGVT. Once the

application binds in the optimized local adapters API stubs, it no longer requires the BBOACALL optimized local adapters transfer vector module in the STEPLIB.

When the first WebSphere Application Server Version 8.0.0.1 cell, node or server is started, and the optimized local adapters module vector is loaded into common storage, applications that use the V8.0.0.1 calling stubs can exploit this new capability. WebSphere Application Server z/OS initialization code is enhanced to load a new copy of the common storage-based optimized local adapters module vector only when it detects a level of the vector higher than the one that was already active.

Use of the optimized local adapters API stubs (BBOA1* modules) shipped prior to V8.0.0.1 is still supported on V8.0.0.1. However, use of the V8.0.0.1 stubs on WebSphere Application Server versions prior to V8.0.0.1 is not supported. When you begin using the V8.0.0.1 optimized local adapters calling stubs, ensure that they are used to interact with WebSphere Application Server Version 8.0.0.1 and newer servers only.

The new optimized local adapters lightweight stubs are supported in the batch, Customer Information Control System (CICS), IMS, and USS environments. For CICS, the requirement for placing the OLAMODS dataset in the CICS DFHRPL DD concatenation remains. For IMS, the requirement for placing the OLAMODS dataset in the DFSESL DD concatenation also remains.

Chapter 8. Developing Dynamic caching

This page provides a starting point for finding information about the dynamic cache service, which improves performance by caching the output of servlets, commands, web services, and JavaServer Pages (JSP) files.

Dynamic caching features include replication of cache entries, cache disk offload, Edge-Side Include caching, web services, and external caching. Use external caching to control caches outside of the application server.

Configuring cacheable objects with the cachespec.xml file

Use this task to define cacheable objects inside the `cachespec.xml`, found inside the web module `WEB-INF` or enterprise bean `META-INF` directory.

Before you begin

Enable the dynamic cache. Refer to the Using the dynamic cache service article for more information.

About this task

You can save a global `cachespec.xml` in the application server properties directory, but the recommended method is to place the cache configuration file with the deployment module. The root element of the `cachespec.xml` file is <cache>, which contains <cache-entry> elements.

gotcha: In situations where there is a global `cachespec.xml` file in the application server properties directory, and a `cachespec.xml` file in an application, the entries in the two cachespec.xml files are merged. If there are conflicting entries in the two files, the entries in the in the `cachespec.xml` file that is in the application override the entries in the global `cachespec.xml` file for that application.

The <cache-entry> element can be nested within the <cache> element or a <cache-instance> element. The <cache-entry> elements that are nested within the <cache> element are cached in the default cache instance. Any <cache-entry> elements that are in the <cache-instance> element are cached in the instance that is specified in the **name** attribute on the <cache-instance> element.

Within a <cache-entry> element are parameters that allow you to complete the following tasks to enable the dynamic cache with the `cachespec.xml` file:

Procedure

1. Develop a `cachespec.xml` file.
   a. Create a caching configuration file.

      In the *<app_server_root>*`/properties` directory, locate the `cachespec.sample.xml` file.
   b. Copy the `cachespec.sample.xml` file to `cachespec.xml` in web module `WEB-INF` or enterprise bean `META-INF` directory.
2. Define the cache-entry elements necessary to identify the cacheable objects. See the cachespec.xml file topic for a list of elements.
3. Develop cache ID rules.

   To cache an object, WebSphere Application Server must know how to generate unique IDs for different invocations of that object. The *<cache-id>* element performs that task. Each cache entry can have multiple cache-ID rules that run in order until either a rule returns cache-ID that is not empty or no more rules remain to run. If no cache-ID generation rules produce a valid cache ID, then the object is not cached. Develop the cache IDs in one of two ways:

- Use the *<component>* element defined in the cache policy of a cache entry (recommended). Refer to the cachespec_xml file topic for more information about the *<component>* element.
- Write custom Java code to build the ID from input variables and system state. To configure the cache entry to use the ID generator, specify your IdGenerator in the XML file by using the *<idgenerator>* tag, for example:

```
<cache-entry>
     <class>servlet</class>
     <name>/servlet/CommandProcessor</name>
  <cache-id>
      <idgenerator>com.mycompany.SampleIdGeneratorImpl</idgenerator>
      <timeout>60</timeout>
  </cache-id>
</cache-entry>
```

4. Specify dependency ID rules. Use dependency ID elements to specify additional cache group identifiers that associate multiple cache entries to the same group identifier.

   The dependency ID is generated by concatenating the dependency ID base string with the values returned by its component elements. If a required component returns a null value, then the entire dependency ID does not generate and is not used. You can validate the dependency IDs explicitly through the dynamic cache API, or use another cache-entry *<invalidation>* element. Multiple dependency ID rules can exist per cache entry. All dependency ID rules run separately. See cachespec.xml file topic for a list of *<component>* elements.
5. Invalidate other cache entries as a side effect of this object start, if relevant. You can define invalidation rules in exactly the same manner as dependency IDs. However, the IDs that are generated by invalidation rules are used to invalidate cache entries that have those same dependency IDs.

   The invalidation ID is generated by concatenating the invalidation ID base string with the values returned by its component element. If a required component returns a null value, then the entire invalidation ID is not generated and no invalidation occurs. Multiple invalidation rules can exist per cache-entry. All invalidation rules run separately.
6. Ensure your cache policy is working correctly. You can modify the policies within the `cachespec.xml` file while your application is running. The dynamic cache reloads the updated file automatically. If you are caching static content and you are adding the cache policy to an application for the first time, you must restart the application. You do not need to restart the application server to activate the new cache policy. Refer to the Verifying the cacheable page topic for more information.

What to do next

Typically you declare several *<cache-entry>* elements inside a `cachespec.xml` file.

When new versions of the `cachespec.xml` are detected, the old policies are replaced. Objects that cached through the old policy file are not automatically invalidated from the cache; they are either reused with the new policy or eliminated from the cache through its replacement algorithm.

For each of the three IDs (cache, dependency, invalidation) generated by cache entries, a `<cache-entry>` can contain multiple elements. The dynamic cache runs the *<cache-id>* rules in order, and the first one that successfully generates an ID is used to cache that output. If the object is to be cached, each one of the *<dependency-id>* elements is run to build a set of dependency IDs for that cache entry. Finally, each of the *<invalidation>* elements are run, building a list of IDs that the dynamic cache invalidates, whether or not this object is cached.

Verifying the cacheable page

Use this task to verify that the dynamic cache service has its cache policies configured correctly and is serving cached content.

Before you begin

The dynamic cache service should be enabled. You should have a cache policy developed for your application. Refer to the Configuring cacheable objects with the cachespec.xml file article for more information. You must have servlet caching enabled in the web container. Refer to the Configuring servlet caching article for more information.

About this task

You can verify the cacheable page by invoking the snoop servlet in the default application. If the dynamic cache is working correctly, refreshing the servlet repeatedly results in viewing cached content.

Procedure

1. View the Snoop servlet in the default application by accessing the URI: `/snoop` The Snoop servlet is a part of the default application. Refer to the Default application article for more information.
2. Invoke and reload the URI several times using a different web browser or using different parameters. This action returns the same output for the snoop servlet. The snoop servlet is now operating incorrectly, because it displays the request information from its first invocation rather than from the current request.
3. Inspect the entry in the cache with the dynamic cache monitor. Refer to the Displaying cache information article for more information.

---

cachespec.xml file

The cache parses the `cachespec.xml` file when the server starts, and extracts a set of configuration parameters from each cache-entry element. Every time a new servlet or other cacheable object initializes, the cache attempts to match each of the cache-entry elements to find the configuration information for that object.

The cache-entry elements can be inside the root cache element or inside a cache-instance element. Cache entries that are in the root element are cached with the default cache instance. Cache entries that are in the <cache-instance> element are cached in that particular cache instance. Different cacheable objects have different class elements. You can define the specific object that a cache policy refers to using the name element.

Location

Place the `cachespec.xml` file with the deployment module. Use an assembly tool to define the cacheable objects. See topics about assembling applications. You can also place a global `cachespec.xml` file in the application server properties directory. In situations where there is a global `cachespec.xml` file in the application server properties directory, and a `cachespec.xml` file in an application, the entries in the two cachespec.xml files are merged. If there are conflicting entries in the two files, the entries in the in the `cachespec.xml` file that is in the application override the entries in the global `cachespec.xml` file for that application.

The `cachespec.dtd` file is available in the application server properties directory. The `cachespec.dtd` file defines the legal structure and the elements that can be in your `cachespec.xml` file.

Usage notes

Cachespec.xml elements

The root element of the `cachespec.xml` file is cache and contains cache-instance and cache-entry elements. The cache-entry elements can also be placed inside of cache-instance elements to make that cache entry part of a cache instance that is different from the default.

cache-instance

```
<cache-instance name="cache_instance_name"></cache-instance>
```

The name attribute is the Java Naming and Directory Interface (JNDI) name of the cache instance that is set in the administrative console.

Each cache-instance element must contain at least one cache-entry element. A cache entry that is matched within a cache-instance element is cached in the servlet cache instance that is specified by the name attribute. If identical cache-entry elements exist across cache-instance elements, the first cache-entry element that is matched is used.

cache-entry

Each cache entry must specify certain basic information that the dynamic cache uses to process that entry. This section explains the function of each cache entry element of the `cachespec.xml` file including:

- class
- name
- sharing-policy
- skip-cache
- property
- cache-id

With the current version of WebSphere Application Server, you can define multiple cache policies for a single servlet. For example, if you define multiple mappings for a servlet in the `web.xml` file, you can create a cache entry for each one of the mappings.

class

```
<class>command | servlet | webservice | JAXRPCClient | static | portlet </class>
```

This element is required and specifies how the application server interprets the remaining cache policy definition. The value `servlet` refers to servlets and JavaServer Pages (JSP) files that are deployed in the WebSphere Application Server servlet engine. The `webservice` class extends the servlet with special component types for web services requests. The `JAXRPCClient` is used to define a cache entry for the web services client cache. The value, `command`, refers to classes using the WebSphere Application Server command programming model. The value, `static`, refers to files that contain static content. The following examples illustrate the class element:

```
<class>command</class>
<class>servlet</class>
<class>webservice</class>
<class>JAXRPCClient</class>
<class>static</class>
<class>portlet</class>
```

name

```
<name>name</name>
```

Use the following guidelines for the name element to specify a cacheable object:

- For commands, this required element must include the package name, if any, and class name, including a trailing `.\class`, of the configured object.

  Important: If you specify command caching in the cachespec.xml file, and servlet caching is not enabled for the application server on which the application runs, you will get an error. The application server still attempts to obtain a cache instance; therefore, enabling servlet caching will eliminate the error.
- For servlets and JSP files, if the `cachespec.xml` file is in the WebSphere Application Server properties directory, this required element must include the full URI of the JSP file or servlet to cache. For servlets and JSP files, if the `cachespec.xml` file is in the web application, this required element can be relative to the specific web application context root.
- For web services, include the Universal Resource Identifier (URI) of the Simple Object Access Protocol (SOAP) router that is associated with the web service that you want to cache.

- For web services client cache, the name is the target end point of the cacheable web service or the URI of the SOAP router that is associated with the cacheable web service. You can use the SOAP address location in the Web Services Description Language (WSDL) file to define the name for the web services client cache.
- For static files, if the `cachespec.xml` file is in the WebSphere Application Server properties directory, this required element must include the full URI of the file to cache. If the `cachespecm.xml` file is in the web application, this required element can be relative to the specific web application context root. For a web application with a context root, the cache policy for files using the static class must be specified in the web application, and not in the properties directory.
- For portlets, if the `cachespec.xml` file is in the WebSphere Application Server properties directory, this required element must include the full context path and name of the portlet to cache. If the `cachespec.xml` file is in the web application, this required element is the portlet name that is relative to the specific web application context root.

Tip: The preferred location of the `cachespec.xml` file is in the web application, not the properties directory.

You can specify multiple name elements within a cache-entry if you have different mappings that refer to the same servlet.

The following examples illustrate the name element:

```
<name>com.mycompany.MyCommand.class</name>
<name>default_host:/servlet/snoop</name>
<name>com.mycompany.beans.MyJavaBean</name>
<name>mywebapp/myjsp.jsp</name>
<name>/soap/servlet/soaprouter</name>
<name>http://remotecompany.com:9080/service/getquote</name>
<name>mywebapp/myLogo.gif</name>
```

sharing-policy

```
<sharing-policy> not-shared | shared-push | shared-pull | shared-push-pull</sharing-policy>
```

When working within a cluster with a distributed cache, these values determine the sharing characteristics of entries that are created from this object. If this element is not present, a not-shared value is assumed. On the z/OS platform, you can enable replication between servants in a base application server by using the DynacacheEnableUnmanagedServerReplication and DynacacheUnmanagedServerReplicationType Java virtual machine (JVM) custom properties. When enabling a replication, the default value is `not-shared` . This property does not affect distribution to Edge Side Include processors through the Edge fragment caching property.

Refer to the Configuring cache replication article for more information.

Table 38. Sharing-policy values. Values and description for the sharing-policy.

Value	Description
not-shared	Cache entries for this object are not shared among different application servers. These entries can contain non-serializable data. For example, a cached servlet can place non-serializable objects into the request attributes, if the <class> type supports it. **Note:** The application server will always replicate invalidation entries. They are not affected by the sharing policy.
shared-push	Cache entries for this object are automatically distributed to the dynamic caches in other application servers or cooperating Java virtual machines (JVMs). Each cache has a copy of the entry at the time it is created. These entries cannot store non-serializable data.
shared-pull	Cache entries for this object are shared between application servers on demand. If an application server gets a cache miss for this object, it queries the cooperating application servers to see if they have the object. If no application server has a cached copy of the object, the original application server runs the request and generates the object. These entries cannot store non-serializable data. This mode of sharing is not recommended.
shared-push-pull	Cache entries for this object are shared between application servers on demand. When an application server generates a cache entry, it broadcasts the cache ID of the created entry to all cooperating application servers. Each server then knows whether an entry exists for any given cache ID. On a given request for that entry, the application server knows whether to generate the entry or pull it from somewhere else. These entries cannot store non-serializable data.

The following example shows a sharing policy:

```
<sharing-policy>not-shared</sharing-policy>
```

skip-cache

Takes the name of a request attribute, which if present in the request context, dictates that the response cannot be retrieved from the cache instance that is specified. This property is useful for previewing content in production systems and verifying that the application is working and performing as expected.

```
<cache>
 <skip-cache-attribute>att1</skip-cache-attribute> <!—Applies only to the base cache- ->
...
<cache-instance name="instance1">
<skip-cache-attribute>att2</skip-cache-attribute> <!-Applies only to this instance- ->
...
</cache-instance>
</cache>
```

property

```
<property name="key">value</property>
```

where *key* is the name of the property for this cache entry element, and *value* is the corresponding value.

You can set optional properties on a cacheable object, such as a description of the configured servlet. The class determines valid properties of the cache entry. At this time, the following properties are defined:

Table 39. Property values. Property values and valid classes.

Property	Valid classes	Value
ApplicationName	All	Overrides the JavaEEName application ID so that multiple applications can share a common cache ID namespace.
EdgeCacheable	Servlet	True or false. The default is `false`. If the property is `true`, then the given servlet or JSP file is externally requested from an Edge Side Include processor. Whether or not the servlet or JSP file is cacheable depends on the rest of the cache specification. The permissible components for general edgecacheable cache entries are PARAMETER, HEADER, COOKIE, and PATH_INFOSERVLET_PATH
ExternalCache	Servlet and portlet	Specifies the external cache name. The external cache name needs to match the external cache group name.

consume-subfragments	Servlet, web service, or portlet	True or false. The default is `false`. When a servlet is cached, only the content of that servlet is stored, and includes placeholders for any other fragments to which it includes or forwards. Consume-subfragments (CSF) tells the cache not to stop saving content when it includes a child servlet. The parent entry, the one marked CSF, includes all the content from all fragments in its cache entry, resulting in one big cache entry that has no includes or forwards, but the content from the whole tree of entries. Consume-subfragments can save a significant amount of application server processing, but is typically only useful when the external HTTP request contains all the information needed to determine the entire tree of included fragments.
		
		Use the <exclude> element to tell the cache to stop consuming for the excluded fragment and instead, create a placeholder for the include or forward. For example, exclude `A.jsp` from the consume-subfragment, as follows:
		`<property name=`
		` "consume-sbufragments">true`
		`<exclude>/A.jsp<exclude>`
		`</property>`

do-not-consume	Servlet, web service, or portlet	True or false. The default is `false`. When a fragment parent has the consume-subfragment property set to true the child fragment content is saved in the cache entry of the parent. Do-not-consume (DNC) tells the cache to stop saving the content for this fragment in the parent cache-entry and create a placeholder instead for the include or forward.
alternate_url	Servlet	Specifies the alternate URL that is used to invoke the servlet or JSP file. The property is valid only if the EdgeCacheable property also is set for the cache entry.
persist-to-disk	All	True or false. The default is `true`. When this property is set to `false`, the cache entry is not written to the disk when overflow or server stopping occurs.

Table 39. Property values (continued). Property values and valid classes.

Property	Valid classes	Value

save-attributes	Servlet and portlet	True or false. The default is `true`. When this property is set to `false`, the request attributes are not saved with the cache entry.
		
		Use the <exclude> element to specify the request attributes that do not apply to the save-attributes property. For example, to save only the attr1 attribute with the cache entry:
		`<property name=`
		`"save-attributes">false`
		`<exclude>attr1</exclude>`
		`</property>`
		
		To save all attributes except the `attr1` attribute in the cache entry, set the property to true in the preceding sample. If you do not use the <exclude> element, either all or no request attributes are saved with the cache entry.

delay-invalidations	Command	True or false. When this property is set to `true`, the commands that are invalidating cached objects based on the invalidation rules in this cache entry invalidate the cache entries after running. By default, the invalidation occurs before the command runs.

store-cookies	Servlet and portlet	On or off. The default is `On`. This property takes one or more cookie name as its argument which is saved along with the cache object and restored by the servlet cache in the response with a set-cookie header.
		
		Save all cookies except cookie1 as part of the cache-entry as follows:
		`<property name=`
		` "store-cookies">true`
		`<exclude>cookie</exclude>`
		`</property>`
		
		Save only cookie1 as part of the cache-entry, as follows:
		`<property name=`
		` "store-cookies">false`
		`<exclude><cookie1</exclude>`
		`</property>`

ignore-get-post	Servlet and portlet	True or false. The default is `false`. When the property is set to `true` the request type is not appended to the cache-id for GET and POST requests unless the requestType component requestType component subelement is defined. By default the request type is automatically appended to the cache-id for GET and POST requests.
ignore-char-encoding	Servlet and portlet	True or false. The default value is `false`. When the property is set to `true`, UTF-8 character encoding is not appended to the cache ID. Appending UTF-8 character encoding to the cache ID might lead to multiple copies of fragments, which unnecessarily increases the size of the cache.

do-not-cache	Servlet and portlet	Defines a fragment that is neither cached nor consumed by its parent.
		`<cache-entry>`
		`...`
		`<property name="do-not-cache">`
		` true</property>`
		
		or
		`<cache-id>`
		`<property name="do-not-cache">`
		` true</property>`
		`</cache-id>`
		`</cache-entry>`

cache-id

To cache an object, the application server must know how to generate a unique ID for different invocations of that object. These IDs are built either from user-written custom Java code or from rules that are defined in the cache policy of each cache entry. Each cache entry can have multiple cache ID rules that run in order until either:

- A rule returns a non-empty cache ID, or
- No more rules are left to run.

If none of the cache ID generation rules produce a valid cache ID, the object is not cached.

Each cache-id element defines a rule for caching an object and is composed of the sub-elements component, timeout, inactivity, priority, property, idgenerator, and metadatagenerator. The following example illustrates a cache-id element:

```
<cache-id>
   component*| timeout? | inactivity? | priority? | property* | idgenerator? | metadatagenerator?
</cache-id>
```

component subelement

Use the component subelement to generate a portion of the cache ID. The component subelement consists of the attributes id, type, and ignore-value, and the elements index, method, field, required, value, and not-value.

- Use the id attribute to identify the component.
- Use the type attribute to identify the type of component. The following table lists the values for the type.

gotcha: When the parameter component subelement is specified in the cachespec.xml file, the web container sets character encoding based on the encoding setting obtained from the request object. If a servlet subsequently invokes the setCharacterEncoding method, the method has not effect because character encoding cannot be changed after it has already been set.

Type	Valid classes	Meaning
method	Command	Calls the indicated method on the command or object
field	Command	Retrieves the named field in the command or object
parameter	Servlet and portlet	Retrieves the named parameter value from the request object
parameter-list	Servlet and portlet	Retrieves a list of values for the named parameter **gotcha:** The cache grabs the values for all of the parameters with this name and uses all of these values, in the order they are grabbed, to create the cache ID
session	Servlet and portlet	Retrieves the named value from the HTTP session
cookie	Servlet	Retrieves the named cookie value
attribute	Servlet and portlet	Retrieves the named request attribute
header	Servlet, web service, and portlet	Retrieves the named request header
pathInfo	Servlet	Retrieves the pathInfo element from the request
servletpath	Servlet	Retrieves the servlet path
locale	Servlet and portlet	Retrieves the request locale **Attention:** The locale component is permissible for edgecacheable entries only, when using RRD. The locale component is not valid for all other ESI versions.
requestType	Servlet and portlet	Retrieves the HTTP request method from the request. **Attention:** The requestType component is permissible for edgecacheable entries only, when using RRD. The requestType component is not valid for all other ESI versions.
tiles_attribute	Servlet and portlet	Retrieves the value of an attribute from a tile.
SOAPEnvelope	Web service and web services client cache	Retrieves the SOAPEnvelope element from a web services request. An ID attribute of Hash uses a Hash of the SOAPEnvelope element, while Literal uses the SOAPEnvelope element as received.

Type	Valid classes	Meaning
SOAPAction	Web service	Retrieves the SOAPAction header, if available, for a web services request.
serviceOperation	Web service	Retrieves the service operation for a web services request
serviceOperationParameter	Web service	Retrieves the specified parameter from a web services request
operation	Web services client cache	Indicates an operation type in the Web Services Description Language (WSDL) file. The id attribute is ignored and the value is the operation or method name. If the namespace of the operation is specified, format the value as `namespaceOfOperation:nameOfOperation`
part	Web services client cache	Indicates an input message part in the WSDL file or a request parameter. Its id attribute is the part or parameter name, and the value is the part or parameter value.

SOAPHeaderEntry	Web services client cache	Retrieves special information in the Simple Object Access Protocol (SOAP) header of the web services request. The id attribute specifies the name of the entry. In addition, the entry of the SOAP header in the SOAP request must have the actor attribute, which contains com.ibm.websphere.cache. For example:
		`<soapenv:Header>`
		`<getQuote soapenv:actor=`
		`"com.ibm.websphere.cache">IBM`
		`</getQuote>`
		`</soapenv:Header>`

portletSession	Portlet	Retrieves the named value from the portlet session
portletWindowId	Portlet	Retrieves the portlet window ID from the portlet request object
portletMode	Portlet	Retrieves the portlet mode from the portlet request object
portletWindowsState	Portlet	Retrieves the portlet window state from the portlet request object
sessionID	Servlet and portlet	Retrieves the HTTP session ID

- Use the ignore-value attribute to specify whether or not to use the value that is returned by this component in cache ID formation. This attribute is optional with a default value of `false`. If the value is `true`, only the ID of the component is used when creating a cache ID, or no output is used when creating a dependency or invalidation ID.
- Use the method element to call a void method on a returned object. You can infinitely nest method and field objects in any combination. The method must be public and is not valid for edge-cacheable components. For example:

  ```
  <component id="getUser" type="method"><method>getUserInfo
  <method>getName</method></method></component>
  ```

  This method is equivalent to getUser().getUserInfo().getName()

  For component types attribute, method, or field that can return an object, when the object returned is a collection or array, the ID is created with a comma separated list of the elements in the collection or array. For example, if the request attribute users returns an array [a, b] and the cache entry is defined like the following example:

  ```
  <cache-entry>
   <class>servlet</class>
   <name>xxx.jsp</name>
   <cache-id>
    .
  ```

```
  .
  <component id="users" type="attribute">
   <required>true</required>
  </component>
  .
  .
 </cache-id>
 <dependency-id>dep
  <component id="users" type="attribute">
   <required>true</required>
  </component>
 </dependency-id>
</cache-entry>
```

The cache id contains the string `users: a,b`. The dependency id is `dep: a,b`.

Use the multipleIDs attribute with the component types to specify and generate multiple dependency IDs (or invalidation IDs), based on the items in the collection or array. For example:

```
<cache-entry>
 <class>servlet</class>
 <name>xxx.jsp</name>
 <cache-id>
  .
  .
   <component id="users" type="attribute">
    <required>true</required>
   </component>
  .
  .
 </cache-id>
 <dependency-id>dep
  <component id="users" type="attribute" multipleIDs="true">
   <required>true</required>
  </component>
 </dependency-id>
</cache-entry>
```

The cache policy will generates the following dependency IDs:

- `dep:a,b`
- `dep:a`
- `dep:b`

Use the index element with the previous component type to add only the value of the element at the specified index position in the collection or array, to the ID that is being created.

```
<cache-entry>
 <class>servlet</class>
 <name>xxx.jsp</name>
 <cache-id>
  .
  .
   <component id="users" type="attribute">
    <required>true</required>
    <index>1</index>
   </component>
  .
  .
 </cache-id>
 <dependency-id>dep
  <component id="users" type="attribute" multipleIDs="true">
   <required>true</required>
  </component>
 </dependency-id>
</cache-entry>
```

The previous cache policy generates the following component to use in the cache ID: `users: b`.
Use the <method> element to call a void method on a returned object.

- Use the field element to access a field in a returned object. You can infinitely nest method and field objects in any combination. The field must be public. This field is not valid for edge-cacheable components. For example:

```
<component id="getUser" type="method"><method>getUserInfo
<field>name</field></method></component>
```

This method is equivalent to the getUser().getUserInfo().name method.

- Use the required element to specify whether or not this component must return a non-null value for this cache ID to represent a valid cache. If set to `true`, this component must return a non-null value for this cache ID to represent a valid cache ID. If set to `false`, the default, a non-null value is used in the formation of the cache ID and a null value means that this component is not used at all in the ID formation. For example:

  ```
  <required>true</required>
  ```
- Use the value element to specify values that must match to use this component in cache ID formation. For example:

  ```
  <component id="getUser" type="method"><value>blue</value>
  <value>red</value> </component>
  ```
- Use the not-value element to specify values that must not match to use this component in cache ID formation. This method is similar to value element, but instead prescribes the defined values from caching. You can use multiple not-value elements when more than one value that is not valid exists. For example:

  ```
  <component id="getUser" type="method">
  <required>true</required>
  <not-value>blue</not-value>
  <not-value>red</not-value></component>
  ```

The component subelement can have either a method and a field element, a value element, or a not-value element. The method and field elements apply to commands only. The following example illustrates the attributes of a component sub-element:

```
<component id="isValid" type="method" ignore-value="true"><component>
```

timeout subelement

The timeout subelement is used to specify an absolute time-to-live (TTL) value for the cache entry. For example,

```
<timeout>value</timeout>
```

where *value* is the amount of time, in seconds, to keep the cache entry. Cache entries that are in memory are kept indefinitely, as long as the entries remain in memory. Cache entries that are stored on disk are evicted if they are not accessed for 24 hours.

inactivity subelement

The inactivity subelement is used to specify a time-to-live (TTL) value for the cache entry based on the last time that the cache entry was accessed. It is a subelement of the cache-id element.

```
<inactivity>value</inactivity>
```

where *value* is the amount of time, in seconds, to keep the cache entry in the cache after the last cache hit.

priority subelement

Use the priority subelement to specify the priority of a cache entry in a cache. The priority weighting is used by the least recently used (LRU) algorithm of the cache to decide which entries to remove from the cache if the cache runs out of storage space. For example,

```
<priority>value</priority>
```

where *value* is a positive integer between 1 and 16 inclusive.

Samples

The following sample keeps the cache entry in the cache for a minimum of 35 seconds and a maximum of 180 seconds. If the cache entry is accessed within each 35 second inactivity period, the inactivity period is extended for another 35 seconds. However, because the timeout element is also configured, the cache entry is always invalidated after 180 seconds. If the cache entry is not accessed within the 35 second period, the entry is removed from the cache.

```
<cache-id>
 <component id="timeout" type="parameter">
  <required>true</required>
 </component>
```

```
 <timeout>180</timeout>
 <inactivity>35</inactivity>
 <priority>1</priority>
</cache-id>
```

The following sample keeps the cache entry in the cache for a minimum of 600 seconds. If the cache entry is accessed within each 600 second period, the inactivity period is extended for another 600 seconds. If the cache entry is not accessed within the 600 second period, the cache entry is removed from the cache.

```
<cache-id>
 <component id="timeout" type="parameter">
  <required>true</required>
 </component>
 <inactivity>600</inactivity>
 <priority>1</priority>
</cache-id>
```

In the following sample, the value for inactivity has no meaning because the timeout period is less than the inactivity period. The cache entry is always invalidated after 180 seconds, no matter how often the cache entry is accessed.

```
<cache-id>
 <component id="timeout" type="parameter">
  <required>true</required>
 </component>
 <timeout>180</timeout>
 <inactivity>600</inactivity>
 <priority>1</priority>
</cache-id>
```

property subelement

Use the property subelement to specify generic properties for the cache entry. For example,

```
<property name="key">value</property>
```

where *key* is the name of the property to define, and *value* is the corresponding value.

For example:

```
<property name="description">The Snoop Servlet</property>
```

Table 40. Property subelement values.. Property valid classes and meaning.

Property	Valid classes	Meaning
sharing-policy/timeout/priority	All	Overrides the settings for the containing cache entry when the request matches this cache ID.
EdgeCacheable	Servlet	Overrides the settings for the containing cache entry when the request matches this cache ID.

idgenerator and metadatagenerator sub-elements

Use the idgenerator element to specify the class name that is loaded for the generation of the cache ID. The IdGenerator element must implement the com.ibm.websphere.servlet.cache.IdGenerator interface for a servlet or the com.ibm.websphere.webservices.IdGenerator interface for the web services client cache. An example of the idgenerator element follows:

```
<idgenerator> class name </idgenerator>
```

Where *class name* is the fully-qualified name of the class to use. Define this generator class in a shared library.

Use the metadatagenerator element inside the cache-id element to specify the class name loaded for the metadata generation. The MetadataGenerator class must implement the com.ibm.websphere.servlet.cache.MetaDataGenerator interface for a servlet or the

com.ibm.websphere.cache.webservices.MetaDataGenerator interface for a web services client cache. The MetadataGenerator class defines properties like timeout, inactivity, external caching properties or dependencies. An example of the `metadatagenerator` element follows:

```
<metadatagenerator> classname </metadatagenerator>
```

In this example, class name is the fully-qualified name of the class to use. Define this generator class in a shared library.

dependency-id element

Use the dependency-id element to specify additional cache identifiers that associate multiple cache entries to the same group identifier.

The value of the dependency-id element is generated by concatenating the dependency ID base string with the values that are returned by its component elements. If a required component returns a null value, the entire dependency does not generate and is not used. Validate the dependency IDs explicitly through the dynamic cache API, or use the invalidation element. Multiple dependency ID rules can exist in one cache-entry element. All dependency rules run separately.

invalidation element

To invalidate cached objects, the application server must generate unique invalidation IDs. Build invalidation IDs by writing custom Java code or through rules that are defined in the cache policy of each cache entry. The following example illustrates an invalidation in the cache policy:

```
<invalidation>component* | invalidationgenerator? </invalidation>
```

invalidationgenerator subelement

The invalidationgenerator element is used with the web services client cache only. Use the invalidationgenerator element to specify the class name to load for generating invalidation IDs. The InvalidationGenerator class must implement the com.ibm.websphere.cache.webservices.InvalidationGenerator interface. An example of the invalidationgenerator element follows:

```
<invalidationgenerator>class name</invalidationgenerator>
```

In this example, classname is the fully qualified name of the class that implements the com.ibm.websphere.cache.webservices.InvalidationGenerator interface. Define this generator class in a shared library.

Example: Configuring the dynamic cache service

This example puts all of the steps together for configuring the dynamic cache service with the `cachespec.xml` file, showing the use of the cache ID generation rules, dependency IDs, and invalidation rules.

Suppose that a servlet manages a simple news site. This servlet uses the query parameter "action" to determine if the request views (query parameter "view") news or updates (query parameter "update") news (used by the administrator). Another query parameter "category" selects the news category. Suppose that this site supports an optional customized layout that is stored in the user's session using the attribute name "layout". Here are example URL requests to this servlet:

`http://yourhost/yourwebapp/newscontroller?action=view&category=sports` (Returns a news page for the sports category)

`http://yourhost/yourwebapp/newscontroller?action=view&category=money` (Returns a news page for the money category)

`http://yourhost/yourwebapp/newscontroller?action=update&category=fashion` (Allows the administrator to update news in the fashion category)

Here are the steps for configuring the dynamic cache service for this example with the `cachespec.xml` file:

1. Define the <cache-entry> elements that are necessary to identify the servlet. In this case, the URI for the servlet is "newscontroller", so this is the cache-entry <name> element. Because this example caches a servlet or JavaServer Pages (JSP) file, the cache entry class is "servlet".

```
<cache-entry>
<name> /newscontroller </name>
<class>servlet  </class>
 </cache-entry>
```

2. Define cache ID generation rules. This servlet caches only when action=view, so one component of the cache ID is the parameter "action" when the value equals "view". The news category is also an essential part of the cache ID. The optional session attribute for the user's layout is included in the cache ID. The cache entry is now:

```
<cache-entry>
 <name> /newscontroller </name>
 <class>servlet  </class>
  <cache-id>
  <component id="action" type="parameter">
   <value>view</value>
   <required>true</required>
  </component>
  <component id="category" type="parameter">
   <required>true</required>
  </component>
  <component id="layout" type="session">
   <required>false</required>
  </component>
 </cache-id>
</cache-entry>
```

3. Define dependency ID rules. For this servlet, a dependency ID is added for the category. Later, when the category is invalidated due to an update event, all views of that news category are invalidated. Following is an example of the cache entry after adding the dependency ID:

```
<cache-entry>
 <name>newscontroller </name>
 <class>servlet  </class>
  <cache-id>
  <component id="action" type="parameter">
   <value>view</value>
   <required>true</required>
  </component>
  <component id="category" type="parameter">
   <required>true</required>
  </component>
  <component id="layout" type="session">
   <required>false</required>
  </component>
 </cache-id>
 <dependency-id>category
  <component id="category" type="parameter">
   <required>true</required>
  </component>
 </dependency-id>
</cache-entry>
```

4. Define invalidation rules. Because a category dependency ID is already defined, define an invalidation rule to invalidate the category when action=update. To incorporate the conditional logic, add

"ignore-value" components into the invalidation rule. These components do not add to the output of the invalidation ID, but only determine whether or not the invalidation ID creates and runs. The final cache-entry now looks like the following:

```
<cache-entry>
 <name>newscontroller </name>
 <class>servlet  </class>
  <cache-id>
  <component id="action" type="parameter">
   <value>view</value>
   <required>true</required>
  </component>
  <component id="category" type="parameter">
   <required>true</required>
  </component>
  <component id="layout" type="session">
   <required>false</required>
  </component>
 </cache-id>
 <dependency-id>category
  <component id="category" type="parameter">
   <required>true</required>
  </component>
 </dependency-id>
 <invalidation>category
  <component id="action" type="parameter" ignore-value="true">
   <value>update</value>
   <required>true</required>
  </component>
  <component id="category" type="parameter">
   <required>true</required>
     </component>
 </invalidation>
</cache-entry>
```

cacheinstances.properties file

Use the information in this document as a reference of the names, values, and explanations that you can use in the cacheinstances.properties file.

The following list provides the property names, associated values, and explanations for the cacheinstance.properties file.

Property name - x is the instance number, which starts with 0	**Version**	**Scope**	**Possible value**	**Description**
Cache core properties				
`cache.instance.x`	5.1.x and later	Per cache instance	any string (no default set)	Specifies cache instance name or JNDI name.
`cache.instance.x. cacheSize`	5.1.x and later	Per cache instance	> 0 (default=2000)	Specifies the maximum number of entries that are held in memory cache.
`cache.instance.x. disableDependencyId`	6.0.2.x and later	Per cache instance	True or false (default=false)	Specifies that the dynamic cache service supports cache entry dependency IDs. Disable this option if you do not need to use dependency IDs. Dependency IDs specify additional cache group identifiers that associate multiple cache entries to the same group identifier in your cache policy.

Property name - x is the instance number, which starts with 0	Version	Scope	Possible value	Description
cache.instance.x. disableTemplates Support	6.0.2.x and later	Per cache instance	True or false (default=false)	Specifies whether template support feature is enabled.
cache.instance.x. useListenerContext	5.1.x and later	Per cache instance	True or false (default=false)	Set this value to true to have invalidation events sent to registered invalidation listeners, using the Java Platform, Enterprise Edition (Java EE) context of the listener. If you want to use listener Java EE context for callback, set this value to true. If you want to use the caller thread context for callback, set this value to false.
cache.instance.x. enableNioSupport	6.0.2.x and later	Per cache instance	True or false (default=false)	Specifies whether DistributedMap or DistributedNioMap is used.
cache.instance.x. memoryCacheSizeInMB	7.0	Per cache instance	> 0 (default: -1 limit does not exist)	Specifies a value for the maximum memory cache size in megabytes (MB)
cache.instance.x. memoryCacheHigh Threshold	7.0	Per cache instance	> 0 % (default=95)	Specifies when the eviction policy runs. The threshold is expressed in terms of the percentage of the memory cache size in MB. The higher value is used when limit memory cache size in MB is specified.
cache.instance.x. memoryCacheLow Threshold	7.0	Per cache instance	> 0 % (default=80)	Specifies when the eviction policy runs. The threshold is expressed in terms of the percentage of the memory cache size in MB. The lesser value is used when limit memory cache size in MB is specified.
cache.instance.x. createCacheAt ServerStartup	7.0	Per cache instance	True or false (default=false)	Specifies whether the configured cache instance is created during the server startup. This is useful when cache replication feature is used. However, the time for server startup will take long.
Cache servlet/JavaServer Pages (JSP) caching properties				
cache.instance.x. cascadeCachespec Properties	6.0.2.19, 6.1.0.9 and later	Per cache instance	True or false (default=false)	A configurable change in the behavior of the cache so that the child pages and fragments inherit the cache specification properties of their parent pages and fragments. If the request for a fragment does not match a defined cache policy, the fragment will inherit the save-attributes and the store-cookies properties from its parent fragment. Enable this cascade of save-attributes and store-cookies properties by setting the value to true.

Property name - x is the instance number, which starts with 0	Version	Scope	Possible value	Description
cache.instance.x. disableStoreCookies	6.0.2.9, 6.1.x and later	Per cache instance	"none", "ALL","All", cache instance name, comma delineated list of cookie names, (default="none")	Specifies whether disable store cookies is NONE or ALL. Stores cookies as part of the response by default unless configured otherwise on a per request basis in cachespec.xml file. There is a risk of sharing cookies between users, which violates security.
cache.instance.x. enableServlet Support	6.0.2.x and later	Per cache instance	True or false (default=false)	Specifies whether the cache instance is servlet cache or object cache.
Cache disk offload properties				
cache.instance.x. enableDiskOffload	5.1.x and later	Per cache instance	True or false (default=false)	Specifies whether disk offload is enabled.
cache.instance.x. diskOffload Location	5.1.x and later	Per cache instance	String – For example: . $(app_server_root) /diskOffload	Specifies the location on the disk to save cache entries when disk offload is enabled.
cache.instance.x. diskCacheSize	5.1.1.13, 6.0.2.17, 6.1.x and later	Per cache instance	>= 0 (0=limit does not exist)	Specifies a value for the maximum disk cache size in number of entries.
cache.instance.x. diskCacheSizeInGB	5.1.1.13, 6.0.2.17, 6.1.x and later	Per cache instance	0 or > 2 in GB (0=limit does not exist)	Specifies a value for the maximum disk cache size in gigabytes (GB).
cache.instance.x. diskCacheEntrySize InMB	5.1.1.13, 6.0.2.17, 6.1.x and later	Per cache instance	>= 0 in MB (0=limit does not exist)	Specifies a value for the maximum size of an individual cache entry in megabytes (MB). Any cache entry that is larger than this, when evicted from memory, will not be offloaded to disk.
cache.instance.x. flushToDiskOnStop	5.1.x and later	Per cache instance	True or false (default = false)	Specifies if in-memory cached objects are saved to disk when the server stops.
cache.instance.x. diskCache PerformanceLevel	5.1.1.13, 6.0.2.17, 6.1.x and later	Per cache instance	0=low 1=balance 2=custom 3=high (default=1)	Specifies the performance level to tune the performance of the disk cache.
cache.instance.x. htodCleanup Frequency	5.1.1.2 and later	Per cache instance	0 <= x <= 1440 in minutes (0=cleanup at midnight)	Specifies a value for the disk cache cleanup frequency, in minutes. If this value is set to 0, the cleanup runs only at midnight. This setting applies only when the Disk Offload Performance Level is low, balanced, or custom. The high performance level does not require disk cleanup, and this value is ignored.
cache.instance.x. htodDelayOffload DepIdBuckets	5.1.1.13, 6.0.2.17, 6.1.x and later	Per cache instance	> 0 (default=1000)	Specifies a value for the maximum number of dependency identifier buckets in the disk cache metadata in memory. If this limit is exceeded, the information is offloaded to the disk. This setting applies only when the disk cache performance level is custom.

Property name - x is the instance number, which starts with 0	Version	Scope	Possible value	Description
cache.instance.x.htodDelayOffloadTemplateBuckets	5.1.1.13, 6.0.2.17, 6.1.x and later	Per cache instance	> 0 (default=100)	Specifies a value for the maximum number of template buckets that are in the disk cache metadata in memory. If this limit is exceeded, the information is offloaded to the disk. This setting applies only when the disk cache performance level is custom.
cache.instance.x htodDelayOffloadEntriesLimit	5.1.1.2 and later	Per cache instance	> 0 (default=1000)	Specifies a value for the maximum number of cache identifiers that are stored for an individual dependency ID or template in the disk cache metadata in memory. If this limit is exceeded, the information is offloaded to the disk. This setting applies only when the disk offload performance level is custom.
cache.instance.x.diskCacheEvictionPolicy	5.1.1.13, 6.0.2.17, 6.1.x and later	Per cache instance	0=disable 1=random 2:size (default=0)	Specifies the eviction algorithm that the disk cache will use to evict entries once the high threshold is reached.
cache.instance.x.diskCacheHighThreshold	5.1.1.13, 6.0.2.17, 6.1.x and later	Per cache instance	> 0 % (default=80)	Specifies when the eviction policy runs. The threshold is expressed in terms of the percentage of the disk cache size in GB or entries. The high value is used when limit disk cache size in GB and limit disk cache size in entries are specified.
cache.instance.x.diskCacheLowThreshold	5.1.1.13, 6.0.2.17, 6.1.x and later	Per cache instance	> 0 % (default=70)	Specifies when the eviction policy runs. The threshold is expressed in terms of the percentage of the disk cache size in GB or entries. The lesser value is used when limit disk cache size in GB and limit disk cache size in entries are specified.
Cache replication properties				
cache.instance.x.enableCacheReplication	6.0.2.x and later	Per cache instance	True or false (default=false)	Specifies whether cache replication is enabled. Use cache replication to have cache entries copied to multiple application servers configured in the same replication domain.
cache.instance.x.replicationType	5.1.x and later	Per cache instance	1 (Not shared, 2 (Push), 4 (Push and pull)	Specifies the global sharing policy for this application server.
cache.instance.x.replicationDomain	6.0.2.x and later	Per cache instance	String – For example: DynamicCacheDomain	Specifies a replication domain from which your data is replicated.
cache.instance.x.useServerClassLoader	5.1.1.9, 6.0.2.9, 6.1.x and later	Per cache instance	True or false (default=false)	Specifies whether using server class loader is enabled. Setting this value to true, deserializes the InvalidationEvent using system classloader first and then using application classloader, if that fails. This improves performance.

Property name - x is the instance number, which starts with 0	Version	Scope	Possible value	Description
cache.instance.x. cacheEntryWindow	5.1.1.13, 6.0.2.17, 6.1.0.7 and later	Per cache instance	> 0 (default=50)	Specifies a limit on the total number of cache entries that are sent by the data replication service (DRS) in terms of number of entries.
cache.instance.x. cachePercentage Window	5.1.1.13, 6.0.2.17, 6.1.0.7 and later	Per cache instance	> 0 % (default=2)	Specifies a limit on the number of cache entries that are sent by DRS in terms of the percentage of total cache in memory.
cache.instance.x. cacheInvalidate EntryWindow	5.1.1.14, 6.0.2.19, 6.1.0.7 and later	Per cache instance	> 0 (default=50)	Specifies a limit on the total number of invalidation events that are sent by DRS in terms of number of entries.
cache.instance.x. cacheInvalidate PercentWindow	5.1.1.14, 6.0.2.19, 6.1.0.7 and later	Per cache instance	> 0 % (default=2)	Specifies a limit on the number of invalidation events that are sent by DRS in terms of the percentage of total cache in memory.
cache.instance.x. filterTimeOut Invalidation	6.0.2.13, 6.1.x and later	Per cache instance	True or false (default=false)	Specifies whether sending invalidations that are based on timeout eviction is enabled.
cache.instance.x. filterLRU Invalidation	6.0.2.13, 6.1.x and later	Per cache instance	True or false (default=false)	Specifies whether sending invalidations that are based on LRU eviction is enabled.
cache.instance.x. ignoreValueIn InvalidationEvent	5.1.1.13, 6.0.2.17, 6.1.x or later	Per cache instance	True or false (default=false)	Specifies whether the cache value of Invalidation event is ignored. If it is true, the cache value of Invalidation event is set to NULL when the code is returned to the caller.

Chapter 9. Developing Dynamic and EJB query

This page provides a starting point for finding information about dynamic query, a WebSphere programming extension for unprecedented application flexibility. This information also includes Enterprise JavaBeans (EJB) query, the Java feature upon which the WebSphere extension is built.

Dynamic query lets you dynamically build and submit queries that select, sort, join, and perform calculations on application data at run time.

Dynamic query service provides the ability to pass in and process EJB query language queries at run time, eliminating the need to hard-code required queries into deployment descriptors during application development.

Developing applications that use EJB query

EJB query language

EJB query language enables you to write queries based on entity beans without knowing the underlying relational schema.

An EJB query is a string that contains the following elements:
- a SELECT clause that specifies the enterprise beans or values to return;
- a FROM clause that names the bean collections;
- an optional WHERE clause that contains search predicates over the collections;
- an optional GROUP BY and HAVING clause; see the topic Aggregation functions.
- an optional ORDER BY clause that specifies the ordering of the result collection.

Collections of entity beans are identified in EJB queries through the use of their abstract schema name in the query FROM clause.

The elements of EJB query language are discussed in more detail in the following related topics.

FROM clause

The FROM clause specifies the collections of objects to which the query is to be applied. Each collection is specified either by an abstract schema name (ASN) or by a path expression identifying a relationship. An identification variable is defined for each collection.

Conceptually, the semantics of the query is to form a temporary collection of tuples, `R`, with elements consisting of all possible combinations of objects from the collections. This collection is subject to the constraints imposed by any path relationships and by the JOIN operation. The JOIN can be either an *inner* or *outer* join.

The identification variables are bound to elements of the tuple. After forming the temporary collection, the search conditions of the WHERE clause are applied to R, and yield a new temporary collection, `R1`. The ORDER BY, GROUP BY, HAVING, and SELECT clauses are applied to R1 to yield the final result.

```
from_clause::=FROM identification_variable_declaration [, {identification_variable_declaration |
collection_member_declaration } ]*

identification_variable_declaration::= range_variable_declaration [join]*

join :=  [ { LEFT [OUTER] | INNER  }]  JOIN  {collection_valued_path_expression | single_valued_path_expression}
 [AS] identifier
```

Examples: Joining collections

`DeptBean` contains records 10, 20, and 30. `EmpBean` contains records 1, 2, and 3 that are related to department 10, and records 4 and 5 that are related to department 20. Department 30 has no employees.

```
SELECT d FROM  DeptBean AS d, EmpBean AS e
WHERE d.name = e.name
```

The comma syntax performs an inner join resulting in all possible combinations. In this example, R would consist of 15 tuples (3 departments x 5 employees). If any collection is empty, then R is also empty. The keyword AS is optional.

This example shows that a collection can be joined with itself.

```
SELECT d FROM DeptBean AS d, DeptBean AS d1
```

R would consist of 9 tuples (3 departments x 3 departments).

Examples: Relationship joins

A collection can be a relationship based on a previously declared identifier as in

```
SELECT e FROM DeptBean AS d , IN (d.emps) AS e
```

R would contain 5 tuples. Department 30 would not appear in R because it contains no employees. Department 10 would appear in 3 tuples and department 20 would appear in 2 tuples. IN can only refer to multi-valued relationships. The following is not valid

```
SELECT m FROM EmpBean e,  IN( e.dept.mgr) as m   INVALID
```

When joining with a relationship the alternate syntax INNER JOIN (keyword INNER is optional) can also be used, as shown here.

```
SELECT e FROM DeptBean AS d INNER JOIN d.emps AS e
```

An ASN declaration (d in the previous query) can be followed by one or more join clauses. The relationship following the JOIN keyword must be related (directly or indirectly) to the ASN declaration. Unlike the case with the IN clause, relationships used in a join clause can be single- or multi-valued. This query has the same semantics as the query

```
SELECT e FROM DeptBean AS d , IN (d.emps) AS e
```

You can use multiple joins together.

```
SELECT m FROM EmpBean e JOIN e.dept d JOIN d.mgr m
```

This is equivalent to

```
SELECT m FROM EmpBean e JOIN e.dept.mgr m
```

Examples: OUTER JOIN

An OUTER JOIN results in a temporary collection that contains combinations of the *left* and *right* operands, subject to the relationship constraints and such that the left operand always appears in R. In the example an outer join results in a temporary collection R that contains department 30, even though the collection d.emps is empty. The tuple contains Department 30 along with a NULL value. References to e in the query yields a null value.

```
SELECT e FROM DeptBean AS d LEFT OUTER JOIN d.emps AS e
```

The keyword OUTER is optional, as shown here.

```
SELECT e FROM DeptBean AS d LEFT JOIN d.emps AS e
```

You can also use combinations of INNER and OUTER JOIN.

```
SELECT m FROM EmpBean e JOIN e.dept d LEFT JOIN d.mgr m
```

Inheritance in EJB query

If an Enterprise JavaBeans (EJB) inheritance hierarchy has been defined for an abstract schema, using the abstract schema name in a query statement implies the collection of objects for that abstract schema as well as all subtypes.

Example: Inheritance

Suppose that bean `ManagerBean` is defined as a subtype of `EmpBean` and `ExecutiveBean` is a subtype of `ManagerBean` in an EJB inheritance hierarchy. The following query returns employees as well as managers and executives:

```
SELECT OBJECT(e) FROM EmpBean e
```

Path expressions

A path expression is an identification variable followed by the navigation operator (.) and a container managed persistence (CMP) or relationship name.

A path expression that leads to a cmr field can be further navigated if the cmr field is single-valued. If the path expression leads to a multi-valued relationship, then the path expression is terminal and cannot be further navigated. If the path expression leads to a CMP field whose type is a value object, it is possible to navigate to attributes of the value object.

Example: Value object

Assume that `address` is a CMP field for `EmpBean`, which is a value object.

```
SELECT  object(e)  FROM EmpBean e
WHERE  e.address.distance('San Jose') < 10  and e.address.zip = 95037
```

It is best to use the composer pattern to map value object attributes to relational columns if you intend to search on value attributes. If you store value objects in serialized format, then each value object must be retrieved from the database and deserialized. Value object methods can only be done in dynamic queries.

A path expression can also navigate to a bean method. The method must be defined on either the remote or local bean interface. Methods can only be used in dynamic queries. You cannot mix both remote and local methods in a single query statement.

If the query contains remote methods, the dynamic query must be executed using the query remote interface. Using the query remote interface causes the query service to activate beans and create instances of the remote bean interface

Likewise, a query statement with local bean methods must be executed with the query local interface. This causes the query service to activate beans and local interface instances.

Do not use get methods to access CMP and cmr fields of a bean.

If a method has overloaded definitions, the overloaded methods must have different number of parameters.

Methods must have non-void return types and method arguments and return types must be either primitive types byte, short, int, long, float, double, boolean, char or wrapper types from the following list:

Byte, Short, Integer, Long, Float, Double, BigDecimal, String, Boolean, Character, java.util.Calendar, java.sql.Date, java.sql.Time, java.sql.Timestamp, java.util.Date

If any input argument to a method is NULL, it is assumed the method returns a NULL value and the method is not invoked.

A collection valued path expression can be used in the FROM clause as a collection member declaration, and with the IS EMPTY, MEMBER OF, and EXISTS predicates in the WHERE clause.

Table 41. FROM clause usage. The following table lists three valid From clause usage and one invalid usage.

FROM clause usage statement	Validity statement
`FROM EmpBean e WHERE e.dept.mgr.name='Bob'`	OK
`FROM EmpBean e WHERE e.dept.emps.name='BOB'`	INVALID -- cannot navigate through emps because it is multivalued
`FROM EmpBean e, IN (e.dept.emps) e1 WHERE e1.name='BOB'`	OK
`FROM EmpBean e WHERE e.dept.emps IS EMPTY`	OK

WHERE clause

The WHERE clause lists search conditions for items to add to a result set.

The WHERE clause contains search conditions composed of the following:
- literal values
- input parameters
- expressions
- basic predicates
- quantified predicates
- BETWEEN predicate
- IN predicate
- LIKE predicate
- NULL predicate
- EMPTY collection predicate
- MEMBER OF predicate
- EXISTS predicate
- IS OF TYPE predicate

If the search condition evaluates to TRUE, the tuple is added to the result set.

Literals:

Literals can be considered constants that do not change in value.

A string literal is enclosed in single quotes. A single quote that occurs within a string literal is represented by two single quotes. For example: 'Tom''s'. A string literal cannot exceed the maximum length that is supported by the underlying persistent datastore.

A numeric literal can be any of the following:
- an exact value such as 57, -957, +66
- any value supported by Java long
- a decimal literal such as 57.5, -47.02
- an approximate numeric value such as 7E3, -57.4E-2

A decimal or approximate numeric value must be in the range supported by the underlying persistent datastore.

A boolean literal can be the keyword TRUE or FALSE and is case insensitive.

Input parameters:

Input parameters are designated by the question mark followed by a number; for example: `?2`. Input parameters are numbered starting at 1 and correspond to the arguments of the finder or select method; therefore, a query must not contain an input parameter that exceeds the number of input arguments.

An input parameter can be a primitive type of byte, short, int, long, float, double, boolean, char or wrapper types of Byte, Short, Integer, Long, Float, Double, BigDecimal, String, Boolean, Char, java.util.Calendar, java.util.Date, java.sql.Date, java.sql.Time, java.sql.Timestamp, an EJBObject, or a binary data string in the form of Java byte[].

An input parameter must not have a NULL value. To search for the occurrence of a NULL value the NULL predicate should be used.

WebSphere Application Server, Expressions:

An expression specifies a value.

Conditional expressions can consist of comparison operators and logical operators (AND, OR, NOT).

Arithmetic expressions can be used in comparison expressions and can be composed of arithmetic operations and functions, path expressions that evaluate to a numeric value and numeric literals and numeric input parameters.

String expressions can be used in comparison expressions and can be composed of string functions, path expressions that evaluate to a string value and string literals and string input parameters. A CMP field of type char is handled as if it were a string of length 1.

Binary expressions can be used in comparison expressions and can be composed of path expressions that evaluate to the Java byte[] type as well as input parameters of type byte[].

Boolean expressions can be used with = and <> comparison and can be composed of path expressions that evaluate to a boolean value and TRUE and FALSE keywords and boolean input parameters.

Reference expressions can be used with = and <> comparison and can be composed of path expressions that evaluate to a cmr field, an identification variable and an input parameter whose type is an EJB reference

Four different expression types are supported for working with date-time types. For portability the java.util.Calendar type should be used. DB2 style date, time and timestamp expressions are supported if the datastore is DB2 and the CMP field is of type java.util.Date, java.sql.Date, java.sql.Time or java.sql.Timestamp. If you use DB2 UDB, you might obtain a syntax error when using the java.sql.Timestamp.ojbect. You must use the syntax TIMESTAMP 'yyyy-mm-dd hh:mm:ss.nnnn'.

A Calendar type can be compared to another Calendar type, an exact numeric literal or input parameter of type long whose value is the standard Java long millisecond value.

The following query finds all employees born before Jan 1, 1990:

```
SELECT OBJECT(e) FROM EmpBean e WHERE e.birthDate <  631180800232
```

Date expressions can be used in comparison expressions and can be composed of operators + - , date duration expressions and date functions, path expressions that evaluate to a date value, string representation of a date and date input parameters.

Time expressions can be used in comparison expressions and can be composed of operators + - , time duration expressions and time functions, path expressions that evaluate to a time value, string representation of time and time input parameters.

Timestamp expressions can be used in comparison expressions and can be composed of operators + - , timestamp duration expressions and timestamp functions, path expressions that evaluate to a timestamp value, string representation of a timestamp and timestamp input parameters.

Standard bracketing ( ) for ordering expression evaluation is supported.

The operators and their precedence order from highest to lowest are:
- Navigation operator (.)
- Arithmetic operators in precedence order:
  - + - unary
  - * / multiply, divide
  - + - add, subtract
- Comparison operators: =, >, <, >=, <=, <>(not equal)
- Logical operator NOT
- Logical operator AND
- Logical operator OR

Null value semantics:

The following describe the semantics of NULL values.
- Comparison or arithmetic operations with an unknown (NULL) value yield an unknown value
- In a Java 2 platform, Enterprise Edition (J2EE) version 1.3 application, a path expression uses an outer-join semantic where a NULL field or cmr value evaluates to NULL. In J2EE version 1.4, the path expression uses an inner-join semantic.
- The IS NULL and IS NOT NULL operators can be applied to path expressions and return TRUE or FALSE. Boolean operators AND, OR and NOT use three valued logic.

Table 42. Null value semantics. The following table describes the semantics of NULL values.

AND	**True**	**False**	**Unknown**
`True`	True	False	Unknown
`False`	False	False	False
`Unknown`	Unknown	False	Unknown

Table 43. Null value semantics. The following table describes the semantics of NULL values.

OR	**True**	**False**	**Unknown**
`True`	True	True	True
`False`	True	False	Unknown
`Unknown`	True	Unknown	Unknown

Table 44. Null value semantics. The following table describes the semantics of NULL values.

	NOT
`True`	False
`False`	True
`Unknown`	Unknown

Example: Null value semantics

```
select object(e) from EmpBean where e.salary > 10  and e.dept.budget > 100
```

If salary is NULL the evaluation of `e.salary > 10` returns unknown and the employee object is not returned. If the cmr field dept or budget is NULL evaluation of `e.dept.budget > 100` returns unknown and the employee object is not returned.

```
select object(e) from EmpBean where e.dept.budget is null
```

In J2EE 1.3 if dept or budget is NULL evaluation of `e.dept.budget` is null returns TRUE and the employee object is returned. In J2EE 1.4 the employee object is returned only if budget is NULL.

```
select object(e) from EmpBean e ,  in (e.dept.emps) e1 where e1.salary > 10
```

If dept is NULL, then the multivalued path expression `e.dept.emps` results in an empty collection (not a collection that contains a NULL value). An employee with a null dept value will not be returned.

```
select object(e) from EmpBean e where  e.dept.emps is empty
```

If dept is NULL the evaluation of the predicate in unknown and the employee object is not returned.

```
select object(e) from EmpBean e , EmpBean e1  where e member of  e1.dept.emps
```

If dept is NULL evaluation of the member of predicate returns unknown and the employee is not returned.

Date time arithmetic and comparisons:

DATE, TIME and TIMESTAMP values can be compared with another value of the same type. Comparisons are chronological. Date time values can also be incremented, decremented, and subtracted.

If the datastore is DB2, then DB2 string representation of DATE, TIME and TIMESTAMP types can also be used.

Table 45. Date, time and timestap formats. A string representation of a date or time can use ISO, USA, EUR or JIS format. A string representation of a timestamp uses ISO format.

Format	Date format	Date examples	Time format	Time examples
ISO	yyyy-mm-dd	1987-02-24 1987-2-24	hh.mm.ss	13.50.00 13.50
USA	mm/dd/yyyy	2/24/1987	hh:mm AM or PM	1:50 pm 02:10 AM
EUR	dd.mm.yyyy	24.02.1987 24.2.1987	hh.mm.ss	13.50.00 13.55
JIS	yyyy-mm-dd	1987-02-24	hh:mm:ss	13:50 13:50:05

Example 1: Date time arithmetic comparisons

```
e.hiredate > '1990-02-24'
```

The timestamp of February 24th, 1990 1:50 pm can be represented as follows:

```
'1990-02-24-13.50.00.000000'  or
'1990-02-24-13.50.00'
```

If the datastore is DB2, DB2 decimal durations can be used in expressions and comparisons. A date duration is a decimal(8,0) number that represents the difference between two dates in the format YYYYMMDD. A time duration is a decimal(6,0) number that represents the difference between two time values as HHMMSS. A timestamp duration is a decimal(20,6) number representing the differences between two timestamp values as YYYYMMDDHHMMSS.ZZZZZZ (ZZZZZZ is the number of microseconds following the decimal point).

Two date values (or time values or timestamp values) can be subtracted to yield a duration. If the second operand is greater than the first the duration is a negative decimal number. A duration can be added or subtracted from a datetime value to yield a new datetime value.

Example 2: Date time arithmetic comparisons

`DATE('3/15/2000') - '12/31/1999'` results in a decimal number 215 which is a duration of 0 years, 2 months and 15 days.

Durations are really decimal numbers and can be used in arithmetic expressions and comparisons.

`( DATE('3/15/2000') - '12/31/1999' ) + 14 > 215` evaluates to TRUE.

`DATE('12/31/1999') + DECIMAL(215,8,0)` results in a date value 3/15/2000.

`TIME('11:02:26') - '00:32:56'` results in a decimal number 102930 which is a time duration of 10 hours, 29 minutes and 30 seconds.

`TIME('00:32:56') + DECIMAL(102930,6,0)` results in a time value of 11:02:26.

`TIME('00:00:59') + DECIMAL(240000,6,0)` results in a time value of 00:00:59.

`e.hiredate + DECIMAL(500,8,0) > '2000-10-01'` means compare the hiredate plus 5 months to the date 10/01/2000.

Basic predicates:

A basic predicate compares two values.

Basic predicates can be of two forms, for example:

```
expression-1  comparison-operator  expression-2
expression-3  comparison-operator ( subselect )
```

The subselect must not return more than one value and the subselect cannot return a type of an Enterprise JavaBeans (EJB) reference. Boolean types and reference types only support = and <> comparisons.

Example: Basic predicates

```
d.name='Java Development'
e.salary > 20000
e.salary > ( select avg(e.salary) from EmpBean e)
```

Quantified predicates:

A quantified predicate compares a value with a set of values produced by a subselect.

Use the syntax:

```
expression   comparison-operator   SOME | ANY |  ALL    ( subselect )
```

The expression must not evaluate to a reference type.

When SOME or ANY is specified the result of the predicate is as follows:
- TRUE if the comparison is true for at least one value returned by the subselect.
- FALSE if the subselect is empty or if the comparison is false for every value returned by the subselect.
- UNKNOWN if the comparison is not true for all of the values returned by the subselect and at least one of the comparisons is unknown because of a null value.

When ALL is specified the result of the predicate is as follows:
- TRUE if the subselect returns empty or if the comparison is true to every value returned by the subselect.

- FALSE if the comparison is false for at least one value returned by the subselect.
- UNKNOWN if the comparison is not false for all values returned by the subselect and at least one comparison is unknown because of a null value.

BETWEEN predicate:

The BETWEEN predicate determines whether a given value lies between two other given values.

The syntax for the predicate is:

```
expression  [NOT]  BETWEEN expression-2  AND expression-3
```

The expression must not evaluate to a boolean or reference type.

Example: BETWEEN predicate

```
e.salary BETWEEN 50000 AND 60000
```

is equivalent to:

```
e.salary >= 50000  AND e.salary <= 60000
e.name NOT BETWEEN 'A' AND 'B'
```

is equivalent to:

```
e.name < 'A'  OR e.name > 'B'
```

IN predicate:

The IN predicate compares a value to a set of values.

It can have one of two forms:

```
expression [NOT] IN  ( subselect )
expression [NOT] IN  ( value1, value2,  .... )
```

ValueN can either be a literal value or an input parameter. The expression cannot evaluate to a reference type.

Example: IN predicate

```
e.salary IN ( 10000, 15000 )
```

is equivalent to

```
( e.salary = 10000  OR  e.salary = 15000 )
e.salary IN ( select  e1.salary from EmpBean e1 where e1.dept.deptno = 10)
```

is equivalent to

```
e.salary = ANY   ( select  e1.salary from EmpBean e1 where e1.dept.deptno = 10)
e.salary NOT IN ( select  e1.salary from EmpBean e1 where e1.dept.deptno = 10)
```

is equivalent to

```
e.salary <> ALL    ( select  e1.salary from EmpBean e1 where e1.dept.deptno = 10)
```

LIKE predicate:

The LIKE predicate searches a string value for a certain pattern.

The syntax for this predicate is:

```
string-expression   [NOT]  LIKE  pattern    [ ESCAPE escape-character ]
```

The pattern value is a string literal or parameter marker of type string in which the underscore (_) stands for any single character and percent (%) stands for any sequence of characters (including empty sequence). Any other character stands for itself. The escape character can be used to search for character _ and %. The escape character can be specified as a string literal or an input parameter.

If the string-expression is null, then the result is unknown.

If both string-expression and pattern are empty, then the result is true.

Example: LIKE predicate
- "`LIKE`" is true
- "`LIKE %`" is true
- `e.name LIKE 12%3` is true for "123" "12993" and false for "1234"
- `e.name LIKE 's_me'` is true for "some" and "same", false for "soome"
- `e.name LIKE '/_foo' escape '/'` is true for "_foo", false for "afoo"
- `e.name LIKE '//_foo' escape '/'` is true for "/afoo" and for "/bfoo"
- `e.name LIKE '///_foo' escape '/'` is true for "/_foo" but false for "/afoo"

NULL predicate:

The NULL predicate tests for null values.

Use the syntax:

```
single-valued-path-expression IS [NOT] NULL
```

Example: NULL predicate

```
e.name IS NULL
e.dept.name IS NOT NULL
e.dept IS NOT NULL
```

EMPTY collection predicate:

You can use the EMPTY collection predicate to test if a multivalued relationship has no members.

Use the following syntax:

```
collection-valued-path-expression  IS [NOT]  EMPTY
```

Example: Empty collection predicate

To find all departments with no employees:

```
SELECT OBJECT(d) FROM DeptBean d  WHERE  d.emps IS EMPTY
```

MEMBER OF predicate:

This expression tests whether the object reference specified by the single valued path expression or input parameter is a member of the designated collection.

If the collection valued path expression designates an empty collection the value of the MEMBER OF expression is FALSE.

```
{ single-valued-path-expression | input_parameter } [ NOT ] MEMBER [ OF ] collection-valued-path-expression
```

Example: MEMBER OF predicate

Find employees that are not members of a given department number:

```
SELECT OBJECT(e) FROM EmpBean e , DeptBean d
WHERE e NOT MEMBER OF d.emps AND d.deptno = ?1
```

Find employees whose manager is a member of a given department number:

```
SELECT OBJECT(e) FROM EmpBean e, DeptBean d
WHERE e.dept.mgr MEMBER  OF d.emps  and d.deptno=?1
```

EXISTS predicate:

The exists predicate tests for the presence or absence of a condition specified by a subselect.

Use the following syntax:

```
EXISTS ( subselect )
EXISTS collection-valued-path-expression
```

The result of EXISTS is true if the subselect returns at least one value or the path expression evaluates to a nonempty collection, otherwise the result is false.

To negate an EXISTS predicate, precede it with the logical operator NOT.

Example: EXISTS predicate

Return departments that have at least one employee earning more than 1000000:

```
SELECT  OBJECT(d) FROM  DeptBean d
WHERE EXISTS ( SELECT  1  FROM IN (d.emps) e WHERE  e.salary > 1000000 )
```

Return departments that have no employees:

```
SELECT OBJECT(d) FROM DeptBean d
WHERE NOT EXISTS  ( SELECT 1 FROM IN (d.emps) e)
```

The previous query can also be written as follows:

```
SELECT OBJECT(d) FROM DeptBean d WHERE NOT EXISTS d.emps
```

IS OF TYPE predicate:

The IS OF TYPE predicate is used to test the type of an Enterprise JavaBeans (EJB) reference. It is similar in function to the Java instance of operator.

IS OF TYPE is used when several abstract beans have been grouped into an EJB inheritance hierarchy. The type names specified in the predicate are the bean abstract names. The ONLY option can be used to specify that the reference must be exactly this type and not a subtype.

```
identification-variable IS OF TYPE ( [ONLY] type-1, [ONLY] type-2, ..... )
```

Example: IS OF TYPE predicate

Suppose that bean `ManagerBean` is defined as a subtype of `EmpBean` and `ExecutiveBean` is a subtype of `ManagerBean` in an EJB inheritance hierarchy.

The following query returns employees as well as managers and executives:

```
SELECT  OBJECT(e) FROM EmpBean e
```

If you are interested in objects which are employees and not managers and not executives:

```
SELECT OBJECT(e) FROM EmpBean e WHERE e IS OF TYPE( ONLY EmpBean )
```

If you are interested in object which are managers or executives:

```
SELECT OBJECT(e) FROM EmpBean e WHERE e IS OF TYPE( ManagerBean)
```

The previous query is equivalent to the following query:

```
SELECT  OBJECT(e) FROM ManagerBean e
```

If you are interested in managers only and not executives:

```
SELECT  OBJECT(e) FROM  EmpBean e WHERE e IS OF TYPE( ONLY ManagerBean)
```

or:

```
SELECT  OBJECT(e) FROM  ManagerBean e
WHERE  e IS OF TYPE (ONLY ManagerBean)
```

Scalar functions

An Enterprise JavaBeans (EJB) query contains scalar functions for doing type conversions, string manipulation, and for manipulating date-time values.

The list of scalar functions is documented in the topic EJB query: Scalar functions.

Example: Scalar functions

Find employees hired in 1999:

```
SELECT OBJECT(e) FROM EmpBean e where YEAR(e.hireDate) = 1999
```

The only scalar functions that are guaranteed to be portable across backend datastore vendors are the following:

- ABS
- MOD
- SQRT
- CONCAT
- LENGTH
- LOCATE
- SUBSTRING
- UCASE
- LCASE

The other scalar functions should be used only when DB2 is the backend datastore.

EJB query: Scalar functions:

Enterprise JavaBeans (EJB) query contains scalar built-in functions for doing type conversions, string manipulation, and for manipulating date-time values.

Details of EJB query scalar built-in functions follow:

Numeric functions

```
ABS ( < any numeric datatype > ) -> < any numeric datatype >
MOD ( <int>, <int> ) -> int
SQRT ( < any numeric datatype > ) -> Double
```

Type conversion functions

```
CHAR ( < any  numeric datatype > ) ->  string
CHAR ( <  string  > ) ->  string
CHAR ( < any datetime  datatype >  [, Keyword k ]) ->  string
```

Datetime datatype is converted to its string representation in a format specified by the keyword k. The valid keywords values are ISO, USA, EUR or JIS. If k is not specified the default is ISO.

```
BIGINT ( < any numeric datatype > ) -> Long
BIGINT ( < string > ) -> Long
```

The function in the second line of the following code converts the argument to an integer n by truncation, and returns the date that is n-1 days after January 1, 0001:

```
DATE ( < date string > ) -> Date
DATE (  < any numeric datatype>) -> Date
```

The following function returns date portion of a timestamp:

```
DATE( timestamp ) -> Date
DATE ( < timestamp-string > ) -> Date
```

The following function converts number to decimal with optional precision p and scale s.

```
DECIMAL ( < any numeric datatype > [, p [ ,s ] ] ) -> Decimal
```

The following function converts string to decimal with optional precision p and scale s.

```
DECIMAL ( < string > [ , p [ , s ] ] ) -> Decimal
```

```
DOUBLE ( < any numeric datatype > ) -> Double
DOUBLE ( < string > ) -> Double
```

```
FLOAT ( < any numeric datatype > ) -> Double
FLOAT ( < string > ) -> Double
```

Float is a synonym for DOUBLE.

```
INTEGER ( < any numeric datatype > ) -> Integer
INTEGER ( < string > ) -> Integer
```

```
REAL ( < any numeric datatype > ) -> Float
```

```
SMALLINT ( < any numeric datatype ) -> Short
SMALLINT ( < string > ) -> Short
```

```
TIME ( < time > ) -> Time
TIME ( < time-string  > ) -> Time
TIME ( < timestamp > ) -> Time
TIME ( < timestamp-string  > ) -> Time
```

```
TIMESTAMP ( < timestamp > ) -> Timestamp
TIMESTAMP ( < timestamp-string > ) -> Timestamp
```

String functions

```
CONCAT ( <string>, <string>  ) -> String
```

The following function returns a character string representing absolute value of the argument not including its sign or decimal point. For example, `digits( -42.35)` is “4235”.

```
DIGITS ( Decimal d  ) -> String
```

The following function returns the length of the argument in bytes. If the argument is a numeric or datetime type, it returns the length of internal representation.

```
LENGTH ( < string >  ) -> Integer
```

The following function returns a copy of the argument string where all upper case characters have been converted to lower case.

```
LCASE ( < string > ) -> String
```

The following function returns the starting position of the first occurrence of argument 1 inside argument 2 with optional start position. If not found, it returns 0.

```
LOCATE ( String s1 , String s2  [, Integer start ] ) -> Integer
```

The following function returns a substring of s beginning at character m and containing n characters. If n is omitted, the substring contains the remainder of string s. The result string is padded with blanks if needed to make a string of length n.

```
SUBSTRING ( String s ,  Integer m [ , Integer n ] ) -> String
```

The following function returns a copy of the argument string where all lower case characters have been converted to upper case.

```
UCASE ( < string > ) -> String
```

Date - time functions

The following function returns the day portion of its argument. For a duration, the return value can be -99 to 99.

```
DAY (  Date ) ->  Integer
DAY ( < date-string > ) ->  Integer
DAY ( < date-duration > ) -> Integer
DAY ( Timestamp  ) ->  Integer
DAY ( < timestamp-string > ) ->  Integer
DAY ( < timestamp-duration > ) -> Integer
```

The following function returns one more than number of days from January 1, 0001 to its argument.

```
DAYS ( Date  ) ->  Integer
DAYS ( < Date-string > ) ->  Integer
DAYS ( Timestamp  ) ->  Integer
DAYS ( < timestamp-string > ) ->  Integer
```

The following function returns the hour part of its argument. For a duration, the return value can be -99 to 99.

```
HOUR ( Time ) -> Integer
HOUR ( < time-string > ) -> Integer
HOUR ( < time-duration > ) ->  Integer
HOUR ( Timestamp ) -> Integer
HOUR ( < timestamp-string > ) -> Integer
HOUR ( < timestamp-duration >  ) -> Integer
```

The following function returns the microsecond part of its argument.

```
MICROSECOND ( Timestamp ) -> Integer
MICROSECOND ( < timestamp-string > ) -> Integer
MICROSECOND ( < timestamp-duration >  ) -> Integer
```

The following function returns the minute part of its argument. For a duration, the return value can be -99 to 99.

```
MINUTE ( Time ) -> Integer
MINUTE ( < time-string > ) -> Integer
MINUTE ( < time-duration > ) ->  Integer
MINUTE ( Timestamp ) -> Integer
MINUTE ( < timestamp-string > ) -> Integer
MINUTE ( < timestamp-duration >  ) -> Integer
```

The following function returns the month portion of its argument. For a duration, the return value can be -99 to 99.

```
MONTH (  Date ) ->  Integer
MONTH ( < date-string > ) ->  Integer
MONTH ( < date-duration > ) -> Integer
MONTH ( Timestamp  ) ->  Integer
MONTH ( < timestamp-string > ) ->  Integer
MONTH ( < timestamp-duration > ) -> Integer
```

The following function returns the second part of its argument. For a duration, the return value can be -99 to 99.

```
SECOND ( Time ) -> Integer
SECOND ( < time-string > ) -> Integer
SECOND ( < time-duration > ) ->  Integer
SECOND ( Timestamp ) -> Integer
SECOND ( < timestamp-string > ) -> Integer
SECOND ( < timestamp-duration >  ) -> Integer
```

The following function returns the year portion of its argument. For a duration, the return value can be -9999 to 9999.

```
YEAR (  Date ) ->  Integer
YEAR ( < date-string > ) ->  Integer
YEAR ( < date-duration > ) -> Integer
YEAR ( Timestamp  ) ->  Integer
YEAR ( < timestamp-string > ) ->  Integer
YEAR ( < timestamp-duration > ) -> Integer
```

Aggregation functions

Aggregation functions operate on a set of values to return a single scalar value. You can use these functions in the select and subselect methods.

The following example illustrates an aggregation:

```
SELECT  SUM (e.salary) FROM EmpBean e WHERE e.dept.deptno =20
```

This aggregation computes the total salary for department 20.

The aggregation functions are AVG, COUNT, MAX, MIN, and SUM. The syntax of an aggregation function is illustrated in the following example:

```
aggregation-function  (    [ ALL |  DISTINCT ]  expression )
```

or:

```
COUNT( [ ALL |  DISTINCT ] identification-variable )
```

or:

```
COUNT( * )
```

The DISTINCT option eliminates duplicate values before applying the function. ALL is the default option and does not eliminate duplicates. Null values are ignored in computing the aggregate function except in the cases of COUNT(*) and COUNT(identification-variable), which return a count of all the elements in the set.

If your datastore is Informix, you must limit the expression argument to a single valued path expression when using the COUNT function or the DISTINCT forms of the functions SUM, AVG, MIN, and MAX.

Defining return type

For a select method using an aggregation function, you can define the return type as a primitive type or a wrapper type. The return type must be compatible with the return type from the datastore. The MAX and MIN functions can apply to any numeric, string or datetime datatype and return the corresponding datatype. The SUM and AVG functions take a numeric type as input, and return the same numeric type that is used in the datastore. The COUNT function can take any datatype, and returns an integer.

When applied to an empty set, the SUM, AVG, MAX, and MIN functions can return a null value. The COUNT function returns zero (0) when it is applied to an empty set. Use wrapper types if the return value might be NULL; otherwise, the container displays an ObjectNotFound exception.

Using GROUP BY and HAVING

The set of values that is used for the aggregate function is determined by the collection that results from the FROM and WHERE clause of the query. You can divide the set into groups and apply the aggregation function to each group. To perform this action, use a GROUP BY clause in the query. The GROUP BY clause defines grouping members, which comprise a list of path expressions. Each path expression specifies a field that is a primitive type of byte, short, int, long, float, double, boolean, char, or a wrapper type of Byte, Short, Integer, Long, Float, Double, BigDecimal, String, Boolean, Character, java.util.Calendar, java.util.Date, java.sql.Date, java.sql.Time or java.sql.Timestamp.

The following example illustrates the use of the GROUP BY clause in a query that computes the average salary for each department:

```
SELECT e.dept.deptno,  AVG ( e.salary) FROM EmpBean e GROUP BY e.dept.deptno
```

In division of a set into groups, a NULL value is considered equal to another NULL value.

Just as the WHERE clause filters tuples (that is, records of the return collection values) from the FROM clause, the groups can be filtered using a HAVING clause that tests group properties involving aggregate functions or grouping members:

```
SELECT e.dept.deptno,  AVG ( e.salary) FROM EmpBean e
GROUP BY e.dept.deptno
HAVING  COUNT(*) > 3  AND  e.dept.deptno > 5
```

This query returns the average salary for departments that have more than three employees and the department number is greater than five.

It is possible to use a HAVING clause without a GROUP BY clause, in which case the entire set is treated as a single group, to which the HAVING clause is applied.

SELECT clause

The SELECT clause consists of either a single identification variable that is defined in the FROM clause, or a single valued path expression that evaluates to an object reference or container managed persistence (CMP) value. You can use the DISTINCT keyword to eliminate duplicate references.

For finder and select queries, the syntax of the SELECT clause is illustrated in the following example:

```
SELECT  [  ALL | DISTINCT  ]
 { single-valued-path-expression  |  aggregation expression  |  OBJECT ( identification-variable )  }
```

For a query that defines a finder method, the query must return an object type consistent with the home that is associated with the finder method. For example, a finder method for a department home can not return employee objects.

Example: SELECT clause

Find all employees that earn more than John:

```
SELECT OBJECT(e) FROM EmpBean ej, EmpBean e
WHERE  ej.name = 'John'  and e.salary > ej.salary
```

Find all departments that have one or more employees who earn less than 20000:

```
SELECT DISTINCT  e.dept  FROM EmpBean e where e.salary < 20000
```

A select method query can have a path expression that evaluates to an arbitrary value:

```
SELECT  e.dept.name  FROM EmpBean e where e.salary < 2000
```

The previous query returns a collection of name values for those departments having employees earning less than 20000.

A select method query can return an aggregate value:

```
SELECT  avg(e.salary)  FROM EmpBean e
```

Example: Valid dynamic queries

For dynamic queries the syntax is as follows:

```
SELECT { ALL | DISTINCT }  [ selection , ]*  selection
selection  ::= { expression   |  scalar-subselect [[AS] id ] }
```

A scalar-subselect is a subselect that returns a single value.

The following are examples of dynamic queries:

```
SELECT e.name, e.salary+e.bonus as total_pay from EmpBean e
SELECT  SUM( e.salary+e.bonus) from EmpBean e where e.dept.deptno = ?1
```

ORDER BY clause

The ORDER BY clause specifies an ordering of the objects in the result collection

Use the syntax:

```
ORDER BY  [ order_element ,]* order_element
order_element ::= { path-expression | integer } [ ASC | DESC ]
```

The path expression must specify a single valued field that is a primitive type of byte, short, int, long, float, double, char or a wrapper type of Byte, Short, Integer, Long, Float, Double, BigDecimal, String, Character, java.util.Calendar, java.util.Date, java.sql.Date, java.sql.Time, java.sql.Timestamp.

ASC specifies ascending order and is the default. DESC specifies descending order.

Integer refers to a selection expression in the SELECT clause.

Example: ORDER BY clause

Return department objects in decreasing deptno order:

```
SELECT  OBJECT(d) FROM  DeptBean d ORDER BY  d.deptno DESC
```

Return employee objects sorted by department number and name:

```
SELECT  OBJECT(e) FROM EmpBean e ORDER BY e.dept.deptno ASC,  e.name DESC
```

UNION clause operation

The UNION clause specifies a combination of the output of two subqueries. The two queries must return the same number of elements and compatible types.

For the purposes of UNION, all Enterprise JavaBeans (EJB) types in the same inheritance hierarchy are considered compatible. UNION requires that equality be defined for the element types.

```
query_expression := query_term [UNION [ALL] query_term]*

query_term :=  {select_clause_dynamic  from_clause  [where_clause]
 [group_by_clause] [having_clause] } | (query_expression) }
```

You cannot use dependent value objects with UNION.

UNION ALL combines all results together in a single collection.

UNION combines results but eliminates duplicates.

If ORDER BY is used together with UNION, the ORDER BY must refer to selection expression using integer numbers.

Examples: UNION operation

This example returns a collection of all employee objects of type EmpBean and all manager objects of type ManagerBean where ManagerBean is a subtype of EmpBean.

```
select e from EmpBean e union all select m from DeptBean d, in(d.mgr) m
```

This example shows a query that is not valid, because EmpBean and DeptBean are not compatible.

```
select e from EmpBean e union all select d from DeptBean d
```

Subqueries

A subquery can be used in quantified predicates, the EXISTS predicate, or the IN predicate. A subquery should only specify a single element in the SELECT clause.

When a path expression appears in a subquery, the identification variable of the path expression must be defined either in the subquery, in one of the containing subqueries, or in the outer query. A scalar subquery is a subquery that returns one value. A scalar subquery can be used in a basic predicate and in the SELECT clause of a dynamic query.

Example: Subqueries

```
SELECT  OBJECT(e) FROM  EmpBean e
WHERE e.salary > ( SELECT  AVG(e1.salary) FROM  EmpBean e1)
```

The previous query returns employees who earn more than average salary of all employees.

```
SELECT  OBJECT(e) FROM EmpBean e WHERE  e.salary >
( SELECT AVG(e1.salary) FROM  IN  (e.dept.emps) e1  )
```

The previous query returns employees who earn more than average salary of their department.

```
SELECT  OBJECT(e) FROM EmpBean e WHERE e.salary =
( SELECT MAX(e1.salary) FROM IN (e.dept.emps) e1  )
```

The previous query returns employees who earn the most in their department.

```
 SELECT OBJECT(e) FROM EmpBean e
WHERE e.salary > ( SELECT AVG(e.salary) FROM EmpBean e1
WHERE YEAR(e1.hireDate) =  YEAR(e.hireDate)  )
```

The previous query returns employees who earn more than the average of employees hired in same year.

EJB query language limitations and restrictions

When using the Enterprise JavaBeans (EJB) query language on the product, deviations can be seen in comparison to standard EJB query language. The limitations and restrictions you must be aware of are listed in the following section.

This topic outlines current known limitations and restrictions.

- EJB query language (QL) queries involving enterprise beans with keys made up of relationships to other enterprise beans appear as not valid and cause errors at deployment time. This is a known problem.
- The IBM EJB QL support extends the EJB 2.0 specification in various ways, including relaxing some restrictions, adding support for more DB2 functions, and so on. If portability across various vendor databases or EJB deployment tools is a concern, then care should be taken to write all EJB QL queries strictly according to Chapter 11 in the EJB 2.0 specification.
- Pre-loading across m:n relationships results in the generation of inaccurate structured query language (SQL). This is a known limitation that may be addressed in the future.
- Pre-loading across self referencing relationships causes inaccurate SQL to be generated.

- Avoid relationships between parent and children enterprise beans within the same inheritance hierarchy that are not well-defined.
- EJB Query Language validation for EJB 2.0 JAR files currently runs as a part of the EJB-RDB Mapping validation. If a mapping document (Map.mapxmi file) does not exist in the project, the EJB queries are not validated.

EJB query compatibility issues with SQL

Because an Enterprise JavaBeans (EJB) query is compiled into structured query language (SQL), you must be aware of compatibility issues between the Java language and SQL.

The two languages differ along the following points that can be critical to correct EJB query formulation:

- The comparison semantics of SQL strings do not exactly match those of the Java language. For example: "A" (the letter A) and"A" (the letter A plus a blank space) are considered equal in SQL, but not in the Java language.
- Comparisons and collating order depend on the underlying database. For example, if you are using DB2 with an EBCDIC code page, the collating order is not the same as doing the sort in a Java program. Some databases sort the NULL value low while others sort the NULL value high.
- An arithmetic overflow causes an exception in SQL, but not in the Java language.
- SQL databases have differing minimum and maximum ranges for floating point values, which can differ from floating point value ranges in the Java language. Values near the range limits of Java Double may fail to translate into SQL.
- Java methods do not translate into SQL; therefore standard EJB queries cannot include Java methods.

  Note: Only with the dynamic EJB query service can you use functions that do not translate into SQL. Such functions include Java methods and converters or composers that are used in mapping enterprise beans to relational databases (RDBs). A standard finder or select query that uses any of these functions fails at deployment time with the message "Cannot push down query". (You can resolve this problem by changing either the query or the mapping.) The dynamic query run time, however, processes the query by performing the operation involving the function in the application server.

Database restrictions for EJB query

The Enterprise JavaBeans (EJB) query functions must adhere to certain restrictions for databases.

General database restriction

- All of the enterprise beans involved in a given query must map to the same data source. The EJB query does not support cross-data source join operations.
- It is possible that a structured query language (SQL) statement generated by the WebSphere Application Server deployment code generation utility for an *ejbSelect* EJB query language query returns rows in a result set that consist of null values in all columns.

  During run time persistence manager saves the set received as a result from this query. When your application retrieves the primary key of the result bean, persistence manager calls the extractor. The extractor is a method that is an EJB deploy generated class. This method returns a value of 0 for any null column entries. This value is passed back to the EJB container to forward to the application. The EJB container invokes the bean instance with the PK value of 0. This could create a problem, as the end user cannot determine if this bean instance has a *null PK* or a *PK value of 0*.

  To avoid this, use the *IS NOT NULL* clause in the finder query to eliminate such null values from the result set.

Specific database restrictions

Different database products place different restrictions on elements that can be included in EJB query statements. Following is a list of those restrictions; check with your database administrator to see if any apply in your environment:

- Certain functions are used in queries that run against DB2 only, because these functions are not supported by other databases. These functions include date and time arithmetic expressions, certain scalar functions including those not listed as portable across vendors, and implied scalar functions when used for mapping certain container managed persistence (CMP) fields. For example, consider mapping an int numeric type to a decimal (5,2) type field. When deployed against a database other than DB2, a finder or select query that contains a CMP field with this particular mapping fails, producing a `Cannot push down query` error message.
- A CMP of type String, when mapped to a character large object (CLOB) in the database, cannot be used in comparison operations because the database does not support CLOB comparisons.
- Databases can impose limits on the length of string values that are used either as literals or input parameters with comparison operators. These limits can hinder query performance. For example: For DB2 on the z/OS platform, the search “name = ?1” can fail if the value of ?1 at run time is greater than 255 in length.
- Mapping a numeric CMP type to a column that contains a dissimilar type can cause unexpected results. For example, consider the case of mapping the int numeric type to a column of type decimal (5,2). This scenario does not preserve an exact decimal value (for example, the value 12.25) over the course of transfer from the database to the enterprise bean CMP field, and back again to the database. This mapping causes replacement of the initial value with a whole number (in this case, 12). Consequently, you want to avoid using the CMP field in comparison operations when the CMP field uses a mapping of this nature.
- Some databases do not support a data type that corresponds to the semantics of java.sql.Time. For example: If a CMP field of type java.sql.Time is mapped to an Oracle DATE column, comparisons on time might not produce the expected result because the year-month-day portion of the column value is truncated in the mapping.
- Some databases treat a zero length string value ('') as a null value; this approach can affect the query results. For the sake of portability, avoid the use of zero length string values.
- Some databases perform division between two integer values using integer arithmetic rules, while others use non-integer rules. This discrepancy might not be desirable in environments that use both kinds of databases. For the sake of portability, avoid the division of integer values in an EJB query.

Rules for data type manipulation in EJB query

When using an Enterprise JavaBeans (EJB) query to work with data types, certain rules must be followed.

You can use a CMP field of any type in a SELECT clause. You must, however, use fields of only the following types in search conditions and in grouping or ordering operations:

- Primitive types: byte, short, int, long, float, double, boolean, char
- Object types: Byte, Short, Integer, Long, Float, Double, BigDecimal, String, Boolean, Character, java.util.Calendar, java.util.Date
- JDBC types: java.sql.Date, java.sql.Time, java.sql.Timestamp
- Binary string: byte

If ALL of the following conditions occur:
- a CMP field of one of the basic types listed previously is mapped to an SQL column using a converter
- the CMP field appears prior to a basic predicate
- following the predicate is a literal or input parameter

then the toData() method of the converter is used to compute the SQL search value.

For example, given a converter that maps the integer value 10 to the string value “Ten” the following EJB query:

```
e.cmp = 10
```

is translated into the following SQL query:

```
column = 'Ten'
```

If you include a more complicated predicate, such as in the following example:

```
e.cmp * 10 >  e.salary
```

in a finder or select query, you receive the `Cannot push down query` error message. Use the dynamic EJB query service for such multi-function queries; the dynamic query run time processes the predicate in the application server.

Overall, converters preserve equality, collating sequence, and NULL values. If a converter does not meet these requirements, avoid using it for CMP field comparison operations.

A user type cannot be used in a comparison operation or expression. You can, however, use subfields of the user type in a path expression. For example, consider the CMP addr field with the type `com.exam.Address`, and street, city, and state subfields. The following syntax for a query on this CMP field is not valid:

```
e.addr =  ?1
```

However, a query that designates one of the subfields is valid:

```
e.addr.street = ?1
```

A CMP field can be mapped to an SQL column using Java serialization. Using the CMP field in predicates or expressions for deployment queries usually results in the `Cannot push down query` error message. The dynamic query run time processes the expression by reading and deserializing all instances of the user type in the application server.

However, this expensive process sacrifices performance. You can maintain performance by using a composer in a deployment EJB query. In the previous example, if you want to map the addr field to a binary type, you use a composer to map each subfield to a binary column in the database.

EJB query: Reserved words

The following words are reserved in WebSphere Application Server Enterprise JavaBeans (EJB) queries.

all, as, distinct, empty, false, from, group, having, in, is, like, select, true, union, where

Avoid using identifiers that start with underscore (for example, _integer) as these are also reserved.

EJB query: BNF syntax

The Backus-Naur Form (BNF) is one of the most commonly used notations for specifying the syntax of programming languages or command sets. This article lists the syntax for Enterprise JavaBeans (EJB) query language.

```
EJB QL ::= [select_clause] from_clause [where_clause] [order_by_clause]

DYNAMIC EJB QL := query_expression  [order_by_clause]

query_expression := query_term [UNION [ALL] query_term]*

query_term :=  {select_clause_dynamic  from_clause  [where_clause]
 [group_by_clause] [having_clause] } | (query_expression) }  [order_by_clause]

from_clause::=FROM identification_variable_declaration
               [, {identification_variable_declaration | collection_member_declaration } ]*

identification_variable_declaration::=collection_member_declaration |
       range_variable_declaration [join]*

join :=  [ { LEFT [OUTER] | INNER  }]  JOIN  {collection_valued_path_expression | single_valued_path_expression}
 [AS] identifier

collection_member_declaration::=
       IN ( collection_valued_path_expression ) [AS] identifier
```

```
range_variable_declaration::=abstract_schema_name [AS] identifier

single_valued_path_expression ::=
       {single_valued_navigation | identification_variable}. ( cmp_field |
 method  |  cmp_field.value_object_attribute |  cmp_field.value_object_method )
          | single_valued_navigation

single_valued_navigation::=
       identification_variable.[  single_valued_cmr_field.  ]*
            single_valued_cmr_field

collection_valued_path_expression ::=
       identification_variable.[  single_valued_cmr_field.  ]*
           collection_valued_cmr_field

select_clause::= SELECT { ALL | DISTINCT }  {single_valued_path_expression |
                         identification_variable |  OBJECT ( identification_variable) |
        aggregate_functions }

select_clause_dynamic ::= SELECT { ALL | DISTINCT }  [ selection , ]*  selection

selection  ::= { expression  |  subselect }  [[AS] id ]

order_by_clause::= ORDER BY [ {single_valued_path_expression | integer}  [ASC|DESC],]*
      {single_valued_path_expression | integer}[ASC|DESC]

where_clause::= WHERE conditional_expression

conditional_expression ::= conditional_term |
                           conditional_expression OR conditional_term
conditional_term ::= conditional_factor |
                     conditional_term AND conditional_factor
conditional_factor ::= [NOT] conditional_primary
conditional_primary::=simple_cond_expression | (conditional_expression)

simple_cond_expression ::= comparison_expression | between_expression |
       like_expression | in_expression | null_comparison_expression |
       empty_collection_comparison_expression | quantified_expression |
       exists_expression | is_of_type_expression  |  collection_member_expression

between_expression ::= expression [NOT] BETWEEN expression AND expression

in_expression ::= single_valued_path_expression [NOT] IN
          { (subselect) |  ( [ atom ,]* atom )  }

atom = { string-literal | numeric-constant | input-parameter }

like_expression ::= expression [NOT] LIKE
                {string_literal | input_parameter}
                [ESCAPE {string_literal | input_parameter}]

null_comparison_expression ::=
       single_valued_path_expression IS [ NOT ] NULL

empty_collection_comparison_expression ::=
       collection_valued_path_expression IS [NOT] EMPTY

collection_member_expression  ::=
       { single_valued_path_expression |  input_paramter }  [ NOT ] MEMBER [ OF ]
         collection_valued_path_expression

quantified_expression ::=
       expression comparison_operator  {SOME | ANY | ALL} (subselect)

exists_expression ::= EXISTS {collection_valued_path_expression |  (subselect)}

subselect ::= SELECT [{ ALL | DISTINCT }]  expression  from_clause [where_clause]
       [group_by_clause] [having_clause]

group_by_clause::= GROUP BY [single_valued_path_expression,]*
                    single_valued_path_expression
```

```
having_clause ::= HAVING conditional_expression

is_of_type_expression ::= identifier  IS OF TYPE
            ([[ONLY] abstract_schema_name,]* [ONLY] abstract_schema_name)

comparison_expression ::=  expression   comparison_operator { expression |  ( subquery ) }

comparison_operator ::=    = | > | >= | < | <= | <>

method ::=  method_name( [[expression , ]* expression ] )

expression ::= term |   expression {+|-} term

term ::=  factor |  term {*|/} factor

factor ::= {+|-} primary

primary ::= single_valued_path_expression | literal |
       ( expression ) |  input_parameter | functions | aggregate_functions

aggregate_functions :=
       AVG([ALL|DISTINCT] expression) |
       COUNT({[ALL|DISTINCT] expression | * | identification_variable }) |
       MAX([ALL|DISTINCT] expression) |
       MIN([ALL|DISTINCT] expression) |
       SUM([ALL|DISTINCT] expression) |

functions ::=
        ABS(expression) |
        BIGINT(expression) |
        CHAR({expression [,{ISO|USA|EUR|JIS}] )  |
        CONCAT (expression , expression ) |
        DATE(expression) |
        DAY({expression ) |
        DAYS( expression) |
        DECIMAL( expression [,integer[,integer]])
        DIGITS( expression) |
        DOUBLE( expression ) |
        FLOAT( expression) |

        MOD ( expression , expression ) |
        MONTH( expression ) |
        REAL( expression) |
        SECOND( expression ) |
        SMALLINT( expression )  |
        SQRT (  expression) |
        SUBSTRING( expression, expression[, expression]) |
        TIME( expression ) |
        TIMESTAMP( expression ) |
        UCASE ( expression) |
        YEAR( expression )

xrel := XREL identification_variable . { single_valued_cmr_field | collection_valued_cmr_field }
             [ , identification_variable . { single_valued_cmr_field | collection_valued_cmr_field } ]*
```

EJB specification and WebSphere query language comparison

WebSphere Application Server extends the Enterprise JavaBeans (EJB) query language with elements of its own.

WebSphere Application Server supports the following extensions to the EJB query language.

Table 46. Extensions supported for the EJB query language. The product supports the following extensions.

Item	
Delimited identifiers	
Dependent Value object attributes used in path expressions	
EJB Inheritance	
EXISTS predicate	
Java methods: EJB bean methods or value object methods	dynamic query only
Multiple element select clauses	dynamic query only
SQL Date/time expressions	
Subqueries, group by, and having clauses	

Using the dynamic query service

There are times in the development process when you might prefer to use the dynamic query service rather than the regular Enterprise JavaBeans (EJB) query service (which can be referred to as *deployment query*). During testing, for instance, the dynamic query service can be used at application run time, so you do not have to re-deploy your application.

About this task

Following are common reasons for using the dynamic query service rather than the regular EJB query service:

- You need to programmatically define a query at application run time, rather than at deployment.
- You need to return multiple CMP or CMR fields from a query. (Deployment queries allow only a single element to be specified in the SELECT clause.) For more information, see the topic, Example: EJB queries.
- You want to return a computed expression in the query.
- You want to use value object methods or bean methods in the query statement. For more information, see the topic, Path expressions.
- You want to interactively test an EJB query during development, but do not want to repeatedly deploy your application each time you update a finder or select query.

The dynamic query API is a stateless session bean; using it is similar to using any other J2EE EJB application bean. It is included in the com.ibm.websphere.ejbquery in the API package.

The dynamic query bean has both a remote and a local interface. If you want to return remote EJB references from the query, or if the query statement contains remote methods, you must use the query remote interface:

remote interface = `com.ibm.websphere.ejbquery.Query`
remote home interface = `com.ibm.websphere.ejbquery.QueryHome`

If you want to return local EJB references from the query, or if the query statement contains local methods, you must use the query local interface:

local interface = `com.ibm.websphere.ejbquery.QueryLocal`
local home interface = `com.ibm.websphere.ejbquery.QueryLocalHome`

Because it uses less application server memory, the local interface ensures better overall EJB performance than the remote.

Procedure

1. Verify that the query.ear application file is installed on the application server on which your application is to run, if that server is different from the default application server created during installation of the product.

   The `query.ear` file is located in the *app_server_root* directory, where `<WAS_HOME>` is the location of the WebSphere Application Server. The product installation program installs the `query.ear` file on the default application server using a JNDI name of

   ```
   com/ibm/websphere/ejbquery/Query
   ```

   (You or the system administrator can change this name.)
2. Set up authorization for the methods executeQuery(), prepareQuery(), and executePlan() in the remote and local dynamic query interfaces to control access to sensitive data. (This step is necessary only if your application requires security.)

   Because you cannot control which ASN names, CMP fields, or CMR fields can be used in a dynamic EJB query, you or your system administrator must place restrictions on use of the methods. If, for example, a user is permitted to run the executeQuery method, he or she can run any valid dynamic query. In a production environment, you certainly want to restrict access to the remote query interface methods.
3. Write the dynamic query as part of your application client code. You can refer to the example topics, Remote interface dynamic query example, and Local interface dynamic query example, as query models; they illustrate which import statements to use.
4. If the CMP you want to query is on a different module, you should:
   a. do a remote lookup on query.ear
   b. map the query.ear file to the server that the queried CMP bean is installed on.
5. Compile and run your client program with the file **qryclient.jar** in the classpath.

Example

Using the remote interface for Dynamic query.

When you run a dynamic Enterprise JavaBeans (EJB) query using the remote interface, you are calling the executeQuery method on the Query interface. The executeQuery method has a transaction attribute of REQUIRED for this interface; therefore you do not need to explicitly establish a transaction context for the query to run.

When you run a dynamic Enterprise JavaBeans (EJB) query using the remote interface, you are calling the executeQuery method on the Query interface. The executeQuery method has a transaction attribute of REQUIRED for this interface; therefore you do not need to explicitly establish a transaction context for the query to run.

Begin with the following import statements:

```
import com.ibm.websphere.ejbquery.QueryHome;
import com.ibm.websphere.ejbquery.Query;
import com.ibm.websphere.ejbquery.QueryIterator;
import com.ibm.websphere.ejbquery.IQueryTuple;
import com.ibm.websphere.ejbquery.QueryException;
```

Next, write your query statement in the form of a string, as in the following example that retrieves the names and ejb-references for underpaid employees:

```
String query =
"select e.name as name , object(e) as emp from EmpBean e where e.salary < 50000";
```

Create a Query object by obtaining a reference from the QueryHome class. (This class defines the executeQuery method.) Note that for the sake of simplicity, the following example uses the dynamic query JNDI name for the Query object:

```
InitialContext ic =  new InitialContext();

Object obj =  ic.lookup("com/ibm/websphere/ejbquery/Query");

QueryHome  qh =
 ( QueryHome) javax.rmi.PortableRemoteObject.narrow( obj, QueryHome.class );
Query qb = qh.create();
```

You then must specify a maximum size for the query result set, which is defined in the QueryIterator object, which is included in the Class QueryIterator. This class is included in the You then must specify a maximum size for the query result set, which is defined in the QueryIterator object, which is included in the QueryIterator API package. This example sets the maximum size of the result set to 99:

```
QueryIterator it = qb.executeQuery(query, null, null ,0, 99 );
```

The iterator contains a collection of IQueryTuple objects, which are records of the return collection values. Corresponding to the criteria of our example query statement, each tuple in this scenario contains one value of *name* and one value of *object(e)*. To display the contents of this query result, use the following code:

```
while (it.hasNext() ) {
 IQueryTuple tuple = (IQueryTuple) it.next();
 System.out.print( it.getFieldName(1) );
 String s = (String) tuple.getObject(1);
 System.out.println( s);
 System.out.println( it.getFieldName(2) );
 Emp e = ( Emp) javax.rmi.PortableRemoteObject.narrow( tuple.getObject(2), Emp.class );
 System.out.println( e.getPrimaryKey().toString());
}
```

The output from the program might look something like the following:

```
name Bob
emp 1001
name Dave
emp 298003
...
```

Finally, catch and process any exceptions. An exception might occur because of a syntax error in the query statement or a run-time processing error. The following example catches and processes these exceptions:

```
} catch (QueryException qe) {
    System.out.println("Query Exception "+ qe.getMessage() );
}
```

Handling large result collections for the remote interface query

If you intend your query to return a large collection, you have the option of programming it to return results in multiple smaller, more manageable quantities. Use the skipRow and maxRow parameters on the remote executeQuery method to retrieve the answer in chunks. For example:

```
int skipRow=0;
int maxRow=100;
QueryIterator it = null;
do {
 it = qb.executeQuery(query, null, null ,skipRow, maxRow );
 while (it.hasNext() ) {
 // display result
 skipRow = skipRow + maxRow;
}
} while ( ! it.isComplete() ) ;
```

Using the local interface for Dynamic query.

When you run a dynamic Enterprise JavaBeans (EJB) query using the local interface, you are calling the executeQuery method on the QueryLocal interface. This interface does not initiate a transaction for the method; therefore you must explicitly establish a transaction context for the query to run.

Note: To establish a transaction context, the following example calls the begin() and commit() methods. An alternative to using these methods is simply embedding your query code within an EJB method that runs within a transaction context.

Begin your query code with the following import statements:

```
import com.ibm.websphere.ejbquery.QueryLocalHome;
import com.ibm.websphere.ejbquery.QueryLocal;
import com.ibm.websphere.ejbquery.QueryLocalIterator;
import com.ibm.websphere.ejbquery.IQueryTuple;
import com.ibm.websphere.ejbquery.QueryException;
```

Next, write your query statement in the form of a string, as in the following example that retrieves the names and ejb-references for underpaid employees:

```
String query =
"select e.name, object(e) from EmpBean e where e.salary < 50000 ";
```

Create a QueryLocal object by obtaining a reference from the QueryLocalHome class. (This class defines the executeQuery method.) Note that in the following example, `ejb/query` is used as a local EJB reference pointing to the dynamic query JNDI name (`com/ibm/websphere/ejbquery/Query`):

```
InitialContext ic =  new InitialContext();
   QueryLocalHome  qh =  ( LocalQueryHome) ic.lookup( "java:comp/env/ejb/query" );
QueryLocal qb = qh.create();
```

The last portion of code initiates a transaction, calls the executeQuery method, and displays the query results. The QueryLocalIterator class is instantiated because it defines the query result set. This class is included in the Class QueryIterator API package. Keep in mind that the iterator loses validity at the end of the transaction; you must use the iterator in the same transaction scope as the executeQuery call.

```
userTransaction.begin();
QueryLocalIterator it = qb.executeQuery(query, null, null);
while (it.hasNext() ) {
 IQueryTuple tuple = (IQueryTuple) it.next();
 System.out.print( it.getFieldName(1) );
 String s = (String) tuple.getObject(1);
 System.out.println( s);
 System.out.println( it.getFieldName(2) );
 EmpLocal e = ( EmpLocal ) tuple.getObject(2);
 System.out.println( e.getPrimaryKey().toString());
}
userTransaction.commit();
```

In most situations, the QueryLocalIterator object is *demand-driven*. That is, it causes data to be returned incrementally: for each record retrieval from the database, the next() method must be called on the iterator. (Situations can exist in which the iterator is not demand-driven. For more information, consult the "Local query interfaces" subsection of the Dynamic query performance considerations topic.)

Because the full query result set materializes incrementally in the application server memory, you can easily control its size. During a test run, for example, you may decide that return of only a few tuples of the query result is necessary. In that case you should use a call of the close() method on the QueryLocalIterator object to close the query loop. Doing so frees SQL resources that the iterator uses. Otherwise, these resources are not freed until the full result set accumulates in memory, or the transaction ends.

Example: Using the remote interface for Dynamic query

When you run a dynamic Enterprise JavaBeans (EJB) query using the remote interface, you are calling the executeQuery method on the Query interface. The executeQuery method has a transaction attribute of REQUIRED for this interface; therefore you do not need to explicitly establish a transaction context for the query to run.

Begin with the following import statements:

```
import com.ibm.websphere.ejbquery.QueryHome;
import com.ibm.websphere.ejbquery.Query;
import com.ibm.websphere.ejbquery.QueryIterator;
import com.ibm.websphere.ejbquery.IQueryTuple;
import com.ibm.websphere.ejbquery.QueryException;
```

Next, write your query statement in the form of a string, as in the following example that retrieves the names and ejb-references for underpaid employees:

```
String query =
"select e.name as name , object(e) as emp from EmpBean e where e.salary < 50000";
```

Create a Query object by obtaining a reference from the QueryHome class. (This class defines the executeQuery method.) Note that for the sake of simplicity, the following example uses the dynamic query JNDI name for the Query object:

```
InitialContext ic =  new InitialContext();

Object obj =  ic.lookup("com/ibm/websphere/ejbquery/Query");

QueryHome  qh =
 ( QueryHome) javax.rmi.PortableRemoteObject.narrow( obj, QueryHome.class );
Query qb = qh.create();
```

You then must specify a maximum size for the query result set, which is defined in the QueryIterator object, which is included in the Class QueryIterator. This class is included in the You then must specify a maximum size for the query result set, which is defined in the QueryIterator object, which is included in the QueryIterator API package. This example sets the maximum size of the result set to 99:

```
QueryIterator it = qb.executeQuery(query, null, null ,0, 99 );
```

The iterator contains a collection of IQueryTuple objects, which are records of the return collection values. Corresponding to the criteria of our example query statement, each tuple in this scenario contains one value of *name* and one value of *object(e)*. To display the contents of this query result, use the following code:

```
while (it.hasNext() ) {
 IQueryTuple tuple = (IQueryTuple) it.next();
 System.out.print( it.getFieldName(1) );
 String s = (String) tuple.getObject(1);
 System.out.println( s);
 System.out.println( it.getFieldName(2) );
 Emp e = ( Emp) javax.rmi.PortableRemoteObject.narrow( tuple.getObject(2), Emp.class );
 System.out.println( e.getPrimaryKey().toString());
}
```

The output from the program might look something like the following:

```
name Bob
emp 1001
name Dave
emp 298003
...
```

Finally, catch and process any exceptions. An exception might occur because of a syntax error in the query statement or a run-time processing error. The following example catches and processes these exceptions:

```
} catch (QueryException qe) {
    System.out.println("Query Exception "+ qe.getMessage() );
}
```

Handling large result collections for the remote interface query

If you intend your query to return a large collection, you have the option of programming it to return results in multiple smaller, more manageable quantities. Use the skipRow and maxRow parameters on the remote executeQuery method to retrieve the answer in chunks. For example:

```
int skipRow=0;
int maxRow=100;
QueryIterator it = null;
do {
 it = qb.executeQuery(query, null, null ,skipRow, maxRow );
 while (it.hasNext() ) {
 // display result
 skipRow = skipRow + maxRow;
}
} while ( ! it.isComplete() ) ;
```

Example: Using the local interface for Dynamic query

When you run a dynamic Enterprise JavaBeans (EJB) query using the local interface, you are calling the executeQuery method on the QueryLocal interface. This interface does not initiate a transaction for the method; therefore you must explicitly establish a transaction context for the query to run.

Note: To establish a transaction context, the following example calls the begin() and commit() methods. An alternative to using these methods is simply embedding your query code within an EJB method that runs within a transaction context.

Begin your query code with the following import statements:

```
import com.ibm.websphere.ejbquery.QueryLocalHome;
import com.ibm.websphere.ejbquery.QueryLocal;
import com.ibm.websphere.ejbquery.QueryLocalIterator;
import com.ibm.websphere.ejbquery.IQueryTuple;
import com.ibm.websphere.ejbquery.QueryException;
```

Next, write your query statement in the form of a string, as in the following example that retrieves the names and ejb-references for underpaid employees:

```
String query =
"select e.name, object(e) from EmpBean e where e.salary < 50000 ";
```

Create a QueryLocal object by obtaining a reference from the QueryLocalHome class. (This class defines the executeQuery method.) Note that in the following example, `ejb/query` is used as a local EJB reference pointing to the dynamic query JNDI name (`com/ibm/websphere/ejbquery/Query`):

```
InitialContext ic =  new InitialContext();
   QueryLocalHome  qh =  ( LocalQueryHome) ic.lookup( "java:comp/env/ejb/query" );
QueryLocal qb = qh.create();
```

The last portion of code initiates a transaction, calls the executeQuery method, and displays the query results. The QueryLocalIterator class is instantiated because it defines the query result set. This class is included in the Class QueryIterator API package. Keep in mind that the iterator loses validity at the end of the transaction; you must use the iterator in the same transaction scope as the executeQuery call.

```
userTransaction.begin();
QueryLocalIterator it = qb.executeQuery(query, null, null);
while (it.hasNext() ) {
 IQueryTuple tuple = (IQueryTuple) it.next();
 System.out.print( it.getFieldName(1) );
 String s = (String) tuple.getObject(1);
 System.out.println( s);
```

```
 System.out.println( it.getFieldName(2) );
 EmpLocal e = ( EmpLocal ) tuple.getObject(2);
 System.out.println( e.getPrimaryKey().toString());
}
userTransaction.commit();
```

In most situations, the QueryLocalIterator object is *demand-driven*. That is, it causes data to be returned incrementally: for each record retrieval from the database, the next() method must be called on the iterator. (Situations can exist in which the iterator is not demand-driven. For more information, consult the "Local query interfaces" subsection of the Dynamic query performance considerations topic.)

Because the full query result set materializes incrementally in the application server memory, you can easily control its size. During a test run, for example, you may decide that return of only a few tuples of the query result is necessary. In that case you should use a call of the close() method on the QueryLocalIterator object to close the query loop. Doing so frees SQL resources that the iterator uses. Otherwise, these resources are not freed until the full result set accumulates in memory, or the transaction ends.

Dynamic query performance considerations

While using a dynamic query can be convenient, there are times when it can have an impact on your application performance.

General performance considerations

Use of the following elements in your dynamic query can diminish application performance somewhat:

- Datatype converters and Java methods

  Why: In general, query operations and predicates are translated into SQL so that the database server can perform them. If your query includes datatype converters (for EJB to RDB mapping, for example) or Java methods, however, the associated predicates and operations of your query must be performed in the memory of the application server.
- EJB methods and criteria that call for the return of EJB references

  Why: Queries that incorporate these elements trigger full activation of EJBs in the memory of the application server. (Returning a list of CMP fields from a query does not cause an EJB to be activated.)

When assessing application performance, you should also be aware that dynamic queries share connections with the persistence manager. Consequently, an application that includes a mixture of finder methods, CMR navigation, and dynamic queries relies on a single shared connection between the persistence manager and the dynamic query service to perform these tasks.

Limiting the return collection size

- **Remote interface queries**: The QueryIterator class of the remote interface mandates that all of your query results materialize in application server memory over the course of one method call. The SQL cursor(s) used to run the EJB query are closed upon completion of that call. Because this requirement poses a high risk for creating bottlenecks within the database server, you need to limit the size of any potentially large result collections.
- **Local interface queries**: In most situations, the QueryLocalIterator object behaves as a wrapper around an SQL cursor. It is *demand-driven*; it causes data to be returned incrementally. For each record retrieval from the database, the next() method must be called on the iterator.

  Use of certain operations in local interface queries, however, overrides the demand-driven behavior. In these cases, the query results fully materialize in memory just as do the result collections of remote interface queries. An example of such a case is:

  ```
  select  e.myBusinessMethod( ) from EmpBean e
   where e.salary < 50000 order by 1 desc
  ```

  This query requires performance of an EJB method to produce the final result collection. Consequently, the full dataset from the database must be returned in one collection to application server memory,

where the EJB method can be run on the dataset in its entirety. For that reason, local interface query operations that invoke EJB methods are generally not demand-driven. You cannot control the return collection size for such queries.

Because they *are* demand-driven, all other local interface queries allow you to control the size of return collections. You can use a call of the close() method on the QueryLocalIterator object to close the query loop after the desired number of return values has been fetched from the datastore. Otherwise, the SQL cursor(s) used to run the EJB query are not closed until the full result set accumulates in memory, or the transaction ends.

Access intent implications for dynamic query

WebSphere Application Server gives you the option to set access intent policies for your entity enterprise beans as a way of managing their transfer of data with the underlying data store. An access intent policy controls the isolation level used on the data source connection, as well as the database locks used during data retrieval. By manipulating these elements, you can maximize the efficiency of your application's data flow.

To learn more, begin with the topic, Access intent policies and the topic, Concurrency control.

When formulating dynamic queries, keep in mind the following considerations concerning their interaction with access intent policies:

- A dynamic query uses the first ASN name in the FROM clause to determine access intent.
- The collection increment attribute of an access intent policy is not used in processing a dynamic query.
- When performed on entity beans that have a pessimistic-Update access intent policy, your dynamic queries must return updateable collections. Therefore you need to formulate your query statements to return only collections of entity beans, *not* collections of CMP fields. For example, the statement `select object(c) from Customer` is valid for a dynamic query performed under the constraint of a pessimistic-Update policy. The statement `select c.name from Customer c`, however, is not a valid dynamic query under this constraint.
- Using pessimistic-Update policy places restrictions on the types of query expressions. The restrictions depend on the back end database type and release. Refer to the topic Access intent – isolation levels and update locks, for details.

Dynamic query API: prepareQuery() and executePlan() methods

Use these methods to more efficiently allocate the overhead associated with dynamic query. They are equivalent in function to the prepareStatement() and executeQuery() methods of the JDBC API.

To perform a dynamic Enterprise JavaBeans (EJB) query, the application server must parse the query string into structured query language (SQL) at run time. You can, of course, eliminate run-time overhead by choosing to perform a standard EJB query instead of a dynamic query. Sometimes referred to as *deployment queries*, standard queries are parsed and built at deployment, then performed by a finder or select method.

Another option is to write code that redistributes dynamic query overhead for better application performance. Begin by calling the prepareQuery() method in place of the executeQuery() method. The prepareQuery() method parses and translates your query, and returns a string called a *query plan*. The plan contains the SQL statement produced by parsing and translation, as well as other information needed by the dynamic query API. Save this string in your application and call the executePlan() method with the string to run your query. (You also might want to use the prepareQuery() method simply to see the SQL translation product; just call the method and display the return value.)

Pass the parameters of your query as an array of type Object on the prepareQuery() and the executePlan() method calls. Ensure that you pass appropriate data types, because the application server validates your query according to parameter type (rather than actual values) when it processes the prepareQuery() method call.

Example code

Note: In the example code that follows, the first executePlan() method call substitutes `parms[0]` for `?1`. Hence the first query performed is functionally equivalent to the following query statement:

```
select e.name as name, object(e) as emp from EmpBean e where e.salary < 50000
```

The second call runs a query that is functionally equivalent to this statement:

```
select e.name as name, object(e) as emp from EmpBean e where e.salary < 60000
```

The example:

```
String query =
"select e.name as name , object(e) as emp from EmpBean e where e.salary < ?1";
QueryIterator it = null;
Integer[] parms = new Integer[1];
parms[0] = new Integer(0);
```

In the call to `prepareQuery()`, pass any Integer value. Doing so defines `?1` as an Integer type, as in the following:

```
String queryPlan= qb.prepareQuery(query, parms, null );

   parms[0] = new Integer(50000);
```

Next you run the query with a real value of `Integer(50000)` for `?1`:

```
select e.name as name, object(e) as emp from EmpBean e where e.salary < 50000it =
 qb.executePlan( queryPlan, parms, 0, 99);

parms[0] = new Integer(60000);
```

Run the query again with a different value of `Integer(60000)` for `?1`:

```
it = qb.executePlan( queryPlan, parms, 0, 99);
```

Dynamic and deployment EJB query services comparison

You can use the dynamic query service to build and execute queries against entity beans constructed dynamically at run time, rather than defining them at deployment time. By using dynamic query you gain the flexibility of queries defined at run time and utilize the power of Enterprise JavaBeans (EJB)-Query Language (QL). Apart from supporting all of the capabilities of an EJB-QL query, dynamic query adds functionality not available to standard static query. Two examples are the ability to select multiple data fields directly from the bean itself (static queries currently only allow one) and executing business methods directly in the query.

You can effectively create more efficient and less resource intensive applications with dynamic query. For example, two data fields are required from the results of a query. Because a standard EJB-QL query can only select one data field, it is necessary to select the entire EJB object and extract the needed data from the returned results through data access methods, possibly traversing Container Managed Relationships (CMR) boundaries in the process. However, when using dynamic query, you can get both pieces of data directly from the query without additional CMR traversal or accessor methods. This principle is the key to evaluating whether or not dynamic query can be used for performance gain. You should review the amount of data that must be retrieved, in addition to the amount of business logic needed to retrieve it, for example, CMR traversal or accessor methods.

Using parameters in the query rather than literal values is another performance consideration. Under most circumstances, it is better to define conditional values as parameters in the query and then pass those parameters through the appropriate mechanisms. By using this method, you have a greater chance of matching a cached query plan, and you eliminate the need to parse and build the plan from scratch. For example, “SELECT Object(o) FROM schemaname AS o WHERE o.fieldname LIKE foo”, is more appropriately expressed as “SELECT Object(o) FROM schemaname AS o WHERE o.fieldname LIKE ?1” with the value foo passed as a parameter to the executeQuery method. The result is that any subsequent

execution of a dynamic query structure that is the same, except for different string literal conditions, is registered as a plan cache hit (which delivers better “observed” performance).

When used as a direct replacement for an equivalent static query, dynamic query is approximately 25% slower than the static variation. This slowdown is due to the need for parsing and building a plan for the query, in addition to executing it. In the static variation, these costs are paid at deploy time. Despite this, the added functionality gained through the use of dynamic query, specifically the ability to select multiple data fields in a single query even across CMRs, creates opportunities to utilize dynamic query for the sake of performance improvement.

Chapter 10. Developing EJB applications

This page provides a starting point for finding information about enterprise beans.

Based on the Enterprise JavaBeans (EJB) specification, enterprise beans are Java components that typically implement the business logic of Java 2 Platform, Enterprise Edition (J2EE) applications as well as access data.

Developing EJB 2.x enterprise beans

Partial column update feature for container managed persistence

The Container Managed Persistence (CMP) bean method `ejbStore` stored all of the persistent attributes of the CMP bean to the database, even if only a subset of persistent attribute fields were changed. This needless performance degradation is eliminated in this release of the product.

Note: Entity beans are not supported in EJB 3.0 modules.

For Enterprise JavaBeans (EJB) 2.x CMP entity beans, you can use the partial update feature to specify how you want to update the persistent attributes of the CMP bean to the database. This feature is provided as a bean level persistence option, called `PartialOperation`, in the access intent policy configured for the bean. PartialOperation has two possible values:

NONE Partial update is turned off. All of the persistent attributes of the CMP bean are stored to the database. This is the default value.

UPDATE_ONLY
Specifies that updates to the database occur only for the persistent attributes of the CMP bean that are changed.

For information on how to set partial update, see “Setting partial update for container-managed persistent beans” on page 315.

Performance

Performing partial updates increases performance in several ways:

- by reducing query execution time, since only a subset of the columns are in the query. Improvement is increased for tables with many columns and indexes. When the table has many indexes only the indexes affected by the updated columns need to be updated by the backend database.
- by reducing network input and output since there is less data to be transmitted.
- by saving any processing time for non-trivially mapped columns. For example, if a column uses converters, composers, and transformations to partially inject the input record.
- by eliminating unnecessary firing of update triggers. If a CMP bean field is not changed, any trigger depending only on the corresponding column is not fired.

Although partial update improves performance, it can adversely affect performance as follows:

- If you enable partial update for a bean that your application modifies several different combinations of columns during the same time span, the prepared statement cache maximum for the connection is reached very quickly. As a result, statement handles are evicted from the cache based on least recent usage. This results in statements being prepared repeatedly, decreasing performance for all CMP functions, not just limited to the ejbStore method.
- Partial update query templates cached in the function set increase memory use. The increase is linear relative to the number of fields in the CMP bean for which the partial update access intent option is turned on.

- The PartialOperation persistent option, when used in combination with the Batch Update persistent option, affects the performance of the batch update because each partial query is different. There is an execution time cost incurred for generating a partial update query string dynamically. Since query fragments are stored for each column, the execution cost to assemble the query fragments is linear, based on the number of CMP bean fields dirtied.
- There are condition checks for each CMP field, for example, to inspect the dirty flags and to execute the preparedStatement setXXX method calls.

Considerations for using partial update

The performance gains you hope to achieve should be weighed against the possible instances where degradation can occur. You can use the following guidelines to help you make the decision.

- Partial update might not benefit an application that only involves a small table with a few columns and simple data types and no update triggers. The cost to assemble the partial query dynamically outweighs the performance gain.
- Partial update is a benefit if there is a complex data type that is not updated often. An example of a complex data type is an employee bean with a “photo” CMP attribute mapped to a BLOB OR VARGRAPHIC, or similar complex backend type, that is typically stored in a different location in the database manager implementation.
- Partial Update might benefit if there are several VARCHAR type columns and only a very few of them are updated.
- It is better not to use the partial operation if the application can randomly be updating different combinations of columns and the number of assignable columns (non-key) is greater than five. This generates different partial queries and fills up the prepared statement cache quickly. But, if the bean does not have too many columns, for example, four or less, and it has complex data types, you might consider turning partial update on, with the option of increasing the statement cache size to ensure an increased number of queries. For information on increasing the statement cache size, refer to the data source settings help.
- Partial Update is beneficial when there are update triggers needed on a subset of columns.
- Partial Update is beneficial when the table has many columns and indexes, and only a few indexes are touched by a typical update.

Restrictions

By default, batch update of update queries is disabled for all CMP beans for which partial update is enabled. In other words, partial update takes precedence over batch update. Batch update of delete and insert queries is not affected.

Batch update performance is affected when both batch update and partial update persistence options are used on the same bean, because each partial query is different. You can use the JVM property, `-Dcom.ibm.ws.pm.grouppartialupdate=true`, to group the similar partial update queries into a batch update. Grouping partial updates only helps when there are several partial queries with the same shape in a transaction. Otherwise, grouping partial updates has the opposite affect on performance. Because this setting is not on a bean level basis, you should be careful when turning it on. Because this affects all beans that have both partial update and batch update on, you must make sure that batch update of partial queries does increase performance when viewed across all the beans for which both updates are on.

To set the JVM property:

1. Open the `server.xml` file.
2. Change the value of `-Dcom.ibm.ws.pm.grouppartialupdate=true` to `-Dcom.ibm.ws.pm.grouppartialupdate=false`.

Setting partial update for container-managed persistent beans

For Enterprise JavaBeans (EJB) 2.x CMP entity beans, you can use the *partial update* feature to specify how you want to update the persistent attributes of the CMP bean to the database. This feature is provided as a bean-level persistence option, called *PartialOperation*, in the access intent policy configured for the bean.

About this task

See the topic Partial operation for container managed persistence in the assembly tool information center to learn how to complete this task with the assembly tool.

Developing EJB 3.x enterprise beans

Enterprise JavaBeans (EJB) 3.1 specification

This topic describes the Enterprise JavaBeans (EJB) 3.1 specification that is the foundation of the development and application programming model for EJB 3.1 applications. Read this topic for a brief overview of the EJB 3.1 specification.

The EJB 3.1 specification focuses on simplification and ease of use. In addition, it adds many new features to the programming model.

- *Singleton session beans* are a new type of session bean. As the name implies, only one instance of the bean exists. A Singleton is useful for storing data that is shared by different parts of an application. Data concurrency might be controlled by either the container or the application itself.
- *Non-persistent EJB Timers* are similar to the persistent EJB Timers that existed before EJB 3.1, except that they exist only in memory and are not stored in a database. Non-persistent timers are useful for scenarios where it is not desirable to retry missed events.
- *Automatically created EJB Timers* are created automatically when the application starts, and they are removed automatically when the application is uninstalled. Automatically created timers might be either persistent or non-persistent. Automatically created timers are useful because they remove the need for the application or an administrator to explicitly create and remove the timers.
- *Calendar based timer expressions* allow developers to specify a timeout schedule using a calendar-based syntax that closely resembles the UNIX Cron functionality. Calendar-based expressions are useful because they make it much easier to specify and understand the timeout schedule for a timer.
- *Asynchronous method invocation* allows applications to run multiple chunks of work in parallel. Asynchronous methods are useful from a performance perspective because work loads are not single threaded, and they are also useful from a simplification perspective because the application programmer is shielded from the complexities associated with multithreaded programming.
- The *No-Interface Local View* further simplifies the plain old Java objects (POJO) programming model. With the No-Interface Local View, EJBs are no longer required to have a bean interface.
- The *embeddable EJB container* allows developers to unit test their EJB function in a Java SE environment. The embeddable EJB container is useful because it allows developers to test EJB function quickly and easily in their personal sandbox environment, and it removes the need to install the EJBs into an application server.
- *Packaging EJB content in WAR modules* allows both web and EJB content to be physically combined into the same module. This packaging option is useful because it might simplify the assembly and installation of the application, and simplifying the interaction between the web and EJB components that are collocated in the same module.

Enterprise JavaBeans (EJB) 3.0 specification

This topic describes the Enterprise JavaBeans (EJB) 3.0 specification that is the foundation of the development and application programming model for the EJB 3.0 applications. Read this topic for a brief overview of the EJB 3.0 specification.

The EJB 3.0 specification has justifiably been called the most important upgrade to the Java Platform, Enterprise Edition 5 (Java EE 5) programming model. The EJB 3.0 specification represents simplification and streamlining of the business logic and persistence programming models used in Java EE. The ultimate source of information is the specification, which is available on the Oracle website.

While the Java Persistence API (JPA) replacement is called an entity class, it should not be confused with entity enterprise beans. A JPA entity is not an enterprise bean and is not required to run in an EJB container.

The EJB 3.0 specification is organized into three areas:

- EJB core contracts and requirements
- EJB 3.0 simplified application programming interface (API)
- JPA

The EJB core contracts and requirements define the service provider interfaces (SPIs) between the enterprise bean instance and the enterprise bean container. This part of the specification also includes the APIs between the enterprise bean provider and the enterprise bean container, protocols, component and container contracts, system level issues, infrastructure services that are provided by the container to the bean and other information about development packaging and deployment for session, message-driven, and entity beans.

The EJB 3.0 simplified API provides information about simplifying EJB APIs and SPIs that exist from previous EJB specification versions.

The JPA document introduces the Plain Old Java Object (POJO)-style persistent entity development guidelines.

Another good source for EJB 3.0 information is Mastering Enterprise JavaBeans 3.0, Fourth Edition. This edition features chapters on session beans and message-driven beans, EJB, and Java EE integration and advanced persistence concepts. Also included is coverage of the JPA and POJO using entities with the EJB programming model.

Application exceptions

Application exceptions alert the client of application specific or business logic issues; they do not report system level exceptions. This topic includes a brief overview of how application exceptions are defined and examples of the `@ApplicationException` annotation and corresponding `application-exception` deployment descriptor element.

Definition of Application Exception

Bean providers define application exceptions along with the business logic of an application. Unlike system exceptions, application exceptions are not used to report system-level errors. Instead, business methods use application exceptions to notify the client of application-level activity that might cause errors; for example, invalid input argument values to a business method. In most cases, clients can return to normal processing after experiencing application exceptions

You can define application exceptions in the throws clause of a method. The method that you use to define the application exception can be that of a business interface, no-interface view, home interface, component interface, message listener interface, or web service endpoint of the enterprise bean. When you define the exception, remember that application exceptions can be:

- A subclass, either direct or indirect, of the java.lang.Exception exception, which renders a *checked exception*
- A subclass of the java.lang.RuntimeException exception, which renders an *unchecked exception*

Attention: You cannot define an application exception as a subclass of java.rmi.RemoteException because this exception and its subclasses are for system-level problems.

The following standard application exceptions and their subclasses are used to report errors to the client:

- javax.ejb.CreateException
- javax.ejb.RemoveException
- javax.ejb.FinderException

The previous application exceptions are defined in the create, remove, and finder methods of the EJBHome interface, the EJBLocalHome interface, or both. These interfaces come from components that are written to the EJB 2.1 client view.

In the Enterprise Java beans 3.0 specification, the @ApplicationException annotation had only one optional parameter of rollback. The corresponding application-exception element had only one optional subelement, rollback, that you set to true or false. The rollback parameter/subelement is used to specify whether the transaction is marked for rollback. By default this value is false. Inheritance of an application exception could not be specified and was not given an explicit default value in the EJB 3.0 specification. The product implementation of the EJB 3.0 specification did not provide application exception inheritance, unless an application exception was defined on the *throws* clause of a business method of a bean. In contrast, the EJB 3.1 specification has introduced the optional `inherited` parameter to the @ApplicationException annotation and the optional `inherited` subelement to the corresponding application-exception deployment descriptor element. By default, marking an exception as an application exception causes all subclasses of that exception to also be application exceptions (that is, `inherited=true`). You can disable the inheriting behavior by setting the `inherited` parameter of the @ApplicationException to false. Likewise, you can disable the inheriting behavior by setting the `inherited` subelement of the application-exception element in the deployment descriptor to false. For more information about application exceptions, refer to section 14.1.1 of the EJB 3.1 specification.

Inherited application exceptions using annotations:

```
import javax.ejb.ApplicationException;

@ApplicationException(inherited=true, rollback=true)
public class RTExceptionA extends RuntimeException{

   //RTExceptionA

}
public class RTExceptionB extends RTExceptionA{

   //RTExceptionB

}
import javax.ejb.ApplicationException;

@ApplicationException(inherited=false, rollback=false)
public class RTExceptionC extends RTExceptionB{

   //RTExceptionC

}
public class RTExceptionD extends RTExceptionC{

   //RTExceptionD

}
```

The previous example yields the following results:

RTExceptionA is an application exception with transaction rollback.

RTExceptionB is an application exception with transaction rollback.

RTExceptionC is an application exception without transaction rollback.

RTExceptionD is not an application exception.

Inherited application exceptions using XML:

```
public class RTExceptionA extends RuntimeException{

   //RTExceptionA

}
public class RTExceptionB extends RTExceptionA{

   //RTExceptionB

}
public class RTExceptionC extends RTExceptionB{

   //RTExceptionC

}
public class RTExceptionD extends RTExceptionC{

   //RTExceptionD

}
```

```
<!-- Example ejb-jar.xml -->
<?xml version="1.0" encoding="UTF-8"?>
<ejb-jar id="ejb-jar_ID" xmlns="http://java.sun.com/xml/ns/javaee"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://java.sun.com/xml/ns/javaee http://java.sun.com/xml/ns/javaee/ejb-jar_3_1.xsd"
    metadata-complete="true" version="3.1">
    <assembly-descriptor>
        <application-exception>
            <exception-class>myXML.example.package.RTExceptionA</exception-class>
            <rollback>true</rollback>
            <inherited>true</inherited>
        </application-exception>
        <application-exception>
            <exception-class>myXML.example.package.RTExceptionC</exception-class>
            <rollback>false</rollback>
            <inherited>false</inherited>
        </application-exception>
    </assembly-descriptor>
</ejb-jar>
```

As in the annotation version, the previous example yields the following results:

RTExceptionA is an application exception with transaction rollback.

RTExceptionB is an application exception with transaction rollback.

RTExceptionC is an application exception without transaction rollback.

RTExceptionD is not an application exception.

Remember: You can use the `rollback` and `inherited` subelements of the `application-exception` to explicitly override the `rollback` and `inherited` attribute values that were specified or implicitly set by the `@ApplicationException` annotation.

When you specify an exception on the throws clause of a business method of a bean, the resulting checked exception is an application exception. All subclasses of this application exception are also application exceptions. No option is available to disable this inheriting behavior of checked application exceptions. You can use the `inherited` element to determine the rollback value of the checked application

exception subclasses. If the `inherited` element of the checked application exception is set to `true` and its `rollback` element is set to `true`, then the subclasses of that checked application exception inherit the `rollback = true` value.

Getting EJB 3.0 application exception inheritance behavior:

You have the following options if you have an existing EJB 3.0 application and you want to continue having the application exception inheritance behavior be false, which means that the subclasses of an application exception are not application exceptions themselves.

- You can modify the exception's `@ApplicationException` annotation of the exception by adding the `inherited` attribute and setting it to `false`.
- You can add a version 3.1 deployment descriptor and explicitly set the `inherited` subelement of the `application-exception` element to `false`. If you have an existing version 3.0 deployment descriptor you must migrate to a version 3.1 deployment descriptor and XSD schema and set the `inherited subelement of the application-exception` element to `false`.

How to get EJB 3.0 application exception inheritance behavior with annotations:

Suppose that you previously had the following code:

```
import javax.ejb.ApplicationException;

@ApplicationException()
public class EJB30_RTException extends RuntimeException{

   //EJB30_RTException, in EJB 3.0 subclasses were not application exceptions

}
```

You must modify the `@ApplicationException` annotation to include the `inherited=false` attribute:

```
import javax.ejb.ApplicationException;

@ApplicationException(inherited=false)
public class EJB30_RTException extends RuntimeException{

   //EJB30_RTException,  now you must explicitly set inherited to false to disable inheritance

}
```

How to get EJB 3.0 application exception inheritance behavior using XML:

Suppose that you previously had the following code:

```
<!-- Example ejb-jar.xml -->

<?xml version="1.0" encoding="UTF-8"?>
  <ejb-jar id="ejb-jar_ID" xmlns="http://java.sun.com/xml/ns/javaee"
      xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
      xsi:schemaLocation="http://java.sun.com/xml/ns/javaee http://java.sun.com/xml/ns/javaee/ejb-jar_3_0.xsd"
      metadata-complete="true" version="3.0">
    <assembly-descriptor>
        <application-exception>
            <exception-class>myXML.example.package.EJB30_RTException</exception-class>
        </application-exception>
    </assembly-descriptor>
</ejb-jar>
```

You must modify your code to include the `inherited` element set to `false` as well as migrate to a version 3.1 deployment descriptor and XSD schema:

```
<!-- Example ejb-jar.xml -->
<?xml version="1.0" encoding="UTF-8"?>
<ejb-jar id="ejb-jar_ID" xmlns="http://java.sun.com/xml/ns/javaee"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://java.sun.com/xml/ns/javaee http://java.sun.com/xml/ns/javaee/ejb-jar_3_1.xsd"
```

```
    metadata-complete="true" version="3.1">
    <assembly-descriptor>
        <application-exception>
            <exception-class>myXML.example.package.EJB30_RTException</exception-class>
            <rollback>false</rollback>
            <inherited>false</inherited>
        </application-exception>
    </assembly-descriptor>
</ejb-jar>
```

EJB 3.x module considerations

When using Enterprise JavaBeans (EJB) 3.x modules, keep in mind the following considerations.

Version 8.0 does not support 1.x and 2.x entity beans in EJB 3.x-level modules

IBMWebSphere Application Server Version 8.0 does not support the use of 1.x and 2.x bean managed persistence (BMP) and container managed persistence (CMP) entity beans in EJB 3.x-level modules. EJB entity beans can be used on V8.0, but they must be packaged in an EJB 2.1 or earlier-level module.

Java Platform, Enterprise Edition (Java EE) applications that are packaged with EJB entity beans in EJB 3.x-level modules fail to install on Version 8.0.

An EJB Java archive (JAR) file is considered to be an EJB 3.x module when either of the following are true:

- The EJB JAR file contains configuration data in an `ejb-jar.xml` file with an EJB 3.0 or EJB 3.1 header specification. For example:

```
<ejb-jar id="ejb-jar_ID" version="3.0"
      xmlns="http://java.sun.com/xml/ns/javaee"
      xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
      xsi:schemaLocation="http://java.sun.com/xml/ns/javaee
http://java.sun.com/xml/ns/javaee/ejb-jar_3_0.xsd">
```

- The EJB JAR file contains beans with EJB 3.x-style source annotations that provide configuration data and does not contain an `ejb-jar.xml` deployment descriptor file.

You need to repackage your EJB 3.x modules using EJB 2.x and earlier modules. Otherwise, the installation of any applications that contain entity beans fail.

Annotations

Consider using annotations versus deployment descriptors, or both. See the topic EJB 3.x metadata annotations for more information about annotations.

EJB module

WebSphere Application Server Version 8.0 supports EJB module Java archive (JAR) files with an `ejb-jar.xml` deployment descriptor declared at the 1.1, 2.0, 2.1, 3.0, or 3.1 level, or with no `ejb-jar.xml` deployment descriptor present. If no deployment descriptor is present, the EJB module is assumed to be at the 3.0 level or greater.

EJB modules that contain EJB 3.x beans must be declared to be at the EJB 3.0 or EJB 3.1 level. This can be accomplished either by setting the `ejb-jar.xml` deployment descriptor level to 3.0 or 3.1, or ensuring that the module does not contain an `ejb-jar.xml` deployment descriptor. If the module level is 2.1 or earlier, no EJB 3.x-specific functions such as annotation scanning or resource injection is performed.

Entity beans are not supported in EJB 3.x level modules. You must place any entity beans in EJB modules at the 2.1 or earlier level.

If you want to package an EJB 3.x module with a deployment descriptor, there are several ways to do it. Package an EJB 3.x module with an EJB 3.x style session and message-driven beans exclusively; with an EJB 2.1 style session and message-driven beans exclusively, or a combination of 2.1 and 3.x style beans. The XML deployment descriptor must be a Version 3.0 or 3.1 deployment descriptor. It is required that 2.1 entity beans are packaged in modules with 2.1 deployment descriptors. EJB modules that contain EJB 3.x beans must be at the EJB 3.0 or EJB 3.1 specification level when running on the product. Prepare the EJB module to support EJB 3.x beans, by setting the `ejb-jar.xml` deployment descriptor level to 3.0 or 3.1, or you can make sure that the module does not contain an `ejb-jar.xml` deployment descriptor. If the module level is EJB 2.1 or earlier, no EJB 3.x functions, including annotation scanning or resource injection is performed at run time.

Java EE application client module

The product provides support for Java EE application client modules. Additionally, it supports injection of EJB references into client components if the injection is defined through the @EJB annotation.

Attention: EJB 3.x does not support the injection of an enterprise bean that creates an enterprise bean of itself. Do not inject an enterprise bean that creates an enterprise bean of itself.

Defining an ejb-ref reference to an EJB 3.x business interface from a Java EE client component descriptor

It is possible to define an ejb-ref from an `application-client.xml` descriptor that points to an EJB 3.x business interface. EJB 3.x business interfaces are accessed directly without the use of a home, yet the ejb-ref element in Java EE requires that a home interface type is specified. Therefore, you must include the <home></home> stanza in the ejb-ref definition, but specify a null value as shown in the example. For the value of the <remote> stanza, specify the EJB 3.x business interface class name. Finally, when you set the binding value, either during application installation or through tooling, specify the location where the EJB 3.x business interface was bound.

For example, the ejb-ref in your client component `application-client.xml` file looks like the following code sample:

```
<ejb-ref id="EJBRef_1">
 <ejb-ref-name>java_comp-env_name_of_ref</ejb-ref-name>
 <ejb-ref-type>Session</ejb-ref-type>
 <home></home>
 <remote>com.ejbs.business.interface.class.name</remote>
</ejb-ref>
```

The corresponding section of the `ibm-application-client-bnd.xmi` file looks like the following code sample. A default EJB binding pattern is used here; the default EJB binding conventions are described in the topic, EJB 3.x applications binding support.

```
<ejbRefBindings xmi:id="EjbRefBinding_1"
         jndiName=EJB3App/EJB3Mod.jar/MyBean##com.ejbs.business.interface.class.name">
 <bindingEjbRef href="application-client.xml#EjbRef_1"/>
</ejbRefBindings>
```

EJB metadata annotations

Annotations enable you to write metadata for Enterprise JavaBeans (EJB) inside your source code. You can use them instead of extensible markup language (XML) deployment descriptor files. Annotations can also be used *with* descriptor files.

If you installed the Feature Pack for EJB 3.0, the default was to scan annotations during the installation of an EJB 3.0 module. For WebSphere Application Server, Version 7.0 and later, the default is not to scan pre-Java EE 5 modules during the application installation or at server startup

To preserve backward compatibility with both the Feature Pack for EJB 3.0 and the Feature Pack for Web Services, you have a choice whether to scan legacy web modules for additional metadata. A server level

switch is defined for each feature pack scan behavior. If the default is not appropriate, the switch must be set on each server and administrative server that requires a change in the default. The switches are server custom properties com.ibm.websphere.webservices.UseWSFEP61ScanPolicy={true|false} and com.ibm.websphere.ejb.UseEJB61FEPScanPolicy={true|false}. To define these properties in the administrative console click **Application servers** > **server name** > **Process definition** > **Java Virtual Machine** > **Custom properties**.

The product also provides default values for most of the EJB annotations it uses. In many cases, omitting an annotation implies that you want to use the default value.

Usually, annotations are found in the *javax.ejb* and *javax.persistence* packages.

EJB 3.x interceptors

An interceptor is a method that is automatically called when the business methods of an Enterprise JavaBeans (EJB) are invoked or lifecycle events of an EJB occur.

There are three kinds of interceptor methods: business method interceptors, timeout method interceptors (which are new in EJB3.1), and lifecycle callback interceptors. Business method interceptors are invoked around the call to a business method. Timeout method interceptors are invoked around the call to an EJB timeout method. Lifecycle callback interceptors are called around one of the PostConstruct, PreDestroy, PrePassivate, or PostActivate lifecycle events. For each interceptor type, an individual class can only declare one interceptor method. However, each class in a class hierarchy can declare an interceptor method for each interceptor type. If an interceptor method in a subclass overrides the same method in a super-class, only the method in the subclass might be invoked.

Interceptor methods are permitted to access and call all resources and components that the associated method is allowed to call. Additionally, interceptor methods execute with the same transaction and security context as the associated method. Except for singleton session beans, lifecycle interceptor methods are executed with local transaction containment (LTC).

You can declare interceptor methods directly in the EJB class or in a separate interceptor class. To declare interceptor methods in a separate class, you must bind the interceptor class to the EJB using either an annotation or XML. Use the following example to declare interceptors using the annotation:

```
@Interceptors({ClassInterceptor1.class, ClassInterceptor2.class})
public class TestBean { /* ... */ }

@Interceptors({ClassInterceptor1.class})
public class TestBean2 {
 @Interceptors({MethodInterceptor1.class, MethodInterceptor2.class})
 public void businessMethod() { /* ... */ }
}
```

Use the following example to declare interceptors using the deployment descriptor:

```
  <assembly-descriptor>
    <interceptor-binding>
      <ejb-name>TestBean</ejb-name>
      <interceptor-class>ClassInterceptor1</interceptor-class>
      <interceptor-class>ClassInterceptor2</interceptor-class>
    </interceptor-binding>

    <interceptor-binding>
      <ejb-name>TestBean2</ejb-name>
      <interceptor-class>ClassInterceptor1</interceptor-class>
    </interceptor-binding>
```

```
    <interceptor-binding>
      <ejb-name>TestBean2</ejb-name>
      <interceptor-class>MethodInterceptor1</interceptor-class>
      <interceptor-class>MethodInterceptor2</interceptor-class>
      <method>
        <method-name>businessMethod</method-name>
      </method>
    </interceptor-binding>
  </assembly-descriptor>
```

You can exclude class-level interceptors from a method by using either the ExcludeClassInterceptors annotation or the exclude-class-interceptors element in the deployment descriptor. Use the following example to exclude the interceptor, ClassInterceptor, from the method, businessMethod.

```
@Interceptors({ClassInterceptor1.class})
public class TestBean2 {
 @ExcludeClassInterceptors
 public void businessMethod() { /* ... */ }

 public void businessMethodWithClassInterceptor1() { /* ... */
}
```

Use the following example to exclude the interceptor from the method using the deployment descriptor:

```
  <assembly-descriptor>
    <interceptor-binding>
      <ejb-name>TestBean2</ejb-name>
      <exclude-class-interceptors>true</exclude-class-interceptors>
      <method>
        <method-name>businessMethod</method-name>
      </method>
    </interceptor-binding>
  </assembly-descriptor>
```

Interceptor methods can have public, protected, package private, or private visibility. Interceptor methods must not be final or static. Business method interceptors and timeout method interceptors must have a return type of java.lang.Object, a single parameter of javax.interceptor.InvocationContext, and a single throws clause type of java.lang.Exception. All lifecycle interceptors must have a return type of void and must not have a throws clause. Lifecycle interceptors declared directly on the EJB class must not have parameters; lifecycle interceptors declared on an EJB superclass or on an interceptor class must have a single parameter of javax.interceptor.InvocationContext. Timeout interceptor methods and lifecycle interceptor methods must not throw application exceptions.

You can use the InvocationContext parameter of an interceptor method to get information about the method being invoked. The getTarget method returns the bean instance being invoked. The getTimer method is applicable to timeout method interceptors only, and it returns the timer being executed. The getMethod method returns the business interface method that is being invoked. The getParameters method returns the parameters being passed to the business method, and the setParameters method allows the parameters to be modified. The getContextData method returns the data association with the method being invoked. Finally, the proceed method invokes either the next interceptor or the target method.

You can declare interceptor methods using either annotations or XML. To declare an interceptor method using an annotation, place the appropriate AroundInvoke, AroundTimeout, PostConstruct, PreDestroy, PrePassivate, or PostActivate annotation on the interceptor method. Use the following example to declare a business method interceptor, a timeout method interceptor, and a PostConstruct lifecycle interceptor method on an EJB class using annotations.

```
@Interceptors({ClassInterceptor.class})
public class TestBean {
 @PostConstruct
 private void beanPostConstruct() { /* ... */ }
```

```
 @AroundInvoke
 protected Object beanAroundInvoke(InvocationContext ic) throws Exception {
  return ic.proceed();
 }

        @AroundTimeout
        protected Object beanAroundTimeout(InvocationContext ic) throws Exception {
  return ic.proceed();
        }
}
```

Use the following example to declare the same interceptor methods on an interceptor class.

```
public class ClassInterceptor {
 @PostConstruct
 private void interceptorPostConstruct(InvocationContext ic) {
  try {
   ic.proceed();
  } catch (Exception ex) { /* ... */ }
 }

 @AroundInvoke
 protected Object interceptorAroundInvoke(InvocationContext ic) throws Exception {
  return ic.proceed();
 }

 @AroundTimeout
 protected Object interceptorAroundTimeout(InvocationContext ic) throws Exception {
  return ic.proceed();
 }
}
```

Alternatively, you can declare an interceptor method in the deployment descriptor with the around-invoke, around-timeout, post-construct, pre-destroy, pre-passivate, and post-activate elements. Use the following example to declare a business method interceptor, a timeout method interceptor, and a PostConstruct lifecycle interceptor method on an EJB class and an interceptor class using the deployment descriptor.

```
  <enterprise-beans>
    <session>
      <ejb-name>TestBean</ejb-name>
      <around-invoke>
        <method-name>beanAroundInvoke</method-name>
      </around-invoke>
      <around-timeout>
        <method-name>beanAroundTimeout</method-name>
      </around-timeout>
      <post-construct>
        <lifecycle-callback-method>beanPostConstruct</lifecycle-callback-method>
      </post-construct>
    </session>
  </enterprise-beans>

  <interceptors>
    <interceptor>
      <interceptor-class>ClassInterceptor</interceptor-class>
      <around-invoke>
        <method-name>interceptorAroundInvoke</method-name>
      </around-invoke>
      <around-timeout>
        <method-name>interceptorAroundTimeout</method-name>
      </around-timeout>
      <post-construct>
        <lifecycle-callback-method>interceptorPostConstruct</lifecycle-callback-method>
      </post-construct>
    </interceptor>
  </interceptors>
```

```
  <assembly-descriptor>
    <interceptor-binding>
      <ejb-name>TestBean</ejb-name>
      <interceptor-class>ClassInterceptor</interceptor-class>
    </interceptor-binding>
  </assembly-descriptor>
```

You can also declare interceptor methods on super-classes. Use the following example to declare a PostActivate interceptor on a bean super-class using annotations:

```
public class TestBean extends BeanSuperClass { /* ... */ }

public class BeanSuperClass {
 @PostActivate
 private void beanSuperClassPostActivate(InterceptorContext ic) {
  try {
   ic.proceed();
  } catch (Exception ex) { /* ... */ }
 }
}
```

Use the following example to declare the same interceptor method on a superclass of an interceptor class using annotations:

```
public class ClassInterceptor extends InterceptorSuperClass { /* ... */ }

public class InterceptorSuperClass {
 @PostActivate
 private void interceptorSuperClassPostActivate(InterceptorContext ic) {
  try {
   ic.proceed();
  } catch (Exception ex) { /* ... */ }
 }
}
```

You can also declare the same interceptor methods using the deployment descriptor. Use the following example to declare an interceptor method on the superclasses of a bean and interceptor class:

```
<enterprise-beans>
  <session>
    <ejb-name>TestBean</ejb-name>
    <post-activate>
      <class>BeanSuperClass</class>
  <lifecycle-callback-method>beanSuperClassPostActivate</lifecycle-callback-method>
    </post-activate>
  </session>
 </enterprise-beans>

 <interceptors>
   <interceptor>
    <interceptor-class>ClassInterceptor</interceptor-class>
    <post-activate>
      <class>InterceptorSuperClass</class>
  <lifecycle-callback-method>interceptorSuperClassPostActivate</lifecycle-callback-method>
    </post-activate>
   </interceptor>
 </interceptors>

 <assembly-descriptor>
   <interceptor-binding>
     <ejb-name>TestBean</ejb-name>
     <interceptor-class>ClassInterceptor</interceptor-class>
   </interceptor-binding>
 </assembly-descriptor>
```

You can declare default interceptors that apply to all session and message-driven beans in a module. Default interceptors can only be declared in the deployment descriptor, and they are specified using an ejb-name of "*". Use the following example to declare a default interceptor.

```
  <assembly-descriptor>
    <interceptor-binding>
      <ejb-name>*</ejb-name>
      <interceptor-class>DefaultInterceptor</interceptor-class>
    </interceptor-binding>
  </assembly-descriptor>
```

You can exclude default interceptors from a specific class or method by using either the ExcludeDefaultInterceptors annotation or the exclude-default-interceptors element in XML. Use the following examples to exclude default interceptors using the annotation:

```
@ExcludeDefaultInterceptors
public class TestBean { /* ... */ }

public class TestBean2 {
 @ExcludeDefaultInterceptors
 public void businessMethod() { /* ... */ }
}
```

Use the following example to excludes default interceptors using the deployment descriptor:

```
  <assembly-descriptor>
    <interceptor-binding>
      <ejb-name>TestBean</ejb-name>
      <exclude-default-interceptors>true</exclude-default-interceptors>
    </interceptor-binding>

    <interceptor-binding>
      <ejb-name>TestBean2</ejb-name>
      <exclude-default-interceptors>true</exclude-default-interceptors>
      <method>
        <method-name>businessMethod</method-name>
      </method>
    </interceptor-binding>
  </assembly-descriptor>
```

When interceptors are invoked for a method, default interceptor classes are invoked first, class-level interceptors are invoked next, and interceptors methods from the EJB class are invoked last. For a single interceptor class hierarchy, interceptor methods are always invoked on the most general super-class first. The default and class-level interceptor classes are invoked in the order specified in the deployment descriptor or the Interceptors annotation. You can override this ordering by specifying the complete list of default and class-level interceptors in the interceptor-order element in the deployment descriptor.

```
  <assembly-descriptor>
    <interceptor-binding>
      <ejb-name>TestBean</ejb-name>
      <!--
        The default ordering would be:
   1. DefaultInterceptor
   2. ClassInterceptor1
   3. ClassInterceptor2

 The following stanza overrides the default ordering.
      -->
      <interceptor-order>
        <interceptor-class>ClassInterceptor2</interceptor-class>
 <interceptor-class>DefaultInterceptor</interceptor-class>
 <interceptor-class>ClassInterceptor1</interceptor-class>
      </interceptor-order>
    </interceptor-binding>
  </assembly-descriptor>
```

Create stubs command

The createEJBStubs command creates stub classes for remote interfaces of Enterprise JavaBeans (EJB) Version 3.0 beans packaged in Java archive (JAR) or Enterprise archive (EAR) files. It also provides an option to create a single stub class from an interface class located in a directory or a JAR file. Several command options are provided to package the generated stub classes in different ways. See the Syntax and Examples sections later in this topic for more details.

This command is found in the <WAS_HOME>/bin directory as:
- createEJBStubs.bat - Windows platforms
- createEJBStubs.sh - Unix based platforms
- createEjbStubs - iSeries platform

The command searches the input JAR or EAR file, looking for EJB version 3.0 modules that contain beans with remote interfaces. When remote interfaces are found, the corresponding stub classes are generated and packaged according to the command options specified. In the case where the input specified is a single interface class, the tool assumes this class is an EJB version 3.0 remote interface class and generates a remote stub class.

For many client-side scenarios, the WebSphere Application Server Just-In-Time (JIT) deployment feature dynamically generates the RMI-IIOP stub classes that are required for invocation of remote EJB 3.0 business interfaces. However, there are some scenarios where the JIT deploy environment is not available to dynamically generate these classes. In these scenarios, the createEJBStubs command must be used instead to generate and embed the client-side stub class files in your client application. If your client environment is one of the following, use the createEJBStubs command:
- “Bare”Java Standard Edition (SE) clients, where a Java SE Java Virtual Machine (JVM) is the client environment.
- A WebSphere Application Server container (web container, EJB container, or application client container) from a version earlier than version 7, or without the Feature Pack for EJB 3.0 applied.
- Non-WebSphere Application Server environments.

Syntax

createEJBStubs input_ class_ name | input_JAR_name | input_EAR_name [**-help**] [**-newfile [new_file]**] [**-updatefile [update_file]**] [**-quiet**] [**-verbose**] [**-logfile log_file**] [**-appendlog**] [**-cp class_path**] [**-trace**]

createEJBStubs

This is the command to create EJB stub classes for a single interface class file, a JAR file, or an EAR file. When invoked without any arguments, or only –help, the createEJBStubs command displays a list of options that can be specified, and a list of example invocations with detailed explanations.

input_class_name or input_EAR_name or input_JAR_name

The first parameter is a required element for the command. It must contain the source class, JAR, or EAR file to process.

This parameter may be the fully qualified name of a single interface class (e.g. com.ibm.myRemoteInterface). Note that the package name segments are separated by “.” characters, no path name proceeds the class name, and the “.class”extension is not included. For this interface class input, you must use the class path option (e.g. –cp my_path, or –cp my_path/my_interfaces.jar) to specify where the interface class will be found. The generated stub class will be placed in the package-defined directory structure, starting with the current directory where the command is invoked.

This parameter may also be a JAR or EAR file. In this case the path must be specified (e.g. my_path/my_Server_App.ear). The generated stub classes will be placed in the same module or

modules with the beans, or in the same module or modules with the remote interface classes, depending on whether the –updatefile option is specified. Details follow later in this section.

-help Provides the command syntax, including a list of options that can be specified, and example invocations with detailed explanations.

-newfile [new_file]
Requests that a new file is generated containing the original files in the input JAR or EAR plus the stub classes. When this option is not specified, the stubs are written back into the original JAR or EAR file. If this option is specified, but the new_file name is not provided, a new file name is constructed by appending the input JAR or EAR file name with "_withStubs". This option is not allowed when the first input parameter is an interface class.

-updatefile [update_file]
Requests that a second file (e.g. in addition to the input file) is updated with stub classes. This option also provides a different packaging behavior. The stub classes are packaged in the same module or modules as the remote interface classes. By contrast, when this option is not specified, the stub classes are packaged in the same module or modules with the bean classes. If this option is specified, but the update_file name is not provided only the original JAR or EAR file is updated with stub classes. This option is not allowed when the first input parameter is an interface class.

-quiet Requests the suppression of messages. The -quiet option cannot be specified with either the –verbose or the –trace options. Error messages are still displayed.

-verbose
Requests that additional informational messages be output. The -verbose option cannot be specified with either the -quiet or the –trace options.

-logfile log_file
Requests that messages be printed to a log file in addition to the console. If this option is specified, the log_file name must also be provided.

-appendlog
Requests that messages be appended to an existing log file. If this option is specified, the -logfile option must also be specified.

-cp class_path
Requests that the classloader includes the specified the class path where additional class or jar files are located, which are necessary for the remote interface classes to be loaded. The class path may include multiple segments where each path is separated from a previous path by the default path separator character of the operating system. Each path can specify either a JAR file, or a directory. If this option is specified, the class_path name must also be provided.

-trace Request that detailed trace output be generated. This is intended to collect information for use by IBM service to resolve problems. The trace output is English-only. This option cannot be specified with either the –quiet or the –verbose options.

Examples

```
createEJBStubs com.ibm.myRemoteInterface -cp my_path
```

Generate the stub class for one remote interface class and place it in the package-defined directory structure, starting at the current directory. The my_path directory will be used as the class path. If the remote interface class to process is in a JAR file, the –cp my_path/my_interfaces.jar syntax must be used for the class path specification.

```
createEJBStubs my_path/my_beans.jar -newfile –quiet
```

Generate the stub classes for all level 3.0 enterprise beans in the my_beans.jar file that have remote interfaces. Both the generated stub classes and the original JAR file contents are packaged into a new JAR file named “my_beans_withStubs.jar” because the optional new_file name parameter is not specified along with the –newfile option. Output messages are suppressed except for error notifications.

```
createEJBStubs my_path/my_Server_App.ear -logfile myLog.out
```

Generate the stub classes for all level 3.0 enterprise beans in the my_Server_App.ear file that have remote interfaces. The generated stub classes are placed into the original EAR file because the –newfile option is not specified. The stub classes are packaged into the same module or modules as the bean classes because the –updatefile option is not specified. Messages are written to both the myLog.out log file and the command window.

```
createEJBStubs my_path/my_Server_App.ear -updatefile my_path/my_Client_interfaces.jar
```

Generate the stub classes for all level 3.0 enterprise beans in the my_Server_App.ear file that have remote interfaces. The generated stub classes are placed into both the original EAR file and the my_Client_interfaces.jar file. The stub classes are packaged into the same module or modules as the remote interface classes because the –updatefile option is specified.

```
createEJBStubs my_path/my_Server_App.ear –updatefile
```

Generate the stub classes for all level 3.0 enterprise beans in the my_Server_App.ear file that have remote interfaces. The generated stub classes are only placed into the original EAR file because the optional update_file name parameter is not provided with the –updatefile option. The stub classes are packaged into the same module or modules as the remote interface classes because the -updatefile option is specified.

Create stubs command

The createEJBStubs command creates stub classes for remote interfaces of Enterprise JavaBeans (EJB) Version 3.x beans packaged in Java archive (JAR), web application archive (WAR), or enterprise archive (EAR) files. It also provides an option to create a single stub class from an interface class located in a directory or a JAR file. Several command options are provided to package the generated stub classes in different ways. See the following syntax and example sections for more details.

This command is found in the <*WAS_HOME*>/`bin` directory as:
- createEJBStubs.bat - Windows platforms
- createEJBStubs.sh - UNIX based platforms
- createEjbStubs - iSeries platform

The command searches the input JAR, WAR, or EAR file, looking for EJB version 3.x modules that contain beans with remote interfaces. When remote interfaces are found, the corresponding stub classes are generated and packaged according to the command options specified. In the case where the input specified is a single interface class, the tool assumes that this class is an EJB version 3.x remote interface class and generates a remote stub class.

For many client-side scenarios, the WebSphere Application Server Just-In-Time (JIT) deployment feature dynamically generates the RMI-IIOP stub classes that are required for invocation of remote EJB 3.x business interfaces. However, there are some scenarios where the JIT deploy environment is not available to dynamically generate these classes. In these scenarios, the createEJBStubs command must be used instead to generate and embed the client-side stub class files in your client application. If your client environment is one of the following, use the createEJBStubs command:
- "Bare" Java Standard Edition (SE) clients, where a Java SE Java Virtual Machine (JVM) is the client environment.

- A WebSphere Application Server container (web container, EJB container, or application client container) from a version earlier than version 7, or without the Feature Pack for EJB 3.0 applied.
- Non-WebSphere Application Server environments.

The JVM running the createEJBStubs command must have the java.io.tmpdir system property defined. The property must point to a readable and writable directory that exists.

In addition to creating stubs for bean content packaged in EAR and JAR files, the command also creates stubs for bean content that is packaged in a WAR file. If an EAR file is specified as the input file, and that EAR file contains a WAR file with remote interfaces, then stubs are generated for those interfaces.

Stubs are placed into the WAR file in the same location as the remote interface or bean class that they correspond to. If the remote interface or bean class that they correspond to is placed loosely in the WEB-INF/classes directory structure, then the stub is placed there as well. If the remote interface or bean class is packaged inside of a JAR file in the WEB-INF/lib directory, then the stub is inserted into that same JAR file. If a stub is generated for a remote interface that is not packaged inside the WAR file, then it is placed loosely in the WEB-INF/classes directory structure.

The createEJBStubs command is not supported for use with a 2.x or 1.x EJB module packaged inside a stand-alone JAR file. The stubs for a 2.x or 1.x EJB module packaged inside a stand-alone JAR file must be generated using the EJBDeploy tool instead. If the createEJBStubs command is run against a 2.x or 1.x EJB module packaged inside a stand-alone JAR file, then the command issues a CNTR9241I message, and does not generate any stubs.

However, the createEJBStubs command is supported for use with 2.x or 1.x EJB modules packaged inside a WAR file. In this case, the createEJBStubs command must be used instead of the EJBDeploy tool.

A client component uses these stubs to communicate with the EJB components running inside the server. The client component must use stub instances that were created by the correct tool. If the client component is communicating with a 2.x or 1.x EJB module packaged inside a stand-alone JAR, then the stubs must come from the EJBDeploy tool. However, if the client component is communicating with a 2.x or 1.x EJB module packaged inside a WAR, then the stubs must come from the createEJBStubs command. A single stub instance cannot be used to communicate with both a 2.x/1.x EJB module packaged inside a stand-alone JAR, and that same 2.x/1.x EJB module packaged inside a WAR.

Syntax

createEJBStubs*input_ class_ name* | *input_JAR_name* | *input_WAR_name* | *input_EAR_name* [**-help**] [**-newfile[new_file]**] [**-updatefile[update_file]**] [**-quiet**] [**-verbose**] [**-logfile log_file**] [**-appendlog**] [**-cp class_path**] [**-trace**]

createEJBStubs

This is the command to create EJB stub classes for a single interface class file, a JAR file, a WAR file, or an EAR file. When invoked without any arguments, or only –help, the createEJBStubs command displays a list of options that can be specified, and a list of example invocations with detailed explanations.

input_class_name **or** *input_EAR_name* **or** *input_JAR_name* **or** *input_WAR_name*

The first parameter is a required element for the command. It must contain the source class, JAR, WAR, or EAR file to process.

This parameter may be the fully qualified name of a single interface class (e.g. com.ibm.myRemoteInterface). Note that the package name segments are separated by "." characters, no path name proceeds the class name, and the ".class" extension is not included. For this interface class input, you must use the class path option (e.g. –cp my_path, or –cp

my_path/my_interfaces.jar) to specify where the interface class is found. The generated stub class is placed in the package-defined directory structure, starting with the current directory where the command is invoked.

This parameter may also be a JAR, WAR, or EAR file. In this case the path must be specified (e.g. my_path/my_Server_App.ear). The generated stub classes are placed in the same module or modules with the beans, or in the same module or modules with the remote interface classes, depending on whether the –updatefile option is specified. See the following sections for more details.

-help Provides the command syntax, including a list of options that can be specified, and example invocations with detailed explanations.

-newfile [new_file]
Requests that a new file is generated containing the original files in the input JAR, WAR, or EAR plus the stub classes. When this option is not specified, the stubs are written back into the original JAR, WAR, or EAR file. If this option is specified, but the new_file name is not provided, a new file name is constructed by appending the input JAR, WAR, or EAR file name with "_withStubs". This option is not allowed when the first input parameter is an interface class.

-updatefile [update_file]
Requests that a second file (e.g. in addition to the input file) is updated with stub classes. This option also provides a different packaging behavior. The stub classes are packaged in the same module or modules as the remote interface classes. By contrast, when this option is not specified, the stub classes are packaged in the same module or modules with the bean classes. If this option is specified, but the update_file name is not provided only the original JAR, WAR, or EAR file is updated with stub classes. This option is not allowed when the first input parameter is an interface class.

-quiet Requests the suppression of messages. The -quiet option cannot be specified with either the –verbose or the –trace options. Error messages are still displayed.

-verbose
Requests that additional informational messages be output. The -verbose option cannot be specified with either the -quiet or the –trace options.

-logfile log_file
Requests that messages be printed to a log file in addition to the console. If this option is specified, the log_file name must also be provided.

-appendlog
Requests that messages be appended to an existing log file. If this option is specified, the -logfile option must also be specified.

-cp class_path
Requests that the class loader includes the specified the class path where additional class or jar files are located, which are necessary for the remote interface classes to be loaded. The class path might include multiple segments where each path is separated from a previous path by the default path separator character of the operating system. Each path can specify either a JAR file, or a directory. If this option is specified, the class_path name must also be provided.

-trace Request that detailed trace output be generated. This is intended to collect information for use by IBM service to resolve problems. The trace output is English-only. This option cannot be specified with either the –quiet or the –verbose options.

Examples

createEJBStubs com.ibm.myRemoteInterface -cp my_path

Generate the stub class for one remote interface class and place it in the package-defined directory structure, starting at the current directory. The my_path directory is used as the class path. If the remote interface class to process is in a JAR file, the –cp my_path/my_interfaces.jar syntax must be used for the class path specification.

createEJBStubs my_path/my_beans.jar -newfile –quiet

Generate the stub classes for all level 3.0 enterprise beans in the my_beans.jar file that have remote interfaces. Both the generated stub classes and the original JAR file contents are packaged into a new JAR file named “my_beans_withStubs.jar” because the optional new_file name parameter is not specified along with the –newfile option. Output messages are suppressed except for error notifications.

createEJBStubs my_path/my_Server_App.ear -logfile myLog.out

Generate the stub classes for all level 3.0 enterprise beans in the my_Server_App.ear file that have remote interfaces. The generated stub classes are placed into the original EAR file because the –newfile option is not specified. The stub classes are packaged into the same module or modules as the bean classes because the –updatefile option is not specified. Messages are written to both the myLog.out log file and the command window.

createEJBStubs my_path/my_Server_App.ear -updatefile my_path/my_Client_interfaces.jar

Generate the stub classes for all level 3.0 enterprise beans in the my_Server_App.ear file that have remote interfaces. The generated stub classes are placed into both the original EAR file and the my_Client_interfaces.jar file. The stub classes are packaged into the same module or modules as the remote interface classes because the –updatefile option is specified.

createEJBStubs my_path/my_Server_App.ear –updatefile

Generate the stub classes for all level 3.0 enterprise beans in the my_Server_App.ear file that have remote interfaces. The generated stub classes are only placed into the original EAR file because the optional update_file name parameter is not provided with the –updatefile option. The stub classes are packaged into the same module or modules as the remote interface classes because the -updatefile option is specified.

createEJBStubs my_path/my_beans.war

Generate the stub classes for all 3.x beans that are packaged in the WAR file and have remote interfaces. The Bean1 class is packaged loosely inside the WEB-INF/classes directory structure, and therefore, the corresponding stub is placed there as well. Likewise, the Bean2 class is packaged inside of the myEJB.jar file in the WEB-INF/lib directory, and therefore, the corresponding stub is inserted into that JAR file.

Developing entity beans

Defining data sources for entity beans

An application that is installed on an application server must have bindings defined before you can start the application. The Enterprise JavaBeans (EJB) references and resource references that are defined in the application must be bound to the actual enterprise beans or resources that are defined in the application server.

Before you begin

Create a data source or JDBC resource and give it a Java Naming and Directory Interface (JNDI) name.

About this task

For more information, see the topic Application bindings.

Before you do this task, it is assumed that the entity beans in your application are container-managed persistence (CMP) enterprise beans.

Note:
The EJB container handles the persistence of the bean attributes in the underlying persistent store. Specify which data store is used by binding an EJB module or individual EJB to a data source.

If you bind an EJB *module* to a data source, all beans in that module use the same data source for persistence. If you specify the data source at the bean level, then that data source is used instead.

See the assembly tool information center for the steps on how to complete this task.

Lightweight local operational mode for entity beans

WebSphere Application Server provides a special operational mode called *lightweight local* mode, which can improve the performance of entity bean methods. You can decide which entity beans in your application to run in this mode.

In lightweight local mode, the container streamlines the processing that it performs before and after every method on the local home interface and local business interface of the bean. This streamlining can result in improved performance when entity bean operations are called locally from within an application. Because some processing is skipped when running in lightweight local mode, this mode can be used in certain scenarios only.

Lightweight local mode is patterned somewhat after the Plain Old Java Object (POJO) entity model introduced in the Enterprise JavaBeans (EJB) 3.0 specification. Using lightweight local mode, you can obtain some of the performance advantages of the POJO entity model without having to convert your existing EJB 2.x application code to the new POJO model. You can apply lightweight local mode to both container-managed persistence (CMP) and bean-managed persistence (BMP) entity types that meet the specific criteria.

Attention: Entity beans are not supported in EJB 3.x modules.

When to use the lightweight local mode

Lightweight local mode is designed for entity beans that are created, found, and called using the *Session Facade* pattern. Under this pattern, entity bean local home and local business methods are called from within methods of a stateless session bean or stateful session bean. The session bean methods, which can be called remotely or locally, provide security control and transaction demarcation for the entity beans that are accessed by the session bean.

You can apply lightweight local mode only to an entity bean that meets the following criteria:
- The bean implements an EJB local interface.
- No security authorization is defined on the entity bean local home or local business interface methods.
- No *run-as* security attribute is defined on the local home or local business methods.
- The classes for the calling bean and the called entity bean are loaded by the same Java class loader.
- The entity bean methods do not call the WebSphere Application Server-specific Internationalization Service or Work Area Service.

The first criterion prevents CMP 1.x beans from supporting lightweight local mode, because the 1.x beans cannot have local interfaces.

In addition, lightweight local mode provides its fullest performance benefits only to entity bean methods that do not need to start a global transaction. This condition is true if you ensure that your entity bean also meets the following criteria:
- A global transaction is already in effect when the entity bean home or business method is called. Typically, this transaction is started by the calling session bean.
- The local business interface methods and the local home methods of the entity bean use the following transaction attributes only: REQUIRED, SUPPORTS, or MANDATORY.

If an entity bean method that is running in lightweight local mode must start a global transaction, the bean still functions normally but only a partial performance benefit is realized.

You can mark an entity bean that defines a remote interface or a TimedObject interface, in addition to the local interface, for lightweight local mode. However, the performance benefit is apparent only when the bean is called through its local interface.

Applying lightweight local mode to an entity bean

WebSphere Application Server provides a special operation mode called *lightweight local* mode, which can improve the performance of entity bean methods. You can decide which entity beans in your application to run in this mode.

About this task

You can apply lightweight local mode to specific EntityBean types within your application with the Marker interface technique.

Marker interface technique

About this task

Use the marker interface technique when a group of beans within the application is related through a common inheritance hierarchy, and all the beans in the hierarchy are to be marked. For an application with a large number of beans in a hierarchy, this technique is the most efficient.

To use a marker interface, code your bean implementation class to implement the **com.ibm.websphere.ejbcontainer.LightweightLocal** interface. The bean implementation class does not need to directly implement the interface; any parent class or interface can also implement it. For details, see the **com.ibm.websphere.ejbcontainer** package in the API section of the information center.

Developing read-only entity beans

In addition to the existing Enterprise JavaBeans (EJB) caching options, you can develop read-only entity beans.

About this task

You are most likely to want to use it under the following conditions:
- Your application uses data that change relatively infrequently. An example might be a retailing application that uses pricing data that only changes once a week or month.
- Your application can tolerate data that might be stale. The degree of *staleness* allowed by the EJB container is configurable by the user.
- The bean is coded in a thread-safe manner, so it can safely be invoked by multiple threads at once.

To use this function, declare the bean type as *read-only*. Declaring a bean type is done the same way that bean caching options are selected - through a selection list within an assembly tool.

To complete this task see the topic, Defining bean cache settings for a bean in the assembly tool information center.

Example: Using a read-only entity bean

A usage scenario and example for writing an Enterprise JavaBeans (EJB) application that uses a read-only entity bean.

Usage scenario

A customer has a database of catalog pricing and shipping rate information that is updated daily no later than 10:00 PM local time (22:00 in 24-hour format). They want to write an EJB application that has read-only access to this data. That is, this application never updates the pricing database. Updating is done through some other application.

Example

The customer's entity bean local interface might be:

```
public interface ItemCatalogData extends EJBLocalObject {

  public int getItemPrice();

  public int getShippingCost(int destinationCode);

}
```

The code in the stateless SessionBean method (assume it is a TxRequired) that invokes this EntityBean to figure out the total cost including shipping, would look like:

```
.....
// Some transactional steps occur prior to this point, such as removing the item from
 // inventory, etc.
 // Now obtain the price of this item and start to calculate the total cost to the purchaser

 ItemCatalogData theItemData =
    (ItemCatalogData) ItemCatalogDataHome.findByPrimaryKey(theCatalogNumber);

int totalcost = theItemData.getItemPrice();

// ...     some other processing, etc. in the interim
// ...
// ...

// Add the shipping costs
totalcost = totalcost + theItemData.getShippingCost(theDestinationPostalCode);
```

At application assembly time, the customer sets the EJB caching parameters for this bean as follows:

- ActivateAt = ONCE
- LoadAt = DAILY
- ReloadInterval = 2200

Note: The reloadInterval and reloadingEnabled attributes of the IBM deployment descriptor extensions, including both the WAR file extension (WEB-INF/ibm-web-ext.xmi) and the application extension (META-INF/ibm-application-ext.xmi) were deprecated.

On the first call to the getItemPrice() method after 22:00 each night, the EJB container reloads the pricing information from the database. If the clock strikes 22:00 between the call to getItemPrice() and getShippingCost(), the getShippingCost() method still returns the value it had prior to any changes to the database that might have occurred at 22:00, since the first method invocation in this transaction occurred prior to 22:00. Thus, the item price and shipping cost used remain in sync with each other.

Creating timers using the EJB timer service for enterprise beans

You can use enterprise beans to take advantage of the EJB timer service to schedule time-based events.

About this task

In support of the EJB 3.1 specification, you can create non-persistent EJB timers. This product also supports the expanded TimerService API for programmatic timer creation. In addition, you can configure the EJB container to automatically create a timer when the application starts.

WebSphere Application Server implements the Enterprise JavaBeans(EJB) timer service. Based on your business needs, you can use persistent timers or non-persistent timers. Persistent timers are helpful if you are creating a timer for a time-based event that requires assurance of timer existence beyond the life cycle of the server. Previously started persistent timers automatically start when your server starts and persist through server shutdowns and restarts. For example, you can use persistent timers to start a system application or send a status notification on the expiration of a timer. Non-persistent timers are helpful in non-critical situations where the timer actions are skipped or redone without negative business impacts, such as polling a temperature.

You can create timers programmatically. You can also create timers automatically by using the @Schedule annotation in the bean class, or by using the timer element in the ejb-jar.xml deployment descriptor. By automatically creating timers, you can schedule a timer without relying on your enterprise bean invocation to programmatically start an EJB timer service creation method.

Persistent timers

Persistent timers are implemented as a scheduler service task. By default, an internal or pre-configured scheduler instance is used to manage those tasks, and they persist in an Apache Derby database associated with the server process.

You can perform basic customizations to the internal scheduler instance. For information about customizing the scheduler instance, see the configuring a timer service information.

The creation and cancellation of Timers is transactional and persistent. If a Timer is created within a transaction and that transaction is later rolled back, the creation of the Timer is rolled back as well. Similar rules apply to the cancellation of a Timer. Previously started Timers are maintained across application server shutdowns and restarts.

Non-persistent timers

EJB 3.1 augments the EJB timer service to enable non-persistent EJB timers in addition to the persistent timers. Non-persistent timers have many of the same semantics and behavior as persistent timers, but without the overhead of a data store. Non-persistent timers have a different life cycle than persistent timers. Where persistent timers are maintained across application server shutdowns and restarts, non-persistent timers are active only while the application server is active. Unlike persistent timers, there are no commands to find or cancel non-persistent timers. Non-persistent timers are canceled when the application server is stopped or fails to remain in an active state.

As with persistent timers, the creation and cancellation of non-persistent timers is transactional. If a timer is created within a transaction and that transaction is later rolled back, the creation of the timer is rolled back as well. Similar rules apply to the cancellation of a timer.

You can configure non-persistent timers to share a thread pool with persistent timers, or to have a unique thread pool that is not shared with persistent timers.

Programmatically created timers

A programmatically created persistent timer is maintained across application server shutdowns and restarts, unless it is canceled. It is the responsibility of application code or system administrator to delete a programmatically created timer which is no longer wanted.

To programmatically create a timer that is associated with your enterprise bean, the bean calls the getTimerService() method on the applicable context instance to get a reference to the TimerService object. The bean also calls one of the TimerService methods, such as createTimer,

to specify the timer for the bean. This Timer instance is now associated with your bean. The TimerService methods are described in the EJB 3.1 specification. You can now pass the Timer instance to other Java code as a local object. After the Java code obtains the Timer instance, the code can use any of the methods defined by the javax.ejb.Timer interface, such as the cancel() or getTimeRemaining() methods.

In a clustered environment, a programmatically created persistent timer can run in any cluster member, but a programmatically created non-persistent timer runs only in the same JVM in which it was created.

Automatically created timers

The EJB 3.1 specification augments the EJB timer service to enable the automatic creation of a timer when your application starts without relying on a bean invocation to programmatically start one of the timer service timer creation methods. Use the @Schedule annotation or the timeout-method deployment descriptor element to automatically create timers. Automatically created timers are created by the container as a result of application deployment.

Note: The CancelEJBTimers command also cancels automatically created timers. When automatically created timers are canceled, the only way to recreate them is to uninstall the application and reinstall it again.

Timers in a clustered environment

In a clustered environment, a persistent timer runs only in one cluster member which might not necessarily be the same cluster member it was created in. A non-persistent timer runs in each cluster member that it was created in - automatic non-persistent timers run in each cluster member that contains the EJB.

Automatic persistent timers are removed from their persistent store when their containing module or application is uninstalled. Therefore, do not update applications that use automatic persistent timers with the Rollout Update feature. Doing so uninstalls and reinstalls the application while the cluster is still operational, which might cause failure in the following cases:

- If a timer running in another cluster member activates after the database entry is removed and before the database entry is recreated, then the timer fails. In this case, a com.ibm.websphere.scheduler.TaskPending exception is written to the First Failure Data Capture (FFDC), along with the SCHD0057W message, indicating that the task information in the database has been changed or canceled.
- If the timer activates on a cluster member that has not been updated after the timer data in the database has been updated, then the timer might fail or cause other failures if the new timer information is not compatible with the old application code still running in the cluster member.

When you use the proxy server in the product, do not define a scheduler at the cell level if that scheduler is configured as the one to use for the EJB timer service. Doing so prevents persistent timers from running. This can happen if the proxy server gets the scheduler lease. Since no applications run in the proxy server, there is no application code to handle the timer events that are sent by the scheduler.

Retries and missed timeouts

If you use EJB timers, you must understand the concepts of failure, retry, and missed timeouts.

- A failure is a timeout execution that is attempted, but does not succeed.
- A retry is an additional attempt to successfully execute a timeout that was previously attempted, but failed.
- A missed execution is a timeout that must have been attempted, but was not, because the server was unavailable or busy retrying a previously failed timeout.

The retry behavior reflects:

- Number of additional times that the server retries the failed timeout

- Interval between these server retries

The missed timeout behavior reflects:

- Whether the server eventually attempts missed timeouts, or not
- If missed timeouts are eventually attempted, when those attempts occur
- Interval between the missed timeout attempts

Table 48. Retry and missed timeout behavior. Retry and missed timeout behavior for both persistent and non-persistent timers.

Characteristic	Default behavior	Configurable
Number of retry attempts	As many as it takes to succeed. Persistent timers are temporarily deactivated if their scheduler failure threshold is reached in a server. For more information, see the topic about stopping tasks that are failing.	Yes, for non-persistent timers
Interval between retry attempts	First retry attempt is immediate. Subsequent retry attempts occur on the configured scheduler poll interval for persistent timers, and on the configured retry interval for non-persistent timers.	Yes
Missed timeout recovery	All missed timeouts are recovered.	No
When missed timeouts are recovered	Both persistent and non-persistent timers recover missed timeouts when the blocking retry attempts stop. Additionally, persistent timers recover timeouts when an unavailable server restarts.	No
Next timeout, after retry attempts are successful and missed timeouts are recovered	At the next originally scheduled time.	No

The configurable characteristics are configured on the scheduler instance for persistent timers and on the non-persistent timer configuration for non-persistent timers.

The following scenarios illustrate how the retry and missed timeout behavior influences the timeouts for both persistent and non-persistent timers.

Persistent timer scenario:

A persistent timer is created and configured to run for the first time at 10:00 am, and then run every hour after that. The scheduler supporting the timer is configured with a 30 second poll interval.

The timer runs at 10:00 am and fails because a database is unavailable. The timer is immediately retried, and retried again every 30 seconds when the scheduler is polled, and keeps failing, until 12:30 pm. At that moment, a retry attempt succeeds because the database is now back online, and therefore the server stops retrying the previously failed attempt.

Now, the server begins to work through the missed timeouts. First, it attempts the timeout that must have run at 11:00 am, which succeeds at 12:31 pm. When the scheduler is polled again 30 seconds later, it attempts the timeout that must have run at 12:00 pm, which succeeds at 12:32 pm. The server is now current, and the next timeout occurs at its originally scheduled time of 1:00 pm, as opposed to an hour after the last success, which would have been 1:32 pm. Going forward, the original schedule is maintained. The schedule is not updated based on the time of the last successful timeout.

Non-persistent timer scenario:

A non-persistent timer is created and configured to run for the first time at 10:00 am, and then run every hour after that. This non-persistent timer is configured to have a retry count of 5, and a retry interval of 30 minutes.

The timer runs at 10:00 am and fails because a database is not available. The timer is immediately retried, and fails again. Now, having executed the initial immediate retry, the server waits for the configured retry interval of 30 minutes between the next retry attempt. Retry attempts occur at 10:30 am and 11:00 am, and both fail. Finally, the fourth retry occurs at 11:30 am, and succeeds because the database is now back online.

Now, the server begins to work through the missed timeouts. The timeout that was originally scheduled for 11:00 am is immediately run, and succeeds at 11:31 am. The server is now current, and the next timeout occurs at its originally scheduled time of 12:00 pm (as opposed to an hour after the last success, which would be 12:32 pm).

Behavior of the getNextTimeout and getTimeRemaining methods

For both persistent and non-persistent timers, the Timer.getNextTimeout method returns a java.util.Date object that indicates the next time the timer is scheduled to execute. When you call the getNextTimeout method from a timeout callback method for an interval or calendar-based timer, the method returns the next scheduled time; for calendar-based timers with no future timeouts, the method throws the NoMoreTimeoutsException exception as required by the EJB 3.1 specification. When you call the getNextTimeout method from a timeout callback method for a single-action timer, the method returns the originally scheduled time. If a timeout callback method fails and retries are being attempted, the getNextTimeout method continues to return the originally scheduled time as if the failed execution had not occurred. In all cases, the Timer.getTimeRemaining method returns the difference in milliseconds between the getNextTimeout returned value and the current system time, which could result in a negative number, if the scheduled execution time was in the past.

Inheritance behavior of automatically created timers

Automatic timer methods in a hierarchy of bean classes cause multiple timers to be created. The number of timers associated with a timer method is not determined by the number of occurrences of the method in the source code. Instead, the number of timers associated with a timer method is determined by the number of beans with visibility to that method. For example:

```
@Stateless
public class Abean {

   @Schedule(hour="1")
   public void timerMethod1()

@Stateless
public class Bbean extends Abean {

   @Schedule(hour="2")
   public void timerMethod2()

@Stateless
public class Cbean extends Bbean {

   @Schedule(hour="2")
   public void timerMethod2()
```

In the previous bean class hierarchy, three automatic timers with callback method Abean.timerMethod1 are created, one for each bean instance with visibility to that method. One timer with callback method Bbean.timerMethod2 is created, and since that method is overridden by bean Cbean, only one timer with callback method Cbean.timerMethod2 is created.

In the previous example, when bean Abean is processed by the container, a single automatic timer is created, with callback method Abean.timerMethod1.

When the bean Bbean is processed by the container, an automatic timer is created with callback method Bbean.timerMethod2, and another automatic timer is created with callback method Abean.timerMethod1.

When the bean Cbean is processed by the container, an automatic timer is created with callback method CBean.timerMethod2. Another automatic timer is created with callback method Abean.timerMethod1. A timer for Bbean.timerMethod2 is not created when processing the bean Cbean. Bbean.timerMethod2 is not visible in the class hierarchy of Cbean because it is overridden by method Cbean.timerMethod2.

Consider another example like the previous one, if the @Stateless annotation were removed from classes Abean and Bbean, so that class Cbean is the only EJB. In that case, the only automatic timers created would be those visible to Cbean - one with callback method Abean.timerMethod1, one with callback method Cbean.timerMethod2.

Although beans can share identical code in an inherited bean callback method, the runtime behavior might be polymorphic. For example:

```
public class Employee {

   @Schedule(hour="1", dayOfMonth="-1", info = "payroll timer")
   public void getSalaryIncrease() {
      printChecks(salary * rate());
   }

   protected float rate() {
      return (float)1.01;
   }

}

public class Manager extends Employee {

   protected float rate() {
      return (float)1.15;
   }

}

public class Executive extends Manager {

   protected float rate() {
      return (float)1.30;
   }

}
```

In the previous example, each bean instance has an automatic timer with callback method getSalaryIncrease(). Although the same callback code is shared by each timer, note that the rate used in calculating the salary increase by each bean is different, due to polymorphism. That is, timer callback methods might be polymorphic in the same way that any Java methods might be.

Procedure

- To create timers programmatically, define the timeout method using the @Timeout annotation, the timeout-method deployment descriptor element, or by implementing the javax.ejb.TimedObject interface.

  A bean can have at most one timeout method for timers that are created programmatically. The timeout method is identified by the @Timeout annotation in the source code, or by the timeout-method deployment descriptor element contained in the ejb-jar.xml file. The timeout method must accept no parameters or a single parameter of type javax.ejb.Timer.

– Define the timeout method by using the @Timeout annotation to create timers programmatically. The following code is an example of using the @Timeout annotation within the MyBeanImpl class:

```
class MyBeanImpl implements MyBean{
@Timeout
void myTimeOutMethod()
```

– Define the timeout method by using the timeout method deployment descriptor element.

You can write your enterprise bean to implement the javax.ejb.TimedObject interface, including the ejbTimeout() method. If the bean implements the TimedObject interface, there is no need to annotate a timeout method, and it is not valid unless that method is the ejbTimeout() method.

The following code snippet illustrates using the timeout method deployment descriptor element within the `ejb-jar.xml` file:

```
<timeout-method>
<method-name>myTimeoutMethod</method-name>
<method-params>
<method-param>javax.ejb.Timer</method-param>
</method-params>
</timeout-method>
```

In this case, the container starts the myTimeoutMethod method on a bean instance when a timer for that instance has expired. The instance is notified by the myTimeoutMethod method of the defined time-based event so the instance can run the associated business logic, based on the timer expiration notification.

Now, you can pass the timer instance to other Java code as a local object. After the Java code obtains the timer instance, the code can use any of the methods defined by the javax.ejb.Timer interface, such as the cancel() or getTimeRemaining() methods.

Note: ForWebSphereApplication Server Version 6, no assembly tool supports the EJB timedObject object. To set the ejbTimeout method transaction attribute, you must manually enter the attributes in the deployment descriptor.

– Define the timeout method by using the javax.ejb.TimedObject interface.

- Write your enterprise bean to implement the javax.ejb.TimedObject interface, including the ejbTimeout() method. The bean calls the EJBContext.getTimerService() method to get an instance of the TimerService object. The bean calls the TimerService method to create a timer. This Timer is now associated with that bean.
- After you create the timer, you can pass the timer instance to other Java code as a local object.

The ejbTimeout method can contain any code that is typically placed in a business method of the bean. Method-level attributes such as *transaction* or *runAs* can be associated with this method by the application assembler. An instance of the timer that causes the method to run is passed in as an argument to ejbTimeout method. The following code snippet illustrates using the javax.ejb.TimedObject interface:

```
import javax.ejb.Timer;
import javax.ejb.TimedObject;
import javax.ejb.TimerService;

public class MyBean implements EntityBean, TimedObject {

  // This method is called by the container when the timer expires.
  public void ejbTimeout(Timer theTimer) {

    //You can place code that is typically placed in an EJB method.

     String whyWasICalled = (String) theTimer.getInfo():
     System.out.println("I was called because of"+ whyWasICalled);
  } // end of method ejbTimeout
```

A timer is created that starts the ejbTimeout method in 30 seconds. A simple string object is passed in at timer creation to identify the timer; for example:

```
// Instance variable to hold the EJB context.
private EntityContext theEJBContext;

// This method is called by the EJB container upon bean creation.
public void setEntityContext(EntityContext theContext) {

// Save the entity context passed in upon bean creation.
  theEJBContext = theContext;

}

// This business method causes the ejbTimeout method to begin in 30 seconds.
public void fireInThirtySeconds() throws EJBException  {

  TimerService theTimerService = theEJBContext.getTimerService();
  String aLabel = "30SecondTimeout";
  Timer theTimer = theTimerService.createTimer(30000, aLabel);

} // end of method fireInThirtySeconds

} // end of class MyBean
```

Note: The EJB 3.x programming model provides additional strategic ways to define persistent and non-persistent timers within your business environments. Although defining persistent timers using the ejbTimeout method with the TimedObject interface is still supported, take advantage of the easy-to-implement EJB annotations to create persistent and non-persistent timers to meet your business needs.

- Determine whether your timer must be single-action, interval, or calendar-based.
  - A single-action timer is scheduled to run once on a specific date or after a specified duration. To specify a single-action timer, use the TimerService.createSingleActionTime or TimerService.createTimer(Date, Serializable) APIs.
  - An interval timer is scheduled to begin on a specific date or after a specified duration and continues to run at a fixed rate until it is canceled. To specify an interval timer, use the TimerService.createIntervalTimer, TimerService.createTimer(long, long, Serializable), or TimerService.createTimer(Date, long, Serializable) APIs.
  - A calendar-based timer is scheduled to run at specific dates and times. To specify a calendar-based timer, either use an automatically created timer or use the TimerService.createCalendarTimer APIs, which accept a javax.ejb.ScheduleExpression argument.

    Note: When the EJB container stores a serialized calendar-based timer in the database, the serialized format is incompatible with the format used in WebSphere Application Server Version 7 and lower. If you use calendar-based timers, you must not configure the scheduler for the EJB container to use database tables that are shared with an older version of WebSphere Application Server.

    When using the TimerService.createCalendarTimer API, several attributes are specified to form an expression like the *cron* job scheduling daemon. The first set of attributes is used to control how date calculations are performed:

Table 49. Attributes that control how dates are calculated.. Attributes that control how dates are calculated

Attribute	Description
start	Specifies a date value that is the inclusive starting point for calculating timeouts. The default value is null, which means the timer can start at any time.
end	Specifies a date value that is the inclusive ending point for calculating timeouts. The default value is null, which means the timer continues to run indefinitely.

Table 49. Attributes that control how dates are calculated. (continued). Attributes that control how dates are calculated

Attribute	Description
timezone	Specifies a valid time zone according to the java.util.TimeZone API. The default value is null, which corresponds to the default time zone of the host server.

The second set of attributes determines when the timer runs. All attributes have a set of allowable values in addition to a special wild-card value *, which represents all possible values for that attribute.

Table 50. Attributes that determine when the timer runs.. Attributes that determine when the timer runs

Attribute	Description
second	Specifies an integer in the range 0 to 59; default 0.
minute	Specifies an integer in the range 0 to 59; default 0.
hour	Specifies an integer in the range 0 to 23; default 0.
dayOfMonth	Specifies an integer in the range 1 to 31; default *. Alternatively, the value can be: • The keyword **Last**, which corresponds to the last day of the month. • An integer in the range -1 to -7, which corresponds to a day before the last day of the month. For example, in a month with 31 days, the value -3 would correspond to the 28 day of the month. • The keyword **1st**, **2nd**, **3rd**, **4th**, **5th**, or **Last** followed by a day of the week keyword **Sun**, **Mon**, **Tue**, **Wed**, **Thu**, **Fri**, or **Sat**. For example, you might use **3rd Sun** and **Last Wed**. You must use the abbreviated English ordinals and keywords.
dayOfWeek	Specifies an integer in the range 0 to 7; default *. These values correspond to the keywords **Sun**, **Mon**, **Tue**, **Wed**, **Thu**, **Fri**, and **Sat**, which can be used instead. The values 0 and 7 both correspond to the keyword **Sun**. When both dayOfMonth and dayOfWeek are a value other than *, only one of the attributes needs to match a given day.
month	Specifies an integer in the range 1 to 12; default *. These values correspond to the keywords **Jan**, **Feb**, **Mar**, **Apr**, **May**, **Jun**, **Jul**, **Aug**, **Sep**, **Oct**, **Nov**, and **Dec**, which can be used instead.
year	Specifies any four-digit calendar year; default *.

You can specify each of these attributes using an **x-y** range notation. For example, **0-3** is a valid range for the hour attribute and **Jun-Aug** is a valid range for the month attribute. Additionally, the second, minute, and hour attributes can be specified using an **x/y** increment notation. For example, **30/10** is a valid increment for the minute attribute, which includes the values 30, 40, and 50.

All attributes can also be specified as comma-delimited lists of single values or ranges of values. For example, the value **4,10-12** is valid for the hour attribute, and it corresponds to the times 4 AM, 10 AM, 11 AM, and 12 PM.

The following example uses the America/New_York time zone value for its calendar operations. The timer runs on the last Friday of the months January, February, March, and June. On those days, it runs every two hours starting at 1:30 AM:

```
TimerService theTimerService = theEJBContext.getTimerService();
Timer theTimer = theTimerService.createCalendarTimer(new ScheduleExpression()
 .timezone("America/New_York")
 .month("Jan-Mar, Jun")
 .dayOfMonth("Last Fri")
 .hour("1/2")
 .minute(30))
```

- To create timers automatically, define the timeout callback method using the @Schedule or @Schedules annotation or using the timer deployment descriptor element. Use annotations to write metadata for EJBs inside your source code. For more details, see the information about EJB 3.x metadata annotations.

A bean can have multiple timeout callback methods for timers that are created automatically. The timeout callback method and automatic timers are identified by the @Schedule or @Schedules annotation in the source code or by using the timer deployment descriptor element in the ejb-jar.xml file. If you specify both annotations for the same method or if you specify an annotation and the timer deployment descriptor element for the same method, the metadata is combined and multiple automatic timers are created. The timeout callback methods must have a void return type and must accept either no parameters or a single parameter of type javax.ejb.Timer. All automatic timers are calendar-based. See information about scheduling calendar-based timers for additional information.

The server creates automatic timers when the application starts for the first time. Subsequent application start operations detect that timers have already been created for this application, and the timers are not recreated even if they were subsequently canceled. For persistent automatic timers, the server stores this data in the scheduler tables. If your application is installed on a server cluster, then you must configure the EJB container on each server to use a shared cluster-scoped scheduler. If your application is installed on independent servers, then you must ensure that each server is configured with a unique database or unique database table prefix. See information about clustered environment considerations for timer service.

The application server automatically removes persistent automatic timers from the database when you uninstall the application while the server is running. If the application server is not running, you must manually delete the automatic timers from the database. Additionally, if you add, remove, or change the metadata for automatic timers while the server is not running, you must manually delete the automatic timers.

– Define the automatic timer by using the @Schedule annotation. The following example uses @Schedule annotation:

```
class MyBeanImpl implements MyBean {
    @Schedule(hour="20", info="single timer", persistent=false)
    public void automatic(Timer t) {
        // ...
    }
}
```

The @Schedule annotation has second, minute, hour, dayOfMonth, dayOfWeek, month, year, and timezone elements that correspond to the same attributes of javax.ejb.ScheduleExpression. The annotation also has a persistent element that you can use to specify whether the server uses the EJB timer service scheduler to persist the timer. By default, automatic timers are persistent. Finally, the annotation also has an info element that you can use to specify application information that is delivered as a java.lang.String object with the javax.ejb.Timer object when the timeout callback method runs.

– Define multiple automatic timers for the same method by using the @Schedules annotation. The following example uses the @Schedules annotation:

```
class MyBeanImpl implements MyBean {
    @Schedules(
        @Schedule(hour="1" info="1AM timer", persistent=false),
        @Schedule(minute="0/30" info="30 minute timer")
    )
    public void automaticMultiple(Timer t) {
        // ...
    }
}
```

– Define timers using the deployment descriptor element. You can use the following subelements of the timer element:

Table 51. Subelements of the timer element. Subelements of the timer element

Element	Required or Optional	Description
schedule	Required	Includes optional second, minute, hour, day-of-month, day-of-week, month, and year subelements that correspond to the same attributes of javax.ejb.ScheduleExpression.

Table 51. Subelements of the timer element (continued). Subelements of the timer element

Element	Required or Optional	Description
start and end	Optional	Specify the inclusive starting and ending points for calculating timeouts.
timeout-method	Required	Specifies the timeout callback method.
persistent	Optional	Specifies whether the server uses the EJB timer service scheduler to persist the timer. By default, automatic timers are persistent.
timezone	Optional	Corresponds to the same attribute of javax.ejb.ScheduleExpression.
info	Optional	Specifies application information that is delivered as a java.lang.String object with the javax.ejb.Timer object when the timeout callback method runs.

The following example uses the timer deployment descriptor element:

```
<session>
  <ejb-name>MyBeanImpl</ejb-name>
  <timer>
    <schedule>
      <hour>20</hour>
    </schedule>
    <start>2000-01-01T13:00:00</start>
    <timeout-method>
      <method-name>automatic</method-name>
    </timeout-method>
    <persistent>false</persistent>
    <timezone>America/New_York</timezone>
    <info>single timer</info>
  </timer>
</session>
```

- Determine whether your timer is persistent or non-persistent.
  - Create a persistent timer.
  - Create a non-persistent timer.
- Deploy your EJB application. After you deploy your EJB application, the enterprise bean must run so that the createTimer methods are called before the timer is created programmatically. If the timer is automatically created, the timer starts when the EJB application is started.

Results

You have programmatically or automatically configured an EJB timer that is either persistent or non-persistent.

Clustered environment considerations for timer service

In a single server environment, it is clear which server instance should invoke the timeout method of the bean on a given bean. In a multi-server clustered environment there are other considerations governing the behavior.

WebSphere Application Server implements the Enterprise JavaBeans (EJB) Timer Service. Based on your business needs, you can use persistent timers or non-persistent timers. Persistent timers are helpful if you are creating a timer for a time-based event that requires assurance of timer existence beyond the life cycle of the server to survive server shutdowns and restarts. Previously started persistent timers automatically start when your server starts and they require a database instance. Non-persistent timers do not use a data store and are canceled when the application server is stopped or fails to remain in an active state. Non-persistent timers exist only on the server where they are created. In a clustered environment, if your EJB application automatically creates a non-persistent timer and this application is mirrored on multiple servers, each server has its own non-persistent timer that runs within that server environment. A programmatically created non-persistent timer only runs in the cluster member that it was created in.

When configuring a persistent timer in a multi-server clustered server environment, consider the following possibilities for the server instance to invoke the timeout method on a given bean:

- Separate timer service database per server process or cluster member. This is the default configuration. Only the server instance or cluster member that created the Timer can access the Timer and run the timeout method of the bean. If the server instance is unavailable, the Timer does not run at the specified time, and does not run until the server is restarted. Also, if an enterprise bean calls the *getTimers()* method, only those timers created on the server instance are found. This can cause unexpected behavior if the enterprise bean attempts to cancel all timers associated with it; for example, when the enterprise bean is removed. This configuration is NOT recommended for production level systems.
- Shared or common timer service database for the cluster. Timers can be created and accessed on any server process or cluster member. Timers created in one server process are found by the *getTimers()* method on other server processes in the cluster. When an entity bean is removed, all timers, no matter where created, are cancelled. However, all timers are executed on a single server in the cluster, that is, the timeout method of the bean is run for all timers on a single server. Which server executes the timers varies depending on which server process obtains a lock on the common database tables. If the server executing timers becomes unavailable, then another server or cluster member takes over and begins executing all timers at their scheduled time. This is the recommended configuration for all production level systems.
-

  Note: When using the EJB Timer service in an application using multi-threaded database access, application flow can introduce deadlock problems.
  To avoid this, use the wsPessimisticUpdate access intent. This access intent causes the finder method in your application to run a *select for update* statement instead of a generic select. This in turn prevents the lock escalation deadlock when multiple threads try to escalate their locks to perform an update.

See the information on using the EJB timer service for enterprise beans to learn how to configure the data source (database) to be used for each server process timer service.

Note: Once the data source for the timer service is changed to point to a different database, the server process automatically attempts to create the required tables in that database on the next server start.
If the user ID associated with the start of the server process is not authorized to create database tables in the configured timer service database, then the tables must be created manually.

Note: When you use the proxy server in the product, do not define a scheduler at the cell level if that scheduler is configured as the one to use for the EJB timer service. Doing so prevents persistent timers from running. This can happen if the proxy server gets the scheduler lease. Since no applications run in the proxy server, there is no application code to handle the timer events that are sent by the scheduler.

Timer service commands

Information about Enterprise JavaBeans (EJB) timers is specific to the application that the timers are created for, and the timers are not visible outside of that application. Therefore, when you manage EJB timers, use the application that contains the enterprise bean and creates the EJB timer.

You can use the following commands during application development to provide basic EJB timer management functions. These commands are not available on *client only* installations.

findEJBTimers

This command displays information about existing persistent EJB timers, based on specified filter criteria.

This command displays information about existing persistent EJB timers, based on specified filter criteria. The syntax for this command is:

```
findEJBTimers server filter [options]
   filter: -all | -timer | -app [-mod [-bean ]]
           -all
           -timer timer id
           -app   application name
           -mod   module name
           -bean  bean name

  options: -host  host name
           -port  portnumber
           -conntype connector type
           -user  userid
           -password password
           -quiet
           -logfile filename
           -replacelog
           -trace
           -help
```

The following options exist:

server Specifies the name of the server process where the EJB timers are located

-all Specifies to find all EJB timers associated with the server process

timer id
Specifies the EJB Timer ID that uniquely identifies the timer

application name
Specifies to find all EJB timers associated with the application

module name
Specifies to find all EJB timers associated with the module

bean name
Specifies to find all EJB timers associated with the enterprise bean

host name
Specifies the host name of the server process

portnumber
Specifies the port of the server process

connector type
Specifies the type of connection. For example, SOAP, RMI, or NONE.

userid Specifies the user to use when connecting to the server process

password
Specifies the password to use when connecting to the server process

quiet Specifies to disable output

logfile Specifies to direct output to a file

replacelog
Specifies to clear the existing log before executing the command

trace Specifies to enable trace

help Specifies to provide command-specific help

Note: If the server you specify is configured to use a scheduler instance that is shared by multiple servers, then EJB timers that are created in any of the server processes might be found.

See the information about locating EJB timers using the findEJBTimers command.

cancelEJBTimers

This command cancels and removes from persistent storage EJB persistent timers based on the specified filter criteria.

The syntax for this command is:

```
cancelEJBTimers server filter [options]
   filter: -all | -timer | -app [-mod [-bean ]]
           -all
           -timer timer id
           -app   application name
           -mod   module name
           -bean  bean name

  options: -host  host name
           -port  portnumber
           -conntype connector type
           -user  userid
           -password password
           -quiet
           -logfile filename
           -replacelog
           -trace
           -help
```

the following options exist:

server Specifies the name of the server process where the EJB timers are located

-all Specifies to find all EJB timers associated with the server process

timer id
Specifies the EJB Timer ID that uniquely identifies the timer

application name
Specifies to find all EJB timers associated with the application

module name
Specifies to find all EJB timers associated with the module

bean name
Specifies to find all EJB timers associated with the enterprise bean

host name
Specifies the host name of the server process

portnumber
Specifies the port of the server process

connector type
Specifies the type of connection. For example, SOAP, RMI, or NONE.

userid Specifies the user to use when connecting to the server process

password
Specifies the password to use when connecting to the server process

quiet Specifies to disable output

logfile Specifies to direct output to a file

replacelog
Specifies to clear the existing log before executing the command

trace Specifies to enable trace

help Specifies to provide command-specific help

Note: If the server you specify is configured to use a scheduler instance that is shared by multiple servers, then EJB timers that are created in any of the server processes might be canceled.

For an example of the cancelEJBTimers command, see the topic CancelEJBTimers command example.

findEJBTimers command:

The following examples illustrate how to use the **findEJBTimers** command to find Enterprise JavaBeans (EJB) timers and explain the output statement. For relevant parameters and syntax information, read about the timer service commands.

To find all EJB timers on a server called `server1`, enter the following command in the `<install-root>\profiles\<profile>\bin` directory:

```
findEJBTimers server1 -all
```

To find all EJB timers on `server1`, associated with the `Increment` bean in the **DefaultApplication**, enter the following command in the `<install-root>\profiles\<profile>\bin` directory:

```
findEJBTimers server1 -app DefaultApplication.ear
                      -mod Increment.jar -bean Increment
```

When EJB timers matching the filter criteria are found, the output appears similar to the following:

```
EJB Timer : 252     Expiration: 5/25/10 10:53 AM     Single
   EJB    : TimerPtestApp, TimerPtestEJB.jar, NoMoreTimeoutsBean
   Info   : Single
   Programmatic timer
EJB Timer : 253     Expiration: 5/25/10 11:47 AM     Calendar
   EJB    : TimerPtestApp, TimerPtestEJB.jar, NoMoreTimeoutsBean
   Automatic timer
Calendar expression: [start=null, end=null, timezone=null, seconds="52",
           minutes="47", hours="11", dayOfMonth="25", month="5", dayOfWeek="*",
           year="2010"]
2 EJB Timer tasks found
```

In this output, the following elements exist:

- `EJB Timer` is the unique identifier of the timer.
- `Expiration` is the next time the timer is expected to execute.
- `Calendar expression` is the calendar expression that defines the timer expiration intervals and frequencies, if the timer expirations were defined by a ScheduleExpression. All automatic timers have expirations defined by a ScheduleExpression.
- `EJB Key` is the `toString()` method output of the primary key for and entity bean. For other EJB types, `Not Available` will be output.
- `Info` is the `toString()` method output of the object passed by the application when the EJB timer was created.

Only the first forty bytes of `toString()` output are displayed for the primary key and timer information. This information is only useful if the application overrides the `toString()` method for these objects.

CancelEJBTimers command example:

The following examples illustrate how to use the command to cancel Enterprise JavaBeans (EJB) timers.

To use the cancelEJBTimer command to cancel all EJB timers on a server called **server1**:

```
cancelEJBTimers server1 -all
```

To cancel all EJB timers on **server1**, associated with the *Increment* bean in the **DefaultApplication**:

```
cancelEJBTimers server1 -app DefaultApplication.ear -mod Increment.jar -bean Increment
```

To cancel a specific EJB timer identified through the FindEJBTimers command or from a system log entry indicating a problem or failure:

```
cancelEJBTimers server1 -id 25
```

Increment in the *DefaultApplication* does not implement the *TimedObject* interface, and so could not actually have associated EJB Timers. Increment is used merely for illustrative purposes in this example.

Note: The CancelEJBTimers command also cancels automatically created persistent timers. When automatically created persistent timers are cancelled, the only way to recreate them is to uninstall the application and reinstall it again.

EJB command group:

The EJB command group for the AdminTask object provides commands that you can use to manipulate enterprise beans.

removeAutomaticEJBTimers

Applications or modules use annotations or XML to instruct the application server to automatically create EJB timers.

Automatically created timers are persisted in the scheduler instance associated with the server that the application or module is running on at the moment the automatic EJB timer is created. Schedules are configured on a per server basis, and thus it is possible for each server in your topology to use a unique scheduler instance. In this case, the scheduler instance specific to each server supports the EJB timers running in that server.

Each scheduler instance is associated with a set of database tables. If you have multiple scheduler instances, configure each scheduler instance with a unique prefix to ensure the instance maps to a unique set of database tables.

When the application or module that requested the automatic EJB timers are removed from a server, the automatic EJB timers must be removed from the corresponding scheduler instance. If the application or module was installed on multiple servers, and each of those servers used a unique scheduler instance, then the timers must be removed from each of those scheduler instances. In other words, automatically created EJB timers are removed on a per server basis.

In some cases, the removal or update of the application or module results in the removal of the automatically created EJB timers from the scheduler instance. In this scenario, no user action is required.

However, in other cases, the removal, or update of the application or module does not result in the removal of the automatically created EJB timers from the scheduler instance. In this case, you must manually remove the EJB timers using the **removeAutomaticEJBTimers** command.

The command is only supported in a connected mode. In a network deployment topology, the deployment manager, NodeAgent, and the managed server that contains the scheduler instance must all be running. In a base topology, the stand-alone server must be running.

In a Rational Application Developer loose configuration scenario, you must manually remove your automatically created EJB timers. Also, programmatically created EJB timers, which are not the same as automatically created EJB timers, are not automatically removed or removed by this command.

In a network deployment topology, when a single module is only installed on a subset of the servers in the topology, the automatically created timers associated with that module must be removed from the scheduler instance(s) associated with that subset of servers only. A scheduler instance corresponding to a server that does not have the module installed on it does not need to be cleaned up.

Target Object: None

Required parameters:

-appName
The name of the application that requested the automatically created EJB timers you want to remove. (String, required)

-serverName
The name of the server that runs the application or module that contains the automatically created EJB timers you want to remove. This parameter represents the logical name of an application server, not a host name. (String, required)

Optional parameters:

-schedulerJNDIName
This parameter represents the JNDI name of the scheduler instance that persists the automatically created EJB timers you want to remove.

A server instance is always configured to use a particular scheduler instance to support automatically created EJB timers. You can explicitly configure which scheduler instance is used, or you can choose to not explicitly configure a scheduler instance. In the latter case a default scheduler instance is used.

If the scheduler instance that contains the automatically created EJB timers you want to remove is the same scheduler instance that is currently configured for the server, then you can omit this parameter. In this case, the command examines the configuration, discovers the scheduler instance that is currently configured, and uses that.

However, if the scheduler instance that is currently configured is *not* the one that contains the EJB timers you want to remove, then specify the JNDI name of the scheduler instance that does contain these timers. (String, optional)

-nodeName
The name of the node that contains the server. (String, required)

-moduleName
The name of the module that requested the automatically created EJB timers you want to remove. If you want to remove all automatically created timers in the application, regardless of which module they are defined in, then this parameter is omitted. This parameter is only specified when you want to remove the automatically created timers requested by one module in the application, but not the timers requested by another module in the same application. (String, optional)

Return value: None

The following information helps to determine when this command is needed:

- WebSphere Application Server attempts to remove automatically created EJB timers when all the following conditions are met:
  - One of the following actions is performed:
    - Application uninstallation
    - Application update
    - Module uninstallation
    - Module update
  - The action was performed in a connected mode (not **wsadmin -conntype none**).

  - The needed servers were running at the time of the action.
    - For a network deployment topology, the deployment manager, node agent, and managed server containing the automatically created EJB timers were all running.
    - For a base topology, the stand-alone server was running.
  - The correct follow-up action was performed.
    - For a network deployment topology, you save your changes and synchronize them to the node agent. If you save your changes but do not synchronize them, then the automatically created EJB timers are *not* removed. The automatically created EJB timers are only removed during the sync processing.
    - For a base topology, you save your changes.
  - The database supporting the scheduler instance was running.
- WebSphere Application Server does *not* remove automatically created EJB timers when *any* of the following conditions occur:
  - Any action is performed other than an update or uninstallation of an application or module.
  - The action (even if it is an application/module uninstallation/update) was performed in disconnected mode.
  - The needed servers were not running.
    - For a network deployment topology, the deployment manager, node agent, or managed server was not running.
    - For a base topology, the stand-alone server was not running
  - The correct follow-up action was not performed.
    - For a network deployment topology, either the save or synchronize was not performed.
    - For a base topology, the save was not performed.
  - The database supporting the scheduler instance was not running.

If WebSphere Application Server encounters an error when attempting to remove automatically created EJB timers from a server, then a warning is written to log file.

If an error occurs, or if the application server did not attempt to remove automatically created EJB timers, or if you are not sure if the automatically created EJB timers were removed, manually issue the **removeAutomaticEJBTimers** command to ensure that the automatically created EJB timers are removed. If the automatically created timers were actually removed from the scheduler instance, running the command is unnecessary, but does no harm.

If you are running in a clustered environment, and your cluster contains multiple nodes, and each of those nodes contains a server that maps to the same cluster level scheduler instance, then the automatically created timers only must be removed from one of the servers. This is because the shared scheduler instance is updated, and all servers using that shared scheduler instance see the change.

As a result, if a server in one node is not running and you receive a log warning that the automatic timers could not be removed from it, but you know that server shares a cluster-level scheduler instance with a server in a different node that was successfully cleared, then no user action is required because the shared scheduler instance has already been updated.

The same is true when there are multiple servers in a cluster, and they are all part of the same node, and share a single cluster-level scheduler instance, and one or more of those cluster members are not running. In this case, the application server issues a log warning that the automatic timers could not be removed from those servers. However if you know that they share a common scheduler instance, and one of the cluster members was successfully cleared, then no user action is required because the shared scheduler instance has already been updated.

If you are running in a network deployment topology and have multiple servers, the type of scheduler used (default versus custom configured) has an impact on performance in regards to scheduler cleanup. The default EJBContainer scheduler is unique per server. If you are using the default EJBContainer scheduler instance, and you have five servers, this means you have five unique scheduler instances, and the automatic timers must be removed from all five of them when the application is updated or removed. However, if you are using a single shared, custom configured scheduler instance, then the automatic timers must only be removed once, from that one scheduler instance.

Example 1

Topology:

- Deployment manager running on workstation A.
- NodeAgent running on workstation B. The node is called Node01.
- Managed server server1 running on workstation C.
- Managed server server2 running on workstation D.
- Security is enabled.
- server2 is currently configured to use the same scheduler instance that contains the timers.

Background:

The testApp application was uninstalled in a connected mode from the administrative console. You want to remove all the automatically created timers in the application, regardless of which module requested them.

The deployment manager, node agent, and server1 servers were running, and the automatic EJB timers were removed from server1. However, server2 was not running, and so the automatic EJB timers were not removed from server2.

Now, you must manually remove the automatic EJB timers from server2.

Action:

- Using Jacl, from a connected wsadmin session in the deployment manager enter the following line of code:

  ```
  $AdminTask removeAutomaticEJBTimers "-appName testApp -serverName server2 -nodeName Node01"
  ```

- Using Jython, from a connected wsadmin session in the deployment manager enter the following line of code:

  ```
  AdminTask.removeAutomaticEJBTimers('-appName testApp -serverName server2 -nodeName Node01')
  ```

Example 2

Topology:

- Stand-alone server1 running on workstation A. The node is called Node01.
- Administrative security is disabled.
- server1 was configured to use scheduler instance `jndi/sched_1` when the automatic EJB timers were created. However, server1 is currently configured to use scheduler instance `jndi/sched_2`.

Background:

The module, mod1, from application, testApp, was uninstalled, but because server1 was configured to use the `jndi/sched_2` instance at the moment of uninstallation, the automatic EJB timers were not removed from scheduler instance `jndi/sched_1`.

Now, you must manually remove the automatic EJB timers from the `jndi/sched_1` scheduler instance on server1.

The application contains modules, mod1 and mod2. Both of these modules requested automatically created EJB timers. The mod2 module is still installed, and you still need the automatically created EJB timers it requested. You only want to remove the automatically created EJB timers requested by mod1.

Action:

- Using Jacl, from a connected wsadmin session in the stand-alone server enter the following line of code:

```
$AdminTask removeAutomaticEJBTimers "-appName testApp -moduleName mod1 -serverName server1 -nodeName Node01 -schedulerJNDIName jndi/sched_1"
```

- Using Jython, from a connected wsadmin session in the stand-alone server enter the following line of code:

```
AdminTask.removeAutomaticEJBTimers('-appName testApp -moduleName mod1 -serverName server1 -nodeName Node01 -schedulerJNDIName jndi/sched_1')
```

Example: Using the Timer Service with the TimedObject interface:

This example shows the implementation of the ejbTimeout() method that is called when the scheduled event occurs.

Note: The EJB 3.x programming model provides additional strategic ways to define persistent and non-persistent timers within your business environments. Although defining persistent timers using the ejbTimeout method with the TimedObject interface is still supported, take advantage of the easy-to-implement EJB annotations to create persistent and non-persistent timers to meet your business needs. See the using the EJB timer service for enterprise beans information to learn more about creating persistent and non-persistent timers using annotations or defining your own timeout methods within a deployment descriptor.

The ejbTimeout method can contain any code that is typically placed in a business method of the bean. Method-level attributes such as transaction or runAs can be associated with this method by the application assembler. An instance of the Timer object that causes the method to fire is passed in as an argument to the ejbTimeout method.

```
import javax.ejb.Timer;
import javax.ejb.TimedObject;
import javax.ejb.TimerService;

public class MyBean implements EntityBean, TimedObject {

  // This method is called by the EJB container upon Timer expiration.
  public void ejbTimeout(Timer theTimer) {

    // Any code typically placed in an EJB method can be placed here.

     String whyWasICalled = (String) theTimer.getInfo():
     System.out.println("I was called because of"+ whyWasICalled);
  } // end of method ejbTimeout
```

A Timer is created that starts the ejbTimeout method in 30 seconds. A simple string object is passed in at Timer creation to identify the Timer.

```
// Instance variable to hold the EJB context.
private EntityContext theEJBContext;

// This method is called by the EJB container upon bean creation.
public void setEntityContext(EntityContext theContext) {

// Save the entity context passed in upon bean creation.
  theEJBContext = theContext;

}

// This business method causes the ejbTimeout method to begin in 30 seconds.
public void fireInThirtySeconds() throws EJBException  {
```

```
  TimerService theTimerService = theEJBContext.getTimerService();
  String aLabel = "30SecondTimeout";
  Timer theTimer = theTimerService.createTimer(30000, aLabel);

} // end of method fireInThirtySeconds

} // end of class MyBean
```

Developing enterprise beans

One of two enterprise bean development scenarios is typically used with the product. The first is command-line using Ant, Make, Maven or similar tools. The second is an IDE-based development and build environment. The steps in this article focus on development without an IDE.

Before you begin

Enterprise JavaBeans (EJB) 2.x beans only: Design a J2EE application and the enterprise beans that it needs.

- Before developing entity beans with container-managed persistence (CMP), read the topic Concurrency control.

EJB 3.x beans only: Design a Java EE application and the enterprise beans that it needs.

- Before developing entity beans with CMP, read the topic, Concurrency control. Keep in mind that EJB 3.x modules do not support entity beans. You must continue to place entity beans in your EJB 2.x-level modules.

About this task

The two basic approaches to select tools for developing enterprise beans are as follows:

- You can use one of the available IDE tools that automatically generate significant parts of the enterprise bean code and contain integrated tools for packaging and testing enterprise beans. The Rational Application Developer product is the recommended IDE.

  Add install_root/dev/JavaEE/j2ee.jar to the IDE project build path to resolve compilation dependencies on the new EJB 3.x API classes. Code assist works when this JAR file is added to the project build path. If you define a server (see J2EE Perspective), point the server to the product installation directory. When you create a Java EE related project in Rational Application Developer, the project automatically adds install_root/dev/JavaEE/j2ee.jar. to the project build path.
- If you have decided to develop enterprise beans without an IDE, you need at least an ASCII text editor. You can also use a Java development tool that does not support enterprise bean development. You can then use tools available in the Java Software Development Kit (SDK) and in this product to assemble, test, and deploy the beans.

  Like the assembly tool, a standard Java EE command-line build environment requires some change to use the EJB 3.x modules. As with previous Java EE application development patterns, you must include the `j2ee.jar` file located in the install_root/dev/JavaEE directory on the compiler class path. An example of a command-line build environment using Ant is located in the install_root/samples/src/TechSamp directory.

The following steps primarily support the second approach, development without an IDE.

Procedure

1. If necessary, migrate any pre-existing code to the required version of the EJB specification.

   Applications written to the EJB specification versions 1.1, 2.0, and 2.1 can run unchanged in the EJB 3.x container. See the topic Migrating enterprise bean code to the supported specification.
2. Write and compile the components of the enterprise bean.
   - At a minimum, a session bean developed with the EJB 3.x specifications requires a bean class.

- At a minimum, an EJB 1.1 session bean requires a bean class, a home interface, and a remote interface. An EJB 1.1 entity bean requires a bean class, a primary-key class, a home interface, and a remote interface.
- At a minimum, an EJB 2.x session bean requires a bean class, a home or local home interface, and a remote or local interface. An EJB 2.x entity bean requires a bean class, a primary-key class, a remote home or local home interface, and a remote or local interface. The types of interfaces go together: If you implement a local interface, you must also define a local home interface.

  Attention: The primary-key class can be *unknown*. See the topic Unknown primary-key class for more information.
- A message-driven bean requires only a bean class.

3. For each entity bean, complete work to handle persistence operations.

   For EJB 3.x modules, consider using the Java Persistence API (JPA) specification to develop plain old Java Object (POJO) persistent entities. Review the topic Java Persistence API for more information. If you choose to develop entity beans to earlier EJB specifications, follow these steps:
   - Create a database schema for the entity bean persistent data.
     – For entity beans with CMP, you must store the bean persistent data in one of the supported databases. The assembly tool automatically generates SQL code for creating database tables for CMP entity beans. If your CMP beans require complex database mappings, it is recommended that you use Rational Application Developer to generate code for the database tables. For more information about using the assembly tools, see the assembly tool information center.
     – For entity beans with bean-managed persistence (BMP), you can create the database and database table by using the database tools or use an existing database and database table.

     For more information about creating databases and database tables, review your database documentation.
   - **(CMP entity beans for EJB 2.x only)**

     Define finder queries with EJB Query Language (EJB QL).

     With EJB QL, you define finders in terms of CMP fields and container-managed relationships, as follows:
     – *Public* finders are visible in the bean home interface. Implemented in the bean class, they return only remote interfaces and collection types.
     – *Private* finders, expressed as SELECT statements, are used only within the bean class. They can return both local and remote interfaces, dependent values, other CMP field types, and collection types.
   - **(CMP entity beans for EJB 1.1 only: an IBM extension)** Create a finder helper interface for each CMP entity bean that contains specialized finder methods (other than the findByPrimaryKey method).

     Logic other than the findByPrimaryKey method is required for each finder method that is contained in the home interface of an entity bean with CMP:
     – The logic must be defined in a public interface named *Name*`BeanFinderHelper`, where *Name* is the name of the enterprise bean, for example, AccountBeanFinderHelper.
     – The logic must be contained in a String constant named *`findMethodName`* `WhereClause`, where *findMethodName* is the name of the finder method. The String constant can contain zero or more question marks (?) that are replaced from left to right with the value of the finder method arguments when that method is called.

Example: Using a read-only entity bean

This usage scenario and example shows how to write an Enterprise JavaBeans (EJB) application that uses a read-only entity bean.

Usage scenario

A customer has a database of catalog pricing and shipping rate information that is updated daily no later than 10:00 PM local time (22:00 in 24-hour format). They want to write an EJB application that has read-only access to this data. That is, this application never updates the pricing database. Updating is done through some other application.

Example

The customer's entity bean local interface might be:

```
public interface ItemCatalogData extends EJBLocalObject {

  public int getItemPrice();

  public int getShippingCost(int destinationCode);

}
```

The code in the stateless SessionBean method (assume it is a TxRequired) that invokes this EntityBean to figure out the total cost including shipping, would look like:

```
.....
// Some transactional steps occur prior to this point, such as removing the item from
 // inventory, etc.
 // Now obtain the price of this item and start to calculate the total cost to the purchaser

 ItemCatalogData theItemData =
    (ItemCatalogData) ItemCatalogDataHome.findByPrimaryKey(theCatalogNumber);

int totalcost = theItemData.getItemPrice();

// ...     some other processing, etc. in the interim
// ...
// ...

// Add the shipping costs
totalcost = totalcost + theItemData.getShippingCost(theDestinationPostalCode);
```

At application assembly time, the customer sets the EJB caching parameters for this bean as follows:

- ActivateAt = ONCE
- LoadAt = DAILY
- ReloadInterval = 2200

Note: The reloadInterval and reloadingEnabled attributes of the IBM deployment descriptor extensions, including both the WAR file extension (WEB-INF/ibm-web-ext.xmi) and the application extension (META-INF/ibm-application-ext.xmi) were deprecated.

On the first call to the getItemPrice() method after 22:00 each night, the EJB container reloads the pricing information from the database. If the clock strikes 22:00 between the call to getItemPrice() and getShippingCost(), the getShippingCost() method still returns the value it had before any changes to the database that might have occurred at 22:00, since the first method invocation in this transaction occurred before 22:00. Thus, the item price and shipping cost used remain in sync with each other.

What to do next

Assemble the beans in one or more EJB modules. See the topic Assembling EJB modules, or Assembling EJB 3.x modules if you are using EJB 3.x beans.

Developing message-driven beans

You can develop a bean implementation class for a message-driven bean as introduced by the Enterprise JavaBeans specification. A message-driven bean (MDB) is a message consumer that implements business logic and runs on the server.

Before you begin

Determine the messaging model you want for your application regarding use of topics, queues, producers and consumers, publish or subscribe, and so on. You can refer to the message-driven bean component contract that is described in the Enterprise JavaBeans™ specification.

About this task

A message-driven bean (MDB) is a consumer of messages from a Java Message Service (JMS) provider. An MDB is invoked on arrival of a message at the destination or endpoint that the MDB services. MDB instances are anonymous, and therefore, all instances are equivalent when not actively servicing a client message. The container controls the life cycle of bean instances, which hold no state that is visible to a client.

The following example is a basic message-driven bean:

```
@MessageDriven(activationConfig={
                @ActivationConfigProperty(propertyName="destination",     propertyValue="myDestination"),
                @ActivationConfigProperty(propertyName="destinationType", propertyValue="javax.jms.Queue")
})
public class MsgBean implements javax.jms.MessageListener {

  public void onMessage(javax.jms.Message msg) {

      String receivedMsg = ((TextMessage) msg).getText();
      System.out.println("Received message: " + receivedMsg);

   }

}
```

As with other enterprise bean types, you can also declare metadata for message-driven beans in the deployment descriptor rather than using annotations, for example:

```
<?xml version="1.0" encoding="UTF-8"?>

<ejb-jar id="EJBJar_1060639024453" version="3.0"
      xmlns="http://java.sun.com/xml/ns/javaee"
      xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
      xsi:schemaLocation="http://java.sun.com/xml/ns/javaee http://java.sun.com/xml/ns/javaee/ejb-jar_3_0.xsd"
      metadata-complete="false">
  <enterprise-beans>

    <message-driven>

      <ejb-name>MsgBean</ejb-name>
      <ejb-class>com.acme.ejb.MsgBean</ejb-class>
      <activation-config>
         <activation-config-property>
            <activation-config-property-name>destination</activation-config-property-name>
            <activation-config-property-value>myDestination</activation-config-property-value>
         </activation-config-property>
         <activation-config-property>
           <activation-config-property-name>destinationType</activation-config-property-name>
           <activation-config-property-value>javax.jms.Queue</activation-config-property-value>
        </activation-config-property>
      </activation-config>
```

```
    </message-driven>

  </enterprise-beans>
</ejb-jar>
```

Procedure

- Code the business logic of the message-driven bean, which must implement the appropriate message listener interface defined by the messaging type; for example, javax.jms.MessageListener. The business logic is invoked when the message listener method of the MDB is called to service a message; for example, `MessageListener.onMessage()`. If the MDB implements more than one interface, denote the message listener interface by coding the `messageListenerInterface` attribute of the `MessageDriven` annotation, or by coding the `<messaging-type>` element of the `message-driven` deployment descriptor element. You do not have to specify which is the message listener interface, as long as there is only one interface other than `java.io.Serializable`, `java.io.Externalizable`, or any of the `javax.ejb` package interfaces.
- You can optionally define message destination references on any type of enterprise bean. A message destination reference is a logical name by which an enterprise bean can refer to a message destination. The `Resource` annotation is used to inject a message destination reference, for example:

  ```
  @Resource (name="jms/Outlet", type=javax.jms.Queue) Queue salesOutlet;
  ```

  Alternatively, you can use the `<message-destination-ref>` element in the deployment descriptor to specify the message destination reference; for example:

  ```
  <message-destination-ref>
     <message-destination-ref-name>jms/Outlet</message-destination-ref-name>
     <message-destination-type>javax.jms.Queue</message-destination-type>
     <injection-target>
       <injection-target-class>com.acme.ejb.MsgBean</injection-target-class>
       <injection-target-name>salesOutlet</injection-target-name>
    </injection-target>
  </message-destination-ref>
  ```

  The `message-destination-ref` element is similar to the `resource-env-ref` element, but also has subelements, `message-destination-usage` with possible values `Produces`, `Consumes` or `ProducesConsumes`, and `message-destination-link`. You can use the `message-destination-link` element to tie two or more message-destination-ref references in the deployment descriptor together, which allows the deployer to bind the destination for several enterprise beans all at once, to the same destination. The message-destination-link value must match the `message-destination-name` value in the `message-destination` element; for example:

  ```
  <ejb-jar>

    <enterprise-beans>

      <session>
        <ejb-name>OutletBean</display-name>
        ...
        <message-destination-ref>
          <message-destination-ref-name>jms/target</message-destination-ref-name>
          <message-destination-type>javax.jms.Queue</message-destination-type>
          <message-destination-usage>Produces</message-destination-usage>
          <message-destination-link>destination</message-destination-link>
        </message-destination-ref>
        ...
      </session>

      <session>
        <ejb-name>InletBean</display-name>
        ...
        <message-destination-ref>
          <message-destination-ref-name>jms/source</message-destination-ref-name>
          <message-destination-type>javax.jms.Queue</message-destination-type>
          <message-destination-usage>Consumes</message-destination-usage>
          <message-destination-link>destination</message-destination-link>
        </message-destination-ref>
        ...
      </session>
  ```

```
    <message-driven>
      <ejb-name>InletBean</display-name>
      ...

      <ejb-name>MsgBean</ejb-name>
      <ejb-class>com.acme.MsgBean</ejb-class>
      <messaging-type>javax.jms.MessageListener</messaging-type>
      <message-destination-type>javax.jms.Queue</message-destination-type>
      <message-destination-link>destination</message-destination-link>

      ...
    </message-driven>

  </enterprise-beans>
      ...
  <assembly-descriptor>
    ...
    <message-destination>
      <message-destination-name>destination</message-destination-name>
    </message-destination>
    ...
  </assembly-descriptor>

</ejb-jar>
```

The `message-destination-link` element can refer to a destination that is defined in a different Java archive (JAR) file within the same application, as with an `ejb-link` element. For example, to link to the destination, `ProduceQueue`, defined in the `grocery.jar` file, enter the following line in the deployment descriptor:

```
<message-destination-link>grocery.jar#ProduceQueue</message-destination-link>
```

- As with any enterprise bean, you can package a message-driven bean in a JAR file, or in a web application archive (WAR) file.

Results

You developed a simple message-driven bean, along with some deployment and packaging options.

What to do next

Read related information about designing an enterprise application that uses message-driven beans.

Enterprise bean development best practices

Use the following guidelines when designing and developing enterprise beans.

- Use a stateless session bean to act as the entry point for business logic.
- Entity beans should use container-managed persistence.
- In an Enterprise JavaBeans (EJB) Version 2.x and later version environments, use local interfaces to improve communication between enterprise beans in the same Java virtual machine.

  Local calls avoid the overhead of RMI/IIOP and use pass-by-reference semantics instead of pass-by-value. For each call, the caller and callee beans share the state of arguments. EJB 2.x and later beans can have both a local and remote interface, but more typically, have one or the other.
- For communicating with remote clients, provide remote and remote home interfaces. For communicating with local clients like servlets, entity beans, and message-driven beans, provide local and local home interfaces.

Batched commands for container managed persistence

From JDBC 2.0 on, **`PreparedStatement`** objects can maintain a list of commands that can be submitted together as a batch. Instead of multiple database round trips, there is only one database round trip for all the batched persistence requests.

You can enable the use of this feature for EJB container managed persistence (CMP). When you do, the run time defers **ejbStore/ejbCreate/ejbRemove** or the equivalent database persistence requests (insert/update/delete) until they are needed. This can be at the end of the transaction, or when a flush is needed for finders related to this EJB type. When the persistence operation finally happens, run time accumulates the database requests and uses JDBC **PreparedStatement** batch operation to make a single JDBC call for multiple rows of the same operation.

The product enables you to make the same settings using assembly tools.

Deferred Create for container managed persistence

For CMP during the **ejbCreate**, the container can create the representation of the entity in the database immediately, or defer it to a later time.

You can turn this option on from the EJB CMP side. When you choose this option, the runtime defers **ejbCreate**, or the equivalent database persistence request, until it is needed. This can be at the end of the transaction, or when a flush is needed for finders related to this EJB type. By doing this you can reduce two round trips for the newly created entity (insert and update) to one (insert).

The product enables you to make the same settings using assembly tools. Review the assembly tools information center at http://publib.boulder.ibm.com/infocenter/radhelp/v7r5mbeta/topic/com.ibm.jee5.doc/topics/cejb3.html

WebSphere extensions to the Enterprise JavaBeans specification

This topic outlines extensions to the Enterprise JavaBeans (EJB) specification provided with the product.

Inheritance in enterprise beans

In the Java language, *inheritance* is the creation of a new class from an existing class or a new interface from an existing interface. This product supports two forms of inheritance: standard class inheritance and EJB inheritance.

In standard class inheritance, the home interface, remote interface, or enterprise bean class inherits properties and methods from base classes that are not themselves enterprise bean classes or interfaces.

By contrast in enterprise bean inheritance, an enterprise bean inherits properties, such as container-managed persistence (CMP) fields and container-managed relationship (CMR) fields, methods, and method-level control descriptor attributes from another enterprise bean.

For more information, see the documentation for the assembly tools.

Optimistic concurrency control for container-managed persistence

This product supports optimistic concurrency control of data access. For more information, see the topic about concurrency control.

Access intents for EJB persistence

This product supports the application of named data-access policies.

Sequence grouping for container-managed persistence

By designating CMP sequence groups for entity beans, you can prevent certain types of database-related exceptions from occurring during the run time of your EJB application. Within each group you specify the

order in which the beans update your relational database tables. For instructions, see the topic about setting the run time for CMP sequence groups.

Performance enhancements

Through the lifetime-in-cache settings, this product provides a way for you to improve performance for beans that are only occasionally updated. For more information, see the topic about entity bean assembly settings in the assembly tool documentation.

Some enterprise beans created with the assembly tools can utilize *read-ahead* for loading a bean and its related beans in a single database operation. An entire object graph or any part of the graph can be preloaded by configuring a finder method to use read-ahead.

Assembly and deployment extensions

This product supports IBM extensions of assembly and deployment options.

Setting the run time for batched commands with JVM arguments

This article explains how to set the run time for batched commands with JVM arguments.

Procedure

1. Open the administrative console.
2. Select **Servers**.
3. Select **Application Servers**.
4. Select the server you want to configure.
5. In the Additional Properties area, select **Process Definition**.
6. In the Additional Properties area, select **Java Virtual Machine**.
7. Update the **Generic JVM arguments** with *-Dcom.ibm.ws.pm.batch=true*.

Setting the run time for deferred create with JVM arguments

For Container Managed Persistence (CMP) to happen during the ejbCreate, the Enterprise JavaBeans (EJB) container can create the representation of the entity in the database immediately, or defer it to a later time.

About this task

When you choose the defer option, the run time defers ejbCreate, or the equivalent database persistence request, until it is needed. This can be at the end of the transaction, or when a flush is needed for finders related to this EJB type. By doing this you can reduce two round trips for the newly created entity (insert and update) to one (insert).

Procedure

1. Open the administrative console.
2. Select **Servers**.
3. Select **Application Servers**.
4. Select the server you want to configure.
5. In the Additional Properties area, select **Process Definition**.
6. In the Additional Properties area, select **Java Virtual Machine**.
7. Update the **Generic JVM arguments** with *-Dcom.ibm.ws.pm.deferredcreate=true*.

Setting persistence manager cache invalidation

To set persistence manager cache invalidation, follow these steps.

Procedure

1. Open the administrative console.
2. Select **Servers**.
3. Select **Application Servers**.
4. Select the server you want to configure.
5. In the Server Infrastructure area, select **Java and Process Management**.
6. Select **Process Definition**.
7. In the Additional Properties area, select **Java Virtual Machine**.
8. Update the **Generic JVM arguments** with *-Dcom.ibm.ws.ejbpersistence.cacheinvalidation=true*.

Setting the system property to enable remote EJB clients to receive nested or root-cause exceptions

You might want to code your application to perform a given action if a certain kind of exception is the root-cause of a failure and is nested within the exception that you receive. The default behavior in the product might mask a nested or root-cause exception in your application.

About this task

The Enterprise JavaBeans (EJB) container creates a TransactionRolledbackException exception for a remote client when it can create a RemoteException exception instead. With the RemoteException exception, the container does not lose the ability to have root-cause information nested inside the exception.

You can set the following Java virtual machine (JVM) system property to **true** through the administrative console for the product: com.ibm.websphere.ejbcontainer.includeRootExceptionOnRollback This change enables the remote client to receive nested exceptions when a rollback occurs.

Note: This property is applicable only for scenarios where the transaction in which the bean method is running was started by the container for this specific method invocation. All of the other scenarios must result in a TransactionRollBackException exception according to the EJB specification.

Procedure

1. Open the administrative console.
2. Select **Servers**.
3. Select **Servers > Application servers > server_name**.
4. Under Server infrastructure, select **Java and Process Management > Process Definition**.
5. Under Additional properties, select **Java virtual machine > Custom properties > New**.
6. In the **Name** entry field, type **com.ibm.websphere.ejbcontainer.includeRootExceptionOnRollback**.
7. In the **Value** entry field, type **true**.
8. Select **OK**.

Unknown primary-key class

When writing an entity bean, the minimum requirements usually include a primary-key class. However, in some cases you might choose not to specify the primary-key class for an entity bean with container-managed persistence (CMP).

Perhaps there is no obvious primary key, or you want to allow the deployer to select the primary key fields at deployment time. The primary key type is usually derived from the type used by the database system that stores the entity objects, and you might not know what this key is.

So, the *unknown key type* is actually a type chosen at deployment time, making it changeable each time the bean is deployed. Your client code must deal with this key as type *Object*.

Currently, WebSphere Application Server supports top-down mapping and enables the deployer to choose *String* keys generated at the application server.

Developing applications using the embeddable EJB container

Use this task to develop applications using the embeddable Enterprise JavaBeans (EJB) container. Applications running in the embeddable container start faster and require a smaller footprint than when running in the full application server. It is an optimal environment for quickly developing and testing applications that might eventually run on the application server.

Before you begin

To create an embeddable EJB container application, you must set your development environment to use Version 6.0 of Java Development Kit (JDK) Version 1.6. Your development environment must also include the WebSphere embeddable container Java archive (JAR) file in the class path. The `com.ibm.ws.ejb.embeddableContainer_8.0.0.jar` file is located in the `\runtimes` directory under the installation directory of WebSphere Application Server.

Restriction: The EJB thin client, `com.ibm.ws.ejb.thinclient_8.0.0.jar`, and the EJB embeddable JAR file, `com.ibm.ws.ejb.embeddableContainer_8.0.0.jar`, cannot coexist in the same class path.

If your beans use the javax.annotation.Resource annotation with the lookup attribute, which is new in EJB 3.1, you must also use the Java Endorsed Standards Override Mechanism to override the javax.annotation.Resource API that is available in the JDK on your system. Copy the `app_server_root\runtimes\endorsed\endorsed_apis_8.0.0.jar` file into a target directory of your choice. Use the **`java.endorsed.dirs`** property on the Java command to specify your directory that contains the copied JAR file.

Procedure

1. Create an EJB 3.X module. When creating this module, you must ensure that it only contains features that are supported by WebSphere embeddable container. For a full list of supported functions, see the “Embeddable EJB container functions” on page 372 topic. Ensure that the EJB modules are on the class path of the embeddable container. You can package the EJB module as directories of classes or as EJB JAR files.
2. Create the main class that launches the embeddable container and starts methods on the enterprise beans. Use the javax.ejb.EJBContainer class to create an instance of the embeddable container (optionally passing container configuration parameters), get the container naming context, and close the embeddable container.

   The following sample code illustrates usage of the embeddable container:

```
//EmbeddableContainerSample.java
import java.util.HashMap;
import java.util.Map;
import javax.ejb.embeddable.EJBContainer;
import my.pkg.MyBeanIface; // this is the local business interface of the
                           // enterprise bean

public class EmbeddableContainerSample {

   public static void main(String[] args) throws Throwable {
```

```
        // Create a properties map to pass to the embeddable container:
        Map<String,Object> properties = new HashMap<String,Object>();

        // Specify that you want to use the WebSphere embeddable container:
        properties.put(EJBContainer.PROVIDER,
            "com.ibm.websphere.ejbcontainer.EmbeddableContainerProvider");

        // Create the container instance, passing it the properties map:
        EJBContainer ec = EJBContainer.createEJBContainer(properties);

        // Use the container context to look up a bean:
        MyBeanIface bean = ec.getContext().lookup(
            "java:global/MyEJBModule/MyBean!my.pkg.MyBeanIface");

        // Invoke a method on the bean instance:
        bean.doStuff();

        ...

        // Close the embeddable container:
        ec.close();

    }
}
```

In this sample code, you created an instance of an embeddable container by specifying the EJBContainer.PROVIDER property to the com.ibm.websphere.ejbcontainer.EmbeddableContainerProvider class, and passing that property to the EJBContainer.createEJBContainer method. You used the container naming context to look up a local enterprise bean, for example, MyBean. The lookup uses the portable global naming syntax.

This sample code relies on the embeddable container to automatically scan the class path to find the EJB module, MyEJBModule. Alternatively, you could have specified the modules you wanted to start using the EJBContainer.MODULES property. Use this property to specify a string or string array of module names that must exist in the JVM class path.

You can also specify a file or file array of modules that do not exist in the class path. This file or file array approach might require you to modify the context class loader on the current thread, if these modules require additional libraries that are also not on the JVM class path.

The following code sample illustrates how to start the embeddable container using a file array.

```
...
// Create the properties object to pass to the embeddable container:
Map<String,Object> props = new HashMap<String,Object>();

// Specify the EJB modules to start when creating the container:
File[] ejbModules = new File[2];
ejbModules[0] = new File("/home/myusername/ejbs/ShoppingCartEJB.jar");
ejbModules[1] = new File("/home/myusername/ejbs/OnlineCatalogEJB.jar");
props.put(EJBContainer.MODULES, ejbModules);

// In this example, both of these modules rely on code in a shared library.
// In order for the embeddable container to load the shared library, the
// context classloader must be able to load that shared library.

// Set up the context classloader so that it can load the shared library:
File sharedLibUtilityFile = new File("/home/myusername/ejbs/SharedLib.jar");
ClassLoader oldCL = Thread.currentThread().getContextClassLoader();
ClassLoader newCL = new URLClassLoader(new URL[]{
   sharedLibUtilityFile.toURI().toURL()}, oldCL);
Thread.currentThread().setContextClassLoader(newCL);

// Now, create the embeddable container, passing it the properties map:
```

```
EJBContainer ec = EJBContainer.createEJBContainer(props);

// Invoke an EJB loaded by the embeddable container:
...
```

After looking up the bean instance, start methods on it. When you finish the container-related tasks, close the container, which starts the bean methods marked as PreDestroy and closes the embeddable container. Close the embeddable container instance before creating a new one.

3. Customize the embeddable container. You can use properties to customize the embeddable EJB container run time. For a full list of supported properties, see the topic Embeddable EJB container custom properties.
4. If you want your application to use resources like data sources, then you can create and configure those resources in the properties map passed to the embeddable container or in a properties file.

   One common usage of the embeddable EJB container is to test applications that eventually run in the application server. Many of these applications rely on JDBC data sources that are configured in the server using the administrative console or **wsadmin** scripting tool. Since these tools do not exist in the embeddable container, you can configure the WebSphere embeddable container to provide these resources by passing properties to it.

   The data source configuration properties can also be stored in a properties file. The embeddable container automatically loads properties stored in a file called embeddable.properties in the current working directory. You can override this file location by specifying the new file location as the value of the com.ibm.websphere.embeddable.configFileName system property.

   The data source configuration properties all start with `DataSource`, and are followed by a term that identifies which data source is being configured. For example, `DataSource.myDataSource.someProperty` applies to a different data source than one named `DataSource.anotherDS.someOtherProperty`. The list of data source properties are located in the embeddable EJB container custom properties information.

   Here is an example of how your application can use data sources:

```
...
InitialContext context = new InitialContext();
DataSource ds = (DataSource) context.lookup("env/jdbc/AcctsPayableDS");
Connection conn = ds.getConnection();
// Use the connection to access the AcctsPayableDS database
...
```

   In the server, a systems administrator has created a data source and bound it in the JNDI name space to `env/jdbc/AcctsPayableDS`. Alternatively the code might have looked up the data source in a java:comp namespace, which is mapped to `env/jdbc/AcctsPayableDS` or specified an EJB field to be injected with the data source. In all cases, a data source must be bound in the namespace. Use the following code to complete this action programmatically when creating the embeddable container instance:

```
...
// Create a properties map to store embeddable container config properties
Map<String,Object> props = new HashMap<String,Object>();

// Set the JNDI name to bind this data source:
props.put("DataSource.ds1.name", "env/jdbc/AcctsPayableDS");

// Set the data source class name ; this is a required property
// This example uses a Derby JDBC driver
props.put("DataSource.ds1.dataSourceClass",
   "org.apache.derby.jdbc.EmbeddedConnectionPoolDataSource");

// Set the database name
props.put("DataSource.ds1.databaseName", "AcctsPayableTestDB");

// Create the embeddable container instance with our custom properties
EJBContainer ec = EJBContainer.createEJBContainer(props);

// Now invoke an EJB in the embeddable container...
...
```

The preceding code creates a simple data source to an Apache Derby database called AcctsPayableTestDB and binds it at `env/jdbc/AcctsPayableDS`. You can complete this same task declaratively by putting the following text into a file called `embeddable.properties` in the current working directory of the JVM. You can also put this text in any text file, and specify that text file in the com.ibm.websphere.embeddable.configFileName system property.

```
DataSource.ds1.name=env/jdbc/AcctsPayableDS
DataSource.ds1.dataSourceClass=org.apache.derby.jdbc.EmbeddedConnectionPoolDataSource
DataSource.ds1.databaseName=AcctsPayableTestDB
```

Use resource references when developing the EJB rather than looking up data sources directly.

5. Your application can use Java EE role-based security, both declarative and programmatic, to verify your EJB role-based security. You can complete the following actions to verify EJB role-based security:
   - Define a user to be used for authorization purposes.
   - Assign users to roles that are declared in your EJB.
   - Test the use of the EJBContext methods, isCallerInRole() and getCallerPrincipal(), in your EJB.

   Here is an example of how your application can use declarative and programmatic security:

```
import java.util.HashMap;
import java.util.Map;
import javax.ejb.EJBContainer;
import my.pkg.MyBeanIface; // this is the local business interface of the
                           // enterprise bean
public class EmbeddableContainerSample {

   public static void main(String[] args) throws Throwable {
      // Create a properties map to pass to the embeddable container:
      Map<String,Object> properties = new HashMap<String,Object>();
      // Specify that you want to use the WebSphere embeddable container:
      properties.put(EJBContainer.PROVIDER,
          "com.ibm.websphere.ejbcontainer.EmbeddableContainerProvider");

      // Specify that you want security checking enabled:
      properties.put("com.ibm.websphere.securityEnabled", "true");

      // Assign the users bob, fred, and mary to the role employee:
      props.put("role.employee", "bob, fred, mary");
      // Assign the user fred to the role manager:
      props.put("role.manager", "fred");
      // The user fred will be used for the runAs role manager:
      props.put("role.runAs.manager", "fred");
      // The user fred will be used for role authorization when invoking
      // methods on the EJB:
      props.put("user.invocation", "fred");
      // Create the container instance, passing it the properties map:
      EJBContainer ec = EJBContainer.createEJBContainer(properties);
      // Use the container context to look up a bean:
      MyBeanIface bean = ec.getContext().lookup(
          "java:global/MyEJBModule/MyBean!my.pkg.MyBeanIface");
      // Invoke a method on the bean instance:
      bean.doStuff();
      ...
      // Close the embeddable container:
      ec.close();
   }
}
```

The preceding code enables security and then creates two roles, `employee` and `manager`, and three users, `bob`, `mary`, and `fred`. It then specifies that the `fred` user is used when running as the `manager` role. Before creating the embeddable container, it sets the invocation user as `fred`. This means that when EJB methods are started, they are started by `fred`, which means that if those methods require the role of `employee` or `manager`, `fred` is able to access those methods.

6. Your application can specify Local Transaction Containment (LTC) behavior per bean. For an explanation of LTC, read about local transaction containment.

Here is an example of how your application can specify the LTC resolver and unresolved action:

```
import java.util.HashMap;
import java.util.Map;
import javax.ejb.EJBContainer;
import my.pkg.MyBeanIface; // this is the local business interface
                           // of the enterprise bean

 public class EmbeddableContainerSample {

   public static void main(String[] args) throws Throwable {

      // Create a properties map to pass to the embeddable container:
      Map<String,Object> properties = new HashMap<String,Object>();
      // Specify that you want to use the WebSphere embeddable container:
      properties.put(EJBContainer.PROVIDER,
          "com.ibm.websphere.ejbcontainer.EmbeddableContainerProvider");

      // Specify that you want the LTC resolver container-at-boundary:
      properties.put("Bean.myApp1#moduleA#bean101.LocalTransaction.Resolver",
                                                  "ContainerAtBoundary");

      // Specify that you want the LTC unresolved action commit:
      properties.put("Bean.myApp1#moduleA#bean101.LocalTransaction.UnresolvedAction",
                                                  "Commit");

      // Create the container instance, passing it the properties map:
      EJBContainer ec = EJBContainer.createEJBContainer(properties);
      // Use the container context to look up a bean:
      MyBeanIface bean = ec.getContext().lookup(
          "java:global/MyEJBModule/MyBean!my.pkg.MyBeanIface");
      // Invoke a method on the bean instance:
      bean.doStuff();
      ...
      // Close the embeddable container:
      ec.close();
   }
}
```

The preceding code sets the resolver action for the specified bean to its non-default value of container-at-boundary, and causes the unresolved action to be the non-default action that commits the transaction.

If an application name is not specified when launching the embeddable container, the *<application_name>* must be omitted. However, you must use the # delimiter. For example:

```
properties.put("Bean.#moduleA#bean101.LocalTransaction.UnresolvedAction", "Commit");
```

Embeddable EJB container

The embeddable Enterprise JavaBeans (EJB) container is a container for enterprise beans that do not require a Java Platform, Enterprise Edition (Java EE).

TheWebSphere Application Server embeddable EJB container is a container for enterprise beans that does not require a Java EE server to run. The EJB programming model and the EJB container services are now available for Java Platform, Standard Edition (Java SE) server.

The following are embeddable container usage scenarios:

- EJB unit testing: developers can test their enterprise beans without needing a full server installation of WebSphere Application Server in their development environment.
- Embedding enterprise beans in Java SE applications: developers can use enterprise beans and the functionality that is provided with an EJB container, for example, dependency injection, transactions, and security in stand-alone desktop applications.

The following advantages exist when using the WebSphere embeddable EJB container:

- No server installation is necessary for EJB development, unit testing, and Java SE-based application deployment.
- The embeddable container is a much smaller footprint, in terms of disk space and main memory, than the server-based container.
- The embeddable container starts faster than the server-based container because it initializes only EJB-related components.

Be aware of the following limitations when using the embeddable container:
- Inbound RMI/IIOP calls are not supported, which means that all EJB clients must exist within the same Java virtual machine (JVM) as the embeddable container.
- Message driven beans (MDB) are not supported.
- The embeddable container cannot be clustered for high availability per workload management. For a complete list of supported functions in the WebSphere embeddable container, see the topic, Embeddable EJB container functions.

Running an embeddable container

Use this task to run an embeddable container. Applications running in the embeddable container start faster and require a smaller footprint than when running in the full application server. It is an ideal environment for quickly developing and testing applications that might eventually run in the application server.

Before you begin

Before running an embeddable container, you must have the following items ready:
- A copy of the *<app_server_root>*\runtimes\com.ibm.ws.ejb.embeddableContainer_8.5.0.jar

  Restriction: The Enterprise JavaBeans (EJB) thin client, com.ibm.ws.ejb.thinclient_8.5.0.jar, and the EJB embeddable Java archive (JAR) file, com.ibm.ws.ejb.embeddableContainer_8.5.0.jar, cannot coexist in the same class path.
- A copy of the *<app_server_root>*\runtimes\endorsed\endorsed_apis_8.5.0.jar file, if you are using the @Resource annotation with the lookup attribute
- One or more EJB modules in JAR files or class directories
- A main class that creates the embeddable container
- A Java SE Development Kit (JDK) or a Java Runtime Environment (JRE) Version 6.0 or later

About this task

The key to running the embeddable container is the class path. The class path must include all the artifacts previously listed. For example, if the main class is my.pkg.MyMainClass, and it uses enterprise beans that are stored in the MyEJBModule.jar file, the following line might run the main class that launches the embeddable container. This example assumes that all JAR files and class directories are in the current working directory.
- Windows:

```
C:\test> java -cp .;com.ibm.ws.ejb.embeddableContainer_8.5.0.jar my.pkg.MyMainClass
```
- UNIX:

```
[test]$ java -cp .:com.ibm.ws.ejb.embeddableContainer_8.5.0.jar:MyEJBModule.jar my.pkg.MyMainClass
```

It is possible to run the embeddable container without specifying all the modules on the class path. This requires the code to specify a File or File array for the MODULES property, and the context class loader for the thread creating the container instance must be able to load the specified files.

If you want to specify embeddable container properties in a text file other than embeddable.properties in the current working directory, then you must specify the com.ibm.websphere.embeddable.configFileName system property; for example:

- Windows:

```
C:\test> java -Dcom.ibm.websphere.embeddable.configFileName="C:\test\my-config.properties"
 -cp .;com.ibm.ws.ejb.embeddableContainer_8.5.0.jar;MyEJBModule.jar my.pkg.MyMainClass
```

- UNIX:

```
[test]$ java -Dcom.ibm.websphere.embeddable.configFileName="/home/myusername/test/my-config.properties"
 -cp .:com.ibm.ws.ejb.embeddableContainer_8.5.0.jar:MyEJBModule.jar my.pkg.MyMainClass
```

When developing an application using JPA in the embeddable EJB container, the class path must include the JPA thin client, `com.ibm.ws.jpa.thinclient_`*n*`.0.jar`, where *n* is the WebSphere Application Server release; for example, 8.5 for Version 8.5. The JPA thin client is located in `\runtimes` where the root directory of the installation image is located.

- Windows:

```
C:\test> java -cp .;com.ibm.ws.ejb.embeddableContainer_8.5.0.jar;%WAS_HOME%\runtimes
  \com.ibm.ws.jpa.thinclient_8.5.0.jar;MyEJBModule.jar my.pkg.MyMainClass
```

- UNIX:

```
[test]$ java -cp .:com.ibm.ws.ejb.embeddableContainer_8.5.0.jar:${WAS_HOME}/runtimes
  /com.ibm.ws.jpa.thinclient_8.5.0.jar:MyEJBModule.jar my.pkg.MyMainClass
```

Note: You can specify the Java agent mechanism to complete the dynamic enhancement at run time. For example, type the following line of code at the command prompt:

- Windows:

```
C:\test> java -javaagent:%WAS_HOME%\runtimes\com.ibm.ws.jpa.thinclient_8.5.0.jar
 -cp .;com.ibm.ws.ejb.embeddableContainer_8.5.0.jar;MyEJBModule.jar my.pkg.MyMainClass
```

- UNIX:

```
[test]$ java -javaagent:${WAS_HOME}/runtimes/com.ibm.ws.jpa.thinclient_8.5.0.jar
 -cp .:com.ibm.ws.ejb.embeddableContainer_8.5.0.jar:MyEJBModule.jar my.pkg.MyMainClass
```

To enable tracing in the embeddable container, you can specify the com.ibm.ejs.ras.lite.traceSpecification system property to a trace specification value as you would specify for the server. By default, the trace is printed to standard output, but you can redirect the output by specifying the com.ibm.ejs.ras.lite.traceFileName system property. The following example shows how you can use both system properties:

- Windows:

```
C:\test> java -Dcom.ibm.ejs.ras.lite.traceSpecification=EJBContainer=all:MetaData=all
 -Dcom.ibm.ejs.ras.lite.traceFileName=trace.log
 -cp .;com.ibm.ws.ejb.embeddableContainer_8.5.0.jar;MyEJBModule.jar my.pkg.MyMainClass
```

- UNIX:

```
[test]$ java -Dcom.ibm.ejs.ras.lite.traceSpecification=EJBContainer=all:MetaData=all
 -Dcom.ibm.ejs.ras.lite.traceFileName=trace.log
 -cp .:com.ibm.ws.ejb.embeddableContainer_8.5.0.jar:MyEJBModule.jar my.pkg.MyMainClass
```

If your beans use the javax.annotation.Resource annotation with the lookup attribute, you must also use the Java Endorsed Standards Override Mechanism to override the javax.annotation.Resource API that is available in the JDK on your system. Copy the *app_server_root*`\runtimes\endorsed\endorsed_apis_8.5.0.jar` file into a target directory of your choice. Use the **java.endorsed.dirs** property on the Java command to specify your directory that contains the copied JAR file. The following example shows how you can specify the java.endorsed.dirs property:

- Windows:

```
C:\test> java -Djava.endorsed.dirs="myTargetDirectory"
 -cp .;com.ibm.ws.ejb.embeddableContainer_8.5.0.jar;MyEJBModule.jar my.pkg.MyMainClass
```

- UNIX:

```
[test]$ java -Djava.endorsed.dirs="myTargetDirectory"
 -cp .:com.ibm.ws.ejb.embeddableContainer_8.5.0.jar:MyEJBModule.jar my.pkg.MyMainClass
```

Embeddable EJB container functions

According to the Enterprise JavaBeans (EJB) 3.1 specification, all embeddable EJB containers that vendors use must at least implement the EJB Lite subset of EJB functionality. The application server also contains additional features that support the EJB Lite subset. Refer to the EJB 3.1 specification for more information.

Attention: Container-managed authentication is only supported with the default container-managed authentication alias. For data sources, the user ID and password fields of the Java EE data source resource, or the embeddable properties data source, are used as the default container-managed authentication alias.

EJB Lite includes:

- Local (and no-interface) session beans with synchronous methods only, which include stateless, stateful, and singleton bean types.
- Declarative and programmatic security.
- Interceptors.
- Support for annotations or XML deployment descriptors, the `ejb-jar.xml` file.
- Java Persistence Architecture (JPA) 2.0.

The WebSphere embeddable container provides the following additional functions:

- Java Database Connectivity (JDBC) data source configuration, usage, and dependency injection.
- Bean validation

  To use bean validation with the embeddable EJB container, the javax.validation classes must exist in the class path. That can be done in one of two ways:
  - Include the JPA thin client that is located in the directory `${WAS_INSTALL_ROOT}\runtimes\com.ibm.ws.jpa.thinclient_8.0.0.jar` in the class path. See the topic, Running an embeddable container, and the information about JPA, for more information.
  - Include a third party bean validation provider Java archive (JAR) file in the class path of the embeddable EJB container run time.

Embeddable EJB container configuration properties

Use the following configuration properties for the embeddable Enterprise JavaBeans (EJB) container.

Table 52. Embeddable EJB container configuration properties. Use the properties for embeddable EJB container configurations.

Property	Type	Default value	Description
com.ibm.websphere.ejbcontainer.cacheSize	java.lang.Long	2 053	Number of buckets for the EJB cache.
com.ibm.websphere.ejbcontainer.cacheSweepInterval	java.lang.Long	3 000	Time between sweeps of the EJB cache to determine whether to remove entries.
com.ibm.websphere.ejbcontainer.inactivePoolCleanupInterval	java.lang.Long	30 000	Time in milliseconds for the clean up thread to wait before cleaning the inactive pool.
com.ibm.websphere.ejbcontainer.passivationDir	java.lang.String	<TempDir>	Directory to passivate stateful beans in. The user must have read and write access to the specified directory.

Table 52. Embeddable EJB container configuration properties (continued). Use the properties for embeddable EJB container configurations.

Property	Type	Default value	Description
com.ibm.websphere.embeddable.configFileName	java.lang.String	<CurrentWorkingDirectory> /embeddable.properties	File name of a properties file containing embeddable EJB container properties. When this file is processed, each property is passed to the newly created EJB container as if they were passed in programmatically. Any properties in the configuration file are overridden by properties passed in programmatically. **Attention:** It is also possible to specify this property as a system property on the command line.

The following table contains configuration properties for data sources. Each property is specific to an individual data source which allows you to configure multiple data sources with different settings. Replace *<data_source_id>* with a unique term that identifies the data source to be configured. Some properties are listed as required for each data source.

Table 53. Embeddable EJB container configuration properties for Java Database Connectivity (JDBC) data sources. Use the embeddable EJB container configuration properties for JDBC data sources.

Property	Type	Description
DataSource.*<data_source_id>*.name	java.lang.String	Required. The Java Naming and Directory Interface (JNDI) string that the container uses to bind this data source in the global namespace of the embeddable container. This string must match the JNDI lookup string used in the application.
DataSource*<data_source_id>*.className	java.lang.String	Required. The Java class name of the data source class. For testing, Apache Derby can be used if *app_server_root*/derby/lib/derby.jar is on the Java Virtual Machine classpath. The supported data source classes for Apache Derby are org.apache.derby.jdbc.EmbeddedConnectionPoolDataSource and org.apache.derby.jdbc.EmbeddedXADataSource.
DataSource.*<data_source_id>*.connectionSharing	java.lang.String	The policy for sharing connections. Valid values are `MatchOriginalRequest` (default), `MatchCurrentState` or `None`. `MatchOriginalRequest` means that a connection request might share if it matches the originally requested settings of an existing connection. `MatchCurrentState` means that a connection request might share if it matches the current settings of an existing connection. `None` means that multiple connection requests do not share the same connection.
DataSource.*<data_source_id>*.databaseName	java.lang.String	The name of the database that this data source connects to.
DataSource.*<data_source_id>*.isolationLevel	java.lang.Integer	The transaction isolation level for connections from this data source. If unspecified, the default is provided by the JDBC driver or database. Valid values are `1` for Read Uncommitted, `2` for Read Committed, `4` for Repeatable Read, or `8` for Serializable. These values come from constants in java.sql.Connection and are subject to change.
DataSource.*<data_source_id>*.maxIdleTime	java.lang.Integer	The number of seconds after which the connection pool can close an unused connection.
DataSource.*<data_source_id>*.maxPoolSize	java.lang.Integer	The maximum number of connections that are created for this data source. After this number of simultaneous connections are in use, future requests to get a connection from this data source are blocked until one or more of the in-use connections have been returned to the pool.
DataSource.*<data_source_id>*.maxStatements	java.lang.Integer	The maximum number of statements cached by the connection pool. This value is divided by the *maxPoolSize* value to determine the number of statements that can be cached for each connection in the pool. A value of `0` disables statement caching.
DataSource.*<data_source_id>*.minPoolSize	java.lang.Integer	The minimum number of connections to keep in the connection pool for this data source. If no connections are in use, the connection pool might discard connections until the pool size reaches this setting. This setting must be non-negative.
DataSource.*<data_source_id>*.password	java.lang.String	Password for the given `user` when accessing the database. Like the preceding property, this property can be omitted if the database does not have security enabled or if the user name and password are provided programmatically when creating the connection.
DataSource.*<data_source_id>*.transactional	java.lang.Boolean	Whether this data source must be enlisted in Java Transaction API (JTA) transactions. Valid values are `true` (default) or `false`.
DataSource.*<data_source_id>*.user	java.lang.String	User name for accessing the database. This property can be omitted if the database does not have security enabled or if the user name and password are provided programmatically when creating the connection.
DataSource.*<data_source_id>.<vendor_property_name _or_connection_pool_property_name>*	java.lang.String	You can also configure other properties: • Vendor-specific data source properties, such as `serverName` and `portNumber` • WebSphere Application Server data source properties, such as `userDefinedErrorMap` and `validateNewConnection` • WebSphere Application Server connection pooling properties, such as `connectionTimeout` and `purgePolicy`
DataSource.*<data_source_id>*.xaRecoveryPassword	java.lang.String	Applies to XA data sources only. Password for XA recovery.

Table 53. Embeddable EJB container configuration properties for Java Database Connectivity (JDBC) data sources (continued). Use the embeddable EJB container configuration properties for JDBC data sources.

Property	Type	Description
DataSource.<*data_source_id*>.xaRecoveryUser	java.lang.String	Applies to XA data sources only. Some databases require a user with special privileges for XA recovery. Use this property to specify a user name for XA recovery instead of the default user.

Use the following properties to configure two data sources.

```
DataSource.ds1.name=env/jdbc/ds1
DataSource.ds1.className=org.apache.derby.jdbc.EmbeddedConnectionPoolDataSource
DataSource.ds1.transactional=true
DataSource.ds1.createDatabase=create
DataSource.ds1.databaseName=jtest1
DataSource.ds1.user=dbuser1
DataSource.ds1.password=dbpwd1
DataSource.ds1.maxPoolSize=5

DataSource.ds2.name=env/jdbc/ds2
DataSource.ds2.className=org.apache.derby.jdbc.EmbeddedXADataSource
DataSource.ds2.connectionSharing=MatchOriginalRequest
DataSource.ds2.createDatabase=create
DataSource.ds2.databaseName=jtest2
DataSource.ds2.user=dbuser2
DataSource.ds2.password=dbpwd2
DataSource.ds2.maxPoolSize=10
DataSource.ds2.minPoolSize=1

DataSource.ds3.name=env/jdbc/ds3
DataSource.ds3.className=com.ibm.db2.jcc.DB2XADataSource
DataSource.ds3.driverType=4
DataSource.ds3.databaseName=DB2COPY1
DataSource.ds3.serverName=mydb2.test.ibm.com
DataSource.ds3.portName=50000
DataSource.ds3.user=dbuser1
DataSource.ds3.password=dbpwd1
```

The first data source, ds1, is bound in the namespace under the name, env/jdbc/ds1, and provides connection pooling for up to five connections to an Apache Derby database. The second data source, ds2, is bound in the namespace at env/jdbc/ds2 and provides XA-compliant connection pooling to an Apache Derby database.

The following table contains configuration properties for EJB bindings. For each property, replace:

- *<app>* with the application name.

  The application name is, by default, the empty string. However the application name can be specified using the EJBContainer.APP_NAME property when calling createEJBContainer.
- *<module>* with the module name.

  The module name is either specified in ejb-jar.xml as <module-name>, is the name of the JAR file without the ".jar" suffix, or is the name of the directory containing the module.
- *<ejb>* with the name of the EJB.

  The name of the EJB is specified in ejb-jar.xml as <ejb-name>, or using the name element when using annotations; for example, @Stateless(name="TestBean"). If no name is specified in the EJB annotation, the simple class name is used; for example, TestBean for the class com.ibm.test.TestBean.
- *<interceptor>* with the name of an interceptor class.
- *<ref>* with the name of the resource reference, EJB reference, or environment entry.

  The reference can be specified in ejb-jar.xml; for example, <res-ref-name>jdbc/mydsref</res-ref-name>, or <ejb-ref-name>java:module/env/myejbref</ejb-ref-name>. Alternatively, the reference can be specified using an annotation; for example @Resource(name="jdbc/mydsref") or @EJB(name="java:module/env/myenvref").

If an application name is not specified when launching the embeddable container, the *<app>* must be omitted. However, you must use the # delimiter. For example, `Bean.#<module>#<bean>.ResourceRef.BindingName.`

Table 54. Embeddable EJB container configuration properties for reference bindings. Use the embeddable EJB container configuration properties for reference bindings.

Property	Type	Description
Bean.*<app>*#*<module>*#*<ejb>*.ResourceRef.BindingName.*<ref>* or Interceptor.*<app>*#*<module>*#*<interceptor>*.ResourceRef.BindingName.*<ref>*	java.lang.String	The JNDI string to use when the resource reference is looked up or injected. This must be the JNDI name of a configured data source.
Bean.*<app>*#*<module>*#*<ejb>*.EJBRef.BindingName.*<ref-name>* or Interceptor.*<app>*#*<module>*#*<interceptor>*.EJBRef.BindingName.*<ref>*	java.lang.String	The JNDI string to use when the EJB reference is looked up or injected. This must be the java:global, java:app, or java:module JNDI string of an EJB in the embeddable EJB container.
Bean.*<app>*#*<module>*#*<ejb>*.EnvEntry.Value.*<ref-name>* or Interceptor.*<app>*#*<module>*#*<interceptor>*.EnvEntry.Value.*<ref>*	java.lang.String	The value to use when the environment entry is looked up or injected. This property overrides the value specified by env-entry-value. The value must be valid for the type of the environment entry.
Bean.*<app>*#*<module>*#*<ejb>*.EnvEntry.BindingName.*<ref>* or Interceptor.*<app>*#*<module>*#*<interceptor>*.EnvEntry.BindingName.*<ref>*	java.lang.String	The JNDI string to use when the environment entry is looked up or injected. This must be the java:global, java:app, or java:module JNDI string of another environment entry in the same embeddable EJB container.
Bean.*<app>*#*<module>*#*<ejb>*.DataSource.BindingName.*<ref>* or Interceptor.*<app>*#*<module>*#*<interceptor>*.DataSource.BindingName.*<ref>*	java.lang.String	The JNDI string to use when the data source is looked up or injected. This must either be the JNDI name of a configured data source or the java:global, java:app, or java:module JNDI string of another data source in the same embeddable EJB container. Application developers should use resource references rather than looking up a data source directly. If an application is coded to look up data sources directly, you can use this property to override data source definitions included in the application. See the information center for more information about data source definitions.

Use the following properties to configure the bindings for an EJB with two references and an interceptor with an environment entry:

```
Bean.#TestModule#TestBean.ResourceRef.BindingName.jdbc/dsref=env/jdbc/ds1
Bean.#TestModule#TestBean.EJBRef.BindingName.ejb/Cart=java:global/CartModule/CartBean
Interceptor.#TestModule#com.ibm.example.LoggerInterceptor.EnvEntry.Value.logFile=/tmp/output.log
```

Note: Use the following properties to override java:module/env/TestDataSource that is defined in an EJB named TestBean in an EJB module named TestModule, with jdbc/MyDataSource that is defined in embeddable properties:

```
Bean.#TestModule#TestBean.DataSource.BindingName.java\:module/env/TestDataSource=jdbc/MyDataSource
```

Table 55. Embeddable EJB container configuration properties for security. Use the embeddable EJB container configuration properties for security.

Property	Type	Default value	Description
com.ibm.websphere.securityEnabled	java.lang.String	false	Determines whether security roles are checked. Valid values are false (default) or true. If true, then security roles are checked; if false, then security roles are not checked.
role.<role_name>	java.lang.String		Maps an EJB role to one or more users. The <role_name> is a role assigned to a method, either through the annotation @RolesAllowed or through the deployment descriptor <method-permission>. The value is a string of comma-delimited user names, for example “bob, mary, john”. The users in the list are allowed to run methods that require the <role_name>.
role.runAs.<role_name>	java.lang.String		Maps one EJB role to one user. The <role_name> is a role assigned to a bean or method, either through the annotation @RunAs or through the deployment descriptor <run-as>. The value is a single user name. The user name is used for any authorization that is required by the bean while it is running.

Table 55. Embeddable EJB container configuration properties for security (continued). Use the embeddable EJB container configuration properties for security.

Property	Type	Default value	Description
user.invocation	java.lang.String		Defines the user that might be used for authorization when the bean is invoked. The value is a single user name. The container checks that this user is mapped to a role that is allowed to run any executed method.

The following table contains configuration properties for the Local Transaction Containment (LTC) behavior. For an explanation of LTC, read about local transaction containment. Each property is specific to a bean.

If an application name is not specified when launching the embeddable container, the *<application_name>* must be omitted. However, you must use the # delimiter. For example, `Bean.#<module_name>#<bean_name>LocalTransaction.Resolver`.

Table 56. Embeddable EJB container configuration properties for Local Transaction Containment. Use the embeddable EJB container configuration properties for Local Transaction Containment.

Property	Type	Default value	Description
Bean.*<application_name>#<module_name>#<bean_name>*.LocalTransaction.Resolver	java.lang.String	Application	Determines the entity that is responsible for local transaction resolution. Valid values are Application (default) or ContainerAtBoundary.
Bean.*<application_name>#<module_name>#<bean_name>*.LocalTransaction.UnresolvedAction	java.lang.String	Rollback	Determines the action taken for unresolved local transactions. Valid values are Rollback (default) or Commit.

The following table contains configuration properties for XA behavior.

Table 57. Embeddable EJB configuration properties for XA. Use the embeddable EJB configuration properties for XA.

Property	Type	Default value	Description
com.ibm.websphere.tx.acceptHeuristicHazard	java.lang.String	false	Specifies whether last participant support is enabled for all modules. The default value is `false`.
com.ibm.websphere.tx.auditRecovery	java.lang.String	true	Specifies whether recovery processing outputs audit messages, which indicate XA resource and XID processing during recovery. When no audit recovery is specified, only a single recovery message is output along with the number of transactions that are recovered, unless an error occurs.
com.ibm.websphere.tx.clientInactivityTimeout	java.lang.String	0	Specifies the maximum duration, in seconds, between transactional requests. Any period of client inactivity that exceeds this timeout value results in the transaction being rolled back. The default setting, `0`, means that no limit exists.
com.ibm.websphere.tx.enableLoggingForHeuristicReporting	java.lang.String	false	This property enables logging for heuristic reporting. If last participant support is enabled, reporting of heuristic outcomes that might occur when the server becomes unavailable requires additional information to be written to the transaction log. If enabled, one additional log write is completed for any transaction that involves both one-phase and two-phase commit resources. No additional records are written for transactions that do not involve a one-phase commit resource.
com.ibm.websphere.tx.heuristicRetryLimit	java.lang.String	0	Specifies the number of times that the transaction service retries a completion signal such as commit or rollback. Retries occur after a transient exception from a resource manager. The default value, `0`, indicates no limit to the number of retries.
com.ibm.websphere.tx.heuristicRetryWait	java.lang.String	0	Specifies the number of seconds that the transaction service waits before retrying a completion signal, such as commit or rollback, after a transient exception from a resource manager.
com.ibm.websphere.tx.LPSHeuristicCompletion	java.lang.String	ROLLBACK (case insensitive)	The heuristic completion action to be taken by the transaction service in a transaction with last participant support when the outcome of the one-phase commit resource is unknown. The values ROLLBACK or COMMIT cause the two-phase commit resources to be completed accordingly. The setting, MANUAL, means that the transaction service takes no action and leave the two-phase commit resources in-doubt. The default value is ROLLBACK.

Table 57. Embeddable EJB configuration properties for XA (continued). Use the embeddable EJB configuration properties for XA.

Property	Type	Default value	Description
com.ibm.websphere.tx.maximumTransactionTimeout	java.lang.String	300	Specifies, in seconds, the upper limit of the transaction timeout value. This timeout value constrains the upper limit of all other transaction timeout values.
com.ibm.websphere.tx.totalTranLifetimeTimeout	java.lang.String	120	Specifies the default maximum time, in seconds, allowed for a transaction before the transaction service initiates timeout. Any transaction that does not begin completion processing before this timeout occurs is rolled back.
com.ibm.websphere.tx.tranLogDirectory	java.lang.String	profiles*server name*\tranlog	Specifies the name of a directory for this server where the transaction service stores log files for recovery.
com.ibm.websphere.tx.tranLogSize	java.lang.String	1024	Specifies the size, in kilobytes, of transaction log files. The minimum file size is 64KB. The default value sets the file size to 1MB.

Configuring EJB 3.1 session bean methods to be asynchronous

Use this task to configure Enterprise JavaBeans (EJB) 3.1 session bean methods to run asynchronously. You can make some or all of your bean methods asynchronous.

Before you begin

Attention: In EJB 3.1 modules, you can set one or more session bean methods to be asynchronous, broadening parallel processing in your application.

- If you are not already familiar with EJB 3.1 asynchronous methods, read about EJB 3.1 asynchronous methods, client programming model for EJB asynchronous methods, bean implementation programming model for EJB asynchronous methods, and EJB container work manager for asynchronous methods. The topics provide an overview of EJB 3.1 asynchronous methods, describe the client and bean implementation programming models, and discuss the work manager that the EJB container uses to dispatch asynchronous methods.
- Develop a new EJB 3.1 session bean for your application, or change an existing session bean so that it conforms to the EJB 3.1 programming model requirements for asynchronous methods. For general information, see information about developing enterprise beans.

About this task

After you have developed a session bean, complete the following steps to make one or more of the bean methods asynchronous.

Procedure

1. Specify one or more methods of the bean implementation class as asynchronous. This can be accomplished by adding @Asynchronous annotations in your bean source code, by adding <async-method> stanzas in your module deployment descriptor, or by adding a combination of both annotations and deployment descriptor stanzas. You can apply the @Asynchronous annotation or its superclasses only, to your bean implementation class. It cannot be applied to interface classes. Also, when the annotation is applied at the class level, all methods of that class are asynchronous. Likewise, all methods of a bean can be configured as asynchronous by applying "*" as the <method-name> in your deployment descriptor.

   See the following examples of applying the @Asynchronous annotation:

   - Apply the @Asynchronous annotation to one method of a bean with a no-interface view. In this example, the m1 method is synchronous and the m2 method is asynchronous.

```
@Stateless @LocalBean
public class MyLocalBean {

   public void m1() {

      // method code
```

```
   }

   @Asynchronous
   public Future<String> m2() {

      // method code

      return new javax.ejb.AsyncResult("Hello, Async World!");
   }
}
```

Important: The javax.ejb.AsyncResult<V> object is a convenience implementation of the Future<V> interface. See the API documentation for more details.

- Apply the @Asynchronous annotation to the class level of a bean class. In this example, both the m1 method and the m2 method are asynchronous on this no-interface view bean.

```
@Stateless @LocalBean @Asynchronouspublic class MyLocalBean {

   public void m1() {

      // method code
   }

   public Future<String> m2() {

      // method code

      return new javax.ejb.AsyncResult("Hello, Async World!");
   }

}
```

- Apply the @Asynchronous annotation to one method of a bean implementation class. In this example, the m1 method is synchronous and the m2 method is asynchronous. This example also demonstrates how the return types might differ between the business interface and the implementation class.

```
public interface MyIntf {

   public void m1();

   public Future<Integer> m2();

}
@Stateless @Local(MyIntf.class)
public class MyBean {

   public void m1() {

      // method code
   }

   @Asynchronous
   public Integer m2() {

      // method code

      return new Integer(3);
   }
}
```

- Apply the @Asynchronous annotation to the class level of a bean implementation class. In this example, both the m1 method and the m2 method are asynchronous.

```
@Stateless @Local(MyIntf.class) @Asynchronous
public class MyBean {
```

```
   public void m1() {

      // method code
   }

   public Integer m2() {

      // method code

      return new Integer(8);
   }
}
```

See the following examples of modifying the EJB module deployment descriptor, `ejb-jar.xml`:

- In this example all business methods of the FullAyncBean bean implementation class and its superclasses are configured as asynchronous with the wildcard (*) method-name element.

```
<session>
   <display-name>FullAsyncEJB</display-name>
   <ejb-name>FullAsyncBean</ejb-name>
   <business-local>com.ibm.sample.async.ejb.FullAsyncIntf</business-local>
   <ejb-class>com.ibm.sample.async.ejb.FullAsyncBean</ejb-class>
   <session-type>Stateless</session-type>   <async-method>
      <method-name>*</method-name>
   </async-method>
</session>
```

- In this example only the specified methods and signatures -- all methods named m1 and the method m2 with a single String parameter -- are configured as asynchronous on the PartiallyAsyncBean bean implementation class.

```
<session>
   <display-name>PartiallyAsyncEJB</display-name>
   <ejb-name>PartiallyAsyncEJB</ejb-name>
   <business-local>com.ibm.sample.async.ejb.PartiallyAsyncIntf</business-local>
   <ejb-class>com.ibm.sample.async.ejb.PartiallyAsyncBean</ejb-class>
   <session-type>Stateless</session-type>   <async-method>
      <method-name>m1</method-name>
   </async-method>
   <async-method>
      <method-name>m2</method-name>
      <method-params>
         <method-param>java.lang.String</method-param>
      </method-params>
   </async-method>
</session>
```

See the following examples of applying a combination of the @Asynchronous annotation in the bean source code and modifying the EJB module deployment descriptor, `ejb-jar.xml`:

- In this example the @Asynchronous annotation configures method m2 to be asynchronous, and the deployment descriptor configures method m1 to also be an asynchronous method.

```
@Stateless @LocalBean
public class MyLocalBean {

   public void m1() {

      // method code
   }

   @Asynchronous
   public Future<String> m2() {

      // method code

      return new javax.ejb.AsyncResult("Hello, Async World!");
   }
}
```

```
<session>
   <display-name>MyLocalEJB</display-name>
   <ejb-name>MyLocalEJB</ejb-name>
   <local-bean/>
   <ejb-class>com.ibm.sample.async.ejb.MyLocalBean</ejb-class>
   <session-type>Stateless</session-type>   <async-method>
      <method-name>m1</method-name>
   </async-method>
</session>
```

- In this example the @Asynchronous annotation for method m2 is ignored because the deployment descriptor header contains the metadata-complete="true" flag. This flag causes configuration information to only be taken from the deployment descriptor elements. The result is that only method m1 of the MyLocalBean implementation is configured to be asynchronous.

```
@Stateless @LocalBean
public class MyLocalBean {

   public void m1() {

      // method code
   }

   @Asynchronous
   public Future<String> m2() {

      // method code

      return new javax.ejb.AsyncResult("Hello, Async World!");
   }
}

<ejb-jar id="ejb-jar_ID" ...
metadata-complete="true" version="3.1">
...
<session>
   <display-name>MyLocalEJB</display-name>
   <ejb-name>MyLocalEJB</ejb-name>
   <local-bean/>
   <ejb-class>com.ibm.sample.async.ejb.MyLocalBean</ejb-class>
   <session-type>Stateless</session-type>   <async-method>
      <method-name>m1</method-name>
   </async-method>
</session>
...
</ejb-jar>
```

2. Verify that the transaction attribute applied to any asynchronous method is either REQUIRED, REQUIRES_NEW, or NOT_SUPPORTED. These transaction attribute types are the only transaction attribute types supported on asynchronous methods. You can complete this action by either applying @TransactionAttribute annotations in the bean source code, by adding <container-transaction> stanzas in the `ejb-jar.xml` file, or by adding a combination of both annotations and <container-transaction> stanzas in the deployment descriptor.

   See the following example of setting the transaction attribute of an asynchronous method using annotations:

```
@Singleton @LocalBean
public class FullAsyncBean {
 @Asynchronous
 @TransactionAttribute(REQUIRED) // the default; specified for illustration
 public void m1() {
  // ...
 }

 @Asynchronous
```

```
 @TransactionAttribute(NOT_SUPPORTED)
 public void m2() {
  // ...
 }

 @Asynchronous
 @TransactionAttribute(REQUIRES_NEW)
 public void m3() {
  // ...
 }

 // ...
}
```

See the following example of setting the transaction attribute of an asynchronous method using the XML deployment descriptor:

```
  <assembly-descriptor>
    <container-transaction>
      <method>
        <ejb-name>FullAsyncBean</ejb-name>
        <method-name>m1</method-name>
      </method>
      <trans-attribute>Required</trans-attribute>
    </container-transaction>

    <container-transaction>
      <method>
        <ejb-name>FullAsyncBean</ejb-name>
        <method-name>m2</method-name>
      </method>
      <trans-attribute>NotSupported</trans-attribute>
    </container-transaction>

    <container-transaction>
      <method>
        <ejb-name>FullAsyncBean</ejb-name>
        <method-name>m3</method-name>
      </method>
      <trans-attribute>RequiresNew</trans-attribute>
    </container-transaction>
  </assembly-descriptor>
```

See the following example of using a combination of both annotations and the XML deployment descriptor to configure the transaction attributes of a bean. In this example the deployment descriptor stanzas for method m3 override the class level annotation. The result is that method m3 is configured as REQUIRES_NEW, while methods m1 and m2 are configured as REQUIRED:

```
@Singleton @LocalBean
@Asynchronous
@TransactionAttribute(REQUIRED) // the default; specified for illustration
public class FullAsyncBean {

 public void m1() {
  // ...
 }

 public void m2() {
  // ...
 }

 public void m3() {
  // ...
 }

 // ...
}
```

```
<assembly-descriptor>

   <container-transaction>
      <method>
         <ejb-name>FullAsyncBean</ejb-name>
         <method-name>m3</method-name>
      </method>
      <trans-attribute>RequiresNew</trans-attribute>
   </container-transaction>

</assembly-descriptor>
```

What to do next

Continue to develop additional components for your application, or if you have finished all components required by your application, assemble and deploy your application. See information about assembling EJB modules and deploying EJB modules.

When you run your application, if it fails when it first attempts to use a session bean that has an asynchronous method, a configuration error might exist. Check the system log file for configuration error messages.

Analyze the trace data or forward it to the appropriate organization for analysis. EJB asynchronous method scheduling and invocation are traced in the EJB container trace. For instructions on enabling this trace see the information about enabling trace on a running server. To analyze trace data, see information about trace output.

Configuring remote asynchronous EJB method results

Use this task to set the maximum number of unclaimed results for a remote asynchronous Enterprise JavaBeans (EJB) method call.

About this task

When a remote asynchronous EJB method is called, the server must save the results of the remote method invocation until the client claims the results using the Future.get method. If the client never claims the result, unclaimed results can accumulate in the server and use memory. To avoid using too much memory, the server limits the number of unclaimed results to 1000 by default. If the number of unclaimed results approaches or exceeds the limit, the server issues the `CNTR0328W` warning.

Procedure

1. Optional: Open the administrative console.
2. Select **Servers**.
3. Select **Server Types**.
4. Select **WebSphere application servers**.
5. Select the server that you want to configure.
6. From Server Infrastructure, select **Java and Process Management Process definition.**
7. From Additional Properties, select **Java Virtual Machine** .
8. In the Additional Properties area, select **Custom Properties** .
9. On the Application servers page, click **New** to specify an arbitrary name and value pair for your server.
10. In the **Name** entry field, type: `com.ibm.websphere.ejbcontainer.maxUnclaimedAsyncResults`
11. In the **Value** entry field, enter the wanted maximum number of unclaimed results. The special value `0` is interpreted as unlimited. The default value is `1000`.
12. Click **OK**.

13. Save the configuration.
14. Restart the server.

Results

The maximum number of unclaimed asynchronous EJB method results for all EJBs is set.

Configuring EJB asynchronous methods using scripting

Use **wsadmin** scripting to configure Enterprise JavaBeans (EJB) asynchronous methods.

Before you begin

You have working knowledge of Jacl or Jython and **wsadmin** scripting.

About this task

The behavior for EJB asynchronous methods is configured using the EJBAsync configuration object in the `server.xml` file. If you are using EJB asynchronous methods, then you might must update the EJBAsync configuration object to obtain the best settings for your environment. The EJBAsync configuration object exists at the server level. This means that each server in a multiple-server environment has its own EJBAsync configuration object and must be configured individually.

Procedure

1. Launch the **wsadmin** scripting tool using the Jython scripting language.
2. Determine the attributes on the EJBAsync configuration object that must be updated. You can update the following attributes on the EJBAsync configuration object:

Table 58. Attributes on EJBAsync configuration object. This table describes the attributes on the EJBAsync configuration object.

Attribute	Description
maxThreads	Specifies the maximum number of threads that are used in the execution of asynchronous EJB methods. The default value is 5.
workReqQSize	Specifies the size of the work request queue. The work request queue is a buffer that holds requested asynchronous methods until a thread is available to run them on. The sum of the maxThreads and the workReqQSize attributes is the total number of allowable in progress method requests. For example, if the maxThreads is set to 5 threads, and the workReqQSize is set to 50, then the total number of allowable in-progress method requests is 55. The default value is 0, indicating that the queue size is managed by the runtime environment. The run time currently uses the larger of 20 and maxThreads.
workReqQFullAction	Specifies the action taken when the thread pool is exhausted, and work request queue is full. If set to 1, an exception occurs instead of waiting for a thread, or a place in the queue, to become available. If set to 0, the thread that is requesting the asynchronous method execution waits until a thread, or place in the queue, becomes available. The default value is 0.
customWorkManagerJNDIName	Specifies the Java Naming and Directory Interface (JNDI) name used to look up the custom defined work manager in the namespace. The default value is null.

Table 58. Attributes on EJBAsync configuration object (continued). This table describes the attributes on the EJBAsync configuration object.

Attribute	Description
useCustomDefinedWM	Specifies whether a custom-defined work manager instance is used, or the default internal work manager instance. When the useCustomDefinedWM attribute is set to true, this means that a custom work manager instance is used. In this case, the customWorkManagerJNDIName attribute must be set, and all other attributes are ignored. When the useCustomDefinedWM attribute is set to `false`, the default, internal work manager instance is used. In this case, the customWorkManagerJNDIName attribute is ignored, and all other attributes are used to help configure the default work manager instance. The default value is false.
futureTimeout	Specifies the amount of time, in seconds, that the server-side future object, which is created as a result of running a fire-and-return asynchronous method, is available. The server-side future object is not valid after you call the get() method, and a value is returned to the remote client. To avoid memory leaks, you must call the get() method on the future object, or specify a positive and non-zero future duration value. A future duration value of zero indicates that the future object never times out. The default value is `86400`, which means that the future object expires and gets cleaned up by the application server after 24 hours and is no longer available. A org.omg.CORBA.OBJECT_NOT_EXIST exception is thrown when a call to the get() method is made after the future object expires. **Note:** This value is only applicable for clients that call the enterprise bean using a remote business interface; the value is not used for local business interface or no-interface views. When the asynchronous work has completed, the server sets an alarm for the duration specified to the server-side future object. When the alarm is activated, the server releases all the resources associated with the future object, making it unavailable to the client. If the client calls the get() method on the future object before the duration amount of time, the alarm is canceled and all the resources associated with the future object are released. **Note:** This attribute might affect the number of future objects on the server. Use the AsynchFutureObjectCount PMI statistic to determine the count of open FutureObjects on the server, which can help you determine whether applications are accumulating future objects without calling the get() method on those objects. See the topic, Enterprise bean counters, for more information.

3. Obtain a reference to the correct EJBAsync configuration object and store it in a variable.

   Using Jacl:

   ```
   set async [$AdminConfig list EJBAsync]
   ```

   Using Jython:

   ```
   async = AdminConfig.list('EJBAsync')
   ```

   If you have a multiple-server environment, then multiple EJBAsync configuration objects are returned. Programmatically loop over the list and select the EJBAsync configuration object that corresponds to the server you must update.

   In a multiple-server environment, as an alternative to programmatically looping over the list of EJBAsync objects, you can manually select the correct EJBAsync object and copy and paste it into your variable.

   For example, the output of the `AdminConfig list` command is:

   ```
   (cells/myNode04Cell/nodes/myCellManager01/servers/dmgr|server.xml#EJBAsync_1)(cells/
   myNode04Cell/nodes/myNode04/servers/server1|server.xml#EJBAsync_1247498700906)
   ```

   You can copy and paste the reference for the needed EJBAsync object into your variable.

   Using Jacl:

   ```
   set async "(cells/myNode04Cell/nodes/myNode04/servers/server1|server.xml#EJBAsync_1247498700906)"
   ```

   Using Jython:

   ```
   async = "(cells/myNode04Cell/nodes/myNode04/servers/server1|server.xml#EJBAsync_1247498700906)"
   ```

4. Update attributes on the EJBAsync configuration object.

   Update attributes on the EJBAsync configuration object using the **AdminConfig modify** command. As input to the command, specify the EJBAsync reference that you obtained in the previous step, and a list of attributeName and attributeValue combinations.

   To set a max thread count of `10` threads, a queue size of `15`, and a futureTimeout of `3600` seconds:

Using Jacl:

```
set update "{maxThreads 10} {workReqQSize 15} {futureTimeout 3600}"
$AdminConfig modify $async $update
```

Using Jython:

```
AdminConfig.modify(async, '[ [maxThreads "10"] [workReqQSize "15"] [futureTimeout "3600"] ]')
```

5. Save the configuration changes.

   Using Jython:

   ```
   AdminConfig.save()
   ```

   Using Jacl:

   ```
   $AdminConfig save
   ```

6. In a Network Deployment environment only, synchronize the node.

   Using Jacl:

   ```
   set sync1 [$AdminControl completeObjectName type=NodeSync,node=<your node>,*]
   $AdminControl invoke $sync1 sync
   ```

   Using Jython:

   ```
   sync1 = AdminControl.completeObjectName('type=NodeSync,node=<your node>,*')
   AdminControl.invoke(sync1, 'sync')
   ```

   You must run the node synchronization in these examples while connected to the server.

Results

As a result of your updates, the EJBAsync configuration object now reflects the attribute values that you specified. Restart your server so that the changes are updated on the server.

EJB 3.1 asynchronous methods

The Enterprise JavaBeans™ (EJB) 3.1 specification includes functionality that application developers can use to configure EJB asynchronous methods, which are run on a separate thread from the caller thread.

This mechanism decouples the client invocation request from the actual method execution. The client thread can continue doing other work while the EJB method is run on a separate thread, as directed by the EJB container.

Later, the client might want to examine the result of the asynchronous method execution, which is sometimes referred to as *fire and return*. In this case, the EJB container returns to the client an object that implements the java.util.concurrent.Future<V> interface. The client can use this object to check status, results, or exceptions from the asynchronous method invocation. Alternatively, asynchronous methods might not return any results, which is sometimes referred to as *fire and forget.*

For more details, see information about how to use EJB asynchronous methods in your application.

Here are some example usage scenarios for EJB asynchronous methods:

- An application has multiple, independent, pieces of work that all must be executed to produce a final result. For example, suppose that a travel reservation consists of three parts:
  1. Making a plane reservation.
  2. Making a rental car reservation.
  3. Making a hotel reservation.

  In this example, a client can use EJB asynchronous methods to process the reservation requests in parallel. After all three reservation methods run, the client aggregates the results into a complete travel reservation.
- An application has multiple, independent, pieces of work that it must run, and the application is not concerned about the results of this work. For example, suppose that a retailer has four branch stores, and the home office wants to print a sales report from each store when the business day ends. The

application developer can use EJB asynchronous methods as a batch processing mechanism. Multiple EJB method calls can be used to send a batch of get sales report requests, one to each branch store.

In this example, presumably the application does not need to check for results from these method calls. Perhaps this is handled by the home office employee who picks up the sales reports from a printer the next morning. Suppose that one of the branch stores failed to provide the requested report. The person collecting the reports can decide if that was expected, for example, the branch store was closed for renovations, or if the get sales report request must be reissued to that branch store.

Developing client code that calls EJB asynchronous methods

You can use the sample code within this topic to develop client code that calls EJB asynchronous methods.

Before you begin

This task assumes that the following interface and bean implementation classes exist:

```
public interface AcmeRemoteInterface {
   void fireAndForgetMethod ();
   Future<Integer> methodWithResults() throws AcmeException1, AcmeException2;
}
```

```
@Stateless
@Remote(AcmeRemoteInterface.class)
@Asynchronous
public class AcmeAsyncBean {
   public void fireAndForgetMethod () {
      // do non-critical work
   }

   public Integer methodWithResults() {
      Integer result;
      // do work, and then return results
      return result;
   }
}
```

About this task

Procedure

- Create client code that calls an asynchronous method where no results are returned, sometimes called a *fire and forget* method. This type of asynchronous method cannot result in application exceptions. However, system exceptions can occur that must be resolved.

  ```
  @EJB AcmeRemoteInterface myAsyncBean;

  try {
     myAsyncBean.fireAndForgetMethod();
  } catch (EJBException ejbex) {
     // Asynchronous method never dispatched, handle system error
  }
  ```

- Create client code that calls an asynchronous method where results are returned.
  - Create client code that calls an asynchronous method where the client waits for up to 5 seconds (the client thread is blocked during this time window) to receive results. Exception handling requirements are the same as in the previous step. For example:

    ```
    myResult = myFutureResult.get(5, TimeUnit.SECONDS);
    ```

  - Create client code that calls an asynchronous method where results are not immediately obtained. After the method has executed, the client retrieves the results. This scheme prevents the client thread from blocking, and the client is free to execute other work while polling for results. Exception

handling requirements are the same as in the previous steps. In this example, the client periodically polls the Future<V> object to determine when the asynchronous method has finished executing. For example:

```
while (!myFutureResult.isDone()) {
// Execute other work while waiting for the asynchronous method to complete.
}

// This call is guaranteed not to block because isDone returned true.
myResult = myFutureResult.get();
```

- Create client code to handle application exceptions. The client code calls an asynchronous method which returns an application exception in the Future<V> object. The following example demonstrates the exception handling code required to determine which application exception occurred.

```
@EJB AcmeRemoteInterface myAsyncBean;

Future<Integer>>myFutureResult = null;
Integer myResult = null;

try {
   myFutureResult = myAsyncBean.methodWithResults();
} catch (EJBException ejbx) {
   // Asynchronous method never dispatched, handle exception
}

// Method is eventually dispatched.  Wait for results.

try {
   myResult = myFutureResult.get();
} catch (ExecutionException ex) {
   // Determine which application exception that occurred during the
   // asynchronous method call.
   Throwable theCause = ex.getCause();
   if (theCause instanceof AcmeException1) {
      // Handle AcmeException1
   } else if (theCause instanceof AcmeException2) {
      // Handle AcmeException2
   } else {
      // Handle other causes.
   }
} catch ( ... ) {
   // Handle other exception.
}
```

- Create client code to identify system exceptions thrown by asynchronous method call during execution. The following example demonstrates the exception handling code required to determine if a system exception occurred.

```
@EJB AcmeRemoteInterface myAsyncBean;

Future<Integer>>myFutureResult = null;
Integer myResult = null;

try {
   myFutureResult = myAsyncBean.methodWithResults();
} catch (EJBException ejbx) {
   // Asynchronous method was not dispatched; handle exception.
}

// Method will eventually be dispatched so block now and wait for results

try {
   myResult = myFutureResult.get();
} catch (ExecutionException ex) {
   // Find the exception class that occurred during the asynchronous method
   Throwable theCause = ex.getCause();
   if (theCause instanceof EJBException) {
      // Handle the EJBException that might be wrapping a system exception
```

```
      // which occurred during the asynchronous method execution.
      Throwable theRootCause = theCause.getCause();
      if (theRootCause != null) {
         // Handle the system exception
      }
   } else ... // handle other causes
} catch (...) {
   // handle other exceptions
}
```

- Optionally create client code to cancel an asynchronous method call. If this attempt is successful, then the Future.isCancelled method returns true and the Future.get methods result in the CancellationException. The following example demonstrates the code required to cancel an asynchronous method call.

```
@EJB AcmeRemoteInterface myAsyncBean;

Future<Integer> myFutureResult = myFutureResult.methodWithResults();
Integer myResult;

if (myFutureResult.cancel(true)) {
   // Asynchronous method was not dispatched.
} else {
   // Asynchronous method already started executing.  The bean can still check
   // whether an attempt was made to cancel the call.
}

if (myFutureResult.isCancelled()) {
   // Asynchronous method call did not start executing because the cancel
   // method returned true in a previous line of the example.
}

try {
   myResult = myFutureResult.get();
} catch (CancellationException ex) {
   // Handle the exception that occurs because the cancel method returned true
   // in a previous line of the example.
}
```

- Optionally create bean code to check whether a client attempted to cancel the asynchronous method call. The following example demonstrates the bean code required to check whether the client attempted to cancel the asynchronous method call. If the client attempted to cancel the work, then the SessionContext.wasCancelCalled method returns true, and the bean code can avoid unnecessary work.

```
@Resource SessionContext myContext;

public Future<Integer> methodWithResults() {
   for (int i = 0; i < 3; i++) {
      // Do one piece of long-running work.

      // Before continuing, check whether the client attempted to cancel this work.
      if (myContext.wasCancelCalled()) {
         throw new AcmeCancelCalledException();
      }
   }

   // ...
}
```

- Pass back multiple output values from the asynchronous method invocation.

  In some cases, a method must pass back multiple pieces of data.

  One way to accomplish this task is by using pass-by-reference semantics. In this approach, an object is passed into the method as a parameter, updated by the method, and then the updated value is available to the client. This approach does work for asynchronous methods, but it is not the optimal pattern.

To return multiple pieces of data, create a wrapper inside the Future object that is returned by the method. In this approach, a wrapper object is defined that contains instance variables which hold the different pieces of data that must be returned. The asynchronous method sets these pieces of data into the wrapper object and returns it, and the client code then retrieves this data from the Future object.

Embedding multiple pieces of data inside the wrapper object is a local or remote, transparent pattern, that identifies exactly when the results are available. In contrast, the traditional pass-by-reference technique does not give the client an easy way to determine when the results are available. The passed in object is not updated until the asynchronous method runs, and the client cannot determine when that has occurred, other than by interrogating the Future object using the Future.isDone() or Future.get() methods.

```
// This is the result object that is returned from the asynchronous method.
// This object is wrappered in a Future object, and it contains the two pieces of data
// that must be returned from the method.
class ResultObject {
     public Boolean myResult;
     pubilc String myInfo;
}
// This is the asynchronous method code that gets the results and returns them.
@Asynchronous
public Future<ResultObject> asyncMethod1(Object someInputData) {
     boolean result = doSomeStuff();
     String info = doSomeMoreStuff();
     ResultObject theResult = new ResultObject();
     theResult.myResult = result;
     theResult.myInfo = info;
     return new javax.ejb.AsyncResult<ResultObject>(theResult);
}
// This is the client code that obtains the ResultObject, and then extracts the needed data from it.
Future<ResultObject> myFutureResult = myBeanRef.asyncMethod1(someInputData);
ResultObject theResult = myFutureResult.get();
boolean didItWork = theResult.myResult;
String explanation = theResult.myInfo;
```

Client programming model for EJB asynchronous methods

As documented in the Enterprise JavaBeans (EJB) 3.1 specification, you can invoke EJB asynchronous methods through the following interface types: local business, remote business, or no-interface view. Invocations through an EJB 2.1 client view, or a web services view, are not allowed.

The interface specification for an EJB asynchronous method must have a return type of void, or of type java.util.concurrent.Future <V>. No other return types are supported on the interface. As documented in the EJB 3.1 specification, the bean implementation method must have the same return type.

When your application does not need to examine the result of an EJB asynchronous method call, use an interface signature with a return type of void. Conversely, when your application needs to examine the result of an EJB asynchronous method call, use an interface with a return type of Future<V>.

In addition to considering whether results are examined, clients must be prepared to handle exceptions. As documented in the EJB 3.1 specification, the client receives an exception if the container is unable to allocate the internal resources required to schedule the asynchronous method for execution. In this case, the client can assume that the asynchronous method does not run. Also, exceptions can occur while the asynchronous method is running on the non-client thread.

Important: When an asynchronous method has a return type of void, the client has no mechanism to retrieve exception information. The EJB container logs an informational message in this case. However, for asynchronous methods that have a return type of Future<V>, the EJB container saves exception information in the Future<V> object. In this case, the get methods associated with the Future<V> object produce the exception, ExecutionException. The client must invoke the getCause method on the ExecutionException to retrieve details about the exception.

Clients must know that the get methods on the Future<V> object block the client thread if the asynchronous method has not finished running when the get method is called. If clients do not want this behavior, they can poll the Future<V> object to determine when the asynchronous method is finished by periodically calling the isDone method.

Finally, clients can use the Future<V> object to cancel an asynchronous method call. If you attempt to cancel an asynchronous method call while it is waiting to run, then it does not run, and other interactions with the Future<V> object reflect the cancellation. Otherwise, if you attempt to cancel an asynchronous method after it has started running, then it continues to run, but the bean method can still determine that the client attempted to cancel the call and respond with an application-specific return value or exception.

Another alternative is for the client to use the get method, which includes a timeout parameter. This get method only waits for results during the specified timeout period. The get method returns to the client as soon as the method has finished running, or when the timeout expires, even if the method has not finished running.

Nested asynchronous calls are supported; an asynchronous method call can be made from within an asynchronous method.

Note: When nesting asynchronous method calls, take into consideration the work manager settings to allow enough resources (maximum number of threads and work request queue size). For more information, read about the EJB container work manager for asynchronous methods.

Read about Developing client code that calls EJB asynchronous methods.

Bean implementation programming model for EJB asynchronous methods

You can configure asynchronous methods on session beans. However, as documented in the Enterprise JavaBeans (EJB) 3.1 specification, asynchronous methods must not be configured on entity beans, or message-driven beans.

Implementations of asynchronous methods must have a return type of void or of type, java.util.concurrent.Future <V>. No other return types are supported on the implementation. As documented in the EJB 3.1 specification, the bean implementation method must have the same return type as the interface specification. For more information, read about the client programming model for EJB asynchronous methods.

Nested asynchronous calls are supported; an asynchronous method call can be made from within an asynchronous method.

Note: When nesting asynchronous method calls, take into consideration the work manager settings to allow enough resources (maximum number of threads and work request queue size). For more information, read about the work manager for asynchronous methods.

Bean implementers must consider how long their asynchronous methods take to run because each request is invoked on a different thread. Another important consideration is the number of asynchronous method requests that an application is likely to start in parallel. These issues are important because the number of threads that are allocated to run asynchronous methods in the server process is a limited resource. Also, the buffer space that is allocated in the server process to queue asynchronous method requests, during times that all the allocated threads are busy, is a limited resource. For more information, read about the client programming model for EJB asynchronous methods.

Finally, bean implementers must follow the EJB 3.1 specification restrictions regarding the transaction attribute settings that are allowed on EJB asynchronous methods. For more information, read about the EJB container work manager for asynchronous methods.

EJB container work manager for asynchronous methods

The default work manager used by the Enterprise JavaBeans (EJB) container to dispatch asynchronous methods is not configurable. The following configuration information is provided to help you understand the limits imposed by this work manager. Remember, one EJB container work manager exists for all asynchronous methods running in the application server process.

The EJB container work manager has the following thread pool settings:

- Minimum number of threads = 1
- Maximum number of threads = 5
- Work request queue size = 0 work objects
- Action taken when buffer overflows = Block
- Remote Future object duration = 86400 seconds

Note: Work request queue size is the maximum number of asynchronous method requests that can be queued while waiting for a thread to become available. If you specify a value of 0 (the default) or blank is specified, the queue size is managed by the run time.

Additionally, the EJB container work manager has configuration settings that specify which service contexts are propagated from the client thread to the work manager thread that runs the asynchronous method. The global transaction service context and the activity session service context are not propagated. The security context, and all of the WebSphere extension contexts, such as work area, internationalization, and so on, are propagated for use on the execution thread.

EJB asynchronous methods settings

Use this page to modify settings on the work manager used in support of Enterprise JavaBeans asynchronous methods.

To view this administrative console page, click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **EJB Container Settings** > **EJB asynchronous method invocation settings**

The Use internal work manager instance and Use custom work manager instance options are *mutually exclusive.*

Use this work manager for asynchronous methods

Specifies a default work manager instance.

The product provides an internal work manager instance for support of EJB asynchronous methods. The internal work manager instance is pre-configured for basic EJB asynchronous method functionality, and provides limited configuration settings.

Clicking this button specifies that you want to use the internal work manager instance to manage your asynchronous method invocations. Selecting this choice precludes the Use custom work manager instance option.

The Use internal work manager instance option is the default. Alternatively, you can use a custom-defined work manager instance.

Use custom work manager instance

Specifies a custom-defined work manager instance.

You can provide a more advanced configuration for EJB asynchronous methods by defining a custom work manager instance.

Selecting this choice allows you to use a work manager instance that you have already defined and configured in a way that is optimal for your environment.

Selecting this choice precludes the Use internal work manager instance option.

Maximum number of threads
Specifies the maximum number of threads that are used in the execution of asynchronous EJB methods. The default is 5.

Work request queue size
Specifies the size of the work request queue. The work request queue is a buffer that holds requested that asynchronous methods until a thread is available to run them on. The default is 0, indicating that the initial size is half way between the minimum and maximum number of threads.

The sum of the maximum number of threads and the work request queue size attributes is the total number of allowable in-progress method requests.

For example, if the maximum number of threads is set to five threads, and the work request queue size is set to 50, then the total number of allowable in-progress method requests is 55.

The default value is 0, indicating that the queue size is managed by the runtime environment. The runtime currently uses the larger of 20 and maxThreads.

Work request queue full action
Specifies the action taken when the thread pool is exhausted, and the work request queue is full. The default is BLOCK.

If set to FAIL, an exception occurs instead of waiting for a thread, or a place in the queue, to become available.

You might want to use this option during development to help identify errors caused by long-running asynchronous methods. You might also use it to help determine the number of threads and queue size that should be configured.

If set to BLOCK, the thread that is requesting that the asynchronous method execution waits until a thread, or a place in the queue, becomes available.

Work Manager JNDI name
Specifies the Java Naming and Directory Interface (JNDI) name used to look up the custom-defined work manager in the namespace.

Remote future object duration
Specifies the amount of time that the server retains the future object of each fire-and-return-results asynchronous method call. If an application does not retrieve the results within the specified period of time, the server purges the results of that method call to prevent memory leakage and a potential OutOfMemory exception. You can specify 0 to never purge the objects; however, specifying a zero value means that the future object never times out and you disable protection from incorrectly written programs that might cause the referenced OutOfMemory exception. The default value is 86400 seconds (24 hours).

Note: If you call the get() or the get(time) method on the future object, then you might decrease performance because blocking can occur until either the work is done or until the specified time has passed. Therefore, to avoid blocking on the get(..) methods, call the isDone() method, which returns immediately. Then, call the get() method after the isDone() method returns true.

Note: This value is only applicable for clients that call the enterprise bean using a remote business interface, the value is not used for local business interface or no-interface views. When the

asynchronous work has completed, the server sets an alarm for the duration specified to the server-side future object. When the alarm is activated, the server releases all the resources associated with the future object, making it unavailable to the client. If the client calls the get() method on the future object before the duration amount of time, the alarm is canceled and all the resources associated with the future object are released.

Developing session beans

Configuring EJB 3.1 session bean methods to be asynchronous

Use this task to configure Enterprise JavaBeans (EJB) 3.1 session bean methods to run asynchronously. You can make some or all of your bean methods asynchronous.

Before you begin

Attention: In EJB 3.1 modules, you can set one or more session bean methods to be asynchronous, broadening parallel processing in your application.

- If you are not already familiar with EJB 3.1 asynchronous methods, read about EJB 3.1 asynchronous methods, client programming model for EJB asynchronous methods, bean implementation programming model for EJB asynchronous methods, and EJB container work manager for asynchronous methods. The topics provide an overview of EJB 3.1 asynchronous methods, describe the client and bean implementation programming models, and discuss the work manager that the EJB container uses to dispatch asynchronous methods.
- Develop a new EJB 3.1 session bean for your application, or change an existing session bean so that it conforms to the EJB 3.1 programming model requirements for asynchronous methods. For general information, see information about developing enterprise beans.

About this task

After you have developed a session bean, complete the following steps to make one or more of the bean methods asynchronous.

Procedure

1. Specify one or more methods of the bean implementation class as asynchronous. This can be accomplished by adding @Asynchronous annotations in your bean source code, by adding <async-method> stanzas in your module deployment descriptor, or by adding a combination of both annotations and deployment descriptor stanzas. You can apply the @Asynchronous annotation or its superclasses only, to your bean implementation class. It cannot be applied to interface classes. Also, when the annotation is applied at the class level, all methods of that class are asynchronous. Likewise, all methods of a bean can be configured as asynchronous by applying "*" as the <method-name> in your deployment descriptor.

   See the following examples of applying the @Asynchronous annotation:

   - Apply the @Asynchronous annotation to one method of a bean with a no-interface view. In this example, the m1 method is synchronous and the m2 method is asynchronous.

```
@Stateless @LocalBean
public class MyLocalBean {

   public void m1() {

      // method code
   }

   @Asynchronous
   public Future<String> m2() {

      // method code
```

```
        return new javax.ejb.AsyncResult("Hello, Async World!");
    }
}
```

Important: The javax.ejb.AsyncResult<V> object is a convenience implementation of the Future<V> interface. See the API documentation for more details.

- Apply the @Asynchronous annotation to the class level of a bean class. In this example, both the m1 method and the m2 method are asynchronous on this no-interface view bean.

```
@Stateless @LocalBean @Asynchronouspublic class MyLocalBean {

    public void m1() {

        // method code
    }

    public Future<String> m2() {

        // method code

        return new javax.ejb.AsyncResult("Hello, Async World!");
    }

}
```

- Apply the @Asynchronous annotation to one method of a bean implementation class. In this example, the m1 method is synchronous and the m2 method is asynchronous. This example also demonstrates how the return types might differ between the business interface and the implementation class.

```
public interface MyIntf {

    public void m1();

    public Future<Integer> m2();

}
@Stateless @Local(MyIntf.class)
public class MyBean {

    public void m1() {

        // method code
    }

    @Asynchronous
    public Integer m2() {

        // method code

        return new Integer(3);
    }
}
```

- Apply the @Asynchronous annotation to the class level of a bean implementation class. In this example, both the m1 method and the m2 method are asynchronous.

```
@Stateless @Local(MyIntf.class) @Asynchronous
public class MyBean {

    public void m1() {

        // method code
    }

    public Integer m2() {
```

```
        // method code

        return new Integer(8);
    }
}
```

See the following examples of modifying the EJB module deployment descriptor, `ejb-jar.xml`:

- In this example all business methods of the FullAyncBean bean implementation class and its superclasses are configured as asynchronous with the wildcard (*) method-name element.

```
<session>
   <display-name>FullAsyncEJB</display-name>
   <ejb-name>FullAsyncBean</ejb-name>
   <business-local>com.ibm.sample.async.ejb.FullAsyncIntf</business-local>
   <ejb-class>com.ibm.sample.async.ejb.FullAsyncBean</ejb-class>
   <session-type>Stateless</session-type>   <async-method>
      <method-name>*</method-name>
   </async-method>
</session>
```

- In this example only the specified methods and signatures -- all methods named m1 and the method m2 with a single String parameter -- are configured as asynchronous on the PartiallyAsyncBean bean implementation class.

```
<session>
   <display-name>PartiallyAsyncEJB</display-name>
   <ejb-name>PartiallyAsyncEJB</ejb-name>
   <business-local>com.ibm.sample.async.ejb.PartiallyAsyncIntf</business-local>
   <ejb-class>com.ibm.sample.async.ejb.PartiallyAsyncBean</ejb-class>
   <session-type>Stateless</session-type>   <async-method>
      <method-name>m1</method-name>
   </async-method>
   <async-method>
      <method-name>m2</method-name>
      <method-params>
         <method-param>java.lang.String</method-param>
      </method-params>
   </async-method>
</session>
```

See the following examples of applying a combination of the @Asynchronous annotation in the bean source code and modifying the EJB module deployment descriptor, `ejb-jar.xml`:

- In this example the @Asynchronous annotation configures method m2 to be asynchronous, and the deployment descriptor configures method m1 to also be an asynchronous method.

```
@Stateless @LocalBean
public class MyLocalBean {

   public void m1() {

      // method code
   }

   @Asynchronous
   public Future<String> m2() {

      // method code

      return new javax.ejb.AsyncResult("Hello, Async World!");
   }
}

<session>
   <display-name>MyLocalEJB</display-name>
   <ejb-name>MyLocalEJB</ejb-name>
   <local-bean/>
   <ejb-class>com.ibm.sample.async.ejb.MyLocalBean</ejb-class>
```

```
   <session-type>Stateless</session-type>   <async-method>
      <method-name>m1</method-name>
   </async-method>
</session>
```

- In this example the @Asynchronous annotation for method m2 is ignored because the deployment descriptor header contains the metadata-complete="true" flag. This flag causes configuration information to only be taken from the deployment descriptor elements. The result is that only method m1 of the MyLocalBean implementation is configured to be asynchronous.

```
@Stateless @LocalBean
public class MyLocalBean {

   public void m1() {

      // method code
   }

   @Asynchronous
   public Future<String> m2() {

      // method code

      return new javax.ejb.AsyncResult("Hello, Async World!");
   }
}

<ejb-jar id="ejb-jar_ID" ...
metadata-complete="true" version="3.1">
...
<session>
   <display-name>MyLocalEJB</display-name>
   <ejb-name>MyLocalEJB</ejb-name>
   <local-bean/>
   <ejb-class>com.ibm.sample.async.ejb.MyLocalBean</ejb-class>
   <session-type>Stateless</session-type>   <async-method>
      <method-name>m1</method-name>
   </async-method>
</session>
...
</ejb-jar>
```

2. Verify that the transaction attribute applied to any asynchronous method is either REQUIRED, REQUIRES_NEW, or NOT_SUPPORTED. These transaction attribute types are the only transaction attribute types supported on asynchronous methods. You can complete this action by either applying @TransactionAttribute annotations in the bean source code, by adding <container-transaction> stanzas in the `ejb-jar.xml` file, or by adding a combination of both annotations and <container-transaction> stanzas in the deployment descriptor.

   See the following example of setting the transaction attribute of an asynchronous method using annotations:

```
@Singleton @LocalBean
public class FullAsyncBean {
 @Asynchronous
 @TransactionAttribute(REQUIRED) // the default; specified for illustration
 public void m1() {
  // ...
 }

 @Asynchronous
 @TransactionAttribute(NOT_SUPPORTED)
 public void m2() {
  // ...
 }

 @Asynchronous
```

```
 @TransactionAttribute(REQUIRES_NEW)
 public void m3() {
  // ...
 }

 // ...
}
```

See the following example of setting the transaction attribute of an asynchronous method using the XML deployment descriptor:

```
  <assembly-descriptor>
    <container-transaction>
      <method>
        <ejb-name>FullAsyncBean</ejb-name>
        <method-name>m1</method-name>
      </method>
      <trans-attribute>Required</trans-attribute>
    </container-transaction>

    <container-transaction>
      <method>
        <ejb-name>FullAsyncBean</ejb-name>
        <method-name>m2</method-name>
      </method>
      <trans-attribute>NotSupported</trans-attribute>
    </container-transaction>

    <container-transaction>
      <method>
        <ejb-name>FullAsyncBean</ejb-name>
        <method-name>m3</method-name>
      </method>
      <trans-attribute>RequiresNew</trans-attribute>
    </container-transaction>
  </assembly-descriptor>
```

See the following example of using a combination of both annotations and the XML deployment descriptor to configure the transaction attributes of a bean. In this example the deployment descriptor stanzas for method m3 override the class level annotation. The result is that method m3 is configured as REQUIRES_NEW, while methods m1 and m2 are configured as REQUIRED:

```
@Singleton @LocalBean
@Asynchronous
@TransactionAttribute(REQUIRED) // the default; specified for illustration
public class FullAsyncBean {

 public void m1() {
  // ...
 }

 public void m2() {
  // ...
 }

 public void m3() {
  // ...
 }

 // ...
}

<assembly-descriptor>

   <container-transaction>
      <method>
         <ejb-name>FullAsyncBean</ejb-name>
         <method-name>m3</method-name>
```

```
        </method>
        <trans-attribute>RequiresNew</trans-attribute>
      </container-transaction>

  </assembly-descriptor>
```

What to do next

Continue to develop additional components for your application, or if you have finished all components required by your application, assemble and deploy your application. See information about assembling EJB modules and deploying EJB modules.

When you run your application, if it fails when it first attempts to use a session bean that has an asynchronous method, a configuration error might exist. Check the system log file for configuration error messages.

Analyze the trace data or forward it to the appropriate organization for analysis. EJB asynchronous method scheduling and invocation are traced in the EJB container trace. For instructions on enabling this trace see the information about enabling trace on a running server. To analyze trace data, see information about trace output.

Configuring remote asynchronous EJB method results

Use this task to set the maximum number of unclaimed results for a remote asynchronous Enterprise JavaBeans (EJB) method call.

About this task

When a remote asynchronous EJB method is called, the server must save the results of the remote method invocation until the client claims the results using the Future.get method. If the client never claims the result, unclaimed results can accumulate in the server and use memory. To avoid using too much memory, the server limits the number of unclaimed results to 1000 by default. If the number of unclaimed results approaches or exceeds the limit, the server issues the `CNTR0328W` warning.

Procedure

1. Optional: Open the administrative console.
2. Select **Servers**.
3. Select **Server Types**.
4. Select **WebSphere application servers**.
5. Select the server that you want to configure.
6. From Server Infrastructure, select **Java and Process Management Process definition.**
7. From Additional Properties, select **Java Virtual Machine** .
8. In the Additional Properties area, select **Custom Properties** .
9. On the Application servers page, click **New** to specify an arbitrary name and value pair for your server.
10. In the **Name** entry field, type: `com.ibm.websphere.ejbcontainer.maxUnclaimedAsyncResults`
11. In the **Value** entry field, enter the wanted maximum number of unclaimed results. The special value `0` is interpreted as unlimited. The default value is `1000`.
12. Click **OK**.
13. Save the configuration.
14. Restart the server.

Results

The maximum number of unclaimed asynchronous EJB method results for all EJBs is set.

Configuring EJB asynchronous methods using scripting

Use **wsadmin** scripting to configure Enterprise JavaBeans (EJB) asynchronous methods.

Before you begin

You have working knowledge of Jacl or Jython and **wsadmin** scripting.

About this task

The behavior for EJB asynchronous methods is configured using the EJBAsync configuration object in the `server.xml` file. If you are using EJB asynchronous methods, then you might must update the EJBAsync configuration object to obtain the best settings for your environment. The EJBAsync configuration object exists at the server level. This means that each server in a multiple-server environment has its own EJBAsync configuration object and must be configured individually.

Procedure

1. Launch the **wsadmin** scripting tool using the Jython scripting language.
2. Determine the attributes on the EJBAsync configuration object that must be updated. You can update the following attributes on the EJBAsync configuration object:

Table 59. Attributes on EJBAsync configuration object. This table describes the attributes on the EJBAsync configuration object.

Attribute	Description
maxThreads	Specifies the maximum number of threads that are used in the execution of asynchronous EJB methods. The default value is `5`.
workReqQSize	Specifies the size of the work request queue. The work request queue is a buffer that holds requested asynchronous methods until a thread is available to run them on. The sum of the maxThreads and the workReqQSize attributes is the total number of allowable in progress method requests. For example, if the maxThreads is set to `5` threads, and the workReqQSize is set to `50`, then the total number of allowable in-progress method requests is `55`. The default value is 0, indicating that the queue size is managed by the runtime environment. The run time currently uses the larger of 20 and maxThreads.
workReqQFullAction	Specifies the action taken when the thread pool is exhausted, and work request queue is full. If set to 1, an exception occurs instead of waiting for a thread, or a place in the queue, to become available. If set to 0, the thread that is requesting the asynchronous method execution waits until a thread, or place in the queue, becomes available. The default value is 0.
customWorkManagerJNDIName	Specifies the Java Naming and Directory Interface (JNDI) name used to look up the custom defined work manager in the namespace. The default value is null.
useCustomDefinedWM	Specifies whether a custom-defined work manager instance is used, or the default internal work manager instance. When the useCustomDefinedWM attribute is set to true, this means that a custom work manager instance is used. In this case, the customWorkManagerJNDIName attribute must be set, and all other attributes are ignored. When the useCustomDefinedWM attribute is set to `false`, the default, internal work manager instance is used. In this case, the customWorkManagerJNDIName attribute is ignored, and all other attributes are used to help configure the default work manager instance. The default value is false.

Table 59. Attributes on EJBAsync configuration object (continued). This table describes the attributes on the EJBAsync configuration object.

Attribute	Description
futureTimeout	Specifies the amount of time, in seconds, that the server-side future object, which is created as a result of running a fire-and-return asynchronous method, is available. The server-side future object is not valid after you call the get() method, and a value is returned to the remote client. To avoid memory leaks, you must call the get() method on the future object, or specify a positive and non-zero future duration value. A future duration value of zero indicates that the future object never times out. The default value is `86400`, which means that the future object expires and gets cleaned up by the application server after 24 hours and is no longer available. A org.omg.CORBA.OBJECT_NOT_EXIST exception is thrown when a call to the get() method is made after the future object expires. **Note:** This value is only applicable for clients that call the enterprise bean using a remote business interface; the value is not used for local business interface or no-interface views. When the asynchronous work has completed, the server sets an alarm for the duration specified to the server-side future object. When the alarm is activated, the server releases all the resources associated with the future object, making it unavailable to the client. If the client calls the get() method on the future object before the duration amount of time, the alarm is canceled and all the resources associated with the future object are released. **Note:** This attribute might affect the number of future objects on the server. Use the AsynchFutureObjectCount PMI statistic to determine the count of open FutureObjects on the server, which can help you determine whether applications are accumulating future objects without calling the get() method on those objects. See the topic, Enterprise bean counters, for more information.

3. Obtain a reference to the correct EJBAsync configuration object and store it in a variable.

   Using Jacl:

   ```
   set async [$AdminConfig list EJBAsync]
   ```

   Using Jython:

   ```
   async = AdminConfig.list('EJBAsync')
   ```

   If you have a multiple-server environment, then multiple EJBAsync configuration objects are returned. Programmatically loop over the list and select the EJBAsync configuration object that corresponds to the server you must update.

   In a multiple-server environment, as an alternative to programmatically looping over the list of EJBAsync objects, you can manually select the correct EJBAsync object and copy and paste it into your variable.

   For example, the output of the `AdminConfig list` command is:

   ```
   (cells/myNode04Cell/nodes/myCellManager01/servers/dmgr|server.xml#EJBAsync_1)(cells/
   myNode04Cell/nodes/myNode04/servers/server1|server.xml#EJBAsync_1247498700906)
   ```

   You can copy and paste the reference for the needed EJBAsync object into your variable.

   Using Jacl:

   ```
   set async "(cells/myNode04Cell/nodes/myNode04/servers/server1|server.xml#EJBAsync_1247498700906)"
   ```

   Using Jython:

   ```
   async = "(cells/myNode04Cell/nodes/myNode04/servers/server1|server.xml#EJBAsync_1247498700906)"
   ```

4. Update attributes on the EJBAsync configuration object.

   Update attributes on the EJBAsync configuration object using the **AdminConfig modify** command. As input to the command, specify the EJBAsync reference that you obtained in the previous step, and a list of attributeName and attributeValue combinations.

   To set a max thread count of `10` threads, a queue size of `15`, and a futureTimeout of `3600` seconds:

   Using Jacl:

   ```
   set update "{maxThreads 10} {workReqQSize 15} {futureTimeout 3600}"
   $AdminConfig modify $async $update
   ```

   Using Jython:

   ```
   AdminConfig.modify(async, '[ [maxThreads "10"] [workReqQSize "15"] [futureTimeout "3600"] ]')
   ```

5. Save the configuration changes.

   Using Jython:

```
AdminConfig.save()
```

Using Jacl:

```
$AdminConfig save
```

6. In a Network Deployment environment only, synchronize the node.

   Using Jacl:

   ```
   set sync1 [$AdminControl completeObjectName type=NodeSync,node=<your node>,*]
   $AdminControl invoke $sync1 sync
   ```

   Using Jython:

   ```
   sync1 = AdminControl.completeObjectName('type=NodeSync,node=<your node>,*')
   AdminControl.invoke(sync1, 'sync')
   ```

   You must run the node synchronization in these examples while connected to the server.

Results

As a result of your updates, the EJBAsync configuration object now reflects the attribute values that you specified. Restart your server so that the changes are updated on the server.

EJB 3.1 asynchronous methods

The Enterprise JavaBeans™ (EJB) 3.1 specification includes functionality that application developers can use to configure EJB asynchronous methods, which are run on a separate thread from the caller thread.

This mechanism decouples the client invocation request from the actual method execution. The client thread can continue doing other work while the EJB method is run on a separate thread, as directed by the EJB container.

Later, the client might want to examine the result of the asynchronous method execution, which is sometimes referred to as *fire and return*. In this case, the EJB container returns to the client an object that implements the java.util.concurrent.Future<V> interface. The client can use this object to check status, results, or exceptions from the asynchronous method invocation. Alternatively, asynchronous methods might not return any results, which is sometimes referred to as *fire and forget.*

For more details, see information about how to use EJB asynchronous methods in your application.

Here are some example usage scenarios for EJB asynchronous methods:

- An application has multiple, independent, pieces of work that all must be executed to produce a final result. For example, suppose that a travel reservation consists of three parts:
  1. Making a plane reservation.
  2. Making a rental car reservation.
  3. Making a hotel reservation.

  In this example, a client can use EJB asynchronous methods to process the reservation requests in parallel. After all three reservation methods run, the client aggregates the results into a complete travel reservation.
- An application has multiple, independent, pieces of work that it must run, and the application is not concerned about the results of this work. For example, suppose that a retailer has four branch stores, and the home office wants to print a sales report from each store when the business day ends. The application developer can use EJB asynchronous methods as a batch processing mechanism. Multiple EJB method calls can be used to send a batch of get sales report requests, one to each branch store.

  In this example, presumably the application does not need to check for results from these method calls. Perhaps this is handled by the home office employee who picks up the sales reports from a printer the next morning. Suppose that one of the branch stores failed to provide the requested report. The person collecting the reports can decide if that was expected, for example, the branch store was closed for renovations, or if the get sales report request must be reissued to that branch store.

Developing client code that calls EJB asynchronous methods

You can use the sample code within this topic to develop client code that calls EJB asynchronous methods.

Before you begin

This task assumes that the following interface and bean implementation classes exist:

```
public interface AcmeRemoteInterface {
   void fireAndForgetMethod ();
   Future<Integer> methodWithResults() throws AcmeException1, AcmeException2;
}
```

```
@Stateless
@Remote(AcmeRemoteInterface.class)
@Asynchronous
public class AcmeAsyncBean {
   public void fireAndForgetMethod () {
      // do non-critical work
   }

   public Integer methodWithResults() {
      Integer result;
      // do work, and then return results
      return result;
   }
}
```

About this task

Procedure

- Create client code that calls an asynchronous method where no results are returned, sometimes called a *fire and forget* method. This type of asynchronous method cannot result in application exceptions. However, system exceptions can occur that must be resolved.

  ```
  @EJB AcmeRemoteInterface myAsyncBean;

  try {
     myAsyncBean.fireAndForgetMethod();
  } catch (EJBException ejbex) {
     // Asynchronous method never dispatched, handle system error
  }
  ```

- Create client code that calls an asynchronous method where results are returned.
  - Create client code that calls an asynchronous method where the client waits for up to 5 seconds (the client thread is blocked during this time window) to receive results. Exception handling requirements are the same as in the previous step. For example:

    ```
    myResult = myFutureResult.get(5, TimeUnit.SECONDS);
    ```

  - Create client code that calls an asynchronous method where results are not immediately obtained. After the method has executed, the client retrieves the results. This scheme prevents the client thread from blocking, and the client is free to execute other work while polling for results. Exception handling requirements are the same as in the previous steps. In this example, the client periodically polls the Future<V> object to determine when the asynchronous method has finished executing. For example:

    ```
    while (!myFutureResult.isDone()) {
    // Execute other work while waiting for the asynchronous method to complete.
    }

    // This call is guaranteed not to block because isDone returned true.
    myResult = myFutureResult.get();
    ```

- Create client code to handle application exceptions. The client code calls an asynchronous method which returns an application exception in the Future<V> object. The following example demonstrates the exception handling code required to determine which application exception occurred.

```
@EJB AcmeRemoteInterface myAsyncBean;

Future<Integer>>myFutureResult = null;
Integer myResult = null;

try {
   myFutureResult = myAsyncBean.methodWithResults();
} catch (EJBException ejbx) {
   // Asynchronous method never dispatched, handle exception
}

// Method is eventually dispatched.  Wait for results.

try {
   myResult = myFutureResult.get();
} catch (ExecutionException ex) {
   // Determine which application exception that occurred during the
   // asynchronous method call.
   Throwable theCause = ex.getCause();
   if (theCause instanceof AcmeException1) {
      // Handle AcmeException1
   } else if (theCause instanceof AcmeException2) {
      // Handle AcmeException2
   } else {
      // Handle other causes.
   }
} catch ( ... ) {
   // Handle other exception.
}
```

- Create client code to identify system exceptions thrown by asynchronous method call during execution. The following example demonstrates the exception handling code required to determine if a system exception occurred.

```
@EJB AcmeRemoteInterface myAsyncBean;

Future<Integer>>myFutureResult = null;
Integer myResult = null;

try {
   myFutureResult = myAsyncBean.methodWithResults();
} catch (EJBException ejbx) {
   // Asynchronous method was not dispatched; handle exception.
}

// Method will eventually be dispatched so block now and wait for results

try {
   myResult = myFutureResult.get();
} catch (ExecutionException ex) {
   // Find the exception class that occurred during the asynchronous method
   Throwable theCause = ex.getCause();
   if (theCause instanceof EJBException) {
      // Handle the EJBException that might be wrapping a system exception
      // which occurred during the asynchronous method execution.
      Throwable theRootCause = theCause.getCause();
      if (theRootCause != null) {
         // Handle the system exception
      }
   } else ... // handle other causes
} catch (...) {
   // handle other exceptions
}
```

- Optionally create client code to cancel an asynchronous method call. If this attempt is successful, then the Future.isCancelled method returns true and the Future.get methods result in the CancellationException. The following example demonstrates the code required to cancel an asynchronous method call.

```
@EJB AcmeRemoteInterface myAsyncBean;

Future<Integer> myFutureResult = myFutureResult.methodWithResults();
Integer myResult;

if (myFutureResult.cancel(true)) {
   // Asynchronous method was not dispatched.
} else {
   // Asynchronous method already started executing.  The bean can still check
   // whether an attempt was made to cancel the call.
}

if (myFutureResult.isCancelled()) {
   // Asynchronous method call did not start executing because the cancel
   // method returned true in a previous line of the example.
}

try {
   myResult = myFutureResult.get();
} catch (CancellationException ex) {
   // Handle the exception that occurs because the cancel method returned true
   // in a previous line of the example.
}
```

- Optionally create bean code to check whether a client attempted to cancel the asynchronous method call. The following example demonstrates the bean code required to check whether the client attempted to cancel the asynchronous method call. If the client attempted to cancel the work, then the SessionContext.wasCancelCalled method returns true, and the bean code can avoid unnecessary work.

```
@Resource SessionContext myContext;

public Future<Integer> methodWithResults() {
   for (int i = 0; i < 3; i++) {
      // Do one piece of long-running work.

      // Before continuing, check whether the client attempted to cancel this work.
      if (myContext.wasCancelCalled()) {
         throw new AcmeCancelCalledException();
      }
   }

   // ...
}
```

- Pass back multiple output values from the asynchronous method invocation.

  In some cases, a method must pass back multiple pieces of data.

  One way to accomplish this task is by using pass-by-reference semantics. In this approach, an object is passed into the method as a parameter, updated by the method, and then the updated value is available to the client. This approach does work for asynchronous methods, but it is not the optimal pattern.

  To return multiple pieces of data, create a wrapper inside the Future object that is returned by the method. In this approach, a wrapper object is defined that contains instance variables which hold the different pieces of data that must be returned. The asynchronous method sets these pieces of data into the wrapper object and returns it, and the client code then retrieves this data from the Future object.

  Embedding multiple pieces of data inside the wrapper object is a local or remote, transparent pattern, that identifies exactly when the results are available. In contrast, the traditional pass-by-reference technique does not give the client an easy way to determine when the results are available. The passed

in object is not updated until the asynchronous method runs, and the client cannot determine when that has occurred, other than by interrogating the Future object using the Future.isDone() or Future.get() methods.

```
// This is the result object that is returned from the asynchronous method.
// This object is wrappered in a Future object, and it contains the two pieces of data
// that must be returned from the method.
class ResultObject {
     public Boolean myResult;
     pubilc String myInfo;
}
// This is the asynchronous method code that gets the results and returns them.
@Asynchronous
public Future<ResultObject> asyncMethod1(Object someInputData) {
     boolean result = doSomeStuff();
     String info = doSomeMoreStuff();
     ResultObject theResult = new ResultObject();
     theResult.myResult = result;
     theResult.myInfo = info;
     return new javax.ejb.AsyncResult<ResultObject>(theResult);
}
// This is the client code that obtains the ResultObject, and then extracts the needed data from it.
Future<ResultObject> myFutureResult = myBeanRef.asyncMethod1(someInputData);
ResultObject theResult = myFutureResult.get();
boolean didItWork = theResult.myResult;
String explanation = theResult.myInfo;
```

Client programming model for EJB asynchronous methods:

As documented in the Enterprise JavaBeans (EJB) 3.1 specification, you can invoke EJB asynchronous methods through the following interface types: local business, remote business, or no-interface view. Invocations through an EJB 2.1 client view, or a web services view, are not allowed.

The interface specification for an EJB asynchronous method must have a return type of void, or of type java.util.concurrent.Future <V>. No other return types are supported on the interface. As documented in the EJB 3.1 specification, the bean implementation method must have the same return type.

When your application does not need to examine the result of an EJB asynchronous method call, use an interface signature with a return type of void. Conversely, when your application needs to examine the result of an EJB asynchronous method call, use an interface with a return type of Future<V>.

In addition to considering whether results are examined, clients must be prepared to handle exceptions. As documented in the EJB 3.1 specification, the client receives an exception if the container is unable to allocate the internal resources required to schedule the asynchronous method for execution. In this case, the client can assume that the asynchronous method does not run. Also, exceptions can occur while the asynchronous method is running on the non-client thread.

Important: When an asynchronous method has a return type of void, the client has no mechanism to retrieve exception information. The EJB container logs an informational message in this case. However, for asynchronous methods that have a return type of Future<V>, the EJB container saves exception information in the Future<V> object. In this case, the get methods associated with the Future<V> object produce the exception, ExecutionException. The client must invoke the getCause method on the ExecutionException to retrieve details about the exception.

Clients must know that the get methods on the Future<V> object block the client thread if the asynchronous method has not finished running when the get method is called. If clients do not want this behavior, they can poll the Future<V> object to determine when the asynchronous method is finished by periodically calling the isDone method.

Finally, clients can use the Future<V> object to cancel an asynchronous method call. If you attempt to cancel an asynchronous method call while it is waiting to run, then it does not run, and other interactions with the Future<V> object reflect the cancellation. Otherwise, if you attempt to cancel an asynchronous method after it has started running, then it continues to run, but the bean method can still determine that the client attempted to cancel the call and respond with an application-specific return value or exception.

Another alternative is for the client to use the get method, which includes a timeout parameter. This get method only waits for results during the specified timeout period. The get method returns to the client as soon as the method has finished running, or when the timeout expires, even if the method has not finished running.

Nested asynchronous calls are supported; an asynchronous method call can be made from within an asynchronous method.

Note: When nesting asynchronous method calls, take into consideration the work manager settings to allow enough resources (maximum number of threads and work request queue size). For more information, read about the EJB container work manager for asynchronous methods.

Read about Developing client code that calls EJB asynchronous methods.

Bean implementation programming model for EJB asynchronous methods

You can configure asynchronous methods on session beans. However, as documented in the Enterprise JavaBeans (EJB) 3.1 specification, asynchronous methods must not be configured on entity beans, or message-driven beans.

Implementations of asynchronous methods must have a return type of void or of type, java.util.concurrent.Future <V>. No other return types are supported on the implementation. As documented in the EJB 3.1 specification, the bean implementation method must have the same return type as the interface specification. For more information, read about the client programming model for EJB asynchronous methods.

Nested asynchronous calls are supported; an asynchronous method call can be made from within an asynchronous method.

Note: When nesting asynchronous method calls, take into consideration the work manager settings to allow enough resources (maximum number of threads and work request queue size). For more information, read about the work manager for asynchronous methods.

Bean implementers must consider how long their asynchronous methods take to run because each request is invoked on a different thread. Another important consideration is the number of asynchronous method requests that an application is likely to start in parallel. These issues are important because the number of threads that are allocated to run asynchronous methods in the server process is a limited resource. Also, the buffer space that is allocated in the server process to queue asynchronous method requests, during times that all the allocated threads are busy, is a limited resource. For more information, read about the client programming model for EJB asynchronous methods.

Finally, bean implementers must follow the EJB 3.1 specification restrictions regarding the transaction attribute settings that are allowed on EJB asynchronous methods. For more information, read about the EJB container work manager for asynchronous methods.

EJB container work manager for asynchronous methods

The default work manager used by the Enterprise JavaBeans (EJB) container to dispatch asynchronous methods is not configurable. The following configuration information is provided to help you understand the limits imposed by this work manager. Remember, one EJB container work manager exists for all asynchronous methods running in the application server process.

The EJB container work manager has the following thread pool settings:

- Minimum number of threads = 1
- Maximum number of threads = 5
- Work request queue size = 0 work objects
- Action taken when buffer overflows = Block
- Remote Future object duration = 86400 seconds

Note: Work request queue size is the maximum number of asynchronous method requests that can be queued while waiting for a thread to become available. If you specify a value of 0 (the default) or blank is specified, the queue size is managed by the run time.

Additionally, the EJB container work manager has configuration settings that specify which service contexts are propagated from the client thread to the work manager thread that runs the asynchronous method. The global transaction service context and the activity session service context are not propagated. The security context, and all of the WebSphere extension contexts, such as work area, internationalization, and so on, are propagated for use on the execution thread.

EJB asynchronous methods settings

Use this page to modify settings on the work manager used in support of Enterprise JavaBeans asynchronous methods.

To view this administrative console page, click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **EJB Container Settings** > **EJB asynchronous method invocation settings**

The Use internal work manager instance and Use custom work manager instance options are *mutually exclusive.*

Use this work manager for asynchronous methods:

Specifies a default work manager instance.

The product provides an internal work manager instance for support of EJB asynchronous methods. The internal work manager instance is pre-configured for basic EJB asynchronous method functionality, and provides limited configuration settings.

Clicking this button specifies that you want to use the internal work manager instance to manage your asynchronous method invocations. Selecting this choice precludes the Use custom work manager instance option.

The Use internal work manager instance option is the default. Alternatively, you can use a custom-defined work manager instance.

Use custom work manager instance:

Specifies a custom-defined work manager instance.

You can provide a more advanced configuration for EJB asynchronous methods by defining a custom work manager instance.

Selecting this choice allows you to use a work manager instance that you have already defined and configured in a way that is optimal for your environment.

Selecting this choice precludes the Use internal work manager instance option.

Maximum number of threads:

Specifies the maximum number of threads that are used in the execution of asynchronous EJB methods. The default is 5.

Work request queue size:

Specifies the size of the work request queue. The work request queue is a buffer that holds requested that asynchronous methods until a thread is available to run them on. The default is 0, indicating that the initial size is half way between the minimum and maximum number of threads.

The sum of the maximum number of threads and the work request queue size attributes is the total number of allowable in-progress method requests.

For example, if the maximum number of threads is set to five threads, and the work request queue size is set to 50, then the total number of allowable in-progress method requests is 55.

The default value is 0, indicating that the queue size is managed by the runtime environment. The runtime currently uses the larger of 20 and maxThreads.

Work request queue full action:

Specifies the action taken when the thread pool is exhausted, and the work request queue is full. The default is BLOCK.

If set to FAIL, an exception occurs instead of waiting for a thread, or a place in the queue, to become available.

You might want to use this option during development to help identify errors caused by long-running asynchronous methods. You might also use it to help determine the number of threads and queue size that should be configured.

If set to BLOCK, the thread that is requesting that the asynchronous method execution waits until a thread, or a place in the queue, becomes available.

Work Manager JNDI name:

Specifies the Java Naming and Directory Interface (JNDI) name used to look up the custom-defined work manager in the namespace.

Remote future object duration:

Specifies the amount of time that the server retains the future object of each fire-and-return-results asynchronous method call. If an application does not retrieve the results within the specified period of time, the server purges the results of that method call to prevent memory leakage and a potential OutOfMemory exception. You can specify 0 to never purge the objects; however, specifying a zero value means that the future object never times out and you disable protection from incorrectly written programs that might cause the referenced OutOfMemory exception. The default value is 86400 seconds (24 hours).

Note: If you call the get() or the get(time) method on the future object, then you might decrease performance because blocking can occur until either the work is done or until the specified time has passed. Therefore, to avoid blocking on the get(..) methods, call the isDone() method, which returns immediately. Then, call the get() method after the isDone() method returns true.

Note: This value is only applicable for clients that call the enterprise bean using a remote business interface, the value is not used for local business interface or no-interface views. When the asynchronous work has completed, the server sets an alarm for the duration specified to the server-side future object. When the alarm is activated, the server releases all the resources

associated with the future object, making it unavailable to the client. If the client calls the get() method on the future object before the duration amount of time, the alarm is canceled and all the resources associated with the future object are released.

Developing stateful session beans

You can create a bean implementation class for a stateful session bean as introduced in the Enterprise JavaBeans™ (EJB) 1.0 specification and significantly simplified by the EJB 3.0 specification. A stateful bean is a type of session bean that is intended for use by a single client during its lifetime and maintains a conversational state with the client that is calling it.

Before you begin

Make sure that you understand the inheritance rules for each annotation you implement. For example, the @TransactionManagement annotation is coded on the stateful session bean class only. You cannot use the @TransactionManagement annotation in the class that it extends, or any class higher in the class inheritance tree.

About this task

Stateful session beans can have the following views: no-interface local view (new in EJB 3.1), business local, business remote, EJB 2.1 local, and EJB2.1 remote client views. One example is a shopping cart where the client adds items to the cart over the course of an on-line shopping session.

The following example shows a basic stateful session bean:

```
package com.ibm.example;

public interface ShoppingCart {
    void addToCart (Object o);
    Collection getContents();
}

package com.ibm.example;

@Stateful
public class ShoppingCartBean implements ShoppingCart {
    private ArrayList contents = new ArrayList();

    public void addToCart (Object o) {
        contents.add(o);
    }
    public Collection getContents() {
        return contents;
    }
}
```

As with other enterprise bean types, you can also declare metadata for stateful session beans in the deployment descriptor rather than using annotations; for example:

```
<?xml version="1.0"?>
<ejb-jar
  xmlns="http://java.sun.com/xml/ns/javaee"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://java.sun.com/xml/ns/javaee http://java.sun.com/xml/ns/javaee/ejb-jar_3_1.xsd"
  version="3.1">
  <enterprise-beans>
    <ejb-name>ShoppingCartBean</ejb-name>
    <business-local>com.ibm.example.ShoppingCart</business-local>
    <ejb-class>com.ibm.example.ShoppingCartBean</ejb-class>
    <session-type>Stateful</session-type>
  </enterprise-beans>
</ejb-jar>
```

Procedure

- Code the initialization and destruction methods, understanding that they run in an unspecified security context and an unspecified transaction context. During initialization, the instance is created, dependency injection occurs, and PostConstruct life cycle interceptor callbacks are invoked. The PreDestroy life cycle interceptor callbacks are invoked for a stateful session bean when a remove method is called. Also keep in mind that the PreDestroy life cycle interceptor callbacks are not called if the stateful session bean times out while in the passive state, or if an unexpected exception occurs during a method invocation on the bean and the bean is discarded.
- Use PrePassivate and PostActivate methods if the stateful session bean can contain state that is not serializable. The container can passivate a stateful session bean instance anytime that it is not enlisted in a transaction or currently running a method request. The stateful session bean instance is moved to the passive state by serializing all the state data. If any of the state data does not serialize, the stateful session bean instance is discarded by the container.
- Consider implementing the optional javax.ejb.SessionSynchronization interface if the state data of the stateful session bean needs to be reset after a transaction rollback. The state data of a stateful session bean is not transactional and is not automatically reset to the initial state as the result of a transaction rollback. By implementing the afterCompletion method of the javax.ejb.SessionSynchronization interface, the stateful session bean instance might reset itself to the initial or consistent state.
- Use the @AccessTimeout notation to prohibit concurrent client requests or limit how long a method waits for the instance lock to be granted. By default, the container allows concurrent client requests, but serializes all method calls and container-invoked callbacks to prevent multi-threaded access to the stateful session bean instance. This behavior is like using container-managed concurrency with write locks for singleton session beans. However, unlike singleton session beans, stateful session beans cannot be configured to use bean-managed concurrency and the lock type cannot be changed. Only the access-timeout value can be modified for stateful session beans. The following code example illustrates a stateful session bean with a concurrent access-timeout value that prohibits concurrent client requests:

```
package com.ibm.example;
@Stateful
public class ShoppingCartBean implements ShoppingCart {
    private ArrayList contents = new ArrayList();

    @AccessTimeout( value=0 )
    public void addToCart (Object o) {
                contents.add(o);
    }
    public Collection getContents() {
                return contents;
    }
}
 package com.ibm.example;
@Stateful
public class ShoppingCartBean implements ShoppingCart {
    private ArrayList contents = new ArrayList();

    @AccessTimeout( value=0 )
    public void addToCart (Object o) {
                contents.add(o);
    }
    public Collection getContents() {
                return contents;
    }
}
```

  If no annotation is provided, the default behavior is to wait until a lock is granted. No time limit exists for how long a client waits for the lock to be granted. Because nothing is coded at the class level, no wait time limit exists for a lock to be granted for all methods of the class. If the @AccessTimeout annotation is used and the container cannot grant the lock within the specified time limit, a javax.ejb.ConcurrentAccessTimeoutException exception occurs on the client. The @AccessTimeout annotation only applies to methods that are declared in the same class as the @AccessTimeout annotation. For a given class, the metadata for the @AccessTimeout annotation is never inherited from a class higher in the class inheritance tree.

An access-timeout value of -1 indicates that concurrent method calls block access to the bean instance indefinitely (the default). An access-timeout value of 0 indicates that concurrent method calls are not allowed. The exception, javax.ejb.ConcurrentAccessException, occurs when concurrency is detected. And any positive value indicates the amount of time to wait until the method can proceed.

Prior to Java EE 6, the only concurrency behavior supported for stateful session beans was an access-timeout of -1, no concurrency. Since the Java EE 6 specification changed the default behavior, a system property is supported that provides the older default behavior. See EJB container system properties for more information about the com.ibm.websphere.ejbcontainer.EE5Compatibility system property.

You can also specify the @AccessTimeout annotation using the XML deployment descriptor, and if you use the XML deployment descriptor, the metadata from the @AccessTimeout annotation is ignored. The following example uses the XML deployment descriptor to specify the same metadata as the previous example.

```
<session>
   <ejb-name>ShoppingCartBean</ejb-name>
   <concurrent-method>
     <method>
       <method-name>addToCart</method-name>
     </method>
     <access-timeout>
       <timeout>0</timeout>
       <unit>Milliseconds</unit>
     </access-timeout>
   </concurrent-method>
 </session>
```

- It is important to know that the XML coding of the concurrent-methodType follows the three styles outlined in the EJB specification for composing the XML for container-transaction method elements. The three styles are: Style 1 uses the special method name * to apply the access-timeout value to all business methods for the specified bean.

```
<!-- Example: Style 1 -->
      <concurrent-method>
        <method>
          <method-name>*</method-name>
        </method>
       <access-timeout>
          <timeout>2000</timeout>
          <unit>Milliseconds</unit>
        </access-timeout>
      </concurrent-method>
```

Style 2 is used to refer to a business method with a specific name and assign it the specified access-timeout value. If the method name is overloaded, meaning multiple methods have the same name but different method signatures, all methods with this name have the specified access-timeout value.

```
<!-- Example: Style 2 -->
      <concurrent-method>
       <method>
          <method-name>businessMethod</method-name>
        </method>
        <access-timeout>
          <timeout>2000</timeout>
          <unit>Milliseconds</unit>
        </access-timeout>
      </concurrent-method>
```

Style 3 is used to refer to a distinct method that matches the given method name and has a method signature that matches the method parameters listed. Style 3 takes precedence over both style 1 and style 2.

```
<!-- Example: Style 3 -->
      <concurrent-method>
        <method>
          <method-name>businessMethod</method-name>
```

```
      <method-params>
        <method-param>long</method-param>
        <method-param>int</method-param>
      </method-params>
    </method>
    <access-timeout>
      <timeout>2000</timeout>
      <unit>Milliseconds</unit>
    </access-timeout>
  </concurrent-method>
```

If style 1 XML is used to define an access-timeout value, then all @AccessTimeout annotations on the bean are ignored because the method level one is used instead.

- Ensure that you understand the inheritance rules for the annotations that you have used.
- Stateful session beans are not reentrant, which means that the stateful session bean method calls itself back. If a reentrant call is made to a stateful session bean, a javax.ejb.ConcurrentAccessTimeoutException exception occurs on the client, regardless of the access-timeout value. This exception does not result in the stateful session bean being discarded, nor does it mark the transaction for rollback, unless the exception is not handled by the caller.

Developing a session bean to have a No-Interface Local view

You can specify that a session bean have a No-Interface view.

About this task

A session bean has a No-Interface Local view when:

- The bean does not expose any other client views (Local, Remote, 2.x Remote Home, 2.x Local Home, Web Service) and its implements clause is empty.
- The bean exposes at least one other client view. The bean designates that it exposes a no-interface view with the @LocalBean annotation on the bean class or in the deployment descriptor.

You can also declare metadata for a session bean with No-Interface Local view in the deployment descriptor rather than using annotations.

The following steps contain code snippets that demonstrate the code to use for a No-Interface view.

Procedure

- Specify that a session bean have No-Interface view because there are no declared interfaces.

```
@Stateless
public class CartBean
```

- Specify that a session bean have No-Interface view using the `@LocalBean` annotation.

```
@Stateless
@LocalBean
@Remote( Cart.class )
public class CartBean implements Cart
```

- Specify metadata for a session bean with No-Interface Local view in the deployment descriptor.

```
<?xml version="1.0"?>
<ejb-jar
  xmlns="http://java.sun.com/xml/ns/javaee"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://java.sun.com/xml/ns/javaee http://java.sun.com/xml/ns/javaee/ejb-jar_3_1.xsd"
  version="3.1">
  <enterprise-beans>
    <session>
      <ejb-name>CartBean</ejb-name>
      <local-bean/>
      <business-remote>com.ibm.example.Cart</business-remote>
      <ejb-class>com.ibm.example.CartBean</ejb-class>

No-Interface Local View

New in Enterprise JavaBeans (EJB) 3.1, session beans might now be exposed to clients through a No-Interface view. In prior versions of the specification, bean developers were required to provide an interface that would be used to expose the bean methods to a client.

The new No-Interface Local View enables the customer to use the Enterprise JavaBeans (EJB) class as the local interface. This is supported when:

- The bean does not expose any other client views (Local, Remote, 2.x Remote Home, 2.x Local Home, Web Service) and its implements clause is empty.
- The bean exposes at least one other client view. The bean designates that it exposes a no-interface view by means of the @LocalBean annotation on the bean class or in the deployment descriptor.

A session bean might now subclass another session bean

New in Enterprise JavaBeans (EJB) 3.1, a session bean might now subclass another session bean. Prior versions of the EJB specification restricted a session bean from inheriting from another session bean.

Important: This new support only enables implementation inheritance but does not provide component inheritance. Therefore, any meta data or annotations on the superclass that defined it to be an enterprise bean, will not be inherited by the subclass.

Developing singleton session beans

Create a bean implementation class for a singleton session bean, introduced by the Enterprise JavaBeans (EJB) 3.1 specification. The EJB container initializes only one instance of a singleton session bean, and that instance is shared by all clients. Because a single instance is shared by all clients, singleton session beans have special life cycle and concurrency semantics.

Before you begin

Make sure that you understand the inheritance rules for each annotation you implement. For example, the @ConcurrencyManagement annotation is coded on the singleton session bean class only. You cannot use the @ConcurrencyManagement annotation in the class that it extends, or any class higher in the class inheritance tree.

About this task

Singleton session beans can have business local, business remote, and web service client views; they cannot have EJB 2.1 local or remote client views. This singleton session bean support replaces the proprietary startup bean functionality, which has been deprecated.

The following example shows a basic singleton session bean:

```
public interface Configuration {
 Object get(String name);
 void set(String name, Object value);
}

@Singleton
public class ConfigurationBean implements Configuration {
 private Map<String, Object> settings = new HashMap<String, Object>();

 public Object get(String name) {
  return settings.get(name);
 }
```

```
 public void set(String name, Object value) {
  settings.put(name,value);
 }
}
```

As with other enterprise bean types, you can also declare metadata for singleton session beans in the deployment descriptor rather than using annotations; for example:

```
<?xml version="1.0"?>
<ejb-jar
  xmlns="http://java.sun.com/xml/ns/javaee"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://java.sun.com/xml/ns/javaee http://java.sun.com/xml/ns/javaee/ejb-jar_3_1.xsd"
  version="3.1"
>
  <enterprise-beans>
    <ejb-name>ConfigurationBean</ejb-name>
    <business-local>com.ibm.example.Configuration</business-local>
    <ejb-class>com.ibm.example.ConfigurationBean</ejb-class>
    <session-type>Singleton</session-type>
  </enterprise-beans>
</ejb-jar>
```

Procedure

- Code the initialization and destruction methods, understanding how they relate to your options for setting the transaction context. During initialization, the instance is created, dependency injection occurs, and PostConstruct life cycle interceptor callbacks are started. The PreDestroy life cycle interceptor callbacks are started for a singleton session bean when its containing application is stopped.

  It can be useful to complete transactional activities during the PostConstruct and PreDestroy life cycle interceptor callbacks. For this reason, singleton session bean life cycle interceptor callbacks have a well-defined transaction context. The following transaction context values are similar to @Timeout methods: only REQUIRED (default), REQUIRES_NEW, and NOT_SUPPORTED can be used, and REQUIRED is translated to REQUIRES_NEW.

  Transaction attributes are only recognized when they are specified on life cycle interceptor methods on the bean class. The same transaction context is used for all life cycle interceptors. The following example illustrates a singleton session bean with transaction attributes specified for the PostConstruct and PreDestroy life cycle interceptor callbacks.

  ```
  @Singleton
  public class ConfigurationBean implements Configuration {
   @PostConstruct
   @TransactionAttribute(REQUIRED) // the default; specified for illustration
   public void initialize() {
    // ...
   }

   @PreDestroy
   @TransactionAttribute(NOT_SUPPORTED)
   public void destroy() {
    // ...
   }

   // ...
  }
  ```

  Instead of using an annotation, you can specify the same metadata using the XML deployment descriptor. If you specify transaction attributes in the XML deployment descriptor, then any metadata obtained from the @TransactionAttribute annotation is ignored. The following example uses the XML deployment descriptor to specify the same metadata as the previous example.

  ```
    <assembly-descriptor>
      <container-transaction>
        <method>
          <ejb-name>ConfigurationBean</ejb-name>
  ```

```
        <method-name>initialize</method-name>
      </method>
      <trans-attribute>Required</trans-attribute>
    </container-transaction>

    <container-transaction>
      <method>
        <ejb-name>ConfigurationBean</ejb-name>
        <method-name>destroy</method-name>
      </method>
      <trans-attribute>NotSupported</trans-attribute>
    </container-transaction>
  </assembly-descriptor>
```

- Unless otherwise specified, the singleton session bean instance is typically initialized when the bean is first used through one of its client views, which is the same as any other session bean. Use the @Startup annotation or the corresponding XML deployment descriptor to mark a bean as a startup bean. Marking a singleton bean as a startup bean means that the EJB container must run the PostConstruct method before it supports any external client requests made to the application to run. A PostConstruct method in a singleton bean can create an EJB timer, add a message to a JMS queue or topic, call an asynchronous EJB method, or initiate other asynchronous mechanisms that call an EJB. However, to avoid a deadlock, the PostConstruct method must not wait for an EJB timer to run, a message-driven bean method to be called, or an asynchronous EJB method to finish.

  Application developers can place business logic in the PostConstruct methods of these startup singleton instances to complete tasks that must be performed before any client work being started by the container, such as preloading caches or initiating asynchronous work within the application.

  The following example illustrates a singleton session bean with startup initialization:

```
@Singleton
@Startup
public class ConfigurationBean implements Configuration {
 @PostConstruct
 public void initialize() {
  // 1. Create the database table if it does not exist.
  // 2. Initialize settings from the database table.
  // 3. Load a cache.
  // 4. Initiate asynchronous work (for example, work to a messaging queue or to
  //    calls to asynchronous session bean methods.
 }

 // ...
}
```

  Instead of using an annotation, you can specify the same metadata using the XML deployment descriptor. Specify `true` to mark this singleton bean as a startup singleton. Conversely, specify `false`, and the @Startup annotation is overridden, if it exists on the class file.

```
    <session>
      <ejb-name>ConfigurationBean</ejb-name>
      <init-on-startup>true</init-on-startup>
    </session>
```

- Determine whether the initialization method of the singleton session bean has an implicit dependency on another singleton session bean.

  If an implicit dependency exists, use dependency metadata to make the dependency explicit. The container ensures that dependency singleton beans are initialized before their dependent beans are initialized and that they are destroyed after their dependent beans are destroyed. The following example illustrates a singleton session bean with dependency metadata:

```
@Singleton
public class DatabaseBean {
 @PostConstruct
 public void initialize() {
  // Create database tables.
 }
}
```

```
@Singleton
@DependsOn({"DatabaseBean"})
public class ConfigurationBean implements Configuration {
 @PostConstruct
 public void initialize() {
  // Initialize settings from a database table.
 }

 // ...
}
```

Additionally, you can make cross-module dependencies by using the ejb-link `module.jar#bean` syntax. Circular dependencies are not supported, and cause an application to fail.

Instead of using an annotation, you can specify the same metadata using the XML deployment descriptor. If you specify dependency metadata in the XML deployment descriptor, then any metadata from the @DependsOn annotation is ignored.

```
<session>
  <ejb-name>ConfigurationBean</ejb-name>
  <depends-on>
    <ejb-name>DatabaseBean</ejb-name>
  </depends-on>
</session>
```

- Decide whether to use container-managed concurrency or bean-managed concurrency. The @Lock and @AccessTimeout annotations are not applicable when bean-managed concurrency is used.

  You can implement the @ConcurrencyManagement annotation on the singleton session bean class only. It cannot be used on the class it extends or any class higher in the class inheritance tree. The following code example illustrates a singleton with bean-managed concurrency:

```
@Singleton
@ConcurrencyManagement(BEAN)
public class ConfigurationBean implements Configuration {
 private Map<String, Object> settings = new HashMap<String, Object>();

 synchronized public Object get(String name) {
  return settings.get(name);
 }

 synchronized public void set(String name, Object value) {
  settings.put(name, value);
 }
}
```

  Instead of using an annotation, you can specify the same metadata using the XML deployment descriptor. If the metadata is specified in both the XML deployment descriptor and using the @ConcurrencyManagement annotation, then the value must match or the application fails. The following example uses the XML deployment descriptor to specify the same metadata as the previous example.

```
<session>
  <ejb-name>ConfigurationBean</ejb-name>
  <concurrency-management-type>Bean</concurrency-management-type>
</session>
```

  The container does not do locking for each method called. Instead, the actual bean is responsible for the locking that is required. In the example, the bean provider has chosen to implement the methods using the synchronized keyword. This is supported for singleton session beans with bean-managed concurrency, but it is not supported for other EJB component types. It is not required for the bean provider to use the synchronized keyword to provide concurrency. For example, the bean provider can use the java.util.concurrent.locks.ReentrantReadWriteLock class that is found in JDK 5 and later.

  The locking semantics required by the EJB 3.1 specification for container-managed concurrency matches the behavior of the java.util.concurrent.locks.ReentrantReadWriteLock class.

- If you are using container-managed concurrency, use the @Lock notation to manage concurrency of methods.

The following code example illustrates singleton with container-managed concurrency.

```
@Singleton
public class ConfigurationBean implements Configuration {
 private Map<String, Object> settings = new HashMap<String, Object>();

 @Lock(READ)
 public Object get(String name) {
  return settings.get(name);
 }

 public void set(String name, Object value) {
  settings.put(name, value);
 }
}
```

Instead of using an annotation, you can specify the same metadata using the XML deployment descriptor. If the metadata is specified in both the XML deployment descriptor and the @Lock annotation, then the metadata obtained from the @Lock annotation is ignored. The following example uses the XML deployment descriptor to specify the same metadata as the previous example.

```
    <session>
      <ejb-name>ConfigurationBean</ejb-name>
      <concurrent-method>
        <method>
          <method-name>get</method-name>
        </method>
        <lock>Read</lock>
      </concurrent-method>
    </session>
```

The example also illustrates annotating a method with @Lock(READ) to indicate that the container must get a read lock when that method is started. When a method is annotated with @Lock, it overrides the @Lock annotation that is specified at the class level. When there is no @Lock annotation at class level, the default is a write lock. In the example, the @Lock(READ) on the method is overriding the default write lock at the class level. When a method is not annotated at the method level and there is no annotation at the class level, the default of write lock is used by the container.

Because most methods require a read lock, use @Lock(READ) at the class level to indicate that all business methods in this class require the container to obtain a read lock. For methods that require a write lock, annotate those methods with @Lock(WRITE) to show that it overrides the read lock that was specified at the class level.

The following example illustrates this technique:

```
@Singleton
@Lock(READ)
public class ConfigurationBean implements Configuration {
 private Map<String, Object> settings = new HashMap<String, Object>();

 public Object get(String name) {
  return settings.get(name);
 }

 @Lock(WRITE)
 public void set(String name, Object value) {
  settings.put(name, value);
 }
}
```

The @Lock annotation applies only to methods that are declared in the same class as the @Lock annotation. For a given class, the metadata for @Lock is never inherited from a class higher in the class inheritance tree. Instead of using an annotation at the class level, the same metadata can be specified in the XML deployment descriptor by using the special method-name *, which matches all methods.

- If you are using container-managed concurrency, use the @AccessTimeout notation to limit how long a method waits for a lock to be granted. The following code example illustrates concurrent access timeouts.

```
@Singleton
public class ConfigurationBean implements Configuration {
 @Lock(READ)
 @AccessTimeout(1000)
 public Object get(String name) {
  // query the database
 }

 public void set(String name, Object value) {
  // update the database
 }
}
```

  If no annotation is provided, the method defaults to wait until a lock is granted. There is no time limit for how long a client waits for the lock to be granted. Because nothing is coded at the class level, there is no wait time limit for a lock to be granted for all methods of the class. If the @AccessTimeout annotation is used and the container cannot grant the lock within the specified time limit, a javax.ejb.ConcurrentAccessTimeoutException is thrown to the client. The @AccessTimeout annotation applies only to methods that are declared in the same class as the @AccessTimeout annotation is in. For a given class, the metadata for the @AccessTimeout annotation is never inherited from a class higher in the class inheritance tree.

  Like the @Lock annotation, you can also specify the @AccessTimeout annotation using the XML deployment descriptor, and if you use the XML deployment descriptor, the metadata from the @AccessTimeout annotation is ignored. The following example uses the XML deployment descriptor to specify the same metadata as the previous example.

```
<session>
  <ejb-name>ConfigurationBean</ejb-name>
  <concurrent-method>
    <method>
      <method-name>get</method-name>
    </method>
    <lock>Read</lock>
    <access-timeout>
      <timeout>1000</timeout>
      <unit>Milliseconds</unit>
    </access-timeout>
  </concurrent-method>
</session>
```

- It is important to know that the XML coding of the concurrent-methodType follows the three styles outlined in the EJB specification for composing the XML for container-transaction method elements.

  Remember that both the lock and access-timeout elements are optional. The three styles are described as follows:

  Style 1 uses the special method name * to apply the lock type, access-timeout value, or both to all business methods for the specified bean.

```
<!-- Example: Style 1 -->

  <concurrent-method>
    <method>
      <method-name>*</method-name>
    </method>
    <lock>Read</lock>
    <access-timeout>
      <timeout>2000</timeout>
      <unit>Milliseconds</unit>
    </access-timeout>
  </concurrent-method>
```

  Style 2 is used to refer to a business method with a specific name and assign it the specified lock type, access-timeout value, or both. If the method name is overloaded, meaning multiple methods have the

same name but different method signatures, all methods with this name have the specified lock type, access-timeout value, or both. Style 2 takes precedence over style 1.

```
<!-- Example: Style 2 -->

      <concurrent-method>
        <method>
          <method-name>businessMethod</method-name>
        </method>
        <lock>Read</lock>
        <access-timeout>
          <timeout>2000</timeout>
          <unit>Milliseconds</unit>
        </access-timeout>
      </concurrent-method>
```

Style 3 is used to refer to a distinct method that matches the given method name and has a method signature which matches the method parameters listed. Style 3 takes precedence over both style 1 and style 2.

```
<!-- Example: Style 3 -->

      <concurrent-method>
        <method>
          <method-name>businessMethod</method-name>
          <method-params>
            <method-param>long</method-param>
            <method-param>int</method-param>
          </method-params>
        </method>
        <lock>Read</lock>
        <access-timeout>
          <timeout>2000</timeout>
          <unit>Milliseconds</unit>
        </access-timeout>
      </concurrent-method>
```

If style 1 XML is used to define a lock type, then all @Lock annotations on the bean are ignored. The same is true for access timeout. If style 1 XML is used to define an access timeout value then all @AccessTimeout annotations on the bean are ignored.

- It is important to understand that the @Lock and @AccessTimeout annotations are treated independently of one another as is the corresponding XML deployment descriptor code for each.

  The implementation of this concept has multiple benefits. This separation of lock type and access timeout helps to prevent you from negatively affecting black box application code by not requiring you to know the lock type. You can safely leave the lock type value and adjust the access timeout value only to fit your environment needs, and avoid possible deadlock situations or other concurrency issues. Consider a scenario where you have a vendor supplied EJB application running and due to system slow down it keeps timing out. You do not want to change the locking logic for fear of causing a deadlock situation but you do want to modify the timeout limit. You can edit the deployment descriptor and specify the access timeout value you need for the methods you want to modify.

  The following example shows how you can specify just a method level @Lock(READ) annotation in the bean implementation and use style 2 for composing XML to specify the access-timeout element to be 2,000 milliseconds, not providing the optional lock element. The result is a method with a read lock that has an access timeout of 2,000 milliseconds.

```
@Singleton
public class ConfigurationBean implements Configuration {

 @Lock(READ)
 public Object businessMethod(long value) {
  // ...
 }

       // ...
}
```

```
    <session>
      <ejb-name>ConfigurationBean</ejb-name>
      <concurrent-method>
        <method>
          <method-name>businessMethod</method-name>
        </method>
        <access-timeout>
          <timeout>2000</timeout>
          <unit>Milliseconds</unit>
        </access-timeout>
      </concurrent-method>
    </session>
```

Similarly, you can use a class level lock annotation and then specify the wanted access timeout value in XML using either style 2, style 3, or both as shown in the following example.

```
@Singleton
@Lock(READ)
public class ConfigurationBean implements Configuration {

 public Object businessMethod(long value) {
  // ...
 }

 public Object businessMethod(long value, int i, Object value) {
  // ...
 }

 public Object businessMethod(long value, int i) {
  // ...
 }

}
```

```
    <session>
      <ejb-name>ConfigurationBean</ejb-name>
      <concurrent-method>
        <method>
          <method-name>businessMethod</method-name>
        </method>
        <access-timeout>
          <timeout>2000</timeout>
          <unit>Milliseconds</unit>
        </access-timeout>
      </concurrent-method>
      <concurrent-method>
        <method>
          <method-name>businessMethod</method-name>
          <method-params>
            <method-param>long</method-param>
            <method-param>int</method-param>
          </method-params>
        </method>
        <access-timeout>
          <timeout>8000</timeout>
          <unit>Milliseconds</unit>
        </access-timeout>
      </concurrent-method>
    </session>
```

The previous code example results in all methods named “businessMethod” having a lock type of read and an access timeout of 2,000 milliseconds. The exception is the one instance of the method “businessMethod” that has a method signature with the first parameter being of type long and the second being of type int, This instance of method "businessMethod" has a lock type of read, but has an access timeout of 8,000 milliseconds. The same principle applies when style 1 XML is used to define

only a lock type, but not an access timeout value. You can add an access timeout value to a specific method or methods using style 2, style 3, or both to get a specific lock type and access timeout value result. The following example illustrates this point:

```
    <session>
      <ejb-name>ConfigurationBean</ejb-name>
      <concurrent-method>
        <method>
          <method-name>*</method-name>
        </method>
        <lock>Read</lock>
      </concurrent-method>
      <concurrent-method>
        <method>
          <method-name>businessMethod</method-name>
        </method>
        <access-timeout>
          <timeout>2000</timeout>
          <unit>Milliseconds</unit>
        </access-timeout>
      </concurrent-method>
    </session>
```

The previous code example results in all business methods having a lock type of read and the method named, businessMethod, having a lock type of read and an access timeout of 2,000 milliseconds. You can also have a class level @Lock annotation to set the lock type for all methods and use style 1 for composing XML to set just the access timeout value for all methods. See the following example:

```
@Singleton
@Lock(READ)
public class ConfigurationBean implements Configuration {

 public Object businessMethod(long value) {
  // ...
 }

        // ...

}
```

```
    <session>
      <ejb-name>ConfigurationBean</ejb-name>
      <concurrent-method>
        <method>
          <method-name>*</method-name>
        </method>
        <access-timeout>
          <timeout>2000</timeout>
          <unit>Milliseconds</unit>
        </access-timeout>
      </concurrent-method>
    </session>
```

The previous example results in all business methods of bean, ConfigurationBean, having a lock type of read and an access timeout value of 2,000 milliseconds.

- Ensure that you understand the inheritance rules for the annotations that you have used.
- Avoid reentrant locking behavior that can occur if a read lock method calls a write lock method in the same singleton session bean.

  Suppose the business method of a singleton session bean either directly or indirectly causes another business method of the singleton session bean to be started. If the first method is a write lock method, then that method can call any other business method of the singleton session bean without any special consideration. However, you might carefully implement a read lock method if it were to call another business method of that same singleton session bean class that is a write lock method. Then a `javax.ejb.IllegalLoopbackException` exception occurs.

Changing singleton session bean locking policy

Use this task to override the default non-fair locking policy for all singleton session bean write locks within the server. This task is for WebSphere Application Server users who do not want lock requests for their Singleton session bean method invocations to follow a non-fair policy.

About this task

Locks for singleton session bean methods are obtained using a *non-fair* locking policy by default. When locks are constructed as *fair*, threads contend for entry using an approximate arrival-order policy. When lock is released, the longest waiting lock is granted regardless if it is reader or writer.

When locks are constructed as non-fair, the order in which locks are obtained is not guaranteed. If readers are active and a writer enters the queue, subsequent readers might get granted the read lock before the writer is granted the lock.

Procedure

1. Optional: Open the administrative console.
2. Select **Servers**.
3. Select **Server Types**.
4. Select **WebSphere application servers**.
5. Select the server that you want to configure.
6. From Server Infrastructure, select **Java and Process Management Process definition.**
7. From Additional Properties, select **Java Virtual Machine**.
8. In the Additional Properties area, select **Custom Properties**.
9. On the Application servers page, click **New** to specify an arbitrary name and value pair for your server.
10. In the **Name** entry field, type: `com.ibm.websphere.ejbcontainer.useFairSingletonLockingPolicy`
11. In the **Value** entry field, type `true`.

    Attention: Entering `true` causes all locks obtained for singleton session bean methods to use a fair policy. Entering `false` causes all locks obtained for singleton session bean methods to use a non-fair policy. The default policy is non-fair.
12. Click **OK**.
13. Save the configuration.
14. Restart the server.

Results

The locking policy has now been set for all locks obtained for singleton session beans within the server.

Programming to use message-driven beans

Applications can use message-driven beans as asynchronous message consumers. You deploy a message-driven bean as a message listener for a destination. When a message arrives at the destination, the EJB container invokes the message-driven bean automatically without an application having to explicitly poll the destination.

About this task

You can use a tool such as Rational Application Developer to develop applications that use message-driven beans. You can use the WebSphere Application Server runtime tools, such as the administrative console, to deploy and administer applications that use message-driven beans.

For more information about implementing enterprise applications that use message-drive beans, see the following topics:

Procedure

- Develop message-driven beans.
- Design an enterprise application to use message-driven beans.
- Develop an enterprise application to use message-driven beans.
- Deploy an enterprise application to use message-driven beans with JCA 1.5-compliant resources.
- Deploy an enterprise application to use message-driven beans with listener ports.

Developing message-driven beans

You can develop a bean implementation class for a message-driven bean as introduced by the Enterprise JavaBeans specification. A message-driven bean (MDB) is a message consumer that implements business logic and runs on the server.

Before you begin

Determine the messaging model you want for your application regarding use of topics, queues, producers and consumers, publish or subscribe, and so on. You can refer to the message-driven bean component contract that is described in the Enterprise JavaBeans™ specification.

About this task

A message-driven bean (MDB) is a consumer of messages from a Java Message Service (JMS) provider. An MDB is invoked on arrival of a message at the destination or endpoint that the MDB services. MDB instances are anonymous, and therefore, all instances are equivalent when not actively servicing a client message. The container controls the life cycle of bean instances, which hold no state that is visible to a client.

The following example is a basic message-driven bean:

```
@MessageDriven(activationConfig={
                @ActivationConfigProperty(propertyName="destination",     propertyValue="myDestination"),
                @ActivationConfigProperty(propertyName="destinationType", propertyValue="javax.jms.Queue")
})
public class MsgBean implements javax.jms.MessageListener {

  public void onMessage(javax.jms.Message msg) {

      String receivedMsg = ((TextMessage) msg).getText();
      System.out.println("Received message: " + receivedMsg);

   }

}
```

As with other enterprise bean types, you can also declare metadata for message-driven beans in the deployment descriptor rather than using annotations, for example:

```
<?xml version="1.0" encoding="UTF-8"?>

<ejb-jar id="EJBJar_1060639024453" version="3.0"
      xmlns="http://java.sun.com/xml/ns/javaee"
      xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
      xsi:schemaLocation="http://java.sun.com/xml/ns/javaee http://java.sun.com/xml/ns/javaee/ejb-jar_3_0.xsd"
      metadata-complete="false">
  <enterprise-beans>

    <message-driven>

      <ejb-name>MsgBean</ejb-name>
```

```
      <ejb-class>com.acme.ejb.MsgBean</ejb-class>
      <activation-config>
         <activation-config-property>
            <activation-config-property-name>destination</activation-config-property-name>
            <activation-config-property-value>myDestination</activation-config-property-value>
         </activation-config-property>
         <activation-config-property>
           <activation-config-property-name>destinationType</activation-config-property-name>
           <activation-config-property-value>javax.jms.Queue</activation-config-property-value>
        </activation-config-property>
      </activation-config>

    </message-driven>

  </enterprise-beans>
</ejb-jar>
```

Procedure

- Code the business logic of the message-driven bean, which must implement the appropriate message listener interface defined by the messaging type; for example, javax.jms.MessageListener. The business logic is invoked when the message listener method of the MDB is called to service a message; for example, `MessageListener.onMessage()`. If the MDB implements more than one interface, denote the message listener interface by coding the `messageListenerInterface` attribute of the `MessageDriven` annotation, or by coding the `<messaging-type>` element of the `message-driven` deployment descriptor element. You do not have to specify which is the message listener interface, as long as there is only one interface other than `java.io.Serializable`, `java.io.Externalizable`, or any of the `javax.ejb` package interfaces.
- You can optionally define message destination references on any type of enterprise bean. A message destination reference is a logical name by which an enterprise bean can refer to a message destination. The `Resource` annotation is used to inject a message destination reference, for example:

  ```
  @Resource (name="jms/Outlet", type=javax.jms.Queue) Queue salesOutlet;
  ```

  Alternatively, you can use the `<message-destination-ref>` element in the deployment descriptor to specify the message destination reference; for example:

  ```
  <message-destination-ref>
     <message-destination-ref-name>jms/Outlet</message-destination-ref-name>
     <message-destination-type>javax.jms.Queue</message-destination-type>
     <injection-target>
       <injection-target-class>com.acme.ejb.MsgBean</injection-target-class>
       <injection-target-name>salesOutlet</injection-target-name>
    </injection-target>
  </message-destination-ref>
  ```

  The `message-destination-ref` element is similar to the `resource-env-ref` element, but also has subelements, `message-destination-usage` with possible values `Produces`, `Consumes` or `ProducesConsumes`, and `message-destination-link`. You can use the `message-destination-link` element to tie two or more message-destination-ref references in the deployment descriptor together, which allows the deployer to bind the destination for several enterprise beans all at once, to the same destination. The message-destination-link value must match the `message-destination-name` value in the `message-destination` element; for example:

  ```
  <ejb-jar>

    <enterprise-beans>

      <session>
        <ejb-name>OutletBean</display-name>
        ...
        <message-destination-ref>
          <message-destination-ref-name>jms/target</message-destination-ref-name>
          <message-destination-type>javax.jms.Queue</message-destination-type>
          <message-destination-usage>Produces</message-destination-usage>
          <message-destination-link>destination</message-destination-link>
        </message-destination-ref>
        ...
  ```

```
    </session>

    <session>
      <ejb-name>InletBean</display-name>
      ...
      <message-destination-ref>
        <message-destination-ref-name>jms/source</message-destination-ref-name>
        <message-destination-type>javax.jms.Queue</message-destination-type>
        <message-destination-usage>Consumes</message-destination-usage>
        <message-destination-link>destination</message-destination-link>
      </message-destination-ref>
      ...
    </session>

    <message-driven>
      <ejb-name>InletBean</display-name>
      ...

      <ejb-name>MsgBean</ejb-name>
      <ejb-class>com.acme.MsgBean</ejb-class>
      <messaging-type>javax.jms.MessageListener</messaging-type>
      <message-destination-type>javax.jms.Queue</message-destination-type>
      <message-destination-link>destination</message-destination-link>

      ...
    </message-driven>

  </enterprise-beans>
      ...
  <assembly-descriptor>
    ...
    <message-destination>
      <message-destination-name>destination</message-destination-name>
    </message-destination>
    ...
  </assembly-descriptor>

</ejb-jar>
```

The `message-destination-link` element can refer to a destination that is defined in a different Java archive (JAR) file within the same application, as with an `ejb-link` element. For example, to link to the destination, `ProduceQueue`, defined in the `grocery.jar` file, enter the following line in the deployment descriptor:

```
<message-destination-link>grocery.jar#ProduceQueue</message-destination-link>
```

- As with any enterprise bean, you can package a message-driven bean in a JAR file, or in a web application archive (WAR) file.

Results

You developed a simple message-driven bean, along with some deployment and packaging options.

What to do next

Read related information about designing an enterprise application that uses message-driven beans.

Designing an enterprise application to use message-driven beans

To help you design your enterprise application, consider a generic enterprise application that uses one message-driven bean to retrieve messages from a JMS queue destination, and passes the messages on to another enterprise bean that implements the business logic.

About this task

To design an enterprise application to use message-driven beans, complete the following steps:

Procedure

1. Identify the message listener interface for the message type that the message-driven bean is to handle. The message-driven bean class must implement this message listener interface. For example, an EJB message-driven bean class used for JMS messaging must implement the javax.jms.MessageListener interface.
2. Identify the resources that the application is to use. This helps to identify the properties of resources that must be used within the application and configured as application deployment descriptors or within WebSphere Application Server.

Table 60. JMS resource types and examples of their properties. The left hand column of this table lists the JMS resource types, and the right hand column shows examples of the properties of each of the JMS resource types shown in the left hand column.

JMS resource type	Properties (for example)
JMS connection factory	**Name:** SamplePtoPQueueConnectionFactory **JNDI Name:** Sample/JMS/QCF
JMS destination	**Name:** Q1 **JNDI Name:** Sample/JMS/Q1
J2C activation specification properties	**Name:** MyMDBsActivationSpec **JNDI Name:** eis/MyMDBsActivationSpec **Destination JNDI Name:** MyQueue **Destination type:** javax.jms.Queue
Message-driven bean (deployment properties)	**Name:** JMSppSampleMDBBean **Transaction type:** Container **Message selector:** JMSType='car' **Acknowledge mode:** Dups OK Acknowledge **Destination type:** javax.jms.Queue **ActivationSpec JNDI name:** MyMDBsActivationSpec
Business logic bean	**Name:** MyLogicBean

   Ensure that you use consistent values where needed; for example, the JNDI name for the J2C activation specification must be the same in both the activation specification and the Message-driven bean deployment attributes.
3. Separate out the business logic. You should develop a message-driven bean to delegate the business processing of incoming messages to another enterprise bean. This provides clear separation of message handling and business processing. This also enables the business processing to be invoked by either the arrival of incoming messages or, for example, from a WebSphere J2EE client.
4. Decide whether to configure security. Messages arriving at a destination being processed by a listener have no client credentials associated with them; the messages are anonymous. Security depends on the role specified by the RunAs Identity for the message-driven bean as an EJB component. For more information about EJB security, see EJB component security.
5. Understand how best effort nonpersistent messages are handled by the default messaging provider.

   If you have a non-transactional message-driven bean, the system either deletes the message when the message-driven bean starts, or when the message-driven bean completes. If the message-driven bean generates an exception, and therefore does not complete, the system takes one of the following actions:

   - If the system is configured to delete the message when the message-driven bean completes, then the message is despatched to a new instance of the message-driven bean, so the message has another opportunity to be processed.
   - If the system is configured to delete the message when the message-driven bean starts, then the message is lost.

   The message is deleted when the message-driven bean starts if the quality of service is set to `Best effort nonpersistent`. For all other qualities of service, the message is deleted when the message-driven bean completes.

Developing an enterprise application to use message-driven beans

Applications can use message-driven beans as asynchronous message consumers. You deploy a message-driven bean as a message listener for a destination. The message-driven bean is invoked by an activation specification or a JMS listener when a message arrives on the input destination that is being monitored.

About this task

You develop an enterprise application to use a message-driven bean as with any other enterprise bean, except that a message-driven bean does not have a home interface or a remote interface.

You should develop your message-driven bean to delegate the business processing of incoming messages to another enterprise bean, which provides clear separation of message handling and business processing. This separation also means that the business processing can be invoked either by the arrival of incoming messages or, for example, by a WebSphere J2EE client. Responses can be handled by another enterprise bean acting as a sender bean, or they can be handled in the message-driven bean.

EJB 2.0 message-driven beans support only Java Message Service (JMS) messaging. EJB 2.1 and EJB 3 message-driven beans can support other messaging types in addition to JMS. All message-driven beans must implement the MessageDrivenBean interface. For JMS messaging, a message-driven bean must also implement the message listener interface javax.jms.MessageListener. Other Java EE Connector Architecture (JCA)-compliant resource adapters might provide their own message listener interfaces that must be implemented.

You can use the New Enterprise Bean wizard of Rational Application Developer to create an enterprise bean with a bean type of `Message-driven bean`. The wizard creates appropriate methods for the type of bean.

By convention, the message-driven bean class is named *name*Bean, where *name* is the name you assign to the message-driven bean; for example:

```
public class MyJMSppMDBBean implements MessageDrivenBean, javax.jms.MessageListener
```

A message-driven bean can be registered with the EJB timer service for time-based event notifications if it also implements the javax.ejb.TimedObject interface, and invokes the timer callback method by the following call: `void ejbTimeout(Timer)`. At the scheduled time, the container then calls the message-driven bean ejbTimeout method.

The message-driven bean class must define and implement the following methods:

- onMessage(message), which must meet the following requirements:
  - The method must have a single argument of type javax.jms.Message.
  - The `throws` clause must not define any application exceptions.
  - If the message-driven bean is configured to use bean-managed transactions, it must call the javax.transaction.UserTransaction interface to scope the transactions. Because these calls occur inside the onMessage() method, the transaction scope does not include the initial message receipt. For more information, see the topic about message-driven beans transaction support.

  To handle the message within the onMessage() method (for example, to pass the message on to another enterprise bean), you use standard JMS. This is known as bean-managed messaging.

  If you are using a JCA-compliant resource adapter with a different message listener interface, another method besides the onMessage() method might be needed. For information about the message listener interface needed, see the documentation that was provided with your JCA-compliant resource adapter.
- ejbCreate()

  You must define and implement an ejbCreate method for each way in which you want a new instance of an enterprise bean to be created.
- ejbRemove()

This method is invoked by the container when a client invokes the remove method inherited by the enterprise bean home interface from the javax.ejb.EJBHome interface. This method must contain any code that you want to execute before an enterprise bean instance is removed from the container (and the associated data is removed from the data source).

- ejbTimeout(Timer)

  This method is needed only to support notifications from the timer service, and contains the business logic that handles time events received.

Procedure

1. Create the Enterprise Application project.
2. Create the message-driven bean class. You can use the New Enterprise Bean wizard of Rational(r) Application Developer to create the enterprise bean with a bean type of `Message-driven bean`.

   For an example of how to create the message-driven bean class, see the Example section of this topic. For more information, see *Creating message-driven beans* in the Rational Application Developer information center. The result of this step is a message-driven bean that can be assembled into an EAR file for deployment.
3. Optional: Use the EJB deployment descriptor editor to review and, if needed, change the deployment attributes. You can use the EJB deployment descriptor editor to review deployment attributes that you specified on the EJB creation wizard (such as **`Transaction type`** and **`Message selector`**) and other default deployment attributes.

   If needed, you can override the values of these attributes later, after the enterprise application has been exported into an EAR file for deployment, as described in “Configuring deployment attributes for a message-driven bean against JCA 1.5-compliant resources” on page 2085 and “Configuring deployment attributes for a message-driven bean against a listener port” on page 2088.

   a. In the property pane, select the **Bean** tab.

   b. On the main panel, configure the **`Transaction type`** attribute.

      `Transaction type`
      This attribute determines whether the message-driven bean manages its own transactions, or whether the container manages transactions on behalf of the bean.
      `Bean` The message-driven bean manages its own transactions.
      `Container`
      The container manages transactions on behalf of the bean.

   c. Under **Activation Configuration**, review the following attributes:

      `acknowledgeMode`
      This attribute determines how the session acknowledges any messages it receives.
      `Auto Acknowledge`
      The session automatically acknowledges delivery of each message.
      `Dups OK Acknowledge`
      The session lazily acknowledges the delivery of messages. This setting is likely to result in the delivery of some duplicate messages if JMS fails, so it should be used only by consumer applications that are tolerant of duplicate messages.

      As defined in the EJB specification, clients cannot use the Message.acknowledge() method to acknowledge messages. If a value of `CLIENT_ACKNOWLEDGE` is passed on the create*xxx*Session call, then messages are automatically acknowledged by the application server and the Message.acknowledge() method is not used.

      Note:

      The acknowledgement is sent when the message is deleted.

      If you have a non-transactional message-driven bean, the system either deletes the message when the message-driven bean starts, or when the message-driven bean

completes. If the message-driven bean generates an exception, and therefore does not complete, the system takes one of the following actions:

- If the system is configured to delete the message when the message-driven bean completes, then the message is despatched to a new instance of the message-driven bean, so the message has another opportunity to be processed.
- If the system is configured to delete the message when the message-driven bean starts, then the message is lost.

The message is deleted when the message-driven bean starts if the quality of service is set to `Best effort nonpersistent`. For all other qualities of service, the message is deleted when the message-driven bean completes.

destinationType
This attribute determines whether the message-driven bean uses a queue or topic destination.
Queue The message-driven bean uses a queue destination.
Topic The message-driven bean uses a topic destination.

subscriptionDurability
This attribute determines whether a JMS topic subscription is durable or nondurable.
Durable
A subscriber registers a durable subscription with a unique identity that is retained by JMS. Subsequent subscriber objects with the same identity resume the subscription in the state it was left in by the earlier subscriber. If there is no active subscriber for a durable subscription, JMS retains the subscription messages until they are received by the subscription or until they expire.
Nondurable
Nondurable subscriptions last for the lifetime of their subscriber object. This means that a client sees the messages published on a topic only while its subscriber is active. If the subscriber is not active, the client is missing messages published on its topic.

A nondurable subscriber can only be used in the same transactional context (for example, a global transaction or an unspecified transaction context) that existed when the subscriber was created.

messageSelector
This attribute determines the JMS message selector that is used to select which messages the message-driven bean receives. For example:

```
JMSType='car' AND color='blue' AND weight>2500
```

The selector string can refer to fields in the JMS message header and fields in the message properties. Message selectors cannot reference message body values.

d. Specify bindings deployment attributes.

Under **WebSphere Bindings**, select the **JCA Adapter** option then specify the bindings deployment attributes:
ActivationSpec JNDI name
This attribute specifies the JNDI name of the activation specification that is used to deploy this message-driven bean. This name must match the name of an activation specification that you define to WebSphere Application Server.
ActivationSpec Authorization Alias
This attribute specifies the name of an authentication alias used for authentication of connections to the JCA resource adapter. An authentication alias specifies the user ID and password that is used to authenticate the creation of a new connection to the JCA resource adapter.
Destination JNDI name
This attribute specifies the JNDI name that the message-driven bean uses to look up the JMS destination in the JNDI namespace.

e. Optional: Specify **Destination Link** to enable message linking.

Message linking allows the routing of messages to a specific message-driven bean in a deployment. Message linking allows message flow to be orchestrated between components in the same application.

For a message to be consumed and processed by a message-driven bean, the<message-destination-link> element must be defined in the deployment descriptor associated with the message-driven bean. The destination identified by the <message-destination-link> element corresponds to the logical destination.

When the <message-destination-ref> includes a <message-destination-link> element, messages are consumed at that destination.

In order to get the message-driven bean to consume messages sent to a destination, you can declare a <message-destination-link> element in the deployment descriptor, or alternatively set it in the activation specification.

4. Assemble and package the application for deployment.

Results

The result of this task is an EAR file, containing the message-driven bean, for the enterprise application that can be deployed in WebSphere Application Server.

Example

The following example shows how to create the message-driven bean class. The example code shows how to access the text and the JMS **MessageID**, from a JMS message of type TextMessage. In this example, first the onMessage() method of a message-driven bean is used to unpack the incoming text message and to extract the text and message identifier; then a private putMessage method (defined within the same message bean class) is used to put the message onto another queue:

```
public void onMessage(javax.jms.Message msg)
{
        String text      = null;
        String messageID = null;

        try
        {
                text = ((TextMessage)msg).getText();

                System.out.println("senderBean.onMessage(), msg text2: "+text);

                //
                // store the message id to use as the Correlator value
                //
                messageID = msg.getJMSMessageID();

                // Call a private method to put the message onto another queue
                putMessage(messageID, text);
        }
        catch  (Exception err)
        {
                err.printStackTrace();
        }
        return;
}
```

What to do next

After you have developed an enterprise application to use message-driven beans, configure and deploy the application. For example, define activation specifications for the message-driven beans and, optionally, change the deployment descriptor attributes for the application. For more information, see “Deploying an

enterprise application to use message-driven beans with JCA 1.5-compliant resources" on page 2084 and "Deploying an enterprise application to use message-driven beans with listener ports" on page 2088.

Assembling EJB 2.1 enterprise beans

Assembling EJB 2.x modules

An enterprise bean is a Java component that can be combined with other resources to create Java EE applications. This topic describes assembling Enterprise JavaBeans (EJB) modules based on the EJB 2.x and earlier specifications.

Before you begin

Create and unit tested an enterprise bean that you want to assemble in an enterprise application and deploy onto an application server.

About this task

Assemble an EJB module to contain enterprise beans and related code artifacts. Group web components, client code, and resource adapter code in separate modules. After the EJB module is assembled, install it as a stand-alone application or combine it with other modules into an enterprise application.

Use an assembly tool to assemble an EJB module in any of the following ways:
- Import an existing EJB module (EJB JAR file)
- Create a EJB module
- Copy code artifacts, such as entity beans, from one EJB module into a new EJB module

For information about assembling EJB modules with an assembly tool, see the Rational Application Developer documentation.

Results

The EJB module is migrated or created, reflecting the Java EE structure that specifies the location of enterprise bean content files, class files, class paths, the deployment descriptor, and supporting metadata. For more information about the location of the content see the assembly tool information center.

What to do next

After you finish assembling your EJB module, you are ready to deploy your module.

Sequence grouping for container-managed persistence in assembled EJB modules

After assembling an Enterprise JavaBeans (EJB) module that contains container-managed persistence (CMP) beans, you can prevent certain types of database-related exceptions from occurring during application run time. Using *sequence grouping*, you can specify the order in which entity beans update relational database tables.

Note: Entity beans are not supported in EJB 3.x modules.

Eliminate exceptions resulting from referential integrity (RI) violations

Sequence grouping is particularly useful for preventing violations of database *referential integrity* (RI). A database RI policy prescribes rules for how data is written to and deleted from the database tables to

maintain relational consistency. Run-time requirements for managing bean persistence, however, can cause an EJB application to violate RI rules, which can cause database exceptions. These runtime requirements mandate that:

- Entity bean creates and remove operations correlate to the database immediately upon method invocation.
- Entity bean changes are cached by the EJB container until either a finder method is called, or the transaction ends.

Consequently, the order in which entity beans update the database is unpredictable. That randomness translates into high risk of the application violating database RI. Although caching the operations for batch processing overrides these runtime requirements, it does not guarantee a bean persistence sequence that follows any given RI policy.

The only way to guarantee a persistence sequence that honors database RI is to designate the sequence, which you do in the EJB deployment descriptor editor of the assembly tool. Through the sequence grouping feature, you assign beans to CMP groups. Within each group, you specify the order in which the persistence manager inserts bean data into the database to accomplish updates without violating RI.

See the “Setting the run time for CMP sequence groups” topic for detailed instructions on designating sequence groups. Consult your database administrator about the RI policy with which you need to synchronize.

Minimize exception risk for optimistic concurrency control schemes

Sequence grouping can also reduce the risk of transaction rollback exceptions for entity beans that are configured for optimistic concurrency control. In these concurrency control schemes, database locks are held for minimal amounts of time so that a maximum number of transactions consistently have access to the data. The relatively unrestricted state of the database can lead to transaction rollback exceptions for two common reasons:

- When concurrent transactions attempt to lock the same table row, database deadlock occurs.
- Transactions can occur in an order that violates application logic.

Use the sequence grouping feature to order bean persistence so that these scenarios are less likely to occur.

Setting the run time for CMP sequence groups

By designating container managed persistence (CMP) sequence groups for entity beans, you can prevent certain types of database-related exceptions during the run time of your Enterprise JavaBeans (EJB) application. Specify in each group the order in which the beans update your relational database tables.

Before you begin

When you define a sequence group, you designate it as one of two types:

- RI_INSERT, for setting a bean persistence sequence to prevent database referential integrity (RI) violations. See the topic Sequence grouping for container-managed persistence in assembled EJB modules for more information.
- UPDATE_LOCK, for setting a bean persistence sequence to minimize exceptions resulting from optimistic concurrency control

About this task

Both types of sequence groups must be created after you have assembled the beans into an EJB module, before installing your application on the product. If you need to edit sequence groups, uninstall the application, make your changes with an assembly tool, and reinstall your application.

Attention: If you already selected or plan to use top-down mapping for mapping your enterprise beans to back-end data, you do not need to create a sequence group with an RI_INSERT type. The product does not generate an RI policy for the database schema that it creates when you select top-down mapping.

To learn how to complete this task see the assembly tool information center.

What to do next

You are now ready to deploy your EJB module or combine it with other modules into a Java EE application. For more information about these two tasks, see the topics Installing enterprise application files and Assembling Java EE client applications.

Assembling EJB 3.x enterprise beans

EJB 3.0 and EJB 3.1 application bindings overview

Prior to starting an application that is installed on an application server, all Enterprise JavaBeans (EJB) references and resource references defined in the application must be bound to the actual artifacts (enterprise beans or resources) defined in the application server.

Starting in Version 8.0, bindings support in the EJB container is expanded. The EJB container assigns default JNDI bindings for EJB 3.x business interfaces based on application name, module name, and component name. You do not have to explicitly define JNDI binding names for each of the interfaces or EJB homes within an EJB 3.x module or no-interface views within an EJB 3.1 module.

When defining bindings, you specify Java Naming and Directory Interface (JNDI) names for the referenceable and referenced artifacts in an application. The jndiName values specified for artifacts must be qualified lookup names.

You do not need to manually assign JNDI bindings names for each of the interfaces, EJB homes, or no-interface views on your enterprise beans in EJB 3.x modules. If you do not explicitly assign bindings, the EJB container assigns default bindings.

Namespaces for default EJB JNDI bindings

Default EJB bindings may be placed by the application server into both the classic and java:[scope] sets of namespaces.

The set of classic namespaces consists of the ejblocal: and Global JNDI namespaces. The classic namespaces include a WebSphere extension, and they existed in the application server prior to version 8.0.

The set of java:[scope] namespaces consists of the java:global, java:app, and java:module namespaces. The java:[scope] namespaces are defined by the Java EE 6 specification, and are introduced into theWebSphere Application Server in Version 8. They are not a replacement for the classic namespaces. Rather, they are added in addition to the classic namespaces.

Classic namespace details

For the EJB 3.x level, the product provides two distinct classic namespaces for EJB interfaces, depending on whether the interface is local or remote. The same provision applies to EJB homes and no-interface views, which can be considered special types of interfaces. The following classic namespaces exist:

- Java virtual machine (JVM)-scoped, ejblocal: namespace
- Global JNDI namespace

Local EJB interfaces, homes, and no-interface views must be bound into a JVM-scoped classic ejblocal: namespace; they are accessible only from within the same application server process.

In contrast, remote EJB interfaces and homes must always be bound into the classic globally scoped WebSphere JNDI namespace; they can be accessed from anywhere, including other server processes and other remote clients. Local interfaces and no-interface views cannot be bound into the classic globally scoped JNDI namespace, nor can remote interfaces be bound into the JVM-scoped classic ejblocal: namespace.

The classic ejblocal: and classic globally scoped JNDI namespaces are separate and distinct. For example, an EJB local interface or no-interface view bound at “ejblocal:AccountHome” is a not the same as a remote interface bound at “AccountHome” in the classic globally scoped namespace. This behavior helps maintain the distinction between your local and remote interface references. Having a JVM-scoped local namespace also makes it possible for your applications to directly look up or reference local EJB interfaces and no-interface views from anywhere in the JVM server process, including across Java Platform, Enterprise Edition (Java EE) application boundaries.

Default classic JNDI bindings for EJB business interfaces in the EJB 3.x container with the Application, Module, and Component names

The EJB container assigns default classic JNDI bindings for EJB 3.x business interfaces based on application name, module name, and component name, so it is important to understand how these names are defined. Each of these names is a character string.

Java EE applications are packaged in a standardized format called an Enterprise Application Archive (EAR) file. The EAR is a packed file format like a .zip or .tar file format, and can thus be visualized as a collection of logical directories and files packed together into a single physical file. Within each EAR file are one or more Java EE module files, which can include:

- Java Application Archive (JAR) files for EJB modules, Java EE application client modules and utility class modules
- Web Application Archive (WAR) files for web modules
- Other technology-specific modules such as Resource Application Archive (RAR) files and other types of modules

Within each module file are typically one or more Java EE components. Examples of Java EE components are enterprise beans, servlets, and application client main classes.

Since Java EE modules are packaged within Java EE application archives, and Java EE components are in turn packaged within Java EE modules, the “nesting path” of each component can be used to uniquely identify every component within a Java EE application archive, according to its application name, module name, and component name.

Application name used in classic bindings

The name of an application is defined by the following (in order of priority):

- The value of the application name specified to the product administrative console, or the **appname** parameter supplied to the **wsadmin** command-line scripting tool, during installation of the application into the product.
- The value of the **<display-name>** parameter within the `META-INF/application.xml` deployment descriptor for the application.
- The EAR file name, excluding the `.ear` file suffix. For example, an application EAR file named `CustomerServiceApp.ear` would have an application name of “CustomerServiceApp” in this case.

The Java EE 6 specification provides for EJB JNDI lookup names of the general form, java:global[/*appName*]/*moduleName*/*beanName*. The *appName* component of the lookup name is shown

as optional because it does not apply to beans deployed in stand-alone modules. Only beans packaged in .ear files contain the *appName* component in the java:global lookup name. The rules that determine the value for *appName* are different from the rules described previously for application names. The *appName* value in the java:global lookup name template shown previously is defined by the following, in order of priority:

- The value of the **<application-name>** parameter within the `application.xml` deployment descriptor for the application.
- The EAR file name, excluding the `.ear` file suffix. For example, an application EAR file named `CustomerServiceApp.ear` has an application name of "CustomerServiceApp". If the application is a stand-alone module, the java:global lookup name does not contain an application component.

The value for *appName* is also the string value bound under the name, java:app/AppName, in accordance with the Java EE 6 specification.

Module name used in classic bindings

The name of a module is defined as the Uniform Resource Identifier (URI) of the module file, relative to the root of the EAR file in which it resides. Stated another way, the module name is the file name of the module relative to the root of the EAR file, including any subdirectories in which the module file is nested. This naming convention is still true even when a logical module name is explicitly specified using the module-name element in the deployment descriptor.

In the following example, the "CustomerServiceApp" application contains three modules whose names are `AccountProcessing.jar`, `Utility/FinanceUtils.jar`, and `AppPresentation.war`:

```
CustomerServiceApp.ear:AccountProcessing.jar
com/mycompany/AccountProcessingServiceBean.class AccountProcessingService.class
Utility/FinanceUtils.jar META-INF/ejb-jar.xml
com/mycompany/InterestCalculatorServiceBean.class InterestCalculatorService.class
AppPresentation.war META-INF/web.xml
```

The Java EE 6 specification provides for EJB JNDI lookup names of the general form, java:global[/*appName*]/*moduleName*/*beanName*. The *appName* component of the lookup name is shown as optional because it does not apply to beans deployed in stand-alone modules. Only beans packaged in `.ear` files contain the *appName* component in the java:global lookup name. Another JNDI lookup name variant that includes the module name is java:app/*moduleName*/*beanName*. The value for *moduleName* is not the module URI. The *moduleName* value in the java:global and java:app lookup name templates is defined by the following, in order of priority:

- The value of the **<module-name>** parameter within the `ejb-jar.xml` or `web.xml` deployment descriptor for the module.
- The module URI, excluding its `.jar` or `.war` suffix. For example, a module with a URI of `CustomerService.jar` or `CustomerService.war` has a module name of "CustomerService".

The value for *moduleName* is also the string value bound under the name, java:module/*moduleName*, in accordance with the Java EE 6 specification. This also applies to client modules. For client modules, the **<module-name>** parameter is located in the `application-client.xml` deployment descriptor file.

EJB component name used in classic bindings

The name of an EJB component is defined by the following value, in order of priority:

- The value of the ejb-name tag associated with the bean in the `ejb-jar.xml` deployment descriptor, if present.
- The value of the "name" parameter, if present, in the @Stateless or @Stateful annotation associated with the bean.
- The name of the bean implementation class, without any package-level qualifier.

Bindings

Review the following bindings that are supported by EJB 3.x modules:
- Default classic bindings for business interfaces, homes, and no-interface views
- Default classic binding pattern
- java:[scope] bindings
- User-defined bindings for EJB business interfaces, homes, and no-interface views
- User-defined bindings for resolving references and injection targets
- Default resolution of EJB references and EJB injections: The AutoLink feature
- Resolution of EJB and resource references and injections: The lookup feature
- “Overriding environment entries defined in applications ” on page 451
- “Overriding data source definitions ” on page 451
- Naming considerations in clustered environments
- User-defined EJB extension settings
- Legacy (XMI) bindings
- User-specified XML bindings

Default classic bindings for EJB business interfaces, homes, and no-interface views

You do not have to explicitly define JNDI binding names for each of the interfaces or EJB homes within an EJB 3.x module or no-interface views within an EJB 3.1 module. If you do not explicitly assign bindings, the EJB container of the product assigns default classic bindings using the rules outlined here. This is different from the EJB support in the product prior to the EJB 3.0 specification being supported.

The EJB container performs two default classic bindings for each interface (business, remote home, or local home) or no-interface view on each enterprise bean. These two classic bindings are referred to here as the views of the interface or no-interface *short* binding and *long* binding. The short binding uses just the package-qualified Java class name of the interface or no-interface view, while the long binding uses the component ID of the enterprise bean as an extra qualifier prior to the package-qualified interface or no-interface view class name, with a hash or number sign (# symbol) between the component ID and the interface or no-interface view class name. You can think of the difference between the two forms as being analogous to a *short* TCP/IP host name (just the machine name) versus a *long* host name (machine name with domain name prepended to it).

For example, the short and long default classic bindings for an interface or no-interface view might be com.mycompany.AccountService and AccountApp/module1.jar/ServiceBean#com.mycompany.AccountService, respectively.

By default, the component ID for EJB default classic bindings is formed using the application name, module name, and component name of the enterprise bean, but you can assign any string you want instead. By defining your own string as the component ID, you can set up a naming convention where the long-form bindings of the enterprise bean share a common user-defined portion, yet also have a system-defined portion based on the name of each interface or no-interface view class. It also allows you to make the default EJB binding names independent of how you have packaged the enterprise beans within the application module hierarchy. Overriding a default component ID of an enterprise bean is described in the “User-defined bindings for EJB business interfaces, homes, and no-interface views” section of this topic.

As mentioned earlier in the section on the classic JVM-scoped local namespace and the classic globally scoped JNDI namespace, all local interfaces, homes, and no-interface views must be bound into the classic ejblocal: namespace, which is accessible only within the same server process (JVM), while remote interfaces and homes must be bound into the classic globally scoped namespace, which is accessible from anywhere in the WebSphere product cell. As you would expect, the EJB container follows these rules for the default bindings.

In addition, the *long* default bindings for remote interfaces follow recommended Java EE best practices in that they are grouped under an ejb context name. By default, EJB remote home and business interfaces are bound into the root of the application server naming context. However, the application server root context is used for binding more than just EJB interfaces, so to keep this context from getting too cluttered, it is a good practice to group EJB-related bindings into a common “ejb” subcontext rather than placing them directly in the server root context. It is like why you would use subdirectories on a disk volume rather than putting all the files in the root directory.

The *short* default bindings for remote interfaces are not bound in the ejb context. The short default bindings are located in the root of the server root context. Even though it is a best practice to group all the EJB-related bindings under an ejb context, there are other considerations including the following situations:

- The short default bindings provide a simple, direct way to access an EJB interface. Placing them directly in the server root context and referring to them by just the interface name or the interface name prepended with ejblocal: was in keeping with that goal of simplicity.
- At the same time, placing the long default bindings in the ejb context, or the ejblocal: context in the case of a local interface, kept those bindings out of the root context of the server and reduced the clutter there enough to allow having the short bindings in the root context.
- It provides a degree of cross-compatibility with other Java EE application servers that use similar naming conventions.

To summarize, all local default bindings, both short and long, are placed in the classic ejblocal: server/JVM-scoped namespace, while remote default bindings are placed in the root context of the server of the classic globally scoped namespace if they are short, or in the <server_root>/ejb context (following the root context of the server) if they are long. Thus, the only default bindings in the globally scoped root context of the server are the short bindings for remote interfaces, which is the best balance between providing a simple, portable usage model and keeping the globally scoped root context of the server from becoming too cluttered.

Default classic binding pattern

The patterns for each type of classic binding are displayed in the table. In these patterns, strings written in *<bracketed italics>* represent a value. For example, *<package.qualified.interface>* might be com.mycompany.AccountService, and *<component-id>* might be AccountApp/module1.jar/ServiceBean.

Table 61. Default binding patterns. Default binding patterns

Binding patterns	Description
ejblocal:*<package.qualified.interface>*	Short form local interfaces, homes, and no-interface views
<package.qualified.interface>	Short form remote interfaces and homes
ejblocal:*<component-id>*#*<package.qualified.interface>*	Long form local interfaces, homes, and no-interface views
ejb/*<component-id>*#*<package.qualified.interface>*	Long form remote interfaces and homes

The *component-id* default pattern is *<application-name>*/*<module-jar-name>*/*<ejb-name>* unless it is overridden in the EJB module binding file using the component-id attribute as described in the next section, “Conflicts in short default binding names when multiple enterprise beans implement the same interface”. The *<module-jar-name>* variable, when not overridden by the EJB module binding file, is the name of the physical module file within the EAR including the extension, for example, `.jar`, `.ear`, `.war`, as described in the previous “Module name” section, even if a logical module name is specified in the deployment descriptor.

Conflicts in short default classic binding names when multiple enterprise beans implement the same interface

When more than one enterprise bean that is running in the application server implements a given interface or no-interface view, the short default classic binding name becomes ambiguous because the short name might refer to any of the Enterprise JavaBeans that implement this interface or no-interface view. To avoid

this situation, you must either explicitly define a binding for each Enterprise JavaBeans that implements the given interface or no-interface view as described in the next section, or disable short default classic bindings for applications containing these Enterprise JavaBeans by defining a WebSphere product JVM custom property, com.ibm.websphere.ejbcontainer.disableShortDefaultBindings. For more information about defining the JVM custom property, read about Java Virtual machine custom properties.

To use this JVM custom property, set the property name to com.ibm.websphere.ejbcontainer.disableShortFormBinding and the property value to either * (asterisk) as a wildcard value to disable short form default classic bindings for all applications in the server, or to a colon-delimited sequence of the Java EE application names for which you want to disable short default classic bindings, for example, PayablesApp:InventoryApp:AccountServicesApp.

Effect of explicit assignment on default classic bindings

If you explicitly assign a binding definition for an interface, home, or no-interface view, no short or long default classic bindings are performed for that interface or no-interface view.

Note: This only applies to the specific interfaces or no-interface views for which you assign an explicit binding. Other interfaces on that enterprise bean, without explicitly assigned bindings, are bound by using default classic binding names.

java:[scope] namespaces

The java:global, java:app, and java:module namespaces are introduced by the Java EE 6 specification. They provide a mechanism for binding and looking up resources that are portable across application servers.

The server always creates a default long-form binding for each EJB interface, including the no-interface view, and places them into the java:global, java:app, and java:module namespaces. A short-form binding is also created and placed into the java:global, java:app, and java:module namespaces, if the bean exposes only one interface, including the no-interface view. The default bindings are only created for session beans. They are not created for entity beans or message driven beans.

The long-form and short-form bindings both contain the application name, the module name, and the bean component name. The application name is defaulted to the base name of the .ear file, without the extension. The application name can be overridden using the application-name element in the application.xml file. The module name is defaulted to the path name of the module, with the extension removed and any directory names included. The module name can be overridden using the module-name element in the ejb-jar.xml or web.xml files. The bean component name defaults to the unqualified name of the bean class. The bean component name can be overridden using the name attribute on the EJB component defining annotation, or the ejb-name element in the ejb-jar.xml file.

The long-form binding pattern is java:global/*<applicationName>*/*<moduleName>*/*<bean component name>*!*<fully qualified interface name>*.

The short-form binding pattern is java:global/*<applicationName>*/*<moduleName>*/*<bean component name>*.

For example, the bean component MyBeanComponent exposes just the one com.foo.MyBeanComponentLocalInterface interface, and is packaged in the `myModule.jar` module in the `myApp.ear` file. As a result, the following bindings are created in the java:[scope] namespaces:

- java:global/myApp/myModule/MyBeanComponent!com.foo.MyBeanComponentLocalInterface
- java:global/myApp/myModule/MyBeanComponent
- java:app/myModule/MyBeanComponent!com.foo.MyBeanComponentLocalInterface
- java:app/myModule/MyBeanComponent

- java:module/MyBeanComponent!com.foo.MyBeanComponentLocalInterface
- java:module/MyBeanComponent

The MyBeanComponent bean can be obtained from the java:[scope] namespaces using one of the following techniques:

- Use the lookup attribute on the @EJB annotation; for example:
  ```
  @EJB(lookup="java:global/myApp/myModule/MyBeanComponent")
  ```
- Use the lookup-name element in ejb-jar.xml; for example:
  ```
  <lookup-name>java:global/myApp/myModule/MyBeanComponent!com.ibm.MyBeanComponentLocalInterfaces</lookup-name>
  ```
- Complete a lookup on the InitialContext object; for example:
  ```
  initialContext.lookup("java:global/myApp/myModule/MyBeanComponent!com.foo.MyBeanComponentLocalInterfaces")
  ```

In addition to the default bindings created by the application server, you can define references in the java:global, java:app, and java:module namespaces. References defined in the java:global, java:app, and java:module namespaces do not go into the component namespace. References defined in the java:global, java:app, or java:module namespaces must be looked up or injected from those namespaces. They cannot be looked up or injected from the component namespace.

A bean component can use the java:module namespace to declare a reference that is usable by a component packaged in the same module. It can use the java:app namespace to declare a reference that is usable by a component packaged in a different module within the same application. It can use the java:global namespace to declare a reference that is usable by a component packaged in a different application.

References with identical names in the java:global, java:app, or java:module namespaces might conflict with each other, just as references with identical names in the component namespace might conflict. A reference scoped to the java:app namespace for one application does not conflict with an identically named reference scoped to the java:app namespace for a different application. Likewise, a reference scoped to the java:module namespace for one module does not conflict with an identically named reference scoped to the java:module namespace for a different module.

A reference can be declared in the java:global namespace using annotations; for example:

```
@EJB(name="java:global/env/myBean")
```

A reference can be declared in the ejb-jar.xml file; for example:

```
<resource-ref>
    <res-ref-name>java:global/env/myDataSource</res-ref-name>
    ....
</resource-ref>
```

For additional documentation on the java:[scope] namespaces, see section 5.2.2 of the Java EE 6 specification and section 4.4 of the Enterprise JavaBeans 3.1 specification.

User-defined bindings for EJB business interfaces, homes, and no-interface views

For cases where you want to manually assign binding locations rather than using the product default bindings, you can use the EJB module binding file to assign your own binding locations to specific interfaces, homes, and no-interface views. You can also use this file to only override the component ID portion of the default bindings on one or more enterprise beans in the module. Overriding the component ID provides a middle ground between using all default bindings and completely specifying the binding name for each interface or no-interface view.

To specify user-defined bindings information for EJB 3.x modules, place the file ibm-ejb-jar-bnd.xml, in the META-INF directory for the EJB Java archive (JAR) file. The suffix on this file is XML. Also, when defining

a classic binding for a local interface or no-interface view, you must preface the name with the string “ejblocal:” so it is bound into the classic JVM-scoped ejblocal: namespace.

The `ibm-ejb-jar-bnd.xml` file is used for EJB 3.0 and later modules that run on the product, whereas the `ibm-ejb-jar.bnd.xmi` file is used for pre-EJB 3.0 modules and for web modules. The binding file format in the `ibm-ejb-jar.bnd.xml` file is different from the XMI file format for the following reasons:

- Bindings and extensions that are declared in the XMI file format depend on the presence of a corresponding `ejb-jar.xml` deployment descriptor file that explicitly refers to unique ID numbers that are attached to elements in that file. This system is no longer viable for EJB 3.0 and later modules, where it is no longer a requirement for the module to contain an `ejb-jar.xml` deployment descriptor.
- The XMI file format was designed to be machine-edited only by the product development tools and system management functions; it was effectively part of the internal implementation of the product and the file structure was never documented externally. This made it impossible for developers to manually edit binding files, or create them as part of a WebSphere independent build process, in a supported way.
- Rather than referring to encoded ID numbers in the `ejb-jar.xml` deployment descriptor, the XML-based binding file refers to an EJB component by its EJB name. Each EJB component in a module has a unique EJB name, either by default or through explicit assignment by the developer. Therefore, this behavior provides an unambiguous way to target bindings and extensions.
- The new binding files are XML-based, and an XML Schema Definition (XSD) file is provided to externally document the structure. These `.xsd` files can be consumed by many common XML file editors to assist in syntactic verification and code completion functions. As a result, it is now possible for developers to produce and edit the binding and extension files independently of the application server infrastructure.

The following table lists the `ibm-ejb-jar-bnd.xml` elements and attributes that are used to assign bindings to EJB interfaces and homes for EJB 3.x modules and no-interface views for EJB 3.1 modules.

Table 62. `ibm-ejb-jar-bnd.xml` elements and attributes. `ibm-ejb-jar-bnd.xml` elements and attributes

Element or attribute	How used	Example	Comments
<session>	Declares a group of binding assignments for a session bean.	`<session name="AccountServiceBean"/>`	Requires name attribute and at least one of the following attributes: simple-binding-name attribute, local-home-binding-name attribute, remote-home-binding-name attribute, or <interface> element.
name	Attribute that identifies the ejb-name of the enterprise bean that a <session>, <message-driven>, or <entity>, or other element applies to.	`<session name="AccountServiceBean"/>`	The name value is the name declared in the <ejb-name> element of an ejb-jar.xml deployment descriptor file, the name attribute of a @Stateful, @Stateless, @Singleton, or @MessageDriven annotation, or defaults to the unqualified class name of the EJB implementation class annotated with the @Session or @MessageDriven annotation (if no <ejb-name> value is declared in the XML deployment descriptor and no name parameter is declared on the annotation).

Table 62. `ibm-ejb-jar-bnd.xml` elements and attributes (continued). `ibm-ejb-jar-bnd.xml` elements and attributes

Element or attribute	How used	Example	Comments
component-id	Attribute that overrides the default component ID value for an enterprise bean. The default long-form classic bindings for this enterprise bean uses the specified component ID instead of *<app_name>/<module_jar_name>/<bean_name>*.	`<session name="AccountServiceBean" component-id="Dept549/AccountProcessor"/>` The previous example results in the bean whose ejb-name is AccountServiceBean, having its long-form default classic local interfaces bound at ejblocal:Department549/AccountProcessor#*<package.qualified.interface>* Its long-form default classic remote interfaces are bound at ejb/Department549/AccountProcessor#*<package.qualified.interface>*	Can be used alone, or in combination with the <interface> element, the local-home-binding-name attribute, or the remote-home-binding-name attribute. Interfaces that are not assigned explicit bindings might have default classic bindings performed using the user-specified component ID value. Interfaces that are assigned explicit bindings are bound using those values. Since the simple-binding-name attribute is intended to apply to all defined interfaces on a given enterprise bean (leaving no interfaces defaulted), applying a component-id in combination with a simple-binding-name is typically not useful.

Table 62. `ibm-ejb-jar-bnd.xml` elements and attributes (continued). `ibm-ejb-jar-bnd.xml` elements and attributes

Element or attribute	How used	Example	Comments
simple-binding-name	A simple mechanism for assigning interface bindings for Enterprise JavaBeans that: • Implement a single EJB 3.x business interface • Implement a pre-EJB 3.0 style component interface (local, remote or both types) with a companion EJB home. The value of the attribute is used as the binding location of the enterprise bean business interface, or the binding location of the Enterprise JavaBeans local, remote homes, or both. The binding is placed in the classic ejblocal: namespace if the interface or home is local, and placed in the root context of the application server of the classic globally scoped JNDI namespace if the interface or home is remote.	`<session name="AccountServiceBean" simple-binding-name="ejb/AccountService"/>` This example results in the bean whose ejb-name is AccountServiceBean, having its local business interface or home, if any, bound at ejblocal:ejb/AccountService in the classic local JVM-scoped EJB namespace, and its remote business interface or home (if any) bound at ejb/AccountService in the root context of the application server of the classic globally scoped JNDI namespace. **Important:** Important:The exact value of the attribute, including, in this specific example, the “ejb” subcontext name is used even if the interface is a local interface bound into the ejblocal: namespace. When user-defined bindings are specified, the exact name specified by the attribute is used.)	Not to be used in combination with local-home-binding-name or remote-home-binding-name attributes, or the <interface> element. Also, must not be used on beans that implement more than one business interface - use the <interface> element in that case instead. If this attribute is used on an enterprise bean that implements more than one business interface, or a combination of business interface and local/remote component interface with home, the resulting bindings are disambiguated by appending a hash or number sign (# symbol) to the attribute value, followed by the package-qualified class name of each interface, home, or both on the enterprise bean. This condition can be avoided, however, by using the <interface> element to define a binding for each of the business interfaces instead of using simple-binding-name. **Important:** Important: defining a simple-binding-name on a bean that implements more than one business interface is not the same as overriding the default component ID for a bean using <component-id>. Remote interface default bindings defined with a component-id are still grouped under the EJB context (as all remote interface default bindings are), while remote interface bindings disambiguated by the EJB container in response to erroneous use of simple-binding-name on a bean with multiple interfaces are not grouped under the ejb context.Additionally, the inclusion of the package-qualified class name always occurs for long-form default classic bindings, whereas with simple-binding-name it occurs only on error conditions, where disambiguation is necessary. Do not depend on the binding name created through disambiguation, since whether that effect occurs might change if the bean is changed to implement more or fewer interfaces.
local-home-binding-name	Attribute to specify the binding location of the local home of an enterprise bean.	`<session name="AccountServiceBean" local-home-binding-name="ejblocal:AccountService"/>`	Not to be used in combination with the simple-binding-name attribute. Since local homes must always be bound into the classic JVM-scoped namespace, the value must begin with the ejblocal: prefix.

Table 62. ibm-ejb-jar-bnd.xml elements and attributes (continued). ibm-ejb-jar-bnd.xml elements and attributes

Element or attribute	How used	Example	Comments
remote-home-binding-name	Attribute to specify the binding location of the remote home of an enterprise bean.	<session name="AccountServiceBean" remote-home-binding-name= "ejb/services/AccountService"/>	Not to be used in combination with the simple-binding-name attribute. The value cannot begin with the classic ejblocal: prefix, since remote homes cannot be bound into the classic ejblocal: namespace.
<interface>	A subelement of the <session> element that assigns a binding to a specific EJB business interface or no-interface view. In contrast to the simple-binding-name, local-home-binding-name and remote-home-binding-name attributes, both a binding-name parameter and a class parameter are necessary (in fact, this distinction is why a separate XML element is necessary rather than an attribute). The class parameter specifies the package-qualified name of the business interface or no-interface view class to be bound.	<interface class="com.ejbs.InventoryService" binding-name="ejb/Inventory"/> (declared as a subelement inside a <session> element)	Not to be used in combination with the simple-binding-name attribute. Since local interfaces and no-interface views must always be bound into the classic JVM-scoped namespace, the binding-name value must begin with the ejblocal: prefix when this element is applied to a local interface or no-interface view.
binding-name	Attribute to specify the binding location of a business interface bound with the <interface> element.	<interface class="com.ejbs.InventoryService" binding-name="ejb/Inventory"/> (declared as a subelement inside a <session> element)	Required in combination with the <interface> element (and used on that element only). Since local interfaces must always be bound into the classic JVM-scoped namespace, the binding-name value must begin with the ejblocal: prefix when applied to a local interface.

Binding file Example 1

The following example is a basic ibm-ejb-jar-bnd.xml file that contains only the elements and attributes that assign binding names to EJB interfaces and no-interface views. It overrides the component ID used for default bindings on the enterprise bean that is named *S01*, and assigns explicit bindings to some of the interfaces on the enterprise beans, *S02* and *S03*, in this module.

```
<?xml version="1.0" encoding="UTF-8?">
<ejb-jar-bnd xmlns=http://websphere.ibm.com/xml/ns/javaee xmlns:xsi="
 http://www.w3.org/2001/XMLSchema-instance "xsi:schemaLocation"=
 http://websphere.ibm.com/xml/ns/javaee
 http://websphere.ibm.com/xml/ns/javaee/ibm-ejb-jar-bnd_1_0.xsd "version 1.0">
 <session name="S01" component-id="Department549/AccountProcessors"/>
 <session name="S02" simple-binding-name="ejb/session/S02"/>
 <session name="S03">
  <interface class="com.ejbs.BankAccountService" binding-name="ejblocal:session/BAS"/>
 </session>
</ejb-jar-bnd>
```

The binding file has the following results:

- The session bean with ejb-name S01 is assigned a user-defined component ID, overriding the default component ID (application name/ejb-jar module name/bean name) for all interfaces and no-interface views on that bean. Local interfaces and no-interface views on this bean are bound at `ejblocal:Department549/AccountProcessors#<package.qualified.interface.name>` while remote interfaces are bound at `ejb/Department549/AccountProcessors#<package.qualified.interface.name>`
- The session bean with ejb-name *S02* is assumed to have a single EJB 3.x business interface or EJB 3.1 no-interface view. Alternatively, it could have a pre-EJB 3.0 “component” interface with local home, remote home, or both local and remote homes. The business interface, or the home or homes of the component interface are bound at ejblocal:ejb/session/S02 if it is local, or ejb/session/S02 if it is remote.

If bean *S02* has more than one business interface, or business interfaces and home, a simple-binding-name is ambiguous. In that case, the container disambiguates the binding assignments by appending #<*package.qualified.interface.name*> to the simple binding name, ejb/session/S02, for each of the bean interfaces.

- The EJB 3.x business interface or EJB 3.1 no-interface view, com.ejbs.BankAccountService, on the session bean with ejb-name *S03* is bound at ejblocal:session/BAS.

All other business interfaces, homes, and no-interface views on this bean, if present, are assigned default classic bindings. The com.ejbs.BankAccountService interface is assumed to be local since it was designated for the ejblocal: namespace in this example; an error occurs if the interface is not local.

The next section expands on this example, introducing elements for resolving the targets of various kinds of reference and injection entries that are declared either in the XML deployment descriptor or through annotations.

User-defined bindings for resolving references and injection targets

The previous section showed examples of assigning user-defined binding names for business interfaces, homes, and no-interface views. This section covers resolving linkage targets for references, injection directives, and message-driven bean destinations.

Table 63. Elements and attributes to resolve linkage targets for references and injection targets. Elements and attributes to resolve linkage targets for references and injection targets

Element or attribute	How used	Example	Comments
<jca-adapter>	Defines the JCA 1.5 adapter activation spec, and a message-destination JNDI location, for delivery of messages to a message-driven bean.	`<jca-adapter activation-spec-binding-name="jms/InternalProviderSpec" destination-binding-name="jms/ServiceQueue"/>`	Requires *activation-spec-binding-name* attribute. If the corresponding message-drive bean does not identify its message destination by using the <message-destination-link> element, then the *destination-binding-name* attribute is also required. Can optionally include activation-spec-auth-alias attribute.
<ejb-ref>	Resolves the target of an ejb-ref declaration, which is declared through the @EJB annotation or through the ejb-ref in the ejb-jar.xml deployment descriptor, providing the linkage between the name declared in the component-scoped java:comp/env namespace and the name of the target enterprise bean in the classic JVM-scoped ejblocal:, or classic globally scoped JNDI namespace.	`<ejb-ref name="com.ejbs.BankAccountServiceBean/s02Ref" binding-name="ejb/session/S02"/>`	Requires the name and binding-name attributes.
<message-driven>	Declares a group of binding assignments for a message-driven bean.	`<message-driven name="EventRecorderBean"> <jca-adapter activation-spec-binding-name="jms/InternalProviderSpec" destination-binding-name="jms/ServiceQueue"/> </message-driven>`	Requires name attribute and <jca-adapter> subelement.

Table 63. Elements and attributes to resolve linkage targets for references and injection targets (continued).
Elements and attributes to resolve linkage targets for references and injection targets

Element or attribute	How used	Example	Comments
<message-destination>	Associates the name of a message destination, which is a logical name defined in a Java EE module deployment descriptor, with a specific global JNDI name, which is an actual name in the JNDI namespace. <message-destination-ref> elements in the Java EE module deployment descriptor, or @Resource injection directives that inject message destinations, can then use the <message-destination-line> element to refer to this message-destination by the destination logical name, rather than requiring individual <message-destination-ref> binding entries in the binding file for each defined message-destination-ref.	`<message-destination name="EventProcessingDestination" binding-name="jms/ServiceQueue"/>`	Requires name and binding-name attributes.
<message-destination-ref>	Resolves the target of a message-destination-ref declaration that is declared through the @Resource annotation or through the message-destination-ref in ejb-jar.xml, providing the linkage between the name declared in the component-scoped java:comp/env namespace and the name of the target resource environment in the global JNDI namespace.	`<message-destination-ref name="com.ejbs.BankAccountServiceBean/serviceQueue" binding-name="jms/ServiceQueue"/>`	Requires the name and binding-name attributes.
<resource-ref>	Resolves the target of a resource-ref declaration that is declared through the @Resource annotation or through resource-ref in ejb-jar.xml, providing the linkage between the name declared in the component-scoped java:comp/env namespace and the name of the target resource in the global JNDI namespace.	`<resource-ref name="com.ejbs.BankAccountServiceBean/dataSource" binding-name="jdbc/Default"/>`	Requires the name and binding-name attributes. Can include the authentication-alias or custom-login-configuration attributes.
<resource-env-ref>	Resolves the target of a resource-env-ref declaration that is declared through the @Resource annotation or through resource-env-ref in ejb-jar.xml, providing the linkage between the name declared in the component-scoped java:comp/env namespace and the name of the target resource environment in the global JNDI namespace.	`<resource-env-ref name="com.ejbs.BankAccountServiceBean/dataFactory" binding-name="jdbc/Default"/>`	Requires the name and binding-name attributes.
<env-entry>	Overrides an environment entry with the specified value represented in string format or object which can be accessed with a JNDI lookup on the specified lookup name applied to the default initial context.	`<env-entry name="java:module/env/taxYear" value="2010"/>` `<env-entry name="java:module/env/taxYear" binding-name="cell/persistent/MyApp/MyModule/taxYear"/`	Requires the name attribute and either the value or the binding-name attribute, but not both.

Table 63. Elements and attributes to resolve linkage targets for references and injection targets (continued).
Elements and attributes to resolve linkage targets for references and injection targets

Element or attribute	How used	Example	Comments
<data-source>	Overrides a data source definition, which is declared through the @DataSourceDefinition annotation or through the data-source element in the application, or a module deployment descriptor, with a managed resource.	`<data-source name="java:module/env/myDS" binding-name="jdbc/DB2DS"/>`	Requires the name and binding-name attributes.
name	Attribute that identifies the naming location, typically within the component-specific java:comp/env namespace, that defines the “source” side of a reference/target linkage, such as in ejb-ref, resource-ref, resource-env-ref, message-destination, or message-destination-ref.	`<ejb-ref name="com.ejbs.BankAccountServiceBean/goodBye" binding-name="ejb/session/S02"/>`	
binding-name	Attribute that identifies the naming location within the classic ejblocal: or classic globally scoped JNDI namespace, or java:global namespace that defines the “target” side of a reference/target linkage, such as in ejb-ref, resource-ref, resource-env-ref, message-destination, or message-destination-ref.	`<ejb-ref name="com.ejbs.BankAccountServiceBean/goodBye" binding-name="ejb/session/S02"/>`	
value	Attribute that specifies the value to use for an env-entry binding.	`<env-entry name="java:module/env/taxYear" value="2010"/>`	
activation-spec-binding-name	Attribute that identifies the JNDI location of the activation specification associated with the JCA 1.5 adapter to be used to deliver messages to a message-driven bean.	`<jca-adapter activation-spec-binding-name="jms/InternalProviderSpec" destination-binding-name="jms/ServiceQueue"/>`	This name must match the name of a JCA 1.5 activation specification that you define to WebSphere Application Server.
activation-spec-auth-alias	Optional attribute that identifies the name of a J2C authentication alias used for authentication of connections to the JCA resource adapter. A J2C authentication alias specifies the user ID and password that is used to authenticate the creation of a new connection to the JCA resource adapter.	`<jca-adapter activation-spec-binding-name="jms/InternalProviderSpec" activation-spec-auth-alias="jms/Service47Alias" destination-binding-name="jms/ServiceQueue"/>`	This name must match the name of a J2C authorization alias that you define to WebSphere Application Server
destination-binding-name	Attribute that identifies the JNDI name that the message-driven bean uses to look up its JMS destination in the JNDI name space.	`<jca-adapter activation-spec-binding-name="jms/InternalProviderSpec" destination-binding-name="jms/ServiceQueue"/>`	This name must match the name of a JMS queue or topic that you define to WebSphere Application Server.
authentication-alias	Optional subelement of the <resource-ref> binding element. If the resource reference is for a connection factory, then an optional JAAS login configuration can be specified; in this case a simple authentication alias name.	`<resource-ref name="com.ejbs.BankAccountServiceBean/dataSource" binding-name="jdbc/Default"> <authentication-alias name="defaultAuth"/> <resource-ref>`	This name must match the name of a JAAS authentication alias that you define to WebSphere Application Server.
custom-login-configuration	Optional subelement of the <resource-ref> binding element. If the resource reference is for a connection factory, then an optional JAAS login configuration can be specified; in this case a set of properties (name/value pairs).	`<resource-ref name="com.ejbs.BankAccountServiceBean/dataSource" binding-name="jdbc/Default"> <custom-login-configuration-name="customLogin"> <property name="loginParm1" value="ABC123"/> <property name="loginParm2" value="DEF456"/> </custom-login-configuration> </resource-ref>`	This name must match the name of a JAAS login configuration that you define to WebSphere Application Server.

Binding file Example 2

The following example is an expansion of the basic ibm-ejb-jar-bnd.xml file introduced in Example 1.

```
<?xml version="1.0" encoding="UTF-8"?>
<ejb-jar-bnd xmlns="http://websphere.ibm.com/xml/ns/javaee" "xmlns:xsi"=
"http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee"
"http://websphere.ibm.com/xml/ns/javaee/ibm-ejb-jar-bnd_1_0.xsd version" "1.0">
 <session name="S01" component-id="Department549/AccountProcessors"/>
 <session name="S02" simple-binding-name="ejb/session/S02"/>
 <session name="S03">
  <interface class="com.ejbs.BankAccountService"
   binding-name="ejblocal:session/BAS"/>
  <ejb-ref name="com.ejbs.BankAccountServiceBean/goodBye"
   binding-name="ejb/session/S02"/>
  <resource-ref name="com.ejbs.BankAccountServiceBean/dataSource"
   binding-name="jdbc/Default"/>
 </session>
 <message-driven name="MO1">
  <jca-adapter activation-spec-binding-name="jms/InternalProviderSpec"
   destination-binding-name=jms/"ServiceQueue"/>
 </message-driven>
 <session name="S04" simple-binding-name="ejb/session/S04">
  <resource-ref name="ejbs.S04Bean/dataSource"
   binding-name="jdbc/Default">
   <authentication-alias name="defaultlogin"/>
  </resource-ref>
 </session>
 <session name="S05">
  <interface class="com.ejbs.InventoryService"
   binding-name="ejb/session/S05Inventory"/>
  <resource-ref name="ejbs.S05Bean/dataSource"
   binding-name="jdbc/Default">
   <custom-login-configuration name="customLogin">
    <property name="loginParm1" value="ABC123"/>
    <property name="loginParm2" value="DEF456"/>
   </custom-login-configuration>
  </resource-ref>
 </session>
</ejb-jar-bnd>
```

This binding has the following results:

1. The business interface, home, and no-interface view bindings for the session beans named S01, S02, and S03 are unchanged from the previous example.
2. The session bean whose ejb-name is *S03* now includes two reference target resolution bindings:
   - The ejb-ref binding resolves the EJB reference defined at java:comp/env/com.ejbs.BankAccountServiceBean/goodBye, to the JNDI location ejb/session/S02 within the root JNDI context of the application server. The EJB reference can also be defined by an @EJB injection in the class com.ejbs.BankAccountServiceBean, into an instance variable named “goodBye”.

     Note: ejb/session/S02 is the JNDI location of session bean *S02* also defined in this same binding file, which means that the reference points to the session bean whose name is *S02*.
   - The resource-ref binding resolves the resource reference defined at java:comp/env/com.ejbs.BankAccountServiceBean/dataSource, to the JNDI location jdbc/Default. The resource reference could also have been defined by a @Resource injection in the class com.ejbs.BankAccountServiceBean, into an instance variable named “dataSource”.
3. Bindings are defined for a message-driven bean whose ejb-name is *M01*. The MDB receives messages from a JMS destination defined to WebSphere Application Server, whose JNDI name is jms/ServiceQueue, using a JCA 1.5 adapter whose JCA 1.5 activation spec has been defined to WebSphere Application Server with the name jms/InternalProviderSpec.
4. The session bean whose ejb-name is *S04* is assumed to have a single business interface or no-interface view, which is bound at ejb/session/S04, if remote or ejblocal:ejb/session/S04, if local. It has a resource-ref with name, java:comp/env/ejbs/S04Bean/dataSource. This can also be the class, ejbs.S04Bean, with an @Resource injection into a variable named, dataSource. This resource-ref resolved to the JNDI location jdbc/Default. The resource-ref refers to a J2C connection and connects to this resource using a simple authentication alias named *defaultlogin* that has been defined in WebSphere Application Server.

5. A business interface binding is defined for the interface whose class name is com.ejbs.InventoryService implemented by the session bean whose ejb-name is *S05*; the interface is assumed to be remote since it is not prefixed with “ejblocal:” and might thus be bound at ejb/session/S05Inventory in the root JNDI context of the server in the classic globally-scoped namespace. Any other business interfaces implemented by this bean are assigned default classic bindings. The bean has a resource-ref with name java:comp/env/ejbs.S05Bean/dataSource (or a @Resource injection in the class ejbs.S05Bean into a variable named “dataSource”) that is resolved to the JNDI location jdbc/Default. The resource-ref refers to a J2C connection and connects to this resource using a custom login configuration that includes two name-value pairs.

Bindings file Example 3

This example later in this section demonstrates how to define and resolve EJB reference bindings to perform JNDI lookups across application server instances within the same WebSphere Application Server cell. It uses two EJB beans: a called bean that defines an explicit binding using the simple-binding-name attribute, and a calling bean that performs an @EJB injection and uses the ejb-ref element within its associated binding file to resolve the reference so it points at the called bean, that resides in a different application server process.

ibm-ejb-jar-bnd.xml (called bean)

```
<?xml version="1.0" encoding="UTF-8"?>
<ejb-jar-bnd xmlns="http://websphere.ibm.com/xml/ns/javaee"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee"
 "http://websphere.ibm.com/xml/ns/javaee/ibm-ejb-jar-bnd_1_0.xsd" version="1.0">
 <session name="FacadeBean" simple-binding-name="ejb/session/FacadeBean"/>
</ejb-jar-bnd>
```

This binding file content assumes that the session bean whose ejb-name is “FacadeBean” implements a single business interface, and thus the simple-binding-name attribute can be used as an alternative to the <interface> subelement. In this case, the FacadeBean implements a single remote business interface, bound at ejb/session/FacadeBean in the server root JNDI context of the application server where the FacadeBean resides.

Code snippet (calling bean)

```
@EJB(name="ejb/FacadeRemoteRef")
FacadeRemote remoteRef;
try {
     output = remoteRef.orderStatus(input);
}
catch (Exception e) {
     // Handle exception, etc.
}
```

This code snippet performs an EJB resource injection into the instance variable named “remoteRef”, which is of type FacadeRemote. The injection overrides the “name” parameter, setting the resulting ejb-ref reference name to ejb/FacadeRemoteRef. The code invokes a business method on the injected reference.

ibm-ejb-jar-bnd.xml (calling bean)

```
<?xml version="1.0" encoding="UTF-8"?>
<ejb-jar-bnd xmlns="http://websphere.ibm.com/xml/ns/javaee"
 "xmlns:xsi="
 "http://www.w3.org/2001/XMLSchema-instance"
 xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee"
 "http://websphere.ibm.com/xml/ns/javaee/ibm-ejb-jar-bnd_1_0.xsd" version="1.0">
 <session name="CallingBean">
  <ejb-ref name="ejb/FacadeRemoteRef"
   binding-name="cell/nodes/S35NLA1/servers/S35serverA1/ejb/session/FacadeBean"/>
 </session>
</ejb-bnd-jar>
```

Finally, this binding file resolves the EJB reference with an ejb-ref name of ejb/FacadeRemoteRef to point to the classic globally scoped JNDI name of cell/nodes/S35NLA1/servers/S35serverA1/ejb/session/FacadeBean. This classic globally scoped JNDI name represents an interface bound at ejb/session/FacadeBean under the server root context of the server named “S35serverA1” on the node

named “S35NLA1” within the WebSphere Application Server cell of the calling bean. To point to a location within a different WebSphere Application Server cell, a CORBAName-style name can be used instead of a standard JNDI name.

Instructions on how to modify the ibm-ejb-jar-bnd.xml file can be found in the topic, Ways to update application files.

The relationship between injections and references

There is a one-to-one correspondence between injection directives and reference declarations - every injection implicitly defines a reference of some type, and conversely, every reference can optionally also define an injection. You can think of an injection annotation as being the mechanism to define references through annotations rather than defining them in the XML deployment descriptor.

By default, an injection defines a reference with a name formed from the package-qualified class name of the component performing the injection, a forward slash (/), then the name of the variable or property being injected into. For example, an injection performed in the class com.ejbs.AccountService, into a variable or property named “depositService”, results in a reference named java:comp/env/com.ejbs.AccountService/depositService. However, specifying the optional “name” parameter on the injection directive overrides this default name and causes the reference to be named according to the value of the “name” parameter.

Knowing this rule, it is easy to see how a bindings file can be used not only to resolve targets for references declared in an XML deployment descriptor, but also to resolve targets for references implicitly declared by an annotation injection directive. Simply use the value of the “name” parameter on the injection annotation, or the default reference name from the class name and variable/property name if no “name” parameter is specified, as if it were the name of the reference declared in an XML deployment descriptor.

Default resolution of EJB references and EJB injections: The EJBLink and AutoLink features

The *EJBLink* and *AutoLink* features are two different mechanisms that resolve references to EJB components that are packaged in the same application and application server process as the referring component. Both EJBLink and AutoLink remove the need to explicitly resolve the EJB reference with binding information. The EJBLink feature is defined by the EJB specification, while the AutoLink feature is a WebSphere Application Server extension.

The EJBLink and AutoLink features use different search criteria to locate the targeted bean component. EJBLink searches for the targeted bean component using the explicitly specified bean name. AutoLink searches for the targeted bean component using the interface that the bean implements. If no explicit bindings are provided, but a bean name is provided, then the EJBLink feature is used. If no explicit bindings are provided, and no bean name is provided, then the AutoLink feature is used. The EJBLink and AutoLink features are never used together as part of the same search process.

Except for the search criteria, the EJBLink and AutoLink features are similar. Both features search a specific module first, and then if needed fall back to searching the other modules in the same application and application server process. Both features require that the search criteria resolve to exactly one bean component, and consider it an error condition when the search criteria resolves to multiple bean components. An error condition exists because the application server does not know that which of the multiple bean components must be used. In this case, the exception com.ibm.websphere.ejbcontainer.AmbiguousEJBReferenceException occurs. This exception is thrown at run time when the referencing component attempts to find the targeted bean component.

The EJBLink feature supports three different formats.

- Specify only the name of the bean component. For example, MyBean.

- Specify the name of the physical module file, including the extension, that contains the targeted bean component, followed by the # character, followed by the name of the bean component. For example, myModule.jar#MyBean
- Specify the logical name of the module that contains the targeted bean component, the slash character (/), followed by the name of the bean component. For example, MyModule/MyBean.

You can optionally specify the logical name of the module using the module-name element in the EJB deployment descriptor for an ejb-jar module, or you can use the module-name element in the web deployment descriptor file for a WAR module that contains EJB content. For a WAR module that contains EJB content, the module-name element specified in the EJB deployment descriptor is ignored, and the module-name element specified in the web deployment descriptor is processed. When no module-name value is specified in the deployment descriptor, a default logical name is assigned to the module. The default logical module name is the base name of the module file, minus the extension. For example, the module file, MyModule.jar, has the default logical module name MyModule.

Specifying the name of the physical module file is still supported even when the module has a logical name. Specifying the logical name of the module is still supported even when no logical module name is configured in the deployment descriptor. In this case, the base name of the module is used as the logical name of the module.

The embeddable EJB container supports all EJBLink formats. To support the physical module file format, the embeddable EJB container does not allow you to start multiple modules with the same base name.

AutoLink is a value-add feature of WebSphere Application Server that eliminates the need to explicitly resolve EJB reference targets in certain usage scenarios. In WebSphere Application Server V8, AutoLink is implemented within the boundaries of each WebSphere Application Server process. The AutoLink algorithm works as follows.

When the EJB container in the product encounters an EJB reference within a given EJB module, it first checks to see if you have explicitly resolved the target of that reference through inclusion of an entry in the binding file of the module. If it finds no explicit resolution of the target in the binding file, the container searches within the referring module for an enterprise bean that implements the interface type or no-interface view you have defined within the reference.

If it finds *exactly one* enterprise bean within the module that implements the interface or no-interface view, it uses that enterprise bean as the target for the EJB reference. If the container cannot locate an enterprise bean of that type within the module, it expands the search scope to the application that the module is part of, and searches other modules within that application that are assigned to the same application server as the referring module. Again, if the container finds *exactly one* enterprise bean that implements the target interface or no-interface view, within the other modules of the application assigned to the same server as the referring module, it uses that enterprise bean as the reference target.

The scope of AutoLink is limited to the application in which the EJB reference appears, and to the application server on which the referring module is assigned. References to enterprise beans in a different application, enterprise beans in a module assigned to a different application server, or to enterprise beans residing in a module that has been assigned to a WebSphere Application Server cluster, must be explicitly resolved using reference target bindings in the `ibm-ejb-jar-bnd.xml` file of the EJB module, or the `ibm-web-bnd.xmi` file of the web module.

It is important to note that AutoLink is only supported for EJB references, not other types of references although it is supported from the EJB container, the web container, and the application client container. Also, because the scope of the AutoLink function is limited to the server that the referring module is assigned to, or in the case of the Java EE client container, to the server that the client container is configured as its JNDI bootstrap server, it is useful mainly in development environments and other single-server usage scenarios. Even with these present limitations, it can be a significant value during the development experience by removing the need to explicitly resolve EJB references.

Resolution of EJB and resource references and injections: The lookup feature

The lookup feature is defined by the EJB 3.1 specification as a mechanism that resolves references to EJBs or resources, by an explicit JNDI name. You can specify the lookup attribute on the javax.ejb.EJB annotation or on the javax.annotation.Resource annotation. The corresponding XML attribute in the `ejb-jar.xml` file is <lookup-name>, on one of the following elements: <ejb-ref>, <ejb-local-ref>, <env-entry>, <resource-ref>, <resource-env-ref>, or <message-destination-ref>. lookup or <lookup-name> is a JNDI name relative to the java:comp/env naming context.

On an EJB reference, lookup or <lookup-name> must not be specified with beanName or with <ejb-link>. The administrative console displays lookup-name and ejb-link as read-only. However, if a JNDI name is specified in the application installation step “Map EJB references to beans”, it overrides the lookup-name or ejb-link value.

Overriding environment entries defined in applications

Applications might define environment entries with values that are suitable for unit testing, but not for integration testing or production use. If you want to override an environment entry value, you can add the following element to the corresponding binding file:

```
<env-entry name="name" value="value"/>
```

where *name* is the env-entry name as it is defined in the application and *value* is the value assigned to the env-entry represented in string format. The string for *value* is parsed according to the type of the environment entry as if the value had been specified in the deployment descriptor using env-entry-value. For example,

```
<env-entry name="java:module/env/taxYear" value="2010"/>
```

associates the env-entry named “java:module/env/taxYear” with a value of “2010”.

Alternatively, you can configure an env-entry as a reference to another object accessible through JNDI. The object returned from the JNDI lookup is used as the env-entry value. The element for that option has the following form:

```
<env-entry name="name" binding-name="lookupName"/>
```

where *name* is the env-entry name as it is defined in the application and *lookupName* is a JNDI name that resolves when applied to a lookup on the default initial context. For example,

```
<env-entry name="java:module/env/taxYear" binding-name="cell/persistent/MyApp/MyModule/taxYear"/>
```

associates the env-entry named “java:module/env/taxYear” with a value returned from a default initial context lookup operation on “cell/persistent/MyApp/MyModule/taxYear”. You are responsible for creating the JNDI object binding. The class of the bound object must be assignable to the object type of the associated env-entry.

Environment entries can be defined at the application level and in EJB, web, and client modules. Those levels correspond to the binding files `application-bnd.xml`, `ejb-jar-bnd.xml`, `web-app-bnd.xml`, and `application-client-bnd.xml`.

Overriding data source definitions

With Java EE 6, you can develop applications that define data sources using the @DataSourceDefinition annotation or <data-source> deployment descriptor entry.

Your applications should look up resource references as opposed to looking up data source definitions directly. If you are installing an existing application that contains direct lookups to a data source definition,

and you want it to use another data source definition, you can override the data source definition with a binding that resolves to a managed resource that you create. Create the binding by adding the following element to your binding file:

```
<data-source name="name" binding-name="lookupName"/>
```

where *name* is the env-entry name as it is defined in the application and *lookupName* is a JNDI name that resolves when applied to a lookup on the default initial context. For example,

```
<data-source name="java:module/env/myDS" binding-name="jdbc/DB2DS"/>
```

causes lookups on “java:module/env/myDS” to resolve to the data source bound with the name, “jdbc/DB2DS”, relative to the default initial context. The data source bound under jdbc/DB2DS can be created, for example, through the administrative console.

Data sources can be defined at the application level and in EJB, web, and client modules. Those levels correspond to the binding files `application-bnd.xml`, `ejb-jar-bnd.xml`, `web-app-bnd.xml`, and `application-client-bnd.xml`.

Naming considerations in clustered and cross-server environments

The classic global JNDI naming conventions in the previous sections apply in non-clustered environments and when the lookup target is within the same cluster as the source of the lookup. When a lookup is performed from outside a cluster on a binding that is within a given cluster, the lookup string must be qualified to indicate the name of the cluster in which the target resides, according to the following convention:

```
cell/clusters/<cluster-name>/<name-binding-location>
```

For example, given an EJB interface binding location within the application server root context:

```
ejb/Department549/AccountProcessors/CheckingAccountReconciler
```

If the EJB implementing this interface is assigned to an application server that is a member of a cluster named Cluster47, the lookup string external to that cluster is as follows:

```
cell/clusters/Cluster47/ejb/Department549/AccountProcessors/CheckingAccountReconciler
```

When a lookup is performed across application server processes, the lookup string must be qualified to indicate the name of the node and server in which the target resides, according to the following convention:

```
cell/nodes/<node-name>/servers/<server-name>/<name binding location>
```

Again, given an EJB interface binding location within the application server root context:

```
ejb/Department549/AccountProcessors/CheckingAccountReconciler
```

If the enterprise bean that is implementing this interface is assigned to an application server named Server47A1 that is located on a node named S47NLA1, the cross-server lookup string is as follows:

```
cell/nodes/S47NLA1/servers/Server47A1/ejb/Department549/AccountProcessors/CheckingAccountReconciler
```

User-defined EJB extension settings

For cases where you want to specify values for WebSphere Application Server EJB Extension settings, you can use an *EJB module extension file* to assign these settings to specific EJB types within that module. You specify extension settings information for EJB 3.x modules by placing one, or both, of two files into the META-INF directory for the EJB JAR file, depending on the type of extension being defined. The names of the two files are `ibm-ejb-jar-ext.xml` and `ibm-ejb-jar-ext-pme.xml`.

Note: The suffix on these files are XML, not XMI as in prior versions of WebSphere Application Server.

The ibm-ejb-jar-ext.xml and ibm-ejb-jar-ext-pme.xml files are used for EJB 3.x modules running in WebSphere Application Server, whereas the ibm-ejb-jar-ext.xmi and ibm-ejb-jar-ext-pme.xmi files are used for pre-3.0 EJB modules. WebSphere Application Server Version 8.0 uses a new XML-based extension file format instead of the previous .xmi file format for the following reasons:

1. Bindings and extensions declared in the xmi file format depend on the presence of a corresponding ejb-jar.xml deployment descriptor file, explicitly referring to unique ID numbers attached to elements in that file. This system is no longer viable for EJB 3.0 and later modules, where it is no longer a requirement for the module to contain an ejb-jar.xml deployment descriptor.
2. The xmi file format was designed to be machine-edited only by WebSphere development tools and system management functions; it was effectively part of WebSphere's internal implementation and the structure of the file was never documented externally. This made it impossible for developers to manually create or edit binding or extension files, or create them as part of a WebSphere independent build process, in a supported manner.
3. Rather than referring to encoded ID numbers in ejb-jar.xml, the XML-based extension file format refers to EJB components by their EJB name. Each EJB component in a module is guaranteed to have a unique EJB name, either by default or through explicit assignment by the developer, so this provides an unambiguous way to target bindings and extensions.
4. The new binding and extension file formats are XML-based, and XML Schema Definition (xsd) files are provided to externally document their structure. These .xsd files might be consumed by many common XML file editors to assist in syntactic verification and code completion functions. As a result, it is now possible for developers to produce and edit these binding and extension files independently of WebSphere Application Server infrastructure, using a generic XML editor or scripting system of their choice.

Extensions defined in META-INF/ibm-ejb-jar-ext.xml

The following tables outlines extension elements and attributes that must be placed in the META-INF/ibm-ejb-jar-ext.xml file. The subsequent section lists elements and attributes that appear in a separate file, META-INF/ibm-ejb-jar-ext-pme.xml.

Table 64. Elements and attributes of the META-INF/ibm-ejb-jar-ext.xml file. Elements and attributes of the META-INF/ibm-ejb-jar-ext.xml file

Element or Attribute	Description	Example	Usage notes
<session>	Declares a group of extension settings for a session bean.	<session name="AccountServiceBean"/>	Requires *name* attribute. In order to have any effect, also include at least one extension setting definition subelement.
<message-driven>	Declares a group of extension settings for a message-driven bean.	<message-driven name="EventProcessorBean"/>	Requires *name* attribute. In order to have any effect, also include at least one extension setting definition subelement.

Table 65. Elements and attributes of the META-INF/ibm-ejb-jar-ext.xml file. Elements and attributes of the META-INF/ibm-ejb-jar-ext.xml file

Element or Attribute	Description	Example	Usage notes
<time-out>	Subelement to the <session> element that optionally declares the number of seconds between method invocations after which a *stateful* session bean might no longer be available.	<session name="ShoppingCartBean"> <time-out value="600"/> </session>	Requires *value* attribute, a positive integer. **Note:** Only applicable to stateful session beans; must not be used on stateless beans. Attribute default: 300 (5 minutes)

Table 65. Elements and attributes of the META-INF/ibm-ejb-jar-ext.xml file (continued). Elements and attributes of the META-INF/ibm-ejb-jar-ext.xml file

Element or Attribute	Description	Example	Usage notes
<bean-cache>	Subelement of <session> element used to declare bean activation/passivation settings for stateful session beans.	<session name="ShoppingCartBean"> <bean-cache activation-policy="TRANSACTION"/> </session>	To have any effect, also include the activation-policy attribute.
activation-policy	Attribute of <bean-cache> element that declares the conditions under which the bean instance might be activated and passivated. Applicable to stateful session beans. Allowable values and their meanings are: • *TRANSACTION:* Indicates that the bean activates at the start of a transaction and passivates (and is removed from the active EJB instance cache) at the end of the transaction. • *ONCE:* Indicates that the bean activates when it is first accessed in the server process, and passivates (and is removed from the active EJB instance cache) at the discretion of the container, for example, when the cache becomes full. • *ACTIVITY_SESSION:* Indicates that the bean activates and passivates as follows: 1. On an ActivitySession boundary, if an ActivitySession context is present on activation 2. On a transaction boundary, if a transaction context (but no ActivitySession context) is present on activation, or 3. on an invocation boundary.	<session name="ShoppingCartBean"> <bean-cache activation-policy="ONCE"/> </session>	Attribute default: ONCE for stateful session beans.

Table 66. Elements and attributes of the META-INF/ibm-ejb-jar-ext.xml file. Elements and attributes of the META-INF/ibm-ejb-jar-ext.xml file

Element or Attribute	Description	Example	Usage notes
<global-transaction>	Subelement to the <session> and <message-driven> elements that can be used to declare the transaction timeout (in seconds) to be used on transactions started by this specific EJB type (overriding the server setting for global transaction timeout) and also might declare whether this EJB type propagates global transaction context received through web service atomic transactions, across the heterogeneous web service environment.	<session name="AccountServiceBean" <global-transaction transaction-timeout="180" send-wsat-context="FALSE"/> </session>	Requires at least one of transaction-timeout or send-wsat-context attributes. Attribute default: Server transaction timeout setting for transaction-timeout; FALSE for send-wsat-context

Table 66. Elements and attributes of the META-INF/ibm-ejb-jar-ext.xml file (continued). Elements and attributes of the META-INF/ibm-ejb-jar-ext.xml file

Element or Attribute	Description	Example	Usage notes

<local-transaction>	Subelement to the <session> and <message-driven> elements that can be used to declare settings related to local transactions. Supported attributes are boundary, resolver, and unresolved-action; these attributes configure, for the component, the behavior of the local transaction containment (LTC) environment of the container that the container establishes whenever a global transaction is not present. The meaning of each attribute is as follows:
	
	Boundary
	
	This setting specifies the containment boundary at which all contained resource manager local transactions (RMLTs) must be completed. Possible values are:
	• *BEAN_METHOD:* This is the default value. If you select this option, RMLTs must be resolved within the same bean method in which they were started.
	• *ACTIVITY_SESSION:* RMLTs must be resolved within the scope of any ActivitySession in which they were started or, if no ActivitySession context is present, within the same bean method in which they were started.
	
	Resolver
	
	This setting specifies the component responsible for initiating and ending RMLTs. Possible values are:
	• *APPLICATION:* This is the default value. The application is responsible for starting RMLTs and for completing them within the local transaction containment (LTC) boundary. Any RMLTs that are not completed by the end of the LTC boundary are cleaned up by the container according to the value of the Unresolved action attribute.
	• *CONTAINER_AT_BOUNDARY:* The container is responsible for starting RMLTs and for completing them within the LTC boundary. The container begins an RMLT when a connection is first used within the LTC scope, and completes it automatically at the end of the LTC scope. If Boundary is set to ActivitySession, the RMLTs are enlisted as ActivitySession resources and directed to complete by the ActivitySession. If Boundary is set to BeanMethod, the RMLTs are committed at the end of the method by the container.
	
	Unresolved Action
	
	This setting specifies the direction that the container requests RMLTs to take, if those transactions are unresolved at the end of the LTC boundary scope and the Resolver is set to Application. Possible values are:
	• *ROLLBACK:* This is the default value. At end of the LTC boundary scope, the container instructs all unresolved RMLTs to roll back.
	• *COMMIT:* At the end of the LTC boundary scope, the container instructs all unresolved RMLTs to commit. The container instructs the RMLTs to commit only in the absence of an unhandled exception. If the application method that is running in the local transaction context ends with an exception, any unresolved RMLTs are rolled back by the container. This is the same behavior as for global transactions.
		`<session`
		` name>="AccountServiceBean">`
		` <local-transaction`
		`  boundary="BEAN_METHOD"`
		`  resolver="APPLICATION"`
		`  unresolved-action="ROLLBACK"/>`
		`</session>`
			Requires at least one of boundary, resolver, or unresolved-action attributes.
			
			Attribute default:
			`boundary="BEAN_METHOD";`
			`resolver="APPLICATION";`
			`unresolved-action=`
			`"ROLLBACK"`

Table 67. Elements and attributes of the META-INF/ibm-ejb-jar-ext.xml file. Elements and attributes of the META-INF/ibm-ejb-jar-ext.xml file

Element or Attribute	Description	Example	Usage notes

<method>	Sub-element to the <method-session-attribute> and <run-as-mode> elements that is used to specify the method name, method signature, or method types to which a given setting might apply. Supported attributes are type, name, and params. Each attribute is described as follows:
	
	type
	• *UNSPECIFIED:* The setting applies to all methods matching the name and params attributes, regardless of interface type.
	• *REMOTE:* The setting applies to remote business interface and remote component interface methods matching the name and params attributes.
	• *LOCAL:* The setting applies to local business interface, local component interface methods, and no-interface views that match the name attribute, params attribute, or both.
	• *HOME:* The setting applies to remote home interface methods matching the name and params attributes matching the name and params attributes.
	• *LOCAL_HOME:* The setting applies to local home interface methods matching the name and params attributes.
	• *SERVICE_ENDPOINT*: The setting applies to methods on the JAX-RPC service endpoint interface matching the name and params attributes.
	
	name
	
	The name of the method to which the setting is applied, or an asterisk (*) if the setting is to be applied to all methods regardless of name.
	
	params
	
	The parameter signature of the method to which the setting is applied. This can be used to uniquely qualify a particular method in cases where more than a single method uses the same name. The parameter signature is a comma-separated list of Java types. Primitive types are specified using their name only; non-primitive types are specified using their fully qualified class or interface name including any Java package, and arrays of Java types are specified by the type of the array element followed by one or more pair of square brackets (for example int[][]).
		`<session`
		` /name="AccountServiceBean">`
		` <method-session-attribute`
		`  type="REQUIRES_NEW">`
		` <method`
		`  type="LOCAL"`
		`  name="debitAccount"`
		`  params="java.lang.String[], int,`
		`  com.xyz.CustomerInfo"/>`
		` </method-session-attribute;>`
		`</session>`	

<run-as-mode>	Sub-element to the <session> and <message-driven> elements that can be used to declare the security identity that a given EJB method might have while the method is being executed. The identity can be set to use the identity of the caller (mode = CALLER_IDENTITY), the identity of the EJB server (mode = SYSTEM_IDENTITY), or the identity of a specific security role (mode = SPECIFIED_IDENTITY).	`<session`
		` name="AccountServiceBean">`
		` <run-as-mode`
		`  mode="SPECIFIED_IDENTITY">`
		` <specified-identity`
		`  role="admin"/>`
		` <method type="UNSPECIFIED"`
		`  name="testRunAsRole"/>`
		` </run-as-mode>`
		`</session>`
			Requires mode attribute and <method> subelement. If the mode is SPECIFIED_IDENTITY, the <specified-identity subelement is also required.

<start-at-app-start>	Subelement to the <session> and <message-driven> elements that can be used to inform the EJB container that specified EJB type might be initialized at the time the application is first started, rather than the time the EJB type is first used by the application.	`<session`
		` name="AccountServiceBean">`
		` <start-at-app-startvalue="TRUE"/>`
		`</session>`
			Requires value attribute.
			
			Attribute default: FALSE (initialize EJB type when EJB is first used by application) for beans other than message-driven beans. Always TRUE for message-driven beans.

Table 67. Elements and attributes of the META-INF/ibm-ejb-jar-ext.xml file (continued). Elements and attributes of the META-INF/ibm-ejb-jar-ext.xml file

Element or Attribute	Description	Example	Usage notes
<resource-ref>	Subelement to the <session> and <message-driven> elements, that might be used to declare additional settings on a Java EE resource reference, such as isolation level to be used on transactions driven through the connection referred to by the reference. Allowable attributes include *isolation-level*. The attributes are defined as follows: *isolation-level* • *TRANSACTION_REPEATABLE_READ:* This isolation level prohibits dirty reads and nonrepeatable reads, but it allows phantom reads. • *TRANSACTION_READ_COMMITTED:* This isolation level prohibits dirty reads, but allows nonrepeatable reads and phantom reads. • *TRANSACTION_READ_UNCOMMITTED:* This isolation level allows reading uncommitted changes (data changed by a different transaction that is still in progress). It also allows dirty reads, nonrepeatable reads, and phantom reads. • *TRANSACTION_SERIALIZABLE:* This isolation level prohibits the following types of reads: 1. Dirty reads, in which a transaction reads a database row containing uncommitted changes from a second transaction, 2. Nonrepeatable reads, in which one transaction reads a row, a second transaction changes the same row, and the first transaction rereads the row and gets a different value, and 3. Phantom reads, in which one transaction reads all rows that satisfy an SQL WHERE condition, a second transaction inserts a row that also satisfies the WHERE condition, and the first transaction applies the same WHERE condition and gets the row inserted by the second transaction. • *TRANSACTION_NONE:* This isolation level indicates that transactions are not supported on this type of resource.	<session name="AccountServiceBean"> <resource-ref name="jdbc/Default" isolation-level="TRANSACTION_NONE"> </session>	Requires name attribute. To have any effect, also include the isolation-level attribute.

Extensions defined in META-INF/ibm-ejb-jar-ext-pme.xml file

The following tables list extension elements and attributes that must be placed in the META-INF/ibm-ejb-jar-ext-pme.xml file.

Table 68. Extensions defined in `META-INF/ibm-ejb-jar-ext-pme.xml`. Extensions defined in META-INF/ibm-ejb-jar-ext-pme.xml

Element or Attribute	Description	Example	Usage notes
<internationalization>	Element that might be used to declare the locale that might be used by the EJB type (locale of the caller or locale of the server).	<internationalization> <application> <ejb name="S01"/> <ejb name="S02"/> </application> <run-as-caller> <method type="LOCAL" name="getFoo" params="int"> <ejb name="C01"/> </method> </run-as-caller> <run-as-server> <method type="LOCAL" name="getBar" params="int"> <ejb name="C02"/> </method> </run-as-server> <run-as-specified name="North American English"> <locale lang="en" country="US" variant="foo"/> <locale lang="en" country="CA" variant="bar" /> <time-zone name="GMT"/> <method type="LOCAL" name="getFoo" params="int"> <ejb name="C03"/> </method> </run-as-specified> <run-as-specified name="North American French"> <locale lang="fr" country="US" variant="foo"/> <locale lang="fr" country="US" variant="bar" /> <time-zone name="GMT" /> <method type="LOCAL" name="getBar" params="int"> <ejb name="C04"/> </method> </run-as-specified> </internationalization>	For information about this extension, see Container internationalization attributes: WebSphere Application Server. Due to the complexity of this function, you might want to use a tool designed for WebSphere Application Server such as Rational Application Developer to produce the wanted extension file stanzas, then modify the XML file as wanted.
<activity-sessions>	Element that optionally declares the type of activity session management to be used on a designated session bean (BEAN or CONTAINER) and for container-managed activity sessions, the type of activity session behavior to be provided by the container.	<activity-sessions> <container-activity-session name="Foo" type="NOT_SUPPORTED"> <methodtype="HOME" name="findByPrimaryKey" params="int"> <ejb name="C01"/> </method> </container-activity-session> <./activity-sessions>	For information about this extension, see Setting EJB module ActivitySession deployment attributes. Due to the complexity of this function, you might want to use a tool designed for WebSphere Application Server such as Rational Application Developer
<app-profiles>	Element that optionally declares application profile settings for one or more EJB files.	<app-profiles> <defined-access-intent-policy name="foo"> <collection-scope type"SESSION"/> <optimistic-read/> <read-ahead-hint hint="foo.bar.baz"/> </defined-access-intent-policy> <run-as-task name="TestEJB1.ejbs.C01LocalHome.createjava.lang.Integer" type="RUN_AS_SPECIFIED_TASK"> <task name="/> <method type="LOCAL" name="getFoo" params="int"> <ejb name="C01"/> </method> </run-as-task> <ejb-component-extension ejb="C01"> <task name="SomeTask"/> </ejb-component-extension> </app-profiles>	Due to the complexity of this function, you might want to use a tool designed for WebSphere Application Server such as Rational Application Developer to produce the wanted extension file stanzas, then modify the XML file as wanted.

Legacy (XMI) bindings

Existing modules and applications can continue to use the legacy binding support provided in the product, therefore, the existing tools and wizards can be used to specify binding and extension information for applications and modules. Use of the legacy support is limited to EAR files and modules using J2EE 1.4-style XML deployment descriptors.

EJB modules that use a version 3.x XML deployment descriptor schema or do not have an XML deployment descriptor file must use either defaulted bindings and AutoLink, or user-specified XML binding files.

It is required that CMP entity beans always be packaged in a module with a 2.1 XML deployment descriptor schema version so that existing tools can be used to provide mappings, bindings, and extension support.

User-specified XML bindings

The default bindings for each interface and AutoLink reference resolution for each reference can be overridden by specifying bindings for the EJB module by creating a `META-INF/ibm-ejb-jar-bnd.xml` file.

The schema files that describe the format are located in the <WAS_HOME>/properties/schemas directory. This form of bindings specification can only be used for modules containing either no XML deployment descriptor or an EJB 3.x deployment descriptor.

Note: It is not required to specify all bindings. Any binding name or reference that is not defined uses the default bindings and AutoLink support.

Bindings can be specified for the following beans:

- Session beans using the <session> element.
- Message Driven beans using the <message-driven> element

The only attributes and subelements supported for the <session> element are:

- id attribute
- name attribute
- simple-binding-name attribute
- component-id attribute
- ejb-ref element
- resource-ref element and its attributes
- resource-env-ref element and its attributes
- message-destination-ref element and its attributes
- env-entry element
- data-source element

The only attributes and sub elements supported for the <message-driven> element are:

- id attribute
- name attribute
- jca-adapter attribute
- ejb-ref element and its attributes
- resource-ref element and its attributes
- resource-env-ref element and its attributes
- message-destination-ref element and its attributes
- env-entry element
- data-source element

EJB 3.x module packaging overview

This topic describes application packaging when you use Enterprise JavaBeans (EJB) 3.x beans.

Packaging applications that use EJB 3.x beans is similar to the assembly requirements for Java Platform, Enterprise Edition (Java EE) 1.4 applications: components are packaged into modules, and modules are packaged into application enterprise archive (EAR) files. The components and modules both have describing metadata provided in an Extensible Markup Language (XML) deployment descriptor. The EJB 3.x specifications support an additional method to describing metadata and for packaging persistence units.

The EAR file is a package file format similar to a .zip or .tar file format. The EAR file can be visualized as a collection of logical directories and files that are packaged together into a simple file. Each EAR file includes one or more Java EE module files, which can include the following modules:

- Java application archive (JAR) files for EJB modules. Java EE application client modules and utility class modules.
- Web application archive (WAR) files for web modules, or EJB content. The WAR file must be version 2.5 or later to contain EJB content.
- Other technology-specific modules such as resource application archive (RAR) files and other types of modules.

EJB modules without deployment descriptors

You can package EJB modules without a deployment descriptor if you are using EJB 3.x beans. To do this, you must create a JAR file or WAR file with metadata in an annotation which is located in the EJB component. EJB 3.x beans do not need an entry in the `ejb-jar.xml` file for metadata that you have defined through annotations.

With EJB 3.0, the default was to scan annotations during the installation of an EJB 3.0 module. For WebSphere Application Server, Version 8.5, the default is not to scan pre-Java EE 5 modules during the application installation or at server startup.

To preserve backward compatibility with both the Feature Pack for EJB 3.0 and the Feature Pack for Web Services, you have a choice whether to scan legacy web modules for additional metadata. A server level switch is defined for each feature pack scan behavior. If the default is not appropriate, the switch must be set on each server and administrative server that requires a change in the default. The switches are server custom properties com.ibm.websphere.webservices.UseWSFEP61ScanPolicy={true|false} and com.ibm.websphere.ejb.UseEJB61FEPScanPolicy={true|false}. To define these properties in the administrative console click **Application servers** > ***server name*** > **Process definition** > **Java Virtual Machine** > **Custom properties**.

EJB modules with deployment descriptors

You can continue to use EJB modules with deployment descriptors. Modules with deployment descriptors can support any EJB specification version level, including EJB 3.x, but generally these descriptors should reflect the implementation requirements of the components in the module.

An EJB module can have an EJB 3.x, 2.x, or 1.x deployment descriptor.

For EJB 2.x or 1.x deployment descriptors, it is assumed that the deployment descriptor contains the full metadata for the module, and no additional scanning of annotation metadata occurs.

The EJB container annotation scanning is performed on EJB modules that either have no deployment descriptor or have an `ejb-jar.xml` deployment descriptor at the EJB 3.0 schema level with the metadata-complete XML attribute set to false or omitted. See the Annotation scanning behavior section for the complete set of rules used by the server to determine if annotation scanning is performed.

Note: You cannot scan for component annotation metadata contained within shared libraries defined using the WebSphere Application Server system management shared library feature. However, content defined as a BLA Asset is scanned for annotation data.

Annotation scanning behavior

The server can inspect the class files in the module for annotation content. The server searches for annotation content that might define a component, a reference to a resource, or a particular behavior. For example, annotations might be used to define an EJB component, or to declare a reference to a data source that must be used by an EJB component, or to declare the transactional or security attributes that are associated with an EJB method. This inspection process is referred to as annotation scanning. If the class files in the module contain annotations that must be respected by the server, then the server must be configured so that annotation scanning occurs. If the class files in the module do not contain annotations, then for performance reasons you can configure the server so that annotation scanning does not occur.

The server uses the following criteria to determine whether it scans content for annotations:

- Whether the ejb-jar.xml deployment descriptor file exists
- Version of the ejb-jar.xml deployment descriptor, when it is exists
- Value of the metadata-complete setting in the ejb-jar.xml deployment descriptor, when it exists
- Version of the web.xml deployment descriptor, when the EJB content is packaged in a WAR module, and the ejb-jar.xml deployment descriptor does not exist
- Value of the metadata-complete setting in the web.xml deployment descriptor, when the EJB content is packaged in a WAR module, and the ejb-jar.xml deployment descriptor does not exist

The following tables indicate how the decision to scan, or not scan, annotations is made for EJB content that is packaged in an EJB JAR module or a WAR module.

Table 69. Annotation scanning for EJB content packaged in an EJB JAR module. Annotation scanning for EJB content packaged in an EJB JAR module

ejb-jar.xml	metadata-complete value in ejb-jar.xml	Are annotations scanned?
Exists, with a version of 2.x or earlier	NA	No
Exists, with a version of 3.x or later	true	No
Exists, with a version of 3.x or later	false (or omitted)	Yes
Does not exist	NA	Yes

Table 70. Annotation scanning for EJB content packaged in a WAR module. Annotation scanning for EJB content packaged in a WAR module

ejb-jar.xml file	metadata-complete value in ejb-jar.xml	web.xml file	metadata-complete value in web.xml	Are annotations scanned?
Exists, with a version of 3.x or later	true	NA	NA	No
Exists, with a version of 3.x or later	false (or omitted)	NA	NA	Yes
Exists, with a version of 2.x or earlier	NA	NA	NA	No
Does not exist	NA	Exists, with a version of 2.5 or later	true	No
Does not exist	NA	Exists, with a version of 2.5 or later	false (or omitted)	Yes
Does not exist	NA	Exists, with a version of 2.4 or earlier	NA	No
Does not exist	NA	Does not exist	NA	Yes

Note:

It is important to understand the distinction between the metadata-complete attribute of the ejb-jar element of the `ejb-jar.xml` deployment descriptor, and the metadata-complete install setting that may be specified during the application or module installation process.

The metadata-complete attribute of the ejb-jar element of the `ejb-jar.xml` file is an XML attribute. It is used by the server to determine if classes must be scanned for annotation data, as just described by the rules in the Annotation Scanning For EJB Content tables.

In contrast, the metadata-complete setting that may be specified at install time is used by the server to help generate the `ejb-jar.xml` file. If no `ejb-jar.xml` file exists in the module, and the metadata-complete install setting is assigned a value of true, then the server scans for annotation content and uses that to generate an `ejb-jar.xml` file, and then sets the metadata-complete XML attribute in that file to a value of true.

Persistence units

Persistence units, including the `persistence.xml` file and the classes associated with it, can be packaged in the module for which they are required. They can also be packaged in the separate utility JAR file that is packaged in the EAR file with its dependent module.

When a separate utility JAR file is packaged, it is necessary for the module that desires it to use the persistence units to declare a dependency on the utility JAR file using the typical MANIFEST. MF Class-Path: declarations. See the example scenario for this packaging method under the section in this topic called “Session facades used for persistence scenario”

Note: Packaging of persistence units contained within shared libraries defined using the WebSphere Application Server system management shared library feature is not supported at this time.

Application packaging

You can mix EJB 2.x and earlier beans with EJB 3.x beans in the same application. However, EJB 3.x beans are not recognized in EJB 2.x or EJB 1.x modules.

In the case that the EAR file only contains the JAR and web application archive (WAR) files, and no `application.xml` file, the product provides a default J2EE 1.4 deployment descriptor that is based on the following defaults that are outlined in the Java EE specification:

- The application name is assumed to be the name of the EAR file, but with the EAR file extension removed.
- Files that are ending in .war are assumed to be web modules. The context root of the web module is the name of the file that is relative to the root of the application package, but with the WAR file extension removed.
- Files that are ending in .jar that are not in the /lib directory, and that contain either an `ejb-jar.xml` file or at least one class that defines a @Stateful, @Stateless, @Singleton, or @MessageDriven annotation, are assumed to be EJB modules.
- Other JAR files that are not in the /lib directory are not assumed to be EJB modules.

If the application archive file contains an `application.xml` descriptor, processing occurs according to the directives in that descriptor.

AutoLink

AutoLink provides the ability to attempt to automatically resolve EJB references to components contained with an EAR file, without having to specify a JNDI binding name. This simplifies application deployment with large numbers of beans and references if they are unique and unambiguous.

Restriction: AutoLink should not be used for references to components deployed on a cluster.

JPA packaging

It is recommend that persistence units be packaged in separate JAR files to make them more accessible and reusable. These can be tested outside the container, with or without actual database persistence occurring. Persistence units can be included in stand-alone applications or into EAR files as utility JAR files. Because of the variety of use cases and potential performance issues when scanning large quantities of classes, it is recommended that the persistence unit defines the classes of the persistence units.

Session facades used for persistence scenario

A common pattern is to use session facades for persistence. Using session bean facades to drive JPA is supported. The EntityManager interface is not thread safe, therefore, servlets should never inject @PersistenceContext. Servlets must either use the facade pattern or use an EntityManagerFactory instance to create an EntityManager on each request.

It is recommended that JPA persistence units be defined in a separate JAR file, apart from the session bean facades. Not only is this a best practice that gives greater flexibility in sharing, it also avoids problems mixing JPA and non-JPA annotated classes.

Typically, a JAR file is created to hold the entity classes and the JPA `persistence.xml` definition and added to the EAR file as a utility JAR file. The EJB 3.x module adds a dependency on the JAR file by declaring it in the EJB 3.x module MANIFEST.MF. For example, if an EAR contains a `TradeApp.ear`, `TradeWeb.war`, `EJB3Trade.jar`, and `TradeInfo.jar` file, the `EJB3Trade.jar` file would have a MANIFEST.MF that looks like the following:

```
Manifest-Version: 1.0
Class-Path: TradeInfo.jar
```

The session facade in the `EJB3Trade.jar` file refers to JPA entity classes and persistence units in the `TradeInfo.jar` file. The web application defined in the `TradeWeb.war` file can do the same to work with the JPA entity objects as Data Transfer Objects flowing between the web and EJB container tiers.

Cross-tier and cross version session bean reference scenario

There are several ways to define and use references to EJB 3.x session beans. For EJB 3.x session to session, the @EJB injection target can be used. For cross-tier, for example, web application to EJB 3.x session, or cross-version, for example, EJB 2.1 session to EJB 3.x session, an XML deployment descriptor reference can be used to define ejb-refs and ejb-local-refs. There are two variations of these, depending on whether an EJB 3.x business interface is referred to, or a pre-EJB 3.x component-style interface that also defines an EJBLocalHome is referred to. Web applications and client applications can also use the @EJB annotation if the component being referenced can be resolved using autolink.

For migration scenarios where session beans are being converted from EJB 2.1 beans to EJB 3.x beans, the pattern is typically to edit the Session bean class, replace the implements SessionBean with implements the business interface, remove extends EJBLocalObject from the local interface and non-business throws clauses, and add the @Stateful @Local @LocalHome(<localhome>.class) or similar annotations. Existing ejb-refs and ejb-local-refs are bound to the new implementation of the session bean.

Note: The default binding name does change.

The previous scenario uses an EJB 2.1-style client pattern with an EJB 3.x-style session bean implementation. For a more current client style, the client-side can be cleaned up to look up the session bean business interface directly, rather than going through a home interface. In this case, it is not necessary to define the @LocalHome(<localhome>.class) annotation. You can use a variant definition of

ejb-ref and ejb-local-ref to do this. Use a `null` value for the local-home element value and bind the ejb-local-ref to the session bean's ejblocal: binding rather than the home binding. For example:

```
<ejb-local-ref id="EJBLocalRef_1154112538064">
 <description>com.ibm.persistence.ejb3.order.facadecom.ibm.persistence.ejb3.order.facade</description>
 <ejb-ref-name>ejb/OrderEJB</ejb-ref-name>
 <ejb-ref-type>Session</ejb-ref-type>
 <local-home></local-home>
 <local>com.ibm.persistence.ejb3.order.facade.OrderProcessor</local>
</ejb-local-ref>
```

The client code also must be adjusted to do the appropriate casting for the object being looked up. In this case, the business interface instead of the home interface:

```
try {
 InitialContext ctx = new InitialContext();
 orderProcessor = (OrderProcessor)ctx.lookup("java:comp/env/ejb/OrderEJB");
}
catch(Exception e)  {
 e.printStackTrace(System.out);
 throw new ServletException(e);
}
```

Assembling EJB 3.x modules

An enterprise bean is a managed Java component that can be combined with other resources to create Java Enterprise Edition (Java EE) applications.

Before you begin

This topic assumes that you have created and unit tested an enterprise bean that you want to assemble in an enterprise application and deploy onto an application server.

About this task

Assemble an EJB 3.x module to contain enterprise beans and related code artifacts. Group web components, client code, and resource adapter code in separate modules. After the EJB module is assembled, install it as a stand-alone application or combine it with other modules into an enterprise application.

To learn about how to assemble an EJB 3.x module with an assembly tool, see the Rational Application Developer documentation.

Rational Application Developer can be extended with additional plug-ins to provide development support specifically for Java Persistence API (JPA).

See the Eclipse open source project, Dali, for a plug-in that provides this extension. See the related links in this topic for the Dali JPA tools website.

Note: Issues and problems using this plug-in need to resolved through the Eclipse open source community.

What to do next

Deploy the EJB module.

Assembling EJB modules

An enterprise bean is a Java component that can be combined with other resources to create Java Platform Enterprise Edition (Java EE) applications. This topic describes assembling Enterprise JavaBeans (EJB) modules based on the EJB specifications.

Before you begin

This topic assumes that you have created and unit tested an enterprise bean file that you want to assemble in an enterprise application and deploy onto an application server.

About this task

Assemble an EJB module to contain enterprise beans and related code artifacts. Group web components, client code, and resource adapter code in separate modules. After assembling an EJB module, you can install it as a stand-alone application or combine it with other modules into an enterprise application.

Use an assembly tool to assemble an EJB module in any of the following ways:
- Import an existing EJB module (EJB JAR file).
- Create a new EJB module.
- Copy code artifacts, such as entity beans, from one EJB module into a new EJB module.

For information on assembling EJB modules, refer to the online documentation or the information center for your assembly tool. The Rational Application Developer product provides supported assembly tools.

Procedure
- Assemble an EJB 2.x module. See the topic Assembling EJB 2.x modules.
- Assemble an EJB 3.x module. See the topic Assembling EJB 3.x modules.

What to do next

After you finish assembling your EJB module, you are ready to deploy your module.

EJB modules

An Enterprise JavaBeans (EJB) module is used to assemble one or more enterprise beans into a single deployable unit. An EJB module is stored in a standard Java archive (JAR) file.

An EJB module contains the following:
- One or more deployable enterprise beans.
- A deployment descriptor, stored in an Extensible Markup Language (XML) file. This file declares the contents of the module, defines the structure and external dependencies of the beans in the module, and describes how the beans are to be used at run time.

  It is not necessary to use XML deployment descriptors in EJB 3.x modules, although XML descriptors are supported. Instead of deployment descriptors, you can use annotations to provide component metadata.

You can deploy an EJB module as a stand-alone application, or combine it with other EJB modules or with web modules to create a Java application. An EJB module is installed and run in an enterprise bean container.

If you want to package an EJB 3.x module with a deployment descriptor, there are several ways to do it. You can package an EJB 3.x module with an EJB 3.x style session and/or message-driven beans exclusively; with an EJB 2.1 style session and/or message-driven beans exclusively, or a combination of 2.1 and 3.x style beans. The XML deployment descriptor must be a Version 3.x deployment descriptor. It is required that 2.1 entity beans are packaged in modules with 2.1 deployment descriptors.

EJB modules that contain EJB 3.x beans must be at the EJB 3.x specification level when running on the product. To set the EJB module to support EJB 3.x beans, you can set the ejb-jar.xml deployment descriptor level to 3.0 or 3.1, or you can make sure that the module does not contain an ejb-jar.xml

deployment descriptor. If the module level is EJB 2.1 or earlier, no EJB 3.x functions, including annotation scanning or resource injection is performed at run time.

For more information about packaging and deployment of EJB 3.x beans, see the topic EJB 3.x module packaging overview.

Local client views

The EJB specification only requires local client views to be supported for EJBs packaged within the same application. This includes local homes, local business interfaces, and the no-interface view. The product permits access to local client views to EJBs packaged within a separate application with some restrictions:

- The local interface and all parameter, return, and exception types used by the local interface must be visible to the class loader of both the calling application and the target EJB application. You can ensure this by either using a shared library associated with a server class loader or by using an isolated shared library associated with both applications. Read the Creating shared libraries topic for more information.
- When the target EJB application is stopped, any cached references to the EJB must be refreshed. You can complete one of the following actions:
  - Restart the calling application. The simplest solution is to restart the calling application whenever you restart a target EJB application on which it relies.
  - Obtain a new reference from JNDI. By default, JNDI lookups from the java namespace are cached, and the cache must either be disabled or cleared to obtain a new reference. Read the Developing applications that use JNDI topic for more information.

    EJB method invocations throw `com.ibm.websphere.ejbcontainer.EJBStoppedException` when the target EJB application has been stopped. If you have cached the EJB reference in an instance variable by using either @EJB injection or JNDI lookup, then you can catch this exception and refresh the EJB reference by performing a non-cached lookup.
  - Enable indirect local EJB proxies for the target EJB application. This causes the local EJB proxy to be refreshed automatically when the application is restarted. Enabling indirect local proxies causes some additional overhead for each EJB method invocation.

    You can enable indirect local proxies using, for example, an administrative console. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name*** > **Custom properties** > **New**. Specify a name of `com.ibm.websphere.ejbcontainer.indirectLocalProxies` and a value of `true` for the custom property, then apply and save the changes.

EJB content in WAR modules

Use this topic to understand the packaging requirements of Enterprise JavaBeans (EJB) content in web application archive (WAR) modules.

Supported EJB content

Except for explicitly stated restrictions, the EJB function that is supported for beans packaged inside EJB Java archive (JAR) modules is also supported for beans packaged inside WAR modules. A bean that is packaged inside a WAR module can have the same behavior as a bean that is packaged inside an EJB JAR module.

All types of EJB 3.x beans are supported in WAR modules, and 2.x and 1.x session beans. See the EJB 3.1 specification for complete details.

Packaging mechanics

The rules for packaging EJB content in a WAR module are different from the rules for packaging EJB content in a JAR module.

The bean class files must be placed in one of two locations within the WAR module:

- Loosely in the WEB-INF/classes directory structure
- Within a JAR file that is placed in the WEB-INF/lib directory

For example, you might loosely place the bean class com.foo.MyBean in the WAR module at this location: WEB-INF/classes/com/foo/MyBean.class.

You might also place this bean class in the myJar.jar file, which is then placed in this location: WEB-INF/lib/myJar.jar.

A WAR module can have some bean code loosely placed in the WEB-INF/classes directory structure, and have other bean code inside JAR files in the WEB-INF/lib directory. It is also valid for a WAR module to have all the bean code in the WEB-INF/classes directory structure and nothing in the WEB-INF/lib directory, or all the bean code in JAR files in the WEB-INF/lib directory and nothing in WEB-INF/classes.

It is valid to have multiple JAR files in the WEB-INF/lib directory, all of which might contain bean code.

If the same bean class is loosely placed in the WEB-INF/classes directory structure and also placed in a JAR file in the WEB-INF/lib directory, then the instance of the class placed loosely in the WEB-INF/classes directory structure is loaded, and the instance placed in a JAR file in the WEB-INF/lib directory is ignored.

If the same bean class is placed in two different JAR files in the WEB-INF/lib directory, it is not known which instance of the class is loaded, and which instance is ignored. At run time, the server arbitrarily picks one class instance and loads it, and ignores the other class instance.

The EJB deployment descriptor files must be placed in the WEB-INF directory. This directory contains the ejb-jar.xml deployment descriptor, and any ibm-ejb-jar-ext and ibm-ejb-jar-bnd XML or XMI bindings and extensions files. EJB descriptor files that are located inside JAR files in the WEB-INF/lib directory are ignored. As with an EJB JAR module, there might be 0 or 1 instance of each EJB descriptor file. There cannot be multiple instances of any EJB descriptor file. This does not include the persistence.xml file, if one exists. Per the Java Persistence API specification, if a persistence.xml file is present, it must remain in a META-INF directory located in either the WEB-INF/classes directory of the WAR module or in a JAR file in the WEB-INF/lib directory of the WAR module. For example:

- WEB-INF/classes/META-INF/persistence.xml
- WEB-INF/lib/MyEntity.jar

The MyEntity.jar contains META-INF/persistence.xml.

If an ejb-jar.xml file is located in a JAR file in the WEB-INF/lib directory, a warning message displays. For example:

```
IWAE0068W The EJB deployment descriptor META-INF/ejb-jar.xml in the library archive
 foo.jar file is ignored. The product does not process the META-INF/ejb-jar.xml deployment
 descriptor in library archives. Move the META-INF/ejb-jar.xml deployment descriptor from the
 library archive to the WEB-INF directory in the WAR module.
```

A WAR module must be version 2.5 or later to contain EJB content. EJB content placed in a WAR module that is version 2.4 or earlier is ignored.

Note: If a WAR module is version 2.5 or later, the web metadata files containing bindings and extensions information must use the XML version of the files, not the XMI version.

Technical differences for enterprise beans that are packaged in a WAR file

The following list contains key technical differences that exist between beans that are packaged in a WAR module and beans that are packaged in an EJB JAR module:

- Shared component namespace

All components in a WAR module share a single component namespace. This means that each EJB component shares a single component namespace with all other EJB components in the WAR file, and any non-EJB components like servlets. In contrast, an EJB component that is packaged in an EJB JAR module has its own private component namespace, which is not shared with any other component.

The shared component namespace has important impacts. First, one component (EJB or non-EJB) might declare a reference, and a different component might search the component namespace for that reference. Second, references declared by one component might conflict with references declared by another component. In contrast, an EJB packaged in an EJB JAR module cannot look up in the component namespace a reference declared by a different EJB or non-EJB component, and it is impossible for a reference declared by the EJB to conflict in the component namespace with a reference declared by any other component, even if the references have the same name.

When using the shared namespace, it is valid for the same reference to be declared multiple times, as long as these reference declarations do not conflict with each other. If the reference declarations do not conflict, then the server behaves as if the reference had been declared exactly once.

If reference declarations do conflict, then an error message is emitted, and the application fails to start. A warning message is emitted for each conflicted reference. The warning message indicates the name of the conflicted reference, and the multiple values assigned to that reference. After all the warning messages are emitted, an exception is thrown.

- Location of EJB descriptor files

  The `ejb-jar.xml` deployment descriptor file, and any other descriptor file, must be placed in the `WEB-INF` directory of the WAR. Any instance of an EJB descriptor file elsewhere in the WAR, including in the `META-INF` directory of a JAR file in the `WEB-INF/lib` directory, is ignored.

- Determining if annotations are scanned

  The rules for determining whether to scan for annotations are different for EJB JAR and WAR modules. See the topic, EJB 3.x module packaging overview, for the complete set of rules.

- Class loading and visibility

  The most common usage pattern for EJB classes that are packaged in a WAR module is local method invocations from web components packaged within the same module. However, these EJB classes can also be accessed by remote method invocations or by clients in other modules. In these cases, it is important to understand the visibility rules of EJB classes that are packaged in a WAR module. Visibility rules are different when compared to EJB classes that are packaged in a JAR module.

  In the case of remote EJB method invocations, there are no visibility differences introduced by packaging the EJB classes in a WAR module. The EJBs are bound into the global namespace and can be looked up from, or injected into, components in other modules. The remote client must make method invocations with an appropriate stub class. Stub class generation is described in this topic under the section, "Stub generation".

  In the case of local EJB method invocations from components in other modules, there are visibility differences because the EJBs are packaged in a WAR module. These visibility differences occur because there are class loader implications that must be considered.

  The content that is packaged in all EJB JAR modules for the entire application is loaded by a single application class loader instance.

  In contrast, all content that is packaged in a WAR module is loaded on a class loader instance that is specific to that WAR module. The single application class loader instance that is used to load all the EJB JAR content, is the parent to each of the class loader instances that are used to load the WAR content.

  The visibility of a class is affected by the class loader instance that loaded it. A class loader instance can see classes loaded by itself, or by a parent class loader. However, a class loader cannot see a class loaded on a class loader that is not itself, nor one of its parents.

  As a result, classes loaded by a class loader specific to a WAR module can see classes in an EJB JAR module, but they cannot see classes in another WAR module. Classes in an EJB JAR module cannot

see classes in any WAR module. For example, if there is EJB content packaged inside EJB JAR module ejb3.jar, and there is also EJB content packaged inside the ejb1.jar file and the ejb2.jar file, then:

- If the ejb1.jar file and the ejb2.jar file are installed as EJB JAR modules, then the content inside the ejb1.jar file, ejb2.jar file, and ejb3.jar file is all loaded on the same class loader instance, which is also used to load any other EJB JAR modules in the application. In this case, the classes in all three JAR files can see each other, because they are all loaded by the same class loader instance.
- If the ejb1.jar file and the ejb2.jar file are both packaged inside the WEB-INF/lib directory of a WAR file, the content inside the ejb1.jar file and the ejb2.jar file is loaded by a single class loader instance. However, this class loader is not the same one used to load the content for the ejb3.jar file and any other EJB JAR in the application. In this case, the classes in the ejb1.jar file and the ejb2.jar file can see each other and can also see the classes in the ejb3.jar file. The classes in the ejb3.jar file cannot see the classes in the ejb1.jar file or the ejb2.jar file.
- If the ejb1.jar file is packaged inside the WEB-INF/lib directory of the firstWar.war file, and the ejb2.jar file is packaged inside the WEB-INF/lib directory of the secondWar.war file, the content in the ejb1.jar file is loaded on one class loader instance, the content in the ejb2.jar file is loaded on a second class loader instance, and the content in the ejb3.jar file and all other EJB JAR in the application is loaded on a third class loader instance. In this case, the classes in the ejb1.jar file and the ejb2.jar file cannot see each other, but they can see the classes in the ejb3.jar file. The classes in the ejb3.jar file cannot see the classes in either the ejb1.jar file or the ejb2.jar file.

One strategy to avoid these class loader complications is to package the EJB interface classes in a shared library.

Note: Do not package the same class, both an EJB JAR module and a WAR module, in the same application. Packaging the same class in multiple locations within the same application might result in confusion regarding which instance of the class is loaded and used at run time. This distinction can matter if the two .class files represent different versions of the class. To avoid this scenario, package the .class file in only one location or change the package structure of the class so that the fully qualified name of the class packaged inside the WAR module is different from the fully qualified name of the class packaged inside the EJB JAR module.

- Application profile extension

  The application profile extension is not supported for EJB classes that are packaged in WAR modules.

Stub generation

Remote access of EJB methods requires the use of client-side stub classes. For most client environments, the product runtime automatically generates the required stub classes. One exception is the thin client environment. For thin clients, the stub classes must be manually generated and packaged with the client.

Use the **createEJBStubs** tool to generate stubs when the EJB content is packaged in a WAR module, regardless of the EJB version.

See the topic, Create stubs command, for more information.

Note: When packaging EJB 2.1 classes in a WAR module, do not include any stub classes generated by the EJBDeploy tool. These stub classes are different than the stub classes automatically generated by the product run time and can cause failures. In most situations the automatically generated stub classes are sufficient. The exception is if a component in the web module must make a remote method invocation on an EJB 2.1 class packaged in another JAR module. In this case, the EJBDeploy generated stub class for the EJB in the other JAR module must be packaged in the WAR module.

EJB 2.x and 1.x content in a WAR module

Except for entity beans, EJB 2.x and 1.x content is supported in a WAR module.

A 2.x or 1.x module packaged inside a WAR file requires an `ejb-jar.xml` deployment descriptor at version 2.x or 1.x in the `WEB-INF` directory of the WAR module. If XMI bindings and extension files are present, you must also package these bindings and files in the `WEB-INF` directory of a WAR module.

Session beans and message driven beans that you implement according to the 2.x or 1.x coding style can be packaged inside a WAR module.

Both bean managed persistence (BMP) and container managed persistence (CMP) entity beans are not supported in a WAR module.

The application profiling and access intent services are not supported in a WAR module. Session beans found in a WAR module cannot access application profiling tasks.

EJB content that you implement according to both the 3.x coding style and the 2.x and 1.x coding styles, can be packaged together in a single WAR module. However, in this case, you must declare any bindings and extensions information with the XML version of the files, not the XMI version.

Moving existing EJB content from EJB JAR modules into WAR modules

One approach is to put the existing EJB JAR file in the `WEB-INF/lib` directory of the WAR file. Then, remove the descriptor files from the `META-INF` directory of the JAR file and place them in the `WEB-INF` directory of the WAR file.

A second approach is to put the class files from the EJB JAR file in the correct location under the `WEB-INF/classes` directory in the WAR module. Then, remove the descriptor files from the `META-INF` directory of the JAR file and place them into the `WEB-INF` directory of the WAR file.

If multiple EJB JAR modules are moved into a single WAR module, you must merge the contents of each of the descriptor files previously found in the `META-INF` directories of the EJB JAR modules into the single version of the descriptor files that are now placed in the `WEB-INF` directory of the WAR file. Examples of descriptor files that may be merged include, but are not limited to, `ejb-jar.xml`, `ibm-ejb-jar-bnd.xml`, `ibm-ejb-jar-ext.xml`, and `ibm-ejb-jar-ext-pme.xml`.

You must inspect the references declared by the various components in the WAR module, both EJB and non-EJB, to ensure that they do not conflict with each other, since everything in the WAR module shares a single component name space.

You must modify the bindings and extension XMI files that are moved from an EJB JAR module to a WAR module in several places to remove references to `META-INF/ejb-jar.xml` and replace them with `WEB-INF/ejb-jar.xml`.

EJB function that is supported in EJB JAR modules, but not in WAR modules

The following EJB function is not supported in WAR modules:

- BMP and CMP entity beans
- Pre EJB 3.1 style startup beans

  Attention: Singleton startup beans defined by EJB 3.1 are supported.

If an entity bean is placed in a WAR module, error messages display, and the application fails to start. For example, the foo entity bean is placed in the foo.war module in the FooApp application. This results in the following messages:

```
CWMDF0025E: Entity beans in EJB web application archive (WAR) modules are not allowed,
 per the EJB 3.1 specification.
WSVR0039E: Unable to start EJB JAR, foo.war: Entity beans in EJB web application archive
 (WAR) modules are not allowed, per the EJB 3.1 specification. The foo bean in the foo.war module
 must be moved to a stand-alone EJB module. Examine the log to see a full list of invalid entity
 beans in a WAR module.
```

EJB 3.x module packaging overview

This topic describes application packaging when you use Enterprise JavaBeans (EJB) 3.x beans.

Packaging applications that use EJB 3.x beans is similar to the assembly requirements for Java Platform, Enterprise Edition (Java EE) 1.4 applications: components are packaged into modules, and modules are packaged into application enterprise archive (EAR) files. The components and modules both have describing metadata provided in an Extensible Markup Language (XML) deployment descriptor. The EJB 3.x specifications support an additional method to describing metadata and for packaging persistence units.

The EAR file is a package file format similar to a .zip or .tar file format. The EAR file can be visualized as a collection of logical directories and files that are packaged together into a simple file. Each EAR file includes one or more Java EE module files, which can include the following modules:

- Java application archive (JAR) files for EJB modules. Java EE application client modules and utility class modules.
- Web application archive (WAR) files for web modules, or EJB content. The WAR file must be version 2.5 or later to contain EJB content.
- Other technology-specific modules such as resource application archive (RAR) files and other types of modules.

EJB modules without deployment descriptors

You can package EJB modules without a deployment descriptor if you are using EJB 3.x beans. To do this, you must create a JAR file or WAR file with metadata in an annotation which is located in the EJB component. EJB 3.x beans do not need an entry in the `ejb-jar.xml` file for metadata that you have defined through annotations.

With EJB 3.0, the default was to scan annotations during the installation of an EJB 3.0 module. For WebSphere Application Server, Version 8.5, the default is not to scan pre-Java EE 5 modules during the application installation or at server startup.

To preserve backward compatibility with both the Feature Pack for EJB 3.0 and the Feature Pack for Web Services, you have a choice whether to scan legacy web modules for additional metadata. A server level switch is defined for each feature pack scan behavior. If the default is not appropriate, the switch must be set on each server and administrative server that requires a change in the default. The switches are server custom properties com.ibm.websphere.webservices.UseWSFEP61ScanPolicy={true|false} and com.ibm.websphere.ejb.UseEJB61FEPScanPolicy={true|false}. To define these properties in the administrative console click **Application servers** > ***server name*** > **Process definition** > **Java Virtual Machine** > **Custom properties**.

EJB modules with deployment descriptors

You can continue to use EJB modules with deployment descriptors. Modules with deployment descriptors can support any EJB specification version level, including EJB 3.x, but generally these descriptors should reflect the implementation requirements of the components in the module.

An EJB module can have an EJB 3.x, 2.x, or 1.x deployment descriptor.

For EJB 2.x or 1.x deployment descriptors, it is assumed that the deployment descriptor contains the full metadata for the module, and no additional scanning of annotation metadata occurs.

The EJB container annotation scanning is performed on EJB modules that either have no deployment descriptor or have an `ejb-jar.xml` deployment descriptor at the EJB 3.0 schema level with the metadata-complete XML attribute set to false or omitted. See the Annotation scanning behavior section for the complete set of rules used by the server to determine if annotation scanning is performed.

Note: You cannot scan for component annotation metadata contained within shared libraries defined using the WebSphere Application Server system management shared library feature. However, content defined as a BLA Asset is scanned for annotation data.

Annotation scanning behavior

The server can inspect the class files in the module for annotation content. The server searches for annotation content that might define a component, a reference to a resource, or a particular behavior. For example, annotations might be used to define an EJB component, or to declare a reference to a data source that must be used by an EJB component, or to declare the transactional or security attributes that are associated with an EJB method. This inspection process is referred to as annotation scanning. If the class files in the module contain annotations that must be respected by the server, then the server must be configured so that annotation scanning occurs. If the class files in the module do not contain annotations, then for performance reasons you can configure the server so that annotation scanning does not occur.

The server uses the following criteria to determine whether it scans content for annotations:

- Whether the ejb-jar.xml deployment descriptor file exists
- Version of the ejb-jar.xml deployment descriptor, when it is exists
- Value of the metadata-complete setting in the ejb-jar.xml deployment descriptor, when it exists
- Version of the web.xml deployment descriptor, when the EJB content is packaged in a WAR module, and the ejb-jar.xml deployment descriptor does not exist
- Value of the metadata-complete setting in the web.xml deployment descriptor, when the EJB content is packaged in a WAR module, and the ejb-jar.xml deployment descriptor does not exist

The following tables indicate how the decision to scan, or not scan, annotations is made for EJB content that is packaged in an EJB JAR module or a WAR module.

Table 71. Annotation scanning for EJB content packaged in an EJB JAR module. Annotation scanning for EJB content packaged in an EJB JAR module

ejb-jar.xml	metadata-complete value in ejb-jar.xml	Are annotations scanned?
Exists, with a version of 2.x or earlier	NA	No
Exists, with a version of 3.x or later	true	No
Exists, with a version of 3.x or later	false (or omitted)	Yes
Does not exist	NA	Yes

Table 72. Annotation scanning for EJB content packaged in a WAR module. Annotation scanning for EJB content packaged in a WAR module

ejb-jar.xml file	metadata-complete value in ejb-jar.xml	web.xml file	metadata-complete value in web.xml	Are annotations scanned?
Exists, with a version of 3.x or later	true	NA	NA	No
Exists, with a version of 3.x or later	false (or omitted)	NA	NA	Yes
Exists, with a version of 2.x or earlier	NA	NA	NA	No
Does not exist	NA	Exists, with a version of 2.5 or later	true	No
Does not exist	NA	Exists, with a version of 2.5 or later	false (or omitted)	Yes

Table 72. Annotation scanning for EJB content packaged in a WAR module (continued). Annotation scanning for EJB content packaged in a WAR module

ejb-jar.xml file	metadata-complete value in ejb-jar.xml	web.xml file	metadata-complete value in web.xml	Are annotations scanned?
Does not exist	NA	Exists, with a version of 2.4 or earlier	NA	No
Does not exist	NA	Does not exist	NA	Yes

Note:

It is important to understand the distinction between the metadata-complete attribute of the ejb-jar element of the `ejb-jar.xml` deployment descriptor, and the metadata-complete install setting that may be specified during the application or module installation process.

The metadata-complete attribute of the ejb-jar element of the `ejb-jar.xml` file is an XML attribute. It is used by the server to determine if classes must be scanned for annotation data, as just described by the rules in the Annotation Scanning For EJB Content tables.

In contrast, the metadata-complete setting that may be specified at install time is used by the server to help generate the `ejb-jar.xml` file. If no `ejb-jar.xml` file exists in the module, and the metadata-complete install setting is assigned a value of true, then the server scans for annotation content and uses that to generate an `ejb-jar.xml` file, and then sets the metadata-complete XML attribute in that file to a value of true.

Persistence units

Persistence units, including the `persistence.xml` file and the classes associated with it, can be packaged in the module for which they are required. They can also be packaged in the separate utility JAR file that is packaged in the EAR file with its dependent module.

When a separate utility JAR file is packaged, it is necessary for the module that desires it to use the persistence units to declare a dependency on the utility JAR file using the typical MANIFEST. MF Class-Path: declarations. See the example scenario for this packaging method under the section in this topic called “Session facades used for persistence scenario”

Note: Packaging of persistence units contained within shared libraries defined using the WebSphere Application Server system management shared library feature is not supported at this time.

Application packaging

You can mix EJB 2.x and earlier beans with EJB 3.x beans in the same application. However, EJB 3.x beans are not recognized in EJB 2.x or EJB 1.x modules.

In the case that the EAR file only contains the JAR and web application archive (WAR) files, and no `application.xml` file, the product provides a default J2EE 1.4 deployment descriptor that is based on the following defaults that are outlined in the Java EE specification:

- The application name is assumed to be the name of the EAR file, but with the EAR file extension removed.
- Files that are ending in .war are assumed to be web modules. The context root of the web module is the name of the file that is relative to the root of the application package, but with the WAR file extension removed.
- Files that are ending in .jar that are not in the /lib directory, and that contain either an `ejb-jar.xml` file or at least one class that defines a @Stateful, @Stateless, @Singleton, or @MessageDriven annotation, are assumed to be EJB modules.
- Other JAR files that are not in the /lib directory are not assumed to be EJB modules.

If the application archive file contains an `application.xml` descriptor, processing occurs according to the directives in that descriptor.

AutoLink

AutoLink provides the ability to attempt to automatically resolve EJB references to components contained with an EAR file, without having to specify a JNDI binding name. This simplifies application deployment with large numbers of beans and references if they are unique and unambiguous.

Restriction: AutoLink should not be used for references to components deployed on a cluster.

JPA packaging

It is recommend that persistence units be packaged in separate JAR files to make them more accessible and reusable. These can be tested outside the container, with or without actual database persistence occurring. Persistence units can be included in stand-alone applications or into EAR files as utility JAR files. Because of the variety of use cases and potential performance issues when scanning large quantities of classes, it is recommended that the persistence unit defines the classes of the persistence units.

Session facades used for persistence scenario

A common pattern is to use session facades for persistence. Using session bean facades to drive JPA is supported. The EntityManager interface is not thread safe, therefore, servlets should never inject @PersistenceContext. Servlets must either use the facade pattern or use an EntityManagerFactory instance to create an EntityManager on each request.

It is recommended that JPA persistence units be defined in a separate JAR file, apart from the session bean facades. Not only is this a best practice that gives greater flexibility in sharing, it also avoids problems mixing JPA and non-JPA annotated classes.

Typically, a JAR file is created to hold the entity classes and the JPA `persistence.xml` definition and added to the EAR file as a utility JAR file. The EJB 3.x module adds a dependency on the JAR file by declaring it in the EJB 3.x module MANIFEST.MF. For example, if an EAR contains a `TradeApp.ear`, `TradeWeb.war`, `EJB3Trade.jar`, and `TradeInfo.jar` file, the `EJB3Trade.jar` file would have a MANIFEST.MF that looks like the following:

```
Manifest-Version: 1.0
Class-Path: TradeInfo.jar
```

The session facade in the `EJB3Trade.jar` file refers to JPA entity classes and persistence units in the `TradeInfo.jar` file. The web application defined in the `TradeWeb.war` file can do the same to work with the JPA entity objects as Data Transfer Objects flowing between the web and EJB container tiers.

Cross-tier and cross version session bean reference scenario

There are several ways to define and use references to EJB 3.x session beans. For EJB 3.x session to session, the @EJB injection target can be used. For cross-tier, for example, web application to EJB 3.x session, or cross-version, for example, EJB 2.1 session to EJB 3.x session, an XML deployment descriptor reference can be used to define ejb-refs and ejb-local-refs. There are two variations of these, depending on whether an EJB 3.x business interface is referred to, or a pre-EJB 3.x component-style interface that also defines an EJBLocalHome is referred to. Web applications and client applications can also use the @EJB annotation if the component being referenced can be resolved using autolink.

For migration scenarios where session beans are being converted from EJB 2.1 beans to EJB 3.x beans, the pattern is typically to edit the Session bean class, replace the implements SessionBean with implements the business interface, remove extends EJBLocalObject from the local interface and

non-business throws clauses, and add the @Stateful @Local @LocalHome(<localhome>.class) or similar annotations. Existing ejb-refs and ejb-local-refs are bound to the new implementation of the session bean.

Note: The default binding name does change.

The previous scenario uses an EJB 2.1-style client pattern with an EJB 3.x-style session bean implementation. For a more current client style, the client-side can be cleaned up to look up the session bean business interface directly, rather than going through a home interface. In this case, it is not necessary to define the @LocalHome(<localhome>.class) annotation. You can use a variant definition of ejb-ref and ejb-local-ref to do this. Use a `null` value for the local-home element value and bind the ejb-local-ref to the session bean's ejblocal: binding rather than the home binding. For example:

```
<ejb-local-ref id="EJBLocalRef_1154112538064">
 <description>com.ibm.persistence.ejb3.order.facadecom.ibm.persistence.ejb3.order.facade</description>
 <ejb-ref-name>ejb/OrderEJB</ejb-ref-name>
 <ejb-ref-type>Session</ejb-ref-type>
 <local-home></local-home>
 <local>com.ibm.persistence.ejb3.order.facade.OrderProcessor</local>
</ejb-local-ref>
```

The client code also must be adjusted to do the appropriate casting for the object being looked up. In this case, the business interface instead of the home interface:

```
try {
 InitialContext ctx = new InitialContext();
 orderProcessor = (OrderProcessor)ctx.lookup("java:comp/env/ejb/OrderEJB");
}
catch(Exception e)  {
 e.printStackTrace(System.out);
 throw new ServletException(e);
}
```

Defining container transactions for EJB modules

Container transaction properties specify how an Enterprise JavaBeans (EJB) container is to manage transaction scopes for the enterprise bean method invocations.

About this task

A transaction attribute is mapped to one or more methods. Some container transaction settings are not available for all enterprise beans. Also, some methods are not available for particular transaction settings and beans. These rules have been implemented in the Add Container Transaction wizard based on the EJB specification.

To complete this task see the topic, Defining container transactions for EJB modules, in the assembly tool information center.

References in application deployment descriptor files

References are logical names used to locate external resources for enterprise applications. References are defined in the application's deployment descriptor file. At deployment, the references are bound to the physical location (global Java Naming and Directory Interface (JNDI) name) of the resource in the target operational environment.

This product supports the following types of references:

- An Enterprise JavaBeans (EJB) reference is a logical name used to locate the home interface of an enterprise bean.
- A resource reference is a logical name used to locate a connection factory object.

These objects define connections to external resources such as databases and messaging systems. The container makes references available in a JNDI naming subcontext. By convention, references are organized as follows:

- EJB references are made available in the java:comp/env/ejb subcontext.
- Resource references are made available as follows:
  - JDBC data source references are declared in the java:comp/env/jdbc subcontext.
  - JMS connection factories are declared in the java:comp/env/jms subcontext.
  - Mail connection factories are declared in the java:comp/env/mail subcontext.
  - URL connection factories are declared in the java:comp/env/url subcontext.

EJB references

Use this page to view and modify the Enterprise JavaBeans (EJB) references to the enterprise beans. References are logical names used to locate external resources for enterprise applications. References are defined in the application's deployment descriptor file. At deployment, the references are bound to the physical location (global Java Naming and Directory Interface (JNDI) name) of the resource in the target operational environment.

If your application defines EJB references, for **Map EJB references to beans**, specify JNDI names for enterprise beans that represent the logical names that are specified in EJB references. Each EJB reference defined in the application must be bound to an EJB file before clicking Finish in the Summary panel.

If the EJB reference is from an EJB 3.x, Web 2.4, Web 2.5, or Client 5.0 module, the JNDI name is optional. If the **Allow EJB reference targets to resolved automatically** option is enabled, the JNDI name is optional for all modules. The runtime provides a container default or automatically resolves the EJB reference if a binding is not provided.

To view this administrative console page, click **Applications** > **Application Types** > **WebSphere enterprise applications** > **application_name** > **EJB references**.

Values are displayed for Lookup name and EJB Link if they are configured in the application. Only one of these values is allowed. If both are set, the value must be overridden by a target resource JNDI name.

Attention: If an application is running, changing an application setting causes the application to restart. On stand-alone servers, the application restarts after you save the change. On multiple-server products, the application restarts after you save the change and files synchronize on the node where the application is installed. To control when synchronization occurs on multiple-server products, deselect **Synchronize changes with nodes** on the Console preferences page.

Module

Specifies the name of the Enterprise JavaBeans module used by your application.

Bean

Specifies the name of an enterprise bean that is contained by the module.

URI

Specifies location of the module relative to the root of the application EAR file.

Resource Reference

Specifies the name of the EJB reference that is used in the enterprise bean, if applicable, and declared in the deployment descriptor of the application module.

Class

Specifies the name of a Java class associated with this enterprise bean.

Target Resource JNDI Name

Specifies the JNDI name of the enterprise bean.

This is a data entry field. To modify the JNDI name bound to this bean, type the new name in this field, then select **OK**.

Information	Value
Data type	String

EJB JNDI names for beans

Use this page to view and modify the Java Naming and Directory Interface (JNDI) names of non-message-driven enterprise beans in your application or module.

If your application uses Enterprise JavaBeans (EJB) 2.1 and earlier modules, on the Provide JNDI names for beans panel, specify a JNDI name for each enterprise bean in every EJB 2.1 and earlier module. You must specify a JNDI name for every EJB 2.1 and earlier enterprise bean defined in the application. For example, for the EJB module MyBean.jar, specify MyBean.

The JNDI name for an EJB module can be used for both EJB 3.x modules and pre-EJB 3.0 modules. For a pre-EJB 3.0 module, you need to provide a JNDI name for the bean. For an EJB 3.x module, you have three options

- Provide no JNDI names at all
- Select the radio button to provide a JNDI name for the bean, or
- Select the radio button to provide local or remote home JNDI names.

If no JNDI name is provided, the run time provides a default value. If JNDI name for the bean is provided, you cannot provide any JNDI name for business interface in the Provide JNDI names for business interfaces panel.

To view this administrative console page, click **Applications** > **Application Types** > **WebSphere enterprise applications** > **application** > **EJB JNDI names**.

Attention: If an application is running, changing an application setting causes the application to restart. On stand-alone servers, the application restarts after you save the change. On multiple-server products, the application restarts after you save the change and files synchronize on the node where the application is installed. To control when synchronization occurs on multiple-server products, deselect **Synchronize changes with nodes** on the Console preferences page.

Module

Specifies the name of the Enterprise JavaBeans module used by your application.

Bean

Specifies the name of an enterprise bean that is contained by the module.

URI

The Uniform Resource Identifier (URI) specifies the location of the module archive relative to the root of the application EAR.

Target Resource JNDI name

Specifies the Java Naming and Directory Interface (JNDI) name of the enterprise bean.

This is a data entry field. To modify the JNDI name bound to this bean, type the new name in this field, then select **OK**.

Information	Value
Data type	String

Bind EJB business settings

Use this administrative console page to specify Java Naming and Directory (JNDI) name bindings for each enterprise bean with a business interface in an EJB module. Each enterprise bean with a business interface in an EJB module must be bound to a JNDI name. For any business interface that does not provide a JNDI name, or if its bean does not provide a JNDI name, a default binding name is provided. If its bean provides a JNDI name, the default JNDI name for the business interface is provided on top of its bean JNDI name by appending the package-qualified class name of the interface.

If you specify the JNDI name for a bean in the Provide JNDI names for beans page, do not specify any business interface JNDI name in this page for the same bean. If you do not specify the JNDI name for a bean in the Provide JNDI names for beans page, you can optionally specify a business interface JNDI name. If you do not specify a business interface JNDI name, the run time provides a container default.

To view this page in the administrative console, click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name*** > **Bind EJB business**.

Attention: If an application is running, changing an application setting causes the application to restart. On stand-alone servers, the application restarts after you save the change. On multiple-server products, the application restarts after you save the change and files synchronize on the node where the application is installed. To control when synchronization occurs on multiple-server products, deselect **Synchronize changes with nodes** on the Console preferences page.

Module

Specifies the EJB module that contains the enterprise beans that bind to the JNDI name.

Bean

Specifies the enterprise bean that binds to the JNDI name.

URI

The Uniform Resource Identifier (URI) specifies the location of the module archive relative to the root of the application EAR.

Business Interface

Specifies the enterprise bean business interface in an EJB module.

For a no-interface view, the business interface value is an empty string ("").

JNDI Name

Specifies the JNDI name associated with the enterprise bean business interface in an EJB module.

Developing EJB 2.x entity beans that use access intents

Using the AccessIntent API

This task describes how to programmatically retrieve and call the AccessIntent API during the execution of bean managed persistence (BMP) entity bean methods.

Procedure

1. Look up the access intent service from the namespace. For example:

```
InitialContext ic = new InitialContext();
AccessIntentService aiService = ic.lookup("java:comp/websphere/AppProfile/AccessIntentService");
```

2. From a method of the remote or local component interface of the BMP, get the current AccessIntent object using the javax.ejb.EntityContext. This object is passed to the BMP when the container calls the setEntityContext method. Assume the EntityContext was stored in a variable named myEntityCtx. For example:

```
AccessIntent ai = aiService.getAccessIntent (myEntityCtx);
```

3. Use the get() methods of AccessIntent interface to obtain the wanted information. For example:

```
int concurrency = ai.getConcurrencyControl();
int accessType = ai.getAccessType();
if ( (concurrency == AccessIntent.CONCURRENCY_CONTROL_PESSIMISTIC)
   && (accessType == AccessIntent.ACCESS_TYPE_UPDATE) ) {
     int exclusive = ai.getPessimisticUpdateLockHint();
     // . . .
}
// . . .
```

   For a detailed example of the use of the AccessIntent API, see the topic Example: Using IBM extended APIs to share connections between CMP beans and BMP beans..

Results

The access intent object reference retrieved from the java:comp lookup is current for the duration of the method in which the reference was looked up. Depending on how you configured the application profile, subsequent calls of the same method might not retrieve the same access intent reference. You can only look up the object reference during the call of a BMP entity bean method; the reference does not exist during a request on a container managed persistence (CMP) entity bean. Therefore, do not cache access intent object references beyond, or used outside of, the scope of the execution of any given BMP method.

AccessIntent interface

The AccessIntent interface is available to bean-managed persistence (BMP) entity beans.

A BMP entity bean can get and use an instance of the AccessIntent interface. For more information see “Using the AccessIntent API” on page 478.

AccessIntent interface

```
package com.ibm.websphere.appprofile.accessintent;

/**
* This interface defines the essential access intents
* available at run time.
*/
public interface AccessIntent {

/**
* Returns the concurrency control intent, which indicates
* the application prefers either pessimistic or optimistic
* concurrency control when accessing the current component
* in the context of the current transaction.
*/
public int getConcurrencyControl();
public final int CONCURRENCY_CONTROL_PESSIMISTIC = 1;
public final int CONCURRENCY_CONTROL_OPTIMISTIC = 2;

/**
* Returns access type intent, which indicates the application
* intends either update or read access of the current component
* in the context of the current transaction.
*/
public int getAccessType();
public final int ACCESS_TYPE_UPDATE= 1;
public final int ACCESS_TYPE_READ = 2;

/**
* Returns an integer value that indicates that the run time should
* assume that there will be no collision on retrieved rows.
*/
public int getPessimisticUpdateLockHint();
public final static int PESSIMISTIC_UPDATE_LOCK_HINT_NOCOLLISION = 1;
```

```
public final static int PESSIMISTIC_UPDATE_LOCK_HINT_WEAKEST_LOCK_AT_LOAD = 2;
public final static int PESSIMISTIC_UPDATE_LOCK_HINT_NONE = 3;
public final static int PESSIMISTIC_UPDATE_LOCK_HINT_EXCLUSIVE = 4;

/*
* Returns an integer value that indicates that the run time should
* assume that there will be collisions on retrieved rows.
*/
public int getPessimisticUpdateLockHint();
public final static int PESSIMISTIC_UPDATE_LOCK_HINT_NOCOLLISION = 1;
public final static int PESSIMISTIC_UPDATE_LOCK_HINT_WEAKEST_LOCK_AT_LOAD = 2;
public final static int PESSIMISTIC_UPDATE_LOCK_HINT_NONE = 3;
public final static int PESSIMISTIC_UPDATE_LOCK_HINT_EXCLUSIVE = 4;

/**
* Returns the collection access intent, which indicates the
* application intends to access the objects returned by the
* currently executing finder in either serial or random fashion.
*/
public int getCollectionAccess();
public final int COLLECTION_ACCESS_RANDOM = 1;
public final int COLLECTION_ACCESS_SERIAL = 2;

/**
* Returns the collection scope, which indicates the maximum
* lifespan of a lazy collection.
*/
public int getCollectionScope();
public final int COLLECTION_SCOPE_TRANSACTION = 1;
public final int COLLECTION_SCOPE_ACTIVITYSESSION = 2;
public final int COLLECTION_SCOPE_TIMEOUT = 3;

/**
* Returns the timeout value in seconds when collectionScope is Timeout.
*/
public int getCollectionTimeout();

/**
* Returns the number of elements the application requests be contained
* in each segment of the element collection returned by the currently
* executing finder.
*/
public int getCollectionIncrement();

/**
* Returns the ReadAheadHint requested by the application for the currently
* executing finder.
*/
public ReadAheadHint getReadAheadHint();

/**
* Returns the number of elements the application requests be contained in
* each segment of a query made on a database.
*/
public int getResourceManagerPreFetchIncrement();

}
```

Assembling access intents to EJB 2.x entity beans

Applying access intent policies to beans

You can apply an access intent policy to an application's entity beans through the assembly tool.

About this task

Container-managed persistence (CMP) developers can use *access intent* to provide hints on how the application server run time should manage the details of persistence without having to explicitly manage any of the persistence logic from within their application.

Using the access intent service is also an option for programmers who develop bean-managed persistence (BMP) entity beans. Because the only meaningful difference between BMP and CMP components is the mechanism that provides the persistence logic, BMP beans leverage access intent hints in the same manner as the EJB container manages accent intent for CMP beans. This ability becomes especially important when BMP entities and CMP entities want to share connections. BMP beans configured with the same concurrency as the CMP beans and implemented to the same isolation level mapping as the CMP can share connections.

Developers can apply access intent policies to BMP entity beans as well as to CMP entity beans. It is expected that BMP developers use only those access intent attributes that are important to a particular BMP bean. The access intent service interface is bound into the *java:comp namespace* for each particular BMP bean. The access intent policy retrieved from the access intent service is current from the time that the *ejbLoad* process is called until the time that the *ejbStore* process completes its invocation.

Note: This is the preferred technique to define access intent policies. Method-level access intent is deprecated in Version 6.0.

Procedure

1. Start an assembly tool.
2. Optional: Open the Java EE perspective to work with Java EE projects. Click **Window > Open Perspective > Other > Java EE**.
3. Optional: Open the Project Explorer view. Click **Window > Show View > Project Explorer**. Another helpful view is the Navigator view (**Window > Show View > Navigator**).
4. Create a new application EAR file or edit an existing one.

   For example, to change attributes of an existing application, use the import wizard to import an EAR file. To start the import wizard:

   a. Select **File > Import > EAR file > Next**
   b. Select the EAR file.
   c. Create a WebSphere Application Server v6.0 type of Server Runtime. Select **New** to open the New Server Runtime Wizard and follow the instructions.
   d. In the *Target server* field, select *WebSphere Application Server v6.0* type of Server Runtime.
   e. Select **Finish**
5. In the Project Explorer view of the J2EE perspective, right-click **Deployment Descriptor: EJB Module Name** under the EJB module for the bean instance, then select **Open With > Deployment Descriptor Editor**. A property dialog notebook for the EJB project is displayed in the property pane.
6. Select the **Access** tab.
7. In the **Access Intent for Entities 2.x (Bean Level)** panel, select the name of the bean.
8. On the right side of the **Access Intent for Entities 2.x (Method Level)** panel, select **Add**. The **Add Access Intent** panel displays.
9. In the **Access intent name** field, select wsPessimisticUpdate from the drop-down list.
10. Optional: Enter a **Description** to help you remember what this policy does.
11. Optional: Change the **Persistence Option** setting
12. Click **Finish**. The access intent policy for the entity bean is shown in the **Access Intent for Entities 2.x (Bean Level)** panel

Configuring read-read consistency checking with an assembly tool

Read-read consistency checking only applies to LifeTimeInCache beans whose data is read from another transaction. The product checks that the data is consistent with the data store, and ensures that it is not updated after checking for access intents that are *repeatable read* (RR).

About this task

For access intents that are *read committed* (RC), the product checks that the data is consistent at the point of checking; it does **not** guarantee that the data does not change after the checking. This makes the behavior of the LifeTimeInCache bean the same as beans that are non-LifeTimeInCache.

To perform this checking, you need to configure CMP entity beans with read-read consistency checking. You can do this using an assembly tool. To learn how to complete this task see the topic, Adding bean-level access intent for entity beans 2.x in the assembly tool information center.

Example: Read-read consistency checking

Read-read consistency checking only applies to LifeTimeInCache beans whose data is read from another transaction.

Usage scenario

For the access intents that are for *repeatable read* (RR), this means the product checks that the data is consistent with that in the data store and ensures that no one updates it after the checking. For the Access Intents that are for *read committed* (RC), this means the product checks that the data is consistent at the point of checking, but it does **not** guarantee that the data does not change after the checking. This makes the behavior of the LifeTimeInCache bean the same as non-LifeTimeInCache beans.

You have three options for setting consistency checking, as shown in the following scenarios concerning the calculation of interest in "Ann's" bank account. In each case, the data store is shared by this Enterprise JavaBeans (EJB) container managed persistence (CMP) application to calculate the interest and other applications, such as EJB bean managed persistence (BMP) , Java Database Connectivity (JDBC), or legacy applications. Also in each case, the EJB account is configured as a *long-lifetime* bean.

NONE

- The server is started.
- User 1 in Transaction 1 calls Account.findByPrimaryKey("10001"), account data for Ann is read from the database, with a balance of $100.
- Ann’s record is cached by the persistence manager (PM) on the server.
- User 2 writes a JDBC call and changes the balance to $120.
- User 3 in Transaction 2 calls Account.findByPrimaryKey() for account "10001", Ann’s data is read from cache, with a balance of $100.
- Calculate Ann’s interest, but the result might not be correct because of the data integrity issue.

Read-read checking AT_TRAN_BEGIN

- The server is started.
- User 1 in Transaction 1 calls Account.findByPrimaryKey("10001"), account data for Ann is read from the database, with a balance of $100.
- Ann’s record is cached by the persistence manager (PM) on the server.
- User 2 writes a JDBC call and changes the balance to $120.
- User 3 in Transaction 2 calls Account.findByPrimaryKey() for account "10001", Ann’s data is read from cache, with a balance of $100.
- PM performs read-read check on Ann's account and finds that the balance of 100 is changed. It issues a database query to retrieve balance of $120, and Ann’s data in the cache is refreshed.

- Calculate Ann's interest, proceed with the transaction because data integrity is protected.

Read-read checking AT_TRAN_END

- The server is started.
- User 1 in Transaction 1 calls Account.findByPrimaryKey("10001"), account data for Ann is read from the database, with a balance of $100.
- Ann's record is cached by the persistence manager (PM) on the server.
- User 2 writes a JDBC call and changes the balance to $120.
- User 3 in Transaction 2 calls Account.findByPrimaryKey() for account "10001", Ann's data is read from database, with balance of $100.
- Calculate Ann's interest.
- During end of transaction 2, PM performs read-read check on Ann's account and finds that the balance of 100 is changed.
- PM rolls back the transaction and invalidates the cache. The transaction fails and again data integrity is protected.

Access intent service

Access intent is an application server runtime service that enables you to precisely manage an application's persistence.

The access intent service defines a set of declarative annotations used by the Enterprise JavaBeans (EJB) container and its agents to make performance optimizations for entity bean access. These annotations are organized into sets called *access intent policies*.

Access intent policies contain a set of annotations considered as hints by the EJB container and its agents. Most access intent policies are hints representing high-level abstractions that can be mapped to a specific back end resource manager. It is the responsibility of the EJB persistence machinery to ensure the necessary concurrency control, connection, and cache management when carrying out the persistence details. The EJB persistence manager can use access intent hints to make better performance decisions when carrying out its assigned task. A smaller number of access intents are hints to the EJB container, influencing the management of EJB collections.

Typically, you configure *bean level* access intent for your applications. You can also apply access intent policies to beans within the scope of *application profiles*. Consequently, you can configure beans with multiple and opposing access intent policies. The application profiling documentation explains in more detail how to configure an application to apply a particular access intent policy to a bean for one request, then apply another access intent policy to the same bean for a different request.

Support for applying access intent policies at the method level is deprecated in WebSphere Application Server Version 6.0. In this practice of configuring access intent, you apply a policy to methods within the scope of an EJB module so that the policy becomes the default access intent for all requests upon those methods.

Access intent design considerations

best-practices: Refrain from over-tuning an application. You can introduce errors by incorrectly using the access intent service. For example, misuse of the wsPessimisticUpdate-NoCollision policy can result in lost updates; inappropriately setting the collection increment value can introduce performance issues; and problem determination is more difficult when an application is configured with multiple access intent policies.

Note: Clarity and simplicity should be your guiding principles when using the access intent service. This is even more important when applying access intent polices within the scope of application profiles.

Even though access intent policies can be configured on any method of an entity bean, some attributes of a policy can only be leveraged by the runtime environment under certain conditions. For example, concurrency and access intent are only used for CMP entity beans when the ejbLoad method is driven to open a connection and read data from a given resource; that data is cached and used to drive the proper queries during invocation of the ejbStore method. Read-ahead hints are only used during the execution of a finder for a bean. The collection increment and resource manager prefetch increment are only used on multi-object finders. Configuring policies on methods that do not use the policy is not an error. Only certain attributes of any policy are used, even when the policy is appropriately applied to a method. However, configuring policies unnecessarily throughout an application obscures the design of the application and complicates the maintenance of the application.

Access intent with BMP entity beans

Access intent's declarative functionality provides great power to you as a CMP entity bean developer. You can provide hints on how the product should manage the details of persistence without having to explicitly manage any of the persistence logic in the application. There are situations, however, in which you might need to develop BMP entity beans. Since the only meaningful difference between BMP and CMP components is who provides the persistence logic, BMP entity beans should be able to leverage access intent hints just as the product does on behalf of CMP entity beans. BMP entity beans that use the access intent service participate in application profiling; that is, the value of the access intent attributes can differ from request to request, allowing the BMP entity bean to seamlessly modify its persistence strategy.

You can apply access intent policies to BMP entity bean methods as well as CMP entity bean methods. Because access intent hints are not contractual in nature, there is no obligation for a BMP entity bean to exploit them. BMP entity beans are expected to use only those access intent attributes that are important to that particular bean.

The current access intent policy is bound into the java:comp namespace for a particular BMP entity bean. That policy is current only for the duration of the method call during which the access intent policy was retrieved. In a typical scenario, you would cache the access type during invocation of the ejbLoad method so that appropriate actions can be taken during invocation of the ejbStore method.

Access intent best practices

When applying access intent policies to EJB methods, consider the following issues.

- Start by configuring the default access intent policy for an entity. After your application is built and started, you can tune certain access paths in your application using application profiling or method-level access intent.
- Don't mix access types. Avoid using both pessimistic and optimistic policies in the same transaction. For most databases, pessimistic and optimistic policies use different isolation levels. This can result in multiple database connections, which prevents you from taking advantage of the performance benefits possible through connection sharing.
- Take care when applying the **wsPessimisticUpdate-NoCollision** policy. This policy does not ensure data integrity. No database locks are held, so concurrent transactions can overwrite each other's updates. Use this policy only if you can be sure that only one transaction attempts to update persistent store at any time.

For further information on Java Persistence API (JPA) Access intent, see the topic on JPA Access intent.

Applying access intent policies to methods

You apply an access intent policy to a method, or set of methods, in an application's entity beans through the assembly tool.

About this task

Note: Method-level access intent is deprecated in Version 6.0.

Procedure

1. Start an assembly tool.
2. Optional: Open the Java EE perspective to work with Java EE projects. Click **Window > Open Perspective > Other > Java EE**.
3. Optional: Open the Project Explorer view. Click **Window > Show View > Project Explorer**. Another helpful view is the Navigator view (**Window > Show View > Navigator**).
4. Create a new application EAR file or edit an existing one.

   For example, to change attributes of an existing application, use the import wizard to import an EAR file. To start the import wizard:

   a. Select **File > Import > EAR file > Next**
   b. Select the EAR file.
   c. Create a WebSphere Application Server v6.0 type of Server Runtime. Select **New** to open the New Server Runtime Wizard and follow the instructions.
   d. In the *Target server* field, select *WebSphere Application Server v6.0* type of Server Runtime.
   e. Select **Finish**
5. In the Project Explorer view of the J2EE perspective, right-click the **Deployment Descriptor: EJB Module Name** under the EJB module for the bean instance, then select **Open With > Deployment Descriptor Editor**. A property dialog notebook for the EJB project is displayed in the property pane.
6. Select the **Access** tab.
7. On the right side of the **Access Intent for Entities 2.x (Method Level)** panel, select **Add**. The **Add Access Intent** panel displays.
8. Specify the **Name** for your new intent policy.
9. Select the **Access intent name** from the drop-down list.
10. Enter a **Description** to help you remember what this policy does.
11. Optional: Select **Read Ahead Hint**. A single access intent read ahead hint might not refer to the same bean type in more than one relationship. For example, if a **Department** enterprise bean has a relationship *employees* with the **Employee** enterprise bean, and also has a relationship *manager* with the **Employee** enterprise bean, then a read ahead hint cannot specify both *employees* and *manager*.
12. Click **Next**. The next **Add Access Intent** panel displays, with optional attributes.
13. Optional: Decide whether or not to overwrite these optional access intent attributes. Click on those you want to change.
14. Click **Next**. The next **Add Access Intent** panel, with a list of Enterprise Beans, displays.
15. Select one or more Enterprise Beans from the list.

    Note: If you selected **Read Ahead Hint** in an earlier step, you can only select **ONE** bean at this step.
16. Click **Next**. The next **Add Access Intent** panel, with a list of methods, displays.
17. Select the methods you want to use.
18. If you *DID NOT* select **Read Ahead Hint** in an earlier step, click **Finish**. If you *DID* select the Read Ahead Hint option, you can click **Next** to specify your Read Ahead Hint for the specified bean. The next **Add Access Intent** panel, with a list of EJB preload paths, displays.
19. Edit the EJB preload path by selecting relationship roles from the **Relationship roles:** window.
20. Click **Finish**. A new entry is created in the **Access Intent for Entities 2.x (Method Level)** panel

Developing applications that use the Java Persistence API

Developing JPA 2.x applications for a Java EE environment

Containers in the application server can provide many of the necessary functions for the Java Persistence API (JPA) in a Java Enterprise Edition (Java EE) environment. The application server also provides JPA command tools to assist you with developing applications in a Java EE environment.

About this task

Attention: When you use these JPA command tools, run them from the <*profile_root*>/bin directory, rather than from the *app_server_root*/bin directory to make sure that you have the latest version of the commands for your release level.

For this task, you must specify the `com.ibm.ws.jpa.thinclient_8.0.0.jar` stand-alone Java archive (JAR) file in your class path. This stand-alone JAR file is available from the installation images. The location of this file on the server installation image is ${*app_server_root*}/runtimes/ `com.ibm.ws.jpa.thinclient_8.0.0.jar`..

Important: JPA applications require different configuration techniques from applications that use container-managed persistence (CMP) or bean-managed persistence (BMP). They do not follow the typical deployment techniques that are associated with applications that implement CMP or BMP. In JPA applications, you must define a persistence unit and configure the appropriate properties to ensure that the applications can run in a Java EE environment.

The container supports all necessary injections to ensure that applications run in the Java EE environment. For example, the container can inject the @PersistenceUnit and @PersistenceContext for your applications.

Procedure

1. Generate your entities classes. These are Plain Old Java Object (POJO) entities. Depending upon your development model, you might use some or all of the JPA tools:
   - **Top-down mapping:** You start from scratch with the entity definitions and the object-relational mappings, and then you derive the database schemas from that data. If you use this approach, you are most likely concerned with creating the architecture of your object model and then writing your entity classes. These entity classes would eventually drive the creation of your database model. If you are using a top-down mapping of the object model to the relational model, develop the entity classes and then use OpenJPA functionality to generate the database tables that are based on the entity classes. The **`wsmapping`** tool helps with this approach.
   - **Bottom-up mapping:** You start with your data model, which are the database schemas, and then you work upwards to your entity classes. The **`wsreversemapping`** tool helps with this approach.
   - **Meet in the middle mapping:** probably the most common development model. You have a combination of the data model and the object model partially complete. Depending on the goals and requirements, you must negotiate the relationships to resolve any differences. Both the **`wsmapping`** tool and the **`wsreversemapping`** tool help with this approach.

   The JPA solution for the application server provides several tools that help with developing JPA applications. Combining these tools with IBM Rational Application Developer provides a solid development environment for either Java EE or Java SE applications. Rational Application Developer includes GUI tools to insert annotations, a customized `persistence.xml` file editor, a database explorer, and other features. Another alternative is the Eclipse Dali project. More information about Rational Application Developer or the Eclipse Dali plug-in can be found at their respective websites.
2. Compile the entity classes.

Compile the entities as you would any Java class, unless you are using the Criteria API. If you are using the Criteria API, you must also generate the Criteria API metamodel classes by including the following option with the **javac** command:

```
-Aopenjpa.metamodel=true
```

The following are examples of how you use this option.

For Linux, UNIX and z/OS platforms:

```
app_server_root/java/bin/javac
-Aopenjpa.metamodel=true
-classpath app_server_root/runtimes/com.ibm.ws.jpa.thinclient_8.0.0.jar
mypackage/MyEntity.java
```

For Windows platform:

```
app_server_root\java\bin\javac
-Aopenjpa.metamodel=true
-classpath app_server_root\runtimes\com.ibm.ws.jpa.thinclient_8.0.0.jar
 mypackage\MyEntity.java
```

Using the **javac** command and the J2EE server plug-in:

For Linux, UNIX and z/OS platforms:

```
app_server_root/java/bin/javac
-Aopenjpa.metamodel=true
-classpath app_server_root/plugins/javax.j2ee.persistence.jar
mypackage/MyEntity.java
```

For Windows platform:

```
app_server_root\java\bin\javac
-Aopenjpa.metamodel=true
-classpath app_server_root\plugins\javax.j2ee.persistence.jar
mypackage\MyEntity.java
```

For more information about using Criteria API and AnnotationProcessor6, refer to the Apache OpenJPA User Guide, Chapter 11: JPA Criteria and Chapter 4: Generation of Canonical Metamodel classes for AnnotationProcessor6 options and the information center topic, Criteria API.

3. Enhance the entity classes using the JPA enhancer tool, **wsenhancer**, for the application server. An enhancer is a tool that automatically adds code to your persistent classes after you have written them. The enhancer post-processes the bytecode that is generated by the Java compiler and adds the fields and methods that are necessary to implement the persistence features. Although JPA for the application server and OpenJPA can automatically enhance the entities at run time, you obtain better performance if you can enhance your entities when you build the application. The application does not attempt to enhance entities that are already enhanced.

   For examples of how to use the **wsenhancer** tool, see the topic, wsenhancer command.

4. Optional: If you are not using the development model for bottom-up mapping, generate or update your database tables automatically or by using the **wsmapping** tool.

   - By default, the object-relational mapping does not occur automatically, but you can configure the application server to provide that mapping with the openjpa.jdbc.SynchronizeMappings property. This property can accelerate development by automatically ensuring that the database tables match the object model. To enable automatic mapping, include the following line in the `persistence.xml` file:

     ```
     <property name="openjpa.jdbc.SynchronizeMappings" value="buildSchema(ForeignKeys=true)"/>
     ```

     Note: To enable automatic object-relational mapping at run time, all of your persistent classes must be listed in the Java .class file, mapping file, and Java archive (JAR) file elements in XML format.

   - To manually update or generate your database tables, run the JPA mapping tool for the application server from the command line to create the tables in the database. For examples on how to run the **wsmapping** tool, see the topic, wsmapping command.

5. Optional: If you are using DB2 and want to use static Structured Query Language (SQL), run the **wsdbgen** command. In order to use the **wsdbgen** command, IBM Optim pureQuery Run time must be installed. The **wsdbgen** command creates the *persistence_unit_name*.pdqxml file under the same META-INF directory where your persistence.xml file is located. If you have multiple persistence units, the **wsdbgen** command must be run for each persistence unit.

   When multiple pdqxml files are referenced by an application, use the **Merge** utility to combine them into a single pdqxml file. Specify the combined pdqxml file as pureQueryXml property of pdqProperties. Refer to the Merge utility documentation in the IBM Integrated Data Management information center.

   Note: Applications that implement the JPA and are configured to run static SQL can experience various exceptions. These exceptions might occur with the **wsdbgen** command, which you can use to prepare the application, or when the application is running and calls a JPA method. To resolve this problem, complete the following steps:

   a. Install the program temporary fixes (PTF) for the iSeries JDBC Driver V5R4. Install PTF numbers SI32561 and SI32562. You can find the PTFs through the IBM System i® Support: PTF Cover Letters website.
   b. If you use DB2 Universal Database for iSeries V6R1 or V5R3, visit the fix website for the appropriate release.
   c. Install the required level of pureQuery, which is Version 1.3.100 or later. For more information, see the IBM Optim pureQuery Runtime website. Install the latest JCC driver, which is Version 3.52.95 or later, with the fix for APAR PK65069. The latest JCC drivers are part of the IBM DB2 software package.
   d. For DB2 on a z/OS server, install PTF UK39204 for the V8 alternate driver or PTF UK39205 for V9, and install the fix for APAR PK67706.

   For examples on how to run this command, see the topic, **wsdbgen** command.
6. Optional: If you are using application-managed identity, generate an application-managed identity class with the **wsappid** tool. When you use an application-managed identity, one or more of the fields must be an identity field. Use an identity class if your entity has multiple identity fields and at least one of the fields is related to another entity. The application-managed identity tool generates Java code that uses the identity class for any persistent type that implements application-managed identity.

   For examples on how to use the **wsappid** tool, see the topic wsappid command.

Example

The following is an example of a persistence.xml file:

```
<?xml version="1.0" encoding="UTF-8"?>
<persistence xmlns="http://java.sun.com/xml/ns/persistence"
             xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" version="2.0"
             xsi:schemaLocation="http://java.sun.com/xml/ns/persistence
http://java.sun.com/xml/ns/persistence/persistence_2_0.xsd">

<persistence-unit name="TheWildZooPU" transaction-type="JTA">
        <jta-data-source>jdbc/DataSourceJNDI</jta-data-source>
        <!-- additional Mapping file, in addition to orm.xml>
        <mapping-file>META-INF/JPAorm.xml</mapping-file>

        <class>com.company.bean.jpa.PersistebleObjectImpl</class>
        <class>com.company.bean.jpa.Animal</class>
        <class>com.company.bean.jpa.Dog</class>
        <class>com.company.bean.jpa.Cat</class>

   <properties>
          <property name="openjpa.ConnectionFactoryProperties"
                    value="PrettyPrint=true, PrettyPrintLineLength=72"/>
          <property name="openjpa.jdbc.SynchronizeMappings"
                    value="buildSchema(ForeignKeys=true)"/>
```

```
        </properties>

    </persistence-unit>
</persistence>
```

What to do next

For more information about the commands, classes or other OpenJPA information, refer to the Apache OpenJPA User Guide.

Developing JPA 2.x applications for a Java SE environment

Prepare persistence applications to test outside of the application server container in a Java SE environment.

About this task

Attention: When you use these JPA command tools, run them from the *profile_root*/`bin` directory, rather than from the *app_server_root*/`bin` directory to make sure that you have the latest version of the commands for your release level.

For this task, you must specify the `com.ibm.ws.jpa.thinclient_8.0.0.jar` stand-alone Java archive (JAR) file in your class path. This stand-alone JAR file is available from the installation images. The location of this file on the server installation image is ${*app_server_root*}/`runtimes/com.ibm.ws.jpa.thinclient_8.0.0.jar`..

Important: Java Persistence API (JPA) applications require different configuration techniques from applications that use container-managed persistence (CMP) or bean-managed persistence (BMP). They do not follow the typical deployment techniques that are associated with applications that implement CMP or BMP. In JPA applications, you must define a persistence unit and configure the appropriate properties in the `persistence.xml` file to ensure that the applications can run in a Java SE environment.

There are some considerations for running JPA applications in a Java SE environment:

- Resource injection is not available. You must configure these services specifically or programmatically.
- The life cycle of the EntityManagerFactory and EntityManager are managed by the application. Applications control the creation, manipulation, and deletion of these constructs programmatically.

Procedure

1. Generate your entities classes.

   These are Plain Old Java Object (POJO) entities. Depending upon your development model, you might use some or all of the JPA tools:

   Top-down mapping
   You start from scratch with the entity definitions and the object-relational mappings, and then you derive the database schemas from that data. If you use this approach, you are most likely concerned with creating the architecture of your object model and then writing your entity classes. These entity classes would eventually drive the creation of your database model. If you are using a top-down mapping of the object model to the relational model, develop the entity classes and then use OpenJPA functionality to generate the database tables that are based on the entity classes. The **`wsmapping`** tool would help with this approach.

   Bottom-up mapping
   You start with your data model, which are the database schemas, and then you work upwards to your entity classes. The **`wsreversemapping`** tool would help with this approach.

   Meet in the middle mapping
   Probably the most common development model. You have a combination of the data model

and the object model partially complete. Depending on the goals and requirements, you must negotiate the relationships to resolve any differences. Both the **wsmapping** tool and the **wsreversemapping** tool would help with this approach.

The JPA solution for the application server provides several tools that help with developing JPA applications. Combining these tools with IBM Rational Application Developer provides a solid development environment for either Java EE or Java SE applications. Rational Application Developer includes GUI tools to insert annotations, a customized`persistence.xml` file editor, a database explorer, and other features. Another alternative is the Eclipse Dali project. More information about Rational Application Developer or the Eclipse Dali plug-in can be found at their respective websites.

2. Compile the entity classes.

   Compile the entities as you would any Java class, unless you are using the Criteria API. If you are using the Criteria API, you must also generate the Criteria API metamodel classes by including the following option with the **javac** command:

   ```
   -Aopenjpa.metamodel=true
   ```

   The following are examples of how you use this option.

   ```
   app_server_root/java/bin/javac
   -Aopenjpa.metamodel=true
   -classpath app_server_root/runtimes/com.ibm.ws.jpa.thinclient_8.0.0.jar
   mypackage/MyEntity.java
   ```

   For more information about using Criteria API and AnnotationProcessor6, refer to the Apache OpenJPA User Guide, Chapter 11: JPA Criteria and Chapter 4: Generation of Canonical Metamodel classes for AnnotationProcessor6 options and the information center topic, Criteria API.

3. Enhance the entity classes using the JPA enhancer tool, or specify the Java agent to perform dynamic enhancement at run time.
   - Use the **wsenhancer** tool. The enhancer post-processes the bytecode that is generated by the Java compiler and adds the fields and methods that are necessary to implement the persistence features. For example examples on how to use the **wsenhancer** tool, see the topic, **wsenhancer** command.
   - You can specify the Java agent mechanism to perform the dynamic enhancement at run time. For example, type the following at the command prompt:

```
java -javaagent:${app_client_root}/runtimes/com.ibm.ws.jpa.thinclient_8.0.0.jar com.xyz.Main
```

   Attention: You can either run the **wsenhancer** tool or specify the **javaagent** command. You do not need to do both.

4. Optional: If you are not using the development model for bottom-up mapping, generate or update your database tables automatically or by using the **wsmapping** tool.
   - By default, the object-relational mapping does not occur automatically, but you can configure the application server to provide that mapping with the openjpa.jdbc.SynchronizeMappings property. This property can accelerate development by automatically ensuring that the database tables match the object model. To enable automatic mapping, include the following line in the `persistence.xml` file:

     ```
     <property name="openjpa.jdbc.SynchronizeMappings" value="buildSchema(ForeignKeys=true)"/>
     ```

     Note: To enable automatic object-relational mapping at run time, all of your persistent classes must be listed in the Java `.class` file, mapping file, and Java archive (JAR) file elements in XML format.
   - To manually update or generate your database tables, run the JPA mapping tool for the application server from the command line to create the tables in the database. For examples on how to run the **wsmapping** tool, see the topic, wsmapping command.
5. Optional: If you are using DB2 and want to use static Structured Query Language (SQL), run the **wsdbgen** command. In order to use the **wsdbgen** command, IBM Optim™ PureQuery Run time must be installed. The **wsdbgen** command creates the *persistence_unit_name*`.pdqxml` file under the same META-INF directory where your `persistence.xml` file is located. If you have multiple persistence units, the **wsdbgen** command must be run for each persistence unit.

When multiple pdqxml files are referenced by an application, use the **Merge** utility to combine them into a single pdqxml file. Specify the combined pdqxml file as pureQueryXml property of pdqProperties. See the Merge utility documentation in the IBM Integrated Data Management information center.

Note: Applications that utilize JPA and are configured to run static SQL can experience various exceptions. These exceptions might occur with the **wsdbgen** command, which you can use to prepare the application, or when the application is running and calls a JPA method. To resolve this problem, complete the following:

a. Install the program temporary fixes (PTF) for the iSeries JDBC Driver V5R4. Install PTF numbers SI32561 and SI32562. You can find the PTFs through the IBM System i Support: PTF Cover Letters website.

b. If you use DB2 Universal Database for iSeries V6R1 or V5R3, visit the fix web site for the appropriate release.

c. Install the required level of IBM Optim PureQuery Run time, which is Version 1.3.100 or later. For more information, see the IBM Data Studio pureQuery Runtime website. Install the latest JCC drivers, which is Version 3.52.95 or later, with the fix for APAR PK65069. The latest JCC drivers are part of the IBM DB2 software package.

d. For DB2 on a z/OS server, install PTF UK39204 for the V8 alternate driver or PTF UK39205 for V9, and install the fix for APAR PK67706.

For examples on how to run this command, see the topic, **wsdbgen** command.

6. Optional: If you are using application-managed identity, generate an application-managed identity class with the **wsappid** tool. When you use an application-managed identity, one or more of the fields must be an identity field. Use an identity class if your entity has multiple identity fields and at least one of the fields is related to another entity. The application-managed identity tool generates Java code that uses the identity class for any persistent type that implements application-managed identity.

   For examples on how to use the **wsappid** tool, see the topic wsappid command.

Example

The following is a sample persistence.xml file for the Java SE Environment:

```
<?xml version="1.0" encoding="UTF-8"?>
<persistence xmlns="http://java.sun.com/xml/ns/persistence"
             xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" version="2.0"
             xsi:schemaLocation="http://java.sun.com/xml/ns/persistence
                 http://java.sun.com/xml/ns/persistence/persistence_2_0.xsd">

    <persistence-unit name="TheWildZooPU" transaction-type="RESOURCE_LOCAL">

        <!-- additional Mapping file, in addition to orm.xml>
        <mapping-file>META-INF/JPAorm.xml</mapping-file>

        <class>com.company.bean.jpa.PersistebleObjectImpl</class>
        <class>com.company.bean.jpa.Animal</class>
        <class>com.company.bean.jpa.Dog</class>
        <class>com.company.bean.jpa.Cat</class>

        <properties>
            <property name="openjpa.ConnectionDriverName"
                      value="org.apache.derby.jdbc.EmbeddedDriver" />
            <property name="openjpa.ConnectionURL"
                      value="jdbc:derby:target/database/jpa-test-database;create=true" />
            <property name="openjpa.Log"
                      value="DefaultLevel=INFO,SQL=TRACE,File=./dist/jpaEnhancerLog.log,Runtime=INFO,Tool=INFO" />
            <property name="openjpa.ConnectionFactoryProperties"
                      value="PrettyPrint=true, PrettyPrintLineLength=72" />
            <property name="openjpa.jdbc.SynchronizeMappings"
                      value="buildSchema(ForeignKeys=true)" />
            <property name="openjpa.ConnectionUserName"
                      value="user" />
```

```
            <property name="openjpa.ConnectionPassword"
                      value="password"/>
        </properties>

    </persistence-unit>

</persistence>
```

What to do next

For more information about any of the commands, classes or other OpenJPA information, refer to the Apache OpenJPA User Guide.

Bean validation in JPA

Data validation is a common task that occurs in all layers of an application, including persistence. The Java Persistence API (JPA) 2.0 provides support for the Bean Validation API so that data validation can be done at run time. This topic includes a usage scenario where bean validation is used in the JPA environment of a sample digital image gallery application.

The Bean Validation API provides seamless validation across technologies on Java Enterprise Edition 6 (Java EE 6) and Java Platform, Standard Edition (JSE) environments. In addition to JPA 2.0, these technologies include JavaServer Faces (JSF) 2.0 and Java EE Connector Architecture (JCA) 1.6. You can read more about bean validation in the topic, Bean Validation API.

There are three core concepts of bean validation: constraints, constraint violation handling, and the validator. If you are running applications in an integrated environment like JPA, there is no need to interface directly with the validator.

Validation constraints are annotations or XML code that are added to a class, field, or method of a JavaBeans component. Constraints can be built in or user-defined. They are used to define regular constraint definitions and for composing constraints. The built-in constraints are defined by the bean validation specification and are available with every validation provider. For a list of built-in constraints, see the topic, Bean validation built-in constraints. If you need a constraint different from the built-in constraints, you can build your own user-defined constraint.

Constraints and JPA

The following usage scenario illustrates how a built-in constraint is used in the JPA architecture of a sample digital image gallery application.

In the first code example, a built-in constraint is added to a simple entity of the JPA model called *image*. An image has an ID, image type, file name, and image data. The image type must be specified and the image file name must include a valid JPEG or GIF extension. The code shows the annotated image entity with some built-in bean validation constraints applied.

```
package org.apache.openjpa.example.gallery.model;

import javax.persistence.Entity;
import javax.persistence.EnumType;
import javax.persistence.Enumerated;
import javax.persistence.GeneratedValue;
import javax.persistence.Id;
import javax.validation.constraints.NotNull;
import javax.validation.constraints.Pattern;

@Entity
public class Image {

    private long id;
    private ImageType type;
```

```
    private String fileName;
    private byte[] data;

    @Id
    @GeneratedValue
    public long getId() {
        return id;
    }

    public void setId(long id) {
        this.id = id;
    }

    @NotNull(message="Image type must be specified.")
    @Enumerated(EnumType.STRING)
    public ImageType getType() {
        return type;
    }

    public void setType(ImageType type) {
        this.type = type;
    }

    @Pattern(regexp = ".*\\.jpg|.*\\.jpeg|.*\\.gif",
        message="Only images of type JPEG or GIF are supported.")
    public String getFileName() {
        return fileName;
    }

    public void setFileName(String fileName) {
        this.fileName = fileName;
    }

    public byte[] getData() {
        return data;
    }

    public void setData(byte[] data) {
        this.data = data;
    }
}
```

The Image class uses two built-in constraints, @NotNull and @Pattern. The @NotNull constraint ensures that an ImageType element is specified and the @Pattern constraint uses regular expression pattern matching to ensure that the image file name is suffixed with a supported image format. Each constraint has corresponding validation logic that gets started at run time when the image entity is validated. If either constraint is not met, the JPA provider throws a ConstraintViolationException with the defined message. The JSR-303 specification also makes provisions for the use of a variable within the message attribute. The variable references a keyed message in a resource bundle. The resource bundle supports environment-specific messages and globalization, translation, and multicultural support of messages.

You can create your own custom validator and constraints. In the previous example, the Image entity used the @Pattern constraint to validate the file name of the image. However, it did not check constraints on the actual image data itself. You can use a pattern-based constraint; however, you do not have the flexibility that you would if you created a constraint specifically for checking constraints on the data. In this case you can build a custom method-level constraint annotation. The following is a custom or user-defined constraint called ImageContent.

```
package org.apache.openjpa.example.gallery.constraint;

import java.lang.annotation.Documented;
import java.lang.annotation.Retention;
import java.lang.annotation.Target;
import static java.lang.annotation.ElementType.METHOD;
import static java.lang.annotation.ElementType.FIELD;
```

```
import static java.lang.annotation.RetentionPolicy.RUNTIME;

import javax.validation.Constraint;
import javax.validation.Payload;

import org.apache.openjpa.example.gallery.model.ImageType;

@Documented
@Constraint(validatedBy = ImageContentValidator.class)
@Target({ METHOD, FIELD })
@Retention(RUNTIME)
public @interface ImageContent {
     String message() default "Image data is not a supported format.";
     Class<?>[] groups() default {};
  Class<? extends Payload>[] payload() default {};
  ImageType[] value() default { ImageType.GIF, ImageType.JPEG };
}
```

Next, you must create the validator class, ImageContentValidator. The logic within this validator gets implemented by the validation provider when the constraint is validated. The validator class is bound to the constraint annotation through the validatedBy attribute on the @Constraint annotation as shown in the following code:

```
package org.apache.openjpa.example.gallery.constraint;
import java.util.Arrays;
import java.util.List;
import javax.validation.ConstraintValidator;
import javax.validation.ConstraintValidatorContext;
import org.apache.openjpa.example.gallery.model.ImageType;
/**
 * Simple check that file format is of a supported type
 */
public class ImageContentValidator implements ConstraintValidator<ImageContent, byte[]> {
    private List<ImageType> allowedTypes = null;
    /**
     * Configure the constraint validator based on the image
     * types it should support.
     * @param constraint the constraint definition
     */
    public void initialize(ImageContent constraint) {
        allowedTypes = Arrays.asList(constraint.value());
    }
    /**
     *Validate a specified value.
     */
    public boolean isValid(byte[] value, ConstraintValidatorContext context) {
        if (value == null) {
            return false;
        }
        // Verify the GIF header is either GIF87 or GIF89
        if (allowedTypes.contains(ImageType.GIF)) {
            String gifHeader = new String(value, 0, 6);
            if (value.length >= 6 &&
                (gifHeader.equalsIgnoreCase("GIF87a") ||
                 gifHeader.equalsIgnoreCase("GIF89a"))) {
                return true;
            }
        }
        // Verify the JPEG begins with SOI and ends with EOI
        if (allowedTypes.contains(ImageType.JPEG)) {
            if (value.length >= 4 &&
                value[0] == 0xff && value[1] == 0xd8 &&
                value[value.length - 2] == 0xff && value[value.length -1] == 0xd9) {
                return true;
            }
        }
```

```
        // Unknown file format
        return false;
    }
}
```

Apply this new constraint to the getData() method on the Image class; for example:

```
@ImageContent
    public byte[] getData() {
        return data;
    }
```

When validation of the data attribute occurs, the isValid() method in the ImageContentValidator is started. This method contains logic for performing simple validation of the format of the binary image data. A potentially overlooked feature in the ImageContentValidator is that it can also validate for a specific image type. By definition, it accepts JPEG or GIF formats, but it can also validate for a specific format. For example, by changing the annotation to the following code example, the validator is instructed to only permit image data with valid JPEG content:

```
@ImageContent(ImageType.JPEG)
    public byte[] getData() {
        return data;
    }
```

Type-level constraints are also a consideration because you might need to validate combinations of attributes on an entity. In the previous examples validation constraints were used on individual attributes. Type-level constraints make it possible to provide collective validation. For example, the constraints applied to the image entity validate that an image type is set (not null), the extension on the image file name is of a supported type, and the data format is correct for the indicated type. But, for example, it does not collectively validate that a file named `img0.gif` is of type GIF and the format of the data is for a valid GIF file image. For more information about type-level constraints, see the white paper, OpenJPA Bean Validation Primer, and the section "Type-level constraints."

Validation groups

Bean validation uses validation groups to determine what type of validation and when validation occurs.

There are no special interfaces to implement or annotations to apply to create a validation group. A validation group is denoted by a class definition.

Note: When using groups, use simple interfaces. Using a simple interface makes validation groups more usable in multiple environments. Whereas, if a class or entity definition is used as a validation group, it might pollute the object model of another application by bringing in domain classes and logic that do no make sense for the application. By default, if a validation group or multiple groups is not specified on an individual constraint, it is validated using the javax.validation.groups.Default group. Creating a custom group is as simple as creating a new interface definition.

For more information about validation groups, read the white paper, OpenJPA Bean Validation Primer, and the section "Validation groups."

JPA domain model

In addition to the Image entity are Album, Creator and Location persistent types. An Album entity contains a reference to collection of its Image entities. The Creator entity contains a reference to the album entities that the image Creator contributed to and a reference to the Image entities created. This provides full navigational capabilities to and from each of the entities in the domain. An embeddable location, has been added to image to support storing location information with the image.

The Album and Creator entities have standard built-in constraints. The embeddable location is more unique in that it demonstrates the use of the @Valid annotation to validate embedded objects. To embed location into an image, a new field and corresponding persistent properties are added to the Image class; for example:

```
private Location location;

    @Valid
    @Embedded
    public Location getLocation() {
        return location;
    }

    public void setLocation(Location location) {
        this.location = location;
    }
```

The @Valid annotation provides chained validation of embeddable objects within a JPA environment. Therefore, when image is validated, any constraints on the location it references are also validated. If @Valid is not specified, the location is not validated. In a JPA environment, chained validation through @Valid is only available for embeddable objects. Referenced entities and collections of entities are validated separately to prevent circular validation.

Bean validation and the JPA environment

The JPA 2.0 specification makes integration with the Bean Validation API simple. In a JSE environment, bean validation is enabled by default when you provide the Bean Validation API and a bean validation provider on your runtime class path. In a Java EE 6 environment, the application server includes a bean validation provider so there is no need to bundle one with your application. In both environments, you must use a Version 2.0 `persistence.xml` file.

A Version 1.0 `persistence.xml` provides no means to configure bean validation. Requiring a Version 2.0 `persistence.xml` prevents a pure JPA 1.0 application from incurring the validation startup and runtime costs. This is important given that there is no standard means for a 1.0-based application to disable validation. In a Java EE 6 environment, enable validation in an existing 1.0 application by modifying the root element of your `persistence.xml` file. The following example represents the `persistence.xml` file:

```
<?xml version="1.0" encoding="UTF-8"?>
<persistence xmlns="http://java.sun.com/xml/ns/persistence"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://java.sun.com/xml/ns/persistence
    http://java.sun.com/xml/ns/persistence/persistence_2_0.xsd"
    version="2.0" >
...
</persistence>
```

Bean validation provides three modes of operation within the JPA environment:

- Auto

  Enables bean validation if a validation provider is available within the class path. Auto is the default.
- Callback

  When callback mode is specified, a bean validation provider must be available for use by the JPA provider. If not, the JPA provider throws an exception upon instantiation of a new JPA entity manager factory.
- None

  Disables bean validation for a particular persistence unit.

Auto mode simplifies deployment, but can lead to problems if validation does not take place because of a configuration problem.

Note: Use either none or callback mode explicitly for consistent behavior.
Also, if none is specified, JPA optimizes at startup and does not attempt to perform unexpected validation. Explicitly disabling validation is especially important in a Java EE 6 environment where the container is mandated to provide a validation provider. Therefore, unless specified, a JPA 2.0 application started in a container has validation enabled. This process adds additional processing during life cycle events.

There are two ways to configure validation modes in JPA 2.0. The simplest way is to add a validation-mode element to the `persistence.xml` with the wanted validation mode as shown in the following example:

```
 <persistence-unit name="auto-validation">
          ...
    <!-- Validation modes: AUTO, CALLBACK, NONE -->
    <validation-mode>AUTO</validation-mode>
    ...
  </persistence-unit>
```

The other way is to configure the validation mode programmatically by specifying the javax.persistence.validation.mode property with value auto, callback, or none when creating a new JPA entity manager factory as shown in the following example:

```
Map<String, String> props = new HashMap<String, String>();
  props.put("javax.persistence.validation.mode", "callback");
        EntityManagerFactory emf =
            Persistence.createEntityManagerFactory("validation", props);
```

Bean validation within JPA occurs during JPA life cycle event processing. If enabled, validation occurs at the final stage of the PrePersist, PreUpdate, and PreRemove life cycle events. Validation occurs only after all user-defined life cycle events, since some of those events can modify the entity that is being validated. By default, JPA enables validation for the default validation group for PrePersist and PreUpdate life cycle events. If you must validate other validation groups or enable validation for the PreRemove event, you can specify the validation groups to validate each life cycle event in the `persistence.xml` as shown in the following example:

```
<persistence-unit name="non-default-validation-groups">
  <class>my.Entity</class>
  <validation-mode>CALLBACK</validation-mode>
  <properties>
   <property name="javax.persistence.validation.group.pre-persist"
       value="org.apache.openjpa.example.gallery.constraint.SequencedImageGroup"/>
   <property name="javax.persistence.validation.group.pre-update"
       value="org.apache.openjpa.example.gallery.constraint.SequencedImageGroup"/>
   <property name="javax.persistence.validation.group.pre-remove"
       value="javax.validation.groups.Default"/>
  </property>
 </persistence-unit>
```

The following example shows various stages of the JPA life cycle, including persist, update, and remove:

```
EntityManagerFactory emf =
            Persistence.createEntityManagerFactory("BeanValidation");
        EntityManager em = emf.createEntityManager();

        Location loc = new Location();
        loc.setCity("Rochester");
        loc.setState("MN");
        loc.setZipCode("55901");
        loc.setCountry("USA");

        // Create an Image with non-matching type and file extension
        Image img = new Image();
        img.setType(ImageType.JPEG);
        img.setFileName("Winter_01.gif");
        loadImage(img);
        img.setLocation(loc);
```

```
// *** PERSIST ***
try {
    em.getTransaction().begin();
    // Persist the entity with non-matching extension and type
    em.persist(img);
} catch (ConstraintViolationException cve) {
    // Transaction was marked for rollback, roll it back and
    // start a new one
    em.getTransaction().rollback();
    em.getTransaction().begin();
    // Fix the file type and re-try the persist.
    img.setType(ImageType.GIF);
    em.persist(img);
    em.getTransaction().commit();
}

// *** UPDATE ***
try {
    em.getTransaction().begin();
    // Modify the file name to a non-matching file name
    // and commit to trigger an update
    img.setFileName("Winter_01.jpg");
    em.getTransaction().commit();
}  catch (ConstraintViolationException cve) {
    // Handle the exception.  The commit failed so the transaction
    // was already rolled back.
    handleConstraintViolation(cve);
}
// The update failure caused img to be detached. It must be merged back
// into the persistence context.
img = em.merge(img);

// *** REMOVE ***
em.getTransaction().begin();
try {
    // Remove the type and commit to trigger removal
    img.setType(ImageType.GIF);
    em.remove(img);
}  catch (ConstraintViolationException cve) {
    // Rollback the active transaction and handle the exception
    em.getTransaction().rollback();
    handleConstraintViolation(cve);
}
em.close();
emf.close();
```

Exceptions

Validation errors can occur in any part of JPA life cycle.

If one or more constraints fail to validate during a life cycle event, a ConstraintViolationException is thrown by the JPA provider. The ConstraintViolationException thrown by the JPA provider includes a set of ConstraintViolations that occurred. Individual constraint violations contain information regarding the constraint, including: a message, the root bean or JPA entity, the leaf bean which is useful when validating JPA embeddable objects, the attribute which failed to validate, and the value that caused the failure. The following is a sample exception handling routine:

```
private void handleConstraintViolation(ConstraintViolationException cve) {
      Set<ConstraintViolation<?>> cvs = cve.getConstraintViolations();
   for (ConstraintViolation<?> cv : cvs) {
     System.out.println("------------------------------------------------");
          System.out.println("Violation: " + cv.getMessage());
          System.out.println("Entity: " + cv.getRootBeanClass().getSimpleName());
          // The violation occurred on a leaf bean (embeddable)
          if (cv.getLeafBean() != null && cv.getRootBean() != cv.getLeafBean()) {
```

```
            System.out.println("Embeddable: " +
cv.getLeafBean().getClass().getSimpleName());
          }
          System.out.println("Attribute: " + cv.getPropertyPath());
          System.out.println("Invalid value: " + cv.getInvalidValue());
      }
    }
```

Constraint violation processing is typically simple when using attribute-level constraints. If you are using a type-level validator with type-level constraints, it can be more difficult to determine which attribute or combination of attributes failed to validate. Also, the entire object is returned as the invalid value instead of an individual attribute. In cases where specific failure information is required, use of an attribute-level constraint or a custom constraint violation might be provided as described in the Bean Validation specification.

Sample

The JPA model and image gallery application usage scenario provided in this topic can be implemented through a sample that is provided in the white paper, *OpenJPA Bean Validation primer*.

wsjpa properties

The extension properties of Java Persistence API (JPA) for WebSphere Application Server can be specified with the openjpa or wsjpa prefix. This topic features the wsjpa properties.

wsjpa.AccessIntent

Use this property to define a TaskName that in the `persistence.xml` file using the wsjpa.AccessIntent property name in a persistence unit. The property value is a list of TaskNames, entity types and access intent definitions.

For more information and examples on how the wsjpa.AccessIntent property is used, see the topic Specifying TaskName in a JPA persistence unit.

wsjpa.jdbc.Schema

Specifies the schema name in a DB2 package collection when using multiple DB2 package collections.

For more information about using the wsjpa.jdbc.Schema property see the topic, Configuring pureQuery to use multiple DB2 package collections.

wsjpa.jdbc.CollectionId

Specifies the collection Id name in a DB2 package collection when using multiple DB2 package collections.

For more information about using the wsjpa.jdbc.CollectionId property see the topics, Configuring pureQuery to use multiple DB2 package collections and Configuring data source JDBC providers to use pureQuery in a Java SE environment.

Criteria API

The Criteria API is an API for building queries with Java objects, as an alternative to building strings for Java Persistence Query Language (JPQL) queries.

The Criteria API supports building queries dynamically at run time, and also the ability to build type-safe queries that can be verified by the compiler. The correctness of JPQL queries cannot be verified by the compiler, and must be verified at run time during testing.

The following is a sample JPQL query that returns a list of employees with less than five years of service:

```
SELECT e FROM Employee e WHERE e.serviceyears < 5
```

Here is a sample of the equivalent Criteria query:

```
QueryBuilder qb = emf.getQueryBuilder();
CriteriaQuery q = qb.create(Employee.class);
Root e = q.from(Employee.class);
q.where(qb.lt(e.get(Employee_.serviceyears), 5));
TypedQuery tq = em.createQuery(q);
List result = q.getResultList();
```

Note: Employee_ is the Metamodel of the Employee class.

Two important features are improvements from JPQL:

- The Criteria API can express queries that are not possible through JPQL. For more detailed information see the section, “Editable data store expressions”, in the developerWorks article, Dynamic, typesafe queries in JPA 2.0.
- A CriteriaQuery can be edited programmatically. For more information see the section, “Editable query”, in the developerWorks article, Dynamic, typesafe queries in JPA 2.0.

You can read more about the Criteria API in the Apache OpenJPA User Guide.

wsappid command

The Java Persistence API (JPA) specification supports an entity primary key to be made up of more than one column. In this case, the primary key is called a composite or compound primary key. Provide an ID class, which is specified by the @IdClass annotation, to manage a composite primary key. Use the identity tool for JPA to generate an ID class for entities that use composite primary keys.

Syntax

Before running the command, you must have a copy of the `persistence.xml` file on the classpath, or specify it as a properties file in the -p [*path_to_persistence.xml*] argument. Issue the command from the `bin` subdirectory of the *profile_root* directory.

The command syntax is as follows:

```
wsappid.sh [parameters][arguments]
```

Parameters

The wsappid tool accepts the standard set of command-line arguments that are defined by the configuration framework along with the following:

- **`-directory/-d`** *<output_directory>*: The path to the output directory.

  If the directory does not match the generated output ID class package, the package structure is created beneath the directory. If this parameter is not specified, the wsappid tool attempts to find the directory of the `.java` file for the class that supports persistence. If a `.java` file is not found, the wsappid tool uses the current directory.
- **`-ignoreErrors/-i`** `<true/t | false/f>`: If this parameter is set to `false`, an exception is occurs when the tool is run on any class that does not use the application identity. An error also occurs if any class does not have the base class in the inheritance hierarchy.
- **`-token/-t`** *<token>*: The token that is used to separate the values of strung primary keys in the string form of the object ID.

  Use this option only if there are multiple primary key fields. The default is "`::`".
- **`-name/-n`** *<id_class_name>*: The name of the identity class to generate.

  If this option is specified, the wsappid tool must run on exactly one class. If the class metadata already names an ID class for the object, this option is ignored. If the name is not fully qualified, the package of the persistence class is appended to form the fully qualified name.
- **`suffix`** *<id_class_suffix>*: A string with which to suffix each persistent class name to form the identity class name.

This option is overridden by the **-name/-n** parameter or by any object ID class that is specified in the metadata.

Each additional argument to the wsappid tool must be one of the following:
- The full name of a persistent class.
- The `.java` name for a persistent class.
- The `.class` file of a persistent class.

Usage

The identity tool used with JPA for application server simplifies the task of creating an identity class for entities that use composite IDs. A composite ID is an identity with more than one field as its primary key. The entity class must be compiled, and primary keys must be identified in the entity class. Run the wsappid tool from the command line in the *profile_root*/bin/ directory. When you run this command, a new class representing the composite ID of the entity is generated. Messages and errors are logged to the console as specified.

Examples

Consider the following entity:

```
@Entity
public class Employee {

@Id
private int division;

@Id private int id;
// . . .
}
```

Before the entity is used, an ID class is needed. For this example, assume that the entity is found in the `src/main/java` directory.

To generate an ID class for the Magazine entity run the following:

```
wsappid.sh -s Id src/main/java/Employee.java -d src/main/java
```

A new class, EmployeeId.java, is generated in the `src/main/java` directory.

Additional information

Read the Application identity tool in persistence classes information in the Apache OpenJPA User Guide for more information.

wsenhancer command

The entity enhancer tool for Java Persistence API (JPA) applications inserts bytecode into an entity class file that supports the JPA provider to manage the state of an entity.

JPA with the application server requires that all entity classes be enhanced if you want to manage their state. In a container-managed environment, automated enhancement is provided by the containers. In a Java SE environment, though, there are no containers to manage persistence and you might use this command frequently before packaging application files for testing. After you have created the JPA entities, you can run the wsenhancer tool to inject bytecode into the entities before packaging the Java archive (JAR) file into the enterprise archive (EAR) file for the application.

Syntax

Before running the command, you must have a copy of the `persistence.xml` file on the classpath, or specify it as a properties file in the -p [*path_to_persistence.xml*] argument. Issue the command from the `bin` subdirectory of the *profile_root* directory.

The command syntax is as follows:

```
wsenhancer.sh [parameters][arguments]
```

Parameters

The enhancer accepts the standard set of command-line arguments defined by the configuration framework along with the following:

- **-directory/-d** *<output directory>*: Specifies the path to the output directory.

  If the directory does not match the enhanced class package, the package structure is created beneath the directory. By default, the enhancer overwrites the original `.class` file.
- **-enforcePropertyRestrictions/-epr** `<true/t | false/f>`: Specifies whether to generate an exception when a property access entity is not obeying the restrictions that are placed on property access.

  The default is set to `false`.
- **-addDefaultConstructor/-adc** `<true/t | false/f>`: Specifies that all of the persistent classes define a no-argument constructor. This flag informs the enhancer to add a protected no-arg constructor to any persistent classes in which the constructor is not already present.
- **-tmpClassLoader/-tcl** `<true/t | false/f>`: Specifies whether the enhancer should load persistent classes with a temporary class loader.

  This function supports other code to load the enhanced version of the class afterward within the same Java virtual machine (JVM). The default is set to true.

  Note: If you are encountering class loading problems when running the enhancer, you can set this flag to `false` as a debugging step.
- For class name, specify one of the following:
  - The full name of a class.
  - The `.java` name for a class.
  - The `.class` file of a class.

If you do not provide arguments to the enhancer, it runs on the classes in your persistent class list.

Usage

To use the wsenhancer tool you need entities defined to the JPA specifications, and the entities must be compiled. Run the wsenhancer tool against the entities before packaging them into a JAR file. If the entities are already packaged, you extract the entity class files, run the enhancer, and recreate the JAR file.

To enhance your entities:

- Verify that your entities are in the class path, if they are not, add them.
- Run the wsenhancer command. It is found in ${profile_root}/bin directory.

Messages and errors are logged to the administrative console as specified in the log settings. After starting the wsenhancer command, your files are enhanced.

Examples

To enhance all entities on the class path:

```
$ cd build
/home/user/myproject/build $ ${profile_root}/bin/wsenhancer.sh
```

All entities in myproject are enhanced.

To enhance a specific entity when you have the source files:

```
$ cd build
/home/user/myproject/build $ ${profile_root}/bin/wsenhancer.sh Magazine.java
```

To enhance a specific entity when you have the compiled class files:

```
$ export CLASSPATH=target/classes
$ ${profile_root}/bin/wsenhancer.sh /bin/wsenhancer.sh target/classes/jpa/example/MyEntity.class
```

The entity, Magazine.java, located in project are enhanced.

Additional information

For more information about enhancement tools, see the section on persistent classes in the Apache OpenJPA documentation.

wsmapping command

The wsmapping tool is used to provide top-down mapping of the entity object model to the database relational model. You can use the wsmapping tool to create database tables.

Syntax

Before running the command, you must have a copy of `persistence.xml` on the class path, or specify it as a properties file in the -p [*path_to_persistence.xml*] argument. Issue the command from the `bin` subdirectory of the *profile_root* directory.

The command syntax is as follows:

```
wsmapping.sh [options][arguments]
```

Parameters

The mapping tool accepts the standard set of command-line arguments defined by the configuration framework with the following options:

- **-schemaAction/-sa** <`add` | `refresh` | `drop` | `build` | `reflect` | `retain` | `createDB` | `import` | `export` | `none`>: The action to implement against the schema.

  These options correspond to the actions of the schema tool. `Add` is the default action if none is specified. Actions can be composed in a list separated by commas.

  Note: The wsmapping tool accepts the -action/-a flag to specify the action to take on individual classes. Unless you are running wsmapping on all of your persistent types at once, or dropping a mapping, you must use the default `add` action or the `build` action. Otherwise, you might inadvertently drop schema components that are used by classes that you are not currently running the tool against.
- **-schemaFile/-sf** <`true/t` | `false/f`>: This option can be used to write the planned schema to an XML document rather than modify the database.

  The XML document can then be modified, manipulated and committed to the database with the schema tool.
- **-sqlFile/-sql** <`stdout` | `output file`>: This option can be used to write the planned schema modifications to an SQL script rather than modify the database.

  Combine this parameter with a **schemaAction** of `build` to generate a script that recreates the schema for the current mappings, even if the schema exists.
- **-dropTables/-dt** <`true/t` | `false/f`>: When this option is set to true, schema drops tables that appear to be unused during `retain` and `refresh` actions.

The default is `true`.

- **`-dropSequences/-dsq`** <`true/t` | `false/f`>: If this option is set to `true`, schema drops sequences that are unused during `retain` and `refresh` actions.

  The default is `true`.
- **`-openjpatables/-ot`** <`true/t` | `false/f`>: When reflecting the schema, this parameter determines whether to reflect on tables and sequences with names that start with OPENJPA_.

  Certain OpenJPA components use these tables and sequences, such as the table schema factory. When using other actions, the openjpaTables parameter controls whether these tables can be dropped or not. The default setting is `false`.
- **`-ignoreErrors/-i`** <`true/t` | `false/f`>: If set to `false`, an exception is occurs if the tool encounters database errors.

  The default is set to `false`.
- **`-schemas/-s`** *<schema list>*: Denotes a list of schema and table names the OpenJPA should access when running the wsschema tool.

  This is the equivalent to setting the openjpa.jdbc.Schemas property to run once. This parameter corresponds to the **`-schemas/-s`** parameter in the wsschema tool. This option is ignored if **`-readSchema/-rs`** is not set to `true`.
- **`-readSchema/-rs`** <`true/t` | `false/f`>: Set this option to `true` to read the entire existing schema when the mapping tool runs.

  Reading the existing schema ensures that OpenJPA does not generate any mappings that use the table, index, primary key or foreign key names that conflict with existing names.

  Note: Depending on the particular JDBC driver, selecting the **`-readSchema/-rs`** function can slow down the process for large schemas.
- **`-primaryKeys/-pk`** <`true/t` | `false/f`>: This flag determines if the primary keys can be manipulated on existing tables.

  The default is `true`.
- **`-foreignKeys/fk`** <`true/t` | `false/f`>: This flag determines if foreign keys can be manipulated on existing tables.

  The default is `true`. This means that to add a new foreign key to a class that has already been mapped, you must explicitly set this parameter flag to `true`.
- **`-indexes/-ix`** <`true/t` | `false/f`>: This flag determines if indexes can be manipulated on existing tables.

  The default is `true`. This means that to add new indexes to a class that has already been mapped, you must explicitly set this parameter flag to `true`.
- **`-sequences/-sq`** <`true/t` | `false/f`>: This flag determines if sequences can be manipulated.

  The default is `true`.
- **`-meta/-m`** <`true/t` | `false/f`>: This flag determines whether a mapping applies to metadata rather than, or in addition to, standard mappings.
- The wsmapping tool accepts the **`-action/-a`** flag to specify the action to take on each class. Multiple actions can be composed in a list, separated by commas. The available actions are:
  - **`buildSchema`**: This is the default action. The **`buildSchema`** action makes the database schema match your existing mappings. If the provided mappings conflict with the class definitions, OpenJPA fails with an informative exception.
  - **`validate`**: Ensure that the mappings for the given classes are valid and that they match the schema of the database. No mappings of tables are changed as a result of this action. An exception occurs if any mappings are invalid.

Each additional argument to the wsmapping tool must be one of the following:

- The full name of a persistent class.
- The `.java` name for a persistent class.
- The `.class` file of a persistent class.

If you do not supply any arguments to the wsmapping tool, it runs on the classes in the persistent classes list.

Usage

Before running the wsmapping tool, you must configure the data source information, including the URL, user, and password. It is required that the wsenhancer tool is run before the wsmapping tool to insert bytecode into the entity classes. Also, the compiled class files for your entities should be on the class path. Assume that entity class files can be found in target/classes, for example:

```
export CLASSPATH=${CLASSPATH}:target/classes

wsmapping.sh ...
```

To create tables, run the wsmapping command from the ${profile_root}/bin directory. When completed, the database tables are created or updated. Messages and errors are logged to the administrative console as specified by log settings.

wsmapping.sh . . . On Windows :

Tip: By specifying the buildSchema parameter to the openjpa.jdbc.SynchronizeMappings property, the mapping tool provides the default mapping that matches with the database schema automatically. You are not required to run this mapping tool if the default mapping satisfies the necessary database schema.

Examples

To create the database tables needed for the `Magazine.java` file:

```
${profile_root}/bin/wsmapping.sh Magazine.java
```

To drop the tables for `Magazine.java`:

```
C:\> %profile_root%/bin/wsmapping.sh -sa dropDB Magazine.java
```

To validate the mappings for all classes on the class path:

```
C:\> %profile_root%/bin/wsmapping.sh -a validate
```

Additional information

See the mapping information in the Apache OpenJPA User Guide for more information and examples.

wsreversemapping command

The wsreversemapping tool generates persistent class definitions and metadata from a database schema.

Syntax

Before running the command, you must have a copy of the `persistence.xml` file on the class path, or specify it as a properties file in the -p [*path_to_persistence.xml*] argument. Issue the command from the `bin` subdirectory of the *profile_root* directory.

The command syntax is as follows:

```
wsreversemapping.sh [parameters][arguments]
```

Parameters

The wsreversemapping tool accepts the standard set of command-line arguments defined by the configuration framework along with the following:

- **-schemas/-s** *<schema and table names>*: A list of schema and table names, separated by commas, to run the wsreversmapping tool on if no XML schema file is supplied.

  Each element of the list must follow the naming conventions for the openjpa.jdbc.Schemas property. If this parameter flag is omitted, it defaults to the value of the **Schemas** property. If the **Schemas** property is not defined, then all schemas are reverse mapped.
- **-package/-p** *<package name>*: The package name of the generated classes.

  If no package name is given, the generated code does not contain package declarations.
- **-directory/-d** *<output directory>*: All generated code and metadata is written to the directory at this path.

  If the path does not match the package of a class, the package structure is created beneath this directory. This parameter defaults to the current directory.
- **-useSchemaName/-sn** <true/t | false/f>: Set this parameter flag to true to include the schema and the table name in the name of each generated class.

  This method can be useful when dealing with multiple schemas that have tables with identical names.
- **-useForeignKeyName/-fkn** <true/t | false/f>: Set this parameter flag to true if you want the field names for relations to be based on the database foreign key name.

  By default, relation field names are derived from the name of the related class.
- **-nullableAsObject/-no** <true/t | false/f>: By default, all non-foreign key columns are mapped to primitives.

  Set this parameter flag to true to generate primitive wrapper fields instead for columns that support null values.
- **-blobAsObject/-bo** <true/t | false/f>: By default, all binary columns are mapped to the byte[] fields.

  Set this parameter flag to true to map them to Object fields instead.

  Attention: When mapped this way, the column is presumed to contain a serialized Java object.
- **-primaryKeyOnJoin/pkj** <true/t | false/f>: The standard reverse mapping tool behavior is to map all tables with primary keys to persistent classes.

  If your schema has primary keys on many join tables as well, set this flag to true to avoid creating classes for those tables.
- **-inverseRelations/-ir** <true/t | false/f>: Set this parameter flag to false to prevent the creation of inverse one-to-many or one-to-one relations for every many-to-one or one-to-one relation detected.
- **-useDatastoreIdentity/-ds** <true/t | false/f>: Set to true to use data store identity for tables that have single numeric primary key columns.

  Typically, the tool uses application identity for all generated classes.
- **-useBuiltinIdentityClass/-bic** <true/t | false/f>: Set this parameter flag to false to prevent the wsreversemapping tool from using built-in application identity classes when possible.

  This forces the tool to create custom application identity classes even when there is only one primary key column.
- **-innerIdentityClasses/-inn** <true/t | false/f>: Set this parameter flag to true to have any generated application identity classed be created as static inner classes within the persistent classes.

  The default setting is false.
- **-identityClassSuffix/-is** *<suffix>*: Suffix to append to the class names to form application identity class names, or for inner identity classes, the inner class name.

  The default suffix is Id.
- **-typeMap/-typ** <type mapping>: A string that specifies the default Java classes to generate for each SQL type that is seen in the schema.

  The format is SQLTYPE1=JavaClass1, SQLTYPE2=JavaClass2. The SQL type name first looks for a customization that is based on SQLTYPE(SIZE,PRECISION), then SQLTYPE(SIZE), and then SQLTYPE. If a column with type CHAR is found, it first looks for the CHAR(50,0) type name specification, then it looks for the CHAR(50), and finally for the CHAR. For example, to generate a char array for every char column whose size is exactly 50 characters, and to generate a short for every type name of INTEGER, you might specify, CHAR(50)=char[],INTEGER=short.

Attention: Various databases report different type names differently, one database type might not work for another database. Enable TRACE level logging on the metadata channel to track which type names JPA for WebSphere Application Server is examining.

- **-customizerClass/-cc** *<class name>*: The full class name of an org.apache.openjpa.jdbc.meta.ReverseCustomizer customization plug-in.

  If you do not specify a reverse customizer of your own, the system defaults to a PropertiesReverseCustomizer. This customizer supports specifying simple customization options in the properties file given with the -customizerProperties flag.
  - **-customizerProperties/-cp***<properties file or resource>*: The path or resource name of a properties file to pass to the reverse customizer on initialization.
  - **-customizer/-c** *<property name> <property value>*: The given property name is matched with the corresponding Java bean property in the specified reverse customizer, and set to the given value.

Usage

The wsreversemapping tool is used to perform reverse (bottom-up) mappings of database tables to entity source files. This is useful if developers want to generate Java files from a database for use in other JPA applications. To run this tool:

- You must have database tables and your database connection configured.
- Run the wsreversemapping tool from the command line in the $ {profile_root}/bin directory.
- The tool generates `.java` files for every class, along with an XML descriptor file, `orm.xml`.

The generated Java files from the wsreversemapping tool might require some editing before they can be used in an application. Also, generated files do not contain annotations. Annotations can be added manually. Messages and errors are logged to the administrative console as specified by the configuration.

Examples

Generate entities based on the information saved in the schema.xml file. Schema.xml was created by running the schema tool. The Java files are created in the **src** directory and use the package com.xyz:

```
${profile_root}/bin/wsreversemapping.sh -pkg com.xyz -d ./src schema.xml
```

Generate entities based on information in a DB2 database. Entities are created in the **src** directory, and use the package com.reversemapped:

```
C:\> %profile_root%/bin/wsreversemapping.bat -sa dropDB Magazine.javapkg com.reversemapped -d src
-connectionDriverName=com.ibm.db2.jcc.DB2Driver -connectionURL=jdbc:db2:localhost:50000/TEST
-connectionUser=db2User -connectionPassword=db2Password
```

Additional information

For more information, read the mapping section in the Apache OpenJPA User Guide.

wsschema command

The schema tool can be used to view the database schema in XML form or match an XML schema to an existing database.

The wsschema tool can reflect on the current database schema, optionally translating it into an XML representation for further manipulation. The schema tool can take an XML schema definition, calculate the differences between the XML and the existing database schema, and apply the necessary changes to make the databases correspond to the XML schema. The XML format used by the schema tool is abstract from the differences in SQL dialects used by different vendors. The tool also automatically adapts its SQL to meet foreign dependencies, thus the schema tool is useful as a general way to manipulate the schemas.

Syntax

The command syntax is as follows:

```
wsschema.sh [parameters][arguments]
```

Issue the command from the `bin` subdirectory of the *profile_root* directory.

Parameters

The wsschema tool accepts the standard set of command-line arguments defined by the configuration framework along with the following:

- **-ignoreErrors/-i** <true/t | false/f>: If set to `false`, an exception occurs if the tool encounters any database errors.

  The default is set to `false`.
- **-file/-f** *<stdout / output file>*: Use this option to write a SQL script for the planned schema modifications, rather than committing them to the database.

  When used with the export or reflect actions, the named file is used to write the exported schema XML. If the file names a resource in the class path, data is written to that resource. Use stdout to write to standard output. The default setting is `stdout`.
- **-openjpatables/-ot** <true/t | false/f>: When reflecting the schema, this parameter determines whether to reflect on tables and sequences whose names start with OPENJPA_.

  Certain OpenJPA components can use such tables and sequences, like the table schema factory. When using other actions, openjpaTables controls if these tables can be dropped. The default setting is `false`.
- **-dropTables/-dt** <true/t | false/f>: When this option is set to `true`, schema drops tables that are unused during retain and refresh actions.

  The default is `true`.
- **-dropSequences/-dsq** <true/t | false/f>: If this option is set to `true`, schema drops sequences that are unused during retain and refresh actions.

  The default is `true`.
- **-sequences/-sq** <true/t | false/f>: This flag determines if sequences can be manipulated.

  The default is `true`.
- **-indexes/-ix** <true/t | false/f>: This flag determines if indexes can be manipulated on existing tables.

  The default is `true`.
- **-primaryKeys/-pk** <true/t | false/f>: This flag determines if primary keys can be manipulated on existing tables.

  The default is `true`.
- **-foreignKeys/fk** <true/t | false/f>: This flag determines if foreign keys can be manipulated on existing tables.

  The default is `true`.
- **-record/-r** <true/t | false/f>: This flag permits or prevents writing schema changes made by the schema tool to the current schema factory.

  Select `true` to permit writing schema changes or false to prevent writing schema changes. The default is set to `true`.
- **-schemas/-s** *<schema list>*: Denotes a list of schema and table names the OpenJPA should access when running the schema tool.

  This is the equivalent to setting the openjpa.jdbc.Schemas property to run one time.

  Important: The schema tool accepts the **-action/-a** flag. Multiple actions can be composed in a list, separated by commas. The available actions are:
  - **add**: This is the default action if no other actions are specified. It updated the schema with the given XML documents by adding tables, columns, indexes, or other components. This action never drops any schema components.

- **retain**: This action keeps all schema components in the given XML definition but drops the rest from the database. This action never adds any schema components.
- **drop**: Drops all schema components in the schema XML. This action drops tables only if they would have 0 columns after dropping all columns listed in the XML.
- **refresh**: This action is the equivalent of the **retain** and the **add** functions.
- **build**: Generates SQL to build a schema matching the one in the supplied XML file. Unlike the**add** action, this option does not take into account the fact that part of the schema defined in the XML file may already exist in the database. This action is typically used with the **-file/-f** parameter flag to write a SQL script. This script can be used later to recreate the schema in the XML.
- **reflect**: Generates an XML representation of the current database schema.
- **createDB**: This action generates SQL to recreate the current database. This action is typically used with the **-file/-f** parameter flag to write a SQL script that can be used to recreate the current schema on a new database.
- **dropDB**: Generates SQL to drop the current database. Like the **createDB** action, this can be used with the **-file/-f** parameter flag to script a database drop rather than manually perform it.
- **import**: Imports the given XML schema definition into the current schema factory.

  Note: This action does nothing if the schema factory does not store a record of the schema.
- **export**: Exports the current schema factory stored schema definition to an XML file.

  Note: This can produce an empty file if the schema factory does not store a record of the schema.
- **deleteTableContents**: This action implements SQL to delete all rows from all tables that OpenJPA finds.

Usage

The wsschema tool is used to obtain an XML file that describes the schema of your database. To generate an XML schema file:

- You must have database tables and your database connection configured.
- Run the wsschema tool from the command line in the $ {profile_root}/bin directory.
- The tool generates an XML file that describes the database schema.

Messages and errors are logged to the administrative console as specified by the configuration.

Examples

Add the necessary schema components to the database to match the given XML document without dropping any data:

```
$ wsschema.sh targetSchema.xml
```

Repeat the same action as the previous example, this time not changing the database but instead writing any planned changes to a SQL script:

```
 wsschema.sh -f script.sql targetSchema.xml
```

Write an SQL script that recreates the current database:

```
$ wsschema.sh -a createDB -f script.sql
```

Refresh the schema and delete all the contents of all the tables that OpenJPA knows about:

```
$ wsschema.bat -a refresh,deleteTableContents
```

Drop the current database:

```
$ wsschema.sh -a dropDB
```

Write an XML representation of the current schema to the file *schema.xml*:

```
$ wsschema.sh -a reflect -f schema.xml
```

Additional information

For more information read the JDBC information in the Apache OpenJPA documentation.

wsdbgen command

The command supports utilization of the pureQuery feature in Java Persistence API (JPA) applications.

This command has been renamed wsdbgen for Feature Pack for OSGi Applications and JPA 2.0 and later releases. The command is used in the same way as the wsdb2gen command. The command, wsdb2gen, which implies for DB2 only, works only for DB2 database in WebSphere Application Server V7.0. In this release, the command can be used for DB2, Informix and Oracle databases. Because of that, a synonym, wsdbgen command, is introduced.

The JPA commands (.bat on Windows or .sh on UNIX) are run from the *profile_root*/`bin` directory, rather than from the *app_server_root*/`bin` directory to make sure that you have the latest version of the commands for your release.

Syntax

The command syntax is as follows:

```
wsdbgen.sh [parameters]
```

Before running the command, your `persistence.xml` file must be in the META-INF directory and the META-INF directory must be in the class path.

Parameters

- **`-help`**: This parameter displays the help information.
- **`-pu`**: The name of the persistence unit defined in `persistence.xml` file.
- **`-collection`**: The collection-id which is assigned to package names. The default is `NULLID`.
- **`-url`**: The URL of the target database.

  This is used to validate the generated SQL. A URL must be specified either in the `persistence.xml` file or as a command option. If both are specified, the URL that is specified in the command option is used.
- **`-user`**: The user ID.
- **`-pw`**: The corresponding password to connect to target database.

  If this parameter is not specified, the value found in the `persistence.xml` file is used.
- **`-package`**: If this parameter is specified, the **`-package`** parameter takes the string value package name and a single database package with the specified name is generated. If the **`-package`** parameter is not specified, then one package is generated for each entity class. The entity name is used as package name if the **`-package`** option is not specified. The name length limit is the database limit -1, for example: 128 - 1 = 127.

Usage

The `persistence.xml` file must be included in the application Java archive (JAR) file and is also used as input in the DB2 bind to create the DB2 package. The command requires a connection to a database to validate generated SQL. The database does not have to be the same as the run time database, but it should be at the same version and release level.

Ensure that the following JAR files are on the class path:

- `pdq.jar`
- `pdqmgmt.jar`
- `db2jcc.jar`
- `db2jcc_licence_cu.jar`

If the database URL specifies a DB2 for z/OS database, then the following JAR file must also be on the class path: `db2jcc_licence_cisuz.jar`

Attention: Read more about the DB2 JAR level compliance for IBM Optim PureQuery Runtime at the IBM Support website: System requirements for IBM Optim PureQuery Runtime for Linux, UNIX, and Windows.

Attention: You can review information about pureQuery StaticBinder in the Data Studio Information Center by reading the topic, “The pureQuery StaticBinder utility.”

Examples

DB2

```
wsdbgen.sh  -pu payroll -collection prod1 -url jdbc:db2://myhostname:50000/proddb  -user produser -pw secret
```

Informix

```
wsdbgen.sh  -pu payroll -collection prod1 -url jdbc:ids://myhostname:9089/proddb  -user produser -pw secret
```

ANT task WsJpaDBGenTask

The ANT task **WsJpaDBGenTask** provides an alternative to the **wsdbgen** command.

The **WsJpaDBGenTask** ANT task utility supports utilizing the pureQuery feature in Java Persistence API (JPA) 2.0 and later applications that do not use DB2 databases. Instead of using the **wsdbgen** from the command line, you can use the example code in your ANT build XML file to use the **WsJpaDBGenTask** in your build process.

Both the PDQ runtime Java archive (JAR) files, `pdq.jar` and `pdqmgmt.jar`, must be specified using the ANT -lib option.

Attention: Read more about the DB2 JAR level compliance for pureQuery at the IBM Support website: System requirements for IBM Optim pureQuery Run time for Linux, UNIX, and Windows.

Example

The following example is run in the Windows environment with the ANT command:

```
C:\jpa\ant jar -noclasspath -lib  c:/was8/dev/JavaEE/j2ee.jar
-lib ${app_server_root}/runtimes/com.ibm.ws.jpa.thinclient_8.0.0.jar
-lib c:/sqllib/java/db2jcc.jar
-lib c:/sqllib/java/db2jcc_license_cu.jar
-lib c:/sqllib/java/pdq.jar
-lib c:/sqllib/java/pdqmgmt.jar
```

When calling the ANT command, the JAR files for pureQuery, JPA, and the JDBC driver must be on the library list.

```
<?xml version="1.0"?>

<fileset dir="classes" includes="**/*.class"/>
<fileset dir="." includes="META-INF/*.xml" />
</jar>
</target>
</project>
```

SQL statement batching for JPA applications

SQL statement batching can improve the performance of your application server.

About this task

Attention: Support for SQL statement batching is no longer a WebSphere Application Server for JPA extension. You can find information regarding statement batching in the Apache OpenJPA documentation.

By default, statement batching is enabled for DB2 and Oracle databases. To enable SQL statement batching and to set the batch limit for JPA applications, you must configure the `persistence.xml` file. The following steps review how to enable and disable statement batching, and set the batch limit:

Procedure

1. Define the UpdateManager property in the `persistence.xml` file. For example:

```
<property name="openjpa.jdbc.UpdateManager"
value="com.ibm.ws.persistence.jdbc.kernel.OperationOrderUpdateManager(batchLimit=100)"/>
```

Note: The example shows that the SQL statement batch limit is set to `100`.

Remember: If you are using a DB2 or an Oracle database, by default the SQL statement batching is enabled and set to `batchLimit=100`. However, if you are using DB2 or Oracle, you are not required to specify this property in the `persistence.xml` file.

2. If you must disable SQL statement batching, set the batchLimit value to `0` or remove the property. However, if you are using a DB2 or an Oracle database, you must specify the DBDictionary property, database, and set the defaultBatchLimit to `0` . For example:

```
<property name="openjpa.jdbc.DBDictionary" value="db2(defaultBatchLimit=0)"/>
```

Results

You have now updated the `persistence.xml` file to enable or disable statement batching and set the batch limit.

Database generated version ID with JPA

Java Persistence API (JPA) for WebSphere Application Server has extended OpenJPA to work with database generated version IDs. These generated version fields, timestamp, or token, can be used to efficiently detect changes to a given row.

Trigger based version ID generation is supported for all databases that WebSphere Application Server supports. Support is based on two Version Strategies in JPA for WebSphere Application Server.

- @VersionStrategy("com.ibm.websphere.persistence.RowChangeTimestampStrategy"), if the entity version field type is Timestamp, and
- @VersionStrategy("com.ibm.websphere.persistence.RowChangeVersionStrategy"), if the entity version field type is Long

The Entity class is defined with the new Version Strategy annotation. The Entity has a surrogate version column. For example,

```
@Entity(name="Item")
@VersionColumn(name="versionField")
@VersionStrategy("com.ibm.websphere.persistence.RowChangeTimestampStrategy")
public class Item implements Serializable
{
 @Id
 private int id2;

 private String name;

 private double price;

   @OneToOne
   private Owner master;
}
```

The create table statement is as follows:

```
CREATE TABLE ITEM
(ID2  INT  NOT NULL,
 NAME  VARCHAR(50) ,
 PRICE   DOUBLE,
 OWNER_ID INT,
             VERSIONFIELD GENERATED ALWAYS FOR EACH ROW ON
              UPDATE AS ROW CHANGE TIMESTAMP
         PRIMARYKEY(ID2));
```

During any updates to Item, insert or update, the VersionColumn value is updated in the database. After the update, the value for VersionColumn is retrieved from the database and updated in the in-memory object. Thereby the objects in the data cache reflect the correct version value. Here the Entity is using the @VersionColumn, which produces a Surrogate Version ID rather than defining an explicit field in the entity.

The Entity could also use @Version annotation to define an explicit version field. The explicit version field could be of type Long or Timestamp corresponding to the @VersionStrategy. During any updates to Item, insert or update, the Version value is updated in the database. After the update, the value for Version is retrieved from the database and updated in the in memory object. Thereby the objects in the data cache reflect the correct version value.

This is an example where the Entity has a version field defined, and the type Timestamp matches the RowChangeTimestampStrategy in the @VersionStrategy. If the version field type is using type long, then the RowChangeVersionStrategy should be annotated to match:

```
@Entity(name="Item")
@VersionStrategy("com.ibm.websphere.persistence.RowChangeTimestampStrategy")
public class Item implements Serializable

{
 @Id
 private int id2;

 private String name;

 private double price;

   @Version
   private Timestamp versionField;

   @OneToOne
   private Owner master;
}
```

Note: Be aware of the following conditions when you use RowChangeVersionStrategy:

- For z/OS DB2 V9 and Linux, UNIX, and Windows DB2 V9.5, the generated database column must be of type timestamp, but both the RowChangeTimestampStrategy and the RowChangeVersionStrategy are supported. Microsoft SQL Server only supports a non-timestamp generated version ID that goes with the RowChangeVersionStrategy. To use the RowChangeTimestampStrategy, you must use a trigger on a timestamp field in the database. For other databases, you can use triggers to simulate database version generation and use either strategy.
- For z/OS DB2 V9, install the PTF for APAR PK67706, and ensure that you have installed the required level of IBM Optim PureQuery Runtime (1.3.100 or later) and JCC drivers (3.52.95 or later).

Mapping persistent properties to XML columns for JPA

If your database supports Extensible Markup Language (XML) column types, you can use mapping tools to manage XML objects. You have the choice of mapping XML columns to a Java string or a Java byte array field.

About this task

Attention: Support for mapping persistent properties to XML columns is no longer a WebSphere Application Server for JPA extension. You can find information regarding XML mapping in the Apache OpenJPA documentation.

JPA for the application server supports the management of XML objects by using a third-party solution for mapping management. These mapping techniques make using the XML objects as strings or byte arrays difficult.

DB2, Oracle, and SQLServer databases support XML column types, XPath queries, and indices over these columns.

Persistent properties to XML mapping

An embedded class with XML column support must use XML marshaling to write the data to the XML column and unmarshalling to retrieve the data from the XML column. The path expressions and predicates over the embedded class are converted to XML predicates, XPATH expressions, or XQuery expressions and are written to the database.

WebSphere Application Server supports JPA applications to use a third-party tool for XML mapping. This is done through the extension points for custom field mappings. The third-party mapping tool uses the extension points by providing a custom value handler for the persistent fields that are mapped to the XML columns. In OpenJPA, this value handler is named org.apache.openjpa.xmlmapping.XmlValueHandler and this handler requires the @Strategy annotation on the Java field that is mapped to the XML column.

Procedure

1. Annotate the entity property using the XML value handler strategy. The mapping of persistent properties to XML columns requires the @Strategy and the @Persistent annotation.

   ```
   @Persistent
   @Strategy("org.apache.openjpa.xmlmapping.XmlValueHandler")
   ```

   The XML value handler for the persistent property is set to org.apache.openjpa.xmlmapping.XmlValueHandler.
2. Change the default for fetch type if it is necessary. For example:

   ```
   @Persistence(fetch=FetchType.LAZY)
   ```

   The fetch type is now LAZY. If a value for the fetch type is not entered, the default is set to EAGER.
3. Annotate your embedded classes with the binding annotations for Java API for XML Binding (JAXB). These bindings can be created from an XML schema by using the Java Architecture for XML Binding Compiler (XJC).
4. Make sure that the class that maps to the root of the XML document is annotated with @XmlRootElement, in addition to the other annotations.
5. Compile your Java sources.
6. Run the enhancer tool on the entities. Refer to the topic on the entity enhancer tool for more information.

Example

For example, shipAddress, a property of Order Entity, is mapped to XML column shipaddr:

```
@Entity
public class Order {
 @Id
 @GeneratedValue(strategy=GenerationType.IDENTITY)
  int oid;
 @Persistent
 @Strategy("org.apache.openjpa.xmlmapping.XmlValueHandler")
      @Column(name="shipaddr")
      Address shipAddress;
...
```

The OpenJPA mapping tool generates a SHIPADDR column with XML type in the table definition for ORDER table.

Directory conventions

References in product information to *app_server_root*, *profile_root*, and other directories imply specific default directory locations. This article describes the conventions in use for WebSphere Application Server.

Default product locations - z/OS

app_server_root
: Refers to the top directory for a WebSphere Application Server node.

  The node may be of any type—application server, deployment manager, or unmanaged for example. Each node has its own *app_server_root*. Corresponding product variables are *was.install.root* and *WAS_HOME*.

  The default varies based on node type. Common defaults are *configuration_root*/AppServer and *configuration_root*/DeploymentManager.

configuration_root
: Refers to the mount point for the configuration file system (formerly, the configuration HFS) in WebSphere Application Server for z/OS.

  The *configuration_root* contains the various *app_server_root* directories and certain symbolic links associated with them. Each different node type under the *configuration_root* requires its own cataloged procedures under z/OS.

  The default is /wasv8config/*cell_name*/*node_name*.

plug-ins_root
: Refers to the installation root directory for Web Server Plug-ins.

profile_root
: Refers to the home directory for a particular instantiated WebSphere Application Server profile.

  Corresponding product variables are *server.root* and *user.install.root.*

  In general, this is the same as *app_server_root*/profiles/*profile_name*. On z/OS, this will always be *app_server_root*/profiles/default because only the profile name "default" is used in WebSphere Application Server for z/OS.

smpe_root
: Refers to the root directory for product code installed with SMP/E or IBM Installation Manager.

  The corresponding product variable is *smpe.install.root*.

  The default is /usr/lpp/zWebSphere/V8R5.

Assembling applications that use the Java Persistence API

Assembling a JPA application in a Java EE environment

You have developed and configured your applications to work with the Java Persistence API (JPA). Now you need to package the JPA applications for your environment.

About this task

Procedure

Package the application. There are several packaging options for an application that uses JPA in a Java EE environment. Choose the packaging option that best suits the JPA usage and configuration within the

modules of your application. These are some of the most common packaging options. For a definitive list of packaging options, see the Java Persistence API specification.

Note: IBM Optim PureQuery Runtime, add the *persistence_unit_name*.pdqxml file to the JPA application JAR file. The files are located in same META-INF directory where the persistence.xml file is located. These persistence files were created during the development task. See the topic, Developing JPA applications for a Java EE environment for more information.

- For a standalone Enterprise JavaBeans (EJB) module or a stand-alone application client module, package the EJB and application client modules in a standard Java archive (JAR) file. Ensure that you package the application with these conditions:
  - The JAR file must contain your EJB class files or the Java class files for the application client.
  - The META-INF directory of the archive must include your persistence.xml file.
  - If your application uses mapping files, orm.xml, or a custom mapping file, the JAR file must also contain those files. If the location of the orm.xml file is not specified in the persistence unit, the default location is the META-INF directory of the JAR file.
  - The Criteria Metamodel class files that are generated by the Annotation Processor when you developed your application needs to be included in the JAR file in the same location as the entity class files.
- For a stand-alone web module, package the application in a standard web application archive (WAR) file. Ensure that you package the application with these conditions:
  - The Criteria Metamodel class files that are generated by the Annotation Processor while developing your application needs to be included in the WAR file in the same location as the entity class files.
  - The WAR file must contain your web application class files. The web application class files must be included in the WEB-INF/classes directory or in a JAR file that is located in the WEB-INF/lib directory of the WAR file.
  - The persistence.xml file must be included in the WEB-INF/classes/META-INF directory or in the META-INF directory of a JAR file that is included in your WEB-INF/lib directory of your WAR file.
  - If your application uses mapping files, orm.xml, or a custom mapping file, the WAR file must also contain those files. Mapping files can reside in the WEB-INF/classes directory or in a JAR file that is contained within the WEB-INF/lib directory of the WAR file. Use the <mapping-file> element of the persistence.xml file to specify the location of mapping files. For example:

    ```
    <mapping-file>META-INF/JPAorm.xml</mapping-file>
    ```
- For enterprise application that contains one or more modules, package the application in a standard Enterprise application archive (EAR) file. An enterprise application can contain one ore more EJB module, web module, or application client module. Ensure that you package the application with these conditions:
  - If multiple modules use the same persistence unit, you can create a persistence archive and package the persistence archive within the EAR file.
  - Include your entity classes, associated Criteria Metamodel classes, any necessary supporting classes, the persistence.xml file, and additional mapping files in the persistence archive file. Follow the packaging rules for EJB and application client modules for the location of your persistence.xml file and mapping files.
  - Each module that uses the persistence archive must have a class path entry in its META-INF/MANIFEST.MF file. Here is an example manifest file:

    ```
    Manifest-Version: 1.0
    Class-Path: MyJPAEntities.jar
    ```
  - If your modules use separate persistence units and share entity classes, you can package the entity classes in a persistence archive and specify different persistence.xml file and mapping files for each module. If the modules do not share entity classes or a persistence configuration, package each module as a standalone EJB module, a stand-alone application client module, or a standalone web application archive and then package them in the EAR file.

What to do next

For more information about the commands, classes or other OpenJPA information, refer to the Apache OpenJPA User Guide.

Assembling JPA applications for a Java SE environment

You have developed and configured your applications to work with the Java Persistence API (JPA). Now you must package the JPA applications for your environment.

About this task

For this task, you must specify the `com.ibm.ws.jpa.thinclient_8.0.0.jar` stand-alone Java archive (JAR) file in your class path. This stand-alone JAR file is available from the client and server installation images. The location of this file on the client installation image is ${*app_client_root*}/runtimes/com.ibm.ws.jpa.thinclient_8.0.0.jar. The location of this file on the server installation image is ${*app_server_root*}/runtimes/com.ibm.ws.jpa.thinclient_8.0.0.jar.

Procedure

1. Package the application.

   Note: Package the persistence units in separate JAR files to make them more accessible and reusable. If you package the persistence units this way, they can be tested outside the container both with and without the occurrence of database persistence. The persistence units can be included in stand-alone applications or they can be packaged into EAR files as persistence archive files. If you package the persistence unit into a persistence archive file, all of the application components must be able to access the persistence archive. The application that uses the persistence units must declare a dependency on the persistence archive using the `MANIFEST.MF Class-Path:` declaration.

   The Criteria Metamodel class files that are generated by the Annotation Processor when you developed your JPA application, must be included in the JAR file in the same location as the entity class files.

   Note: If you are using IBM Optim PureQuery Run time, add the *persistence_unit_name*`.pdqxml` files to the JPA application JAR file. The files are located in same `META-INF` directory where your `persistence.xml` file is located. These persistence files were created during the development task, Developing JPA applications for a Java SE environment.

   To package the application use the following command:

   ```
   jar -cvf ${jar_Name} ${entity_Path}
   ```

   where ${*jar_Name*} represents the name of the JAR file to create, and ${*entityPath*} represents the root location where the entities reside, which is where you compiled them. Make sure that your ${`entity_Path`} also contains the `META-INF/persistence.xml` file.

2. When you run your stand-alone application, specify the JAR files in your class path when starting your application. The JPA runtime starts the stand-alone JAR file, `com.ibm.ws.jpa.thinclient_8.0.0.jar`. For example, use the following Java call to run the com.xyz.Main stand-alone application:

   ```
   java -cp /your/directory/${jar_Name}
   -javaagent:${app_client_root}/runtimes/com.ibm.ws.jpa.thinclient_8.0.0.jarcom.xyz.Main
   ```

What to do next

For more information about any of the commands, classes or other OpenJPA information, refer to the Apache OpenJPA User Guide.

Using JPA access intent

Java Persistence API (JPA) access intent specifies the isolation level and lock level used when reading data from a data source. Access intent controls the Java Database Connectivity (JDBC) isolation level and whether read, update, or exclusive locks are acquired when retrieving data.

About this task

For a JPA persistence provider on the application server, the application can specify isolation and ReadLockMode based on a TaskName. The TaskName provides a better control over applying these characteristics. The application defines a set of entity types and corresponding access intent for each TaskName defined in a persistence unit.

Restriction:

- Access intent is available for application in the Java EE server environment
- Access intent is applicable to non-query entity manager interface methods. Query uses query hint interface to set its isolation and read lock values.
- Access intent is only available for DB2 databases.
- Access intent is in effect only when pessimistic lock manager is used. Add the following to the persistence unit property list. <property name="openjpa.LockManager" value="pessimistic"/>

Table 73. Access intent Properties and Descriptions. The following table compares the Enterprise JavaBeans (EJB) 2.x entity bean access intent with the JPA access intent properties:

WebSphere EJB 2.x entity bean access intent	JPA access intent	Description
optimistic	isolation: Read Committed	Data is read but no lock is held. Version ID is used on update to ensure data integrity. Other transactions can read and update data.
	lockManager: Optimistic	
	query Hint: ReadLockMode: READ	
pessimistic read	isolation: Repeatable Read	Data is read with shared locks. Other transactions attempting to update data are blocked.
	lockManager: Optimistic	
	query Hint: ReadLockMode: READ	
pessimistic update	isolation: Repeatable Read	Data is retrieved with update or exclusive lock. Other writes are blocked until commit. This access intent can be used to serialize update access to data when there are multiple writers.
	lockManager: Pessimistic	
	query Hint: ReadLockMode: WRITE	
pessimistic exclusive	isolation: Serializable	Data is retrieved with update or exclusive lock. Other writes are blocked until commit. This access intent can be used to serialize update access to data when there are multiple writers.
	lockManager: Pessimistic	
	query Hint: ReadLockMode:WRITE	

A TaskName is set on a transaction context by one of the following:

- TaskName is automatically set in the EJB container when a transaction begins using WebSphere local transaction (EJB unspecified transaction), JTA global transaction in a Container-Managed Transaction (CMT) or user-initiated global transaction in a Bean-Managed Transaction (BMT).
- TaskName is manually set in an application using the TaskNameAccessor API provided for JPA.

Using task names supports the specification of access intent on a request scope rather than specifying it in the `persistence.xml` file, which has an application scope across all entities. Often a query is contained

in a method or component which is used in many different transaction contexts. Some of these contexts might require repeatable-read and update lock intent but other contexts do not.

Isolation level and read locks can be specified on:

- An application scope in the `persistence.xml` file. These isolation levels and read lock types are properties specified in the `persistence.xml` file. They apply to all entities that are defined in the persistence unit.
- A transaction scope in the task name. Transaction scoped hints override application scope values.
- Query instance with a query hint. Query hint can be used to override isolation and ReadLockMode for a particular query instance. A query hint overrides isolation level and read locks specified at the application or transaction scope.

Procedure

1. "Setting a TaskName using TaskNameAccessor API" This task explains how to use the TaskNameAccessor API to set JPA TaskName at run time.
2. "Specifying TaskName in a JPA persistence unit" on page 521 This task explains how to specify a TaskName in JPA persistence unit .

What to do next

For more information about Access intent, see the topic, Access intent service.

Setting a TaskName using TaskNameAccessor API

Using the TaskNameAccessor API to set Java Persistence API (JPA) TaskName at runtime.

About this task

In the Enterprise JavaBeans (EJB) container, a task name is automatically set by default upon a transaction begins. This action is performed when a component or business method is invoked in a CMT session bean or when an application invoke the `sessionContext.getTransaction().begin()` in a BMT session bean. This TaskName consists of a concatenation of the fully package qualified session bean type, a dot character and the method name. For example: `com.acme.MyCmtSessionBean.methodABC`.

If using JPA in the context of the web container, an application must use the TaskNameAccessor API to set the TaskName in the current thread of execution.

Note: Once a TaskName is set on a transaction context, application must not set the TaskName again in the same transaction. This will avoid problems with on the JDBC connection for different database access.

This example contains the TaskNameAccessor API definition

```
package com.ibm.websphere.persistence;

public abstract class TaskNameAccessor {

 /**
  * Returns the current task name attached in the current thread context.
  * @return current task name or null if none is found.
  */
 public static String getTaskName ();

 /**
  * Add a user-defined JPA access intent task name to the current thread
  * context.
  *
  * @param taskName
  * @return false if an existing task has already attached in the current
```

```
  *         thread or Transaction Synchronization Registry (TSR) is not
  *         available (i.e. in JSE environment).
  */
 public static boolean setTaskName(String taskName);

}
```

This code example shows how to set a TaskName using TaskNameAccessor.

```
package my.company;

@Remote
class Ejb1 {
    // assumer no tx from the caller
    @TransactionAttribute(Requires)
    public void caller_Method1() {

        // an implicit new transaction begins
        // TaskName "my.company.Ejb1.caller_Method1" set on TSR

        ejb1.callee_Method?();
    }

    @TransactionAttribute(RequiredNew)
    public void callee_Method2() {

        // an implicit new transaction begins i.e. TxRequiredNew.
        // TaskName "my.company.Ejb1.callee_Method2" set on TSR
    }

    @TransactionAttribute(Requires)
    public void callee_Method3() {

        // In caller's transaction, hence TaskName remains
        //     "my.company.Ejb1.caller_Method1"
    }

    @TransactionAttribute(NotSupported)
    public void callee_LocalTx () {

        // Unspecified transaction, a new local transaction implicitly started.
        // TaskName "my.company.Ejb1.callee_LocalTx" set on TSR
    }

}
```

Attention: In the above example, an application must be aware of transaction boundary will be subtly changed if Ejb1 uses local interface (@Local). For example, when `caller_Method1()` calls `callee_Method3` or `callee_LocalTx`, this will be treated as a Java method call. No EJB transaction semantics are honored.

What to do next

Once you have completed this step, continue on with the topic Specify TaskName in a JPA persistence unit.

Specifying TaskName in a JPA persistence unit

Specifying a TaskName in Java Persistence API (JPA) persistence unit

About this task

A TaskName is defined in the `persistence.xml` file using the `wsjpa.AccessIntent` property name in a persistence unit. The property value is a list of TaskNames, entity types and access intent definitions. The following example shows the contents of the `wsjpa.AccessIntent` property name in a persistence unit.

```
<property name  = "wsjpa.AccessIntent"
         value = "Tasks=' <taskName> { <entityName> ( <isolationLockValue> ) } ' "/>
                        A            A              A                    | | |
                        |            |              +--------- , --------+ | |
                        |            +------------------ , -----------------+ |
                        +----------------------- , --------------------------+
  Tasks                       ::= <task> [ ',' <task> ]*

  <task>                      ::= <taskName> '{' <entity> [ ',' <entity> ]* '}'

  <entity>                    ::= <entityName> '(' <isolationLockValues> ')'

  <taskName>                  ::= <fully_qualified_identifier>

  <entityName>                ::= <fully_qualified_identifier>

  <fully_qualified_identifier> ::= <identifier> [ '.' <identifier> ]*

  <identifier>                ::= <idStartCharacter> [ <idCharacter> ]*

  <idStartCharacter>          ::= Character.isJavaIdentifierStart | '?' | '*'

  <idStartCharacter>          ::= Character.isJavaIdentifierPart  | '?' | '*'

  <isolationLockValues>       ::= <isolationLockValue> [ ',' <isolationLockValue> ]

  <isolationLockValue>        ::= <isolation> | <readLock>

  <isolation>                 ::= "isolation" '=' <isolationValue>

  <readLock>                  ::= "readlock" '=' <readlockValue>

  <isolationValue>            ::= "read-uncommitted"|"read-committed"|"repeatable-read"|"serializable"

  <readlockValue>             ::= "read" | "write"
```

Before setting the TaskName in a persistence unit, keep the following in mind:

- White spaces are ignored between tokens.
- Only <isolation> and <readLock> contents are not case sensitive.
- <TaskName> is in the form of a fully package qualified method name, such as com.acme.bean.MyBean.increment, or an arbitrary user-defined task name, such as MyProfile.
- <entityName> is in the form of a fully package qualified class name such as com.acme.bean.Entity1.
- The wild card characters '?' or '*' can be used in <TaskName> and <entityName>. "?" matches any single character and "*" matches zero or more sequence characters.
- Only hintNames isolation and readLock are allowed on a task definition and the order is not significant
- If readLock has the value `write`, then isolation must be `repeatable-read` or `serializable`
- If readLock has the value `read`, it has no effect if the isolation is `read-uncommitted`.

The following code example shows how to specify a TaskName in JPA persistence unit.

```
package my.company;

@Remote
class Ejb1 {
    // assumer no tx from the caller
    @TransactionAttribute(Requires)
    public void caller_Method1() {

        // an implicit new transaction begins
        // TaskName "my.company.Ejb1.caller_Method1" set on TSR

        ejb1.callee_Method?();
    }
```

```
    @TransactionAttribute(RequiredNew)
    public void callee_Method2() {

        // an implicit new transaction begins i.e. TxRequiredNew.
        // TaskName "my.company.Ejb1.callee_Method2" set on TSR
    }

    @TransactionAttribute(Requires)
    public void callee_Method3() {

        // In caller's transaction, hence TaskName remains
        //     "my.company.Ejb1.caller_Method1"
    }

    @TransactionAttribute(NotSupported)
    public void callee_LocalTx () {

        // Unspecified transaction, a new local transaction implicitly started.
        // TaskName "my.company.Ejb1.callee_LocalTx" set on TSR
    }

}
```

Since a wild card can be used to specify TaskName and entity type, multiple specification matches may occur at runtime. The order defined in the `wsjpa.AccessIntent` property will be used to search for task names and entity types.

```
<properties>
  <property name="wsjpa.AccessIntent" value="Tasks="
        *.Task1 { *.Employee1 ( isolation=read-uncommitted                ),
                  *.Employee? ( isolation=repeatable-read,  readlock=write ),
                },
        *       { *.Employee3 ( isolation=serializable,     readlock=write ) },
      '" />
</properties>
```

Associating persistence providers and data sources

Java Persistence API (JPA) applications specify the underlying data source that is used by the persistence provider to access the database.

About this task

The application server provides three methods for defining the data sources in the `persistence.xml` file.

Procedure

- Explicitly specify the Java Naming and Directory Interface (JNDI) name in the `persistence.xml` file, and the application directly references the data source. Switching to another data source requires an update to the `persistence.xml` file.

  JPA has two transactional patterns for accessing a data source:

  – The Java Transaction API (JTA) resource pattern depends on global transactions. The JTA resource pattern is typically used within the scope of an Enterprise JavaBeans (EJB) session facade. This supports the session bean to control transaction and security contexts while JPA handles the persistence mappings. In this case, the application does not use the EntityTransaction interface but relies on the EntityManager enlisted with the global transaction when it is accessed.

  – The non-JTA resource pattern is used when dealing with a single resource in the absence of global transactions. The non-JTA resource pattern is typically used within the scope of a web application or an application client. The application controls the transaction with the data source with the EntityTransaction interface.

Within the application server, the use of the <non-jta-data-source> element requires a special configuration for a non-transactional data source. Data sources that are configured for the application server do not function as a <non-jta-data-source>, because all data sources that are configured by the application server are automatically enlisted with the current transactional context. To prevent this automatic enlistment, add an additional data source custom property `nonTransactionalDataSource=true`:

1. Select **Resources** > **JDBC** > **Data sources**
2. Select the name of the data source that you want to configure.
3. Select **WebSphere Application Server data source properties** from the **Additional Properties** heading.
4. Select **Non-transactional data source**.
5. Click **OK**.

Note: The JPA specification assumes that connections are obtained with an isolation level that does not hold long-term locks in the database, such as `READ_COMMITTED`. This might not match the WebSphere Application Server default isolation level, which is `REPEATABLE_READ` for most databases. You can find the level that is used for your database by reading the topic, Requirements for setting isolation level.

If the default for your database is not `READ_COMMITTED`, you can change the default by adding an additional data source custom property webSphereDefaultIsolationLevel.

Table 74. Isolation level values. This table shows valid isolation level values.

Value	Isolation Level
1	READ_UNCOMMITTED
2	READ_COMMITTED (JPA default)
4	REPEATABLE_READ (WebSphere Application Server default)
8	SERIALIZABLE

If the isolation level is set to a value that holds long-term read locks, configure the JPA provider to use Pessimistic Locking instead of the default Optimistic Locking. For the JPA provider included with WebSphere Application Server, you can do this by adding the following properties to `persistence.xml` file:

```
<property name="openjpa.Optimistic" value="false"/>
<property name="openjpa.LockManager" value=pessimistic"/>
```

The JPA specification mandates that the data sources that are defined in `<jta-data-source>` and `<non-jta-data-source>` elements of a persistence unit register in the JNDI name space. For example, the `persistence.xml` file should contain an entry like the following:

```
<jta-data-source>jdbc/DataSourceJNDI</jta-data-source>
```

- The JPA for WebSphere Application Server solution extends the JNDI data-source implementation to allow you to reference data sources in the component name space. In the EJB or web module deployment descriptor file, this is the <resource-ref> element. You can prefix the data source with java:`comp/env/` so the application indirectly references the data source by using the local JNDI name. In this association, the application does not require updates, you change <resource-ref> to use another data source. See the following example:

  ```
  <jta-data-source>java:comp/env/jdbc/DataSourceJNDI</jta-data-source>
  ```

- You can declare openjpa.Connection* properties in the persistence unit as follows:

  ```
  <property name="openjpa.ConnectionDriverName" value="org.apache.derby.jdbc.EmbeddedDriver" />
  <property name="openjpa.ConnectionURL" value="jdbc:derby:target/database/jpa-test-database;create=true"/>
  ```

  OR

  You can use alternative standard JPA properties that are equivalent to the OpenJPA properties, such as:

Table 75. Standard JPA 2.0 property equivalents. Standard JPA 2.0 properties and the OpenJPA equivalents.

Standard JPA 2.0	OpenJPA Equivalent
javax.persistence.jdbc.driver	openjpa.ConnectionDriverName

Table 75. Standard JPA 2.0 property equivalents (continued). Standard JPA 2.0 properties and the OpenJPA equivalents.

Standard JPA 2.0	OpenJPA Equivalent
javax.persistence.jdbc.url	openjpa.ConnectionURL

What to do next

For information about configuring data sources, see the topic on creating and configuring a data source.

For information about data sources and JPA, see the section on persistence in the Apache OpenJPA User Guide.

Chapter 11. Developing Internationalization service

This page provides a starting point for finding information about globalization and the internationalization service, a WebSphere extension for improving developer productivity.

With the internationalization service, you can automatically recognize the time zone and location information of the calling client so that your application can act appropriately. The technology enables you to deliver each user, around the world, the right date and time information, the appropriate currencies and languages, and the correct date and decimal formats.

This documentation also includes information about internationalizing interface strings using the localizable-text application programming interface.

Task overview: Globalizing applications

An application that can present information to users according to regional cultural conventions is said to be *globalized*: The application can be configured to interact with users from different localities in culturally appropriate ways. In a globalized application, a user in one region sees error messages, output, and interface elements in the requested language. Date and time formats, as well as currencies, are presented appropriately for users in the specified region. A user in another region sees output in the conventional language or format for that region. Globalization consists of two phases: *internationalization* (enabling an application component for multicultural support) and *localization* (translating and implementing a specific regional convention). This product supports globalization through the use of its localizable-text API and internationalization service.

Procedure

- Make sure the server runtime environment is properly configured.

  For more information about supported locales and character encodings, see “Working with locales and character encodings” on page 529.
- Implement message catalogs in your application by using the localizable-text API.

  This product supports the maintenance and deployment of centralized message catalogs for the output of properly formatted, language-specific (*localized*) interface strings.

  For more information about the localizable-text API, see “Task overview: Internationalizing interface strings (localizable-text API)” on page 531.
- Implement more extensive locale support by using the internationalization service.

  With the internationalization service, you can manage the distribution of the internationalization information, or *internationalization context*, that is necessary to support globalized Java Platform, Enterprise Edition (Java EE) application components. Supported application components also include web service client environments and web service-enabled enterprise beans.

  For more information about the internationalization service, see “Task overview: Internationalizing application components (internationalization service)” on page 542.

Globalization

An application that can present information to users according to regional cultural conventions is said to be *globalized*: The application can be configured to interact with users from different localities in culturally appropriate ways. In a globalized application, a user in one region sees error messages, output, and interface elements in the requested language. Date and time formats, as well as currencies, are presented appropriately for users in the specified region. A user in another region sees output in the conventional language or format for that region. Globalization consists of two phases: *internationalization* (enabling an application component for multicultural support) and *localization* (translating and implementing a specific regional convention).

Historically, the creation of globalized applications has been restricted to large corporations writing complex systems. However, given the rise in distributed computing and in the use of the World Wide Web, application developers are pressured to globalize a much wider variety of applications. This trend requires making globalization techniques much more accessible to application developers.

Internationalization of an application is driven by two variables, the time zone and the locale. The *time zone* indicates how to compute the local time as an offset from a standard time like Greenwich Mean Time. The *locale* is a collection of information about language, currency, and the conventions for presenting information like dates. A time zone can cover many locales, and a single locale can span time zones. With both time zone and locale, the date, time, currency, and language for users in a specific region can be determined.

By convention, a given locale is specified with a pair of codes (for language and region) that are governed by different standards. The ISO-639 standard governs the language code; the ISO-3166 standard governs the regional code. In notation, the two codes are typically joined by an underscore (_) character, for example, en_US for English in the United States. In Java code, locales are set and retrieved by means of the java.util.Locale class.

A first step: Localization of interface strings

In an application that is not globalized, the user interface is unalterably written into the application code. Internationalizing a user interface adds a layer of abstraction into the design of an application. The additional layer of abstraction enables you to localize the application for each locale that must be supported by the application.

In a localized application, the locale determines the message catalog from which the application retrieves message strings. Instead of printing an error message, the application represents the error message with some language-neutral information; in the simplest case, each error condition corresponds to a key. To print a usable error message, the application looks up the key in a *message catalog*. Each message catalog is a list of keys with associated strings. Different message catalogs provide strings for the different languages that are supported. The application looks up the key in the appropriate catalog, retrieves the corresponding error message in the requested language, and prints the string for the user.

Localization of text can be used for far more than translating error messages. For example, by using keys to represent each element in a graphical user interface (GUI) and by providing the appropriate message catalogs, the GUI (buttons, menus, and so on) can support multiple languages. Extending support to additional languages requires that you provide message catalogs for those languages; in many cases, the application needs no further modification.

The localizable-text package is a set of Java classes and interfaces that can be used to localize the strings in distributed applications easily. Language-specific string catalogs can be stored centrally so that they can be maintained efficiently.

Globalization challenges in distributed applications

With the advent of Internet-based business computational models, applications increasingly consist of clients and servers that operate in different geographical regions. These differences introduce the following challenges to the task of designing a solid client-server infrastructure:

Clients and servers can run on computers that have different endian architectures or code sets

Clients and servers can reside in computers that have different endian architectures: A client can reside in a little-endian CPU, while the server code runs in a big-endian one. A client might want to call a business method on a server running in a code set different from that of the client.

A client-server infrastructure must define precise endian and code-set tracking and conversion rules. The Java platform has nearly eliminated these problems in a unique way by relying on its

Java virtual machine (JVM), which encodes all of the string data in UCS-2 format and externalizes everything in big-endian format. The JVM uses a set of platform-specific programs for interfacing with the native platform. These programs perform any necessary code set conversions between UCS-2 and the native code set of a platform.

Clients and servers can run on computers with different locale settings

Client and server processes can use different locale settings. For example, a Spanish client might call a business method upon an object that resides on an American English server. Some business methods are locale-sensitive in nature; for example, given a business method that returns a sorted list of strings, the Spanish client expects that list to be sorted according to the Spanish collating sequence, not in the English collating sequence of the server. Because data retrieval and sorting procedures run on the server, the locale of the client must be available to perform a legitimate sort.

A similar consideration applies in instances where the server has to return strings containing date, time, currency, exception messages, and so on, that are formatted according to the cultural expectations of the client.

Clients and servers can reside in different time zones

Client and server processes can run in different time zones. To date, all internationalization literature and resources concentrate mainly on code set and locale-related issues. They have generally ignored the time zone issue, even though business methods can be sensitive to time zone as well as to locale.

For example, suppose that a vendor makes the claim that orders received before 2:00 PM are processed by 5:00 PM the same day. The times given, of course, are in the time zone of the server that is processing the order. It is important to know the time zone of the client to give customers in other time zones the correct times for same-day processing.

Other time zone-sensitive operations include time stamping messages logged to a server, and accessing file or database resources. The concept of Daylight Savings Time further complicates the time zone issue.

Java Platform, Enterprise Edition (Java EE) provides support for application components that run on computers with differing endian architecture and code sets. It does not provide dedicated support for application components that run on computers with different locales or time zones.

The conventional method for solving locale and time zone mismatches across remote application components is to pass one or more extra parameters on all business methods needed to convey the client-side locale or time zone to the server. Although simple, this technique has the following limitations when used in Enterprise JavaBeans (EJB) applications:

- It is intrusive because it requires that one or more parameters be added to all bean methods in the call chain to locale-sensitive or time zone-sensitive methods.
- It is inherently error-prone.
- It is impracticable within applications that do not support modification, such as legacy applications.

The internationalization service addresses the challenges posed by locale and time zone mismatch without incurring the limitations of conventional techniques. The service systematically manages the distribution of internationalization contexts across the various components of EJB applications, including client applications, enterprise beans, and servlets. For more information, see “Task overview: Internationalizing application components (internationalization service)” on page 542.

Working with locales and character encodings

Internationalization support for this product relies on that provided by the Java Platform, Standard Edition (JSE). Support varies by platform.

Procedure

- Verify that the operating system on which the application server is installed supports the locales and encodings that you plan to use.

  Java internationalization support might use underlying services of the operating system. For example, if user IDs for your server are expected to contain non-English characters, make sure that the operating system is configured to process those characters.
- Plan for encoding changes as necessary.

  Consider differences in encoding support among operating system subcomponents. Although this product and the Java platform are based on Unicode encoding, it is not always possible to run applications in a purely Unicode environment.
- Set the console.encoding property as necessary.

Results

If your application produces an UnsupportedEncodingException exception, check your operating system documentation to determine if the target operating system supports the required encoding and adjust the runtime environment as needed. Use the converter.properties file as appropriate to map an unsupported character set to a supported character set. A typical converter.properties file appears below:

```
Shift_JIS=CP943C
EUC-JP=Cp33722C
EUC-JP=Cp33722C
EUC-KR=Cp970
EUC-TW=Cp964
Big5=Co950
GB2312=Cp1386
ISO-2022–KR=ISO2022KR
```

The converter.properties file implements a method for specifying a content type header field that browsers would understand (such as, SHIFT_JIS) and a writer that can output characters correctly (such as, Cp943c).

Language versions offered by this product

This product is offered in several languages, as enabled by the operating platform on which the product is installed.

For the z/OS platform, the following language versions are available:

- English
- Japanese

Task overview: Internationalizing interface strings (localizable-text API)

This topic summarizes the steps involved in implementing message catalogs through the localizable-text API.

About this task

This product supports the maintenance and deployment of centralized message catalogs for the output of properly formatted, language-specific (*localized*) interface strings.

Procedure

1. Identify localizable text in your application.
2. Create the message catalogs that are necessary for the locales to be supported by your application.
3. In your application code, compose the language-specific strings for output.
4. Using an assembly tool, assemble your application code as one or more application components.
5. Prepare the localizable-text package for deployment with your localized application. In this step, you create a deployment Java archive (JAR) file.
6. Assemble the application modules and the deployment JAR file into a Java Platform, Enterprise Edition (Java EE) application.
7. Deploy and manage the application.

Results

Your application is deployed with localized text.

Identifying localizable text

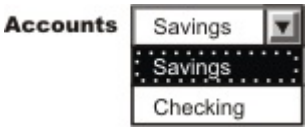
The first step in localizing strings in an application component is identifying the best candidates for translation.

Procedure

1. Determine which elements of the application need translating. Good candidates for localization include the following:
   - Graphical user interfaces: window titles, menus and menu items, buttons, on-screen instructions
   - Prompts in command-line interfaces
   - Application output: messages and logs
2. Assign a unique key to each element for use in message catalogs for the application. The key provides a language-neutral link between the application and language-specific strings in the message catalogs. Establishing a naming convention for keys before creating the catalogs can make writing code with these keys much more intuitive for interface programmers.

Example

Suppose you are localizing the GUI for a banking system, and the first window contains a pull-down list to use for selecting a type of account.



The labels for the list and the account types in the list are good choices for localization. Three elements require keys: the list and two items in the list.

What to do next

Create message catalogs for the language-specific strings.

Creating message catalogs

Perform this task to begin the localization of strings in an application component.

Before you begin

Identify strings that need to be localized.

About this task

You can create a catalog as either a java.util.ResourceBundle subclass or a Java properties file. The properties-file approach is more common, because properties files can be prepared by people without programming experience and swapped without modifying the application code.

Procedure

1. For each string that is identified for localization, add a line to the message catalog that lists the string key and value in the current language. In a properties file, each line has the following structure:

   ```
   key = string associated with the key
   ```

2. Save the catalog, giving it a locale-specific name. To enable resolution to a specific properties file, the Java API specifies naming conventions for the properties files in a resource bundle as *bundleName_localeID*.properties. Give the set of message catalogs a collective name, for example, BankingResources. For information about locale IDs that are recognized by the Java APIs, see “Resources for learning”.

Example

The following English catalog (BankingResources_en.properties) supports the labels for the list and its two list items:

```
accountString = Accounts
savingsString = Savings
checkingString = Checking
```

Do not create compound strings by concatenation (for example, combining the values of savingsString and accountString to form `Savings Accounts` in English. Success depends upon the grammar of the original language (in this case, English) and is not likely to extend to other languages.

The corresponding German catalog (BankingResources_de.properties) supports the labels as follows:

```
accountString = Konten
savingsString = Sparkonto
checkingString = Girokonto
```

What to do next

Write code to compose the language-specific strings.

Composing language-specific strings

Perform this task to complete the localization of strings in an application component.

Before you begin

Create message catalogs for the language-specific strings.

Procedure

1. In application code, create a LocalizableTextFormatter instance, passing in required localization values.
2. Set other localization values as needed for more complex situations.
3. Generate a properly formatted, language-specific string.

What to do next

When the application is finished, deploy your application. For more information, see “Preparing the localizable-text package for deployment” on page 541.

Localization API support

The com.ibm.websphere.i18n.localizabletext package contains classes and interfaces for localizing text.

This package makes extensive use of the internationalization features of the standard Java APIs, including the following classes:

- java.util.Locale
- java.util.TimeZone
- java.util.ResourceBundle
- java.text.MessageFormat

For more information about the standard Java APIs, see “Globalization: Resources for learning” on page 530.

The localizable-text package wraps the Java support and extends it for efficient and simple use in a distributed environment. The primary class used by application programmers is LocalizableTextFormatter. Instances of this class are usually created in server programs, but client programs can also create them. Formatter instances are created for specific resource-bundle names and keys. Client programs that

receive a LocalizableTextFormatter instance call its format method. This method uses the locale of the client application to retrieve the appropriate resource bundle and compose a locale-specific message based on the key.

For example, suppose that a distributed application supports both French and English locales; the server is using an English locale and the client, a French locale. The server creates two resource bundles, one each for English and French. When the client makes a request that triggers a message, the server creates a LocalizableTextFormatter instance that contains the name of the resource bundle and the key for the message and passes the instance back to the client.

When the client receives the LocalizableTextFormatter instance, it calls the format method of the object. By using the locale and name of the resource bundle, the format method determines the name of the resource bundle that supports the French locale and retrieves the message that corresponds to the key from the French resource bundle. Formatting of the message is transparent to the client.

In this simple example, the resource bundles reside centrally with the server. They do not have to exist with the client. Part of what the localizable-text package provides is the infrastructure to support centralized catalogs. This implementation uses an enterprise bean (a stateless session bean provided with the localizable-text package) to access the message catalogs. When the client calls the format method on the LocalizableTextFormatter instance, the following events occur:

1. The client application sets the time-zone and locale values in the LocalizableTextFormatter instance, either by passing them explicitly or through default values.
2. A LocalizableTextFormatterEJBFinder call is made to retrieve a reference to the formatter bean.
3. Information from the LocalizableTextFormatter instance, including the time zone and locale of the client, is sent to the formatting bean.
4. The formatting bean uses the name of the resource bundle, the message key, the time zone, and the locale to compose a language-specific message.
5. The formatter bean returns the formatted message to the client.
6. The formatted message is inserted into the LocalizableTextFormatter instance and returned by the format method.

A call to the format method requires at most one remote call, to contact the formatter bean. As an alternative, the LocalizableTextFormatter instance can cache formatted messages, eliminating the remote call for subsequent uses. In addition, you can set a fallback string so that the application can return a readable string even if it cannot access the appropriate message catalog.

The resource bundles can be stored locally. The localizable-text package provides a static variable that indicates whether the bundles are stored locally (LocalizableConfiguration.LOCAL) or remotely (LocalizableConfiguration.REMOTE). However, the setting of this variable applies to all applications running within the same Java virtual machine.

LocalizableTextFormatter class

The LocalizableTextFormatter class, found in the com.ibm.websphere.i18n.localizabletext package, is the primary programming interface for using the localizable-text package. Instances of this class contain the information needed to create language-specific strings from keys and resource bundles.

The LocalizableTextFormatter class extends the java.lang.Object class and implements the following interfaces:

- java.io.Serializable
- com.ibm.websphere.i18n.localizabletext.LocalizableText
- com.ibm.websphere.i18n.localizabletext.LocalizableTextL
- com.ibm.websphere.i18n.localizabletext.LocalizableTextTZ
- com.ibm.websphere.i18n.localizabletext.LocalizableTextLTZ

Creation and initialization of class instances

The LocalizableTextFormatter class supports the following constructors:
- LocalizableTextFormatter()
- LocalizableTextFormatter(String resourceBundleName, String patternKey, String appName)
- LocalizableTextFormatter(String resourceBundleName, String patternKey, String appName, Object[] args)

The LocalizableTextFormatter instance must have certain values, such as a resource-bundle name, a key, and the name of the formatting application. If you do not pass these values in by using the second constructor listed previously, you can set them separately by making the following calls:
- setResourceBundleName(String resourceBundleName)
- setPatternKey(String patternKey)
- setApplicationName(String appName)

You can use a fourth method, setArguments(Object[] args), to set optional localization values after construction. See “Processing of application-specific values” on page 536 at the end of this topic. For a usage example, see “Composing complex strings” on page 538.

API for formatting text

The formatting methods in the LocalizableTextFormatter class generate a string from a set of message keys and resource bundles, based on some combination of locale and time-zone values. Each method corresponds to one of the four localizable-text interfaces implemented. The following list indicates the interface in which each formatting method is defined:
- LocalizableText.format()
- LocalizableTextL.format(java.util.Locale locale)
- LocalizableTextTZ.format(java.util.TimeZone timeZone)
- LocalizableTextLTZ.format(java.util.Locale locale, java.util.TimeZone timeZone)

The format method with no arguments uses the locale and time-zone values set as defaults for the Java virtual machine. All four methods issue LocalizableException objects as needed.

Location of message catalogs and the appName value

Applications written with the localizable-text package can access message catalogs locally or remotely. In a distributed environment, the use of remote, centrally located message catalogs is appropriate. All clients can use the same catalogs, and maintenance of the catalogs is simplified. Local formatting is useful in test situations and appropriate under some circumstances. To support either local or remote formatting, a LocalizableTextFormatter instance must indicate the name of the formatting application.

For example, when an application formats a message by using remote catalogs, the message is actually formatted by an enterprise bean on the server. Although the localizable-text package contains the code to automate the lookup of the formatter bean and to issue a call to it, the application needs to know the name of the formatter bean. Several methods in the LocalizableTextFormatter class use a value described as `appName`, which refers to the name of the formatting application. It is not necessarily the name of the application in which the value is set.

Caching of messages

LocalizableTextFormatter instances can optionally cache formatted messages so that they do not require reformatting when needed again. By default, caching is not enabled, but you can use a `LocalizableTextFormatter.setCacheSetting(true)` call to enable caching. When caching is enabled and the format method is called, the method determines whether the message is already formatted. If so, the cached message is returned. If the message is not found in the cache, the message is formatted and returned to the caller, and a copy of the message is cached for future use.

If caching is disabled after messages are cached, those messages remain in the cache until the cache is cleared by a call to the LocalizableTextformatter.clearCache method. You can clear the cache at any time; the cache is automatically cleared when any of the following methods is called:
- setResourceBundleName(String resourceBundleName)
- setPatternKey(String patternKey)
- setApplicationName(String appName)
- setArguments(Object[] args)

API for providing fallback information

Under some circumstances, it can be impossible to format a message. The localizable-text package implements a fallback strategy, making it possible to get some information even if a message cannot be formatted correctly into the requested language. The LocalizableTextFormatter instance can optionally store fallback values for a message string, the time zone, and the locale. These values can be ignored unless the LocalizableTextFormatter instance issues an exception. To set fallback values, call the following methods as appropriate:
- setFallBackString(String message)
- setFallBackLocale(Locale locale)
- setFallBackTimeZone(TimeZone timeZone)

For a usage example, see “Generating localized text” on page 540.

Processing of application-specific values

The localizable-text package provides native support for localization based on time zone and locale, but you can construct messages on the basis of other values as well. If you need to consider variables other than locale and time zone in formatting localized text, write your own formatter class.

Your formatter class can extend the LocalizableTextFormatter class or independently implement some or all of the same localizable-text interfaces. As a minimum, your class must implement the java.io.Serializable interface and at least one of the localizable-text interfaces and its corresponding format method. If your class implements more than one localizable-text interface and format method, the order of evaluation of the interfaces is as follows:
1. LocalizableTextLTZ
2. LocalizableTextL
3. LocalizableTextTZ
4. LocalizableText

As an example, the localizable-text package provides a class that reports the time and date (LocalizableTextDateTimeArgument). In that class, date and time formatting is localized in accordance with three values: locale, time zone, and style.

Creating a formatter instance

Perform this task to set localization values for strings in an application component.

About this task

Server programs typically create LocalizableTextFormatter instances that are sent to clients as the result of some operation; clients format the objects at the appropriate time. Less typically, client programs create LocalizableTextFormatter objects locally.

Procedure

1. If needed for your application, write your own formatter class. For more information about implementation, see “LocalizableTextFormatter class” on page 534.
2. In application code, call the appropriate constructor for the formatter class and set required localization values. Some localization values, such as resource bundle name, key and formatting application, must

be set, either through a constructor or soon after construction. Other localization values can be set only as needed. For more information about the API, see the related reference.

Example

The following code creates a LocalizableTextFormatter instance by using the default constructor and then sets the required localization values:

```
import com.ibm.websphere.i18n.localizabletext.LocalizableException;
import com.ibm.websphere.i18n.localizabletext.LocalizableTextFormatter;
import java.util.Locale;

public void drawAccountNumberGUI(String accountType) {
   ...
   LocalizableTextFormatter ltf = new LocalizableTextFormatter();
   ltf.setPatternKey("accountNumber");
   ltf.setResourceBundleName("BankingSample.BankingResources");
   ltf.setApplicationName("BankingSample");
   ...
}
```

The line of code in boldface exploits default behavior of the Java platform. By default, the Java platform looks first for a subclass of java.util.ResourceBundle called BankingResources. When none is found, the Java platform looks for a valid properties file of the same name. In this continuing example, a properties file is found.

The application that is requesting a localized message can specify the locale and time zone for message formatting, or the application can use the default values set for the Java virtual machine.

For example, a GUI can enable users to select the language in which to display the interface. A default value must be set initially so that the GUI can be created properly when the application first starts, but users can then change the locale for the GUI to suit their needs. The following code shows how to change the locale used by an application based on the selection of a menu item:

```
import java.awt.event.ActionListener;
import java.awt.event.ActionEvent;
...
import java.util.Locale;

public void actionPerformed(ActionEvent event) {
   String action = event.getActionCommand();
   ...
   if (action.equals("en_us")) {
      applicationLocale = new Locale("en", "US");
      ...
   }
   if (action.equals("de_de")) {
      applicationLocale = new Locale("de", "DE");
      ...
   }
   if (action.equals("fr_fr")) {
      applicationLocale = new Locale("fr", "FR");
      ...
   }
   ...
}
```

For more information, see “Generating localized text”.

What to do next

Set optional localization values.

Setting optional localization values

In addition to setting localization values that are required by the LocalizableTextFormatter interface, you can set a number of optional values in application code, either through the constructor or by calling any of several methods for that purpose.

About this task

With optional values, you can do the following actions:
- Compose complex strings from variable substrings
- Customize the formatting of strings, considering variables other than time zone and locale

Procedure

1. In application code, add the optional values into an array of type Object.
   ```
   Object[] arg = {new String(getAccountNumber())};
   ```
2. Pass the array into a LocalizableTextFormatter instance. You can pass the array through the appropriate constructor or call the setArguments(Object[]) method. For a usage example, see "Composing complex strings."

   Because the array is passed by value rather than by reference, any updates to the array variable after this point are not reflected in the LocalizableTextFormatter instance unless it is reset by calling the setArguments(Object[]) method.

What to do next

Write code to generate the localized text.

Composing complex strings:

Perform this task to insert variable substrings into a localized string.

Before you begin

Identify strings that need to be localized.

About this task

The localized-text package supports the substitution of variable substrings into a localized string that is retrieved from the message catalog by key.

Procedure

1. In the message catalog, specify the location of the substitution in the string to be retrieved. Variable components are designated by braces (for example, `{0}`).
2. In application code, create a LocalizableTextFormatter instance, passing in an array that contains the variable value. If the variable substring must be localized, you can create a nested LocalizableTextFormatter instance and pass the instance in instead of a value.
3. Generate a localized string. When a format method is called on a formatter instance, the formatter takes each element of the array passed in the previous step and substitutes it for the placeholder with the matching index in the string that is retrieved from the message catalog. For example, the value at index 0 in the array replaces the `{0}` variable in the retrieved string.

Example

The following line from an English message catalog shows a string with a single substitution:

```
successfulTransaction = The operation on account {0} was successful.
```

The same key in message catalogs for other languages has a translation of this string with the variable at the appropriate location for each language.

The following code shows the creation of a single-element argument array and the creation and use of a LocalizableTextFormatter instance:

```
public void updateAccount(String transactionType) {
   ...
   Object[] arg = {new String(this.accountNumber)};
   ...
   LocalizableTextFormatter successLTF =
      new LocalizableTextFormatter ("BankingResources",
                                    "successfulTransaction",
                                    "BankingSample",
                                    arg);
   ...
   successLTF.format(this.applicationLocale);
   ...
}
```

Nesting formatter instances for localized substrings:

The ability to substitute variable substrings into the strings retrieved from message catalogs adds a level of flexibility to the localizable-text package, but this capability is of limited use unless the variable value can be localized. You can localize this value by nesting LocalizableTextFormatter instances.

Before you begin

Identify strings that need to be localized.

Procedure

1. In the message catalog, add entries that correspond to potential values for the variable substring.
2. In application code, create a LocalizableTextFormatter instance for the variable substring, setting required localization values.
3. Create a LocalizableTextFormatter instance for the primary string, passing in an array that contains the formatter instance for the variable substring.

Example

The following line from an English message catalog shows a string entry with two substitutions and entries to support the localizable variable at index 0 (the second variable in the string, the account number, does not need to be localized):

```
successfulTransaction = The {0} operation on account {1} was successful.
depositOpString = deposit
withdrawOpString = withdrawal
```

The following code shows the creation of the nested formatter instance and its insertion (with the account number variable) into the primary formatter instance:

```
public void updateAccount(String transactionType) {
   ...
   // Successful deposit
   LocalizableTextFormatter opLTF =
      new LocalizableTextFormatter("BankingResources",
                                   "depositOpString",
               "BankingSample");
   Object[] args = {opLTF, new String(this.accountNumber)};
   ...
   LocalizableTextFormatter successLTF =
      new LocalizableTextFormatter ("BankingResources",
                                    "successfulTransaction",
```

```
                                    "BankingSample",
                                    args);
   ...
   successLTF.format(this.applicationLocale);
   ...
}
```

Generating localized text

Perform this task to specify the runtime formatting of localized text in an application component.

Before you begin

Create a formatter instance and set the localization values as needed.

Procedure

1. If needed, customize the formatting behavior.
2. In application code, call the appropriate format method.

Example

You can provide fallback behavior for use if the appropriate message catalog is not available at formatting time.

The following code generates a localized string. If the formatting fails, the application retrieves and uses a fallback string instead of the localized string:

```
import com.ibm.websphere.i18n.localizabletext.LocalizableException;
import com.ibm.websphere.i18n.localizabletext.LocalizableTextFormatter;
import java.util.Locale;

public void drawAccountNumberGUI(String accountType){
   ...
   LocalizableTextFormatter ltf = new LocalizableTextFormatter();
   ...
   ltf.setFallBackString("Enter account number: ");
   try {
      msg = new Label(ltf.format(this.applicationLocale), Label.CENTER);
   }
   catch (LocalizableException le) {
      msg = new Label(ltf.getFallBackString(), Label.CENTER);
   }
   ...
}
```

What to do next

When the application is finished, deploy your application. For more information, see “Preparing the localizable-text package for deployment” on page 541.

Customizing the behavior of a formatting method:

Perform this task to change the runtime formatting of localized strings in an application component.

About this task

You can customize formatting behavior by passing your own formatter classes into a LocalizableTextFormatter instance through an array of optional values. This action enables you to consider variables other than locale and time zone when formatting localized text.

Procedure

1. Write your own formatter class. For more information about implementation, see "LocalizableTextFormatter class."
2. In application code, create an instance of your formatter class as appropriate and pass it with any other optional localization values into an instance of LocalizableTextFormatter. When the LocalizableTextFormatter instance reads the instance that has been passed in, it attempts to call the format() method on the passed-in instance. The string returned is then processed with any other elements in the array.

Example

The localizable-text package provides an example of a user-defined class, called LocalizableTextDateTimeArgument. This class enables date and time information to be selectively formatted according to the style values defined in the java.text.DateFormat interface as well as the constants that are defined within the LocalizableTextDateTimeArgument class.

Preparing the localizable-text package for deployment

The LocalizableTextEJBDeploy tool is used to create a deployment Java Archive (JAR) file for the localizable text service. You must deploy the enterprise bean in each enterprise application that requires support for localized text.

Before you begin

Write code to compose the language-specific strings.

Procedure

1. Make sure that the LocalizableTextEJBDeploy tool is included in the class path.

   transition: In versions 6.0.x and earlier, the LocalizableTextEJBDeploy tool used to reside in the file *app_server_root*/`lib/ltext.jar`. It now resides in the file *app_server_root*/`plugins/com.ibm.ws.runtime_1.0.0.jar`.
2. Set up a working directory for the LocalizableTextEJBDeploy tool to use. You need to pass this location to the tool through a command-line interface.
3. Run the LocalizableTextEJBDeploy tool. You might be asked if you want to regenerate deployment code for the LocalizableText bean. Do not redeploy the bean; if you do, an incorrect Java Naming and Directory Interface (JNDI) name will be generated.

   To deploy the bean on multiple hosts and servers, run the tool for each host and server combination. This action generates a unique JNDI name for each deployment. After the tool is run, a deployment JAR file is located in the working directory that you specified.

What to do next

Using an assembly tool, assemble the deployment JAR file in an enterprise application with other application components.

As part of preparing for deployment, perform the following:
- Add the resource bundles for your application to the Enterprise Archive (EAR) file as files.
- Add the location of the EAR file to the server class path for the server so that the resource bundles can be located on the virtual host and server.

The same deployment JAR file can be included in several enterprise applications.

LocalizableTextEJBDeploy command

This topic describes the command-line syntax for the LocalizableTextEJBDeploy tool.

transition: In versions 6.0.x and earlier, the LocalizableTextEJBDeploy tool used to reside in the file *app_server_root*/lib/ltext.jar. It now resides in the file *app_server_root*/plugins/com.ibm.ws.runtime_1.0.0.jar.

```
LocalizableTextEJBDeploy
   -a applicationName
   -h virtualHostName
   -i installationDirectory
   -s serverName
   -w workingDirectory
```

Parameters

The required parameters, which can be specified in any order, follow:

applicationName
The name of the formatting session bean. This name is used in LocalizableTextFormatter instances to specify where the actual formatting occurs. If the name cannot be resolved at run time, the format method issues an exception.

virtualHostName
The name of the virtual host on which the formatting session bean is deployed. This value is case-sensitive on all operating platforms.

installationDirectory
The location at which the application server product is installed.

serverName
The name of the application server. If this argument is not specified, the default server name for the product is used.

workingDirectory
A location for the tool to use temporarily.

Task overview: Internationalizing application components (internationalization service)

This topic summarizes the steps involved in using the internationalization service.

About this task

With the internationalization service, you can manage the distribution of the internationalization information, or *internationalization context*, that is necessary to support globalized Java Platform, Enterprise Edition (Java EE) application components. Supported application components also include web service client environments and web service-enabled enterprise beans.

Procedure

1. Use the internationalization context API within application components to obtain or manage internationalization context.

   Servlet and enterprise bean business methods can use internationalization context to perform locale- and time zone-sensitive localizations. Enterprise JavaBeans (EJB) client applications, and server components that are configured to manage internationalization context must use the internationalization context API to set the context elements scoped to their invocations.

   You use the internationalization context API within Web service-enabled Java EE client programs and stateless session beans in the same manner that you would use conventional Java EE application components, with one exception. Internationalization context propagated over Web service requests contains a time zone ID, whereas conventional Remote Method Invocation/ Internet Inter-ORB Protocol (RMI/IIOP) requests propagate complete time zone information, including the raw offset, Daylight Savings Time information, and so on.

2. Assemble internationalized applications.

   The internationalization type specifies the internationalization policy that applies to a servlet or an enterprise bean and, in particular, indicates whether the application component or its hosting Java EE container manages internationalization context. Container internationalization attributes can be specified for container-managed servlet and enterprise bean business methods. These attributes tailor a policy by indicating which context the container scopes to an invocation. Configuring internationalization policies declaratively prescribes, by means of the application deployment descriptor, the distribution and management of context throughout an application.

   As you edit the deployment descriptor for assembly, you can also set the internationalization type and configure any container internationalization attributes for the servlets and enterprise beans in your application.

   You configure internationalization type and container internationalization attributes for Web service-enabled stateless session beans in the same manner as you do for conventional beans.
3. Manage the internationalization service.

   Use the administrative console to enable the service on all application servers.

   By default, the service is enabled within Java EE client environments but is disabled on application servers. You must enable the service on all application servers hosting your servlets and enterprise beans to use internationalization context.
4. Troubleshoot the internationalization service as needed.

   Use the administrative console to enable the trace service to log internationalization service messages when debugging your applications.

   The trace strings for the internationalization service follow; use both:

   ```
   com.ibm.ws.i18n.context.*=all=enabled:com.ibm.websphere.i18n.context.*=all=enabled
   ```

Internationalization service

In a distributed client-server environment, application processes can run on different machines, configured for different locales, corresponding to different cultural conventions; they can also be located across geographical boundaries. The internationalization service can help manage your application in a globally distributed environment.

For an understanding of how differences in locale impact application development, read “Globalization” on page 527.

Java Platform, Enterprise Edition (Java EE) provides support for application components that run on computers with differing endian architecture and code sets. It does not provide dedicated support for application components that run on computers with different locales or time zones.

The internationalization service addresses the challenges posed by locale and time zone mismatch without incurring the limitations of conventional techniques. The service systematically manages the distribution of internationalization contexts across the various components of EJB applications, including client applications, enterprise beans, and servlets.

The service works by associating an internationalization context with every service request within an application. When a client-side component calls a business method, the internationalization service interposes by obtaining the internationalization context associated with the current client-side process and by attaching that context to the outgoing request. On the server side, the internationalization service again interposes by detaching the context from the incoming request and associating it with the server-side process on which the business method will run, effectively scoping the context to the business method. For HTTP requests, the caller context is constructed from the HTTP attributes and default values. The service propagates internationalization context on subsequent business method invocations in the same manner, which distributes the context of the originating request over the entire chain of business method invocations.

This basic operation of scoping and propagation is defined precisely by *internationalization context management policies*. Internationalization policies specify whether an application component or its hosting Java EE container are to manage internationalization context. For container-managed components, the policy indicates which internationalization context the container scopes to invocations on that component. Server components configured to manage internationalization context, as well as EJB clients, must use the internationalization context API to manage the internationalization context elements scoped to their invocations.

Every application component has a default policy, which can be overridden and tailored for servlets and enterprise beans at assembly time.

At run time, application components can use the internationalization context API to get any element of the internationalization contexts scoped to an invocation. To programmatically access context elements, application components first resolve an internationalization context API reference, then call the appropriate API method to access the various context elements, such as the caller locale or the invocation time zone. These elements can be used in calls to Java SDK internationalization API methods; for example, to perform localizations such as formatting messages, configuring dates, or comparing strings.

Assembling internationalized applications

Perform this task to configure application components for deployment with the internationalization service.

About this task

Use an assembly tool to configure internationalization in the deployment descriptors for servlets and enterprise beans.

Procedure

1. Set the **internationalization type**.

   All servlets and enterprise beans have an internationalization type setting that specifies whether internationalization context is managed by the application component or by its hosting Java Platform, Enterprise Edition (Java EE) container during invocations of their respective life cycle and business methods. The internationalization type can be configured for all server application components except entity beans, which are container-managed only.

   By default, all server components use container-managed internationalization (CMI). The default setting suffices in most cases; when it does not, modify the internationalization type setting by completing the steps that are described in one of the following topics:
   - “Setting the internationalization type for servlets”
   - “Setting the internationalization type for enterprise beans” on page 546
2. Set the **container internationalization attribute**.

   You can associate CMI servlets, and business methods of CMI enterprise beans, with a container internationalization attribute. That attribute specifies which of three internationalization contexts (**Caller**, **Server**, or **Specified**) the container is to scope to an invocation. When running as specified, the container internationalization attribute also specifies the custom internationalization context elements.

   Named container internationalization attributes can be associated with sets of servlets or with sets of Enterprise JavaBeans (EJB) business methods. Initially, CMI servlets and business methods implicitly run as caller and do not associate with a container internationalization attribute. When the implicit behavior or an associated attribute setting is unsuitable, configure an attribute by completing the steps that are described in one of the following topics:
   - “Configuring container internationalization for servlets” on page 545
   - “Configuring container internationalization for enterprise beans” on page 547

Setting the internationalization type for servlets

This task sets the internationalization type for a servlet within a Web module.

Before you begin

This topic assumes that you have an assembly tool such as Rational Application Developer.

For information about assembly, refer to the documentation for your assembly tool. The steps in this topic refer to Rational Application Developer.

This topic assumes that you have started the assembly tool, configured the assembly tool for work on Java Platform, Enterprise Edition (Java EE) modules, and created or imported a dynamic Web project.

Procedure

1. In the Java EE perspective, open the Web project for which you want to set the internationalization type.
   a. Double-click **Dynamic Web Projects**.
   b. Double-click the name of the Web project to see its contents.
   c. Double-click the deployment descriptor object.

   The Web Deployment Descriptor panel is displayed.
2. In the Web Deployment Descriptor panel, click the Servlets tab.
3. Scroll down to **WebSphere Programming Model Extensions** and then **Internationalization**.
4. From the **Servlets and JSPs** list of the Servlets panel, select the servlet for which you want to set the internationalization type.
5. Under **Internationalization**, select a value from the **Internationalization type** list. Valid values are `Application` or `Container`.
6. From the menu bar, click **File > Save**.

Results

The internationalization type setting is assigned to the servlet.

What to do next

If you selected container-managed internationalization, you can then set container-managed internationalization attributes for methods within the servlet. For more information, see "Configuring container internationalization for servlets."

Configuring container internationalization for servlets

This task configures container internationalization for a servlet within a Web module.

Before you begin

This topic assumes that you have an assembly tool such as Rational Application Developer.

For information about assembly, refer to the documentation for your assembly tool. The steps in this topic refer to Rational Application Developer.

This topic assumes that you have started the assembly tool, configured the assembly tool for work on Java Platform, Enterprise Edition (Java EE) modules, and created or imported a dynamic Web project.

You must also have set the internationalization type of one or more servlets in a Web project to `Container`.

About this task

This procedure relates one or more servlets to a container-managed internationalization attribute.

Procedure

1. In the Java EE perspective, open the Web project for which you want to configure container internationalization.
   a. Double-click **Dynamic Web Projects**.
   b. Double-click the name of the Web project to see its contents.
   c. Double-click the deployment descriptor object.

   The Web Deployment Descriptor panel is displayed.
2. In the Web Deployment Descriptor panel, click the Servlets tab.
3. Scroll down to **WebSphere Programming Model Extensions** and then **Internationalization**.
4. Following **Container-managed Internationalization Attribute**, set the **Run As** field by selecting `Caller`, `Server`, or `Specified`.
5. If the servlet is to be run as Specified, select an internationalization policy from the **Specified** list or define a new policy.
   a. To define an internationalization policy, click **New**. The New Specified Initialization wizard is displayed.
   b. In the **Description** field, give the policy a name.
   c. If needed, set a time zone ID and add a time zone description. If you do not find the appropriate time zone in the ID list, click **Customize** to define one relative to Greenwich Mean Time (GMT).
   d. Create at least one locale for the policy. To create a locale, click **Add**; select a language and (optional) geographic region; specify a variant as needed. Add a locale description and click **OK** to finish. The new locale is added to the **Locales** list.
   e. If more than one locale is defined for the policy, select a locale from the **Locales** list and click **Finish**. Otherwise, just click **Finish**
6. From the menu bar, click **File > Save**.

Results

Selected servlets are now configured to run under the associated internationalization settings.

Setting the internationalization type for enterprise beans

This task sets the internationalization type for an enterprise bean within an Enterprise JavaBeans (EJB) module.

Before you begin

This topic assumes that you have an assembly tool such as Rational Application Developer.

For information about assembly, refer to the documentation for your assembly tool. The steps in this topic refer to Rational Application Developer.

This topic assumes that you have started the assembly tool, configured the assembly tool for work on Java Platform, Enterprise Edition (Java EE) modules, and created or imported an EJB project.

About this task

Container-managed internationalization (CMI) is the default type; entity beans cannot be set to application-managed internationalization (AMI). Use CMI also for stateless session beans that are enabled for Web services.

Procedure

1. In the Java EE perspective, open the EJB project for which you want to set the internationalization type.

a. Double-click **EJB Projects**.
b. Double-click the name of the EJB project to see its contents.
c. Double-click the deployment descriptor object.

The EJB Deployment Descriptor panel is displayed.

2. In the EJB Deployment Descriptor panel, click the Internationalization tab. Any enterprise beans that are already configured for AMI are displayed in the **Internationalization type** list.
3. To set the internationalization type for any other enterprise beans to AMI, click **Add** following the **Internationalization type** list. The Internationalization Type wizard opens. Only message-driven or session beans can be selected.
4. Select the beans that you want to set and click **Finish** to exit the wizard.
5. From the menu bar, click **File > Save**.

Results

The internationalization type is assigned to the bean.

What to do next

For beans that use container-managed internationalization, you can then set container-managed internationalization attributes. For more information, see "Configuring container internationalization for enterprise beans."

Configuring container internationalization for enterprise beans

This task configures container internationalization for enterprise bean business methods.

Before you begin

This topic assumes that you have an assembly tool such as Rational Application Developer.

For information about assembly, refer to the documentation for your assembly tool. The steps in this topic refer to Rational Application Developer.

This topic assumes that you have started the assembly tool, configured the assembly tool for work on Java Platform, Enterprise Edition (Java EE) modules, and created or imported an EJB project.

You must also have one or more enterprise beans set to container-managed internationalization (CMI) by default.

About this task

This procedure relates one or more business methods to one or more container-managed internationalization (CMI) attributes. Use this procedure also for stateless session beans that are enabled for Web services.

Procedure

1. In the Java EE perspective, open the EJB project for which you want to configure container internationalization.
   a. Double-click **EJB Projects**.
   b. Double-click the name of the EJB project to see its contents.
   c. Double-click the deployment descriptor object.

   The EJB Deployment Descriptor panel is displayed.

2. In the EJB Deployment Descriptor panel, click the Internationalization tab. Any business methods that are already configured are displayed in the **Internationalization attributes** list.
3. To configure a CMI business method, click **Add** following the **Internationalization attributes** list. The Internationalization Attributes wizard opens.
4. Set the **Run As** field by selecting `Caller`, `Server`, or `Specified`. Add a meaningful description. As a group, the CMI attribute settings comprise an internationalization policy.
   - The description appears as `Internationalization` *`description`* (*`runAsSetting`*) in the **Internationalization attributes** list when you are finished.
   - If you do not provide a description, the policy name appears as `Internationalization` (*`runAsSetting`*).

   If the bean is to be run as Specified, complete the following steps to specify the context elements that the container scopes to bean method invocations.
   a. Set a time zone ID and add a time zone description as needed. If you do not find the appropriate time zone in the ID list, click **Custom** to define one relative to Greenwich Mean Time (GMT).
   b. Set a locale. Select a language and (optional) geographic region; specify a variant as needed. Add a locale description as needed and click **OK** to finish.
5. Click **Next**.
6. Select the beans for which you want to configure method-level internationalization attributes and click **Next**.
7. Select the methods that you want to configure and click **Next**. A check box is displayed next to each method name that you select.
   - Click **Apply to All** to place a check box next to the displayed bean name.
   - Click **Select Beans** to select more beans with CMI.
8. Click **Finish** to exit the wizard.
9. From the menu bar, click **File > Save**.

Results

The bean methods are now configured to run under the associated internationalization settings.

Using the internationalization context API

Enterprise JavaBeans (EJB) client applications, servlets, and enterprise beans can programmatically obtain and manage internationalization context using the internationalization context API. For Web service client applications, you use the API to obtain and manage internationalization context in the same manner as for EJB clients.

Before you begin

The java.util and com.ibm.websphere.i18n.context packages contain all of the classes necessary to use the internationalization service within an EJB application.

Procedure

1. Gain access to the internationalization context API.

   Resolve internationalization context API references once over the life cycle of an application component, within the initialization method of that component (for example, within the init method of servlets, or within the SetXxxContext method of enterprise beans). For Web service client programs, resolve a reference to the internationalization context API during initialization. For stateless session beans enabled for Web services, resolve the reference in the setSessionContext method.
2. Access caller locales and time zones.

   Every remote invocation of an application component has an associated caller internationalization context associated with the thread that is running that invocation. A caller context is propagated by the

internationalization service and middleware to the target of a request, such as an Enterprise JavaBeans (EJB) business method or servlet service method. This task also applies to Web service client programs.

3. Access invocation locales and time zones.

   Every remote invocation of a servlet service or Enterprise JavaBeans (EJB) business method has an invocation internationalization context associated with the thread that is running that invocation. Invocation context is the internationalization context under which servlet and business method implementations run; it is propagated on subsequent invocations by the internationalization service and middleware. This task also applies to Web service client programs.

Results

The resulting components are said to use *application-managed internationalization* (AMI). For more information about AMI, see “Internationalization context: Management policies” on page 564.

Example

Each supported application component uses the internationalization context API differently. Code examples are provided that illustrate how to use the API within each component type. Differences in API usage, as well as other coding tips, are noted in comments that precede the relevant statement blocks.

- Managing internationalization context in an EJB client program
- Managing internationalization context in a servlet
- Managing internationalization context in a session bean
- Representing internationalization context in a SOAP header

Managing internationalization context in an EJB client program: The following code example illustrates how to use the internationalization context API within a contained EJB client program or Web service client program.

```
//----------------------------------------
// Basic Example: J2EE EJB client.
//----------------------------------------
package examples.basic;

//----------------------------------------
// INTERNATIONALIZATION SERVICE: Imports.
//----------------------------------------
import com.ibm.websphere.i18n.context.UserInternationalization;
import com.ibm.websphere.i18n.context.Internationalization;
import com.ibm.websphere.i18n.context.InvocationInternationalization;

import javax.naming.InitialContext;
import javax.naming.Context;
import javax.naming.NamingException;
import java.util.Locale;
import java.util.SimpleTimeZone;

public class EjbClient {

  public static void main(String args[]) {

    //------------------------------------------------
    // INTERNATIONALIZATION SERVICE: API references.
    //------------------------------------------------
    UserInternationalization userI18n = null;
    Internationalization callerI18n = null;
    InvocationInternationalization invocationI18n = null;

    //------------------------------------------------
    // INTERNATIONALIZATION SERVICE: JNDI name.
```

```
  //-------------------------------------------------
  final String UserI18NUrl =
      "java:comp/websphere/UserInternationalization";

  //-------------------------------------------------
  // INTERNATIONALIZATION SERVICE: Resolve the API.
  //-------------------------------------------------
  try {
   Context initialContext = new InitialContext();
   userI18n = (UserInternationalization)initialContext.lookup(
       UserI18NUrl);
   callerI18n = userI18n.getCallerInternationalization();
   invI18n = userI18n.getInvocationInternationalization ();
  } catch (NamingException ne) {
    log("Error: Cannot resolve UserInternationalization: Exception: " + ne);
  } catch (IllegalStateException ise) {
    log("Error: UserInternationalization is not available: " + ise);
  }
  ...

  //-------------------------------------------------------------------
  // INTERNATIONALIZATION SERVICE: Set invocation context.
  //
  // Under Application-managed Internationalization (AMI), contained EJB
  // client programs may set invocation context elements. The following
  // statements associate the supplied invocation locale and time zone
  // with the current thread. Subsequent remote bean method calls will
  // propagate these context elements.
  //-------------------------------------------------------------------
  try {
    invocationI18n.setLocale(new Locale("fr", "FR", ""));
    invocationI18n.setTimeZone("ECT");
  } catch (IllegalStateException ise) {
    log("An anomaly occurred accessing Invocation context: " + ise );
  }
  ...

  //-------------------------------------------------------------------
  // INTERNATIONALIZATION SERVICE: Get locale and time zone.
  //
  // Under AMI, contained EJB client programs can get caller and
  // invocation context elements associated with the current thread.
  // The next four statements return the invocation locale and time zone
  // associated above, and the caller locale and time zone associated
  // internally by the service. Getting a caller context element within
  // a contained client results in the default element of the JVM.
  //-------------------------------------------------------------------
  Locale invocationLocale = null;
  SimpleTimeZone invocationTimeZone = null;
  Locale callerLocale = null;
  SimpleTimeZone callerTimeZone = null;
  try {
    invocationLocale = invocationI18n.getLocale();
    invocationTimeZone =
        (SimpleTimeZone)invocationI18n.getTimeZone();
    callerLocale = callerI18n.getLocale();
    callerTimeZone = SimpleTimeZone)callerI18n.getTimeZone();
  } catch (IllegalStateException ise) {
    log("An anomaly occurred accessing I18n context: " + ise );
  }

  ...
} // main

...
```

```
  void log(String s) {
    System.out.println (((s == null) ? "null" : s));
  }
} // EjbClient
```

Managing internationalization context in a servlet: The following code example illustrates how to use the internationalization context API within a servlet. Note comments in the init and doPost methods.

```
...
//------------------------------------------------------------------
// INTERNATIONALIZATION SERVICE: Imports.
//------------------------------------------------------------------
import com.ibm.websphere.i18n.context.UserInternationalization;
import com.ibm.websphere.i18n.context.Internationalization;
import com.ibm.websphere.i18n.context.InvocationInternationalization;

import javax.naming.InitialContext;
import javax.naming.Context;
import javax.naming.NamingException;
import java.util.Locale;

public class J2eeServlet extends HttpServlet {

  ...
  //------------------------------------------------------------------
  // INTERNATIONALIZATION SERVICE: API references.
  //------------------------------------------------------------------
  protected UserInternationalization userI18n = null;

  }
} // CLASS J2EESessionBean
```

Representing internationalization context in a SOAP header: This code example illustrates how internationalization context is represented within the SOAP header of a Web service request.

```
<InternationalizationContext>
   <Locales>
      <Locale>
         <LanguageCode>ja</LanguageCode>
         <CountryCode>JP</CountryCode>
         <VariantCode>Nihonbushi</VariantCode>
      </Locale>
      <Locale>
         <LanguageCode>fr</LanguageCode>
         <CountryCode>FR</CountryCode>
      </Locale>
      <Locale>
         <LanguageCode>en</LanguageCode>
         <CountryCode>US</CountryCode>
      </Locale>
   </Locales>
   <TimeZoneID>JST</TimeZoneID>
</InternationalizationContext>
```

This representation is valid against the following schema:

```
<?xml version="1.0" encoding="UTF-8"?>
<xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema">
    <xsd:element name="InternationalizationContext"
                 type="InternationalizationContextType">
    </xsd:element>

    <xsd:complexType name="InternationalizationContextType">
```

```
        <xsd:sequence>
            <xsd:element name="Locales"
                         type="LocalesType">
            </xsd:element>
            <xsd:element name="TimeZoneID"
                         type="xsd:string">

                         maxOccurs="1">
            </xsd:element>
         </xsd:sequence>
    </xsd:complexType>

</xsd:schema>
```

Gaining access to the internationalization context API

Perform this task to access the internationalization service by resolving a reference to the internationalization context API.

About this task

Resolve internationalization context API references once over the life cycle of an application component, within the initialization method of that component (for example, within the init method of servlets, or within the SetXxxContext method of enterprise beans). For Web service client programs, resolve a reference to the internationalization context API during initialization. For stateless session beans enabled for Web services, resolve the reference in the setSessionContext method.

Procedure

1. Resolve a reference to the UserInternationalization interface by performing a lookup on the Java Naming and Directory Interface (JNDI) name `java:comp/websphere/UserInternationalization`. For example:

```
//---------------------------------------------------------------------
// Internationalization context imports.
//---------------------------------------------------------------------
import com.ibm.websphere.i18n.context.*;
import javax.naming.*;
```

```
...

public class MyApplication {
  ...

  //------------------------------------------------------------------
  // Resolve a reference to the UserInternationalization interface.
  //------------------------------------------------------------------
  InitialContext initCtx = null;
  UserInternationalization userI18n = null;
  final String UserI18nUrl = "java:comp/websphere/UserInternationalization";
  try {
    initCtx = new InitialContext();
    userI18n = (UserInternationalization)initCtx.lookup(UserI18nUrl);
  }
  catch (NamingException ne) {
    // UserInternationalization URL is unavailable.
  }
```

If the UserInternationalization object is unavailable because of an anomaly or a restriction, the JNDI lookup invocation issues a javax.naming.NameNotFoundException exception that contains the java.lang.IllegalStateException instance.

2. Use the UserInternationalization reference to create references to the CallerInternationalization or InvocationInternationalization objects, which provide access to elements of the Caller or Invocation internationalization contexts, respectively. The CallerInternationalization reference can be bound to the Internationalization interface only; the InvocationInternationalization reference can be bound to either the Internationalization or the InvocationInternationalization interfaces, depending on whether the application requires read-only or read-write access to the invocation context. For example:

```
  ...
  //------------------------------------------------------------------
  // Resolve references to the Internationalization and
  // InvocationInternationalization interfaces.
  //------------------------------------------------------------------
  Internationalization callerI18n = null;
  InvocationInternationalization invocationI18n = null;
  try {
    callerI18n = userI18n.getCallerInternationalization();
    invocationI18n = userI18n.getInvocationInternationalization();
  }
  catch (IllegalStateException ise) {
    // An Internationalization interface(s) is unavailable.
  }
```

Accessing caller locales and time zones

Perform this task to access elements of the caller internationalization context.

Before you begin

An application component must first resolve a reference to the CallerInternationalization object and then bind it to the Internationalization interface.

About this task

Every remote invocation of an application component has an associated caller internationalization context associated with the thread that is running that invocation. A caller context is propagated by the internationalization service and middleware to the target of a request, such as an Enterprise JavaBeans (EJB) business method or servlet service method. This task also applies to Web service client programs.

Procedure

1. Obtain the desired caller context elements.

```
java.util.Locale [] myLocales  = null;
try {
  myLocales  = callerI18n.getLocales();
}
catch (IllegalStateException ise) {
  // The Caller context is unavailable;
  // is the service started and enabled?
}
...
```

The Internationalization interface contains the following methods to get caller internationalization context elements:

- **Locale [] getLocales()** Returns the list of caller locales that are associated with the current thread.
- **Locale getLocale()** Returns the first in the list of caller locales that are associated with the current thread.
- **TimeZone getTimeZone()** Returns the SimpleTimeZone caller that is associated with the current thread.

The Internationalization interface supports read-only access to internationalization context within application components. Methods of the Internationalization interface are available to all EJB application components and are used in the same manner for each, but the method semantics vary according to the component type. For instance, when obtaining the caller locale within an EJB client application, the interface returns the default locale of the host Java virtual machine (JVM); in contrast, when obtaining caller context within a servlet service method (for example, doPost or doGet methods), the interface returns the first locale (accept-language) propagated within the corresponding HTML request. See Internationalization context for a discussion of how the service propagates internationalization context throughout an application.

2. Use the caller context elements to localize computations under a locale or time zone of the calling process.

```
DateFormat df = DateFormat.getDateInstance(myLocale);
String localizedDate = df.getDateInstance().format(aDateInstance);
...
```

Accessing invocation locales and time zones

Perform this task to access elements of the invocation internationalization context.

Before you begin

An application component must first resolve a reference to the InvocationInternationalization object and then bind it to the InvocationInternationalization interface of the internationalization context API.

About this task

Every remote invocation of a servlet service or Enterprise JavaBeans (EJB) business method has an invocation internationalization context associated with the thread that is running that invocation. Invocation context is the internationalization context under which servlet and business method implementations run; it is propagated on subsequent invocations by the internationalization service and middleware. This task also applies to Web service client programs.

Procedure

1. Obtain the desired invocation context elements.

```
java.util.Locale myLocale;
try {
  myLocale = invocationI18n.getLocale();
}
catch (IllegalStateException ise) {
  // The invocation context is unavailable;
  // is the service started and enabled?
}
...
```

The InvocationInternationalization interface contains the following methods to both get and set invocation internationalization context elements:

- **Locale [] getLocales()**. Returns the list of invocation locales that is associated with the current thread.
- **Locale getLocale()**. Returns the first in the list of invocation locales that is associated with the current thread.
- **TimeZone getTimeZone()**. Returns the SimpleTimeZone invocation that is associated with the current thread.
- **setLocales(Locale [])**. Sets the list of invocation locales that are associated with the current thread to the supplied list.
- **setLocale(Locale)**. Sets the list of invocation locales that are associated with the current thread to a list that contains the supplied locale.
- **setTimeZone(TimeZone)**. Sets the invocation time zone that is associated with the current thread to the supplied SimpleTimeZone.
- **setTimeZone(String)**. Sets the invocation time zone that is associated with the current thread to a SimpleTimeZone that has the supplied ID.

The InvocationInternationalization interface supports read and write access to invocation internationalization context within application components. However, according to internationalization context management policies, only components configured to manage internationalization context (application-managed internationalization, or AMI, components) have write access to invocation internationalization context elements. Calls to set invocation context elements within container-managed internationalization (CMI) application components result in a java.lang.IllegalStateException exception. Any differences in how application components can use InvocationInternationalization methods are explained in Internationalization context.

2. Use the invocation context elements to localize a computation under a locale or time zone of the calling process.

```
DateFormat df = DateFormat.getDateInstance(myLocale);
  String localizedDate = df.getDateInstance().format(aDateInstance);
  ...
```

Example

In the following code example, locale (en,GB) and simple time zone (GMT) transparently propagate on the call to the myBusinessMethod method. Server-side application components, such as `myEjb`, can use the InvocationInternationalization interface to obtain these context elements.

```
...
//--------------------------------------------------------------------
// Set the invocation context under which the business method or
// servlet will run and propagate on subsequent remote business
// method invocations.
//--------------------------------------------------------------------
try {
  invocationI18n.setLocale(new Locale("en", "GB"));
  invocationI18n.setTimeZone(SimpleTimeZone.getTimeZone("GMT"));
}
catch (IllegalStateException ise) {
  // Is the component CMI; is the service started and enabled?
}
myEjb.myBusinessMethod();
```

Within CMI application components, the Internationalization and InvocationInternationalization interfaces are semantically equivalent. You can use either of these interfaces to obtain the context associated with the thread on which that component is running. For instance, both interfaces can be used to obtain the list of locales propagated to the servlet doPost service method.

Internationalization context API: Programming reference

Application components programmatically manage internationalization context through the UserInternationalization, Internationalization, and InvocationInternationalization interfaces in the com.ibm.websphere.i18n.context package.

The following code example introduces the internationalization context API:

```
public interface UserInternationalization {
  public Internationalization getCallerInternationalization();
  public InvocationInternationalization
  getInvocationInternationalization();
}

public interface Internationalization {
  public java.util.Locale[] getLocales();
  public java.util.Locale getLocale();
  public java.util.TimeZone getTimeZone();
}

public interface InvocationInternationalization
    extends Internationalization {
  public void setLocales(java.util.Locale[] locales);
  public void setLocale(java.util.Locale jmLocale);
  public void setTimeZone(java.util.TimeZonetimeZone);
  public void setTimeZone(String timeZoneId);
}
```

UserInternationalization interface

The UserInternationalization interface provides factory methods for obtaining references to the CallerInternationalization and InvocationInternationalization context objects. Use these references to access elements of the caller and invocation contexts correlated to the current thread.

Methods of the UserInternationalization interface:

Internationalization getCallerInternationalization()
: Returns a reference implementing the Internationalization interface that supports access to elements of the caller internationalization context correlated to the current thread. If the service is disabled, this method issues an IllegalStateException exception.

InvocationInternationalization getInvocationInternationalization()
: Returns a reference implementing the InvocationInternationalization interface. If the service is disabled, this method issues an IllegalStateException exception.

Internationalization interface

The Internationalization interface declares methods that provide read-only access to internationalization context. Given a caller or invocation internationalization context object created with the UserInternationalization interface, bind the object to the Internationalization interface to get elements of that context type. Observe that caller internationalization context can be accessed only through this interface.

Methods of the Internationalization interface:

Locale[] getLocales()
: Returns the chain of locales within the internationalization context (object) that is bound to the interface, provided the chain is not null; otherwise this method returns a chain of length(1) containing the default locale of the Java virtual machine (JVM).

Locale getLocale()
: Returns the first in the chain of locales within the internationalization context (object) that is bound to the interface, provided the chain is not null; otherwise this method returns the default locale of the JVM.

TimeZone getTimeZone()

Returns the caller time zone (that is, the SimpleTimeZone instance) that is associated with the current thread, provided the time zone is non-null; otherwise this method returns the process time zone.

InvocationInternationalization interface

The InvocationInternationalization interface declares methods that provide read and write access to InvocationInternationalization context. Given an invocation internationalization context object created with the UserInternationalization interface, bind the object to the InvocationInternationalization interface to get and set elements of the invocation context.

According to the container-managed internationalization (CMI) policy, all set methods, setXxx(), issue an IllegalStateException exception when called within a CMI servlet or enterprise bean.

Methods of the InvocationInternationalization interface:

void setLocales(java.util.Locale[] locales)

Sets the chain of locales to the supplied chain, *locales*, within the invocation internationalization context. The supplied chain can be null or have length(>= 0). When the supplied chain is null or has length(0), the service sets the chain of invocation locales to an array of length(1) containing the default locale of the JVM. Null entries can exist within the supplied locale list, for which the service substitutes the default locale of the JVM on remote invocations.

void setLocale(java.util.Locale locale)

Sets the chain of locales within the invocation internationalization context to an array of length(1) containing the supplied locale, *locale*. The supplied locale can be null, in which case the service instead sets the chain to an array of length(1) containing the default locale of the JVM.

void setTimeZone(java.util.TimeZone timeZone)

Sets the time zone within the invocation internationalization context to the supplied time zone, *time zone*. If the supplied time zone is not an exact instance of java.util.SimpleTimeZone or is null, the service sets the invocation time zone to the default time zone of the JVM instead.

void setTimeZone(String timeZoneId)

Sets the time zone within the invocation internationalization context to the java.util.SimpleTimeZone having the supplied ID, *timeZoneId*. If the supplied time zone ID is null or invalid (that is, the ID is not displayed in the list of IDs returned by the java.util.TimeZone.getAvailableIds method) the service sets the invocation time zone to the simple time zone having an ID of GMT, an offset of 00:00, and otherwise invalid fields.

Internationalization context:

An *internationalization context* is a distributable collection of internationalization information containing an ordered list, or chain, of locales and a single time zone, where the locales and time zone are instances of the java.util.Locale and java.util.TimeZone Java SDK types, respectively. A locale chain is ordered according to the user's preference.

The internationalization service manages and makes available two varieties of internationalization context: the *caller context*, which represents the caller's localization environment, and the *invocation context*, which represents the localization environment under which a business method runs. Server application components use elements of the caller and invocation internationalization contexts to appropriately tailor locale-sensitive and time zone-sensitive computations.

The internationalization service does not support time zone types other than the java.util.SimpleTimeZone type that is found in the Java SDK. Unsupported time zone types silently map to the default time zone of the JVM when supplied to internationalization context API methods. For a complete description of the java.util.Locale, java.util.TimeZone and java.util.SimpleTimeZone types, refer the Java SDK API documentation.

Caller context

Caller internationalization context contains the locale chain and time zone received on incoming EJB business method and servlet service method invocations; it is the internationalization context propagated from the calling process. Use caller context elements within server application components to localize computations to the calling component. Caller context is read-only and can be accessed by all application components by using the Internationalization interface of the internationalization context API.

Caller context is computed in the following manner: On an EJB business method or servlet service method invocation, the internationalization service extracts the internationalization context from the incoming request and scopes this context to the method as the caller context. For any missing or null context element, the service inserts the corresponding default element of the JVM (for example, java.util.Locale.getDefault() or java.util.TimeZone.getDefault().) The service performs a similar insertion whenever missing or null Caller context elements are encountered on invocations of stateless session beans that are enabled for Web services.

Formally, caller context is the invocation context of the calling business method or application component.

Invocation context

Invocation internationalization context contains the locale chain and time zone under which EJB business methods and servlet service methods run. It is managed by either the hosting container or the application component, depending on the applicable internationalization policy. On outgoing business method requests, it is the context that propagates to the target process. Use invocation context elements to localize computations under the specified settings of the current application component.

Invocation context is computed in the following manner: On an incoming business method or servlet service method invocation, the internationalization service queries the associated context management policy. If the policy is container-managed internationalization (CMI), the container scopes the context designated by the policy to the invocation; otherwise the policy is application-managed internationalization (AMI), and the container scopes an empty context to the invocation that can be altered by the method implementation.

Application components can access invocation context elements through both the Internationalization and InvocationInternationalization interfaces of the internationalization context API. Invocation context elements can be set (overwritten) under the application-managed internationalization policy only.

On an outgoing business method request, the service obtains the currently scoped invocation context and attaches it to the request. This outgoing exported context becomes the caller context of the target invocation. When supplying invocation context elements, either for export on outgoing requests or through the API, the internationalization service always provides the most recent element set using the API; the service also supplies the corresponding default element of the JVM for any null invocation context element.

Because the internationalization context that is propagated over Web services (SOAP) requests contains a time zone ID rather than the entire state of a java.lang.SimpleTimeZone object, time zone information might be lost when a Web service-enabled client program or session bean becomes involved in remote business computation.

Internationalization context: Propagation and scope:

The scope of internationalization context is implicit. Every Enterprise JavaBeans (EJB) client application, servlet service method, and EJB business method call has two internationalization contexts under which it runs.

For each application component call, the container enters the caller context and the call context, as indicated by the pertinent internationalization policy, into scope before the container delegates to the actual implementation. When the implementation returns, the service removes these contexts from scope. The internationalization service supplies no programmatic mechanism for components to explicitly manage the scope of internationalization context.

The service scopes internationalization context differently with respect to application component type:
- "EJB client programs (contained)"
- "Servlets"
- "Enterprise beans"
- "Web service client programs (contained)" on page 563
- "Stateless session beans that are enabled for Web services" on page 563

Internationalization context observes by-value semantics over remote method requests. Changes to internationalization context elements that are scoped to a call do not affect the corresponding elements of the internationalization context that is scoped to the remote calling process. Also, modifications to context elements obtained using the internationalization context API do not affect the corresponding elements that are scoped to the invocation.

EJB client programs (contained)

Before it calls the main method of a client program, the Java EE client container introduces into scope invocation and caller internationalization some contexts that contain null elements. These contexts remain in scope throughout the life of the program. EJB client programs are the base in a chain of remote business method invocations and, technically, do not have a logical caller context. Accessing a caller context element yields the corresponding default element of the client JVM. On outgoing EJB business method requests, the internationalization service propagates the invocation context to the target process. Any unset (null) invocation context elements are replaced with the default of the JVM when exported by the internationalization context API or by outgoing requests.

Tip:

> To propagate values other than the JVM defaults to remote business methods, EJB client programs, as well as AMI servlets or enterprise beans, must set (override) elements of the invocation context. To learn how to set invocation context elements, see "Accessing invocation locales and time zones" on page 557.

Servlets

On every servlet service method (doGet or doPost) invocation, the Java EE Web container introduces caller and invocation internationalization contexts into scope before delegating to the service method implementation. The caller context contains the accept-languages propagated in the HTTP servlet request, typically from a Web browser. The invocation context contains whichever context is indicated by the container internationalization attribute of the internationalization policy that is associated with the servlet. Any unset (null) invocation context elements are replaced with the default of the server JVM when exported by the internationalization context API or by outgoing requests. The caller and invocation contexts remain effective until immediately after the implementation returns, at which time the container removes them from scope.

Enterprise beans

On every EJB business method invocation, the Java EE EJB container introduces caller and invocation internationalization contexts into scope before delegating to the business method implementation. The caller context contains the internationalization context elements imported from the incoming IIOP request; if the incoming request lacks a particular internationalization context element, the container scopes a null

element. The invocation context contains whichever context is indicated by the container internationalization attribute of the internationalization policy that is associated with the business method.

On outgoing EJB business method requests, the service propagates the invocation context to the target process. Any unset (null) invocation context elements are replaced with the default of the server JVM when exported by the internationalization context API or by outgoing requests. The caller and invocation contexts remain effective until immediately after the implementation returns, when the container removes them from scope.

Consider a simple EJB application with a Java client that calls the remote myBeanMethod bean method. On the client side, the application can use the Internationalization Service API to set invocation context elements. When the client calls myBeanMethod(), the service exports the client invocation context to the outgoing request. On the server side, the service detaches the imported context from the incoming request and scopes it to the method as its caller context; the service also scopes the invocation context to the method as indicated by the associated internationalization context management policy. The EJB container then calls the myBeanMethod method, which can use the internationalization context API to access elements of either the caller or invocation contexts. When the myBeanMethod method returns, the EJB container removes these contexts from scope.

Web service client programs (contained)

Before it calls the main method of a Web service client program, the client container introduces into scope both invocation and caller internationalization contexts that contain null elements. These contexts remain in scope throughout the duration of the program. Web service client programs are the base in a chain of remote business method invocations and, technically, do not have a logical caller context. Accessing a Caller context element yields the corresponding default element of the client virtual machine.

On outgoing Web service requests, the internationalization service transparently creates a SOAP header block that contains the invocation context that is associated with the current thread; the SOAP representation of invocation context is propagated through the request to the target process. Any unset (that is, null) invocation context elements are replaced with the default element of the JVM when exported by the internationalization context API or by outgoing requests. Also, because the header contains only a time zone ID, the additional state of the time zone object (java.lang.SimpleTimeZone) of the invocation context might be lost, because it does not get propagated through the request.

Tip:

> To propagate values other than the JVM defaults to remote business methods, Web service client programs, as well as AMI servlets or enterprise beans, must set (override) elements of the invocation context. For more information, see “Accessing invocation locales and time zones” on page 557.

Stateless session beans that are enabled for Web services

On every method invocation of a Web service-enabled bean, the EJB container introduces caller and invocation internationalization contexts into scope before delegating control to the business method implementation. The caller context contains the internationalization context elements that are imported from the SOAP header block of the incoming request. If the incoming request lacks a particular internationalization context element, the container introduces a null element into scope. The invocation context contains whichever context is indicated by the container internationalization attribute of the internationalization policy that is associated with the business method.

On outgoing EJB business method requests, the service propagates the invocation context to the target process. Any unset (that is, null) invocation context elements are replaced with the default element of the server JVM when exported by the internationalization context API or by outgoing requests. The caller and invocation contexts remain effective until immediately after control returns from the business method implementation, at which time the container removes them from scope.

On outgoing Web service requests, the internationalization service transparently creates a SOAP header block that contains the invocation context associated with the current thread. The SOAP representation of the invocation context is propagated through the request to the target process. Any unset (that is, null) invocation context elements are replaced with the default element of the JVM when exported by the internationalization context API or by outgoing requests.

Thread association considerations

The Web and EJB containers scope internationalization contexts to a method by associating the method with the thread that run the method implementation. Similarly, methods of the internationalization context API either associate context with, or obtain context associated with, the thread on which these methods run.

In cases where new threads are spawned within an application component (for instance, a user-generated thread inside the service method of a servlet, or a system-generated event handling thread in an AWT client) the internationalization contexts associated with the parent thread does not automatically transfer to the newly-spawned thread. In such instances, the service exports the default locale and time zone of the JVM on any remote business method request and on any API calls that run on the new thread.

If the default context is inappropriate, the desired invocation context elements must be explicitly associated to the new thread by using the setXxx methods of the InvocationInternationalization interface. Currently, internationalization context management policies enable invocation context to be set within EJB client programs, as well as within servlets, session beans, and message-driven beans that use application-managed internationalization.

Internationalization context: Management policies:

Internationalization policies prescribe how Java EE application components or their hosting containers manage internationalization context on component invocations. Two internationalization context management policies apply to all component types: Application-managed internationalization (AMI) and Container-managed internationalization (CMI).

These policies are represented in two parts:
- Internationalization type
- Container internationalization attribute

The service defines a default, or implicit, internationalization policy for every application component type. At development time, assemblers can override the default policy for server component types by explicitly configuring their internationalization type, and optional container internationalization attributes. Policies configured during assembly are preserved in the deployment descriptor for the application.

All components have an internationalization type that indicates whether it is AMI or CMI; that is, whether a component is to deploy under the application-managed or the container-managed internationalization policy. Application assemblers can set the internationalization type for servlets, session beans, and message-driven beans. Entity beans are implicitly CMI and EJB clients are implicitly AMI; neither can be configured otherwise.

For CMI servlets and enterprise beans, optional container internationalization attributes can be specified to indicate which invocation internationalization context the container is to scope to service or business methods. A CMI service or business method invocation can run under the context of the caller's process, under the default context of the server JVM, or under a custom context specified in the attribute. Assemblers can specify one container internationalization attribute per disjoint set of CMI servlets within a Web module, or one Attribute per disjoint set of business methods of CMI beans within an EJB module. A container internationalization attribute can be associated with more than one method, but a method cannot be associated with more than one attribute.

When an application server launches an application, the internationalization service collects policy information from the deployment descriptor, then uses this information to construct and associate an internationalization policy to every component invocation. A policy is denoted as:

```
[<Internationalization Type>,<Container Internationalization Attribute>]
```

Several cases exist in which the deployment descriptor seems to lack policy information, for example: EJB client applications have no configurable internationalization policy settings; AMI components do not have container internationalization attributes; and you are not required to specify container internationalization attributes for CMI components. When the service cannot obtain the explicit internationalization type and container attribute settings from a well-formed deployment descriptor, it implicitly inserts the appropriate setting into the policy.

The service observes the following conventions when applying policies to invocations:

- Servlets (service) and EJB business methods lacking all internationalization policy information in the deployment descriptor implicitly run under policy `[CMI,RunAsCaller]`.
- CMI servlets and business methods lacking a container internationalization attribute in the deployment descriptor implicitly run under policy `[CMI,RunAsCaller]`.
- AMI servlets and business methods always lack container internationalization attributes in the deployment descriptor, but implicitly run under the logical policy `[AMI,RunAsServer]`.
- EJB clients always lack internationalization policy information in the deployment descriptor. By definition, EJB clients are implicitly AMI types and run under the invocation context of the JVM; they run under the logical policy `[AMI,RunAsServer]`.

For conditions other than these cited examples, such as a malformed deployment descriptor, refer to Internationalization service errors.

Internationalization policies for EJB clients and HTTP clients cannot be configured; HTTP clients do, however, run under the language priority settings of the hosting Web browser. These settings are configurable under the options dialog of most Web browsers. Refer to your Web browser documentation for details.

Internationalization type:

Every server application component has an *internationalization type* setting that indicates whether the invocation internationalization context is managed by the component or by the hosting Java EE container.

Server application components can be deployed to use one of two types of internationalization context management:

- Application-managed internationalization (AMI)
- Container-managed internationalization (CMI)

A server component can be deployed as AMI or CMI, but not both; CMI is the default. The setting applies to the entire component on every invocation. Entity beans use CMI only. Enterprise JavaBeans (EJB) client applications do not have an internationalization type setting; they implicitly use AMI.

Application-managed internationalization

Under the AMI deployment policy, component developers assume complete control over the invocation internationalization context. AMI components can use the internationalization context API to programmatically set invocation context elements.

AMI components are expected to manage invocation context. Invocations of AMI components implicitly run under the default locale and time zone of the hosting JVM. Invocation context elements not set using the API default to the corresponding elements of the JVM when accessed through the API or when exported on business methods. To export context elements other than the JVM defaults, AMI servlets, AMI enterprise beans, and EJB client applications must set (overwrite) invocation elements using the

internationalization context API. Moreover, the container logically suspends the caller context that is imported on the AMI servlet lifecycle method and AMI EJB business method invocations. To continue propagating the context of the calling process, AMI servlets and enterprise beans must use the API to transfer caller context elements to the invocation context.

Specify AMI for server components that have internationalization context management requirements that are not supported by container-managed internationalization (CMI).

Container-managed internationalization

CMI is the preferred internationalization context management policy for server application components; it is also the default policy. Under CMI, the internationalization service collaborates with the Web and EJB containers to set the invocation internationalization context for servlets and enterprise beans. The service sets invocation context according to the container internationalization attribute of the policy that is associated with a servlet (service method) or an EJB business method.

A CMI policy has a container internationalization attribute that indicates which internationalization context the container is to scope to an invocation. For details, see Container internationalization attributes. By default, invocations of CMI components run under the caller's internationalization context; or rather, they adhere to the implicit policy `[CMI,RunasCaller]` whenever the servlet or business is not associated with an attribute in the deployment descriptor. For complete details, see Internationalization context: Management policies.

Methods within CMI components can obtain elements of the invocation context using the internationalization context API, but cannot set them. Any attempt to set invocation context elements within CMI components results in a java.lang.IllegalStateException exception.

Specify container-managed internationalization for server application components that require standard internationalization context management. Then specify the container internationalization attributes for CMI servlets and for business methods of CMI enterprise beans that you do not want to run under the caller's internationalization context.

Container internationalization attributes:

The internationalization policy of every CMI servlet and EJB business method has a *container internationalization attribute* that specifies which internationalization context the container is to scope to its invocation.

The container internationalization attribute has three main fields:
- Run as
- Locales
- Time zone ID

As a convenience, you can create named container internationalization attributes and associate them to the following subsets:
- CMI servlets within a Web module
- Business methods of CMI enterprise beans within an Enterprise JavaBeans (EJB) module
- Business methods of Web service-enabled session beans. In the following descriptions, the term *supported enterprise bean* refers to both CMI enterprise beans and Web service-enabled session beans.

Run-as field

The **Run-as** field specifies one of three types of invocation context that a container can scope to a method. For servlet service and EJB business methods, the container constructs the invocation

internationalization context according to the **Run as** field setting and associates this context to the current thread before delegating to the method implementation.

By default, invocations of servlet service methods and EJB business methods implicitly run as caller (`RunAsCaller`) unless the **Run as** field of a policy attribute specifies otherwise. EJB client applications and AMI server components always run as server (`RunAsServer`).

You can specify the following invocation context types with the **Run as** field are:

Caller The container calls the method under the internationalization context of the calling process. For any missing context element, the container supplies the corresponding default context element of the Java virtual machine (JVM). Select run as caller when you want the invocation to run under the invocation context of the calling process.

Server
The container calls the method under the default locale and time zone of the JVM. Select run as server when you want the invocation to run under the invocation context of the JVM.

Specified
The container calls the method under the internationalization context specified in the attribute. Select run as specified when you want the invocation to run under the custom invocation context that is specified in the policy; then provide the custom context elements by completing the Locales and Time zone ID fields.

Remember: Java Message Service (JMS) messages do not contain internationalization context. Although container-managed message-driven beans can be configured to run as caller, the container associates the default elements of the server process when calling the onMessage method of any message-driven bean that is configured as `[CMI, RunAsCaller]`. You can also configure the **Run as** field for Web service business methods.

Locales field

The **Locales** field specifies an ordered list of locales that the container scopes to an invocation. A locale represents a specific geographical, cultural, or political region and contains three fields:

- **Language code**. Ideally, language code is one of the lower-case, two-character codes that are defined by the ISO 639 standard; however, language code is not restricted to ISO codes and is not a required field. A valid locale must specify a language code if it does not specify a country code.
- **Country code**. Ideally, country code is one of the upper-case, two-character codes that are defined by the ISO 3166 standard; however, country code is not restricted to ISO codes and is not a required field. A valid locale must specify a country code if it does not specify a language code.
- **Variant**. Variant is a vendor-specific code. Variant is not a required field and serves only to supplement the language and country code fields according to application- or platform-specific requirements.

A valid locale must specify at least a language code or a country code; the variant is always optional. The first locale of the list is returned when accessing invocation context using the getLocale method of the internationalization context API.

Time zone ID field

The **Time zone ID** field specifies an abbreviated identifier for a time zone that the container scopes to an invocation. You can also configure the **Time zone ID** field for Web service business methods.

A time zone represents a temporal offset and computes daylight savings information. A valid ID indicates any time zone supported by the java.util.TimeZone type. Specifically, a valid ID is any of the IDs that appear in the list of time zone IDs returned by method java.util.TimeZone.getAvailableIds(), or a custom ID having the form `GMT[+|-]hh[[:]mm]`; for example, `America/Los_Angeles`, `GMT-08:00` are valid time zone IDs.

Administering the internationalization service

To use internationalization context in an Enterprise JavaBeans (EJB) application, the internationalization service must be enabled in the runtime environments for all server-side components (servlets and enterprise beans, including session beans enabled for Web service usage) as well as all client-side components (EJB client applications and Web service clients).

About this task

If you do not require the internationalization service, do not enable it. Leaving the service disabled prevents any possible performance degradation incurred by the implicit distribution of internationalization resources.

The internationalization service cannot be enabled for HTTP clients, because support for internationalization in that case is provided by the browser, not by the application server.

Procedure

- Enable or disable the internationalization service for servlets and enterprise beans. By default, the service is disabled for server-side components within the application server. You enable the service by using either the administrative console or the wsadmin tool.
- Enable or disable the internationalization service for EJB clients. By default, the service is disabled within the client container. You enable the service by using the launchClient tool.

Enabling the internationalization service for servlets and enterprise beans

Perform this task to enable the internationalization service in the application server runtime environment.

About this task

Any servlet or enterprise bean can use internationalization context if the internationalization service is enabled within the hosting application server instance.

Procedure

1. Start the administrative console.
2. Click **Servers** > **Application servers** > ***server_name*** > **Container services** > **Internationalization service**.
3. Enable the internationalization service.
   a. If not already selected, select the **Enable service at server startup** check box.
   b. Click **OK**.

Results

When you select the **Enable service at server startup** setting, the application server automatically initializes and starts the internationalization service whenever the server starts. If you change this setting, be sure to restart the application server for the new setting to take effect.

To disable the service, clear the **Enable service at server startup** check box. In this case, the internationalization service is initialized but not started when the application server starts.

Example

Alternatively, the internationalization service can be enabled from the command line by using the wsadmin tool. Start the wsadmin tool and enter the following commands:

```
set x [$AdminConfig list I18NService]
$AdminConfig modify $x { { enable true } }
$AdminConfig save
exit
```

What to do next

If you enable or disable the internationalization service, be sure to stop and then restart the application server for the new setting to take effect.

Enabling the internationalization service for EJB clients

By default, the internationalization service is disabled for use within Enterprise JavaBeans (EJB) and Web-service enabled client applications. You must enable the service for client applications as well as for all server instances in the runtime environment.

Procedure

Enable the service.
When calling the launchClient tool, include the argument `-CCDI18NService.enable=true` or `-CCDI18NService.enable=yes`.

Internationalization service settings

Use this page to enable or disable the internationalization service. The internationalization service manages the implicit propagation and scoping of locale and time zone information, called *internationalization context*, within application components. When the service is enabled, application components can use the internationalization context API to programmatically manage locale and time zone information. In turn, components can use that locale and time zone information with the Java Platform, Standard Edition (JSE) Internationalization API to perform localizations. If internationalization support is not required on the server, disabling the service can improve performance.

To view this administrative console page, click **Servers > Server Types > WebSphere application servers >** *server_name*. Then, under Container Settings, click **Container Services > Internationalization Service**.

Enable service at server startup:

Specifies whether the server attempts to start the internationalization service.

Information	Value
Default	Cleared
Range	Valid values are Selected or Cleared

More information about valid values follows:

Selected
When the application server starts, it attempts to start the internationalization service automatically.

Cleared
The server does not try to start the internationalization service.

To enable the internationalization service for applications on this server, the system administrator must select this property and then restart the server.

Internationalization service errors

Certain conditions might cause the internationalization service not to start, to issue java.lang.IllegalStateException exceptions while an application is running, or to exercise default behaviors.

The java.lang.IllegalStateException exception indicates one of the following things:

- An application component attempted an operation that is not supported by the internationalization programming model.

  The IllegalStateException exception is issued whenever a server application component whose internationalization type is set to container-managed internationalization (CMI) attempts to set invocation context. This behavior is a violation of the CMI policy, under which servlets and enterprise beans cannot modify their invocation internationalization context.
- An anomaly occurred that disabled the service.

  For instance, if the internationalization service is not properly initialized, the Java Naming and Directory Interface (JNDI) lookup on the UserInternationalization URL attribute issues a javax.naming.NameNotFoundException exception that contains an IllegalStateException instance.

The following conditions can occur while your internationalized application is running. These conditions might cause the internationalization service not to start, to issue IllegalStateException exceptions, or to exercise default behaviors:
- "The service is disabled "
- "The service is not started"
- "Invalid context element" on page 571
- "Missing context element" on page 572
- "Invalid policy" on page 572
- "Missing policy" on page 572

If you encounter unexpected or exceptional behavior, the problem is likely related to one of these conditions. You need to examine the trace log to investigate these conditions, which requires that you configure the diagnostic trace service to generate messages about internationalization service function.

The trace strings for the internationalization service follow; use both:

```
com.ibm.ws.i18n.context.*=all=enabled:com.ibm.websphere.i18n.context.*=all=enabled
```

The service is disabled

The internationalization service is not initialized when the startup setting is cleared. The service generates a message that indicates whether it is enabled or disabled. Applications cannot access the internationalization API when the service is disabled. If an application attempts a JNDI lookup to obtain the UserInternationalization reference, the lookup fails with a NamingException exception, indicating that the reference cannot be found. In addition, the service does not scope (propagate) internationalization context on incoming (outgoing) business method calls.

The service is not started

The internationalization service is operational whenever it is in the STARTED state. For example, if an application attempts to access internationalization context and the service is not started, the API issues an IllegalStateException exception. In addition, the service does not provide runtime support for servlets and enterprise beans.

As an application server progresses through its life cycle, it initializes, starts, stops, and terminates (destroys) the internationalization service. If an anomaly occurs during initialization, the service does not start. After the service is started, its state can change to BLOCKED in the event that a serious error occurs. The service generates a message for every state change.

If a trace message indicates that the service is not STARTED, examine previous messages to determine the problem. For instance, the internationalization service does not start if the activity service is unavailable and a message is displayed to that effect during initialization of the internationalization service.

During startup, the following messages indicate potential configuration or runtime problems:

No ORB support
The service cannot obtain an instance of the object request broker (ORB). This condition is a fatal error. Examine the `SystemErr.log` and `SystemOut.log` files for information.

Note: This topic references one or more of the application server log files. As a recommended alternative, you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using `SystemOut.log` , `SystemErr.log`, `trace.log`, and `activity.log` files on distributed and IBM i systems. You can also use HPEL in conjunction with your native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.

No TCM support
The service cannot obtain an instance of its thread context manager (TCM). This condition is a fatal error. Examine the `SystemErr.log` and `SystemOut.log` files for information.

No IIOP (activity service) support
The service cannot register with the activity service. This condition is a fatal error. The internationalization service cannot propagate or receive context on Internet Inter-ORB Protocol (IIOP) requests without activity service support. Examine the `SystemErr.log` and `SystemOut.log` files for information.

No AsynchBeans support
The service cannot register into the asynchronous beans environment. This warning indicates that the asynchronous beans environment cannot support internationalization context.

No EJB container support
The service cannot register with the Enterprise JavaBeans (EJB) container. This warning indicates that the internationalization service cannot support enterprise beans. Without EJB container support, internationalization contexts do not scope properly to EJB business methods. Review the trace log for any EJB container-related error conditions.

No Web container support
The service cannot register with the Web container. This warning indicates that the internationalization service cannot support servlets and JavaServer Page (JSP) files. Without Web container support, internationalization contexts do not scope properly to servlet service methods. Review the trace log for any Web container-related error conditions.

No Metadata support
The service cannot register with the metadata service. This warning indicates that the internationalization service cannot process the internationalization policies within application deployment descriptors. Without metadata support, the service associates the default internationalization context management policy, [CMI, RunAsCaller], to every servlet lifecycle method and enterprise bean business method invocation. Review the trace log for any metadata service-related error conditions.

No JNDI (Naming service) support
The service cannot bind the UserInternationalization object into the namespace. This condition is a fatal error. Application components are unable to access internationalization context API references, and are therefore unable to access internationalization context elements. Review the trace log for any Naming (JNDI) service-related error conditions.

No API support
The service cannot obtain an instance of an internationalization context API object. This condition is a fatal error. Application components are unable to access internationalization context API references, and are therefore unable to access internationalization context elements.

Invalid context element

The service detected an invalid internationalization context element. For example, the internationalization service does not support TimeZone instances of a type other than java.util.SimpleTimeZone. If the service encounters an unusable element, it logs a message and substitutes the corresponding default element of the JVM.

Missing context element

The service detected a missing internationalization context element. Incoming requests (for example, from application servers that do not support the internationalization service) lack internationalization context. When the service attempts to access a caller internationalization context element (which does not exist in this case), the service logs a message and substitutes the corresponding default element of the Java virtual machine (JVM).

Whenever possible, enable the internationalization service within all clients and hosting application servers that comprise an internationalized enterprise application. Read more information about Administering the internationalization service in the *Administering applications and their environment* PDF book.

Invalid policy

The internationalization service detected a malformed internationalization policy in the application deployment descriptor. The service replaces the malformed attribute with the appropriate default. For instance, if the internationalization type for an entity bean is set to `Application` during the run of a servlet or EJB business method call, the service logs the inconsistency and enforces the `Container` setting instead.

Also, AMI application components do have an implicit container internationalization attribute. By default they run as server. The service silently enforces the implicit policy, `[AMI, RunAsServer]`, and logs messages to this effect.

Invalid container internationalization attributes are likely to occur when specifying the Locales and Time zone ID fields. When encountering invalid locales and time zone IDs within attributes, the service replaces each value with the corresponding default element of the JVM. Be sure to follow the guidelines provided in the *Developing and deploying applications* PDF book.

Missing policy

The service detected a missing internationalization policy. The service replaces the missing policy with the appropriate default. For instance, if the internationalization type is missing for a servlet or enterprise bean, the service sets the attribute to Container.

Container internationalization attributes are not mandatory for CMI application components. In the event that a CMI servlet or EJB business method lacks a container internationalization attribute, the service silently enforces the implicit policy `[CMI, RunAsCaller]`.

When an application lacks internationalization policies in its deployment descriptor, or metadata support is unavailable, the service logs a message and applies the policy `[CMI, RunAsCaller]` on every servlet service method and EJB business method invocation.

Read the information in the *Developing and deploying applications* PDF book:
- Assembling internationalized applications
- Container internationalization attributes
- Internationalization type

Chapter 12. Developing Mail, URLs, and other Java EE resources

This page provides a starting point for finding information about resources that are used by applications that are deployed on a Java Enterprise Edition (Java EE)-compliant application server. They include:

- JavaMail support for applications to send Internet mail
- URLs, for describing logical locations
- Resource environment entries, for mapping logical names to physical names
- Java DataBase Connectivity (JDBC) resources and other technology for data access (discussed elsewhere)
- Java Message Service (JMS) resources and other messaging system support (discussed elsewhere)

Developing applications that use the JavaMail API

JavaMail API

The JavaMail APIs provide a framework that is platform and protocol independent for building mail client applications that are based on Java. The JavaMail APIs are generic for sending and reading mail. They require service providers, known in the application server as protocol providers, to interact with mail servers that run on pertaining protocols. For example, Simple Mail Transfer Protocol (SMTP) is a popular transport protocol for sending mail. Mail applications can connect to an SMTP server and send mail through it by using this SMTP protocol provider.

The application server supports the JavaMail API, Version 1.4. In the application server, the JavaMail API is supported in all web application components, namely:

- servlets
- JavaServer Pages (JSP) files
- enterprise beans
- application clients

In addition to service providers, the JavaMail API requires the JavaBeans Activation Framework (JAF) to handle mail content that is not plain text, including Multipurpose Internet Mail Extensions (MIME), URL pages, and file attachments.

The JavaMail APIs, the JAF, the service providers, and the protocols are shipped as part of the application server. The API and related specifications are repackaged from materials that are licensed.

Note: If you are using Java 5 to run your code, you will need the JAF 1.1 package. For Java 6 and later, the JAF package is part of the run time environment.

Debugging mail sessions

When you debug a mail application, you can use the mail debugging feature. The mail component generates debugging information, on a per session basis, that can be used for problem determination or tuning.

About this task

Enabling the debug mode triggers the mail component of the application server to print the following data to the standard output stream:

- interactions with the mail servers
- properties of the mail session

This output stream is redirected to the SystemOut.log file for the specific application server.

Note: This topic references one or more of the application server log files. As a recommended alternative, you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using SystemOut.log , SystemErr.log, trace.log, and activity.log files on distributed and IBM i systems. You can also use HPEL in conjunction with your native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.

Procedure

1. Open the administrative console.
2. Click **Resources** > **Mail** > **Mail sessions** > ***mail session***.
3. Click **Enable debug mode**. Debugging is enabled for that session only.
4. Click **Apply** or **OK**.

Example

The following example shows sample mail debugging output:

```

 ... 32 more
```

This output illustrates a connection failure to a Simple Mail Transfer Protocol (SMTP) server because a fictitious name, smtp.coldmail.com, is specified as the server name.

The following list provides tips on reading the previous sample of debugger output:

- The lines headed by `DEBUG` are printed by the mail provider at run time, while the two lines headed by *** are printed by the application server at run time.
- In the second paragraph of code, the first few lines state that some configuration files are skipped. The mail component attempts to load a number of configuration files from different locations at run time. All those files are not required. If a required file cannot be accessed, however, the mail component creates an exception. In this sample, there is no exception and the third-line announces that default providers are loaded.
- The next few lines, headed by either `Providers Listed by Class Name` or `Providers Listed by Protocols`, show the protocol providers that are loaded. The six providers that are listed are the default

protocol providers that come under the built-in mail provider for the application server. If you install special service providers, and these providers are used in the current mail session, those providers are listed here with the default providers.

- The two lines headed by *** and the few lines below them are printed by the application server to show the configuration properties of the current mail session. Although these properties are listed by their internal name rather than the name you establish in the administrative console, you can easily recognize the relationships between them. For example, the mail.store.protocol property corresponds to the **Protocol** property in the **Incoming Mail Properties** section of the console panel for mail session configuration. Review the listed properties and values to verify that they correspond.
- The few lines above the exception stack show the mail activities when sending a message. First, the JavaMail API recognizes that the transport protocol is set to SMTP and that the com.sun.mail.smtp.SMTPTransport provider exists. Next, the output log displays the useEhlo and useAuth parameters, which are used by SMTP. Finally, the log shows the SMTP provider trying to connect to the smtp.coldmail.com mail server.
- The output log show the exception stack next. This data indicates that the specified mail server either does not exist or is not functioning.

Chapter 13. Developing Messaging resources

This page provides a starting point for finding information about the use of asynchronous messaging resources for enterprise applications with WebSphere Application Server.

WebSphere Application Server supports asynchronous messaging based on the Java Message Service (JMS) and the Java EE Connector Architecture (JCA) specifications, which provide a common way for Java programs (clients and Java EE applications) to create, send, receive, and read asynchronous requests, as messages.

JMS support enables applications to exchange messages asynchronously with other JMS clients by using JMS destinations (queues or topics). Some messaging providers also allow WebSphere Application Server applications to use JMS support to exchange messages asynchronously with non-JMS applications; for example, WebSphere Application Server applications often need to exchange messages with WebSphere MQ applications. Applications can explicitly poll for messages from JMS destinations, or they can use message-driven beans to automatically retrieve messages from JMS destinations without explicitly polling for messages.

WebSphere Application Server supports the following messaging providers:

- The WebSphere Application Server default messaging provider (which uses service integration as the provider).
- The WebSphere MQ messaging provider (which uses your WebSphere MQ system as the provider).
- Third-party messaging providers that implement either a JCA Version 1.5 resource adapter or the ASF component of the JMS Version 1.0.2 specification.

Programming to use asynchronous messaging

You can build enterprise applications that use Java Message Service (JMS) APIs directly to provide asynchronous messaging services. You can also use message-driven beans as asynchronous message consumers. If you are writing messaging programs that interoperate between WebSphere Application Server and WebSphere MQ, there are some environmental differences that you need to take into account.

About this task

Enterprise applications can use JMS APIs directly to explicitly poll for messages on a JMS destination, then retrieve messages for processing by business logic beans (enterprise beans).

Message-driven beans can also be used as asynchronous message consumers. When a message arrives at the destination, the EJB container invokes the message-driven bean automatically without an application having to explicitly poll the destination.

Procedure

- “Programming to use JMS and messaging directly” on page 578.

  Your enterprise applications can use Java Message Service (JMS) programming interfaces directly to provide messaging services, and methods that implement business logic.

  If you choose not to use JNDI to obtain configuration information for your messaging provider, for example for connection factories or destinations, you can instead use an API provided by your messaging provider to specify that configuration information programmatically.
- “Programming for interoperation with WebSphere MQ” on page 593

  There are some differences between the WebSphere Application Server environment and the WebSphere MQ environment. If you are writing messaging programs that interoperate between these two environments, you should be aware of these differences and take them into account when designing, coding and deploying your programs.

- “Programming to use message-driven beans” on page 422.

  Applications can use message-driven beans as asynchronous message consumers. You deploy a message-driven bean as a message listener for a destination. When a message arrives at the destination, the EJB container invokes the message-driven bean automatically without an application having to explicitly poll the destination.

Asynchronous beans - WebSphere Trader sample application

The Asynchronous beans - WebSphere Trader sample application illustrates how to implement a streaming stock ticker server and client using asynchronous beans and Java Platform, Enterprise Edition (Java EE) services such as:

- Servlets
- Java Message Service (JMS)
- Session enterprise beans
- Container-managed persistence (CMP) 2.0 enterprise beans
- Message-driven beans (MDB)

This sample uses several parts to maximize the utilization of a server:

- Work - Runs Java EE context-aware code on a thread.
- Alarm - Runs Java EE context-aware code at a given time interval.
- EventSource - A method of broadcasting events to registered listeners.
- SubsystemMonitor - A thread that monitors the status of any asynchronous system and uses an EventSource method to inform registered listeners of the system status.
- WorkManager - Thread configuration and Java EE context policies that are used by various asynchronous beans parts.
- AsynchScope - A collection of alarms, subsystem monitors and other asynchronous scopes that support relationships. This collection uses a single WorkManager thread and is also an event source.
- Startup Bean - A specialized, stateful session enterprise bean that supports bootstrapping asynchronous work when the application starts.

This sample is available from the Samples section of the information center.

Programming to use JMS and messaging directly

Your enterprise applications can use Java Message Service (JMS) programming interfaces directly to provide messaging services, and methods that implement business logic.

About this task

WebSphere Application Server supports asynchronous messaging as a method of communication based on JMS programming interfaces. Using JMS, enterprise applications can exchange messages asynchronously with other JMS clients by using JMS destinations (queues or topics). An enterprise application can explicitly poll for messages on a destination.

If you choose not to use JNDI to obtain configuration information for your messaging provider, for example for connection factories or destinations, you can instead use an API provided by your messaging provider to specify that configuration information programmatically.

If you want to transmit messages between JMS applications and traditional WebSphere MQ applications, you must consider how the JMS message structure is mapped onto a WebSphere MQ message. This includes scenarios where you want to use WebSphere MQ to manipulate messages transmitted between two JMS applications; for example, by using WebSphere MQ as a message broker.

By default, JMS messages held on WebSphere MQ queues use an MQRFH2 header to hold some of the JMS message header information. Many traditional WebSphere MQ applications cannot process messages with these headers, and require their own characteristic headers, for example the MQWIH for WebSphere MQ Workflow applications. For more information about how the JMS message structure is mapped onto a WebSphere MQ message, see the section *Mapping JMS messages* in the WebSphere MQ information center.

Example

This following example shows how to programmatically configure a resource for the default messaging provider.

In this example, a JMS connection to a service integration bus is created by using the API in the com.ibm.websphere.sib package. This is an alternative to using JNDI to look up administratively configured connection factories. After the connection is established, the sample program reads lines of input from the console and sends them as JMS text messages to the specified destination.

This example can be run as a thin client application, or as a stand-alone client application.

      }

    }
  }

}
```

Designing an enterprise application to use JMS

There are many things to consider when designing an enterprise application to use the JMS APIs directly for asynchronous messaging.

Procedure

- For messaging operations, you should write application programs that use only references to the interfaces defined in Sun's javax.jms package.

  JMS defines a generic view of messaging that maps onto the underlying transport. An enterprise application that uses JMS makes use of the following interfaces that are defined in Sun's javax.jms package:

  Connection
  : Provides access to the underlying transport, and is used to create Sessions.

  Session
  : Provides a context for producing and consuming messages, including the methods used to create MessageProducers and MessageConsumers.

  MessageProducer
  : Used to send messages.

  MessageConsumer
  : Used to receive messages.

  The generic JMS interfaces are subclassed into the following more specific versions for point-to-point and publish/subscribe behavior.

Table 76. The point-to-point and publish/subscribe versions of JMS common interfaces. The first column of this table lists the JMS common interfaces, the second column lists the corresponding point-to-point interfaces, and the third column lists the corresponding publish/subscribe interfaces.

JMS common interfaces	Point-to-point interfaces	Publish/subscribe interfaces
ConnectionFactory	QueueConnectionFactory	TopicConnectionFactory
Connection	QueueConnection	TopicConnection
Destination	Queue	Topic
Session	QueueSession,	TopicSession,
MessageProducer	QueueSender	TopicPublisher
MessageConsumer	QueueReceiver, QueueBrowser	TopicSubscriber

For more information about using these JMS interfaces, see the Java Message Service Documentation and the *Using Java* section of the WebSphere MQ information center.

The section "Java Message Service (JMS) Requirements" of the J2EE specification gives a list of methods that must not be called in web and EJB containers:

```
javax.jms.Session method setMessageListener
javax.jms.Session method getMessageListener
javax.jms.Session method run
javax.jms.QueueConnection method createConnectionConsumer
javax.jms.TopicConnection method createConnectionConsumer
javax.jms.TopicConnection method createDurableConnectionConsumer
javax.jms.MessageConsumer method getMessageListener
javax.jms.MessageConsumer method setMessageListener
javax.jms.Connection setExceptionListener
javax.jms.Connection stop
javax.jms.Connection setClientID
```

This method restriction is enforced in WebSphere Application Server by throwing a javax.jms.IllegalStateException exception.

- Applications refer to JMS resources that are predefined, as administered objects, to WebSphere Application Server.

  Details of JMS resources that are used by enterprise applications are defined to WebSphere Application Server and bound into the JNDI namespace by the WebSphere administrative support. An enterprise application can retrieve these objects from the JNDI namespace and use them without needing to know anything about their implementation. This enables the underlying messaging architecture defined by the JMS resources to be changed without requiring changes to the enterprise application.

Table 77. JMS resources for point-to-point and publish/subscribe messaging. The left hand column of this table lists the JMS resources for point-to-point messaging, and the right hand column lists the JMS resources for publish/subscribe.

Point-to-point	Publish/subscribe
ConnectionFactory (or QueueConnectionFactory) Queue	ConnectionFactory (or TopicConnectionFactory) Topic

A connection factory is used to create connections from the JMS provider to the messaging system, and encapsulates the configuration parameters needed to create connections.

- To improve performance, the application server pools connections and sessions with the JMS provider. You have to configure the connection and session pool properties appropriately for your applications, otherwise you might not get the connection and session behavior that you want.
- Applications must not cache JMS connections, sessions, producers or consumers. WebSphere Application Server closes these objects when a bean or servlet completes, and so any attempt to use a cached object will fail with a javax.jms.IllegalStateException exception.

  To improve performance, applications can cache JMS objects that have been looked up from JNDI. For example, an EJB or servlet needs to look up a JMS ConnectionFactory only once, but it must call the

createConnection method on each instantiation. Because of the effect of pooling on connections and sessions with the JMS provider, there should be no performance impact.

- A non-durable subscriber can only be used in the same transactional context (for example, a global transaction or an unspecified transaction context) that existed when the subscriber was created.
- Using durable subscriptions with the default messaging provider. A durable subscription on a JMS topic enables a subscriber to receive a copy of all messages published to that topic, even after periods of time when the subscriber is not connected to the server. Therefore, subscriber applications can operate disconnected from the server for long periods of time, and then reconnect to the server and process messages that were published during their absence. If an application creates a durable subscription, it is added to the runtime list that administrators can display and act on through the administrative console.

  Each durable subscription is given a unique identifier, *clientID##subName* where:

  clientID
  : The client identifier used to associate a connection and its objects with the messages maintained for applications (as clients of the JMS provider). You should use a naming convention that helps you identify the applications, in case you have to relate durable subscriptions to the associated applications for runtime administration.

  subName
  : The subscription name used to uniquely identify a durable subscription within a given client identifier.

  For durable subscriptions created by message-driven beans, these values are set on the JMS activation specification. For other durable subscriptions, the client identifier is set on the JMS connection factory, and the subscription name is set by the application on the createDurableSubscriber operation.

  To create a durable subscription to a topic, an application uses the createDurableSubscriber operation defined in the JMS API:

```
public TopicSubscriber createDurableSubscriber(Topic topic,
                          java.lang.String subName,
                          java.lang.String messageSelector,
                          boolean noLocal)
                          throws JMSException
```

  topic The name of the JMS topic to subscribe to. This is the name of an object supporting the javax.jms.Topic interfaces, such as found by looking up a suitable JNDI entry.

  subName
  : The name used to identify this subscription.

  messageSelector
  : Only messages with properties matching the message selector expression are delivered to consumers. A value of null or an empty string indicates that all messages should be delivered.

  noLocal
  : If set to `true`, this parameter prevents the delivery of messages published on the same connection as the durable subscriber.

  Applications can use a two argument form of the createDurableSubscriber operation that takes only topic and subName parameters. This alternative call directly invokes the four argument version shown above, but sets messageSelector to null (so all messages are delivered) and sets noLocal to false (so messages published on the connection are delivered). For example, to create a durable subscription to the topic called `myTopic`, with the subscription name of `mySubscription`:

```
session.createDurableSubscriber(myTopic,"mySubscription");
```

  If the createDurableSubscription operation fails, it throws a JMS exception that provides a message and linked exception to give more detail about the cause of the problem.

  To delete a durable subscription, an application uses the unsubscribe operation defined in the JMS API

  In normal operation there can be at most one active (connected) subscriber for a durable subscription at a time. However, the subscriber application can be running in a cloned application server, for failover

and load balancing purposes. In this case the “one active subscriber” restriction is lifted to provide a shared durable subscription that can have multiple simultaneous consumers.

For more information about application use of durable subscriptions, see the section “Using Durable Subscriptions” in the JMS specification.

- Decide what message selectors are needed. You can use the JMS message selector mechanism to select a subset of the messages on a queue so that this subset is returned by a receive call. The selector can refer to fields in the JMS message header and fields in the message properties.
- Acting on messages received. When a message is received, you can act on it as needed by the business logic of the application. Some general JMS actions are to check that the message is of the correct type and extract the content of the message. To extract the content from the body of the message, cast from the generic Message class (which is the declared return type of the receive methods) to the more specific subclass, such as TextMessage. It is good practice always to test the message class before casting, so that unexpected errors can be handled gracefully.

  In this example, the instanceof operator is used to check that the message received is of the `TextMessage` type. The message content is then extracted by casting to the TextMessage subclass.

```
       if ( inMessage instanceof TextMessage )

...
            String replyString = ((TextMessage) inMessage).getText();
```

- JMS applications using the default messaging provider can access, without any restrictions, the content of messages that have been received from WebSphere Application Server Version 5 embedded messaging or WebSphere MQ.
- JMS applications can access the full set of JMS_IBM* properties. These properties are of value to JMS applications that use resources provided by the default messaging provider, the V5 default messaging provider, or the WebSphere MQ provider.

  For messages handled by WebSphere MQ, the JMS_IBM* properties are mapped to equivalent WebSphere MQ Message Descriptor (MQMD) fields. For more information about the JMS_IBM* properties and MQMD fields, see the *Using Java* section of the WebSphere MQ information center.
- JMS applications can use report messages as a form of managed request/response processing, to give remote feedback to producers on the outcome of their send operations and the fate of their messages. JMS applications can request a full range of report options using **`JMS_IBM_Report_Xxxx`** message properties. For more information about using JMS report messages, see “JMS report messages” on page 621.
- JMS applications can use the **`JMS_IBM_Report_Discard_Msg`** property to control how a request message is disposed of if it cannot be delivered to the destination queue.

  MQRO_Dead_Letter_Queue
  This is the default. The request message should be written to the dead letter queue.

  MQRO_Discard
  The request message should be discarded. This is usually used in conjunction with MQRO_Exception_With_Full_Data to return an undeliverable request message to its sender.
- Using a listener to receive messages asynchronously. In a client, not in a servlet or enterprise bean, an alternative to making calls to QueueReceiver.receive() is to register a method that is called automatically when a suitable message is available; for example:

```
...
MyClass listener =new MyClass();
queueReceiver.setMessageListener(listener);
//application continues with other application-specific behavior.
...
```

  When a message is available, it is retrieved by the onMessage() method on the listener object.

```
import javax.jms.*;
public class MyClass implements MessageListener
{
public void onMessage(Message message)
```

```
{
System.out.println("message is "+message);
//application specific processing here
...

}
}
```

For asynchronous message delivery, the application code cannot catch exceptions raised by failures to receive messages. This is because the application code does not make explicit calls to receive() methods. To cope with this situation, you can register an ExceptionListener, which is an instance of a class that implements the onException() method. When an error occurs, this method is called with the **JMSException** passed as its only parameter.

For more details about using listeners to receive messages asynchronously, see the Java Message Service Documentation.

Note: An alternative to developing your own JMS listener class, you can use a message-driven bean, as described in Programming with message-driven beans.

- Take care when performing a JMS receive() from a server-side application component if that receive() invocation is waiting on a message produced by another application component that is deployed in the same server. Such a JMS receive() is synchronous, so blocks until the response message is received.

  This type of application design can lead to the consumer or producer problem where the entire set of work threads can be exhausted by the receiving component, which has been blocked waiting for responses, leaving no available worker thread for which to dispatch the application component that would generate the response JMS message. For example, a servlet and a message-driven bean are deployed in the same server. When this servlet dispatches a request it sends a message to a queue that is serviced by the message-driven bean (that is, messages produced by the servlet are consumed by the message-driven bean onMessage() method). The servlet subsequently issues a receive(), waiting for a reply on a temporary ReplyTo queue. The message-driven bean onMessage() method performs a database query and sends back a reply to the servlet on the temporary queue. If a large number of servlet requests occur at once (relative to the number of server worker threads), then all available server worker threads will probably be used to dispatch a servlet request, send a message, and wait for a reply. The application server then enters a condition where no threads remain to process any of the message-driven beans that are now pending. Because the servlets are waiting in blocking receives, the server hangs, likely leading to application failure.

  Possible solutions are:

  1. Ensure that the number of worker threads (# of threads per server region * # of server regions per server) exceeds the number of concurrent dispatches of the application component doing the receive() so that there is always a worker thread available to dispatch the message producing component.
  2. Use an application topology that places the receiver application component in a separate server from the producer application component. Although worker thread usage might still have to be carefully considered under such a deployment scenario, this separation ensures that there are always be threads that cannot be blocked by the message receiving component. There can be other interactions to consider, such as an application server that has multiple applications installed.
  3. Refactor your application to do the message receives from a client component, which will not compete with the producer component for worker threads. Furthermore, the client component can do asynchronous (non-blocking) receives, which are prohibited from J2EE servers. So, for example, the example application above can be refactored to have a client sending messages to a queue and then waiting for a response from the MDB.

- If you want to use authentication with WebSphere MQ or the Version 5 Embedded Messaging support, you cannot have user IDs longer than 12 characters. For example, the default Windows NT user ID, **administrator**, is not valid for use with WebSphere internal messaging, because it contains 13 characters.
- The following points, as defined in the EJB specification, apply to the use of flags on create*xxx*Session calls:

  - The transacted flag passed on create*xxx*Session is ignored inside a global transaction and all work is performed as part of the transaction. Outside of a transaction the transacted flag is used and, if set to `true`, the application should use session.commit() and session.rollback() to control the completion of the work. In an EJB2.0 module, if the transacted flag is set to `true` and outside of an XA transaction, then the session is involved in the WebSphere local transaction and the unresolved action attribute of the method applies to the JMS work if it is not committed or rolled back by the application.
  - Clients cannot use Message.acknowledge() to acknowledge messages. If a value of `CLIENT_ACKNOWLEDGE` is passed on the create*xxx*Session call, then messages are automatically acknowledged by the application server and Message.acknowledge() is not used.
- If you want your application to use WebSphere MQ as an external JMS provider, then send messages within a container-managed transaction.

  When you use WebSphere MQ as an external JMS provider, messages sent within a user-managed transaction can arrive before the transaction commits. This occurs only when you use WebSphere MQ as an external JMS provider, and you send messages to a WebSphere MQ queue within a user-managed transaction. The message arrives on the destination queue before the transaction commits.

  The cause of this problem is that the WebSphere MQ resource manager has not been enlisted in the user-managed transaction.

  The solution is to use a container-managed transaction.

Developing an enterprise application to use JMS

Use this task to develop an enterprise application to use the JMS API directly for asynchronous messaging.

About this task

This topic gives an overview of the steps needed to develop an enterprise application (servlet or enterprise bean) to use the JMS API directly for asynchronous messaging.

This topic only describes the JMS-related case; it does not describe general enterprise application programming, which you should already be familiar with. For detailed information about these steps, and for examples of developing an enterprise application to use JMS, see the Java Message Service Documentation

Details of JMS resources that are used by enterprise applications are defined to WebSphere Application Server and bound into the JNDI namespace by the WebSphere Application Server administrative support.

To use JMS, complete the following general steps:

Procedure

1. Import JMS packages. An enterprise application that uses JMS starts with a number of import statements for JMS, which should include at least the following statements:

   ```
   import javax.jms.*;       //JMS interfaces
   import javax.naming.*;    //Used for JNDI lookup of administered objects
   ```

2. Get an initial context:

   ```
      try     {
           ctx = new InitialContext(env);
   ...
   ```

3. Retrieve administered objects from the JNDI namespace. The InitialContext.lookup() method is used to retrieve administered objects (a JMS connection factory and JMS destinations). The following example shows how to receive a message from a queue:

```
        qcf = (QueueConnectionFactory)ctx.lookup( qcfName );
...
        inQueue = (Queue)ctx.lookup( qnameIn );
...
```

An alternative, but less manageable, approach to obtaining administratively-defined JMS destination objects by JNDI lookup is to use the Session.createQueue(String) method or Session.createTopic(String) method. For example:

```
Queue q = mySession.createQueue("Q1");
```

creates a JMS Queue instance that can be used to reference the existing destination Q1.

In its simplest form, the parameter to these create methods is the name of an existing destination. For more complex situations, applications can use a URI-based format, which allows an arbitrary number of name value pairs to be supplied to set various properties of the JMS destination object.

4. Create a connection to the messaging service provider. The connection provides access to the underlying transport, and is used to create sessions. The createQueueConnection() method on the factory object is used to create the connection.

   ```
   connection = qcf.createQueueConnection();
   ```

   The JMS specification defines that connections should be created in the stopped state. Until the connection starts, MessageConsumers that are associated with the connection cannot receive any messages. To start the connection, issue the following command:

   ```
   connection.start();
   ```

5. Create a session, for sending or receiving messages. The session provides a context for producing and consuming messages, including the methods used to create MessageProducers and MessageConsumers. The createQueueSession method is used on the connection to obtain a session. The method takes two parameters:
   - A boolean that determines whether the session is transacted.
   - A parameter that determines the acknowledge mode.

   ```
   boolean transacted = false;
   session = connection.createQueueSession( transacted,
                                            Session.AUTO_ACKNOWLEDGE);
   ```

   In this example, the session is not transacted, and it should automatically acknowledge received messages. With these settings, a message is backed out only after a system error or if the application terminates unexpectedly.

   The following points, as defined in the EJB specification, apply to these flags:
   - The transacted flag passed on createQueueSession is ignored inside a global transaction and all work is performed as part of the transaction. Outside of a transaction the transacted flag is used and, if set to true, the application should use session.commit() and session.rollback() to control the completion of the work. In an EJB2.0 module, if the transacted flag is set to `true` and outside of an XA transaction, then the session is involved in the WebSphere local transaction and the unresolved action attribute of the method applies to the JMS work if it is not committed or rolled back by the application.
   - Clients cannot use Message.acknowledge() to acknowledge messages. If a value of CLIENT_ACKNOWLEDGE is passed on the create*xxx*Session call, then messages are automatically acknowledged by the application server and Message.acknowledge() is not used.

6. Send a message.
   a. Create MessageProducers to create messages. For point-to-point messaging the MessageProducer is a QueueSender that is created by passing an output queue object (retrieved earlier) into the createSender method on the session. A QueueSender is usually created for a specific queue, so that all messages sent by that sender are sent to the same destination.

      ```
      QueueSender queueSender = session.createSender(inQueue);
      ```

   b. Create the message. Use the session to create an empty message and add the data passed.

JMS provides several message types, each of which embodies some knowledge of its content. To avoid referencing the vendor-specific class names for the message types, methods are provided on the Session object for message creation.

In this example, a text message is created from the outString property:

```
TextMessage outMessage = session.createTextMessage(outString);
```

c. Send the message.

To send the message, the message is passed to the send method on the QueueSender:

```
queueSender.send(outMessage);
```

7. Receive replies.

a. Create a correlation ID to link the message sent with any replies. In this example, the client receives reply messages that are related to the message that it has sent, by using a provider-specific message ID in a JMSCorrelationID.

```
messageID = outMessage.getJMSMessageID();
```

The correlation ID is then used in a message selector, to select only messages that have that ID:

```
String selector = "JMSCorrelationID = '"+messageID+"'";
```

b. Create a MessageReceiver to receive messages. For point-to-point the MessageReceiver is a QueueReceiver that is created by passing an input queue object (retrieved earlier) and the message selector into the createReceiver method on the session.

```
QueueReceiver queueReceiver = session.createReceiver(outQueue, selector);
```

c. Retrieve the reply message. To retrieve a reply message, the receive method on the QueueReceiver is used:

```
Message inMessage = queueReceiver.receive(2000);
```

The parameter in the receive call is a timeout in milliseconds. This parameter defines how long the method should wait if there is no message available immediately. If you omit this parameter, the call blocks indefinitely. If you do not want any delay, use the receiveNoWait()method. In this example, the receive call returns when the message arrives, or after 2000ms, whichever is sooner.

d. Act on the message received. When a message is received, you can act on it as needed by the business logic of the client. Some general JMS actions are to check that the message is of the correct type and extract the content of the message. To extract the content from the body of the message, it is necessary to cast from the generic Message class (which is the declared return type of the receive methods) to the more specific subclass, such as TextMessage. It is good practice always to test the message class before casting, so that unexpected errors can be handled gracefully.

In this example, the instanceof operator is used to check that the message received is of the TextMessage type. The message content is then extracted by casting to the TextMessage subclass.

```
if ( inMessage instanceof TextMessage )

...
        String replyString = ((TextMessage) inMessage).getText();
```

8. Closing down. If the application needs to create many short-lived JMS objects at the Session level or lower, it is important to close all the JMS resources used. To do this, you call the close() method on the various classes (QueueConnection, QueueSession, QueueSender, and QueueReceiver) when the resources are no longer required.

```
queueReceiver.close();
...
queueSender.close();
...
session.close();
```

```
        session = null;
...
        connection.close();
        connection = null;
```

9. Publishing and subscribing to messages. To use JMS Publish/Subscribe support instead of point-to-point messaging, the general actions are the same; for example, to create a session and connection. The exceptions are that topic resources are used instead of queue resources (such as TopicPublisher instead of QueueSender), as shown in the following example to publish a message:

```
// Creating a TopicPublisher
        TopicPublisher pub = session.createPublisher(topic);
...
        pub.publish(outMessage);
...
        // Closing TopicPublisher
        pub.close();
```

10. Handling errors Any JMS runtime errors are reported by exceptions. The majority of methods in JMS throw JMSExceptions to indicate errors. It is good programming practice to catch these exceptions and display them on a suitable output.

    Unlike normal Java exceptions, a JMSException can contain another exception embedded in it. The implementation of JMSException does not include the embedded exception in the output of its toString()method. Therefore, you must check explicitly for an embedded exception and print it out, as shown in the following example:

```
catch (JMSException je)
{
   System.out.println("JMS failed with "+je);
   Exception le = je.getLinkedException();
   if (le != null)
   {
       System.out.println("linked exception "+le);
   }
}
```

What to do next

After you have packaged your application, you can next deploy the application into WebSphere Application Server, as described in “Deploying an enterprise application to use JMS” on page 2083.

Developing a JMS client

Use this task to develop a JMS client application to use messages to communicate with enterprise applications.

About this task

This topic gives an overview of the steps needed to develop a JMS client application. This topic only describes the JMS-related case; it does not describe general client programming, which you should already be familiar with. For detailed information about these steps, and for examples of developing JMS clients, see the Java Message Service Documentation and the *Using Java* section of the WebSphere MQ information center.

A JMS client assumes that the JMS resources (such as a queue connection factory and queue destination) already exist. A client application can obtain suitable JMS resources either by JNDI lookup or programmatically without using JNDI.

For information about the Thin Client for JMS with WebSphere Application Server, which is an embeddable technology that provides JMS V1.1 connections to a WebSphere Application Server default messaging provider messaging engine, see Using JMS to connect to a WebSphere Application Server default messaging provider messaging engine.

For more information about developing client applications and configuring JMS resources for them, see Developing J2EE application client code and related tasks.

To use JMS, a typical JMS client program completes the following general steps. This example is based on the use of JNDI lookups to obtain JMS resources.

Procedure

1. Import JMS packages. An enterprise application that uses JMS starts with a number of import statements for JMS; for example:

```
import javax.naming.Context;
import javax.naming.InitialContext;
import javax.rmi.PortableRemoteObject;
import javax.jms.*;
```

2. Get an initial context.

```
   try     {
        ctx = new InitialContext(env);
...
```

3. Define the parameters that the client is to use; for example, to identify the queue connection factory and to assemble a message to be sent.

```
public class JMSppSampleClient
{
  public static void main(String[] args)
  throws JMSException, Exception

  {
    String  messageID                = null;
    String  outString                = null;
    String  qcfName                  = "java:comp/env/jms/ConnectionFactory";
    String  qnameIn                  = "java:comp/env/jms/Q1";
    String  qnameOut                 = "java:comp/env/jms/Q2";
    boolean verbose                  = false;

    QueueSession           session    = null;
    QueueConnection        connection = null;
    Context                ctx        = null;

    QueueConnectionFactory qcf        = null;
    Queue                  inQueue    = null;
    Queue                  outQueue   = null;

...
```

4. Retrieve administered objects from the JNDI namespace. The InitialContext.lookup() method is used to retrieve administered objects (a queue connection factory and the queue destinations):

```
       qcf = (QueueConnectionFactory)ctx.lookup( qcfName );
...
       inQueue = (Queue)ctx.lookup( qnameIn );
       outQueue = (Queue)ctx.lookup( qnameOut );
...
```

5. Create a connection to the messaging service provider. The connection provides access to the underlying transport, and is used to create sessions. The createQueueConnection() method on the factory object is used to create the connection.

```
       connection = qcf.createQueueConnection();
```

   The JMS specification defines that connections should be created in the stopped state. Until the connection starts, MessageConsumers that are associated with the connection cannot receive any messages. To start the connection, issue the following command:

```
       connection.start();
```

6. Create a session, for sending and receiving messages. The session provides a context for producing and consuming messages, including the methods used to create MessageProducers and MessageConsumers. The createQueueSession method is used on the connection to obtain a session. The method takes two parameters:
   - A boolean that determines whether the session is transacted.
   - A parameter that determines the acknowledge mode.

   ```
   boolean transacted = false;
   session = connection.createQueueSession( transacted,
                                            Session.AUTO_ACKNOWLEDGE);
   ```

   In this example, the session is not transacted, and it should automatically acknowledge received messages. With these settings, a message is backed out only after a system error or if the client application terminates unexpectedly.
7. Send the message.
   a. Create MessageProducers to create messages. For point-to-point the MessageProducer is a QueueSender that is created by passing an output queue object (retrieved earlier) into the createSender method on the session. A QueueSender is usually created for a specific queue, so that all messages sent by that sender are sent to the same destination.

      ```
      QueueSender queueSender = session.createSender(inQueue);
      ```

   b. Create the message. Use the session to create an empty message and add the data passed.

      JMS provides several message types, each of which embodies some knowledge of its content. To avoid referencing the vendor-specific class names for the message types, methods are provided on the Session object for message creation.

      In this example, a text message is created from the outString property, which could be provided as an input parameter on invocation of the client program or constructed in some other way:

      ```
      TextMessage outMessage = session.createTextMessage(outString);
      ```

   c. Send the message.

      To send the message, the message is passed to the send method on the QueueSender:

      ```
      queueSender.send(outMessage);
      ```

8. Receive replies.
   a. Create a correlation ID to link the message sent with any replies. In this example, the client receives reply messages that are related to the message that it has sent, by using a provider-specific message ID in a JMSCorrelationID.

      ```
      messageID = outMessage.getJMSMessageID();
      ```

      The correlation ID is then used in a message selector, to select only messages that have that ID:

      ```
      String selector = "JMSCorrelationID = '"+messageID+"'";
      ```

   b. Create a MessageReceiver to receive messages. For point-to-point the MessageReceiver is a QueueReceiver that is created by passing an input queue object (retrieved earlier) and the message selector into the createReceiver method on the session.

      ```
      QueueReceiver queueReceiver = session.createReceiver(outQueue, selector);
      ```

   c. Retrieve the reply message. To retrieve a reply message, the receive method on the QueueReceiver is used:

      ```
      Message inMessage = queueReceiver.receive(2000);
      ```

      The parameter in the receive call is a timeout in milliseconds. This parameter defines how long the method should wait if there is no message available immediately. If you omit this parameter, the call blocks indefinitely. If you do not want any delay, use the receiveNoWait()method. In this example, the receive call returns when the message arrives, or after 2000ms, whichever is sooner.
   d. Act on the message received. When a message is received, you can act on it as needed by the business logic of the client. Some general JMS actions are to check that the message is of the correct type and extract the content of the message. To extract the content from the body of the message, cast from the generic Message class (which is the declared return type of the receive

methods) to the more specific subclass, such as TextMessage. It is good practice always to test the message class before casting, so that unexpected errors can be handled gracefully.

In this example, the instanceof operator is used to check that the message received is of the TextMessage type. The message content is then extracted by casting to the TextMessage subclass.

```
       if ( inMessage instanceof TextMessage )

...
            String replyString = ((TextMessage) inMessage).getText();
```

9. Closing down. If the application needs to create many short-lived JMS objects at the Session level or lower, it is important to close all the JMS resources used. To do this, you call the close() method on the various classes (QueueConnection, QueueSession, QueueSender, and QueueReceiver) when the resources are no longer required.

```
       queueReceiver.close();
...
       queueSender.close();
...
       session.close();
       session = null;
...
       connection.close();
       connection = null;
```

10. Publishing and subscribing messages. To use publish/subscribe support instead of point-to-point messaging, the general client actions are the same; for example, to create a session and connection. The exceptions are that topic resources are used instead of queue resources (such as TopicPublisher instead of QueueSender), as shown in the following example to publish a message:

```
// Creating a TopicPublisher
       TopicPublisher pub = session.createPublisher(topic);
...
       pub.publish(outMessage);
...
       // Closing TopicPublisher
       pub.close();
```

11. Handling errors Any JMS runtime errors are reported by exceptions. The majority of methods in JMS throw JMSExceptions to indicate errors. It is good programming practice to catch these exceptions and display them on a suitable output.

    Unlike normal Java exceptions, a JMSException can contain another exception embedded in it. The implementation of JMSException does not include the embedded exception in the output of its toString()method. Therefore, you must check explicitly for an embedded exception and print it out, as shown in the following example:

```
catch (JMSException je)
{
   System.out.println("JMS failed with "+je);
   Exception le = je.getLinkedException();
   if (le != null)
   {
       System.out.println("linked exception "+le);
   }
}
```

What to do next

For information about running a client against a specific remote server: “Running a Java EE client application with launchClient” on page 2015.

Programming for interoperation with WebSphere MQ

There are some differences between the WebSphere Application Server environment and the WebSphere MQ environment. If you are writing messaging programs that interoperate between these two environments, you should be aware of these differences and take them into account when designing, coding and deploying your programs.

Procedure

1. Learn more about the environment differences and other relevant concepts in How messages are passed between service integration and a WebSphere MQ network.
2. Read about designing programs that interoperate with WebSphere MQ in "Designing an application for interoperation with WebSphere MQ."

Designing an application for interoperation with WebSphere MQ

To design an application to interoperate with queue managers in a WebSphere MQ network you need to first consider the differences between the two environments, then design your JMS client based on the Java EE pattern, then identify any name-handling incompatibilities between the service integration bus and WebSphere MQ environments, then define the topic mappings.

Before you begin

Identify the WebSphere MQ queues with which your applications will interoperate. The exact names and locations can be left to the installation.

Procedure

1. Familiarize yourself with important reference information for the two interoperating environments, WebSphere MQ and the service integration bus.

   There are three types of reference material:

   - For mapping that is unique to service integration bus messaging, see "Mapping additional MQRFH2 header fields in service integration" on page 607.
   - For mapping between WebSphere Application Server service integration bus messaging and WebSphere MQ, see How service integration converts messages to and from WebSphere MQ format and "Mapping additional MQRFH2 header fields in service integration" on page 607.
   - For the differences between the WebSphere MQ functions and the service integration bus, see "WebSphere MQ functions not supported by service integration" on page 611.

2. Design your JMS client based on the typical Java EE pattern:
   a. Use JNDI to find a ConnectionFactory object.
   b. Use JNDI to find one or more Destination objects.
   c. Use the connection factory to create a JMS Connection object.
   d. Use the JMS connection to create one or more JMS Session objects.
   e. Use a JMS session and the destinations to create the MessageProducer and MessageConsumer objects.
   f. Start delivery of messages by starting the JMS connection.

   At this point a client has the basic JMS setup needed to produce and consume messages.
3. Identify any name-handling incompatibilities between the service integration bus and WebSphere MQ environments. If necessary, identify alias requirements, so that the WebSphere MQ application can handle service integration bus destination names of greater than 48 characters. For more information, see How to address bus destinations and WebSphere MQ queues.
4. Identify any reply destinations that are used by your application and check them for name-handling incompatibilities. For more information, see "Mapping destinations to and from WebSphere MQ queues, topics, and destinations" on page 601.

5. If your application publishes messages that you want to be forwarded to WebSphere MQ brokers, work with your administrator to define appropriate topic mappings on a publish/subscribe broker profile. You must also define topic mappings for any permanent reply topics. See Reply-to topics for request-reply messaging through a WebSphere MQ link and Request-reply messaging through a WebSphere MQ link for more information.

Mapping the message body to and from WebSphere MQ format

The WebSphere MQ message header (MQRFH2) and descriptor (MQMD) can contain information about the format of the WebSphere MQ message body. Service integration uses information contained in the MQRFH2 and MQMD when converting a message from WebSphere MQ format, and puts information into the MQRFH2 and MQMD when converting a message to WebSphere MQ format.

Exchanging messages between JMS programs through service integration and WebSphere MQ

Usually, you do not have to be aware of conversion between message formats to exchange JMS messages between service integration and WebSphere MQ, because service integration performs the appropriate conversion automatically, including character and numeric encoding. However, you might have to learn about message conversion if your JMS applications do not behave as expected, or if your service integration configuration includes JMS programs or mediations that process messages to or from non-JMS WebSphere MQ programs.

If your service integration applications exchange MapMessage objects with WebSphere MQ applications, you might have to specify a non-default map message encoding format.

WebSphere MQ message payload: format indications

The WebSphere MQ format message contains the following two indications of the payload format:

MQRFH2 <mcd> folder, Msd field

This field can contain information about the payload format. This is the “JMS format” information.

- When service integration converts a message to WebSphere MQ format, it automatically sets the appropriate value for the JMS message class.
- When service integration converts a message from WebSphere MQ format, it uses the value in this field (if there is an MQRFH2 that contains the field) to set the JMS message class.

JMS message class	MQRFH2 <mcd> folder, Msd field (“JMS format”)
TextMessage	jms_text
BytesMessage	jms_bytes
StreamMessage	jms_stream
MapMessage	jms_map
ObjectMessage	jms_object
Message	jms_none

If the “JMS format” information is not available, for example if there is no MQRFH2, service integration sets the JMS message class based on the “MQ format”.

For more information about the MQRFH2 <mcd> folder, see the WebSphere MQ Using Java documentation.

MQRFH2 (or MQMD) format field

The MQRFH2 (or the MQMD if there is no MQRFH2) format field contains information about the payload format. This is the “MQ format” information. Typically it contains MQFMT_STRING, which indicates that the payload is character data (and can be translated to a different codepage by

WebSphere MQ), or MQFMT_NONE, which indicates that the payload is not character data. These values are suitable for most JMS messages, and when service integration converts a message to WebSphere MQ format it automatically sets this field to one of the following values:

JMS message class	MQRFH2 (or MQMD) format field ("MQ format")
TextMessage	MQFMT_STRING
BytesMessage	MQFMT_NONE
StreamMessage	MQFMT_STRING
MapMessage	MQFMT_STRING
ObjectMessage	MQFMT_NONE
Message	MQFMT_NONE

If your application constructs messages for a WebSphere MQ application that requires a different format value, you can override the value from the previous table by setting the JMS_IBM_Format property to the required value. A particular example is when the WebSphere MQ application requires an additional header (for example, the MQCIH header for a CICS bridge application). Your application constructs a BytesMessage object that contains the header followed by any other message data, then replaces the default "MQ format" (MQFMT_NONE) by setting the JMS_IBM_Format property to the appropriate value for the header (for example, MQFMT_CICS for an MQCIH header).

When service integration converts a message from WebSphere MQ format, it sets the JMS_IBM_Format property to the value in the "MQ format" field. If the "JMS format" is not available, for example if there is no MQRFH2, service integration sets the JMS message class to TextMessage if the "MQ format" is MQFMT_STRING and to BytesMessage otherwise.

For more information about the MQRFH2 (or MQMD) format field, see the WebSphere MQ Application Programming Reference.

WebSphere MQ message payload: character and numeric encoding

In addition to the format field, the MQRFH2 (or the MQMD if there is no MQRFH2) contains fields that identify the character encoding and numeric encoding for the message payload.

When service integration converts a message to WebSphere MQ format, it automatically selects default values (UTF-8 character encoding and big-endian numeric encoding) that are suitable for most JMS messages. If your application constructs messages for a WebSphere MQ application that requires a different character or numeric encoding, you can override the character encoding value by setting the **JMS_IBM_Character_Set** property to the required coded character set ID (CCSID), or the **JMS_IBM_Encoding** property to the required numeric format, or both. For information about the values you can use for **JMS_IBM_Character_Set** and **JMS_IBM_Encoding**, see the documentation in the WebSphere MQ library.

When the JMS message has a body that is encoded as character data in WebSphere MQ (TextMessage, StreamMessage, or MapMessage), setting **JMS_IBM_Character_Set** causes service integration to convert the text to that coded character set in the WebSphere MQ message body.

When the JMS message has a body that is not character data (BytesMessage or ObjectMessage), setting **JMS_IBM_Character_Set** does not cause service integration to convert the bytes; it indicates to WebSphere MQ that any character data in the message body is already encoded using the specified coded character set. If the value of the **JMS_IBM_Format** is a format that WebSphere MQ recognises, it can convert that character data to the coded character set that the receiving application requires.

When service integration converts a message from WebSphere MQ format, it sets the **JMS_IBM_Character_Set** and **JMS_IBM_Encoding** properties from the fields in the MQRFH2 (or the MQMD if there is no MQRFH2). If the JMS message is a TextMessage, StreamMessage, MapMessage, or ObjectMessage, your application makes no use of the values of the **JMS_IBM_Character_Set** and

JMS_IBM_Encoding properties. If the JMS message is a BytesMessage, then the body of the JMS message is binary data. In this case, your application must be aware of the values of the **JMS_IBM_Character_Set** and **JMS_IBM_Encoding** properties, because they indicate the encoding of any character data or numeric data that is embedded within the binary data of the message.

Mapping the message header fields and properties to and from WebSphere MQ format

When service integration converts a message to WebSphere MQ format, it sets fields in the MQMD and the MQRFH2 based on the service integration message header fields and properties; these include JMS message header fields and properties applicable to the message. When service integration converts a message from WebSphere MQ format, it sets the service integration message header fields and properties from the MQMD and the MQRFH2 in the WebSphere MQ message.

Exchanging messages between JMS programs through service integration and WebSphere MQ

Usually, you do not have to be aware of conversion between message formats to exchange JMS messages between service integration and WebSphere MQ, because service integration performs the appropriate conversion automatically, including character and numeric encoding. However, you might have to learn about message conversion if your JMS applications do not behave as expected, or if your service integration configuration includes JMS programs or mediations that process messages to or from non-JMS WebSphere MQ programs.

If your service integration applications exchange MapMessage objects with WebSphere MQ applications, you might have to specify a non-default map message encoding format.

WebSphere MQ message properties: the MQMD and the MQRFH2

WebSphere MQ messages contain message properties in the message descriptor (MQMD) and in the rules and formatting header 2 (MQRFH2). The WebSphere MQ message always includes an MQMD, but the MQRFH2 is optional because some WebSphere MQ applications cannot process messages that contain an MQRFH2. To simplify interoperation, you can configure service integration to omit the MQRFH2 from messages for applications that cannot process the MQRFH2. When service integration omits the MQRFH2, it discards the corresponding service integration header fields and properties.

Note: A small amount of the MQRFH2 information is also stored in MQMD fields. However, these MQMD fields are not exact equivalents, tend to be less specific, and cannot be relied upon to provide an adequate substitute for the MQRFH2 information. Therefore if the receiving application can accept an MQRFH2 header, you should always provide one.

Similarly, service integration might receive messages from WebSphere MQ applications that generate messages with no MQRFH2. When service integration receives a message with no MQRFH2, it creates a “best guess” service integration header, by getting as much information as it can from the MQMD, and using default values for the other fields.

For detailed information about the contents of the message descriptor and the message headers, see the WebSphere MQ Application Programming Reference. For details of WebSphere MQ JMS support, including details of how WebSphere MQ stores JMS message properties and header fields in the MQMD and the MQRFH2, see WebSphere MQ Using Java.

WebSphere MQ message properties: JMS header fields

The following table shows how service integration maps JMS header fields to and from MQMD and MQRFH2 fields when converting messages to and from WebSphere MQ format.

The table shows the MQRFH2 field as *folder.field*, where *folder* is the name of the MQRFH2 folder that contains the field, and *field* is the name of the field within the MQRFH2 folder.

For several JMS header fields, there is both an MQMD field and an MQRFH2 field. When service integration is converting messages to WebSphere MQ format, it sets both the MQMD and the MQRFH2 fields. When service integration is converting messages from WebSphere MQ format, it sets the JMS header field from the MQRFH2 field if it is available, otherwise from the MQMD field.

Table 78. JMS, MQMD and MQRFH2 header fields. The first column of this table lists the JMS header fields, and the second column shows the MQMD fields that relate to the JMS header fields in the first column. The third column shows the MQRFH2 fields that relate to the JMS header fields in the first column. The fourth column provides links, where required, to the footnotes that appear after the table.

JMS header field	MQMD field	MQRFH2 field	Notes
JMSCorrelationID	**CorrelId**	**jms.Cid**	See Note 1.
JMSDeliveryMode	**Persistence**	**jms.Dlv**	See Note 15.
JMSDestination		**jms.Dst**	See Note 16.
JMSExpiration	**Expiry**	**jms.Exp**	
JMSMessageID	**MsgId**		
JMSPriority	**Priority**		See Note 2.
JMSRedelivered	**BackoutCount**		See Note 3.
JMSReplyTo	**ReplyToQ** and **ReplyToQMgr**	**jms.Rto**	See Note 16.
JMSTimestamp	**PutDate** and **PutTime**	**jms.Tms**	
JMSType		**mcd.Type**	

Note 1: The MQMD **CorrelId** field can hold a standard WebSphere MQ Correlation ID of 48 hexadecimal digits (24 bytes). The **JMSCorrelationID** can be a `byte[]` value, a string value containing hexadecimal characters and prefixed with “ID:”, or an arbitrary string value not beginning “ID:”. The first two of these represent a standard WebSphere MQ Correlation ID and map directly to or from the MQMD **CorrelId** field (truncated or padded with zeros as applicable); they do not use the MQRFH2 **jms.Cid** field. The third (arbitrary string) uses the MQRFH2 **jms.Cid** field; the first 24 bytes of the string, in UTF-8 format, are written into the MQMD **CorrelID**.

Note 2: WebSphere MQ stores the **JMSPriority** value in the MQRFH2 **jms.Pri** field but does not use any value already in that field. Service integration does not check or set the MQRFH2 **jms.Pri** field.

Note 3: Service integration sets the **JMSRedelivered** indicator for a message it receives from WebSphere MQ based on the **BackoutCount** field of the MQMD; a non-zero **BackoutCount** value indicates that a previous receive for the message was rolled back.

WebSphere MQ message properties: JMS defined properties

The following table shows how service integration maps JMS defined properties to and from MQMD and MQRFH2 fields when converting messages to and from WebSphere MQ format.

The table shows the MQRFH2 field as *folder.field*, where *folder* is the name of the MQRFH2 folder that contains the field, and *field* is the name of the field within the MQRFH2 folder.

For several JMS-defined properties, there is both an MQMD field and an MQRFH2 field. When service integration is converting messages to WebSphere MQ format, it sets both the MQMD and the MQRFH2 fields. When service integration is converting messages from WebSphere MQ format, it sets the JMS defined property from the MQRFH2 field if it is available, otherwise from the MQMD field.

Table 79. JMS properties with MQMD and MQRFH2 fields. The first column of this table lists the JMS defined properties, and the second column shows the MQMD fields that relate to the JMS defined properties in the first column. The third column shows the MQRFH2 fields that relate to the JMS defined properties in the first column. The fourth column provides links, where required, to the footnotes that appear after the table.

JMS defined property	MQMD field	MQRFH2 field	Notes
JMSXAppID	**PutApplName**		
JMSXDeliveryCount	**BackoutCount**		
JMSXGroupID	**GroupId**	**jms.Gid**	See Notes 4 and 5.
JMSXGroupSeq	**MsgSeqNumber**	**jms.Seq**	
JMSXUserID	**UserIdentifier**		

Note 4: The MQMD **GroupId** field can hold a standard WebSphere MQ **GroupId** of 48 hexadecimal digits (24 bytes). The **JMSXGroupID** is a string value containing hexadecimal characters and prefixed with "ID:" or an arbitrary string value not beginning "ID:". The first of these represents a standard WebSphere MQ **GroupId** and maps directly to or from the MQMD **GroupId** field (truncated or padded with zeros as applicable). The second (arbitrary string) uses the MQRFH2 **jms.Gid** field; the first 24 bytes of the string, in UTF-8 format, are written into the MQMD **GroupId**.

Note 5: When service integration is converting messages to WebSphere MQ format, if the **JMSXGroupID** has been set then service integration also sets the **MQMF_MSG_IN_GROUP** flag in the **MsgFlags** field of the MQMD. Note that when sending group messages, the sending JMS application must ensure that the **MQMF_LAST_MSG_IN_GROUP** flag is set as required (see "WebSphere MQ message properties: JMS provider-specific properties").

WebSphere MQ message properties: JMS provider-specific properties

The following table shows how service integration maps JMS provider-specific properties to and from MQMD and MQRFH2 fields when converting messages to and from WebSphere MQ format. Typically you use these properties to satisfy special requirements in the receiving application, so you should consult the developer or administrator of the receiving application for details of the required property values.

Table 80. JSM provider-specific properties with MQMD and MQRFH2 fields. The first column of this table lists the JMS provider-specific properties, and the second column shows the MQMD fields that relate to the JMS provider-specific properties in the first column. The third column shows the MQRFH2 fields that relate to the JMS provider-specific properties in the first column. The fourth column provides links, where required, to the footnotes that appear after the table.

JMS provider-specific property	MQMD field	MQRFH2 field	Notes
JMS_IBM_ArmCorrelator		**mqext.Arm**	See Note 6.
JMS_IBM_Character_Set	**CodedCharacterSetId**	**CodedCharacterSetId**	See Note 7.
JMS_IBM_Encoding	**Encoding**	**Encoding**	See Note 7.
JMS_IBM_Feedback	**Feedback**		
JMS_IBM_Format	**Format**	**Format**	See Note 7.
JMS_IBM_Last_Msg_In_Group	**MQMF_LAST_MSG_IN_GROUP**		See Note 8.
JMS_IBM_MQMD_CorrelId	**CorrelId**		See Notes 9 and 10.
JMS_IBM_MQMD_MsgId	**MsgId**		See Notes 9 and 11.
JMS_IBM_MQMD_Persistence	**Persistence**		See Notes 9, 12, and 15.
JMS_IBM_MQMD_ReplyToQ	**ReplyToQ**		See Notes 9, 13, and 16.
JMS_IBM_MQMD_ReplyToQMgr	**ReplyToQMgr**		See Notes 9, 13, and 16.
JMS_IBM_MsgType	**MsgType**		
JMS_IBM_PutDate	**PutDate**		

Table 80. JSM provider-specific properties with MQMD and MQRFH2 fields (continued). The first column of this table lists the JMS provider-specific properties, and the second column shows the MQMD fields that relate to the JMS provider-specific properties in the first column. The third column shows the MQRFH2 fields that relate to the JMS provider-specific properties in the first column. The fourth column provides links, where required, to the footnotes that appear after the table.

JMS provider-specific property	MQMD field	MQRFH2 field	Notes
JMS_IBM_PutTime	**PutTime**		
JMS_IBM_Report_*	**Report**		See Note 14.
JMS_IBM_RMCorrelator		**mqext.Wrm**	
JMS_TOG_ARM_Correlator		**mqext.Arm**	See Note 6.

Note 6: You should use the name **JMS_TOG_ARM_Correlator** for the ARM correlator. The name **JMS_IBM_ArmCorrelator** is available for compatibility with some existing JMS programs.

Note 7: The **JMS_IBM_Character_Set**, **JMS_IBM_Encoding**, and **JMS_IBM_Format** properties contain information about the WebSphere MQ message payload; that is, the part of the WebSphere MQ message that follows the MQRFH2 (if there is one) or the whole WebSphere MQ message, excluding the MQMD, if there is no MQRFH2. For more information about these properties and how to use them, see “Mapping the message body to and from WebSphere MQ format” on page 594.

Note 8: **MQMF_LAST_MSG_IN_GROUP** is one of the flags in the **MsgFlags** field of the MQMD.

Note 9: The **JMS_IBM_MQMD_CorrelId**, **JMS_IBM_MQMD_MsgId**, **JMS_IBM_MQMD_Persistence**, **JMS_IBM_MQMD_ReplyToQ**, and **JMS_IBM_MQMD_ReplyToQMgr** properties allow JMS applications to override the service integration default processing of WebSphere MQ MQMD fields. When service integration converts messages to WebSphere MQ format, service integration sets the corresponding MQMD field for each of these properties if, and only if, that property has been explicitly set by the application (using `setObjectProperty()` or `setNonNullProperty()`).

Service integration sets each of these properties from the corresponding MQMD field when it converts a message from WebSphere MQ format.

Note 10: The **JMS_IBM_MQMD_CorrelId** property overrides the default processing of the **JMSCorrelationID** property. When service integration converts messages to WebSphere MQ format, service integration sets the MQMD **CorrelId** field to the value (`byte[]`) if explicitly set of the **JMS_IBM_MQMD_CorrelId** property, regardless of the value (if any) of the **JMSCorrelationID** property. Setting the **JMS_IBM_MQMD_CorrelId** property does not affect the value of the MQRFH2 **jms.Cid** field.

When service integration converts messages from WebSphere MQ format, service integration sets the **JMS_IBM_MQMD_CorrelId** property to the value (`byte[]`) of the **MQMD CorrelId** field, regardless of the value (if any) of the MQRFH2 **jms.Cid** field.

Note 11: The **JMS_IBM_MQMD_MsgId** property overrides the JMS default processing of the **JMSMessageID** property. When service integration converts messages to WebSphere MQ format, service integration checks whether the **JMS_IBM_MQMD_MsgId** property has been explicitly set. If so, service integration sets the MQMD **MsgId** field to this value (byte[]) , and replaces the unique value of the **JMSMessageID** that JMS allocates to the message.

When service integration converts messages from WebSphere MQ format, service integration sets the **JMS_IBM_MQMD_MsgId** property to the value (`byte[]`) of the MQMD **MsgId** field.

Note 12: The **JMS_IBM_MQMD_Persistence** property overrides the default processing of the **JMSDeliveryMode** property. When service integration converts messages to WebSphere MQ format, service integration sets the MQMD **Persistence** field to the value (integer) if explicitly set of the **JMS_IBM_MQMD_Persistence** property, regardless of the value (if any) of the **JMSDeliveryMode** property. Setting the **JMS_IBM_MQMD_Persistence** property does not affect the value of the MQRFH2 **jms.Dlv** field.

When service integration converts messages from WebSphere MQ format, service integration sets the **JMS_IBM_MQMD_Persistence** property to the value (integer) of the MQMD **Persistence** field, regardless of the value (if any) of the MQRFH2 **jms.Dlv** field.

Note 13: The **JMS_IBM_MQMD_ReplyToQ** and **JMS_IBM_MQMD_ReplyToQMgr** properties override the default processing of the **JMSReplyTo** property. When service integration converts messages to WebSphere MQ format, service integration sets the MQMD **ReplyToQ** field to the value (string) if explicitly set of the **JMS_IBM_MQMD_ReplyToQ** property and the MQMD **ReplyToQMgr** field to the value (string) if explicitly set of the **JMS_IBM_MQMD_ReplyToQMgr** property, regardless of the value (if any) of the **JMSReplyTo** property. Setting the **JMS_IBM_MQMD_ReplyToQ** or **JMS_IBM_MQMD_ReplyToQMgr** field does not affect the value of the MQRFH2 **jms.Rto** field.

When service integration converts messages from WebSphere MQ format, service integration sets the **JMS_IBM_MQMD_ReplyToQ** and **JMS_IBM_MQMD_ReplyToQMgr** property to the values (string) of the MQMD **ReplyToQ** and **ReplyToQMgr** fields, regardless of the value (if any) of the MQRFH2 **jms.Rto** field.

Note 14: For a list of the **JMS_IBM_Report_*** properties, see “Mapping MQMD Report fields to JMS provider-specific properties” on page 605.

Note 15: For more information see “Mapping the JMS delivery option and message reliability to and from the WebSphere MQ persistence value.”

Note 16: For more information see “Mapping destinations to and from WebSphere MQ queues, topics, and destinations” on page 601.

Mapping the JMS delivery option and message reliability to and from the WebSphere MQ persistence value

When converting messages between WebSphere MQ format and service integration format, service integration processes the message header fields and properties relating to message delivery mode, reliability, and persistence.

Quality of service indications in the WebSphere MQ format message

The WebSphere MQ format message contains the following indications of the quality of service:

MQMD persistence

This property is present in all WebSphere MQ format messages. The property specifies the quality of service that WebSphere MQ provides for the message as follows:

MQMD persistence	Quality of service
MQPER_PERSISTENT	Persistent quality of service. WebSphere MQ assures once and once only delivery of the message.
MQPER_NOT_PERSISTENT	Nonpersistent quality of service. WebSphere MQ can discard the message in exceptional circumstances.
MQPER_PERSISTENCE_AS_Q_DEF	WebSphere MQ sets the quality of service (persistent or nonpersistent) to the value configured for the destination queue.

For more information about the WebSphere MQ persistent and nonpersistent qualities of service, see the WebSphere MQ documentation .

MQRFH2 jms.Dlv (JMSDeliveryMode)

This property is present in WebSphere MQ format JMS messages that include the MQRFH2 header. The property contains the **JMSDeliveryMode** that was set when the application issued `send` for the message.

Quality of service indications when service integration converts a message to WebSphere MQ format

Message reliability levels - JMS delivery mode and service integration quality of service describes how service integration sets the message reliability. Briefly: JMS applications send messages with a JMS delivery mode (`persistent` or `nonpersistent`), then service integration uses JMS connection factory settings to map the JMS delivery mode to a service integration message reliability setting, and finally additional settings on bus destinations (including foreign destinations and alias destinations) can override this message reliability. When service integration converts the message to WebSphere MQ format, it sets the **MQMD persistence** indicator as follows:

Service integration message reliability	MQMD persistence
Reliable persistent	Persistent
Assured persistent	Persistent
Reliable nonpersistent	Nonpersistent
Express nonpersistent	Nonpersistent
Best effort nonpersistent	Nonpersistent

The sending application can optionally override this by setting the **JMS_IBM_MQMD_Persistence** message property in the message.

Quality of service indications when service integration converts a message from WebSphere MQ format

When service integration receives a message from WebSphere MQ, it uses the **MQMD persistence** value of the message together with the corresponding service integration reliability value that you configure in the WebSphere MQ link receiver or the WebSphere MQ server queue point to determine the reliability of the service integration message.

Mapping destinations to and from WebSphere MQ queues, topics, and destinations

Service integration messages and WebSphere MQ messages both contain header fields and properties. Some of these header fields and properties contain destinations or destination properties that provide information about send-to and reply-to destinations, and about destinations in the bus forward and reverse routing paths. Because service integration and WebSphere MQ have different definitions for destinations, mappings are used to process the destinations and destination properties when messages are converted between service integration format and WebSphere MQ format.

Destinations and destination properties in the WebSphere MQ format message

The WebSphere MQ format message contains the following information related to destinations:

MQXQH RemoteQName
MQXQH RemoteQMgrName

These fields are present in the MQXQH (the WebSphere MQ Transmission-queue header). The MQXQH is attached to messages only while they travel between WebSphere MQ queue managers, or

between WebSphere MQ queue managers and service integration buses across a WebSphere MQ link. Sending and receiving applications cannot access these fields.

The **RemoteQName** field contains the name of the send-to queue (WebSphere MQ) or send-to destination (service integration). The **RemoteQMgrName** field identifies the queue manager or queue-sharing group (WebSphere MQ) or service integration bus (service integration) where the send-to queue or destination is located. Usually, the **RemoteQMgrName** field contains the name of the remote queue manager, queue-sharing group, or service integration bus, but it can contain a WebSphere MQ queue manager alias or a service integration virtual queue manager name. Note that these fields are not used for topics.

The **RemoteQName** and **RemoteQMgrName** values can be up to a maximum length of 48 characters, and must conform to WebSphere MQ naming restrictions.

MQRFH2 jms.Dst (JMSDestination)

This field is present in WebSphere MQ format JMS messages that include the MQRFH2 header.

The **jms.Dst** field contains a serialized representation (a WebSphere MQ URI) of the send-to JMS destination that was set when the application issued send for the message. Refer to the WebSphere MQ library for more information about the WebSphere MQ URI format for JMS destinations.

When service integration sends a message that has a forward-routing path to WebSphere MQ, it adds an **ibmRoutingPath** attribute to this URI. The **ibmRoutingPath** value identifies the forward routing path from the service integration message. WebSphere MQ does not use the forward routing path, but the send-to destination might be in a remote service integration bus that can use the forward routing path.

MQMD ReplyToQ
MQMD ReplyToQMgr

These fields are present in all WebSphere MQ format messages.

If the sending application specifies a reply-to queue, the **ReplyToQ** field contains the name of the reply-to queue (WebSphere MQ) or reply-to destination (service integration), and the **ReplyToQMgr** field identifies the queue manager or queue-sharing group (WebSphere MQ) or service integration bus (service integration) where that queue is located. Usually, the **ReplyToQMgr** field contains the name of the queue manager, queue-sharing group, or service integration bus, but it can contain a WebSphere MQ queue manager alias or a service integration virtual queue manager name. If the sending application specifies a reply-to topic, or if it does not specify a reply-to destination, these fields contain null values.

The **ReplyToQ** and **ReplyToQMgr** values can be up to a maximum length of 48 characters, and must conform to WebSphere MQ naming restrictions.

MQRFH2 jms.Rto (JMSReplyTo)

This field is present in WebSphere MQ format JMS messages that include the MQRFH2 header and that specify a reply-to destination. WebSphere MQ JMS applications usually use this message attribute as the destination for reply messages, but other (non-JMS) WebSphere MQ applications usually do not use it; they use the MQMD reply-to fields instead.

The **jms.Rto** field contains a serialized representation (a WebSphere MQ URI) of the reply-to JMS destination that is set by the sending JMS application. Refer to the WebSphere MQ library for more information about the WebSphere MQ URI format for JMS destinations.

When service integration sends a message that has a reverse-routing path to WebSphere MQ, service integration adds an **ibmRoutingPath** attribute to this URI. The **ibmRoutingPath** value identifies the reverse-routing path from the service integration message. When the receiving JMS application sends a reply, WebSphere MQ includes the routing path information from the reply-to URI in the send-to URI of the reply message so that service integration can use it for routing the reply message.

Note:

- When the sending application specifies a reply-to queue for a message, that queue is usually located in the bus, queue manager, or queue-sharing group to which the sending application connects. This allows the sending application to receive the reply message from the reply-to queue. Service integration applications that send messages to or through WebSphere MQ should not specify a reply-to queue in a different bus, queue manager, or queue-sharing group.
- It is important to understand that it is the receiving application which uses the reply-to destination in a message. The bus, queue manager, or queue-sharing group to which the receiving application connects must be configured with the information that allows routing to the reply-to destination.

Destination conversion when service integration converts a message to WebSphere MQ format

When service integration converts a message to WebSphere MQ format, it puts the following destination information into the WebSphere MQ format message:

MQXQH RemoteQName
MQXQH RemoteQMgrName

These fields apply only when service integration is sending the message across a WebSphere MQ link, and only when the destination is a queue.

Service integration sets these fields based on the resolved send-to destination for the message; that is, if the send-to destination is an alias, service integration uses the target bus and target identifier. Processing is then as follows:

- If the send-to destination is in an indirectly-connected bus, it stores the destination name (identifier) as the **RemoteQName** and the bus name as the **RemoteQMgrName**.
- If the send-to destination is in the directly-connected bus and the destination name (identifier) is in the form *queue@queueManager*, it stores the queue name (*queue*) as the **RemoteQName** and the queue manager name (*queueManager*) as the **RemoteQMgrName**.
- If the send-to destination is in the directly-connected bus and the destination name (identifier) is not in the form *queue@queueManager*, it stores the destination name as the **RemoteQName** and the bus name as the **RemoteQMgrName**.

If the send-to destination is in an indirectly-attached service integration bus and its destination name does not comply with WebSphere MQ naming restrictions, you must define an alias destination with a compliant name; the sending application must use the compliant (alias) name. In this case, you must define the alias destination in the remote (indirectly-attached) bus, not the local bus.

If the send-to destination is in an indirectly-attached service integration bus and its bus name does not comply with WebSphere MQ naming restrictions, there must be a virtual queue manager name for the indirectly-attached bus. In this case, the local bus must define the indirectly-attached bus with its virtual queue manager name, not its bus name.

For more information about mapping service integration bus names that do not comply with WebSphere MQ naming restrictions, see How to address bus destinations and WebSphere MQ queues.

MQRFH2 jms.Dst (JMSDestination)

If the WebSphere MQ format message includes the MQRFH2 header, service integration serializes the **JMSDestination** header field into a WebSphere MQ URI and stores it in the **JMSDestination** field in the WebSphere MQ message. If the message has a forward-routing path, service integration includes that in the URI as the **ibmRoutingPath** attribute.

MQMD ReplyToQ
MQMD ReplyToQMgr

The sending JMS application can set these fields directly by using the provider-specific JMS message properties **JMS_IBM_MQMD_ReplyToQ** and **JMS_IBM_MQMD_ReplyToQMgr**. If the sending application does not do this, service integration sets the properties if (and only if) the message has a reply-to destination and that destination is a queue.

Service integration sets these fields based on the unresolved reply-to destination for the message; that is, if the reply-to destination is an alias, service integration uses the alias bus and identifier, not the target bus and identifier. Service integration applications should not provide reply-to destinations that are foreign destinations or have names that include the @ character. Provided applications do not do this, processing is as follows:

- The reply-to destination name (identifier) is stored in the **ReplyToQ** field and the reply-to destination bus name (that is, the local bus name) in the **ReplyToQMgr** field.
- If the virtual queue manager name is different from the local bus name, the virtual queue manager name is stored in the **ReplyToQMgr** field instead of the local bus name.

If the real name of the reply-to destination does not comply with WebSphere MQ naming restrictions (including if the name includes the @ character), you must define an alias destination with a compliant name and the sending application must use the compliant (alias) name. In this case, you must define the alias destination in the local bus, not in the remote (indirectly-attached) bus.

MQRFH2 jms.Rto (JMSReplyTo)

If the message has a reply-to destination and the WebSphere MQ format message includes the MQRFH2 header, service integration constructs a WebSphere MQ URI to represent that reply-to destination, and stores the URI in the **JMSReplyTo** property in the WebSphere MQ message. If the reply-to destination is a queue, the URI includes the reply-to destination bus name (the local bus) or the virtual queue manager name (if that is different). If the message has a reverse-routing path, service integration includes that path in the URI in the **ibmRoutingPath** attribute.

Destination conversion when service integration converts a message from WebSphere MQ format

When service integration converts a message from WebSphere MQ format, it uses the following destination information from the WebSphere MQ format message:

MQXQH RemoteQName
MQXQH RemoteQMgrName

These fields are applicable only when service integration is receiving the message across a WebSphere MQ link, and only when the destination is a queue.

Service integration interprets the **RemoteQName** field as the destination identifier (always a queue) for the message, and the **RemoteQMgrName** field as the name of the destination bus for the message. If the **RemoteQMgrName** field contains the virtual queue manager name of the local bus, service integration interprets it as the name of the local bus. Service integration then uses the resulting bus and destination identifier combination (which can be an alias destination in the local bus) to deliver the message in the usual way. For the case where the destination bus is a foreign bus, this includes forwarding the message to that foreign bus.

MQRFH2 jms.Dst (JMSDestination)

If this field is available, service integration uses it to create the **JMSDestination** header field for the message. If the URI includes the **ibmRoutingPath** attribute, service integration uses that to create the forward-routing path for the message.

If this property is not available (for example, if the WebSphere MQ message has no MQRFH2 header), service integration can create a **JMSDestination** header field from the service integration destination where the message is delivered.

MQMD ReplyToQ
MQMD ReplyToQMgr

If these fields contain non-null values, service integration uses them to construct the first element of the reverse-routing path for the service integration message, as follows:

- If **ReplyToQMgr** is the local bus name or virtual queue manager name, service integration sets the bus to the local bus and the destination name (identifier) to **ReplyToQ**.
- If **ReplyToQMgr** is a foreign bus defined in the local bus, service integration sets the bus to **ReplyToQMgr** and the destination name (identifier) to **ReplyToQ**.
- If **ReplyToQMgr** is not the local bus name, virtual queue manager name, or a foreign bus defined in the local bus, service integration sets the bus to the directly-attached WebSphere MQ bus and the destination name (identifier) to *queue@queueManager* where *queue* is **ReplyToQ** and *queueManager* is **ReplyToQMgr**.

MQRFH2 jms.Rto (JMSReplyTo)

If this field is available, service integration uses it with the MQMD **ReplyToQ** and **ReplyToQMgr** fields to construct the reverse-routing path and **JMSReplyTo** header field for the service integration message. It constructs the reverse-routing path from the first element (which it constructs from the MQMD **ReplyToQ** and **ReplyToQMgr** fields) and any remaining elements that it obtains from the **ibmRoutingPath** attribute (if there is one) of the **JMSReplyTo** URI in the WebSphere MQ message. It constructs the **JMSReplyTo** header field from the first element of the reverse-routing path together with the destination attributes of the **JMSReplyTo** URI in the WebSphere MQ message.

Mapping MQMD Report fields to JMS provider-specific properties

JMS applications can use report messages as a form of managed request/response processing, to give remote feedback to producers on the outcome of their send operations and the fate of their messages. A JMS application can request different types of report message by setting JMS_IBM_Report_Xxxx message properties and options.

JMS applications can request the following types of report message by setting the appropriate JMS_IBM_Report_Xxxx message properties and options. The options have the same general syntax and meaning:

MQRO_*report-type*
A report message of the indicated type is generated that contains the WebSphere MQ message descriptor (MQMD) of the original message. It does not contain any message body data.

MQRO_*report-type*_**WITH_DATA**
A report message of the indicated type is generated that contains the MQMD, any MQ headers, and 100 bytes of body data.

MQRO_*report-type*_**WITH_FULL_DATA**
A report message of the indicated type is generated that contains all data from the original message.

Use the following prefix with each option: com.ibm.websphere.sib.api.jms.

For example, to request a Confirm on delivery (COD) report message with full data, the JMS application must set JMS_IBM_Report_COD to the value com.ibm.websphere.sib.api.jms.MQRO_COD_WITH_FULL_DATA.

For each type of report message, the following table shows the JMS_IBM_Report_Xxxx message property that a JMS application can set, and the MQMD Report field options that map to the property.

Type of report message	Description	JMS_IBM_Report_Xxxx message property and options
Exception	Send a report message if the request message cannot be put to the target queue. The exception report messages are generated when a message has been rerouted to an exception destination.	JMS_IBM_Report_Exception • MQRO_EXCEPTION • MQRO_EXCEPTION_WITH_DATA • MQRO_EXCEPTION_WITH_FULL_DATA
Discard	Discard the original request message rather than sending it to an exception destination. You can use this option with the JMS_IBM_Report_Exception property set to MQRO_EXCEPTION_WITH_FULL_DATA to return an undeliverable request message to its sender.	JMS_IBM_Report_Discard_Msg • TRUE • FALSE
Expiration	Send a report message if the request message passes its expiry time.	JMS_IBM_Report_Expiration • MQRO_EXPIRATION • MQRO_EXPIRATION_WITH_DATA • MQRO_EXPIRATION_WITH_FULL_DATA
Confirm on arrival (COA)	Send a report message when the request message has been put to the target queue. For publish/subscribe messaging, the COA report message is generated only on the producers messaging engine. Therefore, such reports are relevant only to local subscriptions. For point-to-point messaging, COA messages are generated when the message arrives at the final destination. For partitioned queues, the report message is generated only when the put operation has committed and a final destination has therefore been selected. Any With_Data or With_Full_Data report options specified are ignored; the COA report message deals only with message headers. If a forward-routing path is used, the COA message are generated when the message arrives at the final destination in the path.	JMS_IBM_Report_COA • MQRO_COA • MQRO_COA_WITH_DATA • MQRO_COA_WITH_FULL_DATA

Type of report message	Description	JMS_IBM_Report_Xxxx message property and options
Confirm on delivery (COD)	Send a report message when the request message has been removed from the queue or topic space by a message consumer. For publish/subscribe messaging, the COD message is generated when all subscribers have received the request message. Therefore, there is one COD message generated for every COA. When a message is consumed by a subscriber, the reference count of the message on the topic space is reduced. When the reference count reaches zero, the message is removed from the topic space then a COD report message is generated. For point-to-point messaging, the COD message is generated after the message has been successfully received by a consuming application. Any With_Data or With_Full_Data report options specified are ignored; the COD report message deals only with message headers.	JMS_IBM_Report_COD • MQRO_COD • MQRO_COD_WITH_DATA • MQRO_COD_WITH_FULL_DATA
Positive action notification (PAN)	Ask the consumer application to send a report message when it has successfully processed the request message.	JMS_IBM_Report_PAN • TRUE • FALSE
Negative action notification (NAN)	Ask the consumer application to send a report message if it has not successfully processed the request message.	JMS_IBM_Report_NAN • TRUE • FALSE

The requesting application can control other aspects of the report message as follows:

- How the message Id is generated for the report message and any reply message:

  MQRO_New_Msg_Id
  This the default. A new message Id is generated for the report message.

  MQRO_Pass_Msg_Id
  The message Id of the report message is set to the message Id of the request message.

- How the correlation Id of the report or reply message is to be set.

  MQRO_Copy_Msg_Id_To_Correl_Id
  This the default. the correlation Id of the report message is set to the message Id of the request message.

  MQRO_Pass_Correl_Id
  The correlation Id of the report message is set to the correlation Id of the request message.

For more information about report messages and the associated properties and options refer to the *Using Java* section of the WebSphere MQ information center, available from the WebSphere MQ library.

Mapping additional MQRFH2 header fields in service integration

In the WebSphere MQ message header (MQRFH2), there are additional fields that are specific to the service integration bus and that allow for functions that are not used in WebSphere MQ. When

WebSphere MQ transports a message from one service integration bus to another service integration bus, these fields convey information that can be used by service integration applications but is not required by WebSphere MQ.

The additional fields are inserted in the MQRFH2 header of application messages, in the <sib> and <jms> folders. These fields do not appear as JMS message fields or properties.

When a message is sent to WebSphere MQ, a <sib> folder is included in the MQRFH2 header of the message if both of the following are true:

- The WebSphere MQ queue point attributes of the service integration destination are configured to use MQRFH2 headers.
- The fields that correspond to the <sib> folder content are set in the service integration message.

MQRFH2 header and field (<jms> folder)	SIBusMessage field or property
Frp (appended to Dst field)	Forward routing path header field
Rrp (appended to Rto field)	Reverse routing path header field

MQRFH2 header and field (<sib> folder)	SIBusMessage field or property
RTopic	Reply topic
RPri	Reply priority
RPer	Reply persistence
RTTL	Reply time to live
JsApiUserId	Application user ID (JMSXUserId) for the service integration application
JsDst	JMS destination
JsFmt	Message format
JsSysMsgId	System message identifier

Mapping the JMS Destination property between service integration and WebSphere MQ

The properties of service integration destinations differ from those used by WebSphere MQ queues, and they cannot be mapped exactly. When service integration uses WebSphere MQ to transport a message, it is useful to keep both representations of the JMS destination property in the message. To address this, when a message leaves service integration and enters WebSphere MQ, an additional **RFH2** property is introduced into the RFH2 header to store the service integration destination property.

The service integration destination property is serialized, formatted as a hexadecimal string, then stored using the **JsDst** property of the service integration RFH2 folder, the <sib> folder. WebSphere MQ applications do not make use of this folder, but if the message is to be retrieved by another service integration application, it can use the information.

For example, a service integration destination SIQ1 is localized on a WebSphere MQ queue MQQ1, residing on queue manager QM1. The following actions occur when a service integration application sends a message to SIQ1:

- A serialized representation of PMQ1 is placed in the <sib> folder of the RFH2 header, using the **JsDst** property.
- The message is stored on MQQ1.
- The string "queue://QM1/MQQ1" is also placed in the <jms> folder of the RFH2 header, using the **Dst** property.

This follows the convention used by the WebSphere MQ messaging provider to encode JMS destinations. If the message is retrieved by a service integration application, the JMS destination can be recovered from the <sib> folder of the RFH2 header. If the message is retrieved by a WebSphere MQ application, the JMS destination can be recovered from the contents of the <jms> folder of the RFH2 header.

Note: If a WebSphere MQ server bus member is configured so that it does not use RFH2 headers, the JMS destination is not preserved when the message enters WebSphere MQ. In this situation, a service integration application can still retrieve the JMS message, but any attempt to examine the JMS destination property causes a JMS exception.

How to process WebSphere MQ message headers

WebSphere MQ messages can optionally include additional headers, or alternative headers, to the MQRFH2 header, which contains JMS properties. WebSphere Application Server application programs can use the com.ibm.mq.headers classes to access headers in messages from WebSphere MQ and to construct headers in messages to WebSphere MQ.

WebSphere MQ message headers

WebSphere MQ messages always include a message descriptor (MQMD). They can also include headers that contain additional information about the messages; for example, messages to or from JMS applications usually include an MQRFH2 header that contains message properties. WebSphere MQ defines the format and usage of some headers (for example, MQRFH2) and also allows users and third-party software providers to define their own custom headers.

Typically it is not necessary for application programs to process WebSphere MQ message headers. Most WebSphere MQ applications either do not use headers at all, or only use the MQRFH2 header, and the service integration and WebSphere MQ messaging providers automatically process the MQRFH2 header when you are communicating with these applications. However, if you are communicating with a WebSphere MQ application that uses or creates additional or different headers, then your WebSphere Application Server application can use the com.ibm.mq.headers classes to create the headers in messages it sends, and process them in messages it receives.

In the WebSphere MQ message, the headers (if there are headers) are at the start of the message, before the message payload. Each header contains fields that describe the following header, or the payload if there are no more headers; the MQMD contains the fields that describe the first header, or the payload if there are no headers. The MQMD and the MQRFH2 header do not normally appear in a JMS message. When the messaging provider converts a WebSphere MQ message into a JMS message, it uses information from the MQMD and MQRFH2 header to set JMS header fields and properties. Similarly, when the messaging provider converts a JMS message into a WebSphere MQ message, it uses the JMS header fields and properties to construct the MQMD and MQRFH2 header.

The JMS provider handles other headers in WebSphere MQ messages by converting the WebSphere MQ message to or from a JMS BytesMessage; the headers appear at the start of the message body, followed by the WebSphere MQ message payload (if any). The **JMS_IBM_Format** property of the JMS message indicates the format of the data in the message body (in this case, first header) and the **JMS_IBM_Encoding** and **JMS_IBM_Character_Set** properties indicate its encoding and CCSID.

Processing WebSphere MQ message headers in a JMS BytesMessage

The com.ibm.mq.headers package contains classes and interfaces that you can use to parse and manipulate WebSphere MQ headers in the body of a JMS BytesMessage. The MQHeader interface provides general-purpose methods for accessing header fields and for reading and writing message content. Each header type has its own class that implements the MQHeader interface and adds getter and setter methods for individual fields. For example, the MQCIH class represents the MQCIH (CICS Bridge) header type. The header classes perform any necessary data conversion automatically, and can read or write data in any specified numeric encoding or character set (CCSID).

Two helper classes, MQHeaderIterator and MQHeaderList, assist with reading and decoding (parsing) the header content in messages:

- MQHeaderIterator works like a java.util.Iterator. For as long as there are more headers in the message, the `next()` method returns `true`, and the `nextHeader()` or `next()` method returns the next header object.
- MQHeaderList works like a java.util.List. Like MQHeaderIterator, it parses header content, but it also allows you to search for particular headers, add new headers, remove existing headers, update header fields, and then write the header content back to a message. Alternatively, you can create an empty MQHeaderList, then populate it with header instances and write it to a message once or repeatedly.

Every header class implements the MQHeader interface, which provides the methods `int read (java.io.DataInput message, int encoding, int characterSet)` and `int write (java.io.DataOutput message, int encoding, int characterSet)`. The java.io.DataInputStream and java.io.DataOutputStream classes implement DataInput and DataOutput respectively. You can obtain DataInput and DataOutput objects from byte arrays carried in JMS messages, as in the following example, which processes a single MQCIH header:

```
import java.io.*;
import javax.jms.*;
import com.ibm.mq.headers.*;
...
BytesMessage bytesMessage = (BytesMessage) msg; // Message received from JMS consumer
byte[] bytes = new byte [(int) bytesMessage.getBodyLength ()];
bytesMessage.readBytes (bytes);
DataInput in = new DataInputStream (new ByteArrayInputStream (bytes));
MQCIH cih = new MQCIH (in,
   bytesMessage.getIntProperty("JMS_IBM_Encoding"),
   819);
```

Alternatively, you can use the MQHeaderIterator class to process a sequence of headers, replacing the line starting `MQCIH cih = new MQCIH` with:

```
MQHeaderIterator it = new MQHeaderIterator (in,
   bytesMessage.getStringProperty("JMS_IBM_Format"),
   bytesMessage.getIntProperty("JMS_IBM_Encoding"),
   819);
while (it.hasNext()) {
   MQHeader item = (MQHeader) it.next();
   ...
}
```

This example creates a single header (an MQCIH type header) and adds it into a BytesMessage:

```
import java.io.*;
import javax.jms.*;
import com.ibm.mq.constants.CMQC;
import com.ibm.mq.headers.*;
...
MQCIH header = new MQCIH();
ByteArrayOutputStream out = new ByteArrayOutputStream ();

header.write (new DataOutputStream (out), CMQC.MQENC_NATIVE, 819);
byte[] bytes = out.toByteArray ();
BytesMessage newMsg = origSes.createBytesMessage();
newMsg.writeBytes(bytes);
```

This example uses the MQHeaderList class to add two headers into a BytesMessage:

```
import java.io.*;
import javax.jms.*;
import com.ibm.mq.constants.CMQC;
import com.ibm.mq.headers.*;
...
byte[] outheaders = null;
byte[] outbody = ...
try {
```

```
    MQHeaderList it = new MQHeaderList ();
    MQHeader header1 = ... // Could be any header type
    MQHeader header2 = ... // Could be any header type
    ByteArrayOutputStream out = new ByteArrayOutputStream ();
    DataOutput dout = new DataOutputStream(out);
    it.add(header1);
    it.add(header2);
    it.write(dout);
    outheaders = out.toByteArray();
} catch (Exception e) {
    System.out.println("error generating MQ message headers : " + e);
}
BytesMessage newMsg = origSes.createBytesMessage();
newMsg.writeBytes(outheaders);
newMsg.writeBytes(bytes);

newMsg.setStringProperty("JMS_IBM_Format", "MQCICS");
newMsg.setIntProperty("JMS_IBM_Encoding", CMQC.MQENC_NATIVE);
newMsg.setIntProperty("JMS_IBM_Character_Set", 819);
```

Always use the correct values for the encoding and characterSet arguments. When you read headers, specify the encoding and CCSID with which the byte content was originally written. When writing headers, specify the encoding and CCSID that you want to produce. The data conversion is performed automatically by the header classes.

More information about the com.ibm.mq.headers classes

The com.ibm.mq.headers package is part of the WebSphere MQ Resource Adapter, which is installed automatically in WebSphere Application Server. This package comprises a set of classes and interfaces that allow the Java programmer to work with WebSphere MQ Message Headers. These include the MQHeaderIterator and MQHeaderList classes mentioned in this topic, and classes for some commonly used WebSphere MQ Message Headers, including:

- MQCIH – CICS bridge header
- MQIIH – IMS information header
- MQSAPH – SAP header

You can also define classes representing your own headers.

WebSphere MQ functions not supported by service integration

There are various functions available in a WebSphere MQ network that are not available on a service integration bus.

The following list helps you identify those functions but it is given as guidance rather than a complete definition. Functions not supported include:

1. Native MQ client (this includes client applications that make use of the base MQ classes for Java) attach.
2. Message segmentation.
3. Message grouping.
4. The MQMD Offset. Original length, MsgFlags, MsgSeqNumber, and GroupId fields are not supported because Message grouping and message segmentation are not supported.
5. Distribution lists.
6. Reference messages.
7. Triggering.
8. Alternate user authority.
9. Pass/set identity context.
10. In a program, setting the attributes of a queue (that is, the equivalent function of MQSET).

11. Confirmation of arrival/delivery.
12. Cluster sender/receiver channels (and cluster workload exits), because a messaging engine cannot participate in a WebSphere MQ cluster.
13. Server and requestor channels.
14. API crossing exits.
15. Data conversion exits.
16. Channel exits.
17. The equivalent to the MCAUSER and PUTAUTH fields of a channel.
18. Networks based on NetBIOS, SPX or SNA.
19. Message based command server.
20. PCF (Programmable Canonical Form messages).
21. Model queues. Service integration does not allow you to define model queues of a given name. Service integration technology supports only one model queue called the SYSTEM.DEFAULT.MODEL.QUEUE.
22. Dynamic queue name prefix length. Service integration suffixes all dynamic queue names with "_Q" and a unique id. This restricts the name specified in the dynamic queue name field of the Object Descriptor to up to 12 chars. If this name is greater than 12 characters, then it is truncated to 12 characters. In service integration, it is not possible to create a dynamic queue with the full name specified in the dynamic queue name field of the Object Descriptor.
23. Mark skip backout option.
24. Signal option on a get request.
25. Version 3 get message options structures.
26. All queue properties (the properties of a service integration destination do not map, one for one, to the properties of a WebSphere MQ local queue, for example).
27. Poisoned messages. Service integration bus local destination definitions have a maximum failed deliveries count (that is, the equivalent to the WebSphere MQ BackoutThreshold value) but there is no equivalent of the WebSphere MQ backout requeue queue name. In service integration technology, poisoned messages are instead backed out to an exception destination. Additionally, in service integration technology, when the number of times an application backs out a poisoned message is equal to the maximum failed deliveries count, the message is automatically backed out to an ExceptionDestination. If there is more than one message in the current unit of recovery, only the poisoned message is backed out to the ExceptionDestination. The remainder of the messages in the unit of recovery are backed out to the destination from which they were read.
28. A strict limitation of 48 bytes on the name of a queue. Service integration bus destination names can be greater than 48 bytes in length. If a destination name is to be returned to a WebSphere MQ JMS application, then it is important to use 48 byte destination lengths. Though, in some cases, it might be feasible to define an alias destination with a name length of up to 48 bytes to map to a local destination with a name of length greater than 48 bytes.

Programming to use message-driven beans

Applications can use message-driven beans as asynchronous message consumers. You deploy a message-driven bean as a message listener for a destination. When a message arrives at the destination, the EJB container invokes the message-driven bean automatically without an application having to explicitly poll the destination.

About this task

You can use a tool such as Rational Application Developer to develop applications that use message-driven beans. You can use the WebSphere Application Server runtime tools, such as the administrative console, to deploy and administer applications that use message-driven beans.

For more information about implementing enterprise applications that use message-drive beans, see the following topics:

Procedure

- Develop message-driven beans.
- Design an enterprise application to use message-driven beans.
- Develop an enterprise application to use message-driven beans.
- Deploy an enterprise application to use message-driven beans with JCA 1.5-compliant resources.
- Deploy an enterprise application to use message-driven beans with listener ports.

Developing message-driven beans

You can develop a bean implementation class for a message-driven bean as introduced by the Enterprise JavaBeans specification. A message-driven bean (MDB) is a message consumer that implements business logic and runs on the server.

Before you begin

Determine the messaging model you want for your application regarding use of topics, queues, producers and consumers, publish or subscribe, and so on. You can refer to the message-driven bean component contract that is described in the Enterprise JavaBeans™ specification.

About this task

A message-driven bean (MDB) is a consumer of messages from a Java Message Service (JMS) provider. An MDB is invoked on arrival of a message at the destination or endpoint that the MDB services. MDB instances are anonymous, and therefore, all instances are equivalent when not actively servicing a client message. The container controls the life cycle of bean instances, which hold no state that is visible to a client.

The following example is a basic message-driven bean:

```
@MessageDriven(activationConfig={
                @ActivationConfigProperty(propertyName="destination",     propertyValue="myDestination"),
                @ActivationConfigProperty(propertyName="destinationType", propertyValue="javax.jms.Queue")
})
public class MsgBean implements javax.jms.MessageListener {

  public void onMessage(javax.jms.Message msg) {

      String receivedMsg = ((TextMessage) msg).getText();
      System.out.println("Received message: " + receivedMsg);

   }

}
```

As with other enterprise bean types, you can also declare metadata for message-driven beans in the deployment descriptor rather than using annotations, for example:

```
<?xml version="1.0" encoding="UTF-8"?>

<ejb-jar id="EJBJar_1060639024453" version="3.0"
      xmlns="http://java.sun.com/xml/ns/javaee"
      xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
      xsi:schemaLocation="http://java.sun.com/xml/ns/javaee http://java.sun.com/xml/ns/javaee/ejb-jar_3_0.xsd"
      metadata-complete="false">
  <enterprise-beans>

    <message-driven>

      <ejb-name>MsgBean</ejb-name>
      <ejb-class>com.acme.ejb.MsgBean</ejb-class>
```

```
      <activation-config>
         <activation-config-property>
            <activation-config-property-name>destination</activation-config-property-name>
            <activation-config-property-value>myDestination</activation-config-property-value>
         </activation-config-property>
         <activation-config-property>
           <activation-config-property-name>destinationType</activation-config-property-name>
           <activation-config-property-value>javax.jms.Queue</activation-config-property-value>
        </activation-config-property>
      </activation-config>

    </message-driven>

  </enterprise-beans>
</ejb-jar>
```

Procedure

- Code the business logic of the message-driven bean, which must implement the appropriate message listener interface defined by the messaging type; for example, javax.jms.MessageListener. The business logic is invoked when the message listener method of the MDB is called to service a message; for example, `MessageListener.onMessage()`. If the MDB implements more than one interface, denote the message listener interface by coding the `messageListenerInterface` attribute of the `MessageDriven` annotation, or by coding the `<messaging-type>` element of the `message-driven` deployment descriptor element. You do not have to specify which is the message listener interface, as long as there is only one interface other than `java.io.Serializable`, `java.io.Externalizable`, or any of the `javax.ejb` package interfaces.
- You can optionally define message destination references on any type of enterprise bean. A message destination reference is a logical name by which an enterprise bean can refer to a message destination. The `Resource` annotation is used to inject a message destination reference, for example:

  ```
  @Resource (name="jms/Outlet", type=javax.jms.Queue) Queue salesOutlet;
  ```

  Alternatively, you can use the `<message-destination-ref>` element in the deployment descriptor to specify the message destination reference; for example:

  ```
  <message-destination-ref>
     <message-destination-ref-name>jms/Outlet</message-destination-ref-name>
     <message-destination-type>javax.jms.Queue</message-destination-type>
     <injection-target>
       <injection-target-class>com.acme.ejb.MsgBean</injection-target-class>
       <injection-target-name>salesOutlet</injection-target-name>
    </injection-target>
  </message-destination-ref>
  ```

  The `message-destination-ref` element is similar to the `resource-env-ref` element, but also has subelements, `message-destination-usage` with possible values `Produces`, `Consumes` or `ProducesConsumes`, and `message-destination-link`. You can use the `message-destination-link` element to tie two or more message-destination-ref references in the deployment descriptor together, which allows the deployer to bind the destination for several enterprise beans all at once, to the same destination. The message-destination-link value must match the `message-destination-name` value in the `message-destination` element; for example:

  ```
  <ejb-jar>

    <enterprise-beans>

      <session>
        <ejb-name>OutletBean</display-name>
        ...
        <message-destination-ref>
          <message-destination-ref-name>jms/target</message-destination-ref-name>
          <message-destination-type>javax.jms.Queue</message-destination-type>
          <message-destination-usage>Produces</message-destination-usage>
          <message-destination-link>destination</message-destination-link>
        </message-destination-ref>
        ...
      </session>
  ```

```
    <session>
      <ejb-name>InletBean</display-name>
      ...
      <message-destination-ref>
        <message-destination-ref-name>jms/source</message-destination-ref-name>
        <message-destination-type>javax.jms.Queue</message-destination-type>
        <message-destination-usage>Consumes</message-destination-usage>
        <message-destination-link>destination</message-destination-link>
      </message-destination-ref>
      ...
    </session>

    <message-driven>
      <ejb-name>InletBean</display-name>
      ...

      <ejb-name>MsgBean</ejb-name>
      <ejb-class>com.acme.MsgBean</ejb-class>
      <messaging-type>javax.jms.MessageListener</messaging-type>
      <message-destination-type>javax.jms.Queue</message-destination-type>
      <message-destination-link>destination</message-destination-link>

      ...
    </message-driven>

  </enterprise-beans>
      ...
  <assembly-descriptor>
    ...
    <message-destination>
      <message-destination-name>destination</message-destination-name>
    </message-destination>
    ...
  </assembly-descriptor>

</ejb-jar>
```

The `message-destination-link` element can refer to a destination that is defined in a different Java archive (JAR) file within the same application, as with an `ejb-link` element. For example, to link to the destination, `ProduceQueue`, defined in the `grocery.jar` file, enter the following line in the deployment descriptor:

```
<message-destination-link>grocery.jar#ProduceQueue</message-destination-link>
```

- As with any enterprise bean, you can package a message-driven bean in a JAR file, or in a web application archive (WAR) file.

Results

You developed a simple message-driven bean, along with some deployment and packaging options.

What to do next

Read related information about designing an enterprise application that uses message-driven beans.

Designing an enterprise application to use message-driven beans

To help you design your enterprise application, consider a generic enterprise application that uses one message-driven bean to retrieve messages from a JMS queue destination, and passes the messages on to another enterprise bean that implements the business logic.

About this task

To design an enterprise application to use message-driven beans, complete the following steps:

Procedure

1. Identify the message listener interface for the message type that the message-driven bean is to handle. The message-driven bean class must implement this message listener interface. For example, an EJB message-driven bean class used for JMS messaging must implement the javax.jms.MessageListener interface.
2. Identify the resources that the application is to use. This helps to identify the properties of resources that must be used within the application and configured as application deployment descriptors or within WebSphere Application Server.

Table 81. JMS resource types and examples of their properties. The left hand column of this table lists the JMS resource types, and the right hand column shows examples of the properties of each of the JMS resource types shown in the left hand column.

JMS resource type	Properties (for example)
JMS connection factory	**Name:** SamplePtoPQueueConnectionFactory **JNDI Name:** Sample/JMS/QCF
JMS destination	**Name:** Q1 **JNDI Name:** Sample/JMS/Q1
J2C activation specification properties	**Name:** MyMDBsActivationSpec **JNDI Name:** eis/MyMDBsActivationSpec **Destination JNDI Name:** MyQueue **Destination type:** javax.jms.Queue
Message-driven bean (deployment properties)	**Name:** JMSppSampleMDBBean **Transaction type:** Container **Message selector:** JMSType='car' **Acknowledge mode:** Dups OK Acknowledge **Destination type:** javax.jms.Queue **ActivationSpec JNDI name:** MyMDBsActivationSpec
Business logic bean	**Name:** MyLogicBean

   Ensure that you use consistent values where needed; for example, the JNDI name for the J2C activation specification must be the same in both the activation specification and the Message-driven bean deployment attributes.
3. Separate out the business logic. You should develop a message-driven bean to delegate the business processing of incoming messages to another enterprise bean. This provides clear separation of message handling and business processing. This also enables the business processing to be invoked by either the arrival of incoming messages or, for example, from a WebSphere J2EE client.
4. Decide whether to configure security. Messages arriving at a destination being processed by a listener have no client credentials associated with them; the messages are anonymous. Security depends on the role specified by the RunAs Identity for the message-driven bean as an EJB component. For more information about EJB security, see EJB component security.
5. Understand how best effort nonpersistent messages are handled by the default messaging provider.

   If you have a non-transactional message-driven bean, the system either deletes the message when the message-driven bean starts, or when the message-driven bean completes. If the message-driven bean generates an exception, and therefore does not complete, the system takes one of the following actions:

   - If the system is configured to delete the message when the message-driven bean completes, then the message is despatched to a new instance of the message-driven bean, so the message has another opportunity to be processed.
   - If the system is configured to delete the message when the message-driven bean starts, then the message is lost.

   The message is deleted when the message-driven bean starts if the quality of service is set to `Best effort nonpersistent`. For all other qualities of service, the message is deleted when the message-driven bean completes.

Developing an enterprise application to use message-driven beans

Applications can use message-driven beans as asynchronous message consumers. You deploy a message-driven bean as a message listener for a destination. The message-driven bean is invoked by an activation specification or a JMS listener when a message arrives on the input destination that is being monitored.

About this task

You develop an enterprise application to use a message-driven bean as with any other enterprise bean, except that a message-driven bean does not have a home interface or a remote interface.

You should develop your message-driven bean to delegate the business processing of incoming messages to another enterprise bean, which provides clear separation of message handling and business processing. This separation also means that the business processing can be invoked either by the arrival of incoming messages or, for example, by a WebSphere J2EE client. Responses can be handled by another enterprise bean acting as a sender bean, or they can be handled in the message-driven bean.

EJB 2.0 message-driven beans support only Java Message Service (JMS) messaging. EJB 2.1 and EJB 3 message-driven beans can support other messaging types in addition to JMS. All message-driven beans must implement the MessageDrivenBean interface. For JMS messaging, a message-driven bean must also implement the message listener interface javax.jms.MessageListener. Other Java EE Connector Architecture (JCA)-compliant resource adapters might provide their own message listener interfaces that must be implemented.

You can use the New Enterprise Bean wizard of Rational Application Developer to create an enterprise bean with a bean type of `Message-driven bean`. The wizard creates appropriate methods for the type of bean.

By convention, the message-driven bean class is named *name*Bean, where *name* is the name you assign to the message-driven bean; for example:

```
public class MyJMSppMDBBean implements MessageDrivenBean, javax.jms.MessageListener
```

A message-driven bean can be registered with the EJB timer service for time-based event notifications if it also implements the javax.ejb.TimedObject interface, and invokes the timer callback method by the following call: `void ejbTimeout(Timer)`. At the scheduled time, the container then calls the message-driven bean ejbTimeout method.

The message-driven bean class must define and implement the following methods:

- onMessage(message), which must meet the following requirements:
  - The method must have a single argument of type javax.jms.Message.
  - The `throws` clause must not define any application exceptions.
  - If the message-driven bean is configured to use bean-managed transactions, it must call the javax.transaction.UserTransaction interface to scope the transactions. Because these calls occur inside the onMessage() method, the transaction scope does not include the initial message receipt. For more information, see the topic about message-driven beans transaction support.

  To handle the message within the onMessage() method (for example, to pass the message on to another enterprise bean), you use standard JMS. This is known as bean-managed messaging.

  If you are using a JCA-compliant resource adapter with a different message listener interface, another method besides the onMessage() method might be needed. For information about the message listener interface needed, see the documentation that was provided with your JCA-compliant resource adapter.
- ejbCreate()

  You must define and implement an ejbCreate method for each way in which you want a new instance of an enterprise bean to be created.
- ejbRemove()

This method is invoked by the container when a client invokes the remove method inherited by the enterprise bean home interface from the javax.ejb.EJBHome interface. This method must contain any code that you want to execute before an enterprise bean instance is removed from the container (and the associated data is removed from the data source).

- ejbTimeout(Timer)

  This method is needed only to support notifications from the timer service, and contains the business logic that handles time events received.

Procedure

1. Create the Enterprise Application project.
2. Create the message-driven bean class. You can use the New Enterprise Bean wizard of Rational(r) Application Developer to create the enterprise bean with a bean type of `Message-driven bean`.

   For an example of how to create the message-driven bean class, see the Example section of this topic. For more information, see *Creating message-driven beans* in the Rational Application Developer information center. The result of this step is a message-driven bean that can be assembled into an EAR file for deployment.
3. Optional: Use the EJB deployment descriptor editor to review and, if needed, change the deployment attributes. You can use the EJB deployment descriptor editor to review deployment attributes that you specified on the EJB creation wizard (such as **`Transaction type`** and **`Message selector`**) and other default deployment attributes.

   If needed, you can override the values of these attributes later, after the enterprise application has been exported into an EAR file for deployment, as described in “Configuring deployment attributes for a message-driven bean against JCA 1.5-compliant resources” on page 2085 and “Configuring deployment attributes for a message-driven bean against a listener port” on page 2088.

   a. In the property pane, select the **Bean** tab.

   b. On the main panel, configure the **`Transaction type`** attribute.

      `Transaction type`
      This attribute determines whether the message-driven bean manages its own transactions, or whether the container manages transactions on behalf of the bean.
      `Bean` The message-driven bean manages its own transactions.
      `Container`
      The container manages transactions on behalf of the bean.

   c. Under **Activation Configuration**, review the following attributes:

      `acknowledgeMode`
      This attribute determines how the session acknowledges any messages it receives.
      `Auto Acknowledge`
      The session automatically acknowledges delivery of each message.
      `Dups OK Acknowledge`
      The session lazily acknowledges the delivery of messages. This setting is likely to result in the delivery of some duplicate messages if JMS fails, so it should be used only by consumer applications that are tolerant of duplicate messages.

      As defined in the EJB specification, clients cannot use the Message.acknowledge() method to acknowledge messages. If a value of `CLIENT_ACKNOWLEDGE` is passed on the create*xxx*Session call, then messages are automatically acknowledged by the application server and the Message.acknowledge() method is not used.

      Note:

      The acknowledgement is sent when the message is deleted.

      If you have a non-transactional message-driven bean, the system either deletes the message when the message-driven bean starts, or when the message-driven bean

completes. If the message-driven bean generates an exception, and therefore does not complete, the system takes one of the following actions:

- If the system is configured to delete the message when the message-driven bean completes, then the message is despatched to a new instance of the message-driven bean, so the message has another opportunity to be processed.
- If the system is configured to delete the message when the message-driven bean starts, then the message is lost.

The message is deleted when the message-driven bean starts if the quality of service is set to `Best effort nonpersistent`. For all other qualities of service, the message is deleted when the message-driven bean completes.

destinationType
This attribute determines whether the message-driven bean uses a queue or topic destination.
Queue The message-driven bean uses a queue destination.
Topic The message-driven bean uses a topic destination.

subscriptionDurability
This attribute determines whether a JMS topic subscription is durable or nondurable.
Durable
A subscriber registers a durable subscription with a unique identity that is retained by JMS. Subsequent subscriber objects with the same identity resume the subscription in the state it was left in by the earlier subscriber. If there is no active subscriber for a durable subscription, JMS retains the subscription messages until they are received by the subscription or until they expire.
Nondurable
Nondurable subscriptions last for the lifetime of their subscriber object. This means that a client sees the messages published on a topic only while its subscriber is active. If the subscriber is not active, the client is missing messages published on its topic.

A nondurable subscriber can only be used in the same transactional context (for example, a global transaction or an unspecified transaction context) that existed when the subscriber was created.

messageSelector
This attribute determines the JMS message selector that is used to select which messages the message-driven bean receives. For example:

```
JMSType='car' AND color='blue' AND weight>2500
```

The selector string can refer to fields in the JMS message header and fields in the message properties. Message selectors cannot reference message body values.

d. Specify bindings deployment attributes.

Under **WebSphere Bindings**, select the **JCA Adapter** option then specify the bindings deployment attributes:
ActivationSpec JNDI name
This attribute specifies the JNDI name of the activation specification that is used to deploy this message-driven bean. This name must match the name of an activation specification that you define to WebSphere Application Server.
ActivationSpec Authorization Alias
This attribute specifies the name of an authentication alias used for authentication of connections to the JCA resource adapter. An authentication alias specifies the user ID and password that is used to authenticate the creation of a new connection to the JCA resource adapter.
Destination JNDI name
This attribute specifies the JNDI name that the message-driven bean uses to look up the JMS destination in the JNDI namespace.

e. Optional: Specify **Destination Link** to enable message linking.

Message linking allows the routing of messages to a specific message-driven bean in a deployment. Message linking allows message flow to be orchestrated between components in the same application.

For a message to be consumed and processed by a message-driven bean, the<message-destination-link> element must be defined in the deployment descriptor associated with the message-driven bean. The destination identified by the <message-destination-link> element corresponds to the logical destination.

When the <message-destination-ref> includes a <message-destination-link> element, messages are consumed at that destination.

In order to get the message-driven bean to consume messages sent to a destination, you can declare a <message-destination-link> element in the deployment descriptor, or alternatively set it in the activation specification.

4. Assemble and package the application for deployment.

Results

The result of this task is an EAR file, containing the message-driven bean, for the enterprise application that can be deployed in WebSphere Application Server.

Example

The following example shows how to create the message-driven bean class. The example code shows how to access the text and the JMS **MessageID**, from a JMS message of type TextMessage. In this example, first the onMessage() method of a message-driven bean is used to unpack the incoming text message and to extract the text and message identifier; then a private putMessage method (defined within the same message bean class) is used to put the message onto another queue:

```
public void onMessage(javax.jms.Message msg)
{
        String text      = null;
        String messageID = null;

        try
        {
                text = ((TextMessage)msg).getText();

                System.out.println("senderBean.onMessage(), msg text2: "+text);

                //
                // store the message id to use as the Correlator value
                //
                messageID = msg.getJMSMessageID();

                // Call a private method to put the message onto another queue
                putMessage(messageID, text);
        }
        catch  (Exception err)
        {
                err.printStackTrace();
        }
        return;
}
```

What to do next

After you have developed an enterprise application to use message-driven beans, configure and deploy the application. For example, define activation specifications for the message-driven beans and, optionally, change the deployment descriptor attributes for the application. For more information, see “Deploying an

enterprise application to use message-driven beans with JCA 1.5-compliant resources" on page 2084 and "Deploying an enterprise application to use message-driven beans with listener ports" on page 2088.

JMS report messages

JMS applications can use report messages as a form of managed request/response processing, to give remote feedback to producers on the outcome of their send operations and the fate of their messages.

JMS applications can request the following types of report message by setting appropriate JMS_IBM_Report_Xxxx message properties and options. The options have the same general syntax and meaning:

MQRO_*report-type*
A report message of the indicated type is generated that contains the MQMD of the original message. It does not contain any message body data.

MQRO_*report-type*_**WITH_DATA**
A report message of the indicated type is generated that contains the MQMD, any MQ headers, and 100 bytes of body data.

MQRO_*report-type*_**WITH_FULL_DATA**
A report message of the indicated type is generated that contains all data from the original message.

Use the following prefix with each option: com.ibm.websphere.sib.api.jms.

For example, to request a Confirm on delivery (COD) report message with full data, the JMS application must set JMS_IBM_Report_COD to the value com.ibm.websphere.sib.api.jms.MQRO_COD_WITH_FULL_DATA.

Type of report message	Description	JMS_IBM_Report_Xxxx message property and options
Exception	Send a report message if the request message cannot be put to the target queue. The exception report messages are generated when a message has been rerouted to an exception destination.	JMS_IBM_Report_Exception • MQRO_EXCEPTION • MQRO_EXCEPTION_WITH_DATA • MQRO_EXCEPTION_WITH_FULL_DATA
Discard	Discard the original request message rather than sending it to an exception destination. You can use this option with the JMS_IBM_Report_Exception property set to MQRO_EXCEPTION_WITH_FULL_DATA to return an undeliverable request message to its sender.	JMS_IBM_Report_Discard_Msg • TRUE • FALSE
Expiration	Send a report message if the request message passes its expiry time.	JMS_IBM_Report_Expiration • MQRO_EXPIRATION • MQRO_EXPIRATION_WITH_DATA • MQRO_EXPIRATION_WITH_FULL_DATA

Type of report message	Description	JMS_IBM_Report_Xxxx message property and options
Confirm on arrival (COA)	Send a report message when the request message has been put to the target queue. For publish/subscribe messaging, the COA report message is generated only on the producers messaging engine. Therefore, such reports are relevant only to local subscriptions. For point-to-point messaging, COA messages are generated when the message arrives at the final destination. For partitioned queues, the report message is generated only when the put operation has committed and a final destination has therefore been selected. Any With_Data or With_Full_Data report options specified are ignored; the COA report message deals only with message headers. If a forward-routing path is used, the COA message are generated when the message arrives at the final destination in the path.	JMS_IBM_Report_COA • MQRO_COA • MQRO_COA_WITH_DATA • MQRO_COA_WITH_FULL_DATA
Confirm on delivery (COD)	Send a report message when the request message has been removed from the queue or topic space by a message consumer. For publish/subscribe messaging, the COD message is generated when all subscribers have received the request message. Therefore, there is one COD message generated for every COA. When a message is consumed by a subscriber, the reference count of the message on the topic space is reduced. When the reference count reaches zero, the message is removed from the topic space then a COD report message is generated. For point-to-point messaging, the COD message is generated after the message has been successfully received by a consuming application. Any With_Data or With_Full_Data report options specified are ignored; the COD report message deals only with message headers.	JMS_IBM_Report_COD • MQRO_COD • MQRO_COD_WITH_DATA • MQRO_COD_WITH_FULL_DATA
Positive action notification (PAN)	Ask the consumer application to send a report message when it has successfully processed the request message.	JMS_IBM_Report_PAN • TRUE • FALSE
Negative action notification (NAN)	Ask the consumer application to send a report message if it has not successfully processed the request message.	JMS_IBM_Report_NAN • TRUE • FALSE

The requesting application can control other aspects of the report message as follows:

- How the message Id is generated for the report message and any reply message:

MQRO_New_Msg_Id
This the default. A new message Id is generated for the report message.

MQRO_Pass_Msg_Id
The message Id of the report message is set to the message Id of the request message.

- How the correlation Id of the report or reply message is to be set.

MQRO_Copy_Msg_Id_To_Correl_Id
This the default. the correlation Id of the report message is set to the message Id of the request message.

MQRO_Pass_Correl_Id
The correlation Id of the report message is set to the correlation Id of the request message.

For more information about report messages and the associated properties and options, see the *Report messages* section of the WebSphere MQ information center.

JMS interfaces

WebSphere Application Server supports applications that use JMS 1.1 domain-independent interfaces (referred to as “common interfaces” in the JMS specification) and JMS 1.0.2 domain-specific interfaces.

With JMS 1.1, the preferred approach for implementing applications is to use common interfaces because they provide a simpler programming model than domain-specific interfaces. Also, applications can create both queues and topics in the same session and coordinate their use in the same transaction. Common interfaces are parents of domain-specific interfaces.

Note: Domain-specific interfaces (provided for JMS 1.0.2 in WebSphere Application Server Version 5) are supported only to provide compatibility for applications that have already been implemented to use those interfaces.

Table 82. The point-to-point and publish/subscribe versions of JMS common interfaces. The first column of the table lists the JMS common interfaces. The second column lists the point-to-point versions of the JMS common interfaces. The third column lists the publish/subscribe versions of the JMS common interfaces.

JMS common interfaces	Point-to-point interfaces	Publish/subscribe interfaces
ConnectionFactory	QueueConnectionFactory	TopicConnectionFactory
Connection	QueueConnection	TopicConnection
Destination	Queue	Topic
Session	QueueSession	TopicSession,
MessageProducer	QueueSender	TopicPublisher
MessageConsumer	QueueReceiver, QueueBrowser	TopicSubscriber

For more information about JMS interfaces, see the JMS documentation at http://java.sun.com/products/jms/docs.html.

Chapter 14. Developing Naming and directory

This page provides a starting point for finding information about naming support. Naming includes both server-side and client-side components. The server-side component is a Common Object Request Broker Architecture (CORBA) naming service (CosNaming). The client-side component is a Java Naming and Directory Interface (JNDI) service provider. JNDI is a core component in the Java Platform, Enterprise Edition (Java EE) programming model.

The WebSphere JNDI service provider can be used to interoperate with any CosNaming name server implementation. Yet WebSphere name servers implement an extension to CosNaming, and the JNDI service provider uses those WebSphere extensions to provide greater capability than CosNaming alone. Some added capabilities are binding and looking up of non-CORBA objects.

Java EE applications use the JNDI service provider supported by WebSphere Application Server to obtain references to objects related to server applications, such as enterprise bean (EJB) homes, which have been bound into a CosNaming name space.

Developing applications that use JNDI

References to enterprise bean (EJB) homes and other artifacts such as data sources are bound to the WebSphere Application Server name space. These objects can be obtained through Java Naming and Directory Interface (JNDI). Before you can perform any JNDI operations, you need to get an initial context. You can use the initial context to look up objects bound to the name space.

About this task

The following examples describe how to get an initial context and how to perform lookup operations.
- Getting the default initial context
- Getting an initial context by setting the provider URL property
- Setting the provider URL property to select a different root context as the initial context
- Looking up an EJB home with JNDI

In these examples, the default behavior of features specific to the WebSphere Application Server JNDI Context implementation is used.

The WebSphere Application Server JNDI context implementation includes special features. JNDI caching enhances performance of repeated lookup operations on the same objects. Name syntax options offer a choice of a name syntaxes, one optimized for typical JNDI clients, and one optimized for interoperability with CosNaming applications. Most of the time, the default behavior of these features is the preferred behavior. However, sometimes you should modify the behavior for specific situations.

JNDI caching and name syntax options are associated with a javax.naming.InitialContext instance. To select options for these features, set properties that are recognized by the WebSphere Application Server initial context factory. To set JNDI caching or name syntax properties which will be visible to the initial context factory, do the following:

Procedure

1. Optional: Configure JNDI caches

   JNDI caching can greatly increase performance of JNDI lookup operations. By default, JNDI caching is enabled. In most situations, this default is the desired behavior. However, in specific situations, use the other JNDI cache options.

Objects are cached locally as they are looked up. Subsequent lookups on cached objects are resolved locally. However, cache contents can become stale. This situation is not usually a problem, since most objects you look up do not change frequently. If you need to look up objects which change relatively frequently, change your JNDI cache options.

JNDI clients can use several properties to control cache behavior.

You can set properties:

- From the command line by entering the actual string value. For example:

  ```
  java -Dcom.ibm.websphere.naming.jndicache.maxentrylife=1440
  ```

- In a `jndi.properties` file by creating a file named `jndi.properties` as a text file with the desired properties settings. For example:

  ```
  ...
  com.ibm.websphere.naming.jndicache.cacheobject=none
  ...
  ```

  If you use this technique, be aware that other instances of the `jndi.properties` file might exist in the classpath, and might contain conflicting property settings. Property settings are determined by the order in which the class loader picks up the `jndi.properties` files. There is no way to control the order that the class loader uses to locate files in the classpath. WebSphere Application Server does not initially contain or create any `jndi.properties` files that set the com.ibm.websphere.naming.jndicache.cacheobject property.

- Within a Java program by using the PROPS.JNDI_CACHE* Java constants, defined in the `com.ibm.websphere.naming.PROPS` file. The constant definitions follow:

  ```
  public static final String JNDI_CACHE_OBJECT =
   "com.ibm.websphere.naming.jndicache.cacheobject";
  public static final String JNDI_CACHE_OBJECT_NONE      = "none";
  public static final String JNDI_CACHE_OBJECT_POPULATED = "populated";
  public static final String JNDI_CACHE_OBJECT_CLEARED   = "cleared";
  public static final String JNDI_CACHE_OBJECT_DEFAULT   =
   JNDI_CACHE_OBJECT_POPULATED;

  public static final String JNDI_CACHE_NAME =
   "com.ibm.websphere.naming.jndicache.cachename";
  public static final String JNDI_CACHE_NAME_DEFAULT = "providerURL";

  public static final String JNDI_CACHE_MAX_LIFE =
   "com.ibm.websphere.naming.jndicache.maxcachelife";
  public static final int    JNDI_CACHE_MAX_LIFE_DEFAULT = 0;

  public static final String JNDI_CACHE_MAX_ENTRY_LIFE =
   "com.ibm.websphere.naming.jndicache.maxentrylife";
  public static final int    JNDI_CACHE_MAX_ENTRY_LIFE_DEFAULT = 0;
  ```

  To use the previous properties in a Java program, add the property setting to a hashtable and pass it to the InitialContext constructor as follows:

  ```
  java.util.Hashtable env = new java.util.Hashtable();
  ...

  // Disable caching
  env.put(PROPS.JNDI_CACHE_OBJECT, PROPS.JNDI_CACHE_OBJECT_NONE); ...
  javax.naming.Context initialContext = new javax.naming.InitialContext(env);
  ```

Following are examples that illustrate how you can use JNDI cache properties to achieve the desired cache behavior. Cache properties take effect when an InitialContext object is constructed.

Example: Controlling JNDI cache behavior from a program

```
import java.util.Hashtable;
import javax.naming.InitialContext;
import javax.naming.Context;
import com.ibm.websphere.naming.PROPS;

/*****
 Caching discussed in this section pertains to the WebSphere Application Server initial context factory.
 Assume the property, java.naming.factory.initial, is set to
 "com.ibm.websphere.naming.WsnInitialContextFactory" as a java.lang.System property.
*****/

Hashtable env;
```

```
Context ctx;

// To clear a cache:

env = new Hashtable();
env.put(PROPS.JNDI_CACHE_OBJECT, PROPS.JNDI_CACHE_OBJECT_CLEARED);
ctx = new InitialContext(env);

// To set a cache's maximum cache lifetime to 60 minutes:

env = new Hashtable();
env.put(PROPS.JNDI_CACHE_MAX_LIFE, "60");
ctx = new InitialContext(env);

// To turn caching off:

env = new Hashtable();
env.put(PROPS.JNDI_CACHE_OBJECT, PROPS.JNDI_CACHE_OBJECT_NONE);
ctx = new InitialContext(env);

// To use caching and no caching:

env = new Hashtable();
env.put(PROPS.JNDI_CACHE_OBJECT, PROPS.JNDI_CACHE_OBJECT_POPULATED);
ctx = new InitialContext(env);
env.put(PROPS.JNDI_CACHE_OBJECT, PROPS.JNDI_CACHE_OBJECT_NONE);
Context noCacheCtx = new InitialContext(env);

Object o;

// Use caching to look up home, since the home should rarely change.
o = ctx.lookup("com/mycom/MyEJBHome");
// Narrow, etc. ...

// Do not use cache if data is volatile.
o = noCacheCtx.lookup("com/mycom/VolatileObject");
// ...
```

Example: Looking up a JavaMail session with JNDI

The following example shows a lookup of a JavaMail resource:

```
// Get the initial context as shown above
...
Session session =
     (Session) initialContext.lookup("java:comp/env/mail/MailSession");
```

2. Optional: Specify the name syntax

   INS syntax is designed for JNDI clients that need to interoperate with CORBA applications. This syntax allows a JNDI client to make the proper mapping to and from a CORBA name. INS syntax is very similar to the JNDI syntax with the additional special character, dot (.). Dots are used to delimit the id and kind fields in a name component. A dot is interpreted literally when it is escaped. Only one unescaped dot is allowed in a name component. A name component with a non-empty id field and empty kind field is represented with only the id field value and must not end with an unescaped dot. An empty name component (empty id and empty kind field) is represented with a single unescaped dot. An empty string is not a valid name component representation.

   JNDI name syntax is the default syntax and is suitable for typical JNDI clients. This syntax includes the following special characters: forward slash (/) and backslash (\). Components in a name are delimited by a forward slash. The backslash is used as the escape character. A forward slash is interpreted literally if it is escaped, that is, preceded by a backslash. Similarly, a backslash is interpreted literally if it is escaped.

   Most WebSphere applications use JNDI to look up EJB objects and do not need to look up objects bound by CORBA applications. Therefore, the default name syntax used for JNDI names is the most convenient. If your application needs to look up objects bound by CORBA applications, you may need to change your name syntax so that all CORBA CosNaming names can be represented.

   JNDI clients can set the name syntax by setting a property. The property setting is applied by the initial context factory when you instantiate a new java.naming.InitialContext object. Names specified in JNDI operations on the initial context are parsed according to the specified name syntax.

You can set the property:

- From a command line, enter the actual string value. For example:

```
java -Dcom.ibm.websphere.naming.name.syntax=ins
```

- Create a file named `jndi.properties` as a text file with the desired properties settings. For example:

```
...
com.ibm.websphere.naming.name.syntax=ins
...
```

  If you use this technique, be aware that other instances of the `jndi.properties` file might exist in the classpath, and might contain conflicting property settings. Property settings are determined by the order in which the class loader picks up the `jndi.properties` files. There is no way to control the order that the class loader uses to locate files in the classpath. WebSphere Application Server does not initially contain or create any `jndi.properties` files that set the com.ibm.websphere.naming.name.syntax property.

- Use the PROPS.NAME_SYNTAX* Java constants, defined in the `com.ibm.websphere.naming.PROPS` file, in a Java program. The constant definitions follow:

```
public static final String NAME_SYNTAX =
    "com.ibm.websphere.naming.name.syntax";
public static final String NAME_SYNTAX_JNDI = "jndi";
public static final String NAME_SYNTAX_INS  = "ins";
```

  To use the previous properties in a Java program, add the property setting to a hashtable and pass it to the InitialContext constructor as follows:

```
java.util.Hashtable env = new java.util.Hashtable();
...
env.put(PROPS.NAME_SYNTAX, PROPS.NAME_SYNTAX_INS); // Set name syntax to INS
...
javax.naming.Context initialContext = new javax.naming.InitialContext(env);
```

Example: Setting the syntax used to parse name strings

The name syntax property can be passed to the InitialContext constructor through its parameter, in the System properties, or in a `jndi.properties` file. The initial context and any contexts looked up from that initial context parse name strings based on the specified syntax.

The following example shows how to set the name syntax to make the initial context parse name strings according to INS syntax.

```
...
import java.util.Hashtable;
import javax.naming.Context;
import javax.naming.InitialContext;
import com.ibm.websphere.naming.PROPS; // WebSphere naming constants
...
Hashtable env = new Hashtable();
env.put(Context.INITIAL_CONTEXT_FACTORY,
      "com.ibm.websphere.naming.WsnInitialContextFactory");
env.put(Context.PROVIDER_URL, ...);
env.put(PROPS.NAME_SYNTAX, PROPS.NAME_SYNTAX_INS);
Context initialContext = new InitialContext(env);
// The following name maps to a CORBA name component as follows:
//    id = "a.name", kind = "in.INS.format"
// The unescaped dot is used as the delimiter.
// Escaped dots are interpreted literally.
java.lang.Object o = initialContext.lookup("a\\.name.in\\.INS\\.format");
...
```

INS name syntax requires that embedded periods (.) in a name such as `in.INS.format` be escaped using a backslash character (\). In a Java String literal, a backslash character (\) must be escaped with another backslash character (\\).

3. Optional: Disable host name normalization

   References to host names, IP addresses, and `localhost` in provider URLs are typically normalized. The format of a normalized host name is the fully-qualified form of the host name. Host name normalization improves system efficiency because it enables the same JNDI cache to be used for a given bootstrap host regardless of the format of the reference in the provider URL. For example, host name normalization enables the same JNDI cache to be used for `myhost`, `myhost.mydomain.com`, and `localhost` references if all of these references refer to the same host.

Because normalized host names are cached, subsequent normalizations execute more quickly. In some network environments, domain name lookup data changes dynamically, causing the cached host name normalization data to become stale. In such environments, you might need to disable hostname normalization. When you disable host normalization, host name and IP addresses are used as is. References to `localhost` typically resolve to the loopback address, 127.0.0.1.

JNDI clients can disable host name normalization by setting a property. The property setting is applied by the initial context factory when you instantiate a new java.naming.InitialContext object.

Use one of the following techniques to set this property:

- You can enter the actual string value from a command line. For example:

  ```
  java -Dcom.ibm.websphere.naming.hostname.normalizer=...none...
  ```

- You can create a file named `jndi.properties` as a text file with the desired properties settings. For example:

  ```
  ...
  com.ibm.websphere.naming.hostname.normalizer=...none...
  ...
  ```

  If you use this technique, be aware that other instances of the `jndi.properties` file might exist in the classpath, and might contain conflicting property settings. Property settings are determined by the order in which the class loader picks up the `jndi.properties` files. There is no way to control the order that the class loader uses to locate files in the classpath. WebSphere Application Server does not initially contain or create any `jndi.properties` files that set the com.ibm.websphere.naming.hostname.normalizer property.

- You can use the PROPS.HOSTNAME_NORMALIZER* Java constants in a Java program. These Java constants are defined in the com.ibm.websphere.naming.PROPS file. Following are the constant definitions to specify if you use this technique:

  ```
  public static final String HOSTNAME_NORMALIZER =
      "com.ibm.websphere.naming.hostname.normalizer";
  public static final String HOSTNAME_NORMALIZER_NONE = "...none...;
  ```

  To use these definitions in a Java program, add the property setting to a hashtable and pass it to the InitialContext constructor:

  ```
  java.util.Hashtable env = new java.util.Hashtable();
  ...
  env.put(PROPS.HOSTNAME_NORMALIZER, PROPS.HOSTNAME_NORMALIZER_NONE);
      // Disable hostname normalization
  ...
  javax.naming.Context initialContext =
     new javax.naming.InitialContext(env);
  ```

Example: Disabling host name normalization

You can pass the host name normalizer property to the InitialContext constructor through the InitialContext constructor parameter in the system properties file, or in a `jndi.properties` file. The initial context and any future contexts looked up from that initial context use this property setting.

The following example shows how to disable host name normalization.

```
...
import java.util.Hashtable;
import javax.naming.Context;
import javax.naming.InitialContext;
import com.ibm.websphere.naming.PROPS; // WebSphere naming constants
...
Hashtable env = new Hashtable();
env.put(Context.INITIAL_CONTEXT_FACTORY,
      "com.ibm.websphere.naming.WsnInitialContextFactory");
env.put(Context.PROVIDER_URL, ...);
env.put(PROPS.HOSTNAME_NORMALIZER, PROPS.HOSTNAME_NORMALIZER_NONE);
Context initialContext = new InitialContext(env);
java.lang.Object o = initialContext.lookup(...);
...
```

Example: Getting the default initial context

There are various ways for a program to get the default initial context.

The following example gets the default initial context. Note that no provider URL is passed to the javax.naming.InitialContext constructor.

```
...
import javax.naming.Context;
import javax.naming.InitialContext;
...
Context initialContext = new InitialContext();
...
```

The default initial context returned depends the runtime environment of the Java Naming and Directory Interface (JNDI) client. Following are the initial contexts returned in the various environments:

Thin client
The initial context is the server root context of the server running on the local host at port 2809.

Pure client
The initial context is the context specified by the java.naming.provider.url property passed to launchClient command with the -CCD command line parameter. The context usually is the server root context of the server at the address specified in the URL, although it is possible to construct a corbaname or corbaloc URL which resolves to some other context.

If no provider URL is specified, it is the server root context of the server running on the host and port specified by the `-CCproviderURL`, or `-CCBootstrapHost` and `-CCBootstrapPort` command line parameters. The default host is the local host, and the default port is 2809.

Server process
The initial context is the server root context for that process.

Even though no provider URL is explicitly specified in the previous example, the InitialContext constructor might find a provider URL defined in other places that it searches for property settings.

Users of properties which affect ORB initialization should read the rest of this section for a deeper understanding of exactly how initial contexts are obtained.

Determining which server is used to obtain the initial context

WebSphere Application Server name servers are CORBA CosNaming name servers, and the product provides a CosNaming JNDI plug-in implementation for JNDI clients to perform naming operations on product namespaces. The CosNaming plug-in implementation is selected through a JNDI property that is passed to the InitialContext constructor. This property is `java.naming.factory.initial`, and it specifies the initial context factory implementation to use to obtain an initial context. The factory returns a javax.naming.Context instance, which is part of its implementation.

The initial context factory, `com.ibm.websphere.naming.WsnInitialContextFactory`, is typically used by applications to perform JNDI operations. The WebSphere Application Server runtime environment is set up to use this initial context factory if one is not specified explicitly by the JNDI client. When the initial context factory is invoked, an initial context is obtained. The following paragraphs explain how the initial context factory obtains the initial context in client and server environments.

- Registration of initial references in server processes

  Every WebSphere Application Server has an ORB used to receive and dispatch invocations on objects running in that server. Services running in the server process can register initial references with the ORB. Each initial reference is registered under a key, which is a string value. An initial reference can be any CORBA object. WebSphere Application Server name servers register several initial contexts as initial references under predefined keys. Each name server initial reference is an instance of the interface org.omg.CosNaming.NamingContext.
- Obtaining initial references in pure client processes

  Pure JNDI clients, that is, JNDI clients which are not running in a WebSphere Application Server process, also have an ORB instance. This client ORB instance can be passed to the InitialContext

constructor, but typically the initial context factory creates and initializes the client ORB instance transparently. A client ORB can be initialized with initial references, but the initial references most likely resolve to objects running in some server. The initial context factory does not define any default initial references when it initializes an ORB. If the `resolve_initial_references` method is invoked on the client ORB when no initial references have been configured, the method invocation fails. This condition is typical for pure client processes. To obtain an initial NamingContext reference, the initial context factory must invoke `string_to_object` with an IIOP type CORBA object URL, such as `corbaloc:iiop:myhost:2809`. The URL specifies the address of the server from which to obtain the initial context. The host and port information is extracted from the provider URL passed to the InitialContext constructor.

If no provider URL is defined, the WebSphere Application Server initial context factory uses the default provider URL of `corbaloc:iiop:localhost:2809`.

The `string_to_object` ORB method resolves the URL and communicates with the target server ORB to obtain the initial reference.

- Obtaining initial references in server processes

  If the JNDI client is running in a WebSphere Application Server process, the initial context factory obtains a reference to the server ORB instance if the JNDI client does not provide an ORB instance. Typically, JNDI clients running in server processes use the server ORB instance; that is, they do not pass an ORB instance to the InitialContext constructor. The name server which is running in the server process sets a provider URL as a java.lang.System property to serve as the default provider URL for all JNDI clients in the process. This default provider URL is `corbaloc:rir:/NameServiceServerRoot`. This URL resolves to the server root context for that server. (The URL is equivalent to invoking `resolve_initial_references` on the ORB with a key of NameServiceServerRoot. The name server registers the server root context as an initial reference under that key.)

- Understanding the legacy ORB protocol

  Releases previous to WebSphere Application Server Version 5 used a different ORB implementation, which used a legacy protocol in contrast with the Interoperable Name Service (INS) protocol now used. This change has affected the implementation of the initial context factory. Certain types of pure clients can experience different behavior when getting initial JNDI contexts as compared to previous releases of WebSphere Application Server. This behavior is discussed in more detail later in this section.

  The following ORB properties are used with the legacy ORB protocol for ORB initialization and are now deprecated:
  - com.ibm.CORBA.BootstrapHost
  - com.ibm.CORBA.BootstrapPort

  The new INS ORB is different in a major respect, in that it exhibits no default behavior if no initial references are defined.

  In the legacy ORB, the bootstrap host and port values defaulted to `localhost` and `900`.

  All initial references were obtained from the server running on the bootstrap host and port. So, if the ORB user provided no bootstrap host and port, all initial references are resolved from the server running on the local host at port 900. The INS ORB has no concept of bootstrap host or bootstrap port. All initial references are defined independently. That is, different initial references could resolve to different servers. If `ORB.resolve_initial_references` is invoked with a key such that the ORB is not initialized with an initial reference having that key, the call fails.

  In releases previous to Version 5, the initial context factory invoked `resolve_initial_references` on the ORB in the absence of any provider URL. This action succeeded if a name server at the default bootstrap host and port was running. In the current release, with the INS ORB, this would fail. (Actually, the ORB would fall back to the legacy protocol during the deprecation period, but when the legacy protocol is no longer supported, the operation would fail.)

  The initial context factory now uses a default provider URL of `corbaloc:iiop:localhost:2809`, and invokes `string_to_object` with the provider URL.

This operation preserves the behavior that pure clients in previous releases experienced when they set no ORB bootstrap properties or provider URL. However, this different initial context factory implementation changes the behavior experienced by certain legacy pure clients, which do not specify a provider URL:
– Clients which set the ORB bootstrap properties previously listed when getting an initial context.
– Clients which supply their own ORB instance to the InitialContext constructor.

There are two ways to circumvent this change of behavior:

– Always specify an IIOP type provider URL. This approach does not depend on the bootstrap host and port properties and continues to work when support for the bootstrap host and port properties is removed. For example, you can express bootstrap host and port property values of `myHost` and `2809`, respectively, as `corbaloc:iiop:myHost:2809`.
– Use an rir type provider URL:
  - Specify `corbaloc:rir:/NameServiceServerRoot` if the ORB is initialized to use a Version 5 server as the bootstrap server.
  - Specify `corbaname:rir:/NameService#domain/legacyRoot` if the ORB is initialized to use a Version 4.0.x server as the bootstrap server.
  - Specify `corbaloc:rir:/NameService` if the ORB is initialized to use a server other than a Version 5 or 4.0.x server as the bootstrap server.

  URLs of this type are equivalent to invoking `resolve_initial_references` on the ORB with the specified key. If the bootstrap host and port properties are being used to initialize the ORB, this approach will not work when the bootstrap and host properties are no longer supported.

• The InitialContext constructor search order for JNDI properties

  If the code snippet shown at the beginning of this section is executed by an application, the bootstrap server depends on the value of the property, java.naming.provider.url.

  If the property is not set (in server processes the default value is set as a system property), the default host of `localhost` and default port of `2809` are used as the address of the server from which to obtain the initial context.

  The JNDI specification describes where the InitialContext constructor looks for java.naming.provider.url property settings, but briefly, the property is picked up from the following places in the order shown:

  InitialContext constructor
  This does not apply to the previous example because the example uses the empty InitalContext constructor.

  System environment
  You can add JNDI properties to the system environment as an option on the Java command invocation and by program code. The recommended way to set the provider URL in the system environment is as an option supplied to the Java command invocation. Setting the provider URL in this manner is not temporal, so that getting a default initial context will always yield the same result. It is generally recommended that program code not set the provider URL property in the system environment because as a side-effect, this could adversely affect other, possibly unrelated, code running elsewhere in the same process.

  `jndi.properties` file
  There may be many `jndi.properties` files that are within the scope of the class loader in effect. All `jndi.properties` files are used for setting JNDI properties, but the provider URL setting is determined by the first `jndi.properties` file returned by the class loader.

Example: Getting an initial context by setting the provider URL property

In general, Java Naming and Directory Interface (JNDI) clients should assume the correct environment is already configured so there is no need to explicitly set property values and pass them to the `InitialContext` constructor. However, a JNDI client might need to access a namespace other than the one identified in its environment. In this case, it is necessary to explicitly set the java.naming.provider.url (provider URL) property used by the `InitialContext` constructor. A provider URL contains bootstrap server

information that the initial context factory can use to obtain an initial context. Any property values passed in directly to the `InitialContext` constructor take precedence over settings of those same properties found elsewhere in the environment.

You can use two different provider URL forms with theWebSphere Application Server initial context factory:
- A CORBA object URL
- An IIOP URL

CORBA object URLs are more flexible than IIOP URLs and are the recommended URL format to use. CORBA object URLs are part of the OMG CosNaming Interoperable Naming Specification. A corbaname URL, for example, can include initial context and lookup name information and can be used as a lookup name without the need to explicitly obtain another initial context. The IIOP URLs are the legacy JNDI format, but are still supported by the WebSphere Application Server initial context factory.

The following examples illustrate the use of these URLs.
- "Using a CORBA object URL"
- "Using a CORBA object URL with multiple name server addresses"
- "Using a CORBA object URL from a non-WebSphere Application Server JNDI implementation" on page 634
- "Using an IIOP URL" on page 634

Using a CORBA object URL

This example shows a CORBA object URL.

```
...
import java.util.Hashtable;
import javax.naming.Context;
import javax.naming.InitialContext;
...
Hashtable env = new Hashtable();
env.put(Context.INITIAL_CONTEXT_FACTORY,
     "com.ibm.websphere.naming.WsnInitialContextFactory");
env.put(Context.PROVIDER_URL, "corbaloc:iiop:myhost.mycompany.com:2809");
Context initialContext = new InitialContext(env);
...
```

Using a CORBA object URL with multiple name server addresses

CORBA object URLs can contain more than one bootstrap address. You can use this feature when attempting to obtain an initial context from a server cluster. You can specify the bootstrap addresses for all servers in the cluster in the URL. The operation succeeds if at least one of the servers is running, eliminating a single point of failure. There is no guarantee of any particular order in which the address list will be processed. For example, the second bootstrap address may be used to obtain the initial context even though the server at the first bootstrap address in the list is available.

Multiple-address provider URLs resolving to servers on non-z/OS systems cannot contain bootstrap addresses for node agent processes. This is because bootstrapping to a nodeagent returns a non-WLM-enabled initial context. As a result, WLM is not used. Instead, the URLs should contain only bootstrap addresses of members of the same cluster so that the initial context is WLM-enabled. If the URLs contain the bootstrap addresses of multiple clusters, incorrect behavior could result. A given name might not resolve, or resolve to the same object on all clusters. When resolving to servers running on the z/OS operating system, the URLs can contain bootstrap addresses for node agent processes since an z/OS a node agent does return a WLM-enabled initial context.

An example of a corbaloc URL with multiple addresses follows.

```
...
import java.util.Hashtable;
import javax.naming.Context;
import javax.naming.InitialContext;
```

```
...
Hashtable env = new Hashtable();
env.put(Context.INITIAL_CONTEXT_FACTORY,
     "com.ibm.websphere.naming.WsnInitialContextFactory");
// All of the servers in the provider URL below are members of
// the same cluster.
env.put(Context.PROVIDER_URL,
     "corbaloc::myhost1:9810,:myhost1:9811,:myhost2:9810");
Context initialContext = new InitialContext(env);
...
```

Using a CORBA object URL from a non-WebSphere Application Server JNDI implementation

Initial context factories for CosNaming JNDI plug-in implementations other than the WebSphere Application Server initial context factory most likely obtain an initial context using the object key, `NameService`. When you use such a context factory to obtain an initial context from a WebSphere Application Server name server, the initial context is the cell root context. Since system artifacts such as EJB homes associated with a server are bound under the server's server root context, names used in JNDI operations must be qualified. If you want to use relative names, ensure your initial context is the server root context under which the target object is bound. In order to make the server root context the initial context, specify a corbaloc provider URL with an object key of `NameServiceServerRoot`.

This example shows a CORBA object type URL from a non-WebSphere Application Server JNDI implementation. This example assumes full CORBA object URL support by the non-WebSphere Application Server JNDI implementation. The object key of `NameServiceServerRoot` is specified so that the initial context will be the specified server's server root context.

```
...
import java.util.Hashtable;
import javax.naming.Context;
import javax.naming.InitialContext;
...
Hashtable env = new Hashtable();
env.put(Context.INITIAL_CONTEXT_FACTORY,
      "com.somecompany.naming.TheirInitialContextFactory");
env.put(Context.PROVIDER_URL,
      "corbaname:iiop:myhost.mycompany.com:9810/NameServiceServerRoot");
Context initialContext = new InitialContext(env);
...
```

If qualified names are used, you can use the default key of `NameService`.

Using an IIOP URL

The IIOP type of URL is a legacy format which is not as flexible as CORBA object URLs. However, URLs of this type are still supported. The following example shows an IIOP type URL as the provider URL.

```
...
import java.util.Hashtable;
import javax.naming.Context;
import javax.naming.InitialContext;
...
Hashtable env = new Hashtable();
env.put(Context.INITIAL_CONTEXT_FACTORY,
     "com.ibm.websphere.naming.WsnInitialContextFactory");
env.put(Context.PROVIDER_URL, "iiop://myhost.mycompany.com:2809");
Context initialContext = new InitialContext(env);
...
```

Example: Setting the provider URL property to select a different root context as the initial context

Each server contains its own server root context, and, when bootstrapping to a server, the server root is the default initial JNDI context. Most of the time, this default is the desired initial context, since system

artifacts such as EJB homes are bound there. However, other root contexts exist, which can contain bindings of interest. It is possible to specify a provider URL to select other root contexts.

Examples for selecting other root contexts follow:
- Initial root contexts with a CORBA object URL
- Initial root contexts with the namespace root property

Selecting the initial root context with a CORBA object URL

There are several object keys registered with the bootstrap server that you can use to select the root context for the initial context. To select a particular root context with a CORBA object URL object key, set the object key to the corresponding value. The default object key is NameService. Using JNDI yields the server root context. A table that lists the different root contexts and their corresponding object key follows:

Root Context	CORBA Object URL Object Key
Server Root	NameServiceServerRoot
Cell Persistent Root	NameServiceCellPersistentRoot
Cell Root	NameServiceCellRoot
Node Root	NameServiceNodeRoot

The following example shows the use of a corbaloc URL with the object key set to select the cell persistent root context as the initial context.

```
...
import java.util.Hashtable;
import javax.naming.Context;
import javax.naming.InitialContext;
...
Hashtable env = new Hashtable();
env.put(Context.INITIAL_CONTEXT_FACTORY,
      "com.ibm.websphere.naming.WsnInitialContextFactory");
env.put(Context.PROVIDER_URL,
      "corbaloc:iiop:myhost.mycompany.com:2809/NameServiceCellPersistentRoot");
Context initialContext = new InitialContext(env);
...
```

Selecting the initial root context with the namespace root property

You can also select the initial root context by passing a namespace root property setting to the InitialContext constructor. Generally, the object key setting previously described is sufficient. Sometimes a property setting is preferable. For example, you can set the root context property on the Java invocation to make which server root is being used as the initial context transparent to the application. The default server root property setting is `defaultroot`, which yields the server root context.

Root Context	Namespace Root Property Value
Server Root	bootstrapserverroot
Cell Persistent Root	cellpersistentroot
Cell Root	cellroot
Node Root	bootstrapnoderoot

The initial context factory ignores the namespace root property if the provider URL contains an object key other than `NameService`.

The following example shows use of the namespace root property to select the cell persistent root context as the initial context. Note that available constants are used instead of hard-coding the property name and value.

```
...
import java.util.Hashtable;
import javax.naming.Context;
import javax.naming.InitialContext;
import com.ibm.websphere.naming.PROPS;
...
Hashtable env = new Hashtable();
env.put(Context.INITIAL_CONTEXT_FACTORY,
      "com.ibm.websphere.naming.WsnInitialContextFactory");
env.put(Context.PROVIDER_URL, "corbaloc:iiop:myhost.mycompany.com:2809");
env.put(PROPS.NAME_SPACE_ROOT, PROPS.NAME_SPACE_ROOT_CELL_PERSISTENT);
Context initialContext = new InitialContext(env);
...
```

Example: Looking up an EJB home or business interface with JNDI

Most applications that use Java Naming and Directory Interface (JNDI) run in a container. Some do not. The name used to look up an object depends on whether or not the application is running in a container. Sometimes it is more convenient for an application to use a corbaname URL as the lookup name. Container-based JNDI clients and thin Java clients can use a corbaname URL.

The following examples show how to perform JNDI lookups from different types of applications.

- "JNDI lookup from an application running in a container"
- "JNDI lookup from an application that does not run in a container" on page 637
- "JNDI lookup with a corbaname URL" on page 639

JNDI lookup from an application running in a container

Applications that run in a container can use `java:` lookup names. Lookup names of this form provide a level of indirection such that the lookup name used to look up an object is not dependent on the object's name as it is bound in the name server's namespace. The deployment descriptors for the application provide the mapping from the `java:` name and the name server lookup name. The container sets up the `java:` namespace based on the deployment descriptor information so that the `java:` name is correctly mapped to the corresponding object.

The following example shows a lookup of an EJB 3.0 remote business interface. The actual home lookup name is determined by the interface's `ibm-ejb-jar-bnd.xml` binding file, if present, or by the default name assigned by the EJB container if no binding file is present. For more information, see topics on default bindings for business interfaces and homes and on user-defined bindings for EJB business interfaces and homes.

```
// Get the initial context as shown in a previous example.
...
// Look up the business interface using the JNDI name.
try {
   java.lang.Object ejbBusIntf =
      initialContext.lookup(
         "java:comp/env/com/mycompany/accounting/Account");
   accountIntf =
      (Account)javax.rmi.PortableRemoteObject.narrow(ejbBusIntf, Account.class);
}
   catch (NamingException e) { // Error getting the business interface
   ...
}
```

The following example shows a lookup of an EJB 1.x or 2.x EJB home. The actual home lookup name is determined by the application's deployment descriptors. The enterprise bean (EJB) resides in an EJB container, which provides an interface between the bean and the application server on which it resides.

```
// Get the initial context as shown in a previous example
...
// Look up the home interface using the JNDI name
try {
   java.lang.Object ejbHome =
```

```
      initialContext.lookup(
         "java:comp/env/com/mycompany/accounting/AccountEJB");
   accountHome = (AccountHome)javax.rmi.PortableRemoteObject.narrow(
      (org.omg.CORBA.Object) ejbHome, AccountHome.class);
}
   catch (NamingException e) { // Error getting the home interface
   ...
}
```

JNDI lookup from an application that does not run in a container

Applications that do not run in a container cannot use `java:` lookup names because it is the container which sets the `java:` namespace up for the application. Instead, an application of this type must look the object up directly from the name server. Each application server contains a name server. System artifacts such as EJB homes are bound relative to the server root context in that name server. The various name servers are federated by means of a system namespace structure. The recommended way to look up objects on different servers is to qualify the name so that the name resolves from any initial context in the cell. If a relative name is used, the initial context must be the same server root context as the one under which the object is bound. The form of the qualified name depends on whether the qualified name is a topology-based name or a fixed name. Examples of each form of qualified name follow.

- **Topology-based qualified names**

  Topology-based qualified names traverse through the system namespace to the server root context under which the target object is bound. A topology-based qualified name resolves from any initial context in the cell.

  The topology-based qualified name depends on whether the object resides on a single server or server cluster. Examples of each lookup follow.

  Single server

  The following example shows a lookup of an EJB business interface that is running in the single server, MyServer, configured in the node, Node1.

  ```
  // Get the initial context as shown in a previous example.
  // Using the form of lookup name below, it does not matter which
  // server in the cell is used to obtain the initial context.
  ...
  // Look up the business interface using the JNDI name
  try {
     java.lang.Object ejbBusIntf = initialContext.lookup(
        "cell/nodes/Node1/servers/MyServer/com/mycompany/accounting/Account");
     accountIntf =
       (Account)javax.rmi.PortableRemoteObject.narrow(ejbBusIntf, Account.class);
  }
  catch (NamingException e) { // Error getting the business interface
     ...
  }
  ```

  The following example shows a lookup of an EJB home that is running in the single server, MyServer, configured in the node, Node1.

```
// Get the initial context as shown in a previous example
// Using the form of lookup name below, it doesn't matter which
// server in the cell is used to obtain the initial context.
...
// Look up the home interface using the JNDI name
try {
   java.lang.Object ejbHome = initialContext.lookup(
      "cell/nodes/Node1/servers/MyServer/com/mycompany/accounting/AccountEJB");
   accountHome = (AccountHome)javax.rmi.PortableRemoteObject.narrow(
      (org.omg.CORBA.Object) ejbHome, AccountHome.class);
}
catch (NamingException e) { // Error getting the home interface
   ...
}
```

Server cluster

The following example shows a lookup of an EJB business interface which is running in the cluster, MyCluster. The name can be resolved if any of the cluster members is running.

```
// Get the initial context as shown in a previous example.
// Using the form of lookup name below, it does not matter which
// server in the cell is used to obtain the initial context.
...
   // Look up the business interface using the JNDI name
try {
   java.lang.Object ejbBusIntf = initialContext.lookup(
      "cell/clusters/MyCluster/com/mycompany/accounting/Account");
   accountIntf =
     (Account)javax.rmi.PortableRemoteObject.narrow(ejbBusIntf, Account.class);
}
catch (NamingException e) { // Error getting the business interface
   ...
}
```

The following example shows a lookup of an EJB home which is running in the cluster, MyCluster. The name can be resolved if any of the cluster members is running.

```
// Get the initial context as shown in a previous example
// Using the form of lookup name below, it does not matter which
// server in the cell is used to obtain the initial context.
...
   // Look up the home interface using the JNDI name
try {
   java.lang.Object ejbHome = initialContext.lookup(
      "cell/clusters/MyCluster/com/mycompany/accounting/AccountEJB");
   accountHome = (AccountHome)javax.rmi.PortableRemoteObject.narrow(
      (org.omg.CORBA.Object) ejbHome, AccountHome.class);
}
catch (NamingException e) { // Error getting the home interface
   ...
}
```

- **Fixed qualified names**

  If the target object has a cell-scoped fixed name defined for it, you can use its qualified form instead of the topology-based qualified name. Even though the topology-based name works, the fixed name does not change with the specific cell topology or with the movement of the target object to a different server.

  An example lookup of an EJB business interface with a qualified fixed name follows.

```
// Get the initial context as shown in a previous example.
// Using the form of lookup name below, it does not matter which
// server in the cell is used to obtain the initial context.
...
// Look up the business interface using the JNDI name
try {
   java.lang.Object ejbBusIntf = initialContext.lookup(
     "cell/persistent/com/mycompany/accounting/Account");
   accountIntf =
     (Account)javax.rmi.PortableRemoteObject.narrow(ejbBusIntf, Account.class);
   }
catch (NamingException e) { // Error getting the business interface
...

}
```

  An example lookup with a qualified fixed name follows:

```
// Get the initial context as shown in a previous example
// Using the form of lookup name below, it doesn't matter which
// server in the cell is used to obtain the initial context.
...
// Look up the home interface using the JNDI name
try {
   java.lang.Object ejbHome = initialContext.lookup(
     "cell/persistent/com/mycompany/accounting/AccountEJB");
   accountHome = (AccountHome)javax.rmi.PortableRemoteObject.narrow(
      (org.omg.CORBA.Object) ejbHome, AccountHome.class);
   }
catch (NamingException e) { // Error getting the home interface
...
}
```

JNDI lookup with a corbaname URL

A corbaname can be useful at times as a lookup name. If, for example, the target object is not a member of the federated namespace and cannot be located with a qualifiied name, a corbaname can be a convenient way to look up the object.

A lookup of an EJB business interface with a corbaname URL follows.

```
// Get the initial context as shown in a previous example.
...
// Look up the business interface using a corbaname URL.
try {
   java.lang.Object ejbBusIntf = initialContext.lookup(
      "corbaname:iiop:someHost:2809#com/mycompany/accounting/Account");
   accountIntf =
     (Account)javax.rmi.PortableRemoteObject.narrow(ejbBusIntf, Account.class);
}
catch (NamingException e) { // Error getting the business interface
   ...
}
```

A lookup with a corbaname URL follows.

```
// Get the initial context as shown in a previous example
...
// Look up the home interface using a corbaname URL
try {
   java.lang.Object ejbHome = initialContext.lookup(
      "corbaname:iiop:someHost:2809#com/mycompany/accounting/AccountEJB");
   accountHome = (AccountHome)javax.rmi.PortableRemoteObject.narrow(
      (org.omg.CORBA.Object) ejbHome, AccountHome.class);
}
catch (NamingException e) { // Error getting the home interface
   ...
}
```

JNDI interoperability considerations

You must take extra steps to enable your programs to interoperate with non-product JNDI clients and to bind resources from MQSeries® to a namespace.

EJB clients running in an environment other than WebSphere Application Server accessing EJB applications running on product servers

When an enterprise bean (EJB) application running in WebSphere Application Server is accessed by a non-product EJB client, the JNDI initial context factory is presumed to be a non-product implementation. In this case, the default initial context is the cell root. If the JNDI service provider being used supports CORBA object URLs, the corbaname format can be used to look up the EJB home.

The construction of the stringified name depends on whether the object is installed on a single server or cluster.

Single server

Following is a URL that has the bootstrap host `myHost`, the port `2809`, and the enterprise bean installed in the server `server1` in node `node1` and bound in that server under the name `myEJB`:

```
initialContext.lookup(
  "corbaname:iiop:myHost:2809#cell/nodes/node1/servers/server1/myEJB");
```

Server cluster

Following is a URL that has the bootstrap host `myHost`, the port `2809`, and the enterprise bean installed in a server cluster named `myCluster` and bound in that cluster under the name `myEJB`:

```
initialContext.lookup(
    "corbaname:iiop:myHost:2809#cell/clusters/myCluster/myEJB");
```

The lookup works with any name server bootstrap host and port configured in the same cell.

The lookup also works if the bootstrap host and port belong to a member of the cluster itself. To avoid a single point of failure, the bootstrap server host and port for each cluster member can be listed in the URL as follows:

```
initialContext.lookup(
    "corbaname:iiop:host1:9810,:host2:9810#cell/clusters/myCluster/myEJB");
```

The name prefix `cell/clusters/myCluster/` is not necessary if boostrapping to the cluster itself, but it will work. The prefix is needed, however, when looking up enterprise beans in other clusters. Name bindings under the `clusters` context are implemented on the name server to resolve to the server root of a running cluster member during a lookup; thus avoiding a single point of failure.

Without CORBA object URL support

If the JNDI initial context factory being used does not support CORBA object URLs, the initial context can be obtained from the server, and the lookup can be performed on the initial context as follows:

```
Hashtable env = new Hashtable();
env.put(CONTEXT.PROVIDER_URL, "iiop://myHost:2809");
Context ic = new InitialContext(env);
Object o = ic.lookup("cell/clusters/myCluster/myEJB");
```

Binding resources from MQSeries 5.2

In releases previous to WebSphere Application Server Version 5.0, the MQSeries jmsadmin tool could be used to bind resources to the namespace. When used with a WebSphere Application Server namespace, the resource is bound within a transient partition in the namespace and does not persist past the life of the server process. Instead of binding the MQSeries resources with the jmsadmin tool, bind them from the administrative console, under **Resources** in the console navigation tree.

JNDI caching

To increase the performance of Java Naming and Directory Interface (JNDI) operations, the product JNDI implementation employs caching to reduce the number of remote calls to the name server for lookup operations. For most cases, use the default cache setting.

When an InitialContext object is instantiated, an association is established between the InitialContext instance and a cache. The initial context and any contexts returned directly or indirectly from a lookup on the initial context are all associated with that same cache instance. By default, the association is based on the provider URL, in particular, the host name and port. The caller can specify the cache name to override this default behavior. A cache instance of a given name is shared by all instances of InitialContext configured to use a cache of that name which were created with the same context class loader in effect. Two enterprise bean (EJB) applications running in the same server will use their own cache instances, if they are using different context class loaders, even if the cache names are the same.

After an association between an InitialContext instance and cache is established, the association does not change. A `javax.naming.Context` object returned from a lookup operation inherits the cache association of the Context object on which the lookup was performed. Changing cache property values with the `Context.addToEnvironment()` or `Context.removeFromEnvironment()` method does not affect cache behavior. You can change properties affecting a given cache instance with each InitialContext instantiation.

A cache is restricted to a process and does not persist past the life of that process. A cached object is returned from lookup operations until either the maximum cache life for the cache is reached, or the maximum entry life for the object's cache entry is reached. After this time, a lookup on the object causes the cache entry for the object to be refreshed. By default, caches and cache entries have unlimited lifetimes.

Usually, cached objects are relatively static entities, and objects becoming stale is not a problem. However, you can set timeout values on cache entries or on a cache so that cache contents are periodically refreshed.

If a bind or rebind operation is executed on an object, the change is not reflected in any caches other than the one associated with the context from which the bind or rebind was issued. This scenario is most likely to happen when multiple processes are involved, since different processes do not share the same cache, and context objects in all threads in a process typically share the same cache instance for a given name service provider.

JNDI cache settings

Various Java Naming and Directory Interface (JNDI) cache property settings follow. Ensure that all property values are string values.

com.ibm.websphere.naming.jndicache.cachename

The name of the cache to associate with an initial context instance can be specified with this property.

It is possible to create multiple InitialContext instances, each operating on the namespace of a different name server. By default, objects from each bootstrap address are cached separately, since they each involve independent namespaces and name collisions could occur if they used the same cache. The provider URL specified when the initial context is created by default serves as the basis for the cache name. With this property, a JNDI client can specify a cache name. Valid options for cache names follow:

Valid options	Resulting cache behavior
providerURL (default)	Use the value for java.naming.provider.url property as the basis for the cache name. Cache names are based on the bootstrap host and port specified in the URL. The boostrap host is normalized to a fully qualfied name, if possible. For example, "corbaname:iiop:server1:2809#some/starting/context" and "corbaloc:iiop://server1" are normalized to the same cache name. If no provider URL is specified, a default cache name is used.
Any string	Use the specified string as the cache name. You can use any arbitrary string with a value other than "providerURL" as a cache name.

com.ibm.websphere.naming.jndicache.cacheobject

Turn caching on or off and clear an existing cache with this property.

By default, when an InitialContext is instantiated, it is associated with an existing cache or, if one does not exist, a new one is created. An existing cache is used with its existing contents. In some circumstances, this behavior is not desirable. For example, when objects that are looked up change frequently, they can become stale in the cache. Other options are available. The following table lists these other options along with the corresponding property value.

Valid values	Resulting cache behavior
populated (default)	Use a cache with the specified name. If the cache already exists, leave existing cache entries in the cache; otherwise, create a new cache.
cleared	Use a cache with the specified name. If the cache already exists, clear all cache entries from the cache; otherwise, create a new cache.
none	Do not cache. If this option is specified, the cache name is irrelevant. Therefore, this option will not disable a cache that is already associated with other InitialContext instances. The InitialContext that is instantiated is not associated with any cache.

com.ibm.websphere.naming.jndicache.maxcachelife

Impose a limit to the age of a cache with this property.

By default, cached objects remain in the cache for the life of the process or until cleared with the com.ibm.websphere.naming.jndicache.cacheobject property set to `cleared`. This property enables a JNDI client to set the maximum life of a cache. This property differs from the maxentrylife property in that the entire cache is cleared when the cache lifetime is reached. The following table lists the various maxcachelife values and their affect on cache behavior:

Valid values	Resulting cache behavior
0 (default)	Make the cache lifetime unlimited.
Positive integer	Set the maximum lifetime of the entire cache, in minutes, to the specified value. When the maximum lifetime for the cache is reached, the next attempt to read any entry from the cache causes the cache to be cleared

com.ibm.websphere.naming.jndicache.maxentrylife

Impose a limit to the age of individual cache entries with this property.

By default, cached objects remain in the cache for the life of the process or until cleared with the com.ibm.websphere.naming.jndicache.cacheobject property set to `cleared`. This property enables a JNDI client to set the maximum lifetime of individual cache entries. This property differs from the maxcachelife property in that individual entries are refreshed individually as their maximum lifetime reached. This might avoid any noticeable change in performance that might occur if the whole cache is cleared at once. The following table lists the various maxentrylife values and their effect on cache behavior:

Valid values	Resulting cache behavior
0 (default)	Lifetime of cache entries is unlimited.
Positive integer	Set the maximum lifetime of individual cache entries, in minutes, to the specified value. When the maximum lifetime for an entry is reached, the next attempt to read the entry from the cache causes the individual cache entry to refresh.

JNDI to CORBA name mapping considerations

WebSphere Application Server name servers are an implementation of the CORBA CosNaming interface. The product provides a Java Naming and Directory Interface (JNDI) implementation which you can use to access CosNaming name servers through the JNDI interface. Issues can exist when mapping JNDI name strings to and from CORBA names.

Each component in a CORBA name consists of an `id` and `kind` field, but a JNDI name component consists of no such fields. Each component in a JNDI name is atomic. Typical JNDI clients do not need to make a distinction between the `id` and `kind` fields of a name component, or know how JNDI name strings map to CORBA names. JNDI clients of this sort can use the JNDI syntax described later in this section. When a name is parsed according to JNDI syntax, each name component is mapped to the `id` field of the corresponding CORBA name component. The `kind` field always has an empty value. This basic syntax is the least obtrusive to the JNDI client in that it has the fewest special characters. However, you cannot represent with this syntax a CORBA name with a non-empty `kind` field. This restriction can prevent EJB applications from interoperating with CORBA applications.

Some clients, however must interoperate with CORBA applications which use CORBA names with non-empty `kind` fields. These JNDI clients must make a distinction between `id` and `kind` so that JNDI names are correctly mapped to CORBA names, particularly when the CORBA names contain components with non-empty `kind` fields. Such JNDI clients can use the INS name syntax. With its additional special character, you can use INS to represent any CORBA name. Use of this syntax is not recommended unless it is necessary, because this syntax is more restrictive from the JNDI client's perspective in that the JNDI client must be aware that name components with multiple unescaped dots are syntactically invalid. INS name syntax is part of the OMG CosNaming Interoperable Naming Specification.

Developing applications that use CosNaming (CORBA Naming interface)

CORBA clients can perform naming operations on WebSphere Application Server name servers through the CosNaming interface.

About this task

The following examples show how to obtain an ORB instance and an initial context as well as how to look up an EJB home.

Procedure

1. Get an initial context.
2. Perform desired CosNaming operations.

Example: Getting an initial context with CosNaming

In WebSphere Application Server, an initial context is obtained from a bootstrap server. The address for the bootstrap server consists of a host and port. To get an initial context, you must know the host and port for the server that is used as the bootstrap server.

Obtaining an initial context consists of two basic steps:
1. Obtain an ORB reference.
2. Use an ORB reference to get an initial context. Alternatively, use an existing ORB and invoke string_to_object with a CORBA object URL with multiple name server addresses to get an initial context.

Obtaining an ORB reference

Pure CosNaming clients, that is clients that are not running in a server process, must create and initialize an ORB instance with which to obtain the initial context. CosNaming clients which run in server processes can obtain a reference to the server ORB with a JNDI lookup. The following examples illustrate how to create and initialize a client ORB and how to obtain a server ORB reference.

Creating a client ORB instance

To create an ORB instance, invoke the static method, org.omg.CORBA.ORB.init. The init method requires a property set to the name of the ORB class you want to instantiate. An ORB implementation with the class name com.ibm.CORBA.iiop.ORB is included with the product. The WebSphere Application Server ORB recognizes additional properties with which you can specify initial references.

The basic steps for creating an ORB are as follows:
1. Create a Properties object.
2. Set the ORB class property to the product's ORB class.
3. Set the initial reference properties.
4. Invoke ORB.init, passing in the Properties object.

```
...
import java.util.Properties;
import org.omg.CORBA.ORB;
...
Properties props = new Properties();
props.put("org.omg.CORBA.ORBClass","com.ibm.ws390.orb.ORB");
props.put("com.ibm.CORBA.ORBInitRef.NameService",
      "corbaloc:iiop:myhost.mycompany.com:2809/NameService");
props.put("com.ibm.CORBA.ORBInitRef.NameServiceServerRoot",
      "corbaloc:iiop:myhost.mycompany.com:2809/NameServiceServerRoot");
ORB _orb = ORB.init((String[])null, props);
...
```

Obtaining a reference to the server ORB

CosNaming clients which run in a server process can obtain a reference to the server ORB with a JNDI lookup on a java: name, shown as follows:

```
...
import javax.naming.Context;
import javax.naming.InitialContext;
import org.omg.CORBA.ORB;
...
Context initialContext = new InitialContext();
ORB orb = (ORB) initialContext.lookup("java:comp/ORB");
...
```

Using an ORB reference to get an initial naming reference

There are two basic ways to get an initial CosNaming context. Both ways involve an ORB method invocation. The first way is to invoke the resolve_initial_references method on the ORB with an initial reference key. For this call to work, the ORB must be initialized with an initial reference for that key. The other way is to invoke the string_to_object method on the ORB, passing in a CORBA object URL with the host and port of the bootstrap server. The following examples illustrate both approaches.

Invoking resolve_initial_references

Once an ORB reference is obtained, invoke the resolve_initial_references method on the ORB to obtain a reference to the initial context. The following code example invokes resolve_initial_reference on an ORB reference.

```
...
import org.omg.CORBA.ORB;
import org.omg.CosNaming.NamingContextExt;
import org.omg.CosNaming.NamingContextExtHelper;
...
// Obtain ORB reference as shown in examples earlier in this section
...
org.omg.CORBA.Object obj = _orb.resolve_initial_references("NameService");
NamingContextExt initCtx = NamingContextExtHelper.narrow(obj);
...
```

Note that the key NameService is passed to the resolve_initial_references method. Other initial context keys are registered in product servers. For example, NameServiceServerRoot can be used to obtain a reference to the server root context in the bootstrap name server. For more information on the initial contexts registered in server ORBs, refer to the topic on initial context support.

Invoking string_to_object with a CORBA object URL

You can use an INS-compliant ORB to obtain an initial context even if the ORB is not initialized with any initial references or bootstrap properties, or if those property settings are for a different server than the name server from which you want to obtain the initial context. To obtain an initial context by explicitly specifying the bootstrap name server, invoke the string_to_object method on the ORB, passing in a CORBA object URL which contains the bootstrap server host and port.

The code in the following example invokes the string_to_object method on an existing ORB reference, passing in a CORBA object URL which identifies the desired initial context.

```
...
import org.omg.CORBA.ORB;
import org.omg.CosNaming.NamingContextExt;
import org.omg.CosNaming.NamingContextExtHelper;
...
// Obtain ORB reference as shown in examples earlier in this section
...
```

```
org.omg.CORBA.Object obj =
 orb.string_to_object("corbaloc:iiop:myhost.mycompany.com:2809/NameService");
NamingContextExt initCtx = NamingContextExtHelper.narrow(obj);
...
```

Note that the key NameService is used in the corbaloc URL. Other initial context keys are registered in product servers. For example, you can use NameServiceServerRoot to obtain a reference to the server root context in the bootstrap name server.

Using an existing ORB and invoking string_to_object with a CORBA object URL

CORBA object URLs can contain more than one bootstrap server address. Use this feature when attempting to obtain an initial context from a server cluster. You can specify the bootstrap server addresses for all servers in the cluster in the URL. The operation will succeed if at least one of the servers is running, eliminating a single point of failure. There is no guarantee of any particular order in which the address list will be processed. For example, the second bootstrap server address may be used to obtain the initial context even though the first bootstrap server in the list is available. An example of a corbaloc URL with multiple addresses follows.

```
...
import org.omg.CORBA.ORB;
import org.omg.CosNaming.NamingContextExt;
import org.omg.CosNaming.NamingContextExtHelper;
...
// Assume orb is an existing ORB instance
org.omg.CORBA.Object obj = orb.string_to_object(
"corbaloc::myhost1:9810,:myhost1:9811,:myhost2:9810/NameService");
NamingContextExt initCtx = NamingContextExtHelper.narrow(obj);
...
```

Example: Looking up an EJB home with CosNaming

You can look up an EJB home or other CORBA object from a WebSphere Application Server name server through the CORBA CosNaming interface.

You can invoke `resolve` or `resolve_str` on the initial context, or you can invoke `string_to_object` on the ORB. You can use a qualified name so that the name resolves regardless of which name server the lookup is executed on, or use an unqualified name that only resolves from the server root context on the name server that actually contains the object binding. (The qualified name traverses the federated system namespace to the specified server root context.)

Qualified and unqualified names

Each application server contains a name server. System artifacts such as EJB homes are bound in that name server. The various name servers are federated by means of a system namespace structure. The recommended way to look up objects on different servers is to use a qualified name.

A qualified name can be a topology-based name, based on the name of the cluster or single server and node that contains the object.

You can define fixed qualified names for objects. With qualified names, you can look up objects residing on different servers from the same initial context by traversing the system namespace structure. Alternatively, you can use an unqualified name, but an unqualified name will only resolve using the name server associated with the object's application server.

CosNaming.resolve (and resolve_str) vs. ORB.string_to_object

If you have an initial context from any name server in a WebSphere Application Server cell, you can look up any CORBA object with a qualified name. You do not need additional host and port information for the target object's name server.

Alternatively, you can look up an object by invoking `string_to_object` on the ORB, passing in a corbaname URL. Typically, an IIOP type URL is specified, so the bootstrap address information required for an initial context must be contained in the URL. You can use a qualified or unqualified stringified name, but an unqualifed name resolves only if the initial context is from the name server in which the object is bound.

The following examples show CosNaming resolve operations using qualified topology-based lookup names and an unqualified lookup name.

CosNaming resolve operation using a qualified name

The topology-based qualified name for an object depends on whether the object is bound in a single server or a server cluster. Examples of each follow.

Single server

The following example shows the lookup of an EJB home that is running in a single server. The enterprise bean that is being looked up is running in the server, `MyServer`, on the node, `Node1`.

```
// Get the initial context as shown in the previous example
// Using the form of lookup name below, it doesn't matter which
// server in the cell is used to obtain the initial context.
...
// Look up the home interface using the name under which the EJB home is bound
org.omg.CORBA.Object ejbHome = initialContext.resolve_str(
  "cell/nodes/Node1/servers/MyServer/mycompany/accounting/AccountEJB");
accountHome =
  (AccountHome)javax.rmi.PortableRemoteObject.narrow(ejbHome, AccountHome.class);
```

Server cluster

The following example shows a lookup of an EJB home that is running in a cluster. The enterprise bean being that is looked up is running in the cluster, Cluster1. The name can be resolved if any of the cluster members is running.

```
// Get the initial context as shown in the previous example
// Using the form of lookup name below, it doesn't matter which
// server in the cell is used to obtain the initial context.
...
// Look up the home interface using the name under which the EJB home is bound
org.omg.CORBA.Object ejbHome = initialContext.resolve_str(
   "cell/clusters/Cluster1/mycompany/accounting/AccountEJB");
accountHome =
   (AccountHome)javax.rmi.PortableRemoteObject.narrow(ejbHome, AccountHome.class);
```

ORB string_to_object operation using an unqualified stringified name

If the resolve operation is being performed on the name server that contains the object, the system namespace does not need to be traversed, and you can use an unqualified lookup name. Note that this name does not resolve on other name servers. If an unqualified name is provided, the object key must be NameServiceServerRoot so that the correct initial context is selected. If a qualified name is provided, you can use the default key of NameService.

The following example shows a lookup of an EJB home. The enterprise bean that is being looked up is bound on the name server running on the host `myHost` on port `2809`. Note the object key of `NameServiceServerRoot`.

```
// Assume orb is an existing ORB instance
...
// Look up the home interface using the name under which the EJB home is bound
org.omg.CORBA.Object ejbHome = orb.string_to_object(
    "corbaname:iiop:myHost:2809/NameServiceServerRoot#mycompany/accounting");
accountHome =
    (AccountHome)javax.rmi.PortableRemoteObject.narrow(ejbHome, AccountHome.class);
```

Chapter 15. Developing Object pools

This page provides a starting point for finding information about object pools.

Object pools provide an effective means of improving application performance at run time, by supporting the reuse of multiple instances of objects.

Using object pools

An object pool helps an application avoid creating new Java objects repeatedly. Most objects can be created once, used and then reused. An object pool supports the pooling of objects waiting to be reused.

About this task

Object pools are not meant to be used for pooling JDBC connections or Java Message Service (JMS) connections and sessions. WebSphere Application Server provides specialized mechanisms for dealing with those types of objects. These object pools are intended for pooling application-defined objects or basic Developer Kit types.

To use an object pool, the product administrator must define an *object pool manager* using the administrative console. Multiple object pool managers can be created in an Application Server cell.

Note: The Object pool manager service is only supported from within the EJB container or Web container. Looking up and using a configured object pool manager from a Java 2 Platform Enterprise Edition (J2EE) application client container is not supported.

Procedure

1. Start the administrative console.
2. Click **Resources > Object pool managers**.
3. Specify a **Scope** value and click **New**.
4. Specify the required properties for work manager settings.
   Scope The scope of the configured resource. This value indicates the location for the configuration file.
   Name The name of the object pool manager. This name can be up to 30 ASCII characters long.
   JNDI Name
   The Java Naming and Directory Interface (JNDI) name for the pool manager.
5. [Optional] Specify a **Description** and a **Category** for the object pool manager.

Results

After you have completed these steps, applications can find the object pool manager by doing a JNDI lookup using the specified JNDI name.

Example

The following code illustrates how an application can find an object pool manager object:

```
InitialContext ic = new InitialContext();
ObjectPoolManager opm = (ObjectPoolManager)ic.lookup("java:comp/env/pool");
```

When the application has an ObjectPoolManager, it can cache an object pool for classes of the types it wants to use. The following is an example:

```
ObjectPool arrayListPool = null;
ObjectPool vectorPool = null;
try
```

```
{
 arrayListPool = opm.getPool(ArrayList.class);
 vectorPool = opm.getPool(Vector.class);
}
catch(InstantiationException e)
{
 // problem creating pool
}
catch(IllegalAccessException e)
{
 // problem creating pool
}
```

When the application has the pools, the application can use them as in the following example:

```
ArrayList list = null;
try
{
 list = (ArrayList)arrayListPool.getObject();
 list.clear(); // just in case
 for(int i = 0; i < 10; ++i)
 {
  list.add("" + i);
 }
 // do what ever we need with the ArrayList
}
finally
{
 if(list != null) arrayListPool.returnObject(list);
}
```

This example presents the basic pattern for using object pooling. If the application does not return the object, then the only adverse effect is that the object cannot be reused.

Object pool managers

Object pool managers control the reuse of application objects and Developer Kit objects, such as Vectors and HashMaps.

Multiple object pool managers can be created in an Application Server cell. Each object pool manager has a unique cell-wide Java Naming and Directory Interface (JNDI) name. Applications can find a specific object pool manager by doing a JNDI lookup using the specific JNDI name.

The object pool manager and its associated objects implement the following interfaces:

```
public interface ObjectPoolManager
{
 ObjectPool getPool(Class aClass)
  throws InstantiationException, IllegalAccessException;
 ObjectPool createFastPool(Class aClass)
  throws InstantiationException, IllegalAccessException;

}

public interface ObjectPool
{
 Object getObject();
 void returnObject(Object o);

}
```

The getObject() method removes the object from the object pool. If a getObject() call is made and the pool is empty, then an object of the same type is created. A returnObject( ) call puts the object back into the object pool. If returnObject() is not called, then the object is no longer allocatable from the object pool. If the object is not returned to the object pool, then it can be garbage collected.

Each object pool manager can be used to pool any Java object with the following characteristics:
- The object must be a public class with a public default constructor.
- If the object implements the java.util.Collection interface, it must support the optional clear() method.

Each pooled object class must have its own object pool. In addition, an application gets an object pool for a specific object using either the ObjectPoolManager.getPool() method or the ObjectPoolManager.createFastPool() method. The difference between these methods is that the getPool() method returns a pool that can be shared across multiple threads. The createFastPool() method returns a pool that can only be used by a single thread.

If in a Java virtual machine (JVM), the getPool() method is called multiple times for a single class, the same pool is returned. A new pool is returned for each call when the createFastPool() method is called. Basically, the getPool() method returns a pool that is thread-synchronized.

The pool for use by multiple threads is slightly slower than a fast pool because of the need to handle thread synchronization. However, extreme care must be taken when using a fast pool.

Consider the following interface:

```
public interface PoolableObject
{
 void init();
 void returned();
}
```

If the objects placed in the pool implement this interface and the ObjectPool.getObject() method is called, the object that the pool distributes has the init() method called on it. When the ObjectPool.returnObject() method is called, the PoolableObject.returned() method is called on the object before it is returned to the object pool. Using this method objects can be pre-initialized or cleaned up.

It is not always possible for an object to implement PoolableObject. For example, an application might want to pool ArrayList objects. The ArrayList object needs clearing each time the application reuses it. The application might extend the ArrayList object and have the ArrayList object implement a poolable object. For example, consider the following:

```
public class PooledArrayList extends ArrayList implements PoolableObject
{
 public PooledArrayList()
 {
 }

 public void init() {
 }

 public void returned()
 {
  clear();
 }
}
```

If the application uses this object, in place of a true ArrayList object, the ArrayList object is cleared automatically when it is returned to the pool.

Clearing an ArrayList object simply marks it as empty and the array backing the ArrayList object is not freed. Therefore, as the application reuses the ArrayList, the backing array expands until it is big enough for all of the application requirements. When this point is reached, the application stops allocating and copying new backing arrays and achieves the best performance.

It might not be possible or desirable to use the previous procedure. An alternative is to implement a custom object pool and register this pool with the object pool manager as the pool to use for classes of

that type. The class is registered by the WebSphere administrator when the object pool manager is defined in the cell. Take care that these classes are packaged in Java Archive (JAR) files available on all of the nodes in the cell where they might be used.

Object pool managers collection

An object pool manages a pool of arbitrary objects and helps applications avoid creating new Java objects repeatedly. Most objects can be created once, used and then reused. An object pool supports the pooling of objects waiting to be reused. These object pools are not meant to be used for pooling Java Database Connectivity connections or Java Message Service (JMS) connections and sessions. WebSphere Application Server provides specialized mechanisms for dealing with those types of objects. These object pools are intended for pooling application-defined objects or basic Developer Kit types.

To view this administrative console page, click **Resources > Object pool managers**.

To use an object pool, the product administrator must define an object pool manager using the administrative console. Multiple object pool managers can be created in an Application Server cell.

Name

Specifies the name by which the object pool manager is known for administrative purposes.

Information	Value
Data type	String
Range	1 through 30 ASCII characters

JNDI name

Specifies the Java Naming and Directory Interface (JNDI) name for the object pool manager.

Information	Value
Data type	String

Scope

Specifies the scope of the configured resource. This value indicates the location for the configuration file.

Description

Specifies the description of the object pool manager.

Information	Value
Data type	String

Category

Specifies the category name used to classify or group this object pool manager.

Information	Value
Data type	String

Object pool managers settings

An object pool manages a pool of arbitrary objects and helps applications avoid creating new Java objects repeatedly. Most objects can be created once, used and then reused. An object pool supports the pooling of objects waiting to be reused. These object pools are not meant to be used for pooling Java Database Connectivity connections or Java Message Service (JMS) connections and sessions. WebSphere Application Server provides specialized mechanisms for dealing with those types of objects. These object pools are intended for pooling application-defined objects or basic Developer Kit types.

To view this administrative console page, click **Resources > Object pool managers >** *objectpoolmanager_name*

To use an object pool, the product administrator must define an object pool manager using the administrative console. Multiple object pool managers can be created in an Application Server cell.

Scope:

Specifies the scope of the configured resource. This value indicates the location for the configuration file.

Name:

The name by which the object pool manager is known for administrative purposes.

Information	Value
Data type	String
Range	1 through 30 ASCII characters

JNDI Name:

The Java Naming and Directory Interface (JNDI) name for the object pool manager.

Information	Value
Data type	String

Description:

A description of the object pool manager.

Information	Value
Data type	String

Category:

A category name used to classify or to group this object pool manager.

Information	Value
Data type	String

Custom object pool collection:

An object pool manages a pool of arbitrary objects and helps applications avoid creating new Java objects repeatedly. Most objects can be created once, used and then reused. An object pool supports the pooling of objects waiting to be reused. These object pools are not meant to be used for pooling Java Database Connectivity connections or Java Message Service (JMS) connections and sessions. WebSphere Application Server provides specialized mechanisms for dealing with those types of objects. These object pools are intended for pooling application-defined objects or basic Developer Kit types.

To view this administrative console page, click **Resources > Object pool managers >** *objectpoolmanager_name* **> Custom object pools**.

Use custom object pools to insert additional logic around the following mechanisms:

- Constructing an object pool (A list of properties can be set)
- Flushing the object pool

- Getting objects from the pool
- Returning objects from the pool

These features allow for actions such as, clearing the state of an object when returning it to the pool, configuring the state of an object when retrieving it from the pool, or configuring generic pools and sending instructions on how to behave using custom properties.

To use an object pool the product administrator must define an object pool manager using the administrative console. You can create multiple object pool managers in an Application Server cell.

Pool class name:

Specifies the fully qualified class name of the objects that are stored in the custom object pool.

Information	**Value**
Data type	String

Pool implementation class name:

Specifies the fully qualified class name of the implementation class for the custom object pool.

Information	**Value**
Data type	String

Custom object pool settings:

An object pool manages a pool of arbitrary objects and helps applications avoid creating new Java objects repeatedly. Most objects can be created once, used and then reused. An object pool supports the pooling of objects waiting to be reused. These object pools are not meant to be used for pooling Java Database Connectivity connections or Java Message Service (JMS) connections and sessions. WebSphere Application Server provides specialized mechanisms for dealing with those types of objects. These object pools are intended for pooling application-defined objects or basic Developer Kit types.

To view this administrative console page, click **Resources > Object pool managers >** *objectpoolmanager_name* **> Custom object pools >** *objectpool_name*.

Use custom object pools to insert additional logic around the following mechanisms:

- Constructing an object pool (A list of properties can be set)
- Flushing the object pool
- Getting objects from the pool
- Returning objects from the pool

These features allow for actions such as, clearing the state of an object when returning it to the pool, configuring the state of an object when retrieving it from the pool, or configuring generic pools and sending instructions on how to behave using custom properties.

To use an object pool, the product administrator must define an object pool manager using the administrative console. Multiple object pool managers can be created in an Application Server cell.

Pool Class Name:

The fully qualified class name of the objects that are stored in the object pool.

Information	**Value**
Data type	String

Pool Impl Class Name:

The fully qualified class name of the CustomObjectPool implementation class for this object pool.

Information	Value
Data type	String

Object pool service settings

Use this page to enable or disable the object pool service, which manages object pool resources used by the server.

To view this administrative console page, click **Servers > Server Types > WebSphere application servers >** *server_name* > Container Services > **Object pool service**.

Enable service at server startup

Specifies whether the server attempts to start the object pool service.

Information	Value
Default	Cleared
Range	**Selected** When the application server starts, it attempts to start the object pool service automatically. **Cleared** The server does not try to start the object pool service. If object pool resources are used on this server, then the system administrator must start the object pool service manually or select this property, and then restart the server.

Object pools: Resources for learning

This topic provides links to find relevant supplemental information about object pools.

Use the following links to find relevant supplemental information about object pools. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

Furthermore, these links provide guidance on using object pools. Since object pooling is a general topic and the WebSphere Application Server product implementation is only one way to use it, you must understand when object pooling is necessary. These articles help you make that decision.

Programming model and decisions

- Build your own ObjectPool in Java to boost application speed
- Improve the robustness and performance of your ObjectPool
- Recycle broken objects in resource pools

MBeans for object pool managers and object pools

Legacy MBean names for object pool managers and object pools are deprecated. The legacy names are based on the object pool manager name (which is not required to be unique) rather than the object pool manager JNDI name.

About this task

For object pools, the legacy name is also lacking any identifier of the version of the pooled class. Additionally, object pool Performance Monitoring Instrumentation (PMI) statistics are aggregated for object pools with the same legacy object pool MBean name.

For example, if the object pool manager and pooled class are as follows:

```
object pool manager name:               My ObjectPool
object pool manager JNDI name:          op/MyObjectPool
pooled class name:                      java.util.ArrayList
hash code of java.util.ArrayList.class: 1111eb3f (hexadecimal)
```

the legacy object pool manager MBean name will be:

```
ObjectPoolManager_My ObjectPool
```

and the legacy object pool MBean name will be:

```
ObjectPool_My ObjectPool_java.util.ArrayList
```

Instead of using the deprecated legacy MBean names, use the MBean names that are based on the JNDI name of the object pool manager.

For the example above, the JNDI name-based object pool manager MBean name is:

```
ObjectPoolManager_op/MyObjectPool
```

and the JNDI name-based object pool MBean name is:

```
ObjectPool_op/MyObjectPool_java.util.ArrayList.class@1111eb3f
```

Formats for MBean names

Type	Name format
Deprecated legacy object pool manager MBean name:	ObjectPoolManager_[object pool manager name]
JNDI name-based object pool manager MBean name:	ObjectPoolManager_[object pool manager JNDI name]
Deprecated legacy object pool MBean name:	ObjectPool_[object pool manager name]_[pooled class name]
JNDI name-based object pool MBean name:	ObjectPool_[object pool manager JNDI name]_[pooled class name].class@[hexadecimal representation of the hash code of the pooled class' java.lang.Class reference]

In all of the above formats, characters that are not valid for MBean names are replaced with the '.' character.

Chapter 16. Developing Object Request Broker (ORB)

This page provides a starting point for finding information about the Object Request Broker (ORB). The product uses an ORB to manage communication between client applications and server applications as well as among product components. These Java Platform, Enterprise Edition (Java EE) standard services are relevant to the ORB: Remote Method Invocation/Internet Inter-ORB Protocol (RMI/IIOP) and Java Interface Definition Language (Java IDL).

The ORB provides a framework for clients to locate objects in the network and call operations on those objects as though the remote objects were located in the same running process as the client, providing location transparency.

Developing Object Request Brokers

Client-side programming tips for the Object Request Broker service

Every Internet InterORB Protocol (IIOP) request and response exchange consists of a client-side ORB and a server-side ORB. It is important that any application that uses IIOP is properly programmed to communicate with the client-side Object Request Broker (ORB).

The following tips should help you ensure that an application that uses IIOP to handle request and response exchanges is properly programmed to communicate with the client-side Object Request Broker (ORB).

Resolution of initial references to services

Client applications can use the ORBInitRef and ORBDefaultInitRef properties to configure the network location that the ORB service uses to find a service such as naming. When set, these properties are included in the parameters that are used to initialize the ORB, as illustrated in the following example:

```
org.omg.CORBA.ORB.init(java.lang.String[] args,
                       java.util.Properties props)
```

You can set these properties in client code or by command-line argument. It is possible to specify more than one service location by using multiple ORBInitRef property settings (one for each service), but only a single ORBDefaultInitRef value can be specified.

For setting in client code, these properties are com.ibm.CORBA.ORBInitRef.*service_name* and com.ibm.CORBA.ORBDefaultInitRef, respectively. For example, to specify that the naming service (NameService) is located in sample.server.com at port 2809, set the com.ibm.CORBA.ORBInitRef.NameService property to `corbaloc::sample.server.com:2809/NameService`.

For setting by command-line argument, these properties are -ORBInitRef and -ORBDefaultInitRef, respectively. To locate the same naming service specified previously, use the following Java command:

After these properties are set for services that the ORB supports, Java Platform, Enterprise Edition (Java EE) applications can call the resolve_initial_references function on the ORB, as defined in the CORBA/IIOP specification, to obtain the initial reference to a given service.

Preferred API for obtaining an ORB instance

For Java EE applications, you can use either of the following approaches. However, it is strongly recommended that you use the Java Naming and Directory Interface (JNDI) approach to ensure that the same ORB instance is used throughout the client application; you avoid the unintended inconsistencies that might occur when different ORB instances are used.

JNDI approach: For Java EE applications (including enterprise beans, Java EE clients and servlets), you can obtain an ORB instance by creating a JNDI InitialContext object and looking up the ORB under the `java:comp/ORB` name, as illustrated in the following example:

```
javax.naming.Context ctx = new javax.naming.InitialContext();
org.omg.CORBA.ORB orb =
   (org.omg.CORBA.ORB)javax.rmi.PortableRemoteObject.narrow(ctx.lookup("java:comp/ORB"),
                                                            org.omg.CORBA.ORB.class);
```

The ORB instance obtained using JNDI is a singleton object, shared by all the Java EE components that are running in the same Java virtual machine process.

Note: You must use the JNDI approach if you want to take advantage of WLM functionality and cluster failover within the application. For information on how to obtain an InitialContext from a server cluster, see the example for using a CORBA object URL with multiple name server addresses, which is in the topic on getting an initial context by setting the provider URL property.

CORBA approach: Because thin-client applications do not run in a Java EE container, they cannot use JNDI interfaces to look up the ORB. In this case, you can obtain an ORB instance by using CORBA programming interfaces, as follows:

```
java.util.Properties props = new java.util.Properties();
java.lang.String[] args = new java.lang.String[0];
org.omg.CORBA.ORB orb = org.omg.CORBA.ORB.init(args, props);
```

In contrast to the JNDI approach, the CORBA specification requires that a new ORB instance be created each time the ORB.init method is called. If necessary to change the ORB default settings, you can add ORB property settings to the Properties object that is passed in the ORB.init method call.

The use of the com.ibm.ejs.oa.EJSORB.getORBinstance method, supported in previous releases of this product is deprecated.

API restrictions with sharing an ORB instance among Java EE application components

For performance reasons, it often makes sense to share a single ORB instance among components in a Java EE application. As required by the Java EE Specification, Version 1.3, all web and EJB containers provide an ORB instance in the JNDI namespace as `java:comp/ORB`. Each container can share this instance among application components but is not required to. For proper isolation between application components, application code must comply with the following restrictions:

- Do not call the ORB shutdown or destroy methods
- Do not call org.omg.CORBA_2_3.ORB methods register_value_factory, or unregister_value_factory

In addition, do not share an ORB instance among application components in different Java EE applications.

Required use of rmic and idlj that ship with the IBM Developer Kit

The Java Runtime Environment (JRE) used by this product includes the **rmic** and **idlj** tools. You use the tools to generate Java language bindings for the CORBA/IIOP protocol.

During product installation, the tools are installed in the *app_server_root*`/java/ibm_bin` directory. Versions of these tools included with Java development kits in the `$JAVA_HOME/bin` directory other than the IBM Developer Kit installed with this product are incompatible with this product.

When you install this product, the *app_server_root*`/java/ibm_bin` directory is included in the $PATH search order to enable use of the rmic and idlj scripts provided by IBM. Because the scripts are in the *app_server_root*`/java/ibm_bin` directory instead of the JRE standard *app_server_root*`/java/bin` directory, it is unlikely that you can overwrite them when applying maintenance to a JRE not provided by IBM.

In addition to the rmic and idlj tools, the JRE also includes Interface Definition Language (IDL) files. The files are based on those defined by the Object Management Group (OMG) and can be used by applications that need an IDL definition of selected ORB interfaces. The files are placed in the *app_server_root*/java/ibm_lib directory.

Before using either the rmic or idlj tool, ensure that the *app_server_root*/java/ibm_bin directory is included in the proper PATH variable search order in the environment. If your application uses IDL files in the *app_server_root*/java/ibm_lib directory, also ensure that the directory is included in the PATH variable.

Directory conventions

References in product information to *app_server_root*, *profile_root*, and other directories imply specific default directory locations. This article describes the conventions in use for WebSphere Application Server.

Default product locations - z/OS

app_server_root
: Refers to the top directory for a WebSphere Application Server node.

  The node may be of any type—application server, deployment manager, or unmanaged for example. Each node has its own *app_server_root*. Corresponding product variables are *was.install.root* and *WAS_HOME*.

  The default varies based on node type. Common defaults are *configuration_root*/AppServer and *configuration_root*/DeploymentManager.

configuration_root
: Refers to the mount point for the configuration file system (formerly, the configuration HFS) in WebSphere Application Server for z/OS.

  The *configuration_root* contains the various *app_server_root* directories and certain symbolic links associated with them. Each different node type under the *configuration_root* requires its own cataloged procedures under z/OS.

  The default is /wasv8config/*cell_name*/*node_name*.

plug-ins_root
: Refers to the installation root directory for Web Server Plug-ins.

profile_root
: Refers to the home directory for a particular instantiated WebSphere Application Server profile.

  Corresponding product variables are *server.root* and *user.install.root.*

  In general, this is the same as *app_server_root*/profiles/*profile_name*. On z/OS, this will always be *app_server_root*/profiles/default because only the profile name "default" is used in WebSphere Application Server for z/OS.

smpe_root
: Refers to the root directory for product code installed with SMP/E or IBM Installation Manager.

  The corresponding product variable is *smpe.install.root*.

  The default is /usr/lpp/zWebSphere/V8R5.

Chapter 17. Developing OSGi applications

You can develop bundles, optionally group them into composite bundles, and add them to an OSGi application or a bundle repository.

Procedure

- Develop an OSGi application.

  As an introduction to developing an OSGi application, you can develop a simple hello-world OSGi application, which consists of two bundles. One bundle defines a hello service, and the other is a client bundle that uses this service to produce the message “OSGi Service: Hello World!”.
- Develop a composite bundle.

  A composite bundle groups shared bundles together into aggregates. It provides one or more packages at specific versions to an OSGi application. You can also extend a deployed application by adding one or more composite bundles to the composition unit for the application.
- Convert existing applications to OSGi applications.

  You can convert an enterprise application or a Spring application to an OSGi application.

What to do next

You might also want to explore the sample OSGi applications.

OSGi application design guidelines

When developing OSGi applications for WebSphere Application Server, consider these design guidelines to make the most efficient use of OSGi technology.

The design guidelines described in this topic are:

1. Use OSGi services to configure EJB dependencies
2. Do not use the java:global or java:app namespaces

Details for each of these guidelines are provided in the sections that follow.

1. Use OSGi services to configure EJB dependencies

If your OSGi application has a client bundle that references an EJB in a service bundle, use OSGi services to configure the EJB dependency.

Complete the following steps:

1. Declare the EJB in the Export-EJB header in the bundle manifest file of the service bundle, so that the EJB is registered in the OSGi service registry.
2. Use a reference element in the Blueprint XML file of the client bundle to inject and call the EJB; for more information, see References and the Blueprint Container

Here’s why

Configuring EJB dependencies by using OSGi services reduces the risk of the web or EJB container of the client bundle being recycled, or the client bundle itself being restarted, either of which might result in the temporary unavailability of one or more application endpoints.

2. Do not use the java:global or java:app namespaces

Do not use the `java:global` or `java:app` namespace references to bind to EJBs unless necessary.

Here's why

These namespace references have the following fixed formats:

```
java:global/application_name/module_name/ejb_name
java:app/module_name/ejb_name
```

However, the constituent parts of these references can change after an OSGi application is updated, so that the references must be modified accordingly, which makes this approach impractical. Furthermore, the exposure of the name of the underlying EJB in the reference, rather than using an abstraction such as an intermediate JNDI name, violates the principles of modular application design.

Instead, use OSGi services to configure EJB dependencies, or declare an EJB reference and map it to the EJB JNDI name.

Note: If you define `java:global` or `java:app` references in an @EJB annotation, or in a binding file, you receive a warning when you deploy the OSGi application as a business-level application.

Developing an OSGi application

As an introduction to developing an OSGi application, you can develop a simple hello-world OSGi application, which consists of two bundles. One bundle defines a hello service, and the other is a client bundle that uses this service to produce the message "OSGi Service: Hello World!".

About this task

An OSGi application is a Java application that uses OSGi technologies. OSGi applications are collections of OSGi bundles (typically bundles that use the Blueprint component model), and can expose or consume a number of services. The OSGi application described in these topics demonstrates the use of the OSGi service registry to share the hello service between the defining bundle and the client bundle. All interactions with the service registry are handled through Blueprint.

OSGi bundles are packaged as Java archive (.jar) files. A single OSGi application is packaged in an enterprise bundle archive (.eba) file, just as an enterprise application is packaged in an enterprise archive (.ear) file. In this example application, the bundles are packaged directly in the .eba file. However the .eba file does not have to contain the bundles; they can be pulled in at run time.

Note: The steps in the following procedure are specific to this example application, and lead you through creating the application artifacts by using IBM Rational Application Developer Version 8 or a similar tool.

Procedure

1. Create your service bundle.
2. Create your client bundle.
3. Create your OSGi application.

What to do next

After you create your OSGi application, you can deploy the application to WebSphere Application Server by using either the administrative console or wsadmin commands; for details, see "Deploying an OSGi application as a business-level application" on page 2091.

You might also want to explore the sample OSGi applications.

Creating a service bundle

For the simple hello-world OSGi application, the service bundle implements the HelloWorldEBA interface, and exports it as an OSGi service.

About this task

A bundle, the modular unit in the OSGi model, is a JAR file that includes the OSGi application metadata. This metadata is defined in the manifest file of the JAR file, `META-INF/MANIFEST.MF`.

IBM Rational Application Developer Version 8 provides graphical support for creating and packaging bundles. The sample procedure that follows uses this tool. You can also use other tools, and the steps are adaptable to other tools.

This sample procedure builds the following two bundles.

- `com.ibm.ws.eba.helloWorld.api`: this bundle declares the HelloWorldEBA interface.
- `com.ibm.ws.eba.helloWorld.service`: this bundle implements the HelloWorldEBA interface, and exports it as an OSGi service. The exported service is used by client bundle `com.ibm.ws.eba.helloWorld.client`, as described in "Creating a client bundle" on page 665.

Procedure

1. Create the com.ibm.ws.eba.helloWorld.api bundle. This bundle declares the HelloWorldEBA interface.
   a. Click **File** > **New** > **OSGi Bundle Project**. The OSGi Bundle Project panel is displayed.
   b. Configure the project.
      - For the **Project name**, enter `com.ibm.ws.eba.helloWorld.api`.
      - Clear the **Add bundle to application** check box. If you leave this check box selected, a new OSGi application project is created automatically, and the bundle is added to it. Here, however, the application project will be created manually in a separate task, "Creating an OSGi application" on page 668.
      - Leave the other options as the default values.
   c. Click **Next**. The Java Configuration panel is displayed. Accept the default values for all the options on this panel.
   d. Click **Next**. The OSGi bundle settings panel is displayed. Accept the default values for all the options on this panel.
   e. Click **Finish**.

   You have created your OSGi project.
2. Declare the `HelloWorldEBA` interface.

   Create a package called `com.ibm.ws.eba.helloWorld.api`, that includes an interface called `HelloWorldEBA`. Code this interface to contain just one method: `hello()`.
   a. Under your `com.ibm.ws.eba.helloWorld.api` project, right-click the folder `src`, then select **New** > **Package**.
   b. Name the new package `com.ibm.ws.eba.helloWorld.api`.
   c. Click **Finish**.
   d. Right-click the new package, then select **New** > **Interface**.
   e. Name the new interface `HelloWorldEBA`.
   f. Click **Finish**.
   g. Copy and paste the following method to replace the content of the interface file:

```
package com.ibm.ws.eba.helloWorld.api;
public interface HelloWorldEBA {

    public void hello();
}
```

h. Save and close the file.

3. Configure the com.ibm.ws.eba.helloWorld.api package as an exported package.

   Edit the bundle manifest in the com.ibm.ws.eba.helloWorld.api project to allow other bundles to load classes from the com.ibm.ws.eba.helloWorld.api package. Classes that are in packages not exported in the bundle manifest are private to the defining bundle and cannot be loaded by any other bundle.

   a. Open the bundle MANIFEST.MF file with the manifest editor. This file is in the BundleContent/META-INF directory.
   b. Click the **Runtime** tab.
   c. In the Exported Packages pane, click **Add**.
   d. Select the com.ibm.ws.eba.helloWorld.api package from the list, then click **OK**.
   e. In the Exported Packages pane, click **Properties**.
   f. In the **Properties** dialog, set the **version** to 1.0.0, then click **OK**.
   g. Save and close the file.

4. Create the com.ibm.ws.eba.helloWorld.service bundle. This bundle implements the HelloWorldEBA interface.

   a. Click **File** > **New** > **OSGi Bundle Project**. The OSGi Bundle Project panel is displayed.
   b. Configure the project.
      - For the **Project name**, enter com.ibm.ws.eba.helloWorld.service.
      - Clear the **Add bundle to application** check box. If you leave this check box selected, a new OSGi application project is created automatically, and the bundle is added to it. Here, however, the application project will be created manually in a separate task, “Creating an OSGi application” on page 668.
      - Leave the other options as the default values.
   c. Click **Next**. The Java Configuration panel is displayed. Accept the default values for all the options on this panel.
   d. Click **Next**. The OSGi bundle settings panel is displayed. Accept the default values for all the options on this panel.
   e. Click **Finish**.

5. Make the HelloWorldEBA interface available to the service implementation bundle.

   Edit the client bundle manifest to make classes inside the com.ibm.ws.eba.helloWorld.api package available to the service implementation bundle. The com.ibm.ws.eba.helloWorld.api package is part of the com.ibm.ws.eba.helloWorld.api bundle.

   a. Expand the com.ibm.ws.eba.helloWorld.service project.
   b. Open the bundle MANIFEST.MF file with the manifest editor. This file is in the BundleContent/META-INF directory.
   c. Click the **Dependencies** tab.
   d. In the Imported Packages pane, click **Add**.
   e. In the Package Selection dialog, enter com.ibm.ws.eba, select com.ibm.ws.eba.helloWorld.api from the Exported Packages list, then click **OK**. The package is added to the Imported Packages list.
   f. In the Imported Packages list, select the com.ibm.ws.eba.helloWorld.api package then click **Properties**.
   g. In the **Properties** dialog, set the **minimum version** to 1.0.0 Inclusive, and set the **maximum version** to 1.1.0 Exclusive, then click **OK**. The entry for this package in the Imported Packages list is updated to com.ibm.ws.eba.helloWorld.api [1.0.0,1.1.0).

This version syntax means “exported packages with versions between 1.0.0 inclusive and 1.1.0 exclusive will match this import”. For more information on the version syntax, see section 3.2.6 “Version Ranges” of the OSGi Service Platform Release 4 Version 4.2 Core Specification.

This version range has been specified to ensure that the implementation bundle uses an updated version of the package only if it differs in the value of the micro version, because a major change, such as removing a method from an interface, or a minor change, such as adding a method to an interface, could cause the implementation bundle to cease functioning correctly.

h. Save and close the file.

6. Implement the HelloWorld service.

   Create a package called `com.ibm.ws.eba.helloWorld.service`, that includes an implementation class called `HelloWorldService`. Code this class to implement the hello() method from the `HelloWorldEBA` interface. This implementation of the class causes “OSGi Service: Hello World!” to be displayed.

   a. Under your `com.ibm.ws.eba.helloWorld.service` project, right-click the folder `src`, then select **New** > **Package**.
   b. Name the new package `com.ibm.ws.eba.helloWorld.service`.
   c. Click **Finish**.
   d. Right-click the new package, then select **New** > **Class**.
   e. Name the new interface implementation class `HelloWorldService`.
   f. Click **Add** alongside the **Interfaces** field.
   g. Enter `Hello`, select `HelloWorldEBA` from the **Matching items** list, then click **OK**.
   h. Ensure that the **Inherited abstract methods** check box is selected.
   i. Click **Finish**.
   j. Provide implementation code for the inherited `hello()` method. Replace the line

      ```
      // TODO Auto-generated method stub
      ```

      with the line

      ```
      System.out.println("OSGi Service: Hello World!");
      ```

      The complete code for the implementation class should now be as follows:

      ```
      package com.ibm.ws.eba.helloWorld.service;

      import com.ibm.ws.eba.helloWorld.api.HelloWorldEBA;

      public class HelloWorldService implements HelloWorldEBA {

          @Override
          public void hello() {
              System.out.println("OSGi Service: Hello World!");
          }

      }
      ```

   k. Save and close the file.

7. Export the helloWorld service by using OSGi Blueprint XML.

   A Blueprint configuration contains the bundle component assembly and configuration information. It also describes how components are registered in the OSGi service registry, or how they look up services from the OSGi service registry. This information is used at run time to instantiate and configure the required components when the bundle is started.

   a. In the project `com.ibm.ws.eba.helloWorld.service`, create a Blueprint XML file:
      1) Right-click the `com.ibm.ws.eba.helloWorld.service` project, and select **New** > **Blueprint File**.
      2) Accept the default values for all the options on this panel.
      3) Click **Finish**.
   b. Add a bean element to the Blueprint XML file.

1) In the **Design** tab, click **Add** in the Overview pane.
2) Select **Bean**, and click **OK**.
3) Click **Browse**, select `HelloWorldService`, and click **OK**.
4) In the **Bean ID** field, enter `HelloEBA`, then click **OK** to add the bean element.

c. Add a service element to the Blueprint XML file.
1) Select **Blueprint** in the Overview pane, and click **Add**.
2) Select **Service**, and click **OK**.
3) Click **Browse** alongside the **Service Interface** field.
4) Enter `Hello`, select `HelloWorldEBA` from the **Matching items** list, and click **OK**.
5) Click **Browse** alongside the **Bean Reference** field, select `HelloEBA`, then click **OK**.
6) Click **OK** to add the service element.

d. Examine the Blueprint XML source code.

Select the **Source** tab. The source code should be as follows:

```
<?xml version="1.0" encoding="UTF-8"?>
<blueprint xmlns="http://www.osgi.org/xmlns/blueprint/v1.0.0">
  <bean id="helloEBA"
    class="com.ibm.ws.eba.helloWorld.service.HelloWorldService"/>
  <service id=HelloEBAService ref="helloEBA"
    interface="com.ibm.ws.eba.helloWorld.api.HelloWorldEBA"/>
</blueprint>
```

In the previous code block:

- The `bean` element defines a Blueprint component to be instantiated. In this example, the `bean` element causes bean `helloEBA` to be instantiated, by calling the constructor for the `com.ibm.ws.eba.helloWorld.service.HelloWorldService` class.
  - The **`id`** attribute identifies the bean. You must specify this attribute if the bean is referenced from elsewhere in the Blueprint information, for example from the `service` element.
  - The **`class`** attribute specifies which implementation class of the bean is instantiated.
- The `service` element defines the registration of a component in the OSGi service registry. In this example, the `service` element registers the bean with the name `helloEBA` as a service in the OSGi service registry with interface `com.ibm.ws.eba.helloWorld.api.HelloWorldEBA`, specified by the interface attribute.
  - The **`ref`** attribute refers to the **`id`** of the bean to be registered. This **`id`** is defined in the `bean` element.
  - The **`interface`** attribute refers to the interface that the bean class implements.
