Product overview

The WebSphere® eXtreme Scale licensed program is an elastic, scalable, in-memory data grid. The data grid dynamically caches, partitions, replicates, and manages application data and business logic across multiple servers. WebSphere eXtreme Scale performs massive volumes of transaction processing with high efficiency and linear scalability. With WebSphere eXtreme Scale, you can also get qualities of service such as transactional integrity, high availability, and predictable response times.

  Permissions for the use of these publications is granted subject to the following terms and conditions.
- Hardware and software requirements
  Browse an overview of hardware and operating system requirements. Although you are not required to use a specific level of hardware or operating system for WebSphere eXtreme Scale, formally supported hardware and software options are available on the Systems Requirements page of the product

support site. If a conflict exists between the information center and the System Requirements page, the information at the website takes precedence. Prerequisite information in the information center is provided as a convenience only.

- Directory conventions
  The following directory conventions are used throughout the documentation to reference special directories such as *wxs_install_root* and *wxs_home*. You access these directories during several different scenarios, including during installation and use of command-line tools.
- WebSphere eXtreme Scale technical overview
  WebSphere eXtreme Scale is an elastic, scalable, in-memory data grid. It dynamically caches, partitions, replicates, and manages application data and business logic across multiple servers.
- Caching overview
  WebSphere eXtreme Scale can operate as an in-memory database processing space, which you can use to provide in-line caching for a database back-end or to serve as a side-cache. In-line caching uses eXtreme Scale as the primary means for interacting with the data. When eXtreme Scale is used as a side-cache, the back-end is used in conjunction with the data grid. This section describes various cache concepts and scenarios and discusses the available topologies for deploying a data grid.
- Cache integration overview
  The crucial element that gives WebSphere eXtreme Scale the capability to perform with such versatility and reliability is its application of caching concepts to optimize the persistence and recollection of data in virtually any deployment environment.
- Database integration: Write-behind, in-line, and side caching
  WebSphere eXtreme Scale is used to front a traditional database and eliminate read activity that is normally pushed to the database. A coherent cache can be used with an application directly or indirectly using an object relational mapper. The coherent cache can then offload the database or backend from reads. In a slightly more complex scenario, such as transactional access to a data set where only some of the data requires traditional persistence guarantees, filtering can be used to offload even write transactions.
- Serialization overview
  Data is always expressed, but not necessarily stored, as Java™ objects in the data grid. WebSphere eXtreme Scale uses multiple Java processes to serialize the data, by converting the Java object instances to bytes and back to objects again, as needed, to move the data between client and server processes.
- Scalability overview
  WebSphere eXtreme Scale is scalable through the use of partitioned data, and can scale to thousands of containers if required because each container is independent from other containers.
- Availability overview
- Transaction processing overview
  WebSphere eXtreme Scale uses transactions as its mechanism for interaction with data.
- Security overview
  WebSphere eXtreme Scale can secure data access, including allowing for integration with external security providers.
- REST data services overview
  The WebSphere eXtreme Scale REST data service is a Java HTTP service that is compatible with Microsoft WCF Data Services (formally ADO.NET Data Services) and implements the Open Data Protocol (OData). Microsoft WCF Data Services is compatible with this specification when using Visual Studio 2008 SP1 and the .NET Framework 3.5 SP1.

WebSphere eXtreme Scale overview

The WebSphere® eXtreme Scale licensed program is an elastic, scalable, in-memory data grid. The data grid dynamically caches, partitions, replicates, and manages application data and business logic across multiple servers. WebSphere eXtreme Scale performs massive volumes of transaction processing with high efficiency and linear scalability. With WebSphere eXtreme Scale, you can also get qualities of service such as transactional integrity, high availability, and predictable response times.

WebSphere eXtreme Scale can be used in different ways. You can use the product as a very powerful cache, as an in-memory database processing space to manage application state, or to build Extreme Transaction Processing (XTP) applications. These XTP capabilities include an application infrastructure to support your most demanding business-critical applications.

Elastic scalability

Elastic scalability is possible through the use of distributed object caching. With elastic scalability, the data grid monitors and manages itself. The data grid can add or remove servers from the topology, which increases or decreases memory, network throughput, and processing capacity as needed. When a scale-out process is initiated, capacity is added to the data grid while it is running without requiring a restart. Conversely, a scale-in process immediately removes capacity. The data grid is also self-healing by automatically recovering from failures.

WebSphere eXtreme Scale versus an in-memory database

WebSphere eXtreme Scale cannot be considered an actual in-memory database. An in-memory database is too simple to handle some of the complexities that WebSphere eXtreme Scale can manage. If an in-memory database has a server that fails, it cannot repair the issue. A failure can be disastrous if your entire environment is on that one server.

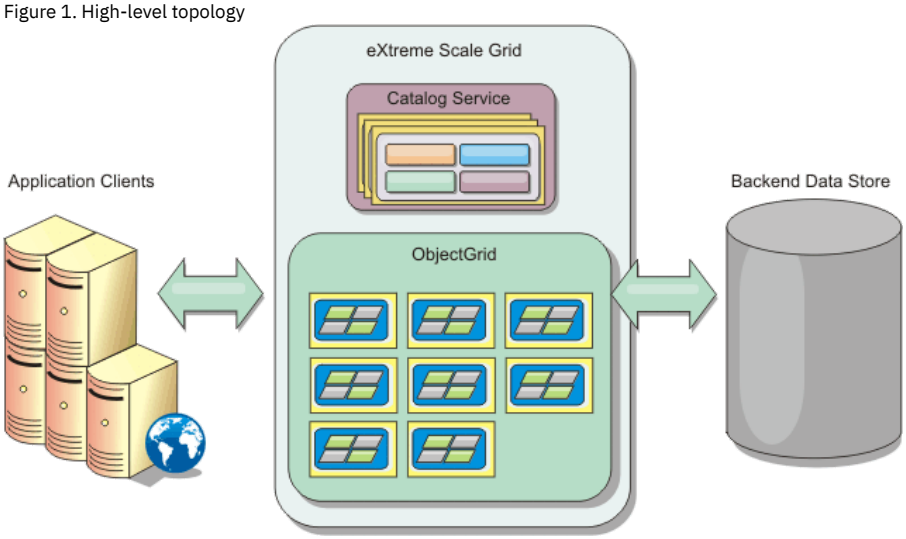
To tackle the problem of this type of failure, eXtreme Scale splits the given data set into partitions, which are equivalent to constrained tree schemas. Constrained tree schemas describe the relationship between entities. When you are using partitions, the entity relationships must model a tree data structure. In this structure, the head of the tree is the root entity and is the only entity that is partitioned. All other children of the root entity are stored in the same partition as the root entity. Each partition exists as a primary copy, or shard. A partition also contains replica shards for backing up the data. An in-memory database cannot provide this function because it is not structured and dynamic in this way. With an in-memory database, you must implement the operations that WebSphere eXtreme Scale does automatically. You can run SQL operations on in-memory databases, improving the processing speed compared to databases that are not in memory. WebSphere eXtreme Scale has its own query language instead of SQL support. This query language is more elastic, enables partitioning of data, and provides dependable failure recovery.

WebSphere eXtreme Scale with databases

With the write-behind cache feature, WebSphere eXtreme Scale can serve as a front-end cache for a database. By using this front-end cache, throughput increases while reducing database load and contention. WebSphere eXtreme Scale provides predictable scaling in and scaling out at predictable processing cost.

The following image shows that in a distributed, coherent cache environment, the eXtreme Scale clients send and receive data from the data grid. The data grid can be automatically synchronized with a backend data store. The cache is coherent because all of the clients see the same data in the cache. Each piece of data is stored on exactly one writable server in the cache. Having one copy of each record resolves the problem of having to maintain many copies of the same data, and it also prevents any version conflicts that might occur. A coherent cache holds more data as more servers are added to the data grid, and scales linearly as the data grid grows in size. The data can also be optionally replicated for more fault tolerance.

Figure 1. High-level topology



WebSphere eXtreme Scale has servers, called *container servers*, that provide its in-memory data grid. These servers can run inside WebSphere Application Server, or on simple Java™ Standard Edition (J2SE) Java virtual machines. More than one container server can run on a single physical server. As a result, the in-memory data grid can be large. The data grid is not limited by, and does not have an impact on, the memory or address space of the application or the application server. The memory can be the sum of the memory of several hundred, or thousand, Java virtual machines, running on many different physical servers.

As an in-memory database processing space, WebSphere eXtreme Scale can be backed by disk, database, or both.

While eXtreme Scale provides several Java APIs, many use cases require no user programming, just configuration and deployment in your WebSphere infrastructure.

Data grid overview

The simplest eXtreme Scale programming interface is the ObjectMap interface, which is a simple map interface that includes: a map.put(key,value) method to put a value in the cache, and a map.get(key) method to later retrieve the value.

The fundamental data grid paradigm is a key-value pair, where the data grid stores values (Java objects), with an associated key (another Java object). The key is later used to retrieve the value. In eXtreme Scale, a map consists of entries of such key-value pairs.

WebSphere eXtreme Scale offers a number of data grid configurations, from a single, simple local cache, to a large distributed cache, using multiple Java virtual machines or servers.

In addition to storing simple Java objects, you can store objects with relationships. You can use a query language that is like SQL, with `SELECT … FROM … WHERE` statements to retrieve these objects. For example, an order object might have a customer object and multiple item objects associated with it. WebSphere eXtreme Scale supports one-to-one, one-to-many, many-to-one, and many-to-many relationships.

WebSphere eXtreme Scale also supports an EntityManager programming interface for storing entities in the cache. This programming interface is like entities in Java Enterprise Edition. Entity relationships can be automatically discovered from an entity descriptor XML file or annotations in the Java classes. You can retrieve an entity from the cache by primary key using the find method on the EntityManager interface. Entities can be persisted to or removed from the data grid within a transaction boundary.

Consider a distributed example where the key is a simple alphabetic name. The cache might be split into four partitions by key: partition 1 for keys starting with A-E, partition 2 for keys starting with F-L, and so on. For availability, a partition has a primary shard and a replica shard. Changes to the cache data are made to the primary shard, and replicated to the replica shard. You configure the number of servers that contain the data grid data, and eXtreme Scale distributes the data into shards over these server instances. For availability, replica shards are placed in separate physical servers from primary shards.

WebSphere eXtreme Scale uses a catalog service to locate the primary shard for each key. It handles moving shards among eXtreme Scale servers when the physical servers fail and later recover. For example, if the server containing a replica shard fails, eXtreme Scale allocates a new replica shard. If a server containing a primary shard fails, the replica shard is promoted to be the primary shard. As before, a new replica shard is constructed.

What's new in Version 8.5

WebSphere® eXtreme Scale includes many new features in Version 8.5. Use this topic to learn about the latest product updates.

8.5

Installation Manager

You can now install WebSphere eXtreme Scale using Installation Manager. Learn more...
8.5

All 64-bit Java Runtime Environments supported

You can now install the product and run the monitoring console on all 64-bit platforms. Learn more...
8.5

View cache entries, query and invalidate operations in the web console and xscmd utility

You can view the keys of the cache entries in your data grid in the web console and **xscmd** utility. You can run regular expressions on the keys in your data grid to retrieve sets of data from a map. You can also invalidate sets of data based on the regular expression or partition. Learn more...
8.5

Retrieve environment information with the xscmd utility

You can use the **xscmd** utility with the **-c showinfo** command to view important details about the servers running in your WebSphere eXtreme Scale environment. Learn more...
8.5

Spring cache provider

With Spring cache abstraction, you can transparently add caching to your existing Spring application that uses the WebSphere eXtreme Scale as the cache provider. Learn more...
8.5

Liberty profile support

The Liberty profile is a highly composable, fast to start, dynamic application server runtime environment. You install the Liberty profile when you install WebSphere eXtreme Scale Version 8.5 with WebSphere Application Server Version 8.5. Because the Liberty profile does not include a Java runtime environment (JRE), you must install a JRE that is provided by either Oracle or IBM. Learn more...

8.5

JTA support for connecting applications to eXtreme Scale clients

WebSphere eXtreme Scale provides support for Java Transaction API (JTA). Through JTA, client management is simplified and accomplished using Java Platform, Enterprise Edition (Java EE). The JCA specification also supports resource adapters that you can use to connect applications to eXtreme Scale clients. Through support from the eXtreme Scale resource adapter, Java Platform, Enterprise Edition (Java EE) applications can look up eXtreme Scale client connections, and demarcate local transactions using Java EE local transactions or using the eXtreme Scale APIs. Learn more...

8.5

CatalogDomainManager API for connecting to specific catalog domains using JTA

The CatalogDomainManager API allows WebSphere eXtreme Scale clients and servers that run in WebSphere Application Server to connect to specific catalog service domains that are defined in the administrative console. Learn more...

Accessing last-minute updates, limitations, and known problems

The release notes are available on the product support site as technotes. To see a list of all the technotes for WebSphere® eXtreme Scale, go to the Support Web page. Clicking the links provided here will result in a search of the Support Web page for the relevant release notes, which will be returned as a list.

- To see a list of the release notes for Version 8.5, go to the Support Web page.

Accessing system and software requirements

The hardware and software requirements are documented on the following pages:

- Detailed system requirements

Accessing product documentation

For the entire information set, go to the Library page.

Accessing the product support Web site

To search for the latest technotes, downloads, fixes, and other support-related information, go to the Support Portal.

Contacting IBM Software Support

If you encounter a problem with the product, first try the following actions:

- Follow the steps described in the product documentation
- Look for related documentation in the online help
- Look up error messages in the message reference

If you cannot resolve your problem by any of the preceding methods, contact IBM® Technical Support.

Notices

Such information may be available, subject to appropriate terms and conditions, including in some cases, payment of a fee.

The licensed program described in this document and all licensed material available for it are provided by IBM under terms of the IBM Customer Agreement, IBM International Program License Agreement or any equivalent agreement between us.

Any performance data contained herein was determined in a controlled environment. Therefore, the results obtained in other operating environments may vary significantly. Some measurements may have been made on development-level systems and there is no guarantee that these measurements will be the same on generally available systems. Furthermore, some measurements may have been estimated through extrapolation. Actual results may vary. Users of this document should verify the applicable data for their specific environment.

Information concerning non-IBM products was obtained from the suppliers of those products, their published announcements or other publicly available sources. IBM has not tested those products and cannot confirm the accuracy of performance, compatibility or any other claims related to non-IBM products. Questions on the capabilities of non-IBM products should be addressed to the suppliers of those products.

All statements regarding IBM's future direction or intent are subject to change or withdrawal without notice, and represent goals and objectives only.

All IBM prices shown are IBM's suggested retail prices, are current and are subject to change without notice. Dealer prices may vary.

This information is for planning purposes only. The information herein is subject to change before the products described become available.

This information contains examples of data and reports used in daily business operations. To illustrate them as completely as possible, the examples include the names of individuals, companies, brands, and products. All of these names are fictitious and any similarity to the names and addresses used by an actual business enterprise is entirely coincidental.

COPYRIGHT LICENSE:

This information contains sample application programs in source language, which illustrate programming techniques on various operating platforms. Programming interface information

This publication. primarily documents information that is NOT intended to be used as Programming Interfaces of WebSphere® eXtreme Scale. This publication also documents intended Programming Interfaces that allow the customer to write programs to obtain the services of WebSphere eXtreme Scale. This information is identified where it occurs, either by an introductory statement to a chapter or section or by the following marking: Programming Interface information.

Trademarks

IBM, the IBM logo, and ibm.com are trademarks or registered trademarks of International Business Machines Corp., registered in many jurisdictions worldwide. Other product and service names might be trademarks of IBM or other companies. A current list of IBM trademarks is available on the Web at "Copyright and trademark information" at www.ibm.com/legal/copytrade.shtml.

Hardware and software requirements

Browse an overview of hardware and operating system requirements. Although you are not required to use a specific level of hardware or operating system for WebSphere® eXtreme Scale, formally supported hardware and software options are available on the Systems Requirements page of the product support site. If a conflict exists between the information center and the System Requirements page, the information at the website takes precedence. Prerequisite information in the information center is provided as a convenience only.

See the System Requirements page for the official set of hardware and software requirements.

You can install and deploy the product in Java™ EE and Java SE environments. You can also bundle the client component with Java EE applications directly without integrating with WebSphere Application Server.

Hardware requirements

WebSphere eXtreme Scale does not require a specific level of hardware. The hardware requirements are dependent on the supported hardware for the Java Platform, Standard Edition installation that you use to run WebSphere eXtreme Scale. If you are using eXtreme Scale with WebSphere Application Server or another Java Platform, Enterprise Edition implementation, the hardware requirements of these platforms are sufficient for WebSphere eXtreme Scale.

Operating system requirements

8.5+ Each Java SE and Java EE implementation requires different operating system levels or fixes for problems that are discovered during the testing of the Java implementation. The levels required by these implementations are sufficient for eXtreme Scale.

8.5+

Installation Manager requirements

Before you can install WebSphere eXtreme Scale, you must install Installation Manager. You can install Installation Manager using the product media, using a file obtained from the Passport Advantage® site, or using a file containing the most current version of Installation Manager from the IBM® Installation Manager download website. See IBM Installation Manager and WebSphere eXtreme Scale product offerings for more information.

Web browser requirements

The web console supports the following Web browsers:

- Mozilla Firefox, version 3.5.x and later
- Microsoft Internet Explorer, version 7 and later

WebSphere Application Server requirements

8.5

- WebSphere Application Server Version 6.1.0.41 or later
- WebSphere Application Server Version 7.0.0.19 or later
- WebSphere Application Server Version 8.0.0.2 or later
- WebSphere Application Server Version 8.5.0.1 or later

See the Recommended fixes for WebSphere Application Server for more information.

Java requirements

8.5 Other Java EE implementations can use the eXtreme Scale run time as a local instance or as a client to eXtreme Scale servers. To implement Java SE, you must use Version 5 or later.

Directory conventions

The following directory conventions are used throughout the documentation to reference special directories such as *wxs_install_root* and *wxs_home*. You access these directories during several different scenarios, including during installation and use of command-line tools.

wxs_install_root
: The *wxs_install_root* directory is the root directory where WebSphere® eXtreme Scale product files are installed. The *wxs_install_root* directory can be the directory in which the trial archive is extracted or the directory in which the WebSphere eXtreme Scale product is installed.

  - Example when extracting the trial:
    Example: /opt/IBM/WebSphere/eXtremeScale
  - Example when WebSphere eXtreme Scale is installed to a stand-alone directory:
    UNIX **Example:** /opt/IBM/eXtremeScale

    Windows **Example:** C:\Program Files\IBM\WebSphere\eXtremeScale
  - Example when WebSphere eXtreme Scale is integrated with WebSphere Application Server:
    Example: /opt/IBM/WebSphere/AppServer

wxs_home
: The *wxs_home* directory is the root directory of the WebSphere eXtreme Scale product libraries, samples, and components. This directory is the same as the *wxs_install_root* directory when the trial is extracted. For stand-alone installations, the *wxs_home* directory is the ObjectGrid subdirectory within the *wxs_install_root* directory. For installations that are integrated with WebSphere Application Server, this directory is the optionalLibraries/ObjectGrid directory within the *wxs_install_root* directory.

  - Example when extracting the trial:
    Example: /opt/IBM/WebSphere/eXtremeScale
  - Example when WebSphere eXtreme Scale is installed to a stand-alone directory:
    UNIX **Example:** /opt/IBM/eXtremeScale/ObjectGrid

    Windows **Example:** *wxs_install_root*\ObjectGrid
  - Example when WebSphere eXtreme Scale is integrated with WebSphere Application Server:
    Example: /opt/IBM/WebSphere/AppServer/optionalLibraries/ObjectGrid

was_root
: The *was_root* directory is the root directory of a WebSphere Application Server installation:
  Example: /opt/IBM/WebSphere/AppServer

restservice_home
: The *restservice_home* directory is the directory in which the WebSphere eXtreme Scale REST data service libraries and samples are located. This directory is named restservice and is a subdirectory under the *wxs_home* directory.

- Example for stand-alone deployments:
  Example: /opt/IBM/WebSphere/eXtremeScale/ObjectGrid/restservice

  Example: *wxs_home*\restservice

- Example for WebSphere Application Server integrated deployments:
  Example: /opt/IBM/WebSphere/AppServer/optionalLibraries/ObjectGrid/restservice

tomcat_root
: The *tomcat_root* is the root directory of the Apache Tomcat installation.
Example: /opt/tomcat5.5

wasce_root
: The *wasce_root* is the root directory of the WebSphere Application Server Community Edition installation.
Example: /opt/IBM/WebSphere/AppServerCE

java_home
: The *java_home* is the root directory of a Java™ Runtime Environment (JRE) installation.
UNIX **Example:** /opt/IBM/WebSphere/eXtremeScale/java

Windows **Example:** *wxs_install_root*\java

samples_home
: The *samples_home* is the directory in which you extract the sample files that are used for tutorials.
UNIX **Example:** *wxs_home*/samples

Windows **Example:** *wxs_home*\samples

dvd_root
: The *dvd_root* directory is the root directory of the DVD that contains the product.
Example: dvd_root/docs/

equinox_root

WebSphere eXtreme Scale technical overview

WebSphere® eXtreme Scale is an elastic, scalable, in-memory data grid. It dynamically caches, partitions, replicates, and manages application data and business logic across multiple servers.

Because WebSphere eXtreme Scale is not an in-memory database, you must consider specific configuration requirements. The first step to deploying a data grid is to start a core group and catalog service. The catalog service acts as coordinator for all other Java™ virtual machines that are participating in the data grid and manages configuration information. WebSphere eXtreme Scale processes are started with commands that you issue on the command line.

The next step is to start container server processes for the data grid to store and retrieve data. As container servers are started, they automatically register themselves with the core group and catalog service. By registering, the catalog servers can cooperate in providing data grid services. More servers increase both data grid capacity and reliability.

A local data grid is a simple, single-instance grid where all the data is in the one data grid. To effectively use WebSphere eXtreme Scale as an in-memory database processing space, you can configure and deploy a distributed data grid. The data in the distributed grid is spread out over the various eXtreme Scale servers so that each server contains only some of the data. This portion of data is a partition.

A key distributed data grid configuration parameter is the number of partitions in the grid. The grid data is partitioned into this number of subsets, each of which is called a partition. The catalog service locates the partition for the data based on its key. The number of partitions directly affects the capacity and scalability of the data grid. A server can contain one or more data grid partitions. As a result, the memory space of the servers limits the size of a partition. Conversely, increasing the number of partitions increases the capacity of the data grid. The maximum capacity of a data grid is the number of partitions times the usable memory size of each server. A server can be a JVM, but you can define your container server to suit your deployment environment.

The data of a partition is stored in a shard. For availability, a data grid can be configured with replicas, which can be synchronous or asynchronous. Changes to the grid data are made to the primary shard, and replicated to the replica shards. The total memory that is used or required by a data grid can be calculated with the following equation: `the size of the data grid times (1 (for the primary) + the number of replicas).`

WebSphere eXtreme Scale distributes the shards of a data grid over the number of servers that are in the data grid. These servers might be on the same or different physical servers. For availability, replica shards are placed in separate physical servers from primary shards.

WebSphere eXtreme Scale monitors the status of its servers and moves shards during shard or physical server failure and recovery. For example, if the server that contains a replica shard fails, WebSphere eXtreme Scale allocates a new replica shard, and replicate data from the primary to the new replica. If a server that contains a primary shard fails, the replica shard is promoted to be the primary shard, and, a new replica shard is constructed. If you start an extra server for the data grid, the shards are balanced over all servers. This rebalancing is called scale-out. Similarly, for scale-in, you might stop one of the servers to reduce the resources that are used by a data grid. As a result, the shards are balanced over the remaining servers.

Caching overview

WebSphere® eXtreme Scale can operate as an in-memory database processing space, which you can use to provide in-line caching for a database back-end or to serve as a side-cache. In-line caching uses eXtreme Scale as the primary means for interacting with the data. When eXtreme Scale is used as a side-cache, the back-end is used in conjunction with the data grid. This section describes various cache concepts and scenarios and discusses the available topologies for deploying a data grid.

- Caching architecture: Maps, containers, clients, and catalogs
  With WebSphere eXtreme Scale, your architecture can use local in-memory data caching or distributed client-server data caching.
- IBM eXtremeMemory
  IBM® eXtremeMemory enables objects to be stored in native memory instead of the Java™ heap. By moving objects off the Java heap, you can avoid garbage collection pauses, leading to more constant performance and predicable response times.
- Zones
  Zones give you control over shard placement. Zones are user-defined logical groupings of physical servers. The following are examples of different types of zones: different blade servers, chassis of blade servers, floors of a building, buildings, or different geographical locations in a multiple data center environment. Another use case is in a virtualized environment where many server instances, each with a unique IP address, run on the same physical server.
- Evictors
  Evictors remove data from the data grid. You can either set a time-based evictor or because evictors are associated with BackingMaps, use the BackingMap interface to specify the pluggable evictor.
- OSGi framework overview
  OSGi defines a dynamic module system for Java. The OSGi service platform has a layered architecture, and is designed to run on various standard Java profiles. You can start WebSphere eXtreme Scale servers and clients in an OSGi container.

Caching architecture: Maps, containers, clients, and catalogs

With WebSphere® eXtreme Scale, your architecture can use local in-memory data caching or distributed client-server data caching.

WebSphere eXtreme Scale requires minimal additional infrastructure to operate. The infrastructure consists of scripts to install, start, and stop a Java™ Platform, Enterprise Edition application on a server. Cached data is stored in the eXtreme Scale server, and clients remotely connect to the server.
Distributed caches offer increased performance, availability and scalability and can be configured using dynamic topologies, in which servers are automatically balanced. You can also add additional servers without restarting your existing eXtreme Scale servers. You can create either simple deployments or large, terabyte-sized deployments in which thousands of servers are needed.

- Catalog service
  The catalog service controls placement of shards and discovers and monitors the health of container servers in the data grid. The catalog service hosts logic that should be idle and has little influence on scalability. It is built to service hundreds of container servers that become available simultaneously, and run services to manage the container servers.
- Container servers, partitions, and shards
  The container server stores application data for the data grid. This data is generally broken into parts, which are called partitions. Partitions are hosted across multiple shard containers. As a result, each container server hosts a subset of the complete data. A JVM might host one or more shard containers and each shard container can host multiple shards.
- Maps
  A map is a container for key-value pairs, which allows an application to store a value indexed by a key. Maps support indexes that can be added to index attributes on the key or value. These indexes are automatically used by the query runtime to determine the most efficient way to run a query.
- Clients
  Clients connect to a catalog service, retrieve a description of the server topology, and communicate directly to each server as needed. When the server topology changes because new servers are added or existing servers have failed, the dynamic catalog service routes the client to the appropriate server that is hosting the data. Clients must examine the keys of application data to determine which partition to route the request. Clients can read data from multiple partitions in a single transaction. However, clients can update only a single partition in a transaction. After the client updates some entries, the client transaction must use that partition for updates.

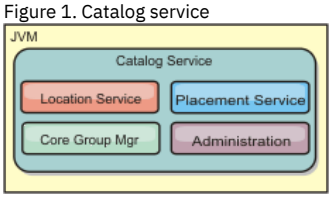
Planning the topology

Catalog service

The catalog service controls placement of shards and discovers and monitors the health of container servers in the data grid. The catalog service hosts logic that should be idle and has little influence on scalability. It is built to service hundreds of container servers that become available simultaneously, and run services to manage the container servers.

Figure 1. Catalog service



The catalog server responsibilities consist of the following services:

Location service
: The location service runs on the data grid members to provide locality to clients and container servers. Container servers register with the location service to register the hosted applications. Clients can then use the location service to search for container servers to host applications.

Placement service
: The catalog service manages the placement of shards across available container servers. The placement service is responsible for maintaining balance across physical resources and allocating individual shards to their host container server. The placement service runs as a One of N elected service in the cluster and in the data grid. This means that exactly one instance of the placement service is running. If an instance fails, another process is elected and takes over. To provide redundancy, the state of the catalog service is replicated across all the servers that are hosting the catalog service.

Core group manager
: The core group manages peer grouping for availability monitoring, organizes container servers into small groups of servers, and automatically federates the groups of servers.

  The catalog service uses the high availability manager (HA manager) to group processes together for availability monitoring. Each grouping of the processes is a core group. The core group manager dynamically groups the processes together. These processes are kept small to allow for scalability. Each core group elects a leader that is responsible for sending heartbeat messages to the core group manager. These messages detect if an individual member failed or is still available. The heartbeat mechanism is also used to detect if all the members of a group failed, which causes the communication with the leader to fail.

  The core group manager is responsible for organizing containers into small groups of servers that are loosely federated to make a data grid. When a container server first contacts the catalog service, it waits to be assigned to either a new or existing group. An eXtreme Scale deployment consists of many such groups, and this grouping is a key scalability enabler. Each group consists of Java™ virtual machines. An elected leader uses the heartbeat mechanism to monitor the availability of the other groups. The leader relays availability information to the catalog service to allow for failure reaction by reallocation and route forwarding.

Administration
: The catalog service is also the logical entry point for system administration. The catalog service hosts a Managed Bean (MBean) and provides Java Management Extensions (JMX) URLs for any of the servers that the catalog service is managing.

For high availability, configure a catalog service domain. A catalog service domain consists of multiple Java virtual machines, including a master JVM and a number of backup Java virtual machines. For more information, see High availability catalog service.

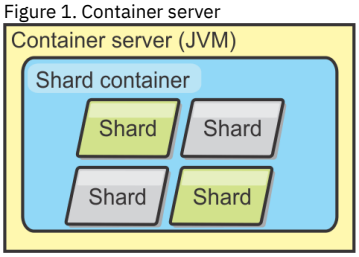
Container servers, partitions, and shards

The container server stores application data for the data grid. This data is generally broken into parts, which are called partitions. Partitions are hosted across multiple shard containers. As a result, each container server hosts a subset of the complete data. A JVM might host one or more shard containers and each shard container can host multiple shards.

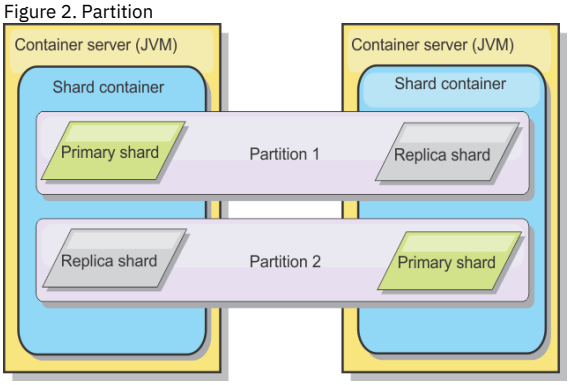
Remember: Plan out the heap size for the container servers, which host all of your data. Configure the heap settings accordingly.
Figure 1. Container server



Partitions host a subset of the data in the grid. WebSphere® eXtreme Scale automatically places partitions in a container. A partition consists of one primary shard and optional replica shards. When more container servers become available, replica shards are created and placed. Existing primary and replica shards are also distributed to new containers to maintain an equals number of shards on each container server.

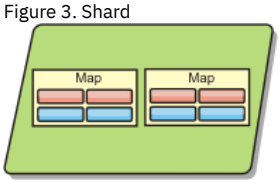
Important: Before final deployment, choose the number of partitions carefully. WebSphere eXtreme Scale uses a hash code to locate partitions in the network and this number cannot be changed dynamically. As a general rule, you can overestimate the number of partitions.

Figure 2. Partition



Shards are instances of partitions and have one of two roles: primary or replica. The primary shard and its replicas make up the physical manifestation of the partition. Every partition has several shards that each host all of the data contained in that partition. One shard is the primary, and the others are replicas, which are redundant copies of the data in the primary shard. A primary shard is the only partition instance that allows transactions to write to the cache. A replica shard is a "mirrored" instance of the partition. It receives updates synchronously or asynchronously from the primary shard. The replica shard only allows transactions to read from the cache. Replicas are never hosted in the same container server as the primary and are not normally hosted on the same machine as the primary.

Figure 3. Shard



To increase the availability of the data, or increase persistence guarantees, replicate the data. However, replication adds cost to the transaction and trades performance in return for availability. With eXtreme Scale, you can control the cost as both synchronous and asynchronous replication is supported, as well as hybrid replication models using both synchronous and asynchronous replication modes. A synchronous replica shard receives updates as part of the transaction of the primary shard to guarantee data consistency. A synchronous replica can double the response time because the transaction has to commit on both the primary and the synchronous replica before the transaction is complete. An asynchronous replica shard receives updates after the transaction commits to limit impact on performance, but introduces the possibility of data loss as the asynchronous replica can be several transactions behind the primary.

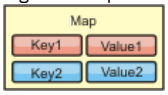
Maps

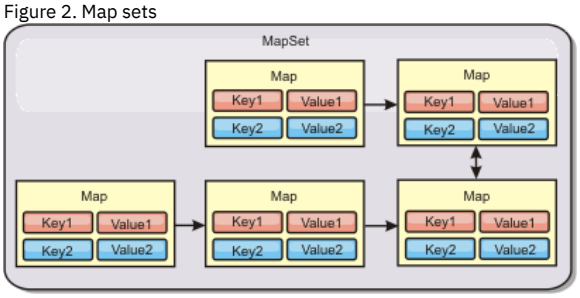
A map is a container for key-value pairs, which allows an application to store a value indexed by a key. Maps support indexes that can be added to index attributes on the key or value. These indexes are automatically used by the query runtime to determine the most efficient way to run a query.

Figure 1. Map



A map set is a collection of maps with a common partitioning algorithm. The data within the maps are replicated based on the policy defined on the map set. A map set is only used for distributed topologies and is not needed for local topologies.

Figure 2. Map sets



A map set can have a schema associated with it. A schema is the metadata that describes the relationships between each map when using homogeneous Object types or entities.
WebSphere® eXtreme Scale can store serializable Java™ objects in each of the maps using the ObjectMap API for Java clients. A schema can be defined over the maps to identify the relationship between the objects in the maps where each map holds objects of a single type. Defining a schema for maps is required to query the contents of the map objects. WebSphere eXtreme Scale can have multiple map schemas defined.

For more information about caching objects, see Getting started tutorial module 2: Create a client application.

WebSphere eXtreme Scale can also store entities using the EntityManager API. Each entity is associated with a map. The schema for an entity map set is automatically discovered using either an entity descriptor XML file or annotated Java classes. Each entity has a set of key attributes and set of non-key attributes. An entity can also have relationships to other entities. WebSphere eXtreme Scale supports one to one, one to many, many to one and many to many relationships. Each entity is physically mapped to a single map in the map set. Entities allow applications to easily have complex object graphs that span multiple Maps. A distributed topology can have multiple entity schemas.

For more information about caching objects with the EntityManager API, see Caching objects and their relationships (EntityManager API).

Clients

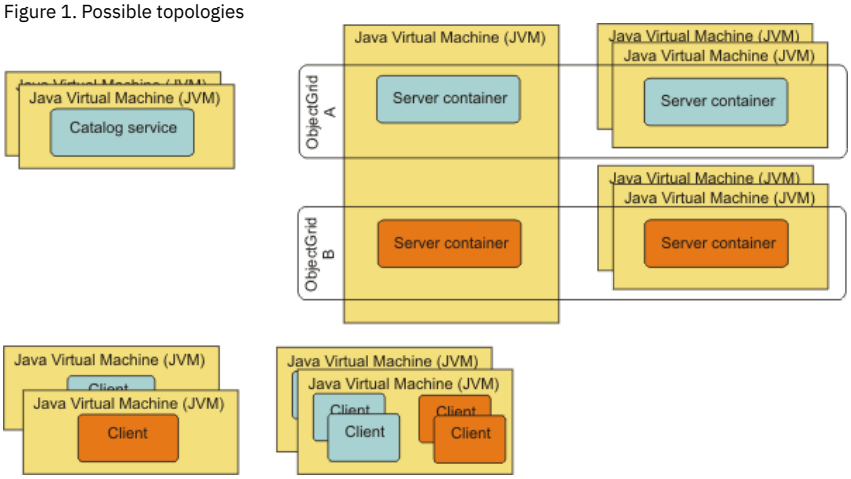
Clients connect to a catalog service, retrieve a description of the server topology, and communicate directly to each server as needed. When the server topology changes because new servers are added or existing servers have failed, the dynamic catalog service routes the client to the appropriate server that is hosting the data. Clients must examine the keys of application data to determine which partition to route the request. Clients can read data from multiple partitions in a single transaction. However, clients can update only a single partition in a transaction. After the client updates some entries, the client transaction must use that partition for updates.

Java clients

Java client applications run on Java™ virtual machines (JVM) and connect to the catalog service and container servers.

- A catalog service exists in its own data grid of Java virtual machines. A single catalog service can be used to manage multiple clients or container servers.
- A container server can be started in a JVM by itself or can be loaded into an arbitrary JVM with other containers for different data grids.
- A client can exist in any JVM and communicate with one or more data grids. A client can also exist in the same JVM as a container server.

Figure 1. Possible topologies



Zones

Zones give you control over shard placement. Zones are user-defined logical groupings of physical servers. The following are examples of different types of zones: different blade servers, chassis of blade servers, floors of a building, buildings, or different geographical locations in a multiple data center environment.

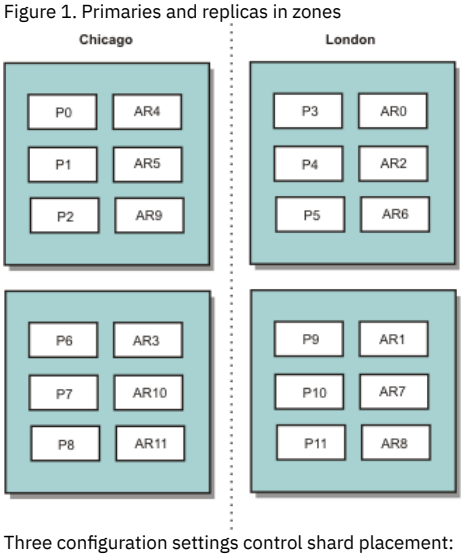
Another use case is in a virtualized environment where many server instances, each with a unique IP address, run on the same physical server.

Zones defined between data centers

The classic example and use case for zones is when you have two or more geographically dispersed data centers. Dispersed data centers spread your data grid over different locations for recovery from data center failure. For example, you might want to ensure that you have a full set of asynchronous replica shards for your data grid in a remote data center. With this strategy, you can recover from the failure of the local data center transparently, with no loss of data. Data centers themselves have high speed, low latency networks. However, communication between one data center and another has higher latency. Synchronous replicas are used in each data center where the low latency minimizes the impact of replication on response times. Using asynchronous replication reduces impact on response time. The geographic distance provides availability in case of local data center failure.

In the following example, primary shards for the Chicago zone have replicas in the London zone. Primary shards for the London zone have replicas in the Chicago zone.

Figure 1. Primaries and replicas in zones



Three configuration settings control shard placement:

- Deployment file
- Group containers
- Specify rules

The following sections explain the different options, presented loosely from least to most complicated.

Development mode

In your deployment XML file, set: `developmentMode="false"`.

This simple step activates the first shard placement policy.

For more information about the XML file, see Deployment policy descriptor XML file.

Policy 1: Shards for the same partition are placed in separate physical servers.

Consider a simple example of a data grid with one replica shard. With this policy, the primary and replica shards for each partition are on different physical servers. If a single physical server fails, no data is lost. The primary or replica shard for each partition are on different physical servers that did not fail, or both are on some other physical server that did not fail.

The high availability and simplicity of this policy make it the most efficient setting for all production environments. In many cases, applying this policy is the only step required for effectively controlling shard placement in your environment.

In applying this policy, a physical server is defined by an IP address. Shards are placed in container servers. Container servers have an IP address, for example, the -listenerHost parameter on the start server script. Multiple container servers can have the same IP address.

Since a physical server has multiple IP addresses, consider the next step for more control of your environment.

Group container servers

Container servers are assigned to zones with the -zone parameter on the start server script. In a WebSphere Application Server environment, zones are defined through node groups with a specific name format: `ReplicationZone<Zone>`. In this way, you choose the name and membership of your zones. For more information, see Defining zones for container servers.

Policy 2: Shards for the same partition are placed in separate zones.

Consider extending the example of a data grid with one replica shard by deploying it across two data centers. Define each data center as an independent zone. Use a zone name of DC1 for the container servers in the first data center, and DC2 for the container servers in the second data center. With this policy, the primary and replica shards for each partition would be in different data centers. If a data center fails, no data is lost. For each partition, either its primary or replica shard is in the other data center.

With this policy, you can control shard placement by defining zones. You choose your physical or logical boundary or grouping of interest. Then, choose a unique zone name for each group, and start the container servers in each of your zones with the name of the appropriate zone. Shards are placed so that shards for the same partition are placed in separate zones.

Zone rules

The finest level of control over shard placement is achieved using zone rules. Zone rules are specified in the zoneMetadata element of the deployment policy descriptor XML file. A zone rule defines a set of zones in which shards are placed. A shardMapping element assigns a shard to a zone rule. The shard attribute of the shardMapping element specifies the shard type:

- P specifies the primary shard
- S specifies synchronous replica shards
- A specifies asynchronous replica shards.

If more than one synchronous or asynchronous replica exist, then you must provide shardMapping elements of the appropriate shard type. The exclusivePlacement attribute of the zoneRule element determines the placement of shards in the same partition in zones. The exclusivePlacement attribute values are:

- `true` (a shard cannot be placed in the same zone as another shard from the same partition).

  Remember: For the "true" case, you must have at least as many zones in the rule as you have shards using it. Doing so ensures that each shard can be in its own zone.

- `false` (shards from the same partition can be placed in the same zone.

The default setting is true.

For more information, see Example: Zone definitions in the deployment policy descriptor XML file.

Extended use cases

The following are various use cases for shard placement strategies:

Rolling upgrades

Consider a scenario in which you want to apply rolling upgrades to your physical servers, including maintenance that requires restarting your deployment. In this example, assume that you have a data grid spread across 20 physical servers, defined with one synchronous replica. You want to shut down 10 of the physical servers at a time for the maintenance.
When you shut down groups of 10 physical servers, no partition has both its primary and replica shards on the servers you are shutting down. Otherwise, you lose the data from that partition.

The easiest solution is to define a third zone. Instead of two zones of 10 physical servers each, use three zones, two with seven physical servers, and one with six. Spreading the data across more zones allows for better failover for availability.

Rather than defining another zone, the other approach is to add a replica.

Upgrading WebSphere® eXtreme Scale

When you are upgrading WebSphere eXtreme Scale software in a rolling manner with data grids that contain live data, consider the following issues. The catalog service software version must be greater than or equal to the container server software versions. Upgrade all the catalog servers first with a rolling strategy. Read more about upgrading your deployment in the topicUpdating eXtreme Scale servers.

Changing data model

A related issue is how to change the data model or schema of objects that are stored in the data grid without causing downtime. It would be disruptive to change the data model by stopping the data grid and restarting with the updated data model classes in the container server classpath, and reloading the data grid. An alternative would be to start a new data grid with the new schema, copy the data from the old data grid to the new data grid, then shut down the old data grid.

Each of these processes are disruptive and result in downtime. To change the data model without downtime, store the object in one of these formats:

- Use XML as the value
- Use a blob made with Google protobuf
- Use JavaScript Object Notation (JSON)

Write serializers to go from plain old Java object (POJO) to one of these formats easily on the client side. Schema changes become easier.
Virtualization

Cloud computing and virtualization are popular emerging technologies. By default, two shards for the same partition are never placed on the same IP address as described in Policy 1. When you are deploying on virtual images, such as VMware, many server instances, each with a unique IP address, can be run on the same physical server. To ensure that replicas can only be placed on separate physical servers, you can use zones to solve the problem. Group your physical servers into zones, and use zone placement rules to keep primary and replica shards in separate zones.

Zones for wide-area networks

You might want to deploy a single data grid over multiple buildings or data centers with slower network connections. Slower network connections lead to lower bandwidth and higher latency connections. The possibility of network partitions also increases in this mode due to network congestion and other factors.

To deal with these risks, the catalog service organizes container servers into core groups that exchange heartbeats to detect container server failure. These core groups do not span zones. A leader within each core group pushes membership information to the catalog service. The catalog service verifies any reported failures before responding to membership information by heartbeating the container server in question. If the catalog service sees a false failure detection, the

catalog service takes no action. The core group partition heals quickly. The catalog service also heartbeats core group leaders periodically at a slow rate to handle the case of core group isolation.

Evictors

Evictors remove data from the data grid. You can either set a time-based evictor or because evictors are associated with BackingMaps, use the BackingMap interface to specify the pluggable evictor.

Evictor types

A default TTL evictor is created with every dynamic backing map. The evictor removes entries based on a time to live concept.

None
: Specifies that entries never expire and therefore are never removed from the map.

Creation time
: Specifies that entries are evicted depending on when they were created.

  If you are using the Creation time (CREATION_TIME ttlType) evictor, the evictor evicts an entry when its time from creation equals its TTL (TimeToLive attribute) value, which is set in milliseconds in your application configuration. If you set the TTL TTL (TimeToLive attribute) value to 10 seconds, the entry is automatically evicted ten seconds after it was inserted.

  It is important to take caution when setting this value for the Creation time evictor type(CREATION_TIME ttlType). This evictor is best used when reasonably high amounts of additions to the cache exist that are only used for a set amount of time. With this strategy, anything that is created is removed after the set amount of time.

  The Creation time evictor type (CREATION_TIME ttlType) is useful in scenarios such as refreshing stock quotes every 20 minutes or less. Suppose a Web application obtains stock quotes, and getting the most recent quotes is not critical. In this case, the stock quotes are cached in a data grid for 20 minutes. After 20 minutes, the map entries expire and are evicted. Every twenty minutes or so, the data grid uses the Loader plug-in to refresh the data with data from the database. The database is updated every 20 minutes with the most recent stock quotes.

Last access time
: Specifies that entries are evicted depending upon when they were last accessed, whether they were read or updated.

Last update time
: Specifies that entries are evicted depending upon when they were last updated.

  If you are using the Last access time (LAST_ACCESS_TIME) or the Last update time evictor type (LAST_UPDATE_TIME ttlType attribute), set the TTL value (TimeToLive attribute) to a lower number than if you are using the Creation time evictor(CREATION_TIME ttlType). The entries TimeToLive attribute are reset every time it is accessed. In other words, if the TimeToLive attribute value is equal to 15 and an entry has existed for 14 seconds but then gets accessed, it does not expire again for another 15 seconds. If you set the TTL value to a relatively high number, many entries might never be evicted. However, if you set the value to something like 15 seconds, entries might be removed when they are not often accessed.

  The Last access time (LAST_ACCESS_TIME) or Last update time evictor type (LAST_UPDATE_TIME ttlType) are useful in scenarios such as holding session data from a client, using a data grid map. Session data must be destroyed if the client does not use the session data for some period of time. For example, the session data times out after 30 minutes of no activity by the client. In this case, using an evictor type of Last access time (LAST_ACCESS_TIME) or Last update time (LAST_UPDATE_TIME) with the TTL value set to 30 minutes is appropriate for this application.

You can also write your own evictors: For more information, see Custom evictors.

Pluggable evictor

The default TTL evictor uses an eviction policy that is based on time, and the number of entries in the BackingMap has no affect on the expiration time of an entry. You can use an optional pluggable evictor to evict entries based on the number of entries that exist instead of based on time.

The following optional pluggable evictors provide some commonly used algorithms for deciding which entries to evict when a BackingMap grows beyond some size limit.

- The LRUEvictor evictor uses a least recently used (LRU) algorithm to decide which entries to evict when the BackingMap exceeds a maximum number of entries.
- The LFUEvictor evictor uses a least frequently used (LFU) algorithm to decide which entries to evict when the BackingMap exceeds a maximum number of entries.

The BackingMap informs an evictor as entries are created, modified, or removed in a transaction. The BackingMap keeps track of these entries and chooses when to evict one or more entries from the BackingMap instance.

A BackingMap instance has no configuration information for a maximum size. Instead, evictor properties are set to control the evictor behavior. Both the LRUEvictor and the LFUEvictor have a maximum size property that is used to cause the evictor to begin to evict entries after the maximum size is exceeded. Like the TTL evictor, the LRU and LFU evictors might not immediately evict an entry when the maximum number of entries is reached to minimize impact on performance.

If the LRU or LFU eviction algorithm is not adequate for a particular application, you can write your own evictors to create your eviction strategy.

Memory-based eviction

Important: Memory-based eviction is only supported on Java™ Platform, Enterprise Edition Version 5 or later.
All built-in evictors support memory-based eviction that can be enabled on the BackingMap interface by setting the evictionTriggers attribute of BackingMap to `MEMORY_USAGE_THRESHOLD`. For more information about how to set the evictionTriggers attribute on BackingMap, see BackingMap interface and ObjectGrid descriptor XML file.

Memory-based eviction is based on heap usage threshold. When memory-based eviction is enabled on BackingMap and the BackingMap has any built-in evictor, the usage threshold is set to a default percentage of total memory if the threshold has not been previously set.

When you are using memory-based eviction, you should configure the garbage collection threshold to the same value as their target heap utilization. For example, if the memory-based eviction threshold is set at 50 percent and the garbage collection threshold is at the default 70 percent level, then the heap utilization can go as high as 70 percent. This heap utilization increase occurs because memory-based eviction is only triggered after a garbage collection cycle.

To change the default usage threshold percentage, set the memoryThresholdPercentage property on container and server property file for eXtreme Scale server process. To set the target usage threshold on a client process, you can use the MemoryPoolMXBean.

The memory-based eviction algorithm used by WebSphere eXtreme Scale is sensitive to the behavior of the garbage collection algorithm in use. The best algorithm for memory-based eviction is the IBM default throughput collector. Generation garbage collection algorithms can cause undesired behavior, and so you should not use these algorithms with memory-based eviction.

To change the usage threshold percentage, set the memoryThresholdPercentage property on the container and server property files for eXtreme Scale server processes.

During runtime, if the memory usage exceeds the target usage threshold, memory-based evictors start evicting entries and try to keep memory usage below the target usage threshold. However, no guarantee exists that the eviction speed is fast enough to avoid a potential out of memory error if the system runtime continues to quickly consume memory.

OSGi framework overview

OSGi defines a dynamic module system for Java™. The OSGi service platform has a layered architecture, and is designed to run on various standard Java profiles. You can start WebSphere® eXtreme Scale servers and clients in an OSGi container.

Benefits of running applications in the OSGi container

WebSphere eXtreme Scale OSGi support allows you to deploy the product in the Eclipse Equinox OSGi framework. Previously, if you wanted to update the plug-ins used by eXtreme Scale, you had to restart the Java virtual machine (JVM) to apply the new versions of the plug-ins. With the dynamic update capability that the OSGi framework provides, now you can update the plug-in classes without restarting the JVM. These plug-ins are exported by user bundles as services. WebSphere eXtreme Scale accesses the service or services by looking them up in the OSGi registry.

eXtreme Scale containers can be configured to start more easily and dynamically using either the OSGi configuration admin service or with OSGi Blueprint. If you want to deploy a new data grid with its placement strategy, you can do so by creating an OSGi configuration or by deploying a bundle with eXtreme Scale descriptor XML files. With OSGi support, application bundles containing eXtreme Scale configuration data can be installed, started, stopped, updated, and uninstalled without restarting the whole system. With this capability, you can upgrade the application without disrupting the data grid.

Plug-in beans and services can be configured with custom shard scopes, enabling sophisticated options to integrate with other services in the data grid. Each plug-in can use OSGi Blueprint rankings to verify that every instance of the plug-in is activated is at the correct version. An OSGi-managed bean (MBean) and **xscmd** utility are provided, which allow you to query the eXtreme Scale plug-in OSGi services and their rankings.

This capability allows administrators to quickly recognize potential configuration and administration errors and upgrade the plug-in service rankings in use by eXtreme Scale .

OSGi bundles

To interact with and deploy plug-ins in the OSGi framework, you must use *bundles*. In the OSGi service platform, a bundle is a Java archive (JAR) file that contains Java code, resources, and a manifest that describes the bundle and its dependencies. The bundle is the unit of deployment for an application. The

eXtreme Scale product supports the following bundle types:

Server bundle
: The server bundle is the objectgrid.jar file and is installed with the server feature of the eXtreme Scale stand-alone installation. It is required for running eXtreme Scale servers and can also be used for runningeXtreme Scale clients, or local, in-memory caches. The bundle ID for the objectgrid.jar file is com.ibm.websphere.xs.server_`<version>`, where the version is in the format: `<Version>.<Release>.<Modification>`. For example, the server bundle for eXtreme Scale version 7.1.1 is com.ibm.websphere.xs.server_7.1.1.

Client bundle
: The client bundle is the ogclient.jar file and is installed with the client feature of the eXtreme Scale stand-alone installations and is used to run eXtreme Scale clients or local, in-memory caches. The bundle ID for the ogclient.jar file is com.ibm.websphere.xs.client_`version`, where the version is in the format: `<Version>.<Release>.<Modification>`. For example, the client bundle for eXtreme Scale version 7.1.1 is com.ibm.websphere.xs.client_7.1.1.

Introduction: Starting and configuring the eXtreme Scale server and container to run plug-ins in the OSGi framework

Cache integration overview

The crucial element that gives WebSphere® eXtreme Scale the capability to perform with such versatility and reliability is its application of caching concepts to optimize the persistence and recollection of data in virtually any deployment environment.

8.5+ Spring cache provider

Spring Framework Version 3.1 introduced a new cache abstraction. With this new abstraction, you can transparently add caching to an existing Spring application. You can use WebSphere eXtreme Scale as the cache provider for the cache abstraction.

- Liberty profile
  The Liberty profile is a highly composable, fast-to-start, dynamic application server runtime environment.
- JPA level 2 (L2) cache plug-in
  WebSphere eXtreme Scale includes level 2 (L2) cache plug-ins for both OpenJPA and Hibernate Java™ Persistence API (JPA) providers. When you use one of these plug-ins, your application uses the JPA API. A data grid is introduced between the application and the database, improving response times.
- HTTP session management
  The session replication manager that is shipped with WebSphere eXtreme Scale can work with the default session manager in WebSphere Application Server. Session data is replicated from one process to another process to support user session data high availability.
- Dynamic cache provider overview
  The WebSphere Application Server provides a dynamic cache service that is available to deployed Java EE applications. This service is used to cache data such as output from servlet, JSP, or commands, and object data programmatically specified within an enterprise application with the DistributedMap APIs.
  .

Liberty profile

8.5+ The Liberty profile is a highly composable, fast-to-start, dynamic application server runtime environment.

You install the Liberty profile when you install WebSphere® eXtreme Scale with WebSphere Application Server Version 8.5. Because the Liberty profile does not include a Java™ runtime environment (JRE), you have to install a JRE provided by either Oracle or IBM®.

For more information about supported Java environments and locations, see Minimum supported Java levels in the WebSphere Application Server Information Center.

This server supports two models of application deployment:

- Deploy an application by dropping it into the dropins directory.
- Deploy an application by adding it to the server configuration.

The Liberty profile supports a subset of the following parts of the full WebSphere Application Server programming model:

- Web applications
- OSGi applications
- Java Persistence API (JPA)

Associated services such as transactions and security are only supported as far as is required by these application types and by JPA.
Features are the units of capability by which you control the pieces of the runtime environment that are loaded into a particular server. The Liberty profile includes the following main features:

- Bean validation
- Blueprint
- Java API for RESTful Web Services
- Java Database Connectivity (JDBC)
- Java Naming and Directory Interface
- Java Persistence API (JPA)
- JavaServer Faces (JSF)
- JavaServer Pages (JSP)
- Lightweight Directory Access Protocol (LDAP)
- Local connector (for Java Management Extensions (JMX) clients)
- Monitoring
- OSGi JPA (JPA support for OSGi applications)
- Remote connector (for JMX clients)
- Secure Sockets Layer (SSL)
- Security
- Servlet
- Session persistence
- Transaction
- Web application bundle (WAB)
- z/OS® security
- z/OS transaction management
- z/OS z/OS workload management

You can work with the runtime environment directly, or using the WebSphere Application Server Developer Tools for Eclipse.

On distributed platforms, the Liberty profile provides both a development and an operations environment. On the Mac, it provides a development environment.

z/OS On z/OS systems, the Liberty profile provides an operations environment. You can work natively with this environment using the MVS™ console. For application development, consider using the Eclipse-based developer tools on a separate distributed system, on Mac OS, or in a Linux shell on z/OS.

Running the Liberty profile with a third-party JRE

When you use a JRE that Oracle provides, special considerations must be taken to run WebSphere eXtreme Scale with the Liberty profile.

Classloader deadlock
: You might experience a classloader deadlock which has been worked around using the following JVM_ARGS settings. If you experience a deadlock in BundleLoader logic, add the following arguments:

```
export JVM_ARGS="$JVM_ARGS -XX:+UnlockDiagnosticVMOptions -XX:+UnsyncloadClass"
```

- Data caching and the Liberty profile
  You can use data caching products with the WebSphere Application Server Liberty profile to develop HTTP sessions, client-server connections through the REST gateway, and manage other cache integration scenarios.

Data caching and the Liberty profile

8.5+ You can use data caching products with the WebSphere® Application Server Liberty profile to develop HTTP sessions, client-server connections through the REST gateway, and manage other cache integration scenarios.

In WebSphere eXtreme Scale, you can use the Liberty profile to connect to the data grid. For example, when you install WebSphere eXtreme Scale with the Liberty profile, you have access to features that you can use to manage HTTP session applications, Java client applications, and REST client applications that are installed in the Liberty profile.

The following features contain information about the main available features. Including a feature in the configuration might cause one or more features to be loaded automatically. Each feature includes a brief description and an example of how the feature is declared

Server feature

The server feature contains the capability for running an eXtreme Scale server, both catalog and container. Add the server feature when you want to run a catalog server in the Liberty profile or when you want to deploy a grid application into the Liberty profile.

wlp_install_root/usr/server/*server_name*/server.xml file

```
<server description="WebSphere eXtreme Scale Server">

  <featureManager>
    <feature>eXtremeScale.server-1.1</feature>
  </featureManager>
```

```
  <xsServer/>
</server>
```

Client feature

The client feature contains most of the programming model for eXtreme Scale. Add the client feature when you have an application that is running in the Liberty profile that is going to use eXtreme Scale APIs.

wlp_install_root/usr/server/*wlp_install_root*/server.xml file

```
<server description="WebSphere eXtreme Scale Client">

  <featureManager>
    <feature>eXtremeScale.client-1.1</feature>
  </featureManager>

 </server>
```

Web feature

The web feature is deprecated. Use the webApp feature when you want to replicate HTTP session data for fault tolerance.

The web feature contains the capability to extend the Liberty profile web application. Add the web feature when you want to replicate HTTP session data for fault tolerance.

wlp_install_root/usr/server/*server_name*/server.xml file

```
<server description="WebSphere eXtreme Scale enabled Web Server">

  <featureManager>
    <feature>eXtremeScale.web-1.1</feature>
  </featureManager>

  <xswebAppV85/>
</server>
```

REST feature

Use the Representational State Transfer (REST) gateway to access simple data grids that are hosted by a collective in the Liberty profile.

wlp_install_root/usr/server/*server_name*/server.xml file

```
<server description="WebSphere eXtreme Scale enabled Web Server">

<featureManager>
<feature>eXtremeScale.rest-1.1</feature>
</featureManager>

<xsRest/>
</server>
```

JPA level 2 (L2) cache plug-in

WebSphere® eXtreme Scale includes level 2 (L2) cache plug-ins for both OpenJPA and Hibernate Java™ Persistence API (JPA) providers. When you use one of these plug-ins, your application uses the JPA API. A data grid is introduced between the application and the database, improving response times.

Using eXtreme Scale as an L2 cache provider increases performance when you are reading and querying data and reduces load to the database. WebSphere eXtreme Scale has advantages over built-in cache implementations because the cache is automatically replicated between all processes. When one client caches a value, all other clients are able to use the cached value that is locally in-memory.

You can configure the topology and properties for the L2 cache provider in the persistence.xml file. For more information about configuring these properties, see JPA cache configuration properties for both OpenJPA and Hibernate Version 3.0.

Tip: The JPA L2 cache plug-in requires an application that uses the JPA APIs. If you want to use WebSphere eXtreme Scale APIs to access a JPA data source, use the JPA loader. For more information, see JPA Loaders.

JPA L2 cache topology considerations

The following factors affect which type of topology to configure:

1. **How much data do you expect to be cached?**
   - If the data can fit into a single JVM heap, use the Embedded topology or Intra-domain topology.
   - If the data cannot fit into a single JVM heap, use the Embedded, partitioned topology, or Remote topology
2. **What is the expected read-to-write ratio?**
   The read-to-write ratio affects the performance of the L2 cache. Each topology handles read and write operations differently.
   - Embedded topology: local read, remote write

- Intra-domain topology: local read, local write
- Embedded, partitioned topology: Partitioned: remote read, remote write
- Remote topology: remote read, remote write.

Applications that are mostly read-only should use embedded and intra-domain topologies when possible. Applications that do more writing should use intra-domain topologies.

3. **What is percentage of data is queried versus found by a key?**
   When enabled, query operations make use of the JPA query cache. Enable the JPA query cache for applications with high read to write ratios only, for example when you are approaching 99% read operations. If you use JPA query cache, you must use the Embedded topology or Intra-domain topology.

   The find-by-key operation fetches a target entity if the target entity does not have any relationship. If the target entity has relationships with the EAGER fetch type, these relationships are fetched along with the target entity. In JPA data cache, fetching these relationships causes a few cache hits to get all the relationship data.

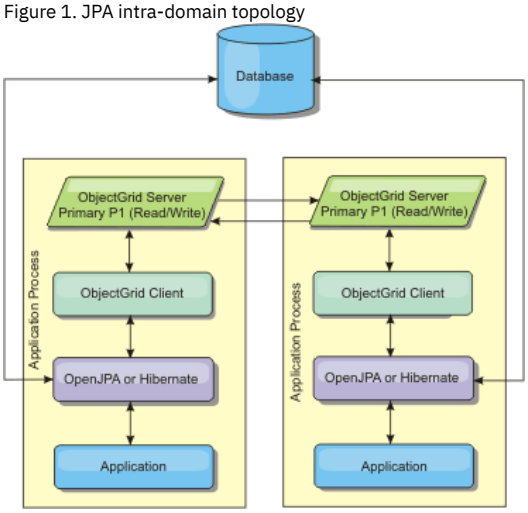
4. **What is the tolerated staleness level of the data?**
   In a system with few JVMs, data replication latency exists for write operations. The goal of the cache is to maintain an ultimate synchronized data view across all JVMs. When you are using the intra-domain topology, a data replication delay exists for write operations. Applications using this topology must be able to tolerate stale reads and simultaneous writes that might overwrite data.

Intra-domain topology

With an intra-domain topology, primary shards are placed on every container server in the topology. These primary shards contain the full set of data for the partition. Any of these primary shards can also complete cache write operations. This configuration eliminates the bottleneck in the embedded topology where all the cache write operations must go through a single primary shard.

In an intra-domain topology, no replica shards are created, even if you have defined replicas in your configuration files. Each redundant primary shard contains a full copy of the data, so each primary shard can also be considered as a replica shard. This configuration uses a single partition, similar to the embedded topology.

Figure 1. JPA intra-domain topology



Related JPA cache configuration properties for the intra-domain topology:

```
ObjectGridName=objectgrid_name,ObjectGridType=EMBEDDED,PlacementScope=CONTAINER_SCOPE,PlacementScopeTopology=HUB | RING
```

Advantages:

- Cache reads and updates are local.
- Simple to configure.

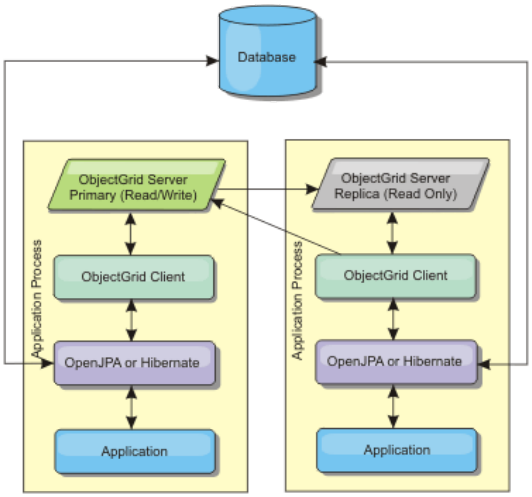
Limitations:

- This topology is best suited for when the container servers can contain the entire set of partition data.
- Replica shards, even if they are configured, are never placed because every container server hosts a primary shard. However, all the primary shards are replicating with the other primary shards, so these primary shards become replicas of each other.

Embedded topology

Tip: Consider using an intra-domain topology for the best performance.
An embedded topology creates a container server within the process space of each application. OpenJPA and Hibernate read the in-memory copy of the cache directly and write to all of the other copies. You can improve the write performance by using asynchronous replication. This default topology performs best when the amount of cached data is small enough to fit in a single process. With an embedded topology, create a single partition for the data.

Figure 2. JPA embedded topology



Related JPA cache configuration properties for the embedded topology:

```
ObjectGridName=objectgrid_name,ObjectGridType=EMBEDDED,MaxNumberOfReplicas=num_replicas,ReplicaMode=SYNC | ASYNC | NONE
```

Advantages:

- All cache reads are fast, local accesses.
- Simple to configure.

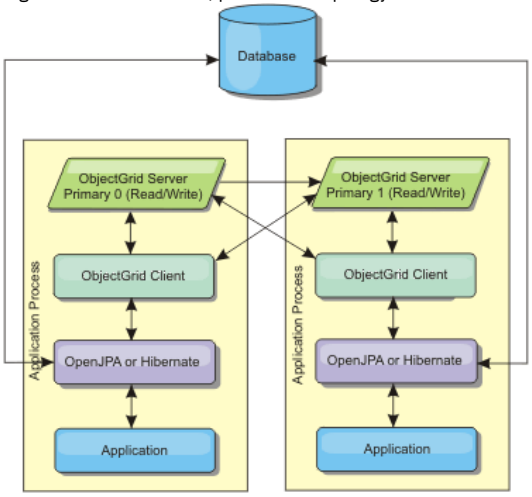
Limitations:

- Amount of data is limited to the size of the process.
- All cache updates are sent through one primary shard, which creates a bottleneck.

Embedded, partitioned topology

Tip: Consider using an intra-domain topology for the best performance.
CAUTION:
Do not use the JPA query cache with an embedded partitioned topology. The query cache stores query results that are a collection of entity keys. The query cache fetches all entity data from the data cache. Because the data cache is divided up between multiple processes, these additional calls can negate the benefits of the L2 cache.
When the cached data is too large to fit in a single process, you can use the embedded, partitioned topology. This topology divides the data over multiple processes. The data is divided between the primary shards, so each primary shard contains a subset of the data. You can still use this option when database latency is high.

Figure 3. JPA embedded, partitioned topology



Related JPA cache configuration properties for the embedded, partitioned topology:

```
ObjectGridName=objectgrid_name,ObjectGridType=EMBEDDED_PARTITION,ReplicaMode=SYNC | ASYNC | NONE,
NumberOfPartitions=num_partitions,ReplicaReadEnabled=TRUE | FALSE
```

Advantages:

- Stores large amounts of data.
- Simple to configure
- Cache updates are spread over multiple processes.

Limitation:

- Most cache reads and updates are remote.

For example, to cache 10 GB of data with a maximum of 1 GB per JVM, 10 Java virtual machines are required. The number of partitions must therefore be set to 10 or more. Ideally, the number of partitions must be set to a prime number where each shard stores a reasonable amount of memory. Usually, the numberOfPartitions setting is equal to the number of Java virtual machines. With this setting, each JVM stores one partition. If you enable replication, you must increase the number of Java virtual machines in the system. Otherwise, each JVM also stores one replica partition, which consumes as much memory as a primary partition.

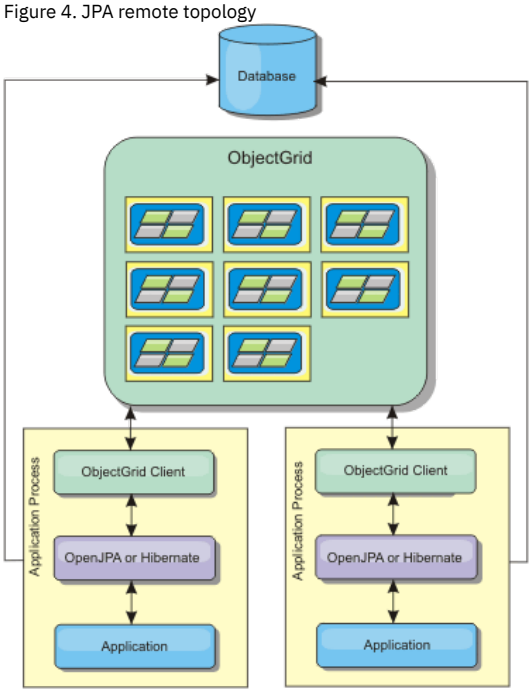
Read about Sizing memory and partition count calculation to maximize the performance of your chosen configuration.

For example, in a system with four Java virtual machines, and the numberOfPartitions setting value of `4`, each JVM hosts a primary partition. A read operation has a 25 percent chance of fetching data from a locally available partition, which is much faster compared to getting data from a remote JVM. If a read operation, such as running a query, needs to fetch a collection of data that involves 4 partitions evenly, 75 percent of the calls are remote and 25 percent of the calls are local. If the ReplicaMode setting is set to either `SYNC` or `ASYNC` and the ReplicaReadEnabled setting is set to `true`, then four replica partitions are created and spread across four Java virtual machines. Each JVM hosts one primary partition and one replica partition. The chance that the read operation runs locally increases to 50 percent. The read operation that fetches a collection of data that involves four partitions evenly has 50 percent remote calls and 50 percent local calls. Local calls are much faster than remote calls. Whenever remote calls occur, the performance drops.

Remote topology

CAUTION:
Do not use the JPA query cache with a remote topology. The query cache stores query results that are a collection of entity keys. The query cache fetches all entity data from the data cache. Because the data cache is remote, these additional calls can negate the benefits of the L2 cache.
Tip: Consider using an intra-domain topology for the best performance.
A remote topology stores all of the cached data in one or more separate processes, reducing memory use of the application processes. You can take advantage of distributing your data over separate processes by deploying a partitioned, replicated eXtreme Scale data grid. As opposed to the embedded and embedded partitioned configurations described in the previous sections, if you want to manage the remote data grid, you must do so independent of the application and JPA provider.

Figure 4. JPA remote topology



Related JPA cache configuration properties for the remote topology:

`ObjectGridName=`*`objectgrid_name`*`,ObjectGridType=REMOTE,AllowNearCache=TRUE`

Note: The AllowNearCache property is optional. If it is not included in the configuration, the default value is FALSE. This property is only used by a remote object grid type as long as the remote object grid server is also enabled for near caching as defined in the ObjectGrid descriptor XML file. To enable the L2 cache provider for near caching, set the property AllowNearCache is set to `TRUE`.
The REMOTE ObjectGrid type does not require any property settings because the ObjectGrid and deployment policy is defined separately from the JPA application. The JPA cache plug-in remotely connects to an existing remote ObjectGrid.

Because all interaction with the ObjectGrid is remote, this topology has the slowest performance among all ObjectGrid types.

Advantages:

- Stores large amounts of data.
- Application process is free of cached data.
- Cache updates are spread over multiple processes.
- Flexible configuration options.

Limitation:

- All cache reads and updates are remote.

- JPA cache configuration properties for both OpenJPA and Hibernate Version 3.0
  WebSphere eXtreme Scale includes level 2 cache plug-ins for both OpenJPA and Hibernate Java Persistence API (JPA) providers. To configure the L2 cache plug-in, you must update properties in the persistence.xml file.
- Configuring the OpenJPA cache plug-in
  You can configure both DataCache and QueryCache implementations for OpenJPA.
- Configuring the Hibernate cache plug-in
  You can enable the cache to use the Hibernate cache plug-in by specifying properties files.

HTTP session management

The session replication manager that is shipped with WebSphere® eXtreme Scale can work with the default session manager in WebSphere Application Server. Session data is replicated from one process to another process to support user session data high availability.

Features

The session manager has been designed so that it can run in any Java™ Platform, Enterprise Edition Version 6 or later container. Because the session manager does not have any dependencies on WebSphere APIs, it can support various versions of WebSphere Application Server, as well as vendor application server environments.

The HTTP session manager provides session replication capabilities for an associated application. The session replication manager works with the session manager for the web container. Together, the session manager and web container create HTTP sessions and manage the life cycles of HTTP sessions that are associated with the application. These life cycle management activities include: the invalidation of sessions based on a timeout or an explicit servlet or JavaServer Pages (JSP) call and the invocation of session listeners that are associated with the session or the web application. The session manager persists its sessions in a fully replicated, clustered and partitioned data grid. The use of the WebSphere eXtreme Scale session manager enables the session manager to provide HTTP session failover support when application servers are shut down or end unexpectedly. The session manager can also work in environments that do not support affinity, when affinity is not enforced by a load balancer tier that sprays requests to the application server tier.

Usage scenarios

The session manager can be used in the following scenarios:

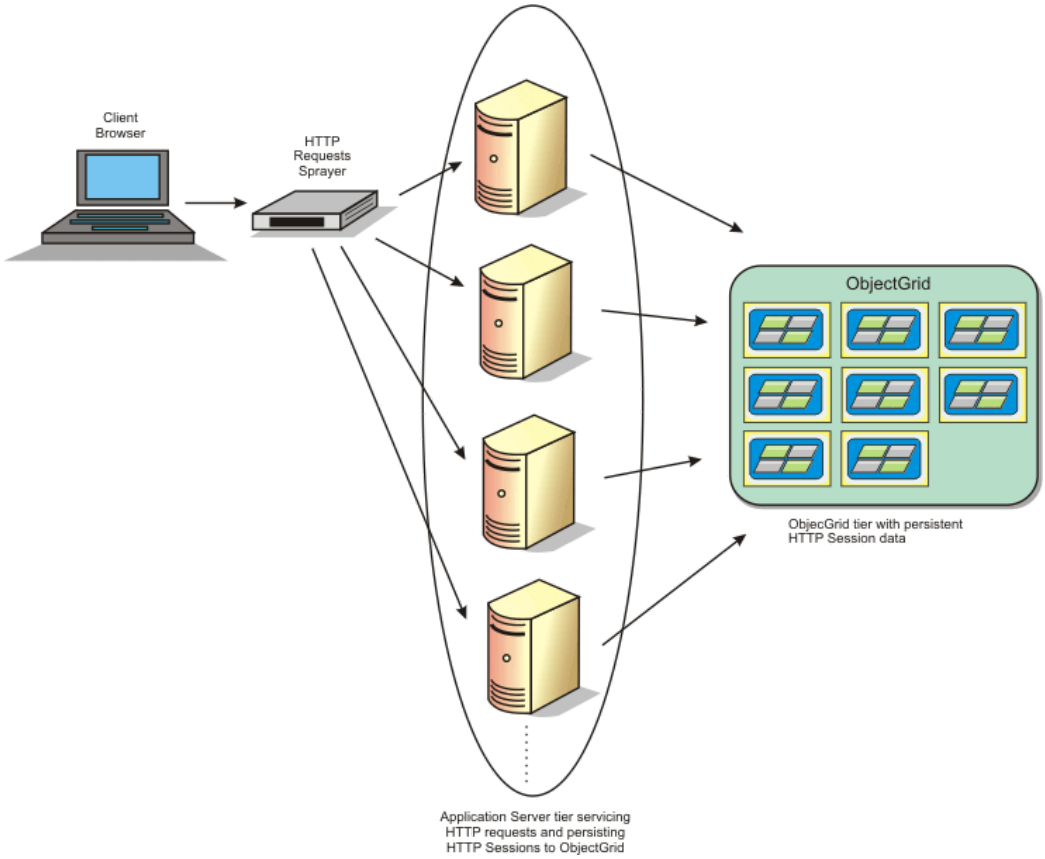
- In environments that use application servers at different versions of WebSphere Application Server, such as in a migration scenario.
- In deployments that use application servers from different vendors. For example, an application that is being developed on open source application servers and that is hosted on WebSphere Application Server. Another example is an application that is being promoted from staging to production. Seamless migration of these application server versions is possible while all HTTP sessions are live and being serviced.
- In environments that require the user to persist sessions with higher quality of service (QoS) levels. Session availability is better guaranteed during server failover than default WebSphere Application Server QoS levels.
- In an environment where session affinity cannot be guaranteed, or environments in which affinity is maintained by a vendor load balancer. With a vendor load balancer, the affinity mechanism must be customized to that load balancer.
- In any environment to offload the processing required for session management and storage to an external Java process.
- In multiple cells to enable session failover between cells.
- In multiple data centers or multiple zones.

How the session manager works

The session replication manager uses a session listener to listen on the changes of session data. The session replication manager persists the session data into an ObjectGrid instance either locally or remotely. You can add the session listener and servlet filter to every web module in your application with tooling that ships with WebSphere eXtreme Scale. You can also manually add these listeners and filters to the web deployment descriptor of your application.

This session replication manager works with each vendor web container session manager to replicate session data across Java virtual machines. When the original server dies, users can retrieve session data from other servers.

Figure 1. HTTP session management topology with a remote container configuration



Deployment topologies

The session manager can be configured using two different dynamic deployment scenarios:

Embedded, network attached eXtreme Scale container servers
: In this scenario, the eXtreme Scale servers are collocated in the same processes as the servlets. The session manager can communicate directly to the local ObjectGrid instance, avoiding costly network delays. This scenario is preferable when running with affinity and performance is critical.

Remote, network attached eXtreme Scale container servers
: In this scenario, the eXtreme Scale servers run in external processes from the process in which the servlets run. The session manager communicates with a remote eXtreme Scale server grid. This scenario is preferable when the web container tier does not have the memory to store the session data. The session data is offloaded to a separate tier, which results in lower memory usage on the web container tier. Higher latency occurs because the data is in a remote location.

Generic embedded container startup

eXtreme Scale automatically starts an embedded ObjectGrid container inside any application-server process when the web container initializes the session listener or servlet filter, if the objectGridType property is set to `EMBEDDED`. See Servlet context initialization parameters for details.

You are not required to package an ObjectGrid.xml file and objectGridDeployment.xml file into your web application WAR or EAR file. The default ObjectGrid.xml and objectGridDeployment.xml files are packaged in the product JAR file. Dynamic maps are created for various web application contexts by default. Static eXtreme Scale maps continue to be supported.

This approach for starting embedded ObjectGrid containers applies to any type of application server. The approaches involving a WebSphere Application Server component or WebSphere Application Server Community Edition GBean are deprecated.

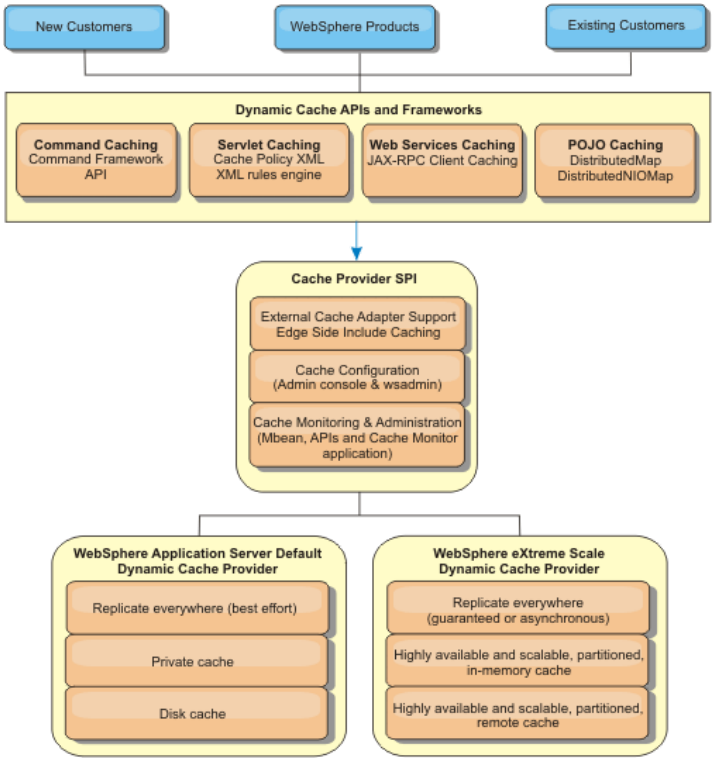
Dynamic cache provider overview

The WebSphere® Application Server provides a dynamic cache service that is available to deployed Java™ EE applications. This service is used to cache data such as output from servlet, JSP, or commands, and object data programmatically specified within an enterprise application with the DistributedMap APIs. .

Initially, the only service provider for the dynamic cache service was the default dynamic cache engine that is built into WebSphere Application Server. You can also specify WebSphere eXtreme Scale to be the cache provider for any cache instance. By setting up this capability, you can enable applications that use the dynamic cache service, to use the features and performance capabilities of WebSphere eXtreme Scale.

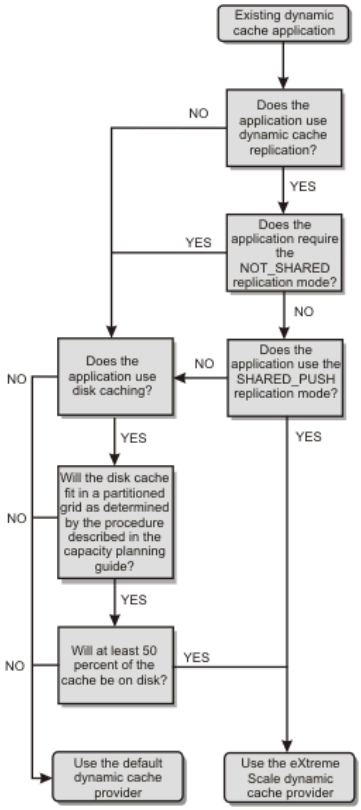


Deciding how to use WebSphere eXtreme Scale

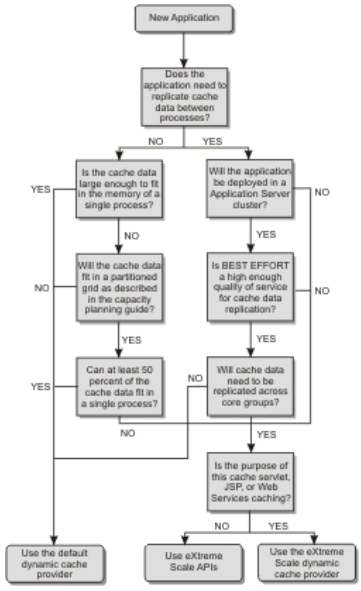
The available features in WebSphere eXtreme Scale significantly increase the distributed capabilities of the dynamic cache service beyond what is offered by the default dynamic cache provider and data replication service. With eXtreme Scale, you can create caches that are truly distributed between multiple servers, rather than just replicated and synchronized between the servers. Also, eXtreme Scale caches are transactional and highly available, ensuring that each server sees the same contents for the dynamic cache service. WebSphere eXtreme Scale offers a higher quality of service for cache replication provided via DRS.

However, these advantages do not mean that the eXtreme Scale dynamic cache provider is the right choice for every application. Use the decision trees and feature comparison matrix below to determine what technology fits your application best.

Decision tree for migrating existing dynamic cache applications



Decision tree for choosing a cache provider for new applications



Feature comparison

Table 1. Feature comparison

Cache features	Default provider	eXtreme Scale provider	eXtreme Scale API
Local, in-memory caching	Yes	via Near-cache capability	via Near-cache capability
Distributed caching	via DRS	Yes	Yes
Linearly scalable	No	Yes	Yes
Reliable replication (synchronous)	No	Yes	Yes
Disk overflow	Yes	N/A	N/A
Eviction	LRU/TTL/heap-based	LRU/TTL (per partition)	LRU/TTL (per partition)
Invalidation	Yes	Yes	Yes

Cache features	Default provider	eXtreme Scale provider	eXtreme Scale API
Relationships	Dependency / template ID relationships	Yes	No (other relationships are possible)
Non-key lookups	No	No	via Query and index
Back-end integration	No	No	via Loaders
Transactional	No	Yes	Yes
Key-based storage	Yes	Yes	Yes
Events and listeners	Yes	No	Yes
WebSphere Application Server integration	Single cell only	Multiple cell	Cell independent
Java Standard Edition support	No	Yes	Yes
Monitoring and statistics	Yes	Yes	Yes
Security	Yes	Yes	Yes

Table 2. Seamless technology integration

Cache features	Default provider	eXtreme Scale provider	eXtreme Scale API
WebSphere Application Server servlet/JSP results caching	V5.1+	V6.1.0.25+

Cache features	Default provider	eXtreme Scale provider	eXtreme Scale API
Command-based API	Command framework API	Command framework API	DataGrid API
Map-based API	DistributedMap API	DistributedMap API	ObjectMap API
EntityManager API			x

For a more detailed description on how eXtreme Scale distributed caches work, see Planning the topology.

Note: An eXtreme Scale distributed cache can only store entries where the key and the value both implement the java.io.Serializable interface.

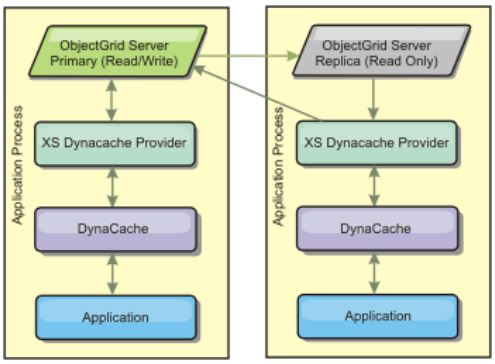
Topology

Deprecated: The local, embedded, and embedded-partitioned topology types are deprecated.
A dynamic cache service that is created with eXtreme Scale as the provider can be deployed in any of three available topologies. With these topologies you can customize the cache specifically to performance, resource, and administrative needs. These topologies are: embedded, embedded partitioned, and remote.

Embedded topology

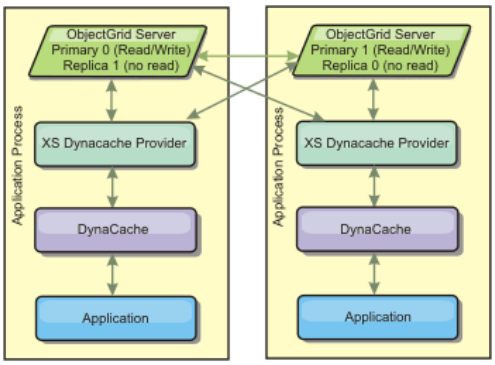
The embedded topology is similar to the default dynamic cache and DRS provider. Distributed cache instances created with the embedded topology keep a full copy of the cache within each eXtreme Scale process that accesses the dynamic cache service, allowing all read operations to occur locally. All write operations go through a single-server process, in which the transactional locks are managed, before being replicated to the rest of the servers. Consequently, this topology is better for workloads where cache-read operations greatly outnumber cache-write operations.

With the embedded topology, new or updated cache entries are not immediately visible on every single server process. A cache entry will not be visible, even to the server that generated it, until it propagates through the asynchronous replication services of WebSphere eXtreme Scale . These services operate as fast as the hardware will allow, but there is still a small delay. The embedded topology is shown in the following image:



Embedded partitioned topology

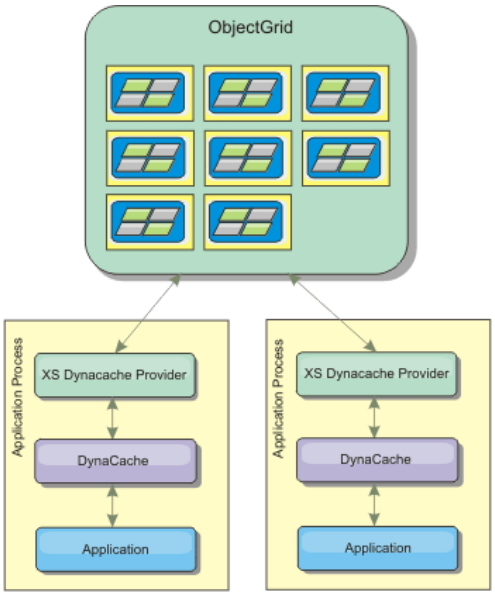
For workloads where cache-writes occur as often as or more frequently than reads, the embedded partitioned or remote topologies are recommended. The embedded partitioned topology keeps all of the cache data within the WebSphere Application Server processes that access the cache. However, each process only stores a portion of the cache data. All reads and writes for the data located on this “partition” go through the process, meaning that most requests to the cache will be fulfilled with a remote procedure call. This results in a higher latency for read operations than the embedded topology, but the capacity of the distributed cache to handle read and write operations will scale linearly with the number of WebSphere Application Server processes accessing the cache. Also, with this topology, the maximum size of the cache is not bound by the size of a single WebSphere process. Because each process only holds a portion of the cache, the maximum cache size becomes the aggregate size of all the processes, minus the overhead of the process. The embedded partitioned topology is shown in the following image:



For example, assume you have a grid of server processes with 256 megabytes of free heap each to host a dynamic cache service. The default dynamic cache provider and the eXtreme Scale provider using the embedded topology would both be limited to an in-memory cache size of 256 megabytes minus overhead. See the Capacity Planning and High Availability section later in this document. The eXtreme Scale provider using the embedded partitioned topology would be limited to a cache size of one gigabyte minus overhead. In this manner, the WebSphere eXtreme Scale provider makes it possible to have an in-memory dynamic cache services that are larger than the size of a single server process. The default dynamic cache provider relies on the use of a disk cache to allow cache instances to grow beyond the size of a single process. In many situations, the WebSphere eXtreme Scale provider can eliminate the need for a disk cache and the expensive disk storage systems needed to make them perform.

Remote topology

The remote topology eliminates the need for a disk cache. All of the cache data is stored outside of WebSphere Application Server processes. WebSphere eXtreme Scale supports standalone container processes for cache data. These container processes have a lower overhead than a WebSphere Application Server process and are also not limited to using a particular Java Virtual Machine (JVM). For example, the data for a dynamic cache service being accessed by a 32-bit WebSphere Application Server process could be located in an eXtreme Scale container process running on a 64-bit JVM. This allows users to use the increased memory capacity of 64-bit processes for caching, without incurring the additional overhead of 64-bit for application server processes. The remote topology is shown in the following image:



Data compression

Another performance feature offered by the WebSphere eXtreme Scale dynamic cache provider that can help users manage cache overhead is compression. The default dynamic cache provider does not allow for compression of cached data in memory. With the eXtreme Scale provider, this becomes possible. Cache compression using the deflate algorithm can be enabled on any of the three distributed topologies. Enabling compression will increase the overhead for read and write operations, but will drastically increase cache density for applications like servlet and JSP caching.

Local in-memory cache

The WebSphere eXtreme Scale dynamic cache provider can also be used to back dynamic cache instances that have **replication disabled**. Like the default dynamic cache provider, these caches can store non-serializable data. They can also offer better performance than the default dynamic cache provider on large

multi-processor enterprise servers because the eXtreme Scale code path is designed to maximize in-memory cache concurrency.

Dynamic cache engine and eXtreme Scale functional differences

Users should not notice a functional difference between the two caches except that the WebSphere eXtreme Scale backed caches do not support disk offload or statistics and operations related to the size of the cache in memory.

No appreciable difference exists in the results returned by most dynamic cache API calls, regardless of whether you are using the default dynamic cache provider or the eXtreme Scale cache provider. For some operations, you cannot emulate the behavior of the dynamic cache engine with eXtreme Scale.

Dynamic cache statistics

Dynamic cache statistics are reported via the CacheMonitor application or the dynamic cache MBean. When using the eXtreme Scale dynamic cache provider, statistics will still be reported through these interfaces, but the context of the statistical values will be different.

If a dynamic cache instance is shared between three servers named A, B, and C, then the dynamic cache statistics object only returns statistics for the copy of the cache on the server where the call was made. If the statistics are retrieved on server A, they only reflect the activity on server A.

With eXtreme Scale , there is only a single distributed cache shared among all the servers, so it is not possible to track most statistics on a server-by-server basis like the default dynamic cache provider does. A list of the statistics reported by the Cache Statistics API and what they represent when you are using the WebSphere eXtreme Scale dynamic cache provider follows. Like the default provider, these statistics are not synchronized and therefore can vary up to 10% for concurrent workloads.

- **Cache Hits** : Cache hits are tracked per server. If traffic on Server A generates 10 cache hits and traffic on Server B generates 20 cache hits, the cache statistics will report 10 cache hits on Server A and 20 cache hits on Server B.
- **Cache Misses**: Cache misses are tracked per server just like cache hits.
- **Memory Cache Entries**: This statistic reports the number of cache entries in the distributed cache. Every server that accesses the cache will report the same value for this statistic, and that value will be the total number of cache entries in memory over all the servers.
- **Memory Cache Size in MB**: This metric is supported only for caches using the remote, embedded, or embedded_partitioned topologies. It reports the number of megabytes of Java heap space consumed by the cache, across the entire grid. This statistic reports heap usage only for the primary partitions; you must take replicas into account. Because the default setting for the remote and embedded_partitioned topologies is one asynchronous replica, double this number to get the true memory consumption of the cache.
- **Cache Removes**: This statistic reports the total number of entries removed from the cache by any method, and is an aggregate value for the whole distributed cache. If traffic on Server A generates 10 invalidations and traffic on Server B generates 20 invalidations, then the value on both servers will be 30.
- **Cache Least Recently Used (LRU) Removes**: This statistic is aggregate, like cache removes. It tracks the number of entries that were removed to keep the cache under its maximum size.
- **Timeout Invalidations**: This is also an aggregate statistic, and it tracks the number of entries that were removed because they timed out.
- **Explicit Invalidations** : Also an aggregate statistic, this tracks the number of entries that were removed with direct invalidation by key, dependency ID or template.
- **Extended Stats** : The eXtreme Scale dynamic cache provider exports the following extended stat key strings.
  - **com.ibm.websphere.xs.dynacache.remote_hits**: The total number of cache hits tracked at the eXtreme Scale container. This is an aggregate statistic, and its value in the extended stats map is a `long`.
  - **com.ibm.websphere.xs.dynacache.remote_misses**: The total number of cache misses tracked at the eXtreme Scale container. An aggregate statistic, its value in the extended stats map is a `long`.

Reporting reset statistics

The dynamic cache provider allows you to reset cache statistics. With the default provider the reset operation only clears the statistics on the affected server. The eXtreme Scale dynamic cache provider tracks most of its statistical data on the remote cache containers. This data is not cleared or changed when the statistics are reset. Instead the default dynamic cache behavior is simulated on the client by reporting the difference between the current value of a given statistic and the value of that statistic the last time reset was called on that server.

For example, if traffic on Server A generates 10 cache removes, the statistics on Server A and on Server B will report 10 removes. Now, if the statistics on Server B are reset and traffic on Server A generates an additional 10 removes, the statistics on Server A will report 20 removes and the stats on Server B will report 10 removes.

Dynamic cache events

The dynamic cache API allows users to register event listeners. When you are using eXtreme Scale as the dynamic cache provider, the event listeners work as expected for local in-memory caches.

For distributed caches, event behavior will depend on the topology being used. For caches using the embedded topology, events will be generated on the server that handles the write operations, also known as the primary shard. This means that only one server will receive event notifications, but it will have all the event notifications normally expected from the dynamic cache provider. Because WebSphere eXtreme Scale chooses the primary shard at runtime, it is not possible to ensure that a particular server process always receives these events.

Embedded partitioned caches generate events on any server that hosts a partition of the cache. For example, if a WebSphere Application Server Network Deployment environment has 11 application servers that host 11 partitions for a cache, then each server receives the dynamic cache events for the cache entries that it hosts. No single server process would see all of the events unless all 11 partitions were hosted in that server process. As with the embedded topology, it is not possible to ensure that a particular server process receives a particular set of events or any events at all.

Caches that use the remote topology do not support dynamic cache events.

MBean calls

The WebSphere eXtreme Scale dynamic cache provider does not support disk caching. Any MBean calls relating to disk caching do not work.

Dynamic cache replication policy mapping

The WebSphere Application Server built-in dynamic cache provider supports multiple cache replication policies. These policies can be configured globally or on each cache entry. See the dynamic cache documentation for a description of these replication policies.

The eXtreme Scale dynamic cache provider does not honor these policies directly. The replication characteristics of a cache are determined by the configured eXtreme Scale distributed topology type and apply to all values placed in that cache, regardless of the replication policy set on the entry by the dynamic cache service. The following is a list of all the replication policies supported by the dynamic cache service and illustrates which eXtreme Scale topology provides similar replication characteristics.

Note that the eXtreme Scale dynamic cache provider ignores DRS replication policy settings on a cache or cache entry. Users must choose the topology that appropriate to their replication needs.

- NOT_SHARED – currently none of the topologies provided by the eXtreme Scale dynamic cache provider can approximate this policy. This means that all data stored into the cache must have keys and values that implement java.io.Serializable.
- SHARED_PUSH – The embedded topology approximates this replication policy. When a cache entry is created it is replicated to all the servers. Servers only look for cache entries locally. If an entry is not found locally, it is assumed to be non-existent and the other servers are not queried for it.
- SHARED_PULL and SHARED_PUSH_PULL – The embedded partitioned and remote topologies approximate this replication policy. The distributed state of the cache is completely consistent between all the servers.

This information is provided mainly so you can make sure that the topology meets your distributed consistency needs. For example, if the embedded topology is a better choice for your deployment and performance needs, but you require the level of cache consistency provided by SHARED_PUSH_PULL, then consider using embedded partitioned, even though the performance may be slightly lower.

Configuring the dynamic cache provider for WebSphere eXtreme Scale

Database integration: Write-behind, in-line, and side caching

WebSphere® eXtreme Scale is used to front a traditional database and eliminate read activity that is normally pushed to the database. A coherent cache can be used with an application directly or indirectly using an object relational mapper. The coherent cache can then offload the database or backend from reads. In a slightly more complex scenario, such as transactional access to a data set where only some of the data requires traditional persistence guarantees, filtering can be used to offload even write transactions.

You can configure WebSphere eXtreme Scale to function as a highly flexible in-memory database processing space. However, WebSphere eXtreme Scale is not an object relational mapper (ORM). It does not know where the data in the data grid came from. An application or an ORM can place data in an eXtreme Scale server. It is the responsibility of the source of the data to make sure that it stays consistent with the database where data originated. This means eXtreme Scale cannot invalidate data that is pulled from a database automatically. The application or mapper must provide this function and manage the data stored in eXtreme Scale.
Figure 1. ObjectGrid as a database buffer

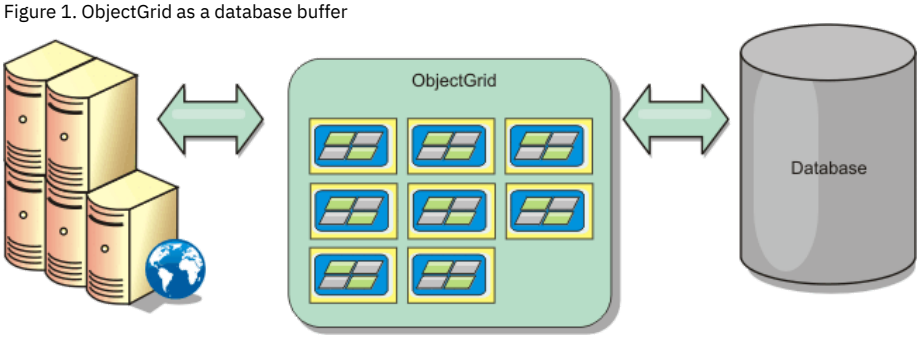

Figure 2. ObjectGrid as a side cache

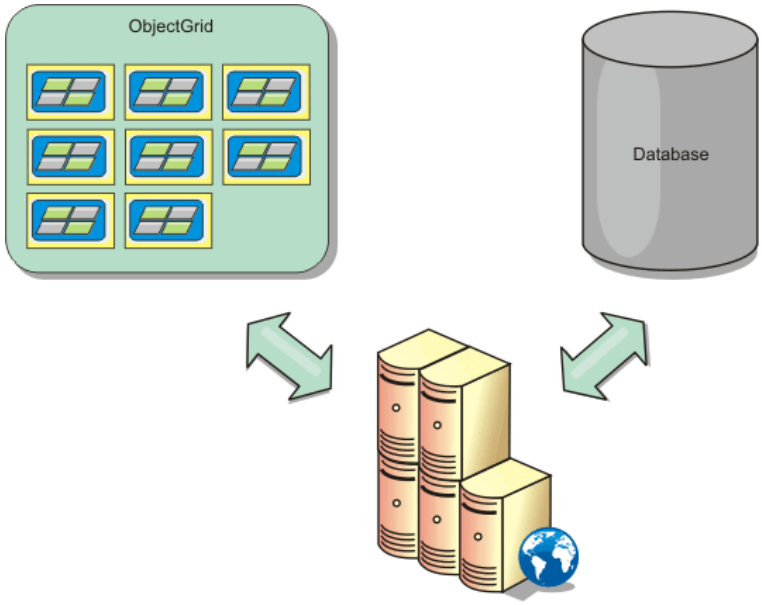

- Sparse and complete cache
  WebSphere eXtreme Scale can be used as a sparse cache or a complete cache. A sparse cache only keeps a subset of the total data, while a complete cache keeps all of the data. and can be populated lazily, as the data is needed. Sparse caches are normally accessed using keys (instead of indexes or queries) because the data is only partially available.
- Side cache
  When WebSphere eXtreme Scale is used as a side cache, the back end is used with the data grid.
- In-line cache
  You can configure in-line caching for a database back end or as a side cache for a database. In-line caching uses eXtreme Scale as the primary means for interacting with the data. When eXtreme Scale is used as an in-line cache, the application interacts with the back end using a Loader plug-in.
- Write-behind caching
  You can use write-behind caching to reduce the overhead that occurs when updating a database you are using as a back end.
- Loaders
  With a Loader plug-in, a data grid map can behave as a memory cache for data that is typically kept in a persistent store on either the same system or another system. Typically, a database or file system is used as the persistent store. A remote Java™ virtual machine (JVM) can also be used as the source of data, allowing hub-based caches to be built using eXtreme Scale. A loader has the logic for reading and writing data to and from a persistent store.
- Data preloading and warm-up
  In many scenarios that incorporate the use of a loader, you can prepare your data grid by preloading it with data.
- Database synchronization techniques
  When WebSphere eXtreme Scale is used as a cache, applications must be written to tolerate stale data if the database can be updated independently from an eXtreme Scale transaction. To serve as a synchronized in-memory database processing space, eXtreme Scale provides several ways of keeping the cache updated.
- Data invalidation
  To remove stale cache data, you can use invalidation mechanisms.
- Indexing
  Use the MapIndexPlugin plug-in to build an index or several indexes on a BackingMap to support non-key data access.
- JPA Loaders
  The Java Persistence API (JPA) is a specification that allows mapping Java objects to relational databases. JPA contains a full object-relational mapping (ORM) specification using Java language metadata annotations, XML descriptors, or both to define the mapping between Java objects and a relational database. A number of open-source and commercial implementations are available.

Sparse and complete cache

WebSphere® eXtreme Scale can be used as a sparse cache or a complete cache. A sparse cache only keeps a subset of the total data, while a complete cache keeps all of the data. and can be populated lazily, as the data is needed. Sparse caches are normally accessed using keys (instead of indexes or queries) because the data is only partially available.

Sparse cache

When a key is not present in a sparse cache, or the data is not available and a cache miss occurs, the next tier is invoked. The data is fetched, from a database for example, and is inserted into the data grid cache tier. If you are using a query or index, only the currently loaded values are accessed and the requests are not forwarded to the other tiers.

Complete cache

A complete cache contains all of the required data and can be accessed using non-key attributes with indexes or queries. A complete cache is preloaded with data from the database before the application tries to access the data. A complete cache can function as a database replacement after data is loaded. Because all of the data is available, queries and indexes can be used to find and aggregate data.

Side cache

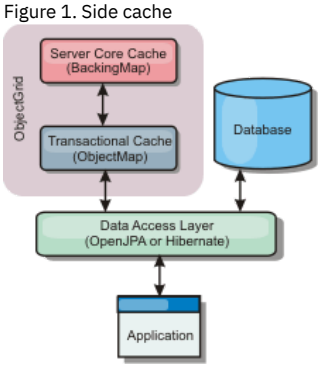
When WebSphere® eXtreme Scale is used as a side cache, the back end is used with the data grid.

Side cache

You can configure the product as a side cache for the data access layer of an application. In this scenario, WebSphere eXtreme Scale is used to temporarily store objects that would normally be retrieved from a back-end database. Applications check to see if the data grid contains the data. If the data is in the data grid, the data is returned to the caller. If the data does not exist, the data is retrieved from the back-end database. The data is then inserted into the data grid so that the next request can use the cached copy. The following diagram illustrates how WebSphere eXtreme Scale can be used as a side-cache with an arbitrary data access layer such as OpenJPA or Hibernate.

Side cache plug-ins for Hibernate and OpenJPA

Figure 1. Side cache



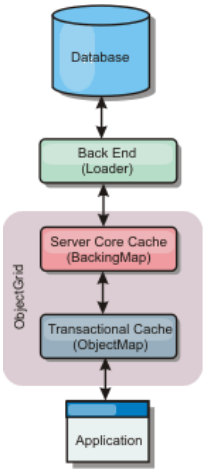
Cache plug-ins for both OpenJPA and Hibernate are included in WebSphere eXtreme Scale, so you can use the product as an automatic side-cache. Using WebSphere eXtreme Scale as a cache provider increases performance when reading and querying data and reduces load to the database. There are advantages that WebSphere eXtreme Scale has over built-in cache implementations because the cache is automatically replicated between all processes. When one client caches a value, all other clients can use the cached value.

In-line cache

You can configure in-line caching for a database back end or as a side cache for a database. In-line caching uses eXtreme Scale as the primary means for interacting with the data. When eXtreme Scale is used as an in-line cache, the application interacts with the back end using a Loader plug-in.

In-line cache

When used as an in-line cache, WebSphere® eXtreme Scale interacts with the back end using a Loader plug-in. This scenario can simplify data access because applications can access the eXtreme Scale APIs directly. Several different caching scenarios are supported in eXtreme Scale to make sure the data in the cache and the data in the back end are synchronized. The following diagram illustrates how an in-line cache interacts with the application and back end.
Figure 1. In-line cache



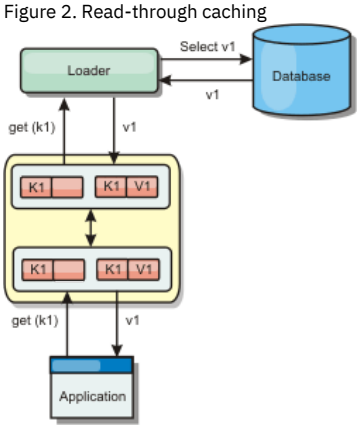
The in-line caching option simplifies data access because it allows applications to access the eXtreme Scale APIs directly. WebSphere eXtreme Scale supports several in-line caching scenarios, as follows.

- Read-through
- Write-through
- Write-behind

Read-through caching scenario

A read-through cache is a sparse cache that lazily loads data entries by key as they are requested. This is done without requiring the caller to know how the entries are populated. If the data cannot be found in the eXtreme Scale cache, eXtreme Scale will retrieve the missing data from the Loader plug-in, which loads the data from the back-end database and inserts the data into the cache. Subsequent requests for the same data key will be found in the cache until it is removed, invalidated or evicted.

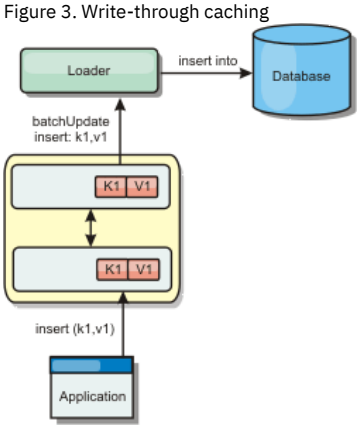
Figure 2. Read-through caching



Write-through caching scenario

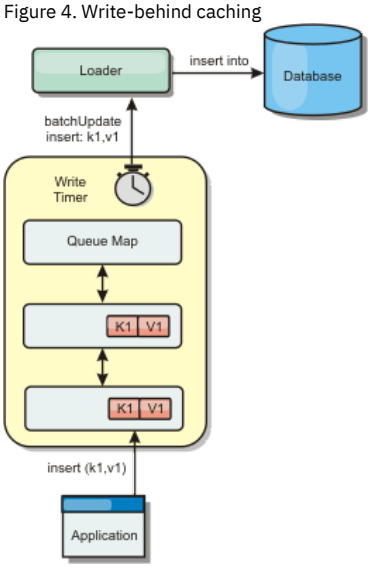
In a write-through cache, every write to the cache synchronously writes to the database using the Loader. This method provides consistency with the back end, but decreases write performance since the database operation is synchronous. Since the cache and database are both updated, subsequent reads for the same data will be found in the cache, avoiding the database call. A write-through cache is often used in conjunction with a read-through cache.

Figure 3. Write-through caching



Write-behind caching scenario

Database synchronization can be improved by writing changes asynchronously. This is known as a write-behind or write-back cache. Changes that would normally be written synchronously to the loader are instead buffered in eXtreme Scale and written to the database using a background thread. Write performance is significantly improved because the database operation is removed from the client transaction and the database writes can be compressed.
Figure 4. Write-behind caching



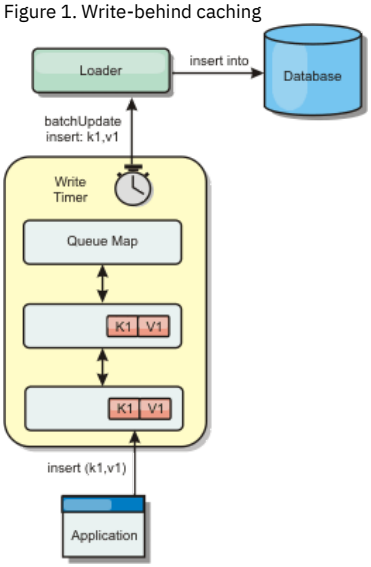
Write-behind caching

You can use write-behind caching to reduce the overhead that occurs when updating a database you are using as a back end.

Write-behind caching overview

Write-behind caching asynchronously queues updates to the Loader plug-in. You can improve performance by disconnecting updates, inserts, and removes for a map, the overhead of updating the back-end database. The asynchronous update is performed after a time-based delay (for example, five minutes) or an entry-based delay (1000 entries).

Figure 1. Write-behind caching



The write-behind configuration on a BackingMap creates a thread between the loader and the map. The loader then delegates data requests through the thread according to the configuration settings in the BackingMap.setWriteBehind method. When an eXtreme Scale transaction inserts, updates, or removes an entry from a map, a LogElement object is created for each of these records. These elements are sent to the write-behind loader and queued in a special ObjectMap called a queue map. Each backing map with the write-behind setting enabled has its own queue maps. A write-behind thread periodically removes the queued data from the queue maps and pushes them to the real back-end loader.

The write-behind loader only sends insert, update, and delete types of LogElement objects to the real loader. All other types of LogElement objects, for example, EVICT type, are ignored.

Write-behind support *is* an extension of the Loader plug-in, which you use to integrate eXtreme Scale with the database. For example, consult the Configuring JPA loaders information about configuring a JPA loader.

Benefits

Enabling write-behind support has the following benefits:

- **Back end failure isolation:** Write-behind caching provides an isolation layer from back end failures. When the back-end database fails, updates are queued in the queue map. The applications can continue driving transactions to eXtreme Scale. When the back end recovers, the data in the queue map is pushed to the back-end.
- **Reduced back end load:** The write-behind loader merges the updates on a key basis so only one merged update per key exists in the queue map. This merge decreases the number of updates to the back-end database.
- **Improved transaction performance:** Individual eXtreme Scale transaction times are reduced because the transaction does not need to wait for the data to be synchronized with the back-end.

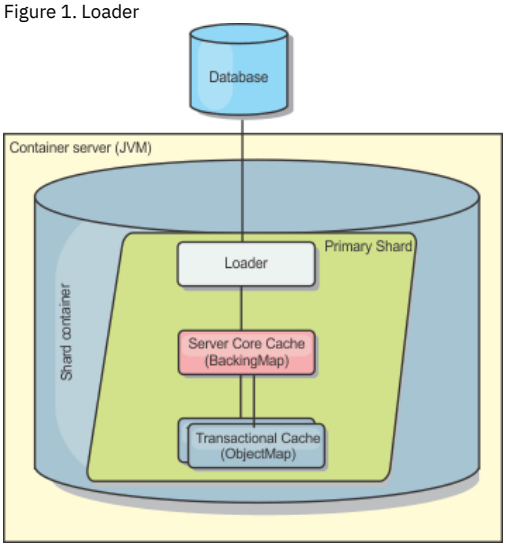
Loaders

With a Loader plug-in, a data grid map can behave as a memory cache for data that is typically kept in a persistent store on either the same system or another system. Typically, a database or file system is used as the persistent store. A remote Java™ virtual machine (JVM) can also be used as the source of data, allowing hub-based caches to be built using eXtreme Scale. A loader has the logic for reading and writing data to and from a persistent store.

Overview

Loaders are backing map plug-ins that are invoked when changes are made to the backing map or when the backing map is unable to satisfy a data request (a cache miss). The Loader is invoked when the cache is unable to satisfy a request for a key. The Loader logic provides a read-through capability for the cache, which means that data is populated into the cache on demand. Since the entire data set does not need to be loaded upon startup, the cache can be populated lazily. A loader also allows updates to the database when cache values change. All changes within a transaction are grouped together to allow the number of database interactions to be minimized. A TransactionCallback plug-in is used in conjunction with the loader to trigger the demarcation of the backend transaction. Using this plug-in is important when multiple maps are included in a single transaction or when transaction data is flushed to the cache without committing.

Figure 1. Loader



In order to avoid database locking on the row that requires updating, the loader can also perform optimistic transaction locking. In this scenario, no locking is required on a row. The update is overqualified to ensure that only rows that are in the same state as those originally read are changed. By storing a version attribute in the cache value, the loader can also see the before and after image of the value as it is updated in the cache. This value can then be used when updating the database or back end to verify that the data has not been updated. A Loader can also be configured to preload the data grid when it is started. When partitioned, a Loader instance is associated with each partition. If the "Company" Map has ten partitions, there are ten Loader instances, one per primary partition. When the primary shard for the Map is activated, the preloadMap method for the loader is invoked synchronously or asynchronously which allows loading the map partition with data from the back-end to occur automatically. When invoked synchronously, all client transactions are blocked, preventing inconsistent access to the data grid. Alternatively, a client preloader can be used to load the entire data grid.

Two built-in loaders can greatly simplify integration with relational database back ends. The JPA loaders utilize the Object-Relational Mapping (ORM) capabilities of both the OpenJPA and Hibernate implementations of the Java Persistence API (JPA) specification. See JPA Loaders for more information.

If you are using loaders in a multiple data center configuration, you must consider how revision data and cache consistency is maintained between the data grids. For more information, see Loader considerations in a multi-master topology.

Loader configuration

To add a Loader into the BackingMap configuration, you can use programmatic configuration or XML configuration. A loader has the following relationship with a backing map.

- A backing map can have only one loader.
- A client backing map (near cache) cannot have a loader.
- A loader definition can be applied to multiple backing maps, but each backing map has its own loader instance.

Data preloading and warm-up

In many scenarios that incorporate the use of a loader, you can prepare your data grid by preloading it with data.

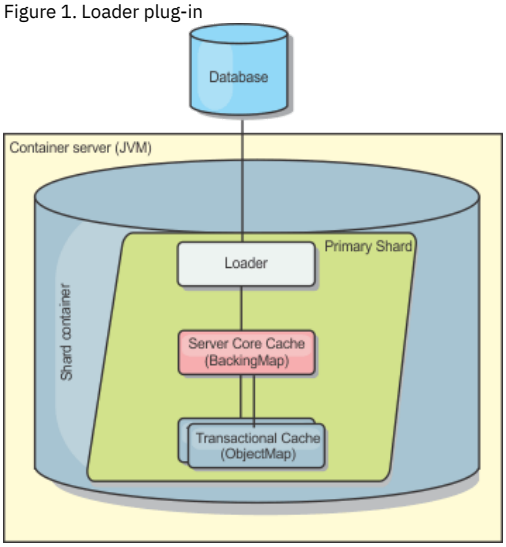
When used as a complete cache, the data grid must hold all of the data and must be loaded before any clients can connect to it. When you are using a sparse cache, you can warm up the cache with data so that clients can have immediate access to data when they connect.

Two approaches exist for preloading data into the data grid: Loader plug-in or client loader.

Loader plug-in

The Loader plug-in is associated with each map and is responsible for synchronizing a single primary partition shard with the database. The preloadMap method of the :Loader plug-in runs automatically when a shard is activated. For example, if you have 100 partitions, 100 loader instances exist, each loading the data for its partition. When run synchronously, all clients are blocked until the preload completes.

Figure 1. Loader plug-in

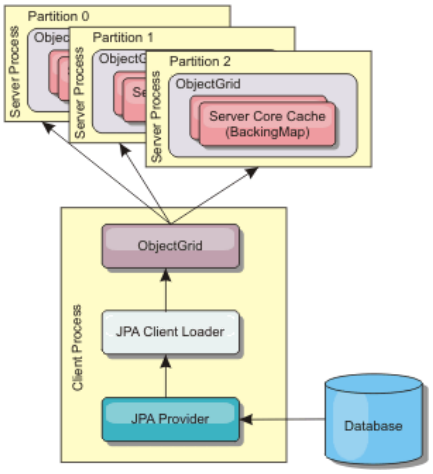


For more information about the Loader plug-in, see Plug-ins for communicating with databases.

Client loader

A client loader is a pattern for using one or more clients to load the data grid with data. Using multiple clients to load grid data can be effective when the partition scheme is not stored in the database. You can invoke client loaders manually or automatically when the data grid starts. Client loaders can optionally use the StateManager to set the state of the data grid to preload mode, so that clients are not able to access the data grid while it is preloading the data. WebSphere® eXtreme Scale includes a Java Persistence API (JPA)-based loader that you can use to automatically load the data grid with either the OpenJPA or Hibernate JPA providers. For more information about cache providers, see JPA level 2 (L2) cache plug-in.

Figure 2. Client loader



Database synchronization techniques

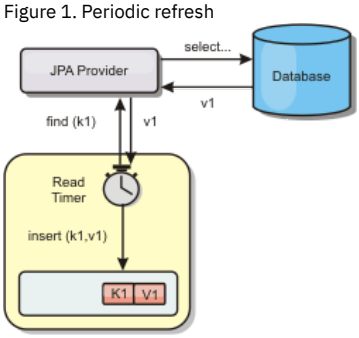
When WebSphere® eXtreme Scale is used as a cache, applications must be written to tolerate stale data if the database can be updated independently from an eXtreme Scale transaction. To serve as a synchronized in-memory database processing space, eXtreme Scale provides several ways of keeping the cache updated.

Database synchronization techniques

Periodic refresh

The cache can be automatically invalidated or updated periodically using the Java™ Persistence API (JPA) time-based database updater.The updater periodically queries the database using a JPA provider for any updates or inserts that have occurred since the previous update. Any changes identified are automatically invalidated or updated when used with a sparse cache. If used with a complete cache, the entries can be discovered and inserted into the cache. Entries are never removed from the cache.

Figure 1. Periodic refresh



Eviction

Sparse caches can utilize eviction policies to automatically remove data from the cache without affecting the database. There are three built-in policies included in eXtreme Scale: time-to-live, least-recently-used, and least-frequently-used. All three policies can optionally evict data more aggressively as memory becomes constrained by enabling the memory-based eviction option. See Plug-ins for evicting cache objects for further details.

Event-based invalidation

Sparse and complete caches can be invalidated or updated using an event generator such as Java Message Service (JMS). Invalidation using JMS can be manually tied to any process that updates the back-end using a database trigger. A JMS ObjectGridEventListener plug-in is provided in eXtreme Scale that can notify clients when the server cache has any changes. This can decrease the amount of time the client can see stale data.

Programmatic invalidation

The eXtreme Scale APIs allow manual interaction of the near and server cache using the Session.beginNoWriteThrough(), ObjectMap.invalidate() and EntityManager.invalidate() API methods. If a client or server process no longer needs a portion of the data, the invalidate methods can be used to remove data from the near or server cache. The beginNoWriteThrough method applies any ObjectMap or EntityManager operation to the local cache without calling the loader. If invoked from a client, the operation applies only to the near cache (the remote loader is not invoked). If invoked on the server, the operation applies only to the server core cache without invoking the loader.

Data invalidation

To remove stale cache data, you can use invalidation mechanisms.

8.5+

Administrative invalidation

You can use the web console or the **xscmd** utility to invalidate data based on the key. You can filter the cache data with a regular expression and then invalidate the data based on the regular expression.

Event-based invalidation

Sparse and complete caches can be invalidated or updated using an event generator such as Java™ Message Service (JMS). Invalidation using JMS can be manually tied to any process that updates the back-end using a database trigger. A JMS ObjectGridEventListener plug-in is provided in eXtreme Scale that can notify clients when the server cache changes. This type of notification decreases the amount of time the client can see stale data.

Event-based invalidation normally consists of the following three components.

- **Event queue:** An event queue stores the data change events. It could be a JMS queue, a database, an in-memory FIFO queue, or any kind of manifest as long as it can manage the data change events.
- **Event publisher:** An event publisher publishes the data change events to the event queue. An event publisher is usually an application you create or an eXtreme Scale plug-in implementation. The event publisher knows when the data is changed or it changes the data itself. When a transaction commits, events are generated for the changed data and the event publisher publishes these events to the event queue.
- **Event consumer:** An event consumer consumes data change events. The event consumer is usually an application to ensure the target grid data is updated with the latest change from other grids. This event consumer interacts with the event queue to get the latest data change and applies the data changes in the target grid. The event consumers can use eXtreme Scale APIs to invalidate stale data or update the grid with the latest data.

For example, JMSObjectGridEventListener has an option for a client-server model, in which the event queue is a designated JMS destination. All server processes are event publishers. When a transaction commits, the server gets the data changes and publishes them to the designated JMS destination. All the client processes are event consumers. They receive the data changes from the designated JMS destination and apply the changes to the client's near cache.

See Configuring Java Message Service (JMS)-based client synchronization for more information.

Programmatic invalidation

The WebSphere® eXtreme Scale APIs allow manual interaction of the near and server cache using the Session.beginNoWriteThrough(), ObjectMap.invalidate() and EntityManager.invalidate() API methods. If a client or server process no longer needs a portion of the data, the invalidate methods can be used to remove data from the near or server cache. The beginNoWriteThrough method applies any ObjectMap or EntityManager operation to the local cache without calling the loader. If invoked from a client, the operation applies only to the near cache (the remote loader is not invoked). If invoked on the server, the operation applies only to the server core cache without invoking the loader.

You can use programmatic invalidation with other techniques to determine when to invalidate the data. For example, this invalidation method uses event-based invalidation mechanisms to receive the data change events, and then uses APIs to invalidate the stale data.

Indexing

Use the MapIndexPlugin plug-in to build an index or several indexes on a BackingMap to support non-key data access.

Index types and configuration

The indexing feature is represented by the MapIndexPlugin plug-in or Index for short. The Index is a BackingMap plug-in. A BackingMap can have multiple Index plug-ins configured, as long as each one follows the Index configuration rules.

You can use the indexing feature to build one or more indexes on a BackingMap. An index is built from an attribute or a list of attributes of an object in the BackingMap. This feature provides a way for applications to find certain objects more quickly. With the indexing feature, applications can find objects with a specific value or within a range of values of indexed attributes.

Two types of indexing are possible: static and dynamic. With static indexing, you must configure the index plug-in on the BackingMap before initializing the ObjectGrid instance. You can do this configuration with XML or programmatic configuration of the BackingMap. Static indexing starts building an index during ObjectGrid initialization. The index is always synchronized with the BackingMap and ready for use. After the static indexing process starts, the maintenance of the index is part of the eXtreme Scale transaction management process. When transactions commit changes, these changes also update the static index, and index changes are rolled back if the transaction is rolled back.

With dynamic indexing, you can create an index on a BackingMap before or after the initialization of the containing ObjectGrid instance. Applications have life cycle control over the dynamic indexing process so that you can remove a dynamic index when it is no longer needed. When an application creates a dynamic

index, the index might not be ready for immediate use because of the time it takes to complete the index building process. Because the amount of time depends upon the amount of data indexed, the DynamicIndexCallback interface is provided for applications that want to receive notifications when certain indexing events occur. These events include ready, error, and destroy. Applications can implement this callback interface and register with the dynamic indexing process.

If a BackingMap has an index plug-in configured, you can obtain the application index proxy object from the corresponding ObjectMap. Calling the getIndex method on the ObjectMap and passing in the name of the index plug-in returns the index proxy object. You must cast the index proxy object to an appropriate application index interface, such as MapIndex, MapRangeIndex, or a customized index interface. After obtaining the index proxy object, you can use methods defined in the application index interface to find cached objects.

The steps to use indexing are summarized in the following list:

- Add either static or dynamic index plug-ins into the BackingMap.
- Obtain an application index proxy object by issuing the getIndex method of the ObjectMap.
- Cast the index proxy object to an appropriate application index interface, such as MapIndex, MapRangeIndex, or a customized index interface.
- Use methods that are defined in application index interface to find cached objects.

The HashIndex class is the built-in index plug-in implementation that can support both of the built-in application index interfaces: MapIndex and MapRangeIndex. You also can create your own indexes. You can add HashIndex as either a static or dynamic index into the BackingMap, obtain either MapIndex or MapRangeIndex index proxy object, and use the index proxy object to find cached objects.

Default index

If you want to iterate through the keys in a local map, you can use the default index. This index does not require any configuration, but it must be used against the shard, using an agent or an ObjectGrid instance retrieved from the ShardEvents.shardActivated(ObjectGrid shard) method.

Data quality consideration

The results of index query methods only represent a snapshot of data at a point of time. No locks against data entries are obtained after the results return to the application. Application has to be aware that data updates may occur on a returned data set. For example, the application obtains the key of a cached object by running the findAll method of MapIndex. This returned key object is associated with a data entry in the cache. The application should be able to run the get method on ObjectMap to find an object by providing the key object. If another transaction removes the data object from the cache just before the get method is called, the returned result will be null.

Indexing performance considerations

One of the main objectives of the indexing feature is to improve overall BackingMap performance. If indexing is not used properly, the performance of the application might be compromised. Consider the following factors before using this feature.

- **The number of concurrent write transactions:** Index processing can occur every time a transaction writes data into a BackingMap. Performance degrades if many transactions are writing data into the map concurrently when an application attempts index query operations.
- **The size of the result set that is returned by a query operation:** As the size of the resultset increases, the query performance declines. Performance tends to degrade when the size of the result set is 15% or more of the BackingMap.
- **The number of indexes built over the same BackingMap:** Each index consumes system resources. As the number of the indexes built over the BackingMap increases, performance decreases.

The indexing function can improve BackingMap performance drastically. Ideal cases are when the BackingMap has mostly read operations, the query result set is of a small percentage of the BackingMap entries, and only few indexes are built over the BackingMap.

JPA Loaders

The Java™ Persistence API (JPA) is a specification that allows mapping Java objects to relational databases. JPA contains a full object-relational mapping (ORM) specification using Java language metadata annotations, XML descriptors, or both to define the mapping between Java objects and a relational database. A number of open-source and commercial implementations are available.

You can use a Java Persistence API (JPA) loader plug-in implementation with eXtreme Scale to interact with any database supported by your chosen loader. To use JPA, you must have a supported JPA provider, such as OpenJPA or Hibernate, JAR files, and a META-INF/persistence.xml file in your class path.

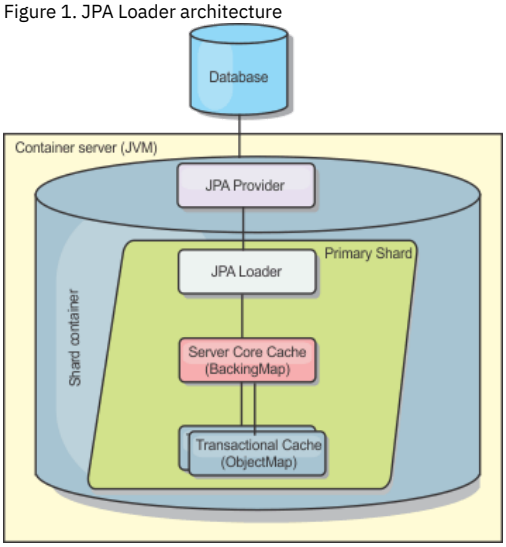
The JPALoader com.ibm.websphere.objectgrid.jpa.JPALoader and the JPAEntityLoader com.ibm.websphere.objectgrid.jpa.JPAEntityLoader plug-ins are two built-in JPA loader plug-ins that are used to synchronize the ObjectGrid maps with a database. You must have a JPA implementation, such as Hibernate or OpenJPA, to use this feature. The database can be any back end that is supported by the chosen JPA provider.

You can use the JPALoader plug-in when you are storing data using the ObjectMap API. Use the JPAEntityLoader plug-in when you are storing data using the EntityManager API.

JPA loader architecture

The JPA Loader is used for eXtreme Scale maps that store plain old Java objects (POJO).

Figure 1. JPA Loader architecture



When an ObjectMap.get(Object key) method is called, the eXtreme Scale run time first checks whether the entry is contained in the ObjectMap layer. If not, the run time delegates the request to the JPA Loader. Upon request of loading the key, the JPALoader calls the JPA EntityManager.find(Object key) method to find the data from the JPA layer. If the data is contained in the JPA entity manager, it is returned; otherwise, the JPA provider interacts with the database to get the value.

When an update to ObjectMap occurs, for example, using the ObjectMap.update(Object key, Object value) method, the eXtreme Scale run time creates a LogElement for this update and sends it to the JPALoader. The JPALoader calls the JPA EntityManager.merge(Object value) method to update the value to the database.

For the JPAEntityLoader, the same four layers are involved. However, because the JPAEntityLoader plug-in is used for maps that store eXtreme Scale entities, relations among entities could complicate the usage scenario. An eXtreme Scale entity is distinguished from JPA entity. For more details, see JPAEntityLoader plug-in.For more information, see JPAEntityLoader plug-in.For more information, see the information about the JPAEntityLoader plug-in in the *Programming Guide*.

Methods

Loaders provide three main methods:

1. get: Returns a list of values that correspond to the list of keys that are passed in by retrieving the data using JPA. The method uses JPA to find the entities in the database. For the JPALoader plug-in, the returned list contains a list of JPA entities directly from the find operation. For the JPAEntityLoader plug-in, the returned list contains eXtreme Scale entity value tuples that are converted from the JPA entities.
2. batchUpdate: Writes the data from ObjectGrid maps to the database. Depending on different operation types (insert, update, or delete), the loader uses the JPA persist, merge, and remove operations to update the data to the database. For the JPALoader, the objects in the map are directly used as JPA entities. For the JPAEntityLoader, the entity tuples in the map are converted into objects which are used as JPA entities.
3. preloadMap: Preloads the map using the ClientLoader.load client loader method. For partitioned maps, the preloadMap method is only called in one partition. The partition is specified the preloadPartition property of the JPALoader or JPAEntityLoader class. If the preloadPartition value is set to less than zero, or greater than (*total_number_of_partitions* - 1), preload is disabled.

Both JPALoader and JPAEntityLoader plug-ins work with the JPATxCallback class to coordinate the eXtreme Scale transactions and JPA transactions. JPATxCallback must be configured in the ObjectGrid instance to use these two loaders.

Configuration and programming

If you are using JPA loaders in a multi-master environment, see Loader considerations in a multi-master topology. For more information about configuring JPA loaders, see Configuring JPA loaders. For more information about programming JPA loaders, see JPA loader programming considerations.

Serialization overview

Data is always expressed, but not necessarily stored, as Java™ objects in the data grid. WebSphere® eXtreme Scale uses multiple Java processes to serialize the data, by converting the Java object instances to bytes and back to objects again, as needed, to move the data between client and server processes.

When data is serialized, it is converted into a data stream for transmission over a network in the following situations:

- When clients communicate with servers, and those servers send information back to the client
- When servers replicate data from one server to another

Alternatively, you might decide to forgo the serialization process through WebSphere eXtreme Scale and store raw data as byte arrays. Byte arrays are much cheaper to store in memory. The Java virtual machine (JVM) has fewer objects to search for during garbage collection. The objects can be deserialized only when they are needed. Use byte arrays only if access to the objects with queries or indexes is not required. Because the data is stored as bytes, eXtreme Scale has no metadata for describing attributes to query.

Serialization for Java applications

To serialize data, you can use Java serialization, the ObjectTransformer plug-in, or the DataSerializer plug-ins. To optimize serialization with any of these options, you can use the COPY_TO_BYTES mode to improve performance up to 70 percent. With COPY_TO_BYTES mode, the data is serialized when transactions commit, which means that serialization happens only one time. The serialized data is sent unchanged from the client to the server or from the server to replicated server. By using the COPY_TO_BYTES mode, you can reduce the memory footprint that a large graph of objects can use.

Use the following figures to help you determine which type of serialization method is most appropriate for your development needs.

Figure 1. Serialization methods that are available when you are running logic that interacts with data objects directly in the data grid shard

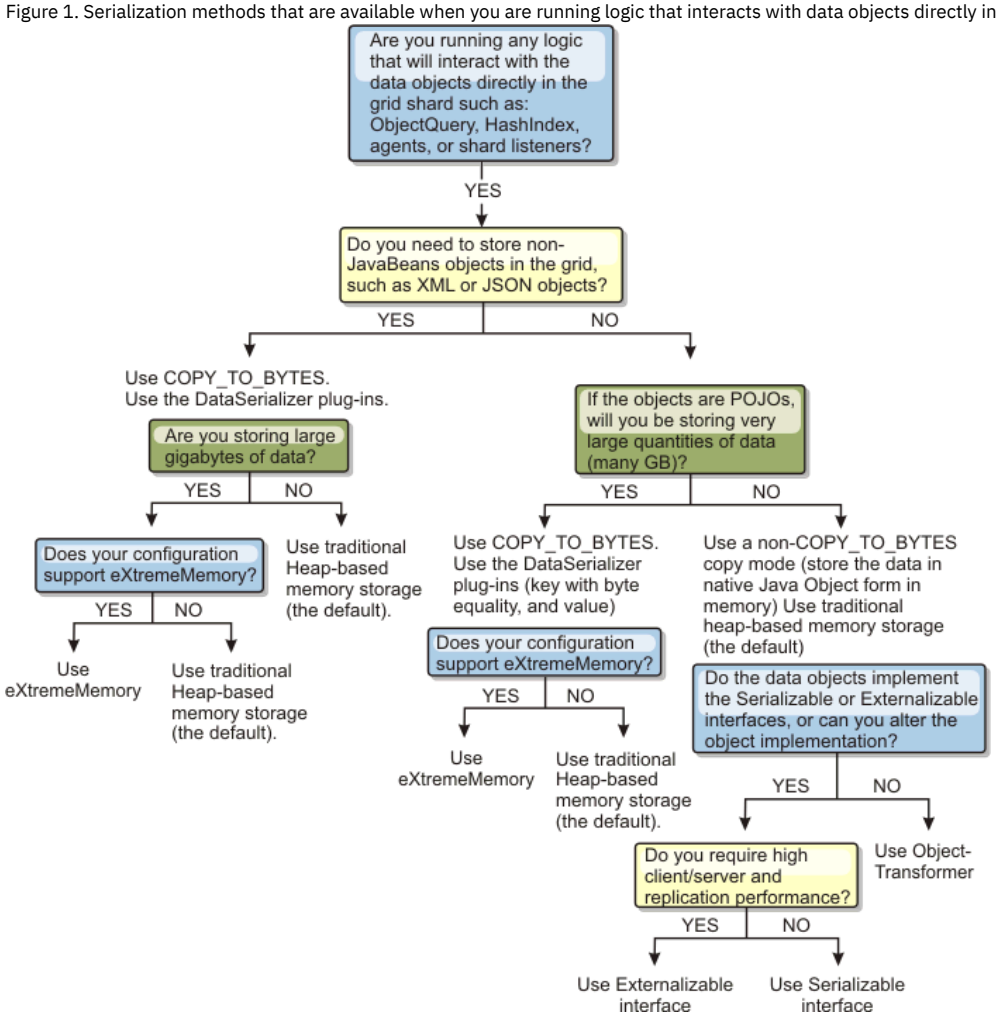

Figure 2. Serialization methods when you are not directly interacting with the data grid shard.

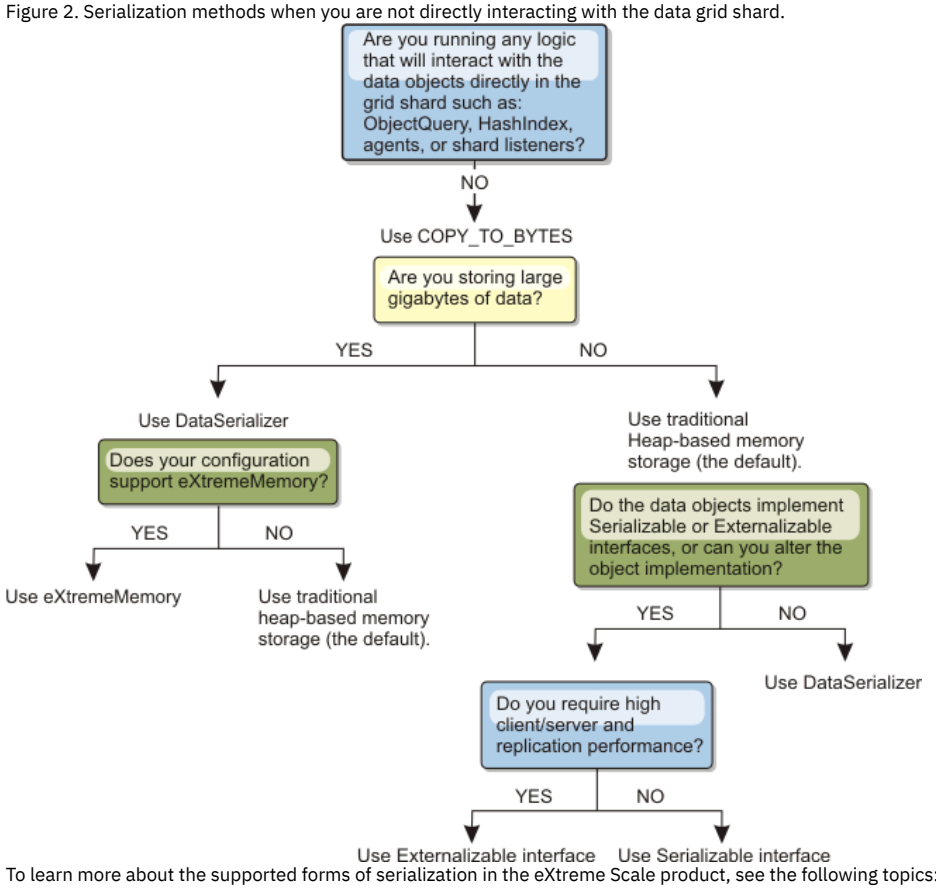

To learn more about the supported forms of serialization in the eXtreme Scale product, see the following topics:

- Serialization using Java
  Java serialization refers to either default serialization, which uses the Serializable interface, or custom serialization, which uses both the Serializable and Externalizable interfaces.
- ObjectTransformer plug-in
  With the ObjectTransformer plug-in, you can serialize, deserialize, and copy objects in the cache for increased performance.
- Serialization using the DataSerializer plug-ins
  Use the DataSerializer plug-ins to efficiently store arbitrary data in WebSphere eXtreme Scale so that existing product APIs can efficiently interact with your data.

Serialization using Java

Java serialization refers to either default serialization, which uses the Serializable interface, or custom serialization, which uses both the Serializable and Externalizable interfaces.

Default serialization

To use default serialization, implement the java.io.Serializable interface, which includes the API that converts objects into bytes, which are later deserialized. Use the java.io.ObjectOutputStream class to persist the object. Then, call the ObjectOutputStream.writeObject() method to initiate serialization and flatten the Java object.

Custom serialization

Some cases exist where objects must be modified to use custom serialization, such as implementing the java.io.Externalizable interface or by implementing the writeObject and readObject methods for classes implementing the java.io.Serializable interface. Custom serialization techniques should be employed when the objects are serialized using mechanisms other than the ObjectGrid API or EntityManager API methods.

For example, when objects or entities are stored as instance data in a DataGrid API agent or the agent returns objects or entities, those objects are not transformed using an ObjectTransformer. The agent, will however, automatically use the ObjectTransformer when using `EntityMixin` interface. See DataGrid agents and entity based Maps for further details.

ObjectTransformer plug-in

With the ObjectTransformer plug-in, you can serialize, deserialize, and copy objects in the cache for increased performance.

The ObjectTransformer interface has been replaced by the DataSerializer plug-ins, which you can use to efficiently store arbitrary data in WebSphere® eXtreme Scale so that existing product APIs can efficiently interact with your data.

If you see performance issues with processor usage, add an ObjectTransformer plug-in to each map. If you do not provide an ObjectTransformer plug-in, up to 60-70 percent of the total processor time is spent serializing and copying entries.

Purpose

With the ObjectTransformer plug-in, your applications can provide custom methods for the following operations:

- Serialize or deserialize the key for an entry
- Serialize or deserialize the value for an entry
- Copy a key or value for an entry

If no ObjectTransformer plug-in is provided, you must be able to serialize the keys and values because the ObjectGrid uses a serialize and deserialize sequence to copy the objects. This method is expensive, so use an ObjectTransformer plug-in when performance is critical. The copying occurs when an application looks up an object in a transaction for the first time. You can avoid this copying by setting the copy mode of the Map to NO_COPY or reduce the copying by setting the copy mode to COPY_ON_READ. Optimize the copy operation when needed by the application by providing a custom copy method on this plug-in. Such a plug-in can reduce the copy overhead from 65–70 percent to 2/3 percent of total processor time.

The default copyKey and copyValue method implementations first attempt to use the clone method, if the method is provided. If no clone method implementation is provided, the implementation defaults to serialization.

Object serialization is also used directly when the eXtreme Scale is running in distributed mode. The LogSequence uses the ObjectTransformer plug-in to help serialize keys and values before transmitting the changes to peers in the ObjectGrid. You must take care when providing a custom serialization method instead of using the built-in Java™ developer kit serialization. Object versioning is a complex issue and you might encounter problems with version compatibility if you do not ensure that your custom methods are designed for versioning.

The following list describes how the eXtreme Scale tries to serialize both keys and values:

- If a custom ObjectTransformer plug-in is written and plugged in, eXtreme Scale calls methods in the ObjectTransformer interface to serialize keys and values and get copies of object keys and values.
- If a custom ObjectTransformer plug-in is not used, eXtreme Scale serializes and deserializes values according to the default. If the default plug-in is used, each object is implemented as externalizable or is implemented as serializable.
    - If the object supports the Externalizable interface, the writeExternal method is called. Objects that are implemented as externalizable lead to better performance.
    - If the object does not support the Externalizable interface and does implement the Serializable interface, the object is saved using the ObjectOutputStream method.

Using the ObjectTransformer interface

An ObjectTransformer object must implement the ObjectTransformer interface and follow the common ObjectGrid plug-in conventions.

Two approaches, programmatic configuration and XML configuration, are used to add an ObjectTransformer object into the BackingMap configuration as follows.

Programmatically plug in an ObjectTransformer object

The following code snippet creates the custom ObjectTransformer object and adds it to a BackingMap:

```
ObjectGridManager objectGridManager = ObjectGridManagerFactory.getObjectGridManager();
ObjectGrid myGrid = objectGridManager.createObjectGrid("myGrid", false);
BackingMap backingMap = myGrid.getMap("myMap");
MyObjectTransformer myObjectTransformer = new MyObjectTransformer();
backingMap.setObjectTransformer(myObjectTransformer);
```

XML configuration approach to plug in an ObjectTransformer

Assume that the class name of the ObjectTransformer implementation is the com.company.org.MyObjectTransformer class. This class implements the ObjectTransformer interface. An ObjectTransformer implementation can be configured using the following XML:

```
<?xml version="1.0" encoding="UTF-8"?>
<objectGridConfig xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://ibm.com/ws/objectgrid/config ../objectGrid.xsd"
    xmlns="http://ibm.com/ws/objectgrid/config">
    <objectGrids>
        <objectGrid name="myGrid">
            <backingMap name="myMap" pluginCollectionRef="myMap" />
        </objectGrid>
    </objectGrids>

    <backingMapPluginCollections>
        <backingMapPluginCollection
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_cxsplugobjtrans_myMap">
            <bean
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_cxsplugobjtrans_ObjectTransformer"
className="com.company.org.MyObjectTransformer" />
        </backingMapPluginCollection>
    </backingMapPluginCollections>
</objectGridConfig>
```

ObjectTransformer usage scenarios

You can use the ObjectTransformer plug-in in the following situations:

- Non-serializable object
- Serializable object but improve serialization performance
- Key or value copy

In the following example, ObjectGrid is used to store the Stock class:

```
/**
* Stock object for ObjectGrid demo
*
*
*/
public class Stock implements Cloneable {
    String ticket;
    double price;
    String company;
    String description;
    int serialNumber;
    long lastTransactionTime;
    /**
    * @return Returns the description.
    */
    public String getDescription() {
        return description;
    }
    /**
    * @param description The description to set.
    */
    public void setDescription(String description) {
        this.description = description;
    }
    /**
    * @return Returns the lastTransactionTime.
    */
    public long getLastTransactionTime() {
        return lastTransactionTime;
    }
    /**
    * @param lastTransactionTime The lastTransactionTime to set.
    */
    public void setLastTransactionTime(long lastTransactionTime) {
        this.lastTransactionTime = lastTransactionTime;
    }
```

```
    /**
    * @return Returns the price.
    */
    public double getPrice() {
        return price;
    }
    /**
    * @param price The price to set.
    */
    public void setPrice(double price) {
        this.price = price;
    }
    /**
    * @return Returns the serialNumber.
    */
    public int getSerialNumber() {
        return serialNumber;
    }
    /**
    * @param serialNumber The serialNumber to set.
    */
    public void setSerialNumber(int serialNumber) {
        this.serialNumber = serialNumber;
    }
    /**
    * @return Returns the ticket.
    */
    public String getTicket() {
        return ticket;
    }
    /**
    * @param ticket The ticket to set.
    */
    public void setTicket(String ticket) {
        this.ticket = ticket;
    }
    /**
    * @return Returns the company.
    */
    public String getCompany() {
        return company;
    }
    /**
    * @param company The company to set.
    */
    public void setCompany(String company) {
        this.company = company;
    }
    //clone
    public Object clone() throws CloneNotSupportedException
    {
        return super.clone();
    }
}
```

You can write a custom object transformer class for the Stock class:

```
/**
* Custom implementation of ObjectGrid ObjectTransformer for stock object
*
*/
public class MyStockObjectTransformer implements ObjectTransformer {
/* (non-Javadoc)
* @see
* com.ibm.websphere.objectgrid.plugins.ObjectTransformer#serializeKey
* (java.lang.Object,
* java.io.ObjectOutputStream)
*/
public void serializeKey(Object key, ObjectOutputStream stream) throws IOException {
    String ticket= (String) key;
    stream.writeUTF(ticket);
}

/* (non-Javadoc)
* @see com.ibm.websphere.objectgrid.plugins.
ObjectTransformer#serializeValue(java.lang.Object,
java.io.ObjectOutputStream)
*/
public void serializeValue(Object value, ObjectOutputStream stream) throws IOException {
    Stock stock= (Stock) value;
    stream.writeUTF(stock.getTicket());
    stream.writeUTF(stock.getCompany());
    stream.writeUTF(stock.getDescription());
    stream.writeDouble(stock.getPrice());
    stream.writeLong(stock.getLastTransactionTime());
    stream.writeInt(stock.getSerialNumber());
}

/* (non-Javadoc)
* @see com.ibm.websphere.objectgrid.plugins.
ObjectTransformer#inflateKey(java.io.ObjectInputStream)
```

```
*/
public Object inflateKey(ObjectInputStream stream) throws IOException, ClassNotFoundException {
    String ticket=stream.readUTF();
    return ticket;
}

/* (non-Javadoc)
* @see com.ibm.websphere.objectgrid.plugins.
ObjectTransformer#inflateValue(java.io.ObjectInputStream)
*/

public Object inflateValue(ObjectInputStream stream) throws IOException,        ClassNotFoundException {
    Stock stock=new Stock();
    stock.setTicket(stream.readUTF());
    stock.setCompany(stream.readUTF());
    stock.setDescription(stream.readUTF());
    stock.setPrice(stream.readDouble());
    stock.setLastTransactionTime(stream.readLong());
    stock.setSerialNumber(stream.readInt());
    return stock;
}

/* (non-Javadoc)
* @see com.ibm.websphere.objectgrid.plugins.
ObjectTransformer#copyValue(java.lang.Object)
*/
public Object copyValue(Object value) {
    Stock stock = (Stock) value;
    try {
        return stock.clone();
    }
    catch (CloneNotSupportedException e)
    {
        // display exception message    }
}

/* (non-Javadoc)
* @see com.ibm.websphere.objectgrid.plugins.
ObjectTransformer#copyKey(java.lang.Object)
*/
public Object copyKey(Object key) {
    String ticket=(String) key;
    String ticketCopy= new String (ticket);
    return ticketCopy;
}
}
```

Then, plug in this custom MyStockObjectTransformer class into the BackingMap:

```
ObjectGridManager ogf=ObjectGridManagerFactory.getObjectGridManager();
ObjectGrid og = ogf.getObjectGrid("NYSE");
BackingMap bm = og.defineMap("NYSEStocks");
MyStockObjectTransformer ot = new MyStockObjectTransformer();
bm.setObjectTransformer(ot);
```

Serialization using the DataSerializer plug-ins

Use the DataSerializer plug-ins to efficiently store arbitrary data in WebSphere eXtreme Scale so that existing product APIs can efficiently interact with your data.

Serialization methods such as Java serialization and the ObjectTransformer plug-in allow data to be marshalled over the network. In addition, when you use these serialization options with the COPY_TO_BYTES copy mode, moving data between clients and servers becomes less expensive and performance is improved. However, these options do not solve the following issues that can exist:

- Keys are not stored in bytes; they are still Java objects.
- Server-side code must still inflate the object; for example, query and index still use reflection and must inflate the object. Additionally, agents, listeners, and plug-ins still need the object form.
- Classes still need to be in the server classpath.
- Data is still in Java serialization form (ObjectOutputStream).

The DataSerializer plug-ins introduce an efficient way of solving these problems. Specifically, the DataSerializer plug-in gives you a way to describe your serialization format, or byte array, to WebSphere eXtreme Scale so that the product can interrogate the byte array without requiring a specific object format. The public DataSerializer plug-in classes and interfaces are in the package, com.ibm.websphere.objectgrid.plugins.io. For more information, refer to the API documentation.
Important: Entity Java objects are not stored directly into the BackingMaps when you use the EntityManager API. The EntityManager API converts the entity object to Tuple objects. Entity maps are automatically associated with a highly optimized ObjectTransformer. Whenever the ObjectMap API or EntityManager API is used to interact with entity maps, the ObjectTransformer entity is invoked. Therefore, when you use entities, no work is required for serialization because the product automatically completes this process for you.

Scalability overview

WebSphere® eXtreme Scale is scalable through the use of partitioned data, and can scale to thousands of containers if required because each container is independent from other containers.

WebSphere eXtreme Scale divides data sets into distinct partitions that can be moved between processes or even between physical servers at run time. You can, for example, start with a deployment of four servers and then expand to a deployment with 10 servers as the demands on the cache grow. Just as you can add more physical servers and processing units for vertical scalability, you can extend the elastic scaling capability horizontally with partitioning. Horizontal scaling is a major advantage to using WebSphere eXtreme Scale over an in-memory database. In-memory databases can only scale vertically.

With WebSphere eXtreme Scale, you can also use a set of APIs to gain transactional access this partitioned and distributed data. The choices you make for interacting with the cache are as significant as the functions to manage the cache for availability from a performance perspective.

Note: Scalability is not available when containers communicate with one another. The availability management, or core grouping, protocol is an $O(N^2)$ heartbeat and view maintenance algorithm, but is mitigated by keeping the number of core group members under 20. Only peer to peer replication between shards exists.

Distributed clients

The WebSphere eXtreme Scale client protocol supports very large numbers of clients. The partitioning strategy offers assistance by assuming that all clients are not always interested in all partitions because connections can be spread across multiple containers. Clients are connected directly to the partitions so latency is limited to one transferred connection.

- Data grids, partitions, and shards
  A data grid is divided into partitions. A partition holds an exclusive subset of the data. A partition contains one or more shards: a primary shard and replica shards. Replica shards are not necessary in a partition, but you can use replica shards to provide high availability. Whether your deployment is an independent in-memory data grid or an in-memory database processing space, data access in eXtreme Scale relies heavily on shards.
- Partitioning
  Use partitioning to scale out an application. You can define the number of partitions in your deployment policy.
- Placement and partitions
  You have two placement strategies available for WebSphere eXtreme Scale: fixed partition and per-container. The choice of placement strategy affects how your deployment configuration places partitions over the remote data grid.
- Single-partition and cross-data-grid transactions
  The major distinction between WebSphere eXtreme Scale and traditional data storage solutions like relational databases or in-memory databases is the use of partitioning, which allows the cache to scale linearly. The important types of transactions to consider are single-partition and every-partition (cross-data-grid) transactions.
- Scaling in units or pods
  Although you can deploy a data grid over thousands of Java virtual machines, you might consider splitting the data grid into units or pods to increase the reliability and ease of testing of your configuration. A pod is a group of servers that is running the same set of applications.

Data grids, partitions, and shards

A data grid is divided into partitions. A partition holds an exclusive subset of the data. A partition contains one or more shards: a primary shard and replica shards. Replica shards are not necessary in a partition, but you can use replica shards to provide high availability. Whether your deployment is an independent in-memory data grid or an in-memory database processing space, data access in eXtreme Scale relies heavily on shards.

The data for a partition is stored in a set of shards at run time. This set of shards includes a primary shared and possibly one or more replica shards. A shard is the smallest unit that eXtreme Scale can add or remove from a Java™ virtual machine.

Two placement strategies exist: fixed partition placement (default) and per container placement. The following discussion focuses on the usage of the fixed partition placement strategy.

Total number of shards

If your environment includes 10 partitions that hold 1 million objects with no replicas, then 10 shards would exist that each store 100,000 objects. If you add a replica to this scenario, then an extra shard exists in each partition. In this case, 20 shards exist: 10 primary shards and 10 replica shards. Each one of these shards store 100,000 objects. Each partition consists of a primary shard and one or more (N) replica shards. Determining the optimal shard count is critical. If you configure few shards, data is not distributed evenly among the shards, resulting in out of memory errors and processor overloading issues. You must have at least 10 shards for each JVM as you scale. When you are initially deploying the data grid, you would potentially use many partitions.

Number of shards per JVM scenarios

Scenario: small number of shards for each JVM

Data is added and removed from a JVM using shard units. Shards are never split into pieces. If 10 GB of data existed, and 20 shards exist to hold this data, then each shard holds 500 MB of data on average. If nine Java virtual machines host the data grid, then on average each JVM has two shards. Because 20 is not evenly divisible by 9, a few Java virtual machines have three shards, in the following distribution:

- Seven Java virtual machines with two shards
- Two Java virtual machines with three shards

Because each shard holds 500 MB of data, the distribution of data is unequal. The seven Java virtual machines with two shards each host 1 GB of data. The two Java virtual machines with three shards have 50% more data, or 1.5 GB, which is a much larger memory burden. Because the two Java virtual machines are hosting three shards, they also receive 50% more requests for their data. As a result, having few shards for each JVM causes imbalance. To increase the performance, you increase the number of shards for each JVM.

Scenario: increased number of shards per JVM

In this scenario, consider a much larger number of shards. In this scenario, there are 101 shards with nine Java virtual machines hosting 10 GB of data. In this case, each shard holds 99 MB of data. The Java virtual machines have the following distribution of shards:

- Seven Java virtual machines with 11 shards
- Two Java virtual machines with 12 shards

The two Java virtual machines with 12 shards now have just 99 MB more data than the other shards, which is a 9% difference. This scenario is much more evenly distributed than the 50% difference in the scenario with few shards. From a processor use perspective, only 9% more work exists for the two Java virtual machines with the 12 shards compared to the seven Java virtual machines that have 11 shards. By increasing the number of shards in each JVM, the data and processor use is distributed in a fair and even way.

When you are creating your system, use 10 shards for each JVM in its maximally sized scenario, or when the system is running its maximum number of Java virtual machines in your planning horizon.

Additional placement factors

The number of partitions, the placement strategy, and number and type of replicas are set in the deployment policy. The number of shards that are placed depend on the deployment policy that you define. The minSyncReplicas, developmentMode, maxSyncReplicas, and maxAsyncReplicas attributes affect where partitions and replicas are placed.

The following factors affect when shards can be placed:

- The **xscmd -c suspendBalancing** and **xscmd -c resumeBalancing** commands.
- The server properties file, which has the placementDeferralInterval property that defines the number of milliseconds before shards are placed on the container servers.
- The numInitialContainers attribute in the deployment policy.

If the maximum number of replicas are not placed during the initial startup, additional replicas might be placed if you start additional servers later. When you are planning the number of shards per JVM, the maximum number of primary and replica shards is dependent on having enough JVMs started to support the configured maximum number of replicas. A replica is never placed in the same process as its primary. If a process is lost, both the primary and the replica are lost. When the developmentMode attribute is set to `false`, the primary and replicas are not placed on the same physical server.

Partitioning

Use partitioning to scale out an application. You can define the number of partitions in your deployment policy.

About partitioning

Partitioning is not like Redundant Array of Independent Disks (RAID) striping, which slices each instance across all stripes. Each partition hosts the complete data for individual entries. Partitioning is a very effective means for scaling, but is not applicable to all applications. Applications that require transactional guarantees across large sets of data do not scale and cannot be partitioned effectively. WebSphere® eXtreme Scale does not currently support two-phase commit across partitions.

Important: Select the number of partitions carefully. The number of partitions that are defined in the deployment policy directly affects the number of container servers to which an application can scale. Each partition is made up of a primary shard and the configured number of replica shards. The `(Number_Partitions*(1 + Number_Replicas))` formula is the number of containers that can be used to scale out a single application.

Using partitions

A data grid can have up to thousands of partitions. A data grid can scale up to the number of partitions times the number of shards per partition. For example, if you have 16 partitions and each partition has one primary and one replica, or two shards, then you can potentially scale to 32 Java™ virtual machines. In this case, one shard is defined for each JVM. You must choose a reasonable number of partitions based on the expected number of Java virtual machines that you are likely to use. Each shard increases processor and memory usage for the system. The system is designed to scale out and handle this overhead based on the number Java virtual machines that are available.

Applications should not use thousands of partitions if the application runs on a data grid of four container server Java virtual machines. The application should be configured to have a reasonable number of shards for each container server JVM. For example, an unreasonable configuration is 2000 partitions with two shards that are running on four container Java virtual machines. This configuration results in 4000 shards that are placed on four container Java virtual machines or 1000 shards per container JVM.

A better configuration would be under 10 shards for each expected container JVM. This configuration still gives the possibility of allowing for elastic scaling that is ten times the initial configuration while keeping a reasonable number of shards per container JVM.

Consider this scaling example: you currently have six physical servers with two container Java virtual machines per physical server. You expect to grow to 20 physical servers over the next three years. With 20 physical servers, you have 40 container server Java virtual machines, and choose 60 to be pessimistic. You want four shards per container JVM. You have 60 potential containers, or a total of 240 shards. If you have a primary and replica per partition, then you want 120 partitions. Therefore, if you expect to scale to 20 computers, then 20 shards per container Java virtual machines are required (when 240 shards are divided by 12 container JVMs) for the initial deployment.

ObjectMap and partitioning

When you use the fixed partition placement strategy using the default value FIXED_PARTITIONS, maps are split across partitions and keys hash to different partitions. The client does not need to know to which partition the keys belong. If a mapSet has multiple maps, the maps should be committed in separate transactions.

Entities and partitioning

Entity manager entities have an optimization that helps clients that are working with entities on a server. The entity schema on the server for the map set can specify a single root entity. The client must access all entities through the root entity. The entity manager can then find related entities from that root in the same partition without requiring the related maps to have a common key. The root entity establishes affinity with a single partition. This partition is used for all entity fetches within the transaction after affinity is established. This affinity can save memory because the related maps do not require a common key. The root entity must be specified with a modified entity annotation as shown in the following example:

```
@Entity(schemaRoot=true)
```

Use the entity to find the root of the object graph. The object graph defines the relationships between one or more entities. Each linked entity must resolve to the same partition. All child entities are assumed to be in the same partition as the root. The child entities in the object graph are only accessible from a client from the root entity. Root entities are always required in partitioned environments when using an eXtreme Scale client to communicate to the server. Only one root entity type can be defined per client. Root entities are not required when using Extreme Transaction Processing (XTP) style ObjectGrids, because all communication to the partition is accomplished through direct, local access and not through the client and server mechanism.

Placement and partitions

You have two placement strategies available for WebSphere® eXtreme Scale: fixed partition and per-container. The choice of placement strategy affects how your deployment configuration places partitions over the remote data grid.

Fixed partition placement

You can set the placement strategy in the deployment policy XML file. The default placement strategy is fixed-partition placement, enabled with the `FIXED_PARTITIONS` setting. The number of primary shards that are placed across the available containers is equal to the number of partitions that you configured with the numberOfPartitions attribute. If you configured replicas, the minimum total number of shards that are placed is defined by the following formula: `((1 primary shard + minimum synchronous shards) * partitions defined)`. The maximum total number of shards that are placed is defined by the following formula: `((1 primary shard + maximum synchronous shards + maximum asynchronous shards) * partitions)`. Your

WebSphere eXtreme Scale deployment spreads these shards over the available containers. The keys of each map are hashed into assigned partitions that are based on the total partitions you defined. They keys hash to the same partition even if the partition moves because of failover or server changes.

For example, if the numberPartitions value is 6 and the minSync value is 1 for MapSet1, the total shards for that map set is 12 because each of the six partitions requires a synchronous replica. If three containers are started, WebSphere eXtreme Scale places four shards per container for MapSet1.

Per-container placement

The per-container placement strategy is enabled when you set the placementStrategy attribute to `PER_CONTAINER` in the map set element in the deployment XML file. With this strategy, the number of primary shards that are placed on each new container is equal to the number of partitions, *P*, that you configured. The WebSphere eXtreme Scale deployment environment places *P* replicas of each partition for each remaining container. The numInitialContainers setting is ignored when you are using per-container placement. The partitions get larger as the containers grow. The keys for maps are not fixed to a certain partition in this strategy. The client routes to a partition and uses a random primary. If a client wants to reconnect to the same session that it used to find a key again, it must use a session handle.

For more information, see SessionHandle for routing.

For failover or stopped servers, the WebSphere eXtreme Scale environment moves the primary shards in the per-container placement strategy if they still contain data. If the shards are empty, they are discarded. In the per-container strategy, old primary shards are not kept because new primary shards are placed for every container.

WebSphere eXtreme Scale allows per-container placement as an alternative to what could be termed the "typical" placement strategy, a fixed-partition approach with the key of a Map hashed to one of those partitions. In a per-container placement, your deployment places the partitions on the set of online container servers and automatically scales them out or in as containers are added or removed from the server data grid. A data grid with the fixed-partition approach works well for key-based grids, where the application uses a key object to locate data in the grid. The following discusses the alternative.

Example of a per-container data grid

Data grids that are configured to use a per-container placement strategy are different. You can specify that the data grid uses the per-container placement strategy by setting the placementStrategy attribute in your deployment XML file to PER_CONTAINER. Instead of configuring how many partitions total you want in the data grid, you specify how many partitions you want per container that you start.

For example, if you set five partitions per container, five new anonymous partition primaries are created when you start that container server, and the necessary replicas are created on the other deployed container servers.

The following is a potential sequence in a per-container environment as the data grid grows.

1. Start container C0 hosting five primaries (P0 - P4).
    - C0 hosts: P0, P1, P2, P3, P4.
2. Start container C1 hosting five more primaries (P5 - P9). Replicas are balanced on the containers.
    - C0 hosts: P0, P1, P2, P3, P4, R5, R6, R7, R8, R9.
    - C1 hosts: P5, P6, P7, P8, P9, R0, R1, R2, R3, R4.
3. Start container C2 hosting five more primaries (P10 - P14). Replicas are balanced further.
    - C0 hosts: P0, P1, P2, P3, P4, R7, R8, R9, R10, R11, R12.
    - C1 hosts: P5, P6, P7, P8, P9, R2, R3, R4, R13, R14.
    - C2 hosts: P10, P11, P12, P13, P14, R5, R6, R0, R1.

The pattern continues as more containers are started, creating five new primary partitions each time and rebalancing replicas on the available containers in the data grid.

Note: WebSphere eXtreme Scale does not move primary shards when the per-container placement strategy is used, only replicas.
The partition numbers are arbitrary and have nothing to do with keys, so you cannot use key-based routing. If a container stops, then the partition IDs created for that container are no longer used, so there is a gap in the partition IDs. In the example, there would no longer be partitions P5 - P9 if the container C1 failed, leaving only P0 - P4 and P10 - P14, so key-based hashing is impossible.

Using numbers like five or even more likely 10 for how many partitions per container work best if you consider the consequences of a container failure. To spread the load of hosting shards evenly across the data grid, you need more than just one partition for each container. If you had a single partition per container, then when a container fails, only one container (the one hosting the corresponding replica shard) must bear the full load of the lost primary. In this case, the load is immediately doubled for the container. However, if you have five partitions per container, then five containers pick up the load of the lost container, lowering impact on each by 80 percent. Using multiple partitions per container generally lowers the potential impact on each container substantially. More directly, consider a case in which a container spikes unexpectedly–the replication load of that container is spread over five containers rather than only one.

A per-container policy

Several scenarios make the per-container strategy an ideal configuration, such as with HTTP session replication or application session state. In such a case, an HTTP router assigns a session to a servlet container. The servlet container needs to create an HTTP session and chooses one of the five local partition primaries for the session. The "ID" of the partition that is chosen is then stored in a cookie. The servlet container now has local access to the session state, which means zero latency access to the data for this request as long as you maintain session affinity. And eXtreme Scale replicates any changes to the partition.

In practice, remember the repercussions of a case in which you have multiple partitions per container (say five again). With each new container started, you have five more partition primaries and five more replicas. Over time, more partitions should be created and they should not move or be destroyed. But this is not how the containers would behave. When a container starts, it hosts five primary shards, which can be called "home" primaries, existing on the respective containers that created them. If the container fails, the replicas become primaries and eXtreme Scale creates five more replicas to maintain high availability (unless you disabled auto repair). The new primaries are in a different container than the one that created them, which can be called "foreign" primaries. The application should never place new state or sessions in a foreign primary. Eventually, the foreign primary has no entries and eXtreme Scale automatically deletes it and its associated replicas. The foreign primaries' purpose is to allow existing sessions to still be available (but not new sessions).

A client can still interact with a data grid that does not rely on keys. The client just begins a transaction and stores data in the data grid independent of any keys. It asks the Session for a SessionHandle object, a serializable handle that allows the client to interact with the same partition when necessary. WebSphere eXtreme Scale chooses a partition for the client from the list of home partition primaries. It does not return a foreign primary partition. The SessionHandle can be serialized in an HTTP cookie, for example, and later convert the cookie back into a SessionHandle. Then, the WebSphere eXtreme Scale APIs can obtain a Session that is bound to the same partition with the SessionHandle.

Note: You cannot use agents to interact with a PER_CONTAINER data grid.

Advantages

The per-container placement strategy is different from a normal fixed partition or hash data grid because the client stores data in a place in the grid. The client gets a handle to it and uses the handle to access it again. There is no application-supplied key as there is in the fixed-partition placement strategy.

Your deployment does not make a new partition for each Session. So in a per-container deployment, the keys that are used to store data in the partition must be unique within that partition. For example, you can have your client generate a unique SessionID and then use it as the key to find information in Maps in that partition. Multiple client sessions then interact with the same partition so the application needs to use unique keys to store session data in each partition.

The previous examples used five partitions, but the numberOfPartitions parameter in the object grid XML file can be used to specify the partitions as required. Instead of per data grid, the setting is per container. (The number of replicas is specified in the same way as with the fixed-partition policy.)

The per-container policy can also be used with multiple zones. If possible, eXtreme Scale returns a SessionHandle to a partition whose primary is in the same zone as that client. The client can specify the zone as a parameter to the container or by using an API. The client zone ID can be set to serverproperties or clientproperties.

The per-container strategy for a data grid suits applications that store conversational type state rather than database-oriented data. The key to access the data would be a conversation ID and is not related to a specific database record. It provides higher performance (because the partition primaries can be collocated with the servlets for example) and easier configuration (without having to calculate partitions and containers).

Single-partition and cross-data-grid transactions

The major distinction between WebSphere® eXtreme Scale and traditional data storage solutions like relational databases or in-memory databases is the use of partitioning, which allows the cache to scale linearly. The important types of transactions to consider are single-partition and every-partition (cross-data-grid) transactions.

In general, interactions with the cache can be categorized as single-partition transactions or cross-data-grid transactions.

Single-partition transactions

Single-partition transactions are the preferable method for interacting with caches that are hosted by WebSphere eXtreme Scale. When a transaction is limited to a single partition, then by default it is limited to a single Java™ virtual machine, and therefore a single server computer. A server can complete *M* number of these transactions per second, and if you have *N* computers, you can complete `M*N` transactions per second. If your business increases and you need to perform twice as many of these transactions per second, you can double *N* by buying more computers. Then you can meet capacity demands without changing the application, upgrading hardware, or even taking the application offline.

In addition to letting the cache scale so significantly, single-partition transactions also maximize the availability of the cache. Each transaction only depends on one computer. Any of the other `(N-1)` computers can fail without affecting the success or response time of the transaction. So if you are running 100 computers and one of them fails, only 1 percent of the transactions in flight at the moment that server failed are rolled back. After the server fails, WebSphere eXtreme Scale relocates the partitions that are hosted by the failed server to the other 99 computers. During this brief period, before the operation completes, the other 99 computers can still complete transactions. Only the transactions that would involve the partitions that are being relocated are blocked. After the failover process is complete, the cache can continue running, fully operational, at 99 percent of its original throughput capacity. After the failed server is replaced and returned to the data grid, the cache returns to 100 percent throughput capacity.

Cross-data-grid transactions

In terms of performance, availability and scalability, cross-data-grid transactions are the opposite of single-partition transactions. Cross-data-grid transactions access every partition and therefore every computer in the configuration. Each computer in the data grid is asked to look up some data and then return the result. The transaction cannot complete until every computer has responded, and therefore the throughput of the entire data grid is limited by the slowest computer. Adding computers does not make the slowest computer faster and therefore does not improve the throughput of the cache.

Cross-data-grid transactions have a similar effect on availability. Extending the previous example, if you are running 100 servers and one server fails, then 100 percent of the transactions that are in progress at the moment that server failed are rolled back. After the server fails, WebSphere eXtreme Scale starts to relocate the partitions that are hosted by that server to the other 99 computers. During this time, before the failover process completes, the data grid cannot process any of these transactions. After the failover process is complete, the cache can continue running, but at reduced capacity. If each computer in the data grid serviced 10 partitions, then 10 of the remaining 99 computers receive at least one extra partition as part of the failover process. Adding an extra partition increases the workload of that computer by at least 10 percent. Because the throughput of the data grid is limited to the throughput of the slowest computer in a cross-data-grid transaction, on average, the throughput is reduced by 10 percent.

Single-partition transactions are preferable to cross-data-grid transactions for scaling out with a distributed, highly available, object cache like WebSphere eXtreme Scale. Maximizing the performance of these kinds of systems requires the use of techniques that are different from traditional relational methodologies, but you can turn cross-data-grid transactions into scalable single-partition transactions.

Best practices for building scalable data models

The best practices for building scalable applications with products like WebSphere eXtreme Scale include two categories: foundational principles and implementation tips. Foundational principles are core ideas that need to be captured in the design of the data itself. An application that does not observe these principles is unlikely to scale well, even for its mainline transactions. Implementation tips are applied for problematic transactions in an otherwise well-designed application that observes the general principles for scalable data models.

Foundational principles

Some of the important means of optimizing scalability are basic concepts or principles to keep in mind.

Duplicate instead of normalizing

The key thing to remember about products like WebSphere eXtreme Scale is that they are designed to spread data across a large number of computers. If the goal is to make most or all transactions complete on a single partition, then the data model design needs to ensure that all the data the transaction might need is in the partition. Most of the time, the only way to achieve this is by duplicating data.

For example, consider an application like a message board. Two important transactions for a message board are showing all the posts from a user and all the posts on a topic. First, consider how these transactions would work with a normalized data model that contains a user record, a topic record, and a post record that contains the actual text. If posts are partitioned with user records, then displaying the topic becomes a cross-grid transaction, and vice versa. Topics and users cannot be partitioned together because they have a many-to-many relationship.

The best way to make this message board scale is to duplicate the posts, storing one copy with the topic record and one copy with the user record. Then, displaying the posts from a user is a single-partition transaction, displaying the posts on a topic is a single-partition transaction, and updating or deleting a post is a two-partition transaction. All three of these transactions scale linearly as the number of computers in the data grid increases.

Scalability rather than resources

The biggest obstacle to overcome when you are considering denormalized data models is the impact that these models have on resources. Keeping two, three, or more copies of some data can seem to use too many resources to be practical. When you are confronted with this scenario, remember the following facts: Hardware resources get cheaper every year. Second, and more importantly, WebSphere eXtreme Scale eliminates most hidden costs that are associated with deploying more resources.

Measure resources in terms of cost rather than computer terms such as megabytes and processors. Data stores that work with normalized relational data generally must be on the same computer. This required collocation means that a single larger enterprise computer must be purchased rather than several smaller computers. With enterprise hardware, it is not uncommon for one computer that is capable of completing one million transactions per second to cost much more than the combined cost of 10 computers capable of doing 100,000 transactions per second each.

A business cost in adding resources also exists. A growing business eventually runs out of capacity. When you run out of capacity, you either need to shut down while moving to a bigger, faster computer, or create a second production environment to which you can switch. Either way, additional costs will come in the form of lost business or maintaining almost twice the capacity needed during the transition period.

With WebSphere eXtreme Scale, the application does not need to be shut down to add capacity. If your business projects that you need 10 percent more capacity for the coming year, then increase the number of computers in the data grid by 10 percent. You can increase this percentage without application downtime and without purchasing excess capacity.

Avoid data transformations

When you are using WebSphere eXtreme Scale, data should be stored in a format that is directly consumable by the business logic. Breaking the data down into a more primitive form is costly. The transformation needs to be done when the data is written and when the data is read. With relational databases, this transformation is done out of necessity because the data is ultimately persisted to disk frequently. With WebSphere eXtreme Scale, these transformations are not necessary. Usually, data is stored in memory and can therefore be stored in the exact form that the application needs.

Observing this simple rule helps denormalize your data in accordance with the first principle. The most common type of transformation for business data is the JOIN operations that are necessary to turn normalized data into a result set that fits the needs of the application. Storing the data in the correct format implicitly avoids performing these JOIN operations and produces a denormalized data model.

Eliminate unbounded queries

No matter how well you structure your data, unbounded queries do not scale well. For example, do not have a transaction that asks for a list of all items that are sorted by value. This transaction might work at first when the total number of items is 1000, but when the total number of items reaches 10 million, the transaction returns all 10 million items. If you run this transaction, the two most likely outcomes are the transaction timing out, or the client encounters an out-of-memory error.

The best option is to alter the business logic so that only the top 10 or 20 items can be returned. This logic alteration keeps the size of the transaction manageable no matter how many items are in the cache.

Define schema

The main advantage of normalizing data is that the database system can take care of data consistency behind the scenes. When data is denormalized for scalability, this automatic data consistency management no longer exists. You must implement a data model that can work in the application layer or as a plug-in to the distributed data grid to guarantee data consistency.

Consider the message board example. If a transaction removes a post from a topic, then the duplicate post on the user record must be removed. Without a data model, it is possible a developer might write the application code to remove the post from the topic and forget to remove the post from the user record. However, if the developer is using a data model instead of interacting with the cache directly, the removePost method on the data model pulls the user ID from the post, looks up the user record, and removes the duplicate post behind the scenes.

Alternately, you can implement a listener that runs on the actual partition that detects the change to the topic and automatically adjusts the user record. A listener might be beneficial because the adjustment to the user record might happen locally if the partition happens to have the user record. If the user record is on a different partition, the transaction takes place between servers instead of between the client and server. The network connection between servers is likely to be faster than the network connection between the client and the server.

Avoid contention

Avoid scenarios such as having a global counter. The data grid does not scale if a single record is being used a disproportionate number of times compared to the rest of the records. The performance of the data grid is limited by the performance of the computer that holds the record.

In these situations, try to break up the record so it is managed per partition. For example, consider a transaction that returns the total number of entries in the distributed cache. Instead of having every insert and remove operation access a single record that increments, have a listener on each partition track the insert and remove operations. With this listener tracking, insert and remove can become single-partition operations.

Reading the counter becomes a cross-data-grid operation. Usually, it was already as inefficient as a cross-data-grid operation because its performance was tied to the performance of the computer that is hosting the record.

Implementation tips

You can also consider the following tips to achieve the best scalability.

Use reverse-lookup indexes

Consider a properly denormalized data model where customer records are partitioned based on the customer ID number. This partitioning method is the logical choice because nearly every business operation that is performed with the customer record uses the customer ID number. However, an important transaction that does not use the customer ID number is the login transaction. It is more common to have user names or email addresses for login instead of customer ID numbers.

The simple approach to the login scenario is to use a cross-data-grid transaction to find the customer record. As explained previously, this approach does not scale.

The next option might be to partition on user name or email. This option is not practical because all the customer ID-based operations become cross-data-grid transactions. Also, the customers on your site might want to change their user name or email address. Products like WebSphere eXtreme Scale need the value that is used to partition the data to remain constant.

The correct solution is to use a reverse lookup index. With WebSphere eXtreme Scale, a cache can be created in the same distributed grid as the cache that holds all the user records. This cache is highly available, partitioned, and scalable. This cache can be used to map a user name or email address to a customer ID. This cache turns login into a two partition operation instead of a cross-grid operation. This scenario is not as good as a single-partition transaction, but the throughput still scales linearly as the number of computers increases.

Compute at write time

Commonly calculated values like averages or totals can be expensive to produce because these operations usually require reading a large number of entries. Because reads are more common than writes in most applications, it is efficient to compute these values at write time and then store the result in the cache. This practice makes read operations both faster and more scalable.

Optional fields

Consider a user record that holds a business, home, and telephone number. A user might have all, none or any combination of these numbers defined. If the data were normalized, then a user table and a telephone number table would exist. The telephone numbers for a user can be found with a JOIN operation between the two tables.

De-normalizing this record does not require data duplication, because most users do not share telephone numbers. Instead, empty slots in the user record must be allowed. Instead of having a telephone number table, add three attributes to each user record, one for each telephone number type. This addition of attributes eliminates the JOIN operation and makes a telephone number lookup for a user a single-partition operation.

Placement of many-to-many relationships

Consider an application that tracks products and the stores in which the products are sold. A single product is sold in many stores, and a single store sells many products. Assume that this application tracks 50 large retailers. Each product is sold in a maximum of 50 stores. Each store sells thousands of products.

Keep a list of stores inside the product entity (arrangement A), instead of keeping a list of products inside each store entity (arrangement B). Looking at some of the transactions this application must run illustrates why arrangement A is more scalable.

First look at updates. With arrangement A, removing a product from the inventory of a store locks the product entity. If the data grid holds 10000 products, only 1/10000 of the grid must be locked to complete the update. With arrangement B, the data grid only contains only 50 stores, so 1/50 of the data grid must be locked to complete the update. So even though both of these updates might be considered single-partition operations, arrangement A scales out more efficiently.

Now, considering reads with arrangement A, looking up the stores at which a product is sold is a single-partition transaction that scales and is fast because the transaction only transmits a small amount of data. With arrangement B, this transaction becomes a cross-data-grid transaction because each store entity must be accessed to see if the product is sold at that store, which reveals an enormous performance advantage for arrangement A.

Scaling with normalized data

One legitimate use of cross-data-grid transactions is to scale data processing. If a data grid has 5 computers and a cross-data-grid transaction is dispatched that sorts through about 100,000 records on each computer, then that transaction sorts through 500,000 records. If the slowest computer in the data grid can perform 10 of these transactions per second, then the data grid is capable of sorting through 5,000,000 records per second. If the data in the grid doubles, then each computer must sort through 200,000 records, and each transaction sorts through 1,000,000 records. This data increase decreases the throughput of the slowest computer to 5 transactions per second, reducing the throughput of the data grid to 5 transactions per second. Still, the data grid sorts through 5,000,000 records per second.

In this scenario, doubling the number of computers allows each computer to return to its previous load of sorting through 100,000 records, allowing the slowest computer to process 10 of these transactions per second. The throughput of the data grid stays the same at 10 requests per second, but now each transaction processes 1,000,000 records. As a result, the data grid doubled its capacity in terms of processing records to 10,000,000 per second.

Applications such as a search engine that needs to scale both in terms of data processing to accommodate the increasing size of the Internet and throughput to accommodate growth in the number of users, you must create multiple data grids, with a round robin of the requests between the data grids. If you must scale up the throughput, add computers and add another data grid to service requests. If data processing must be scaled up, add more computers and keep the number of data grids constant.

Scaling in units or pods

Although you can deploy a data grid over thousands of Java virtual machines, you might consider splitting the data grid into units or pods to increase the reliability and ease of testing of your configuration. A pod is a group of servers that is running the same set of applications.

Deploying a large single data grid

Testing has verified that eXtreme Scale can scale out to over 1000 JVMs. Such testing encourages building applications to deploy single data grids on large numbers of boxes. Although it is possible to do this, it is not recommended, for several reasons:

1. **Budget concerns:** Your environment cannot realistically test a 1000-server data grid. However, it can test a much smaller data grid considering budget reasons, so you do not need to buy twice the hardware, especially for such a large number of servers.
2. **Different application versions:** Requiring a large number of boxes for each testing thread is not practical. The risk is that you are not testing the same factors as you would in a production environment.
3. **Data loss:** Running a database on a single hard drive is unreliable. Any problem with the hard drive causes you to lose data. Running a growing application on a single data grid is similar. You will likely have bugs in your environment and in your applications. So placing all of the data on a single large system will often lead to a loss of large amounts of data.

Splitting the data grid

Splitting the application data grid into pods (units) is a more reliable option. A pod is a group of servers that are running a homogenous application stack. Pods can be of any size, but ideally they should consist of about 20 physical servers. Instead of having 500 physical servers in a single data grid, you can have 25 pods of 20 physical servers. A single version of an application stack should run on a given pod, but different pods can have their own versions of an application stack.

Generally, an application stack considers levels of the following components.

- Operating system
- Hardware
- JVM
- WebSphere® eXtreme Scale version
- Application
- Other necessary components

A pod is a conveniently sized deployment unit for testing. Instead of having hundreds of servers for testing, it is more practical to have 20 servers. In this case, you are still testing the same configuration as you would have in production. Production uses grids with a maximum size of 20 servers, constituting a pod. You can stress-test a single pod and determine its capacity, number of users, amount of data, and transaction throughput. This makes planning easier and follows the standard of having predictable scaling at predictable cost.

Setting up a pod-based environment

In different cases, the pod does not necessarily have to have 20 servers. The purpose of the pod size is for practical testing. The size of a pod should be small enough that if a pod encounters problems in production, the fraction of transactions affected is tolerable.

Ideally, any bug impacts a single pod. A bug would only have an impact on four percent of the application transactions rather than 100 percent. In addition, upgrades are easier because they can be rolled out one pod at a time. As a result, if an upgrade to a pod creates problems, the user can switch that pod back to the prior level. Upgrades include any changes to the application, the application stack, or system updates. As much as possible, upgrades should only change a single element of the stack at a time to make problem diagnosis more precise.

To implement an environment with pods, you need a routing layer above the pods that is forwards and backwards compatible if pods get software upgrades. Also, you should create a directory that includes information about which pod has what data. You can use another eXtreme Scale data grid for this with a database behind it, preferably using the write-behind scenario.) This yields a two-tier solution. Tier 1 is the directory and is used to locate which pod handles a specific transaction. Tier 2 is composed of the pods themselves. When tier 1 identifies a pod, the setup routes each transaction to the correct server in the pod, which is usually the server holding the partition for the data used by the transaction. Optionally, you can also use a near cache on tier 1 to lower the impact associated with looking up the correct pod.

Using pods is slightly more complex than having a single data grid, but the operational, testing, and reliability improvements make it a crucial part of scalability testing.

Availability overview

- High availability
  With high availability, WebSphere® eXtreme Scale provides reliable data redundancy and detection of failures.
- Replicas and shards
  With eXtreme Scale, an in-memory database or shard can be replicated from one Java™ virtual machine (JVM) to another. A shard represents a partition that is placed on a container. Multiple shards that represent different partitions can exist on a single container. Each partition has an instance that is a primary shard and a configurable number of replica shards. The replica shards are either synchronous or asynchronous. The types and placement of replica shards are determined by eXtreme Scale using a deployment policy, which specifies the minimum and maximum number of synchronous and asynchronous shards.

High availability

With high availability, WebSphere® eXtreme Scale provides reliable data redundancy and detection of failures.

WebSphere eXtreme Scale self-organizes data grids of Java™ virtual machines into a loosely federated tree. The catalog service is at the root and core groups hold container servers are at the leaves of the tree. See Caching architecture: Maps, containers, clients, and catalogs for more information.

Important terms

- **Heartbeat**: A signal that is sent between servers to convey that they are running.
- **Quorum**: A group of catalog servers that communicate and conduct placement operations in the data grid. This group consists of all of the catalog servers in the data grid, unless you manually override the quorum mechanism with administrative actions.
- **Brownout**: A temporary loss of connectivity between one or more servers.
- **Blackout**: A permanent loss of connectivity between one or more servers.
- **Data center**: A geographically located group of servers that are generally connected with a local area network (LAN).
- **Zone**: A zone is a configuration option that is used to group servers together that share some physical characteristic. Examples of zones for a group of servers include: a data center, an area network, a building, or a floor of a building.
- **Network partition**: Two catalog servers act as primaries concurrently. Both servers make changes to the catalog server state, which leads to data corruption.

- Core groups
  A core group is a high availability domain of container servers. The catalog service places container servers into core groups of a limited size. A core group tries to detect the failure of its members. A single member of a core group is elected to be the core group leader. The core group leader periodically tells the catalog service that the core group is alive and reports any membership changes to the catalog service. A membership change might be a Java virtual machine (JVM) failure or a newly added JVM that joins the core group.
- High availability catalog service
  A catalog service domain is the data grid of catalog servers you are using, which retain topology information for all of the container servers in your eXtreme Scale environment. The catalog service controls balancing and routing for all clients.
- Catalog server quorums
  The catalog service domain is a fixed set of catalog server Java virtual machines (JVM). For the best performance, do not configure catalog service domains to span data centers. When the quorum mechanism is enabled, all the catalog servers in the quorum must be available and communicating with each other for placement operations to occur in the data grid. The catalog service responds to container server lifecycle events while the catalog service has quorum. These lifecycle events include the placement or removal of shards on a container server when the container server stops or starts. When a brownout scenario or other failure occurs, not all members of the quorum are available. So, you must override quorum because placement operations do not occur if the quorum is not available.
- Replication for availability
  Replication provides fault tolerance and increases performance for a distributed eXtreme Scale topology. Replication is enabled by associating backing maps with a map set.

Replication for availability

Replication provides fault tolerance and increases performance for a distributed eXtreme Scale topology. Replication is enabled by associating backing maps with a map set.

About map sets

A map set is a collection of maps that are categorized by a partition-key. This partition-key is derived from the key on the individual map by taking its hash modulo the number of partitions. If one group of maps within the map set has partition-key X, those maps are stored in a corresponding partition X in the data grid. If another group has partition-key Y, all of the maps are stored in partition Y, and so on. The data within the maps is replicated based on the policy defined on the map set. Replication occurs on distributed topologies.

Map sets are assigned the number of partitions and a replication policy. The map set replication configuration identifies the number of synchronous and asynchronous replica shards for the map set must in addition to the primary shard. For example, if one synchronous and one asynchronous replica exist, all of the BackingMaps that are assigned to the map set each have a replica shard distributed automatically within the set of available container server s for the data grid. The replication configuration can also enable clients to read data from synchronously replicated servers. This can spread the load for read requests over additional servers in the data grid. Replication has a programming model impact only when preloading the backing maps.

Map preloading

For a description of preloading methods, including client loaders, see Data preloading and warm-up.

Maps can be associated with Loaders. A loader is used to fetch objects when they cannot be found in the map (a cache miss) and also to write changes to a back-end when a transaction commits. Loaders can also be used for preloading data into a map. The preloadMap method of the Loader interface is called on each map when its corresponding partition in the map set becomes a primary. The preloadMap method is not called on replicas. It attempts to load all the intended

referenced data from the back-end into the map using the provided session. The relevant map is identified by the BackingMap argument that is passed to the preloadMap method.

```
void preloadMap(Session session, BackingMap backingMap) throws LoaderException;
```

Preloading in partitioned map set

Maps can be partitioned into N partitions. Maps can therefore be striped across multiple servers, with each entry identified by a key that is stored only on one of those servers. Very large maps can be held in a data grid because the application is no longer limited by the heap size of a single JVM to hold all the entries of a Map. Applications that want to preload with the preloadMap method of the Loader interface must identify the subset of the data that it preloads. A fixed number of partitions always exists. You can determine this number by using the following code example:

```
int numPartitions = backingMap.getPartitionManager().getNumOfPartitions();
int myPartition = backingMap.getPartitionId();
```

This code example shows that an application can identify the subset of the data to preload from the database. Applications must always use these methods even when the map is not initially partitioned. These methods allow flexibility: If the map is later partitioned by the administrators, then the loader continues to work correctly.
The application must issue queries to retrieve the *myPartition* subset from the backend. If a database is used, then it might be easier to have a column with the partition identifier for a given record unless there is some natural query that allows the data in the table to partition easily.

Performance

The preload implementation copies data from the back-end into the map by storing multiple objects in the map in a single transaction. The optimal number of records to store per transaction depends on several factors, including complexity and size. For example, after the transaction includes blocks of more than 100 entries, the performance benefit decreases as you increase the number of entries. To determine the optimal number, begin with 100 entries and then increase the number until the performance benefit decreases to none. Larger transactions result in better replication performance. Remember, only the primary runs the preload code. The preloaded data is replicated from the primary to any replicas that are online.

Preloading map sets

If the application uses a map set with multiple maps then each map has its own loader. Each loader has a preload method. Each map is loaded serially by the data grid. It might be more efficient to preload all the maps by designating a single map as the preloading map. This process is an application convention. For example, two maps, department and employee, might use the department Loader to preload both the department and the employee maps. This procedure ensures that, transactionally, if an application wants a department then the employees for that department are in the cache. When the department Loader preloads a department from the back-end, it also fetches the employees for that department. The department object and its associated employee objects are then added to the map using a single transaction.

Recoverable preloading

Some customers have very large data sets that need caching. Preloading this data can be very time consuming. Sometimes, the preloading must complete before the application can go online. You can benefit from making preloading recoverable. Suppose there are a million records to preload. The primary is preloading them and fails at the 800,000th record. Normally, the replica chosen to be the new primary clears any replicated state and starts from the beginning. eXtreme Scale can use a ReplicaPreloadController interface. The loader for the application would also need to implement the ReplicaPreloadController interface. This example adds a single method to the Loader: `Status checkPreloadStatus(Session session, BackingMap bmap);`. This method is called by the eXtreme Scale run time before the preload method of the Loader interface is normally called. The eXtreme Scale tests the result of this method (Status) to determine its behavior whenever a replica is promoted to a primary.

Table 1. Status value and response

Returned status value	eXtreme Scale response
Status.PRELOADED_ALREADY	eXtreme Scale does not call the preload method at all because this status value indicates that the map is fully preloaded.
Status.FULL_PRELOAD_NEEDED	eXtreme Scale clears the map and calls the preload method normally.
Status.PARTIAL_PRELOAD_NEEDED	eXtreme Scale leaves the map as-is and calls preload. This strategy allows the application loader to continue preloading from that point onwards.

Clearly, while a primary is preloading the map, it must leave some state in a map in the map set that is being replicated so that the replica determines what status to return. You can use an extra map named, for example, RecoveryMap. This RecoveryMap must be part of the same map set that is being preloaded to ensure that the map is replicated consistently with the data being preloaded. A suggested implementation follows.

As the preload commits each block of records, the process also updates a counter or value in the RecoveryMap as part of that transaction. The preloaded data and the RecoveryMap data are replicated atomically to the replicas. When the replica is promoted to primary, it can now check the RecoveryMap to see what has happened.

The RecoveryMap can hold a single entry with the state key. If no object exists for this key then you need a full preload (checkPreloadStatus returns FULL_PRELOAD_NEEDED). If an object exists for this state key and the value is COMPLETE, the preload completes, and the checkPreloadStatus method returns PRELOADED_ALREADY. Otherwise, the value object indicates where the preload restarts and the checkPreloadStatus method returns: `PARTIAL_PRELOAD_NEEDED`. The loader can store the recovery point in an instance variable for the loader so that when preload is called, the loader knows the starting point. The RecoveryMap can also hold an entry per map if each map is preloaded independently.

Handling recovery in synchronous replication mode with a Loader

The runtime is designed not to lose committed data when the primary fails. The following section shows the algorithms used. These algorithms apply only when a replication group uses synchronous replication. A loader is optional.

The runtime can be configured to replicate all changes from a primary to the replicas synchronously. When a synchronous replica is placed, it receives a copy of the existing data on the primary shard. During this time, the primary continues to receive transactions and copies them to the replica asynchronously. The replica is not considered to be online at this time.

After the replica catches up the primary, the replica enters peer mode and synchronous replication begins. Every transaction committed on the primary is sent to the synchronous replicas and the primary waits for a response from each replica. A synchronous commit sequence with a Loader on the primary looks like the following set of steps:

Table 2. Commit sequence on the primary

Step with loader	Step without loader
Get locks for entries	same
Flush changes to the loader	no-op
Save changes to the cache	same
Send changes to replicas and wait for acknowledgment	same
Commit to the loader through the TransactionCallback plug-in	Plug-in commit called, but does nothing
Release locks for entries	same

Notice that the changes are sent to the replica before they are committed to the loader. To determine when the changes are committed on the replica, revise this sequence: At initialize time, initialize the tx lists on the primary as below.

```
CommitedTx = {}, RolledBackTx = {}
```

During synchronous commit processing, use the following sequence:

Table 3. Synchronous commit processing

Step with loader	Step without loader
Get locks for entries	same
Flush changes to the loader	no-op
Save changes to the cache	same
Send changes with a committed transaction, roll back transaction to replica, and wait for acknowledgment	same
Clear list of committed transactions and rolled back transactions	same
Commit the loader through the TransactionCallBack plug-in	TransactionCallBack plug-in commit is still called, but typically does not do anything
If commit succeeds, add the transaction to the committed transactions, otherwise add to the rolled back transactions	no-op
Release locks for entries	same

For replica processing, use the following sequence:

1. Receive changes
2. Commit all received transactions in the committed transaction list
3. Roll back all received transactions in the rolled back transaction list
4. Start a transaction or session
5. Apply changes to the transaction or session
6. Save the transaction or session to the pending list
7. Send back reply

Notice that on the replica, no loader interactions occur while the replica is in replica mode. The primary must push all changes through the Loader. The replica does not push any changes. A side effect of this algorithm is that the replica always has the transactions, but they are not committed until the next primary transaction sends the commit status of those transactions. The transactions are then committed or rolled back on the replica. Until then, the transactions are not committed. You can add a timer on the primary that sends the transaction outcome after a small period (a few seconds). This timer limits, but does not eliminate, any staleness to that time window. This staleness is only a problem when using replica read mode. Otherwise, the staleness does not have an impact on the application.

When the primary fails, it is likely that a few transactions were committed or rolled back on the primary, but the message never made it to the replica with these outcomes. When a replica is promoted to the new primary, one of the first actions is to handle this condition. Each pending transaction is reprocessed against the new primary's set of maps. If there is a Loader, then each transaction is given to the Loader. These transactions are applied in strict first in first out (FIFO) order. If a transaction fails, it is ignored. If three transactions are pending, A, B, and C, then A might commit, B might rollback, and C might also commit. No one transaction has any impact on the others. Assume that they are independent.

A loader might want to use slightly different logic when it is in failover recovery mode versus normal mode. The loader can easily know when it is in failover recovery mode by implementing the ReplicaPreloadController interface. The checkPreloadStatus method is only called when failover recovery completes. Therefore, if the apply method of the Loader interface is called before the checkPreloadStatus method, then it is a recovery transaction. After the checkPreloadStatus method is called, the failover recovery is complete.

Load balancing across replicas

The eXtreme Scale, unless configured otherwise, sends all read and write requests to the primary server for a given replication group. The primary must service all requests from clients. You might want to allow read requests to be sent to replicas of the primary. Sending read requests to the replicas allows the load of the read requests to be shared by multiple Java™ Virtual Machines (JVM). However, using replicas for read requests can result in inconsistent responses.

Load balancing across replicas is typically used only when clients are caching data that is changing all the time or when the clients are using pessimistic locking.

If the data is continually changing and then being invalidated in client near caches, the primary should see a relatively high get request rate from clients as a result. Likewise, in pessimistic locking mode, no local cache exists, so all requests are sent to the primary.

If the data is relatively static or if pessimistic mode is not used, then sending read requests to the replica does not have a large impact on performance. The frequency of get requests from clients with caches that are full of data is not high.

When a client first starts, its near cache is empty. Cache requests to the empty cache are forwarded to the primary. The client cache gets data over time, causing the request load to drop. If many clients start concurrently, then the load might be significant and replica read might be an appropriate performance choice.

Client-side replication

With eXtreme Scale, you can replicate a server map to one or more clients by using asynchronous replication. A client can request a local read-only copy of a server side map by using the ClientReplicableMap.enableClientReplication method.

```
void enableClientReplication(Mode mode, int[] partitions,
ReplicationMapListener listener) throws ObjectGridException;
```

The first parameter is the replication mode. This mode can be a continuous replication or a snapshot replication. The second parameter is an array of partition IDs that represent the partitions from which to replicate the data. If the value is null or an empty array, the data is replicated from all the partitions. The last parameter is a listener to receive client replication events. See ClientReplicableMap and ReplicationMapListener in the API documentation for details.

After the replication is enabled, then the server starts to replicate the map to the client. The client is eventually only a few transactions behind the server at any point in time.

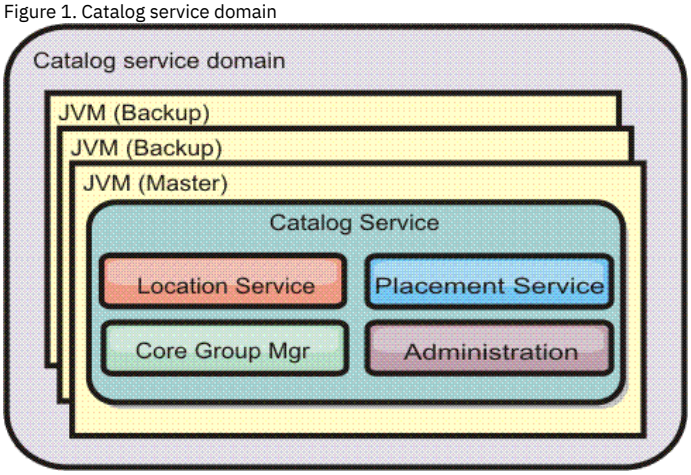
High availability catalog service

A catalog service domain is the data grid of catalog servers you are using, which retain topology information for all of the container servers in your eXtreme Scale environment. The catalog service controls balancing and routing for all clients.

For more information about catalog servers, see Catalog service.

Figure 1. Catalog service domain



When multiple catalog servers start, one of the servers is elected as the master catalog server that accepts heartbeats and handles system data changes in response to any catalog service or container changes.

When clients contact any one of the catalog servers, the routing table for the catalog service domain is propagated to the clients through the Common Object Request Broker Architecture (CORBA) service context.

Configure at least three catalog servers in the catalog service domain. Catalog servers must be installed on separate nodes or separate installation images from your container servers to ensure that you can seamlessly upgrade your servers at a later date. If your configuration has zones, you can configure one catalog server per zone.

When a container server contacts one of the catalog servers, the routing table for the catalog service domain is also propagated to the catalog server and container server through the CORBA service context. Furthermore, if the contacted catalog server is not currently the master catalog server, the request is

automatically rerouted to the current master catalog server and the routing table for the catalog server is updated.

Note: A catalog service domain and the container server data grid are very different. The catalog service domain is for high availability of your system data. The container server data grid is for your data high availability, scalability, and workload management. Therefore, two different routing tables exist: the routing table for the catalog service domain and the routing table for the container server data grid shards.

Catalog service domain heart-beating

The catalog service domain looks like a private core group with a static membership and a quorum mechanism. It detects failures the same way as a normal core group. However, the behavior is modified to include quorum logic. The catalog service also uses a less aggressive heart-beating configuration.

Catalog server quorums

The catalog service domain is a fixed set of catalog server Java virtual machines (JVM). For the best performance, do not configure catalog service domains to span data centers. When the quorum mechanism is enabled, all the catalog servers in the quorum must be available and communicating with each other for placement operations to occur in the data grid. The catalog service responds to container server lifecycle events while the catalog service has quorum. These lifecycle events include the placement or removal of shards on a container server when the container server stops or starts. When a brownout scenario or other failure occurs, not all members of the quorum are available. So, you must override quorum because placement operations do not occur if the quorum is not available.

Failure classification

Single failure: When the failure of one container server or catalog server occurs in the environment, it is considered to be a single failure event. When a single failure event occurs, recovery can occur without data loss.

Double failure: When two failures of any server processes occur simultaneously, data loss can occur on the second failure. Because of the second failure, applications might lose write access to the data that was stored on the failed container server. To prevent double failures, you can isolate components of the data grid from each other. For more information, see Zones.

Quorum loss

If the catalog service loses quorum, it waits for quorum to be reestablished. While the catalog service does not have quorum, it ignores lifecycle events from catalog and container servers.

WebSphere® eXtreme Scale expects to lose quorum for the following scenarios:

- **A catalog server fails**
  A catalog server that fails causes quorum to be lost. If a JVM fails, quorum can be reestablished by either overriding quorum or by restarting the failed catalog server.
- **Brownout occurs**
  A brownout is when a temporary loss of connectivity occurs. Brownouts are transient and clear within seconds or minutes. Brownouts can be frequent and repeated depending on the cause. Brownouts can be caused by network partitions, long garbage collection pauses, operating system level swapping, or disk I/O problems. Quorum is the mechanism for reacting to brownouts in the catalog server that are long enough to cause heartbeat failures. While the product tries to maintain normal operation during the brownout period, a brownout is regarded as a single failure event. The failure is expected to be fixed and then normal operation resumes with no actions necessary.

WebSphere eXtreme Scale does not lose quorum when a catalog server is stopped with the stop command or any other administrative actions. The system knows that the server instance stopped, which is different from a JVM failure or brownout. The quorum drops to one less server, preserving quorum. The remaining servers still have quorum. Restarting the catalog server sets quorum back to the previous number.

Client behavior during quorum loss

If the client can connect to a catalog server, the client can bootstrap to the data grid whether the catalog service domain has quorum or not. The client tries to connect to any catalog server instance to obtain a route table and then interact with the data grid. If no container failures or connectivity issues happen during the quorum loss event, then clients can still fully interact with the container servers.

Recovery after quorum is reestablished

If quorum is lost for any reason, when quorum is reestablished, a recovery protocol is run. When the quorum loss event occurs, all heartbeating for core groups is suspended and failure reports are also ignored. After quorum is back, any container server failures that occurred while quorum was lost are processed. Any shards that were hosted on container servers that were reported as failed are recovered. If primary shards were lost, then surviving replica shards become primary shards. If replica shards were lost, more replica shards are created.

Scenarios for overriding quorum

Quorum loss due to a catalog server failure or a network brownout recovers automatically after the catalog server is restarted or the network brownout ends. When intermittent failures are occurring, such as network instability, you must remove the problematic catalog servers by manually ending the catalog server processes. Then, you can override quorum.

When you override quorum, the catalog service assumes that quorum is achieved with the current membership. Container server lifecycle events are processed. When you run an override quorum command, you are informing the catalog service domain that the failed catalog servers do not have a chance of recovering.

The following list considers some scenarios for overriding quorum. In the configuration, you have three catalog servers: A, B, and C.

- **Brownout:** Brownout scenarios occur and are resolved fairly quickly. The C catalog server is isolated temporarily. The catalog service loses quorum and waits for the brownout to complete. After the brownout is over, the C catalog server rejoins the catalog service domain and quorum is reestablished. Your application sees no problems during this time. You do not need to take any administrative actions.
- **JVM process failure:** The JVM for the C catalog server fails and the catalog service loses quorum. You can override quorum immediately, which restarts the processing of container server lifecycle events. Then, diagnose why the C catalog server failed and resolve any issues. When you are sure that the problem is resolved, you can restart the C catalog server. The C catalog server joins the catalog service domain again when it restarts. Your application sees no problems during this time.
- **Problematic or repeated brownouts:** In this scenario, the A and B catalog servers are on one side of the network partition, while the C catalog server is on the other. You must be careful about when you override quorum in this scenario. You do not want to override quorum just as the brownout temporarily heals, and then have the brownout occur again. If this scenario were to occur, both sides of the network partition could become primary, causing a split brain condition.
- **Multiple failures:** During a failure scenario, catalog server C and one or more container servers are lost. Ensure that the failing servers are stopped. Then, override quorum. The surviving catalog servers use the remaining container servers to run a full recovery by replacing shards that were hosted in the failed container servers. The catalog service is now running with a full quorum of the A and B catalog servers. The application might see delays or exceptions during the interval between the start of the blackout and when quorum is overridden. After quorum is overridden, the data grid recovers and normal operation is resumed. If multiple containers were lost that included primary and all replica shards for particular partitions, data loss for those partitions occurs.

Majority quorum

For added flexibility to the standard quorum support in WebSphere eXtreme Scale, a new quorum type is available called majority quorum. In this quorum type, WebSphere eXtreme Scale does not leave quorum if there are greater than half the catalog servers still running. For example, if there are three catalog servers and one of them cannot communicate with the other two catalog servers, then the other two catalogs stay in quorum. The other two catalogs allow for placement changes to occur. If the other catalog rejoins the group, WebSphere eXtreme Scale tries to let it join dynamically if possible. Otherwise, the catalog is restarted so that it can properly rejoin the catalog cluster. Majority quorum automatically resolves catalog server failures on the majority side when a brownout event affects the catalog servers. Also, this quorum policy greatly reduces the need to recycle the catalogs that were partitioned when they rejoin. Even if the primary catalog server was partitioned, when it rejoins the cluster, the catalog server is merged back and only one primary remains in the cluster. To enable majority quorum, see Configuring the quorum mechanism. However, if you have four catalog servers and two are isolated, then there is no majority and WebSphere eXtreme Scale leaves quorum. Therefore, a majority quorum policy equates to`<number of catalog servers configured in a cluster>/2 +1`.

Note: If a brownout event occurs and affects container servers on the non-majority side, then the container servers need to be recycled when the brownout recovers. Also, if there are concerns of frequent and repeated brownouts within your environment, then standard quorum might prove to be a better option than majority quorum. This way, you can investigate and fix the environmental issue, rather than continually moving data around during repeated container error recovery.

Deciding on a quorum policy for your environment

Use the table to help you decide what type of quorum policy would make sense for your environment, or if you should enable quorum at all.

Quorum state	How does this policy behave during a brownout?	What is the motivation for usage?	Associated risks to consider
Standard	• All configured catalog cluster members need to be able to communicate with each other in order for placement changes to occur as a result of changes in container server lifecycle • Fully removes need to recycle catalogs.	Prevent under any circumstance the need to recycle the grid due to state corruption caused by catalogs that become divergent during periods where communication does not work.	Requires manual intervention to initiate any container failure recovery. This means failure placement will not occur until quorum is overridden. If a container is lost while quorum is violated, then the shards on that container are not available until quorum is overridden. If a client cannot reach a primary shard due to loss of the shard or network issues, it will not be able to update data. In cases where replicaReadEnabled is set to true, the client will not be able to access the data either, until quorum is overridden or reestablished.

Quorum state	How does this policy behave during a brownout?	What is the motivation for usage?	Associated risks to consider
None (No Quorum)	• When communication is broken between multiple catalog servers, each catalog can potentially promote itself as the primary. The result is a conflict on where various partitions can reside. The conflicts can also lead to inconsistent copies of customer data. • The catalog cluster state can also become corrupted in such scenarios, resulting in the need to recycle the catalogs. However, recycle can happen automatically depending on whether the container reconnect settings are enabled or disabled.	You should not manually intervene and let WebSphere eXtreme Scale recycle or shutdown catalogs automatically.	Catastrophic, repeated, insidious communication errors can lead to repeated data movement as a result of constant failure recovery. In worst cases, most of the grid must recycle to achieve consistency when environmental issues are fixed.

Replicas and shards

With eXtreme Scale, an in-memory database or shard can be replicated from one Java™ virtual machine (JVM) to another. A shard represents a partition that is placed on a container. Multiple shards that represent different partitions can exist on a single container. Each partition has an instance that is a primary shard and a configurable number of replica shards. The replica shards are either synchronous or asynchronous. The types and placement of replica shards are determined by eXtreme Scale using a deployment policy, which specifies the minimum and maximum number of synchronous and asynchronous shards.

Shard types

Replication uses three types of shards:

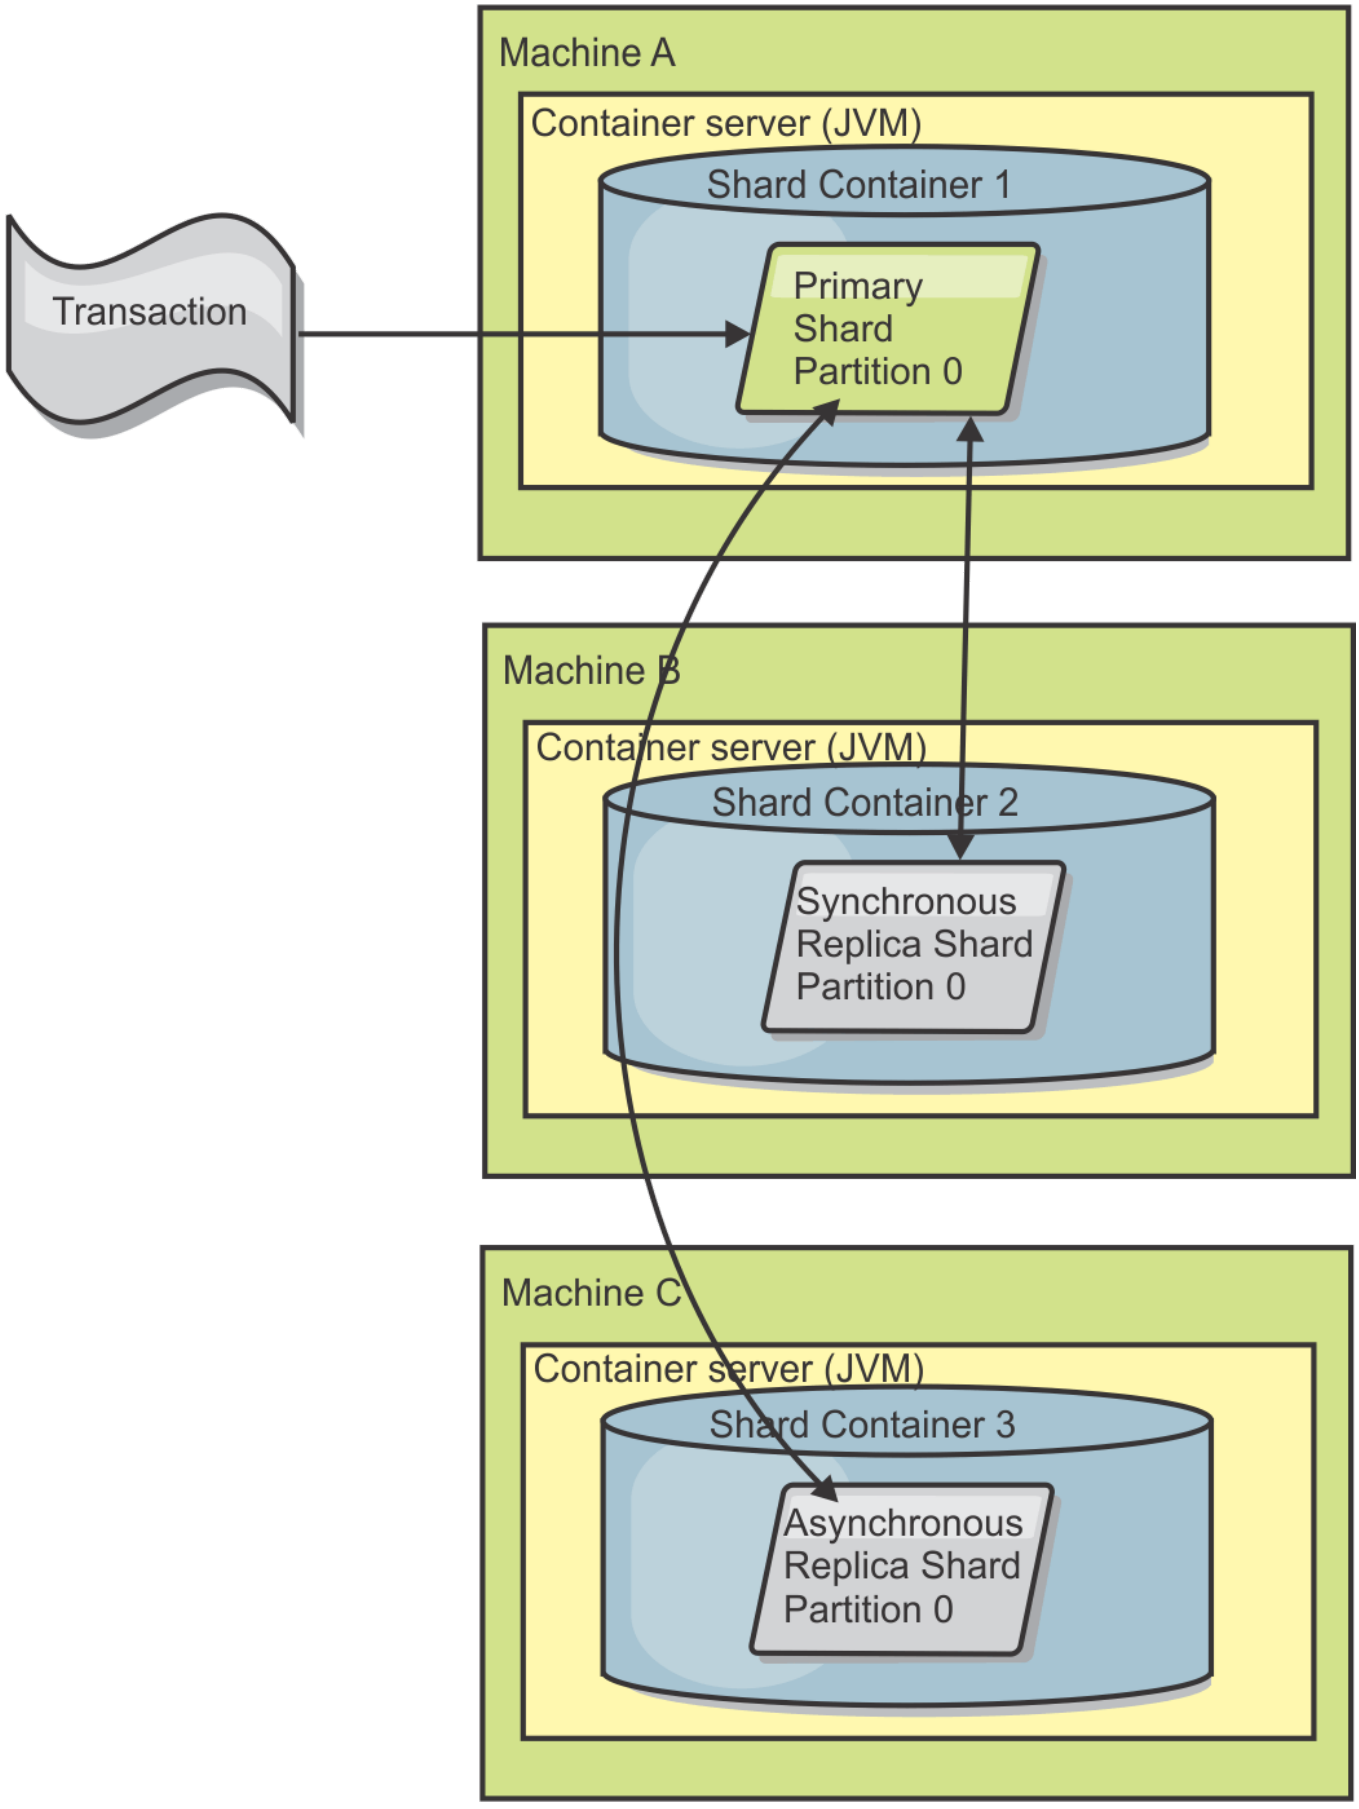
- Primary
- Synchronous replica
- Asynchronous replica

The primary shard receives all insert, update and remove operations. The primary shard adds and removes replicas, replicates data to the replicas, and manages commits and rollbacks of transactions.

Synchronous replicas maintain the same state as the primary. When a primary replicates data to a synchronous replica, the transaction is not committed until it commits on the synchronous replica.

Asynchronous replicas might or might not be at the same state as the primary. When a primary replicates data to an asynchronous replica, the primary does not wait for the asynchronous replica to commit.

Figure 1. Communication path between a primary shard and replica shards



Minimum synchronous replica shards

When a primary prepares to commit data, it checks how many synchronous replica shards voted to commit the transaction. If the transaction processes normally on the replica, it votes to commit. If something went wrong on the synchronous replica, it votes not to commit. Before a primary commits, the number of synchronous replica shards that are voting to commit must meet the minSyncReplica setting from the deployment policy. When the number of synchronous replica shards that are voting to commit is too low, the primary does not commit the transaction and an error results. This action ensures that the required number of synchronous replicas are available with the correct data. Synchronous replicas that encountered errors reregister to fix their state. For more information about reregistering, see Replica shard recovery.

The primary throws a ReplicationVotedToRollbackTransactionException error if too few synchronous replicas voted to commit.

Replication and Loaders

Normally, a primary shard writes changes synchronously through the Loader to a database. The Loader and database are always in sync. When the primary fails over to a replica shard, the database and Loader might not be in synch. For example:

- The primary can send the transaction to the replica and then fail before committing to the database.
- The primary can commit to the database and then fail before sending to the replica.

Either approach leads to either the replica being one transaction in front of or behind the database. This situation is not acceptable. eXtreme Scale uses a special protocol and a contract with the Loader implementation to solve this issue without two phase commit. The protocol follows:

Primary side

- Send the transaction along with the previous transaction outcomes.
- Write to the database and try to commit the transaction.
- If the database commits, then commit on eXtreme Scale. If the database does not commit, then roll back the transaction.
- Record the outcome.

Replica side

- Receive a transaction and buffer it.
- For all outcomes, send with the transaction, commit any buffered transactions and discard any rolled back transactions.

Replica side on failover

- For all buffered transactions, provide the transactions to the Loader and the Loader attempts to commit the transactions.
- The Loader needs to be written to make each transaction is idempotent.
- If the transaction is already in the database, then the Loader performs no operation.
- If the transaction is not in the database, then the Loader applies the transaction.
- After all transactions are processed, then the new primary can begin to serve requests.

This protocol ensures that the database is at the same level as the new primary state.

Replica behavior during failures

Synchronous replica behavior

The primary shard can accept new transactions during brownout or blackout conditions if the number of replicas online is at least at the minsync property value for the map set. If any new transactions are processed on the primary shard while the link to the synchronous replica is broken, the replica is resynchronized with the current state of the primary when the link is reestablished.

Attention: Do not configure synchronous replication between data centers or over a WAN-style link.
Asynchronous replica behavior

While the connection is broken, the primary shard can accept new transactions. The primary shard buffers the changes up to a limit. If the connection with the replica is reestablished before that limit is reached, then the replica is updated with the buffered changes. If the limit is reached, then the primary deletes the buffered list and when the replica reattaches then it is cleared and resynchronized.

- Shard placement
  The catalog service is responsible for placing shards. Each ObjectGrid has a number of partitions, each of which has a primary shard and an optional set of replica shards. The catalog service allocates the shards by balancing them so that they are evenly distributed over the available container servers. Replica and primary shards for the same partition are never placed on the same container server or the same IP address, unless the configuration is in development mode.
- Reading from replicas
  You can configure map sets such that a client is permitted to read from a replica rather than being restricted to primary shards only.
- Load balancing across replicas
  Load balancing across replicas is typically used only when clients are caching data that is changing all the time or when the clients are using pessimistic locking.
- Shard lifecycles
  Shards go through different states and events to support replication. The lifecycle of a shard includes coming online, run time, shut down, fail over and error handling. Shards can be promoted from a replica shard to a primary shard to handle server state changes.
- Map sets for replication
  Replication is enabled by associating BackingMaps with a map set.

Shard placement

The catalog service is responsible for placing shards. Each ObjectGrid has a number of partitions, each of which has a primary shard and an optional set of replica shards. The catalog service allocates the shards by balancing them so that they are evenly distributed over the available container servers. Replica and primary shards for the same partition are never placed on the same container server or the same IP address, unless the configuration is in development mode.

If a new container server starts, then eXtreme Scale retrieves shards from relatively overloaded container servers to the new empty container server. This movement of shards enables horizontal scaling.

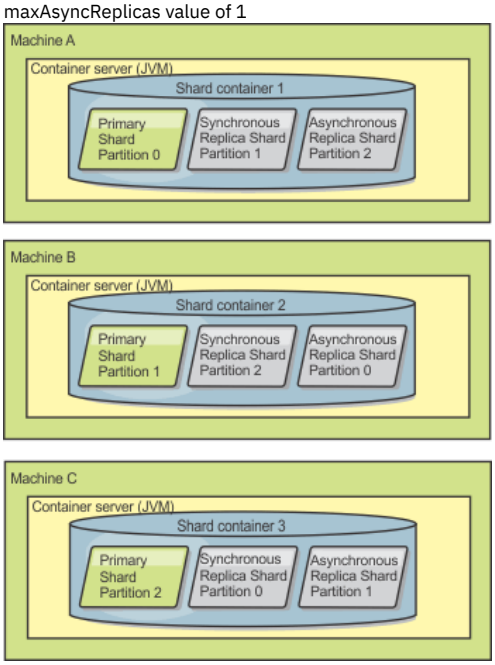
Scaling out

Scaling out means that when extra container servers are added to a data grid, eXtreme Scale tries to move existing shards, primaries or replicas, from the old set of container servers to the new set. This movement expands the data grid to take advantage of the processor, network and memory of the newly added container servers. The movement also balances the data grid and tries to ensure that each JVM in the data grid hosts the same amount of data. As the data grid expands, each server hosts a smaller subset of the total grid. eXtreme Scale assumes that data is distributed evenly among the partitions. This expansion enables scaling out.

Scaling in

Scaling in means that if a JVM fails, then eXtreme Scale tries to repair the damage. If the failed JVM had a replica, then eXtreme Scale replaces the lost replica by creating a new replica on a surviving JVM. If the failed JVM had a primary, then eXtreme Scale finds the best replica on the survivors and promotes the replica to be the new primary. eXtreme Scale then replaces the promoted replica with a new replica that is created on the remaining servers. To maintain scalability, eXtreme Scale preserves the replica count for partitions as servers fail.

Figure 1. Placement of an ObjectGrid map set with a deployment policy of 3 partitions with a minSyncReplicas value of 1, a maxSyncReplicas value of 1, and a maxAsyncReplicas value of 1



Reading from replicas

You can configure map sets such that a client is permitted to read from a replica rather than being restricted to primary shards only.

It can often be advantageous to allow replicas to serve as more than simply potential primaries in the case of failures. For example, map sets can be configured to allow read operations to be routed to replicas by setting the replicaReadEnabled option on the MapSet to true. The default setting is false.

For more information on the MapSet element, see Deployment policy descriptor XML file.

Enabling reading of replicas can improve performance by spreading read requests to more Java™ virtual machines. If the option is not enabled, all read requests such as the ObjectMap.get or the Query.getResultIterator methods are routed to the primary. When replicaReadEnabled is set to true, some get requests might return stale data, so an application using this option must be able to tolerate this possibility. However, a cache miss will not occur. If the data is not on the replica, the get request is redirected to the primary and tried again.

The replicaReadEnabled option can be used with both synchronous and asynchronous replication.

Load balancing across replicas

Load balancing across replicas is typically used only when clients are caching data that is changing all the time or when the clients are using pessimistic locking.

The eXtreme Scale, unless configured otherwise, sends all read and write requests to the primary server for a given replication group. The primary must service all requests from clients. You might want to allow read requests to be sent to replicas of the primary. Sending read requests to the replicas allows the load of the read requests to be shared by multiple Java™ Virtual Machines (JVM). However, using replicas for read requests can result in inconsistent responses.

Load balancing across replicas is typically used only when clients are caching data that is changing all the time or when the clients are using pessimistic locking.

If the data is continually changing and then being invalidated in client near caches, the primary should see a relatively high get request rate from clients as a result. Likewise, in pessimistic locking mode, no local cache exists, so all requests are sent to the primary.

If the data is relatively static or if pessimistic mode is not used, then sending read requests to the replica does not have a big impact on performance. The frequency of get requests from clients with caches that are full of data is not high.

When a client first starts, its near cache is empty. Cache requests to the empty cache are forwarded to the primary. The client cache gets data over time, causing the request load to drop. If a large number of clients start concurrently, then the load might be significant and replica read might be an appropriate performance choice.

Shard lifecycles

Shards go through different states and events to support replication. The lifecycle of a shard includes coming online, run time, shut down, fail over and error handling. Shards can be promoted from a replica shard to a primary shard to handle server state changes.

Lifecycle events

When primary and replica shards are placed and started, they go through a series of events to bring themselves online and into listening mode.

Primary shard

The catalog service places a primary shard for a partition. The catalog service also does the work of balancing primary shard locations and initiating failover for primary shards.

When a shard becomes a primary shard, it receives a list of replicas from the catalog service. The new primary shard creates a replica group and registers all the replicas.

When the primary is ready, an open for business message displays in the SystemOut.log file for the container on which it is running. The open message, or the CWOBJ1511I message, lists the map name, map set name, and partition number of the primary shard that started.

```
CWOBJ1511I: mapName:mapSetName:partitionNumber (primary) is open for business.
```

See Shard placement for more information on how the catalog service places shards.

Replica shard

Replica shards are mainly controlled by the primary shard unless the replica shard detects a problem. During a normal lifecycle, the primary shard places, registers, and de-registers a replica shard.

When the primary shard initializes a replica shard, a message displays the log that describes where the replica runs to indicate that the replica shard is available. The open message, or the CWOBJ1511I message, lists the map name, map set name, and partition number of the replica shard. This message follows:

```
CWOBJ1511I: mapName:mapSetName:partitionNumber (synchronous replica) is open for business.
```

or

```
CWOBJ1511I: mapName:mapSetName:partitionNumber (asynchronous replica) is open for business.
```

Asynchronous replica shard: An asynchronous replica shard polls the primary for data. The replica automatically will adjust the poll timing if it does not receive data from the primary, which indicates that it is caught up with the primary. It also will adjust if it receives an error that might indicate that the primary has failed, or if there is a network problem.

When the asynchronous replica starts replicating, it prints the following message to the SystemOut.log file for the replica. This message might print more than one time per CWOBJ1511 message. It will print again if the replica connects to a different primary or if template maps are added.

```
CWOBJ1543I: The asynchronous replica objectGridName:mapsetName:partitionNumber started or
continued replicating from the primary. Replicating for maps: [mapName]
```

Synchronous replica shard: When the synchronous replica shard first starts, it is not yet in peer mode. When a replica shard is in peer mode, it receives data from the primary as data comes into the primary. Before entering peer mode, the replica shard needs a copy of all of the existing data on the primary shard.

The synchronous replica copies data from the primary shard similar to an asynchronous replica by polling for data. When it copies the existing data from the primary, it switches to peer mode and begins to receive data as the primary receives the data.

When a replica shard reaches peer mode, it prints a message to the SystemOut.log file for the replica. The time refers to the amount of time that it took the replica shard to get all of its initial data from the primary shard. The time might display as zero or very low if the primary shard does not have any existing data to replicate. This message may print more than one time per CWOBJ1511 message. It will print again if the replica connects to a different primary or if template maps are added.

```
CWOBJ1526I: Replica objectGridName:mapsetName:partitionNumber:mapName entering peer
mode after X seconds.
```

When the synchronous replica shard is in peer mode, the primary shard must replicate transactions to all peer mode synchronous replicas. The synchronous replica shard data remains at the same level as the primary shard data. If a minimum number of synchronous replicas or minSync is set in the deployment policy, that number of synchronous replicas must vote to commit before the transaction can successfully commit on the primary.

Recovery events

Replication is designed to recover from failure and error events. If a primary shard fails, another replica takes over. If errors are on the replica shards, the replica shard attempts to recover. The catalog service controls the placement and transactions of new primary shards or new replica shards.

Replica shard becomes a primary shard

A replica shard becomes a primary shard for two reasons. Either the primary shard stopped or failed, or a balance decision was made to move the previous primary shard to a new location.

The catalog service selects a new primary shard from the existing synchronous replica shards. If a primary move needs to take place and there are no replicas, a temporary replica will be placed to complete the transition. The new primary shard registers all of the existing replicas and accepts transactions as the new primary shard. If the existing replica shards have the correct level of data, the current data is preserved as the replica shards register with the new primary shard. Asynchronous replicas will poll against the new primary.

Figure 1. Example placement of an ObjectGrid map set for the partition0 partition. The deployment policy has a minSyncReplicas value of 1, a maxSyncReplicas value of 2, and a maxAsyncReplicas value of 1.

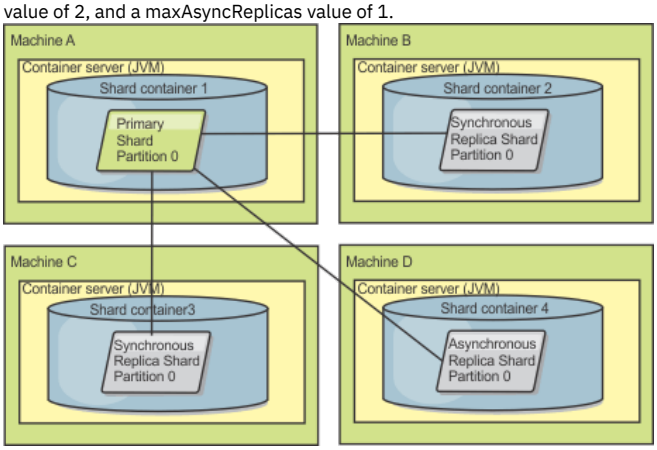


Figure 2. The container for the primary shard fails

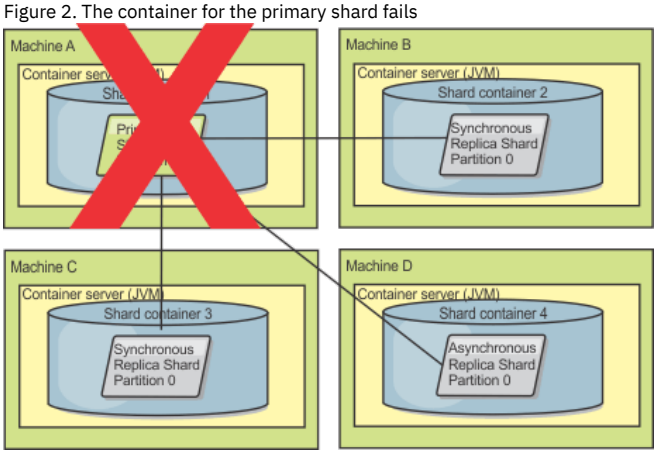

Figure 3. The synchronous replica shard on ObjectGrid container 2 becomes the primary shard

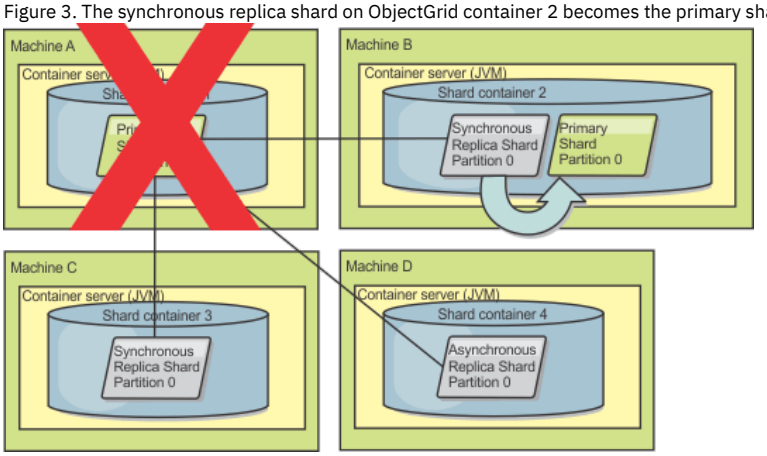

Figure 4. Machine B contains the primary shard. Depending on how automatic repair mode is set and the availability of the containers, a new synchronous replica shard might or might not be placed on a machine.

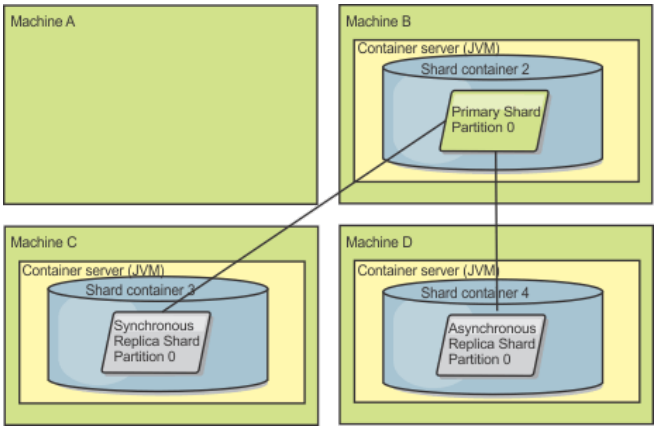

Replica shard recovery

A synchronous replica shard is controlled by the primary shard. However, if a replica shard detects a problem, it can trigger a reregister event to correct the state of the data. The replica clears the current data and gets a fresh copy from the primary.

When a replica shard initiates a reregister event, the replica prints a log message.

```
CWOBJ1524I: Replica listener
objectGridName:mapSetName:partition must re-register with the primary.
Reason: Exception listed
```

If a transaction causes an error on a replica shard during processing, then the replica shard is in an unknown state. The transaction successfully processed on the primary shard, but something went wrong on the replica. To correct this situation, the replica initiates a reregister event. With a new copy of data from the primary, the replica shard can continue. If the same problem reoccurs, the replica shard does not continuously reregister. See Failure events for more details.

Failure events

A replica can stop replicating data if it encounters error situations for which the replica cannot recover.

Too many register attempts

If a replica triggers a reregister multiple times without successfully committing data, the replica stops. Stopping prevents a replica from entering an endless reregister loop. By default, a replica shard tries to reregister three times in a row before stopping.

If a replica shard reregisters too many times, it prints the following message to the log.

```
CWOBJ1537E: objectGridName:mapSetName:partition exceeded the maximum number
of times to reregister (timesAllowed) without successful transactions..
```

If the replica is unable to recover by reregistering, a pervasive problem might exist with the transactions that are relative to the replica shard. A possible problem could be missing resources on the classpath if an error occurs while inflating the keys or values from the transaction.

Failure while entering peer mode

If a replica attempts to enter peer mode and experiences an error processing the bulk existing data from the primary (the checkpoint data), the replica shuts down. Shutting down prevents a replica from starting with incorrect initial data. Because it receives the same data from the primary if it reregisters, the replica does not retry.

If a replica shard fails to enter peer mode, it prints the following message to the log:

```
CWOBJ1527W Replica objectGridName:mapSetName:partition:mapName failed to enter peer mode after numSeconds seconds.
```

An additional message displays in the log that explains why the replica failed to enter peer mode.

Recovery after re-register or peer mode failure

If a replica fails to re-register or enter peer mode, the replica is in an inactive state until a new placement event occurs. A new placement event might be a new server starting or stopping. You can also start a placement event by using the triggerPlacement method on the PlacementServiceMBean Mbean.

Map sets for replication

Replication is enabled by associating BackingMaps with a map set.

A map set is a collection of maps that are categorized by partition-key. This partition-key is derived from the individual map's key by taking its hash modulo the number of partitions. If one group of maps within the map set has partition-key X, those maps will be stored in a corresponding partition X in the data grid. If another group has partition-key Y, all of the maps will be stored in partition Y, and so on. Also, the data within the maps is replicated based on the policy defined on the map set, which is only used for distributed eXtreme Scale topologies (unnecessary for local instances).

See Partitioning for more details.

Map sets are assigned what number of partitions they will have and a replication policy. The map set replication configuration simply identifies the number of synchronous and asynchronous replica shards a map set should have in addition to the primary shard. For example, if there is to be 1 synchronous and 1 asynchronous replica, all of the BackingMaps assigned to the map set will each have a replica shard distributed automatically within the set of available

containers for the eXtreme Scale. The replication configuration can also enable clients to read data from synchronously replicated servers. This can spread the load for read requests over additional servers in the eXtreme Scale. Replication only has a programming model impact when preloading the BackingMaps.

Transaction processing overview

WebSphere® eXtreme Scale uses transactions as its mechanism for interaction with data.

Transaction processing in Java applications

To interact with data, the thread in your application needs its own session. When the application wants to use the ObjectGrid on a thread, call one of the ObjectGrid.getSession methods to obtain a session. With the session, the application can work with data that is stored in the ObjectGrid maps.

When an application uses a Session object, the session must be in the context of a transaction. A transaction begins and commits or begins and rolls back with the begin, commit, and rollback methods on the Session object. Applications can also work in auto-commit mode, in which the Session automatically begins and commits a transaction whenever an operation runs on the map. Auto-commit mode cannot group multiple operations into a single transaction. Auto-commit mode is the slower option if you are creating a batch of multiple operations into a single transaction. However, for transactions that contain only one operation, auto-commit is the faster option.

When your application is finished with the Session, use the optional Session.close() method to close the session. Closing the Session releases it from the heap and allows subsequent calls to the getSession() method to be reused, improving performance.

- Transactions
  Transactions have many advantages for data storage and manipulation. You can use transactions to protect the data grid from concurrent changes, to apply multiple changes as a concurrent unit, to replicate data, and to implement a lifecycle for locks on changes.
- CopyMode attribute
  You can tune the number of copies by defining the CopyMode attribute of the BackingMap or ObjectMap objects in the ObjectGrid descriptor XML file.
- Locking strategies
  Locking strategies include pessimistic, optimistic, and none. To choose a locking strategy, you must consider issues such as the percentage of each type of operations you have, whether you use a loader, and so on.
- Lock types
  When you are using pessimistic and optimistic locking, shared (S), upgradeable (U) and exclusive (X) locks are used to maintain consistency. Understanding locking and its behavior is important when you have pessimistic locking enabled. With optimistic locking, the locks are not held. Different types of locks are compatible with others in various ways. Locks must be handled in the correct order to avoid deadlock scenarios.
- Deadlocks
  Deadlocks can occur when two transactions try to update the same cache entry.
- Data access and transactions
  WebSphere eXtreme Scale uses transactions. After an application has a connection to a data grid, you can access and interact with data in the data grid.
- Transaction isolation
  You can use one of three transaction isolation levels to tune the locking semantics that maintain consistency in each cache map: repeatable read, read committed and read uncommitted.
- Single-partition and cross-data-grid transactions
  The major distinction between WebSphere eXtreme Scale and traditional data storage solutions like relational databases or in-memory databases is the use of partitioning, which allows the cache to scale linearly. The important types of transactions to consider are single-partition and every-partition (cross-data-grid) transactions.
- JMS for distributed transaction changes
  Use Java™ Message Service (JMS) for distributed transaction changes between different tiers or in environments on mixed platforms.

Transactions

Transactions have many advantages for data storage and manipulation. You can use transactions to protect the data grid from concurrent changes, to apply multiple changes as a concurrent unit, to replicate data, and to implement a lifecycle for locks on changes.

When a transaction starts, WebSphere® eXtreme Scale allocates a special difference map to hold the current changes or copies of key and value pairs that the transaction uses. Typically, when a key and value pair is accessed, the value is copied before the application receives the value. In Java™ applications, the difference map tracks all changes for operations such as insert, update, get, and remove. Keys are not copied because they are assumed to be immutable. If a transaction is rolled back, then the difference map information is discarded, and locks on entries are released. When a transaction commits, the changes are applied to the maps and locks are released.

If an ObjectTransformer object is specified in a Java application, then this object is used for copying the value. If the transaction is using optimistic locking, then before images of the values are also tracked for comparison when the transaction commits.

If optimistic locking is being used in a Java application, then eXtreme Scale compares the before image versions of the values with the values that are in the map. These values must match for the transaction to commit. This comparison enables a multiple version locking scheme, but at a cost of two copies being made when the transaction accesses the entry. All values are copied again and the new copy is stored in the map. WebSphere eXtreme Scale performs this copy to protect itself against the application changing the application reference to the value after a commit.

You can avoid using several copies of the information. The application can save a copy by using pessimistic locking instead of optimistic locking as the cost of limiting concurrency. The copy of the value at commit time can also be avoided if the application agrees not to change a value after a commit.

Advantages of transactions

Use transactions for the following reasons:
By using transactions, you can:

- Roll back changes if an exception occurs or business logic needs to undo state changes.
- To apply multiple changes as an atomic unit at commit time.
- Hold and release locks on data to apply multiple changes as an atomic unit at commit time.
- Protect a thread from concurrent changes.
- Implement a lifecycle for locks on changes.
- Produce an atomic unit of replication.

Transaction size

Larger transactions are more efficient, especially for replication. However, larger transactions can adversely affect concurrency because the locks on entries are held for a longer time. If you use larger transactions, you can increase replication performance. This performance increase is important when you are pre-loading a Map. Experiment with different batch sizes to determine what works best for your scenario.
Larger transactions also help with loaders. If a loader is being used that can run SQL batching, then significant performance gains are possible depending on the transaction and significant load reductions on the database side. This performance gain depends on the Loader implementation.

Automatic commit mode

If no transaction is actively started, then when an application interacts with an ObjectMap object, an automatic begin and commit operation is done on behalf of the application. This automatic begin and commit operation works, but prevents rollback and locking from working effectively. Synchronous replication speed is impacted because of the very small transaction size. If you are using an entity manager application, then do not use automatic commit mode because objects that are looked up with the EntityManager.find method immediately become unmanaged on the method return and become unusable.

External transaction coordinators

Typically, transactions begin with the session.begin method and end with the session.commit method. However, when eXtreme Scale is embedded, the transactions might be started and ended by an external transaction coordinator. If you are using an external transaction coordinator, you do not need to call the session.begin method and end with the session.commit method. If you are using WebSphere Application Server, you can use the WebSphereTranscationCallback plug-in.
8.5+

Java EE transaction integration

eXtreme Scale includes a Java Connector Architecture (JCA) 1.5 compliant resource adapter that supports both client connections to a remote data grid and local transaction management. Java Platform, Enterprise Edition (Java EE) applications such as servlets, JavaServer Pages (JSP) files and Enterprise JavaBeans (EJB) components can demarcate eXtreme Scale transactions using the standard javax.resource.cci.LocalTransaction interface or the eXtreme Scale session interface.
When the running in WebSphere Application Server with last participant support enabled in the application, you can enlist the eXtreme Scale transaction in a global transaction with other two-phase commit transactional resources.

- Transaction processing in Java EE applications
  WebSphere eXtreme Scale provides its own resource adapter that you can use to connect applications to the data grid and process local transactions.

Transaction processing in Java EE applications

8.5+ WebSphere® eXtreme Scale provides its own resource adapter that you can use to connect applications to the data grid and process local transactions.

Through support from the eXtreme Scale resource adapter, Java™ Platform, Enterprise Edition (Java EE) applications can look up eXtreme Scale client connections and demarcate local transactions using Java EE local transactions or using the eXtreme Scale APIs. When the resource adapter is configured, you can complete the following actions with your Java EE applications:

- Look up or inject eXtreme Scale resource adapter connection factories within a Java EE application component.
- Obtain standard connection handles to the eXtreme Scale client and share them between application components using Java EE conventions.
- Demarcate eXtreme Scale transactions using either the javax.resource.cci.LocalTransaction API or the com.ibm.websphere.objectgrid.Session interface.
- Use the entire eXtreme Scale client API, such as the ObjectMap API and EntityManager API.

The following additional capabilities are available with WebSphere Application Server:

- Enlist eXtreme Scale connections with a global transaction as a last participant with other two-phase commit resources. The eXtreme Scale resource adapter provides local transaction support, with a single-phase commit resource. With WebSphere Application Server, your applications can enlist one, single-phase commit resource into a global transaction through last participant support.
- Automatic resource adapter installation when the profile is augmented.
- Automatic security principal propagation.

Administrator responsibilities

The eXtreme Scale resource adapter is installed into the Java EE application server or embedded with the application. After you install the resource adapter, the administrator creates one or more resource adapter connection factories for each catalog service domain and optionally each data grid instance. The connection factory identifies the properties that are required to communicate with the data grid.

Applications reference the connection factory, which establishes the connection to the remote data grid. Each connection factory hosts a single eXtreme Scale client connection that is reused for all application components.
Important: Because the eXtreme Scale client connection might include a near cache, applications must not share a connection. A connection factory must exist for a single application instance to avoid problems sharing objects between applications.
The connection factory hosts an eXtreme Scale client connection, which is shared between all referencing application components. You can use a managed bean (MBean) to access information about the client connection or to reset the connection when it is no longer needed.

Application developer responsibilities

An application developer creates resource references for managed connection factories in the application deployment descriptor or with annotations. Each resource reference includes a local reference for the eXtreme Scale connection factory, as well as the resource-sharing scope.
Important: Enabling resource sharing is important because it allows the local transaction to be shared between application components.
Applications can inject the connection factory into the Java EE application component, or it can look up the connection factory using Java Naming Directory Interface (JNDI). The connection factory is used to obtain connection handles to the eXtreme Scale client connection. The eXtreme Scale client connection is managed independently from the resource adapter connection and is established on first use, and reused for all subsequent connections.

After finding the connection, the application retrieves an eXtreme Scale session reference. With the eXtreme Scale session reference, the application can use the entire eXtreme Scale client APIs and features.

You can demarcate transactions in one of the following ways:

- Use the com.ibm.websphere.objectgrid.Session transaction demarcation methods.
- Use the javax.resource.cci.LocalTransaction local transaction.
- Use a global transaction, when you use WebSphere Application Server with last participant support enabled. When you select this approach for demarcation, you must:
  - Use an application-managed global transaction with the javax.transaction.UserTransaction.
  - Use a container-managed transaction.

Application deployer responsibilities

The application deployer binds the local reference to the resource adapter connection factory that the application developer defines to the resource adapter connection factories that the administrator defines. The application deployer must assign the correct connection factory type and scope to the application and ensure that the connection factory is not shared between applications to avoid Java object sharing. The application deployer is also responsible for configuring and mapping other appropriate configuration information that is common to all connection factories.

CopyMode attribute

You can tune the number of copies by defining the CopyMode attribute of the BackingMap or ObjectMap objects in the ObjectGrid descriptor XML file.

For Java™ applications, you can tune the number of copies by defining the CopyMode attribute of the BackingMap or ObjectMap objects.

The copy mode has the following values:

- COPY_ON_READ_AND_COMMIT
- COPY_ON_READ
- NO_COPY
- COPY_ON_WRITE
- COPY_TO_BYTES
- COPY_TO_BYTES_RAW

The COPY_ON_READ_AND_COMMIT value is the default. The COPY_ON_READ value copies the initial data when it is retrieved, but does not copy at commit time. This mode is safe if the application does not modify a value after committing a transaction. The NO_COPY value does not copy data, which is only safe for read-only data. If the data never changes, then you do not need to copy it for isolation reasons.
Be careful when you use the NO_COPY attribute value with maps that can be updated. WebSphere® eXtreme Scale uses the copy on first touch to allow the transaction rollback. The application only changed the copy, and as a result, eXtreme Scale discards the copy. If the NO_COPY attribute value is used, and the application modifies the committed value, completing a rollback is not possible. Modifying the committed value leads to problems with indexes, replication, and so on because the indexes and replicas update when the transaction commits. If you modify committed data and then roll back the transaction, which does not actually roll back at all, then the indexes are not updated and replication does not take place. Other threads can see the uncommitted changes immediately, even if they have locks. Use the NO_COPY attribute value for read-only maps or for applications that complete the appropriate copy before modifying the value. If you

use the NO_COPY attribute value and call IBM® support with a data integrity problem, you are asked to reproduce the problem with the copy mode set to COPY_ON_READ_AND_COMMIT.

The COPY_TO_BYTES value stores values in the map in a serialized form. At read time, eXtreme Scale inflates the value from a serialized form and at commit time it stores the value to a serialized form. With this method, a copy occurs at both read and commit time.

The default copy mode for a map can be configured on the BackingMap object. You can also change the copy mode on maps before you start a transaction by using the ObjectMap.setCopyMode method.

An example of a backing map snippet from an objectgrid.xml file that shows how to set the copy mode for a backing map follows. This example assumes that you are using cc as the objectgrid/config namespace.

```
<cc:backingMap name="RuntimeLifespan" copyMode="NO_COPY"/>
```

Locking strategies

Locking strategies include pessimistic, optimistic, and none. To choose a locking strategy, you must consider issues such as the percentage of each type of operations you have, whether you use a loader, and so on.

Locks are bound by transactions. You can specify the following locking settings:

No locking
: Running without the locking setting is the fastest. If you are using read-only data, then you might not need locking.

Pessimistic locking
: Acquires locks on entries, then and holds the locks until commit time. This locking strategy provides good consistency at the expense of throughput.

Optimistic locking
: Takes a before image of every record that the transaction touches and compares the image to the current entry values when the transaction commits. If the entry values change, then the transaction rolls back. No locks are held until commit time. This locking strategy provides better concurrency than the pessimistic strategy, at the risk of the transaction rolling back and the memory cost of making the extra copy of the entry.

Optimistic no versioning locking
: This locking strategy allows you to disable version control. This is important because near cache is only enabled if you are doing Optimistic locking. With the current implementation, you need a plug-in or callback handler to handle version control. However, using the OPTIMISTIC_NO_VERSIONING locking strategy to disable version control on the client and only enable it on the server, is an additional performance savings.

Lock manager

When either a PESSIMISTIC or an OPTIMISTIC locking strategy is used, a lock manager is created for the BackingMap. The lock manager uses a hash map to track entries that are locked by one or more transactions. If many map entries exist in the hash map, more lock buckets can result in better performance. The risk of Java™ synchronization collisions is lower as the number of buckets grows. More lock buckets also lead to more concurrency. The previous examples show how an application can set the number of lock buckets to use for a given BackingMap instance.

8.5 To avoid a java.lang.IllegalStateException exception, you must call the setNumberOfLockBuckets method before the initialize or getSession methods on the ObjectGrid instance. The setNumberOfLockBuckets method parameter is a Java primitive integer that specifies the number of lock buckets to use. Using a prime number can allow for a uniform distribution of map entries over the lock buckets. A good starting point for best performance is to set the number of lock buckets to about 10 percent of the expected number of BackingMap entries.

Pessimistic locking

The PESSIMISTIC lock strategy acquires locks for cache entries and should be used when data is changed frequently. Any time a cache entry is read, a lock is acquired and conditionally held until the transaction completes. The duration of some locks can be tuned using transaction isolation levels for the session.

Use the pessimistic locking strategy for read and write maps when other locking strategies are not possible. When an ObjectGrid map is configured to use the pessimistic locking strategy, a pessimistic transaction lock for a map entry is obtained when a transaction first gets the entry from the BackingMap. The pessimistic lock is held until the application completes the transaction. Typically, the pessimistic locking strategy is used in the following situations:

- When the BackingMap is configured with or without a loader and versioning information is not available.
- When the BackingMap is used directly by an application that needs help from the eXtreme Scale for concurrency control.
- When versioning information is available, but update transactions frequently collide on the backing entries, resulting in optimistic update failures.

The pessimistic locking strategy has the greatest impact on performance and scalability. Therefore, use this strategy only for read and write maps when other locking strategies are not viable. For example, these situations might include when optimistic update failures occur frequently, or when recovery from optimistic failure is difficult for an application to handle.

When you use pessimistic locking, you can use lock methods to lock data, or keys, without returning any data values. For a list of the methods and what kind of locks they acquire, see Lock types.

Optimistic locking

The default lock strategy is OPTIMISTIC. Use optimistic locking when data is changed infrequently. Locks are only held for a short duration while data is being read from the cache and copied to the transaction. When the transaction cache is synchronized with the main cache, any cache objects that have been updated are checked against the original version. If the check fails, then the transaction is rolled back and an OptimisticCollisionException exception results.

The optimistic locking strategy assumes that no two transactions might attempt to update the same map entry while the transactions are running concurrently. The lock is not held for the lifecycle of the transaction because it is unlikely that more than one transaction might update the map entry concurrently. The optimistic locking strategy is typically used in the following situations:

- When a BackingMap is configured and versioning information is available. The BackingMap can be configured with or without a loader.
- When a BackingMap has mostly transactions that are read operations. Insert, update, or remove operations on map entries do not occur often on the BackingMap.
- When a BackingMap is inserted, updated, or removed more frequently than it is read, but transactions rarely collide on the same map entry.

Like the pessimistic locking strategy, the methods on the ObjectMap interface determine how eXtreme Scale automatically attempts to acquire a lock mode for the map entry that is being accessed. However, the following differences between the pessimistic and optimistic strategies exist:

- Like the pessimistic locking strategy, an S lock mode is acquired by the get and getAll methods when the method is called. However, with optimistic locking, the S lock mode is not held until the transaction is completed. Instead, the S lock mode is released before the method returns to the application. The purpose of acquiring the lock mode is so that eXtreme Scale can ensure that only committed data from other transactions is visible to the current transaction. After eXtreme Scale has verified that the data is committed, the S lock mode is released. At commit time, an optimistic versioning check is performed to ensure that no other transaction has changed the map entry after the current transaction released its S lock mode. If an entry is not fetched from the map before it is updated, invalidated, or deleted, the eXtreme Scale run time implicitly fetches the entry from the map. This implicit get operation is performed to get the current value at the time the entry was requested to be modified.
- Unlike pessimistic locking strategy, the getForUpdate and getAllForUpdate methods are handled exactly like the get and getAll methods when the optimistic locking strategy is used. That is, an S lock mode is acquired at the start of the method and the S lock mode is released before returning to the application.

All other ObjectMap methods are handled the same as the pessimistic locking strategy. When the commit method is called, an X lock mode is obtained for any map entry that is inserted, updated, removed, touched, or invalidated. The X lock mode is held until the transaction completes commit processing.

The optimistic locking strategy assumes that no concurrently running transactions attempt to update the same map entry. Because of this assumption, the lock mode does not need to be held for the life of the transaction because it is unlikely that more than one transaction might update the map entry concurrently. However, because a lock mode was not held, another concurrent transaction might potentially update the map entry after the current transaction has released its S lock mode.
To handle this possibility, eXtreme Scale gets an X lock at commit time and performs an optimistic versioning check to verify that no other transaction has changed the map entry after the current transaction read the map entry from the BackingMap. If another transaction changes the map entry, the version check fails and an OptimisticCollisionException exception occurs. This exception forces the current transaction to be rolled back and the application must try the entire transaction again. The optimistic locking strategy is useful when a map is mostly read and it is unlikely that updates for the same map entry might occur.

Optimistic no versioning

You can enable OPTIMISTIC_NO_VERSIONING locking either through the client override XML file or programmatically. See the following examples of both approaches:
Client override XML file example

```
<objectGrid name="lockStrategyGrid">
            <backingMap name="opt_with_noversion" lockStrategy="OPTIMISTIC_NO_VERSIONING"/>
            <backingMap name="opt_with_none" lockStrategy="NONE"/>
            <backingMap name="optnoversion_with_opt" lockStrategy="OPTIMISTIC"/>
            <backingMap name="optnoversion_with_none" lockStrategy="NONE"/>
        </objectGrid>
```

Programmatic example

```
ObjectGridConfiguration lsConfig = ObjectGridConfigFactory.createObjectGridConfiguration("lockStrategyGrid");
                BackingMapConfiguration oMapWithOVConfig =
ObjectGridConfigFactory.createBackingMapConfiguration("opt_with_noversion");
                oMapWithOVConfig.setLockStrategy(LockStrategy.OPTIMISTIC_NO_VERSIONING);
                lsConfig.addBackingMapConfiguration(oMapWithOVConfig);
```

No locking

If locking is not required because the data is never updated or is only updated during quiet periods, you can disable locking by using the NONE lock strategy. This strategy is very fast because a lock manager is not required. The NONE lock strategy is ideal for look-up tables or read-only maps.

When a BackingMap is configured to use no locking strategy, no transaction locks for a map entry are obtained.
Using no locking strategy is useful when an application is a persistence manager such as an Enterprise JavaBeans (EJB) container or when an application uses Hibernate to obtain persistent data. In this scenario, the BackingMap is configured without a loader and the persistence manager uses the BackingMap as a data cache. In this scenario, the persistence manager provides concurrency control between transactions that are accessing the same Map entries.

WebSphere® eXtreme Scale does not need to obtain any transaction locks for concurrency control. This situation assumes that the persistence manager does not release its transaction locks before updating the ObjectGrid map with committed changes. If the persistence manager releases its locks, then a pessimistic or optimistic lock strategy must be used. For example, suppose that the persistence manager of an EJB container is updating an ObjectGrid map with data that was committed in the EJB container-managed transaction. If the update of the ObjectGrid map occurs before the persistence manager transaction locks are released, then you can use the no lock strategy. If the ObjectGrid map update occurs after the persistence manager transaction locks are released, then you must use either the optimistic or pessimistic lock strategy.

Another scenario where no locking strategy can be used is when the application uses a BackingMap directly and a Loader is configured for the map. In this scenario, the loader uses the concurrency control support that is provided by a relational database management system (RDBMS) by using either Java database

connectivity (JDBC) or Hibernate to access data in a relational database. The loader implementation can use either an optimistic or pessimistic approach. A loader that uses an optimistic locking or versioning approach helps to achieve the greatest amount of concurrency and performance. For more information about implementing an optimistic locking approach, see the OptimisticCallback section in Configuring database loaders. If you are using a loader that uses pessimistic locking support of an underlying backend, you might want to use the forUpdate parameter that is passed on the get method of the Loader interface. Set this parameter to true if the getForUpdate method of the ObjectMap interface was used by the application to get the data. The loader can use this parameter to determine whether to request an upgradeable lock on the row that is being read. For example, DB2® obtains an upgradeable lock when an SQL select statement contains a `FOR UPDATE` clause. This approach offers the same deadlock prevention that is described in Pessimistic locking.

JMS for distributed transaction changes

Use Java™ Message Service (JMS) for distributed transaction changes between different tiers or in environments on mixed platforms.

JMS is an ideal protocol for distributed changes between different tiers or in environments on mixed platforms. For example, some applications that use eXtreme Scale might be deployed on IBM® WebSphere® Application Server Community Edition, Apache Geronimo, or Apache Tomcat, whereas other applications might run on WebSphere Application Server Version 6.x. JMS is ideal for distributed changes between eXtreme Scale peers in these different environments. The high availability manager message transport is very fast, but can only distribute changes to Java virtual machines that are in a single core group. JMS is slower, but allows larger and more diverse sets of application clients to share an ObjectGrid. JMS is ideal when sharing data in an ObjectGrid between a fat Swing client and an application deployed on WebSphere Extended Deployment.

The built-in Client Invalidation Mechanism and Peer-to-Peer Replication are examples of JMS-based transactional changes distribution. See Configuring Java Message Service (JMS)-based client synchronization and Configuring peer-to-peer replication with JMS for more information.

Implementing JMS

JMS is implemented for distributing transaction changes by using a Java object that behaves as an ObjectGridEventListener. This object can propagate the state in the following four ways:

1. Invalidate: Any entry that is evicted, updated or deleted is removed on all peer Java virtual machines when they receive the message.
2. Invalidate conditional: The entry is evicted only if the local version is the same or older than the version on the publisher.
3. Push: Any entry that was evicted, updated, deleted or inserted is added or overwritten on all peer Java virtual machines when they receive the JMS message.
4. Push conditional: The entry is only updated or added on the receive side if the local entry is less recent than the version that is being published.

Listen for changes for publishing

The plug-in implements the ObjectGridEventListener interface to intercept the transactionEnd event. When eXtreme Scale invokes this method, the plug-in attempts to convert the LogSequence list for each map that is touched by the transaction to a JMS message and then publish it. The plug-in can be configured to publish changes for all maps or a subset of maps. LogSequence objects are processed for the maps that have publishing enabled. The LogSequenceTransformer ObjectGrid class serializes a filtered LogSequence for each map to a stream. After all LogSequences are serialized to the stream, then a JMS ObjectMessage is created and published to a well-known topic.

Listen for JMS messages and apply them to the local ObjectGrid

The same plug-in also starts a thread that spins in a loop, receiving all messages that are published to the well known topic. When a message arrives, it passes the message contents to the LogSequenceTransformer class where it is converted to a set of LogSequence objects. Then, a no-write-through transaction is started. Each LogSequence object is provided to the Session.processLogSequence method, which updates the local Maps with the changes. The processLogSequence method understands the distribution mode. The transaction is committed and the local cache now reflects the changes. For more information about using JMS to distribute transaction changes, see Distributing changes between peer JVMs.

Single-partition and cross-data-grid transactions

The major distinction between WebSphere® eXtreme Scale and traditional data storage solutions like relational databases or in-memory databases is the use of partitioning, which allows the cache to scale linearly. The important types of transactions to consider are single-partition and every-partition (cross-data-grid) transactions.

In general, interactions with the cache can be categorized as single-partition transactions or cross-data-grid transactions.

Single-partition transactions

Single-partition transactions are the preferable method for interacting with caches that are hosted by WebSphere eXtreme Scale. When a transaction is limited to a single partition, then by default it is limited to a single Java™ virtual machine, and therefore a single server computer. A server can complete *M* number of these transactions per second, and if you have *N* computers, you can complete `M*N` transactions per second. If your business increases and you need to perform twice as many of these transactions per second, you can double *N* by buying more computers. Then you can meet capacity demands without changing the application, upgrading hardware, or even taking the application offline.

In addition to letting the cache scale so significantly, single-partition transactions also maximize the availability of the cache. Each transaction only depends on one computer. Any of the other `(N-1)` computers can fail without affecting the success or response time of the transaction. So if you are running 100 computers and one of them fails, only 1 percent of the transactions in flight at the moment that server failed are rolled back. After the server fails, WebSphere eXtreme Scale relocates the partitions that are hosted by the failed server to the other 99 computers. During this brief period, before the operation completes, the other 99 computers can still complete transactions. Only the transactions that would involve the partitions that are being relocated are blocked. After the failover process is complete, the cache can continue running, fully operational, at 99 percent of its original throughput capacity. After the failed server is replaced and returned to the data grid, the cache returns to 100 percent throughput capacity.

Cross-data-grid transactions

In terms of performance, availability and scalability, cross-data-grid transactions are the opposite of single-partition transactions. Cross-data-grid transactions access every partition and therefore every computer in the configuration. Each computer in the data grid is asked to look up some data and then return the result. The transaction cannot complete until every computer has responded, and therefore the throughput of the entire data grid is limited by the slowest computer. Adding computers does not make the slowest computer faster and therefore does not improve the throughput of the cache.

Cross-data-grid transactions have a similar effect on availability. Extending the previous example, if you are running 100 servers and one server fails, then 100 percent of the transactions that are in progress at the moment that server failed are rolled back. After the server fails, WebSphere eXtreme Scale starts to relocate the partitions that are hosted by that server to the other 99 computers. During this time, before the failover process completes, the data grid cannot process any of these transactions. After the failover process is complete, the cache can continue running, but at reduced capacity. If each computer in the data grid serviced 10 partitions, then 10 of the remaining 99 computers receive at least one extra partition as part of the failover process. Adding an extra partition increases the workload of that computer by at least 10 percent. Because the throughput of the data grid is limited to the throughput of the slowest computer in a cross-data-grid transaction, on average, the throughput is reduced by 10 percent.

Single-partition transactions are preferable to cross-data-grid transactions for scaling out with a distributed, highly available, object cache like WebSphere eXtreme Scale. Maximizing the performance of these kinds of systems requires the use of techniques that are different from traditional relational methodologies, but you can turn cross-data-grid transactions into scalable single-partition transactions.

Best practices for building scalable data models

The best practices for building scalable applications with products like WebSphere eXtreme Scale include two categories: foundational principles and implementation tips. Foundational principles are core ideas that need to be captured in the design of the data itself. An application that does not observe these principles is unlikely to scale well, even for its mainline transactions. Implementation tips are applied for problematic transactions in an otherwise well-designed application that observes the general principles for scalable data models.

Foundational principles

Some of the important means of optimizing scalability are basic concepts or principles to keep in mind.

Duplicate instead of normalizing

The key thing to remember about products like WebSphere eXtreme Scale is that they are designed to spread data across a large number of computers. If the goal is to make most or all transactions complete on a single partition, then the data model design needs to ensure that all the data the transaction might need is in the partition. Most of the time, the only way to achieve this is by duplicating data.

For example, consider an application like a message board. Two important transactions for a message board are showing all the posts from a user and all the posts on a topic. First, consider how these transactions would work with a normalized data model that contains a user record, a topic record, and a post record that contains the actual text. If posts are partitioned with user records, then displaying the topic becomes a cross-grid transaction, and vice versa. Topics and users cannot be partitioned together because they have a many-to-many relationship.

The best way to make this message board scale is to duplicate the posts, storing one copy with the topic record and one copy with the user record. Then, displaying the posts from a user is a single-partition transaction, displaying the posts on a topic is a single-partition transaction, and updating or deleting a post is a two-partition transaction. All three of these transactions scale linearly as the number of computers in the data grid increases.

Scalability rather than resources

The biggest obstacle to overcome when you are considering denormalized data models is the impact that these models have on resources. Keeping two, three, or more copies of some data can seem to use too many resources to be practical. When you are confronted with this scenario, remember the following facts: Hardware resources get cheaper every year. Second, and more importantly, WebSphere eXtreme Scale eliminates most hidden costs that are associated with deploying more resources.

Measure resources in terms of cost rather than computer terms such as megabytes and processors. Data stores that work with normalized relational data generally must be on the same computer. This required collocation means that a single larger enterprise computer must be purchased rather than several smaller computers. With enterprise hardware, it is not uncommon for one computer that is capable of completing one million transactions per second to cost much more than the combined cost of 10 computers capable of doing 100,000 transactions per second each.

A business cost in adding resources also exists. A growing business eventually runs out of capacity. When you run out of capacity, you either need to shut down while moving to a bigger, faster computer, or create a second production environment to which you can switch. Either way, additional costs will come in the form of lost business or maintaining almost twice the capacity needed during the transition period.

With WebSphere eXtreme Scale, the application does not need to be shut down to add capacity. If your business projects that you need 10 percent more capacity for the coming year, then increase the number of computers in the data grid by 10 percent. You can increase this percentage without application downtime and without purchasing excess capacity.

Avoid data transformations

When you are using WebSphere eXtreme Scale, data should be stored in a format that is directly consumable by the business logic. Breaking the data down into a more primitive form is costly. The transformation needs to be done when the data is written and when the data is read. With relational databases, this transformation is done out of necessity because the data is ultimately persisted to disk frequently. With WebSphere eXtreme Scale, these transformations are not necessary. Usually, data is stored in memory and can therefore be stored in the exact form that the application needs.

Observing this simple rule helps denormalize your data in accordance with the first principle. The most common type of transformation for business data is the JOIN operations that are necessary to turn normalized data into a result set that fits the needs of the application. Storing the data in the correct format implicitly avoids performing these JOIN operations and produces a denormalized data model.

Eliminate unbounded queries

No matter how well you structure your data, unbounded queries do not scale well. For example, do not have a transaction that asks for a list of all items that are sorted by value. This transaction might work at first when the total number of items is 1000, but when the total number of items reaches 10 million, the transaction returns all 10 million items. If you run this transaction, the two most likely outcomes are the transaction timing out, or the client encounters an out-of-memory error.

The best option is to alter the business logic so that only the top 10 or 20 items can be returned. This logic alteration keeps the size of the transaction manageable no matter how many items are in the cache.

Define schema

The main advantage of normalizing data is that the database system can take care of data consistency behind the scenes. When data is denormalized for scalability, this automatic data consistency management no longer exists. You must implement a data model that can work in the application layer or as a plug-in to the distributed data grid to guarantee data consistency.

Consider the message board example. If a transaction removes a post from a topic, then the duplicate post on the user record must be removed. Without a data model, it is possible a developer might write the application code to remove the post from the topic and forget to remove the post from the user record. However, if the developer is using a data model instead of interacting with the cache directly, the removePost method on the data model pulls the user ID from the post, looks up the user record, and removes the duplicate post behind the scenes.

Alternately, you can implement a listener that runs on the actual partition that detects the change to the topic and automatically adjusts the user record. A listener might be beneficial because the adjustment to the user record might happen locally if the partition happens to have the user record. If the user record is on a different partition, the transaction takes place between servers instead of between the client and server. The network connection between servers is likely to be faster than the network connection between the client and the server.

Avoid contention

Avoid scenarios such as having a global counter. The data grid does not scale if a single record is being used a disproportionate number of times compared to the rest of the records. The performance of the data grid is limited by the performance of the computer that holds the record.

In these situations, try to break up the record so it is managed per partition. For example, consider a transaction that returns the total number of entries in the distributed cache. Instead of having every insert and remove operation access a single record that increments, have a listener on each partition track the insert and remove operations. With this listener tracking, insert and remove can become single-partition operations.

Reading the counter becomes a cross-data-grid operation. Usually, it was already as inefficient as a cross-data-grid operation because its performance was tied to the performance of the computer that is hosting the record.

Implementation tips

You can also consider the following tips to achieve the best scalability.

Use reverse-lookup indexes

Consider a properly denormalized data model where customer records are partitioned based on the customer ID number. This partitioning method is the logical choice because nearly every business operation that is performed with the customer record uses the customer ID number. However, an important transaction that does not use the customer ID number is the login transaction. It is more common to have user names or email addresses for login instead of customer ID numbers.

The simple approach to the login scenario is to use a cross-data-grid transaction to find the customer record. As explained previously, this approach does not scale.

The next option might be to partition on user name or email. This option is not practical because all the customer ID-based operations become cross-data-grid transactions. Also, the customers on your site might want to change their user name or email address. Products like WebSphere eXtreme Scale need the value that is used to partition the data to remain constant.

The correct solution is to use a reverse lookup index. With WebSphere eXtreme Scale, a cache can be created in the same distributed grid as the cache that holds all the user records. This cache is highly available, partitioned, and scalable. This cache can be used to map a user name or email address to a customer ID. This cache turns login into a two partition operation instead of a cross-grid operation. This scenario is not as good as a single-partition transaction, but the throughput still scales linearly as the number of computers increases.

Compute at write time

Commonly calculated values like averages or totals can be expensive to produce because these operations usually require reading a large number of entries. Because reads are more common than writes in most applications, it is efficient to compute these values at write time and then store the result in the cache. This practice makes read operations both faster and more scalable.

Optional fields

Consider a user record that holds a business, home, and telephone number. A user might have all, none or any combination of these numbers defined. If the data were normalized, then a user table and a telephone number table would exist. The telephone numbers for a user can be found with a JOIN operation between the two tables.

De-normalizing this record does not require data duplication, because most users do not share telephone numbers. Instead, empty slots in the user record must be allowed. Instead of having a telephone number table, add three attributes to each user record, one for each telephone number type. This addition of attributes eliminates the JOIN operation and makes a telephone number lookup for a user a single-partition operation.

Placement of many-to-many relationships

Consider an application that tracks products and the stores in which the products are sold. A single product is sold in many stores, and a single store sells many products. Assume that this application tracks 50 large retailers. Each product is sold in a maximum of 50 stores. Each store sells thousands of products.

Keep a list of stores inside the product entity (arrangement A), instead of keeping a list of products inside each store entity (arrangement B). Looking at some of the transactions this application must run illustrates why arrangement A is more scalable.

First look at updates. With arrangement A, removing a product from the inventory of a store locks the product entity. If the data grid holds 10000 products, only 1/10000 of the grid must be locked to complete the update. With arrangement B, the data grid only contains only 50 stores, so 1/50 of the data grid must be locked to complete the update. So even though both of these updates might be considered single-partition operations, arrangement A scales out more efficiently.

Now, considering reads with arrangement A, looking up the stores at which a product is sold is a single-partition transaction that scales and is fast because the transaction only transmits a small amount of data. With arrangement B, this transaction becomes a cross-data-grid transaction because each store entity must be accessed to see if the product is sold at that store, which reveals an enormous performance advantage for arrangement A.

Scaling with normalized data

One legitimate use of cross-data-grid transactions is to scale data processing. If a data grid has 5 computers and a cross-data-grid transaction is dispatched that sorts through about 100,000 records on each computer, then that transaction sorts through 500,000 records. If the slowest computer in the data grid can perform 10 of these transactions per second, then the data grid is capable of sorting through 5,000,000 records per second. If the data in the grid doubles, then each computer must sort through 200,000 records, and each transaction sorts through 1,000,000 records. This data increase decreases the throughput of the slowest computer to 5 transactions per second, reducing the throughput of the data grid to 5 transactions per second. Still, the data grid sorts through 5,000,000 records per second.

In this scenario, doubling the number of computers allows each computer to return to its previous load of sorting through 100,000 records, allowing the slowest computer to process 10 of these transactions per second. The throughput of the data grid stays the same at 10 requests per second, but now each transaction processes 1,000,000 records. As a result, the data grid doubled its capacity in terms of processing records to 10,000,000 per second.

Applications such as a search engine that needs to scale both in terms of data processing to accommodate the increasing size of the Internet and throughput to accommodate growth in the number of users, you must create multiple data grids, with a round robin of the requests between the data grids. If you must scale up the throughput, add computers and add another data grid to service requests. If data processing must be scaled up, add more computers and keep the number of data grids constant.

Security overview

WebSphere® eXtreme Scale can secure data access, including allowing for integration with external security providers.

Note: In an existing non-cached data store such as a database, you likely have built-in security features that you might not need to actively configure or enable. However, after you have cached your data with eXtreme Scale, you must consider the important resulting situation that your backend security features are no longer in effect. You can configureeXtreme Scale security on necessary levels so that your new cached architecture for your data is also secured.
A brief summary of eXtreme Scale security features follows. For more detailed information about configuring security see the *Administration Guide* and the *Programming Guide*.

Distributed security basics

Distributed eXtreme Scale security is based on three key concepts:

Trustable authentication
: The ability to determine the identity of the requester. WebSphere eXtreme Scale supports both client-to-server and server-to-server authentication.

Authorization
: The ability to give permissions to grant access rights to the requester. WebSphere eXtreme Scale supports different authorizations for various operations.

Secure transport
: The safe transmission of data over a network. WebSphere eXtreme Scale supports the Transport Layer Security/Secure Sockets Layer (TLS/SSL) protocols.

Authentication

WebSphere eXtreme Scale supports a distributed client server framework. A client server security infrastructure is in place to secure access to eXtreme Scale servers. For example, when authentication is required by the eXtreme Scale server, an eXtreme Scale client must provide credentials to authenticate to the server. These credentials can be a user name and password pair, a client certificate, a Kerberos ticket, or data that is presented in a format that is agreed upon by client and server.

Authorization

WebSphere eXtreme Scale authorizations are based on subjects and permissions. You can use the Java™ Authentication and Authorization Services (JAAS) to authorize the access, or you can plug in a custom approach, such as Tivoli® Access Manager (TAM), to handle the authorizations. The following authorizations can be given to a client or group:

Map authorization
: Perform insert, read, update, evict, or delete operations on Maps.

ObjectGrid authorization
: Perform object or entity queries on ObjectGrid objects.

DataGrid agent authorization
: Allow DataGrid agents to be deployed to an ObjectGrid.

Server side map authorization
: Replicate a server map to client side or create a dynamic index to the server map.

Administration authorization
: Perform administration tasks.

Transport security

To secure the client server communication, WebSphere eXtreme Scale supports TLS/SSL. These protocols provide transport layer security with authenticity, integrity, and confidentiality for a secure connection between an eXtreme Scale client and server.

Grid security

In a secure environment, a server must be able to check the authenticity of another server. WebSphere eXtreme Scale uses a shared secret key string mechanism for this purpose. This secret key mechanism is similar to a shared password. All the eXtreme Scale servers agree on a shared secret string. When a server joins the data grid, the server is challenged to present the secret string. If the secret string of the joining server matches the one in the master server, then the joining server can join the grid. Otherwise, the join request is rejected.

Sending a clear text secret is not secure. The eXtreme Scale security infrastructure provides a SecureTokenManager plug-in to allow the server to secure this secret before sending it. You can choose how you implement the secure operation. WebSphere eXtreme Scale provides an implementation, in which the secure operation is implemented to encrypt and sign the secret.

Java Management Extensions (JMX) security in a dynamic deployment topology

JMX MBean security is supported in all versions of eXtreme Scale. Clients of catalog server MBeans and container server MBeans can be authenticated, and access to MBean operations can be enforced.

Local eXtreme Scale security

Local eXtreme Scale security is different from the distributed eXtreme Scale model because the application directly instantiates and uses an ObjectGrid instance. Your application and eXtreme Scale instances are in the same Java virtual machine (JVM). Because no client-server concept exists in this model, authentication is not supported. Your applications must manage their own authentication, and then pass the authenticated Subject object to the eXtreme Scale. However, the authorization mechanism that is used for the local eXtreme Scale programming model is the same as what is used for the client-server model.

Configuration and programming

For more information about configuring and programming for security, see Security integration with external providers and Security API.

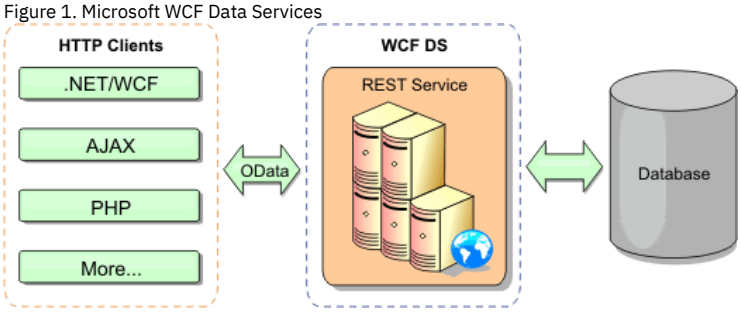
REST data services overview

The WebSphere® eXtreme Scale REST data service is a Java™ HTTP service that is compatible with Microsoft WCF Data Services (formally ADO.NET Data Services) and implements the Open Data Protocol (OData). Microsoft WCF Data Services is compatible with this specification when using Visual Studio 2008 SP1 and the .NET Framework 3.5 SP1.

Compatibility requirements

The REST data service allows any HTTP client to access a data grid. The REST data service is compatible with the WCF Data Services support supplied with the Microsoft .NET Framework 3.5 SP1. RESTful applications can be developed with the rich tooling provided by Microsoft Visual Studio 2008 SP1. The figure provides an overview of how WCF Data Services interacts with clients and databases.

Figure 1. Microsoft WCF Data Services



WebSphere eXtreme Scale includes a function-rich API set for Java clients. As shown in the following figure, the REST data service is a gateway between HTTP clients and the WebSphere eXtreme Scale data grid, communicating with the grid through an WebSphere eXtreme Scale client. The REST data service is a Java servlet, which allows flexible deployments for common Java Platform, Enterprise Edition (JEE) platforms, such as WebSphere Application Server. The REST data service communicates with the WebSphere eXtreme Scale data grid using the WebSphere eXtreme Scale Java APIs. It allows WCF Data Services clients or any other client that can communicate with HTTP and XML.

Figure 2. WebSphere eXtreme Scale REST data service

Features

This version of the eXtreme Scale REST data service supports the following features:

- Automatic modeling of eXtreme Scale EntityManager API entities as WCF Data Services entities, which includes the following support:
  - Java data type to Entity Data Model type conversion
  - Entity association support
  - Schema root and key association support, which is required for partitioned data grids

  See Entity model for more information.
- Atom Publish Protocol (AtomPub or APP) XML and JavaScript Object Notation (JSON) data payload format.
- Create, Read, Update and Delete (CRUD) operations using the respective HTTP request methods: POST, GET, PUT and DELETE. In addition, the Microsoft extension: MERGE is supported.
- Simple queries, using filters
- Batch retrieval and change set requests
- Partitioned data grid support for high availability
- Interoperability with eXtreme Scale EntityManager API clients
- Support for standard Java EE Web servers
- Optimistic concurrency
- User authorization and authentication between the REST data service and the eXtreme Scale data grid

Known problems and limitations

- Tunneled requests are not supported.

Scenarios

	Scenarios include real-world information to build a complete picture. Complete a scenario to understand new concepts or to accomplish common WebSphere® eXtreme Scale tasks.

- Scenario: Using an OSGi environment to develop and run eXtreme Scale plug-ins
  Use these scenarios to complete common tasks in an OSGi environment. For example, the OSGi framework is ideal for starting servers and clients in an OSGi container, which allows you to dynamically add and update WebSphere eXtreme Scale plug-ins to the runtime environment.

- 8.5+ Scenario: Using JCA to connect transactional applications to eXtreme Scale clients
  The following scenario is about connecting clients to applications that participate in transactions.
- Scenario: Configuring HTTP session failover in the Liberty profile
  You can configure a web application server so that, when the web server receives an HTTP request for session replication, the request is forwarded to one or more servers that run in the Liberty profile.
- 8.5+ Scenario: Running grid servers in the Liberty profile using Eclipse tools
  You can use Eclipse tools to run WebSphere eXtreme Scale servers in the WebSphere Application Server Liberty profile. The Eclipse tools offer a convenient way of running your servers in the same Eclipse environment where you develop, configure, and deploy your eXtreme Scale applications.
- Migrating a WebSphere Application Server memory-to-memory replication or database session to use WebSphere eXtreme Scale session management
  You can migrate any previously set memory-to-memory replication session or database session to use WebSphere eXtreme Scale session management.

Scenario: Using an OSGi environment to develop and run eXtreme Scale plug-ins

Use these scenarios to complete common tasks in an OSGi environment. For example, the OSGi framework is ideal for starting servers and clients in an OSGi container, which allows you to dynamically add and update WebSphere® eXtreme Scale plug-ins to the runtime environment.

Before you begin

Read the OSGi framework overview topic to learn more about OSGi support and the benefits that it can offer.

About this task

The following scenarios are about building and running dynamic plug-ins, which allows you to dynamically install, start, stop, modify, and uninstall plug-ins. You might also complete another likely scenario, which allows you to use the OSGi framework without dynamic capabilities. You can still package your applications as bundles, which are defined by and communicated through services. These service-based bundles offer multiple benefits, which include more efficient development and deployment capabilities.

Scenario goals

After completing this scenario, you will know how to complete the goals:

- Build eXtreme Scale dynamic plug-ins to use in an OSGi environment.
- Run eXtreme Scale containers in an OSGi environment without dynamic capabilities.

1. OSGi framework overview
   OSGi defines a dynamic module system for Java. The OSGi service platform has a layered architecture, and is designed to run on various standard Java profiles. You can start WebSphere eXtreme Scale servers and clients in an OSGi container.
2. Installing the Eclipse Equinox OSGi framework with Eclipse Gemini for clients and servers
   If you want to deploy WebSphere eXtreme Scale in the OSGi framework, then you must set up the Eclipse Equinox Environment.
3. Running eXtreme Scale containers with non-dynamic plug-ins in an OSGi environment
   If you do not need to use the dynamic capability of an OSGi environment, you can still take advantage of tighter coupling, declarative packaging, and service dependencies that the OSGi framework offers.
4. Administering eXtreme Scale servers and applications in an OSGi environment
   Use this topic to install the WebSphere eXtreme Scale server bundle, an optional fragment that allows loading of your application bundles and non-dynamic user classes, such as plug-ins, agents, data objects, and so on.
5. Building and running eXtreme Scale dynamic plug-ins for use in an OSGi environment
   All eXtreme Scale plug-ins can be configured for an OSGi environment. The primary benefit of dynamic plug-ins is that they allow you to upgrade them without shutting down the grid. This allows you to evolve an application without restarting the grid container processes.
6. Running eXtreme Scale containers with dynamic plug-ins in an OSGi environment
   If your application is hosted in the Eclipse Equinox OSGi framework with Eclipse Gemini or Apache Aries, then you can use this task to help you install and configure your WebSphere eXtreme Scale application in OSGi.

OSGi framework overview

OSGi defines a dynamic module system for Java™. The OSGi service platform has a layered architecture, and is designed to run on various standard Java profiles. You can start WebSphere® eXtreme Scale servers and clients in an OSGi container.

Benefits of running applications in the OSGi container

WebSphere eXtreme Scale OSGi support allows you to deploy the product in the Eclipse Equinox OSGi framework. Previously, if you wanted to update the plug-ins used by eXtreme Scale, you had to restart the Java virtual machine (JVM) to apply the new versions of the plug-ins. With the dynamic update capability that the OSGi framework provides, now you can update the plug-in classes without restarting the JVM. These plug-ins are exported by user bundles as services. WebSphere eXtreme Scale accesses the service or services by looking them up in the OSGi registry.

eXtreme Scale containers can be configured to start more easily and dynamically using either the OSGi configuration admin service or with OSGi Blueprint. If you want to deploy a new data grid with its placement strategy, you can do so by creating an OSGi configuration or by deploying a bundle with eXtreme Scale descriptor XML files. With OSGi support, application bundles containing eXtreme Scale configuration data can be installed, started, stopped, updated, and uninstalled without restarting the whole system. With this capability, you can upgrade the application without disrupting the data grid.

Plug-in beans and services can be configured with custom shard scopes, enabling sophisticated options to integrate with other services in the data grid. Each plug-in can use OSGi Blueprint rankings to verify that every instance of the plug-in is activated is at the correct version. An OSGi-managed bean (MBean) and **xscmd** utility are provided, which allow you to query the eXtreme Scale plug-in OSGi services and their rankings.

This capability allows administrators to quickly recognize potential configuration and administration errors and upgrade the plug-in service rankings in use by eXtreme Scale .

OSGi bundles

To interact with and deploy plug-ins in the OSGi framework, you must use *bundles*. In the OSGi service platform, a bundle is a Java archive (JAR) file that contains Java code, resources, and a manifest that describes the bundle and its dependencies. The bundle is the unit of deployment for an application. The eXtreme Scale product supports the following bundle types:

Server bundle
: The server bundle is the objectgrid.jar file and is installed with the server feature of the eXtreme Scale stand-alone installation. It is required for running eXtreme Scale servers and can also be used for runningeXtreme Scale clients, or local, in-memory caches. The bundle ID for the objectgrid.jar file is com.ibm.websphere.xs.server_`<version>`, where the version is in the format: `<Version>.<Release>.<Modification>`. For example, the server bundle for eXtreme Scale version 7.1.1 is com.ibm.websphere.xs.server_7.1.1.

Client bundle
: The client bundle is the ogclient.jar file and is installed with the client feature of the eXtreme Scale stand-alone installations and is used to run eXtreme Scale clients or local, in-memory caches. The bundle ID for the ogclient.jar file is com.ibm.websphere.xs.client_`version`, where the version is in the format: `<Version>.<Release>.<Modification>`. For example, the client bundle for eXtreme Scale version 7.1.1 is com.ibm.websphere.xs.client_7.1.1.

Introduction: Starting and configuring the eXtreme Scale server and container to run plug-ins in the OSGi framework

Installing the Eclipse Equinox OSGi framework with Eclipse Gemini for clients and servers

If you want to deploy WebSphere® eXtreme Scale in the OSGi framework, then you must set up the Eclipse Equinox Environment.

About this task

The task requires that you download and install the Blueprint framework, which allows you to later configure JavaBeans and expose them as services. The use of services is important because you can expose plug-ins as OSGi services so they can be used by the eXtreme Scale run time environment. The product supports two blueprint containers within the Eclipse Equinox core OSGi framework: Eclipse Gemini and Apache Aries. Use this procedure to set up the Eclipse Gemini container.

Procedure

1. Download Eclipse Equinox SDK Version 3.6.1 or later from the Eclipse website. Create a directory for the Equinox framework, for example: /opt/equinox. These instructions refer to this directory as equinox_root. Extract the compressed file in the equinox_root directory.
2. Download the gemini-blueprint incubation 1.0.0 compressed file from the Eclipse website. Extract the file contents into a temporary directory, and copy the following extracted files to the equinox_root/plugins directory:

```
dist/gemini-blueprint-core-1.0.0.jar
dist/gemini-blueprint-extender-1.0.0.jar
dist/gemini-blueprint-io-1.0.0.jar
```

Attention: Depending on the location where you download the compressed Blueprint file, the extracted files might have the extension, RELEASE.jar, much like the Spring framework JAR files in the next step. You must verify that the file names match the file references in the config.ini file.

3. Download the Spring Framework Version 3.0.5 from the following SpringSource web page: http://www.springsource.com/download/community. Extract it into a temporary directory, and copy the following extracted files to the equinox_root/plugins directory:

```
org.springframework.aop-3.0.5.RELEASE.jar
org.springframework.asm-3.0.5.RELEASE.jar
org.springframework.beans-3.0.5.RELEASE.jar
org.springframework.context-3.0.5.RELEASE.jar
org.springframework.core-3.0.5.RELEASE.jar
org.springframework.expression-3.0.5.RELEASE.jar
```

4. Download the AOP Alliance Java™ archive (JAR) file from the SpringSource web page. Copy the com.springsource.org.aopalliance-1.0.0.jar to the equinox_root/plugins directory.
5. Download the Apache commons logging 1.1.1 JAR file from the SpringSource web page. Copy the com.springsource.org.apache.commons.logging-1.1.1.jar file to the equinox_root/plugins directory.
6. Download the Luminis OSGi Configuration Admin command-line client. Use this JAR file bundle to manage OSGi administrative configurations. Copy the net.luminis.cmc-0.2.5.jar to the equinox_root/plugins directory.
7. Download the Apache Felix file installation Version 3.0.2 bundle from the following web page: http://felix.apache.org/site/index.html. Copy the org.apache.felix.fileinstall-3.0.2.jar file to the equinox_root/plugins directory.
8. Create a configuration directory inside equinox_root/plugins directory; for example:

```
mkdir equinox_root/plugins/configuration
```

9. Create the following config.ini file in the equinox_root/plugins/configuration directory, replacing *equinox_root* with the absolute path to your equinox_root directory and removing all trailing spaces after the backslash on each line. You must include a blank line at the end of the file; for example:

```
osgi.noShutdown=true
osgi.java.profile.bootdelegation=none
org.osgi.framework.bootdelegation=none
eclipse.ignoreApp=true
osgi.bundles=\
org.eclipse.osgi.services_3.2.100.v20100503.jar@1:start, \
org.eclipse.osgi.util_3.2.100.v20100503.jar@1:start, \
org.eclipse.equinox.cm_1.0.200.v20100520.jar@1:start, \
com.springsource.org.apache.commons.logging-1.1.1.jar@1:start, \
com.springsource.org.aopalliance-1.0.0.jar@1:start, \
org.springframework.aop-3.0.5.RELEASE.jar@1:start, \
org.springframework.asm-3.0.5.RELEASE.jar@1:start, \
org.springframework.beans-3.0.5.RELEASE.jar@1:start, \
org.springframework.context-3.0.5.RELEASE.jar@1:start, \
org.springframework.core-3.0.5.RELEASE.jar@1:start, \
org.springframework.expression-3.0.5.RELEASE.jar@1:start, \
org.apache.felix.fileinstall-3.0.2.jar@1:start, \
net.luminis.cmc-0.2.5.jar@1:start, \
gemini-blueprint-core-1.0.0.jar@1:start, \
gemini-blueprint-extender-1.0.0.jar@1:start, \
gemini-blueprint-io-1.0.0.jar@1:start
```

If you have already set up the environment, you can clean up the Equinox plug-in repository by removing the following directory: equinox_root\plugins\configuration\org.eclipse.osgi.

10. Run the following commands to start equinox console.
If you are running a different version of Equinox, then your JAR file name is different from the one in the following example:

```
java -jar plugins\org.eclipse.osgi_3.6.1.R36x_v20100806.jar -console
```

- Installing eXtreme Scale bundles
WebSphere eXtreme Scale includes bundles that can be installed into an Eclipse Equinox OSGi framework. These bundles are required to start eXtreme Scale servers or use eXtreme Scale clients in OSGi. You can install the eXtreme Scale bundles using the Equinox console or using the config.ini configuration file.

Introduction: Starting and configuring the eXtreme Scale server and container to run plug-ins in the OSGi framework

Installing eXtreme Scale bundles

WebSphere® eXtreme Scale includes bundles that can be installed into an Eclipse Equinox OSGi framework. These bundles are required to start eXtreme Scale servers or use eXtreme Scale clients in OSGi. You can install the eXtreme Scale bundles using the Equinox console or using the config.ini configuration file.

Before you begin

This task assumes that you have installed the following products:

- Eclipse Equinox OSGi framework
- eXtreme Scale stand-alone client or server

About this task

eXtreme Scale includes two bundles. Only one of the following bundles is required in an OSGi framework:

objectgrid.jar
: The server bundle is the objectgrid.jar file and is installed with the eXtreme Scale stand-alone server installation and is required for running eXtreme Scale servers and can also be used for running eXtreme Scale clients, or local, in-memory caches. The bundle ID for the objectgrid.jar file is com.ibm.websphere.xs.server_`<version>`, where the version is in the format: `<Version>.<Release>.<Modification>`. For example, the server bundle for this release is `com.ibm.websphere.xs.server_8.5.0`.

ogclient.jar
: The ogclient.jar bundle is installed with the eXtreme Scale stand-alone and client installations and is used to run eXtreme Scale clients or local, in-memory caches. The bundle ID for ogclient.jar file is com.ibm.websphere.xs.client_`<version>`, where the version is in the format: `<Version>_<Release>_<Modification`. For example, the client bundle for this release is `com.ibm.websphere.xs.server_8.5.0`.

For more information about developing eXtreme Scale plug-ins, see the System APIs and Plug-ins topic.
Related concepts:
Embedded server API

Install the eXtreme Scale client or server bundle into the Eclipse Equinox OSGi framework using the Equinox console

Procedure

1. Start the Eclipse Equinox framework with the console enabled; for example:
   `java_home/bin/java -jar <equinox_root>/plugins/org.eclipse.osgi_3.6.1.R36x_v20100806.jar -console`
2. Install the eXtreme Scale client or server bundle in the Equinox console:

   ```
   osgi> install file:///<path to bundle>
   ```

3. Equinox displays the bundle ID for the newly installed bundle:

   ```
   Bundle id is 25
   ```

4. Start the bundle in the Equinox console, where `<id>` is the bundle ID assigned when the bundle was installed:

   ```
   osgi>  start <id>
   ```

5. Retrieve the service status in the Equinox console to verify that the bundle has started; for example:

   ```
   osgi> ss
   ```

   When the bundle starts successfully, the bundle displays the ACTIVE state; for example:

   ```
   25      ACTIVE      com.ibm.websphere.xs.server_8.5.0
   ```

Install the eXtreme Scale client or server bundle into the Eclipse Equinox OSGi framework using the config.ini file

Procedure

1. Copy the eXtreme Scale client or server (objectgrid.jar or ogclient.jar) bundle from the `<wxs_install_root>/ObjectGrid/lib` to the Eclipse Equinox plug-ins directory; for example: <equinox_root>/plugins
2. Edit the Eclipse Equinox config.ini configuration file, and add the bundle to the osgi.bundles property; for example:

   ```
   osgi.bundles=\
   org.eclipse.osgi.services_3.2.100.v20100503.jar@1:start, \
   org.eclipse.osgi.util_3.2.100.v20100503.jar@1:start, \
   org.eclipse.equinox.cm_1.0.200.v20100520.jar@1:start, \
   objectgrid.jar@1:start
   ```

   Important: Verify that a blank line exists after the last bundle name. Each bundle is separated by a comma.
3. Start the Eclipse Equinox framework with the console enabled; for example:
   `java_home/bin/java -jar <equinox_root>/plugins/org.eclipse.osgi_3.6.1.R36x_v20100806.jar -console`
4. Retrieve the service status in the Equinox console to verify that the bundle has started:

```
osgi> ss
```

When the bundle starts successfully, the bundle displays the ACTIVE state; for example:

```
25      ACTIVE      com.ibm.websphere.xs.server_8.5.0
```

Results

The eXtreme Scale server or client bundle is installed and started in your Eclipse Equinox OSGi framework.

Running eXtreme Scale containers with non-dynamic plug-ins in an OSGi environment

If you do not need to use the dynamic capability of an OSGi environment, you can still take advantage of tighter coupling, declarative packaging, and service dependencies that the OSGi framework offers.

Before you begin

1. Develop your application using WebSphere® eXtreme Scale APIs and plug-ins.
2. Package the application in one or more OSGi bundles with the appropriate import or export dependencies that are declared in one or more bundle manifests. Ensure that all classes or packages that are required for the plug-ins, agents, data objects, and so on, are exported.

About this task

With dynamic plug-ins, you can upgrade your plug-ins without stopping the grid. To use this capability, the original and new plug-ins must be compatible. If you do not need to update plug-ins, or can afford to stop the grid to upgrade them, then you may not need the complexity of dynamic plug-ins. However, there are still good reasons to run your eXtreme Scale application in an OSGi environment. These reasons include the tighter coupling, declarative package, service dependencies, and so on.

One concern with hosting the grid or client in an OSGi environment without using dynamic plug-ins (more specifically, without declaring the plug-ins using OSGi services) is how the eXtreme Scale bundle loads the plug-in classes. The eXtreme Scale bundle relies on OSGi services to load plug-in classes, which allows the bundle to invoke object methods on classes in other bundles without directly importing the packages of those classes.

When the plug-ins are not made available via OSGi services, the eXtreme Scale bundle must be able to load the plug-in classes directly. Rather than modifying the manifest of the eXtreme Scale bundle to import user classes and packages, create a bundle fragment that adds the necessary package imports. The fragment can also import the classes needed for other non-plug-in user classes, such as data objects and agent classes.

Procedure

1. Create an OSGi fragment that uses the eXtreme Scale bundle (client or server, depending on the intended deployment environment) as its host. The fragment declares dependencies (Import-Package) on all of the packages that one or more plug-ins must load. For example, if you are installing a serializer plug-in whose classes reside in the com.mycompany.myapp.serializers package and depends on classes in the com.mycompany.myapp.common package, then your fragment META-INF/MANIFEST.MF file resembles the following example:

   ```
   Bundle-ManifestVersion: 2
   Bundle-Name: Plug-in fragment for XS serializers
   Bundle-SymbolicName: com.mycompany.myapp.myfragment; singleton:=true
   Bundle-Version: 1.0.0
   Fragment-Host: com.ibm.websphere.xs.server; bundle-version=7.1.1
   Manifest-Version: 1.0
   Import-Package: com.mycompany.myapp.serializers,
    com.mycompany.myapp.common
   …
   ```

   This manifest must be packaged in a fragment JAR file, which in this example is com.mycompany.myapp.myfragment_1.0.0.jar.
2. Deploy both the newly created fragment, the eXtreme Scale bundle, and application bundles to your OSGi environment. Now, start the bundles.

Results

You can now test and run your application in the OSGi environment without using OSGi services to load user classes, such as plug-ins and agents.

Next topic: Administering eXtreme Scale servers and applications in an OSGi environment
Related concepts:
Java plug-ins overview
Related tasks:
Starting eXtreme Scale servers using the Eclipse Equinox OSGi framework

Administering eXtreme Scale servers and applications in an OSGi environment

Use this topic to install the WebSphere® eXtreme Scale server bundle, an optional fragment that allows loading of your application bundles and non-dynamic user classes, such as plug-ins, agents, data objects, and so on.

Before you begin

1. Install and start a supported OSGi framework. Currently Equinox is the only supported OSGi implementation. If your application uses Blueprint, make sure to install and start a supported Blueprint implementation. Apache Aries and Eclipse Gemini are both supported.
2. Open the OSGi console.

Procedure

1. Install the eXtreme Scale server bundle. You must know the file URL of the bundle Java archive (JAR) file. For example:

```
osgi> install file:///home/user1/myOsgiEnv/plugins/objectgrid.jar
Bundle id is 41

osgi>
```

   The eXtreme Scale bundle is now installed, but not yet resolved.
2. If the eXtreme Scale server must load user classes directly, rather than using dynamic plug-ins exposed via OSGi services, then you must also install a user-developed fragment that either provides those classes or imports them. If you are using dynamic plug-ins and not using agents, you can skip this step. Here is an example of how to install a custom fragment:

```
osgi> install file:///home/user1/myOsgiEnv/plugins/myFragment.jar
Bundle id is 42

osgi> ss

Framework is launched.

id      State       Bundle
...
41      INSTALLED   com.ibm.websphere.xs.server_7.1.1
42      INSTALLED   com.mycompany.myfragment_1.0.0

osgi>
```

   Now the eXtreme Scale server bundle and the custom fragment that attaches to the bundle are both installed.
3. Start the eXtreme Scale server bundle; for example:

```
osgi> start 41

osgi> ss

Framework is launched.

id      State       Bundle
...
41      ACTIVE      com.ibm.websphere.xs.server_7.1.1
                      Fragments=42
42      RESOLVED    com.mycompany.myfragment_1.0.0
                      Master=41

osgi>
```

4. Now install and start all user application bundles using the same previously mentioned commands. To start a grid on this server, the server and container definition must be declared using Blueprint, or the application must start the server and container programmatically from a bundle activator or some other mechanism.

Results

The eXtreme Scale server bundle and application are deployed, started, and ready to accept work.
Previous topic: Running eXtreme Scale containers with non-dynamic plug-ins in an OSGi environment
Next topic: Building and running eXtreme Scale dynamic plug-ins for use in an OSGi environment

Building and running eXtreme Scale dynamic plug-ins for use in an OSGi environment

All eXtreme Scale plug-ins can be configured for an OSGi environment. The primary benefit of dynamic plug-ins is that they allow you to upgrade them without shutting down the grid. This allows you to evolve an application without restarting the grid container processes.

About this task

WebSphere® eXtreme Scale OSGi support allows you to deploy the product in an OSGi framework, such as Eclipse Equinox. Previously, if you wanted to update the plug-ins used by eXtreme Scale, you had to restart the Java virtual machine (JVM) to apply the new versions of the plug-ins. With the dynamic plug-in support provided by eXtreme Scale and the ability to update bundles that the OSGi framework provides, you can now update the plug-in classes without restarting the

JVM. These plug-ins are exported by *bundles* as services. WebSphere eXtreme Scale accesses the service by looking up the OSGi registry. In the OSGi service platform, a bundle is a Java archive (JAR) file that contains Java code, resources, and a manifest that describes the bundle and its dependencies. The bundle is the unit of deployment for an application.

Procedure

1. Build eXtreme Scale dynamic plug-ins.
2. Configure eXtreme Scale plug-ins with OSGi Blueprint.
3. Install and starting OSGi-enabled plug-ins.

- Building eXtreme Scale dynamic plug-ins
  WebSphere eXtreme Scale includes ObjectGrid and BackingMap plug-ins. These plug-ins are implemented in Java and are configured using the ObjectGrid descriptor XML file. To create a dynamic plug-in that can be dynamically upgraded, they need to be aware of ObjectGrid and BackingMap life cycle events because they might need to complete some actions during an update. Enhancing a plug-in bundle with life cycle callback methods, event listeners, or both allows the plug-in to complete those actions at the appropriate times.
- Configuring eXtreme Scale plug-ins with OSGi Blueprint
  All eXtreme Scale ObjectGrid and BackingMap plug-ins can be defined as OSGi beans and services using the OSGi Blueprint Service available with Eclipse Gemini or Apache Aries.
- Installing and starting OSGi-enabled plug-ins
  In this task, you install the dynamic plug-in bundle into the OSGi framework. Then, you start the plug-in.

Previous topic: Administering eXtreme Scale servers and applications in an OSGi environment

Building eXtreme Scale dynamic plug-ins

WebSphere® eXtreme Scale includes ObjectGrid and BackingMap plug-ins. These plug-ins are implemented in Java™ and are configured using the ObjectGrid descriptor XML file. To create a dynamic plug-in that can be dynamically upgraded, they need to be aware of ObjectGrid and BackingMap life cycle events because they might need to complete some actions during an update. Enhancing a plug-in bundle with life cycle callback methods, event listeners, or both allows the plug-in to complete those actions at the appropriate times.

Before you begin

This topic assumes that you have built the appropriate plug-in. For more information about developing eXtreme Scale plug-ins, see the System APIs and plug-ins topic.

About this task

All eXtreme Scale plug-ins apply to either a BackingMap or ObjectGrid instance. Many plug-ins also interact with other plug-ins. For example, a Loader and TransactionCallback plug-in work together to properly interact with a database transaction and the various database JDBC calls. Some plug-ins might also need to cache configuration data from other plug-ins to improve performance.

The BackingMapLifecycleListener and ObjectGridLifecycleListener plug-ins provide life cycle operations for the respective BackingMap and ObjectGrid instances. This process allows plug-ins to be notified when the parent BackingMap or ObjectGrid and their respective plug-ins might be changed. BackingMap plug-ins implement the BackingMapLifecyleListener interface, and ObjectGrid plug-ins implement the ObjectGridLifecycleListener interface. These plug-ins are automatically invoked when the life cycle of the parent BackingMap or ObjectGrid changes. For more information about life cycle plug-ins, see the Managing plug-in life cycles topic.

You can expect to enhance bundles using the life cycle methods or event listeners in the following common tasks:

- Starting and stopping resources, such as threads or messaging subscribers.
- Specifying that a notification occur when peer plug-ins have been updated, allowing direct access to the plug-in and detecting any changes.

Whenever you access another plug-in directly, access that plug-in through the OSGi container to ensure that all parts of the system reference the correct plug-in. If, for example, some component in the application directly references, or caches, an instance of a plug-in, it will maintain its reference to that version of the plug-in, even after that plug-in has been dynamically updated. This behavior can cause application-related problems as well as memory leaks. Therefore, write code that depends on dynamic plug-ins that obtain its reference using OSGi, getService() semantics. If the application must cache one or more plug-ins, it listens for life cycle events using ObjectGridLifecycleListener and BackingMapLifecycleListener interfaces. The application must also be able to refresh its cache when necessary, in a thread safe manner.

All eXtreme Scale plug-ins used with OSGi must also implement the respective BackingMapPlugin or ObjectGridPlugin interfaces. New plug-ins such as the MapSerializerPlugin interface enforce this practice. These interfaces provide the eXtreme Scale runtime environment and OSGi a consistent interface for injecting state into the plug-in and controlling its life cycle.

Use this task to specify that a notification occurs when peer plug-ins are updated, you might create a listener factory that produces a listener instance.

Procedure

- Update the ObjectGrid plug-in class to implement the ObjectGridPlugin interface. This interface includes methods that allow eXtreme Scale to initialize, set the ObjectGrid instance and destroy the plug-in. See the following code example:

```
package com.mycompany;
import com.ibm.websphere.objectgrid.plugins.ObjectGridPlugin;
```

```
...

public class MyTranCallback implements TransactionCallback, ObjectGridPlugin {

    private ObjectGrid og = null;

    private enum State {
        NEW, INITIALIZED, DESTROYED
    }

    private State state = State.NEW;

    public void setObjectGrid(ObjectGrid grid) {
        this.og = grid;
    }

    public ObjectGrid getObjectGrid() {
        return this.og;
    }
    void initialize() {
        // Handle any plug-in initialization here.  This is called by
        // eXtreme Scale, and not the OSGi bean manager.
        state = State.INITIALIZED;
    }
    boolean isInitialized() {
        return state == State.INITIALIZED;
    }

    public void destroy() {
        // Destroy the plug-in and release any resources.  This
        // can be callsed by the OSGi Bean Manager or by eXtreme Scale.
        state = State.DESTROYED;
    }

    public boolean isDestroyed() {
        return state == State.DESTROYED;
    }
}
```

- Update the ObjectGrid plug-in class to implement the ObjectGridLifecycleListener interface. See the following code example:

```
package com.mycompany;
import com.ibm.websphere.objectgrid.plugins.ObjectGridLifecycleListener;
      import com.ibm.websphere.objectgrid.plugins.ObjectGridLifecycleListener.LifecycleEvent;
      ...

      public class MyTranCallback implements TransactionCallback, ObjectGridPlugin, ObjectGridLifecycleListener{
          public void objectGridStateChanged(LifecycleEvent event) {
              switch(event.getState()) {
              case NEW:
              case DESTROYED:
              case DESTROYING:
              case INITIALIZING:
                  break;
              case INITIALIZED:
                  // Lookup a Loader or MapSerializerPlugin using
                  // OSGi or directly from the ObjectGrid instance.
                  lookupOtherPlugins()
                  break;
              case STARTING:
              case PRELOAD:
                  break;
              case ONLINE:
                  if (event.isWritable()) {
                      startupProcessingForPrimary();
                  } else {
                      startupProcessingForReplica();
                  }
                  break;
              case QUIESCE:
                  if (event.isWritable()) {
                      quiesceProcessingForPrimary();
                  } else {
                      quiesceProcessingForReplica();
                  }
                  break;
              case OFFLINE:
                  shutdownShardComponents();
                  break;
              }
          }
          ...
      }
```

- Update a BackingMap plug-in. Update the BackingMap plug-in class to implement the BackingMap plu-in interface. This interface includes methods that allow eXtreme Scale to initialize, set the BackingMap instance, and destroy the plug-in. See the following code example:

```
package com.mycompany;
import com.ibm.websphere.objectgrid.plugins.BackingMapPlugin;
...
```

```
public class MyLoader implements Loader, BackingMapPlugin {

    private BackingMap bmap = null;

    private enum State {
        NEW, INITIALIZED, DESTROYED
    }

    private State state = State.NEW;

    public void setBackingMap(BackingMap map) {
        this.bmap = map;
    }

    public BackingMap getBackingMap() {
        return this.bmap;
    }
    void initialize() {
        // Handle any plug-in initialization here.  This is called by
        // eXtreme Scale, and not the OSGi bean manager.
        state = State.INITIALIZED;
    }
    boolean isInitialized() {
        return state == State.INITIALIZED;
    }

    public void destroy() {
        // Destroy the plug-in and release any resources.  This
        // can be callsed by the OSGi Bean Manager or by eXtreme Scale.
        state = State.DESTROYED;
    }

    public boolean isDestroyed() {
        return state == State.DESTROYED;
    }
}
```

- Update the BackingMap plug-in class to implement the BackingMapLifecycleListener interface. See the following code example:

```
package com.mycompany;

    import com.ibm.websphere.objectgrid.plugins.BackingMapLifecycleListener;
    import com.ibm.websphere.objectgrid.plugins.BackingMapLifecycleListener.LifecycleEvent;
    ...

    public class MyLoader implements Loader, ObjectGridPlugin, ObjectGridLifecycleListener{
        ...
        public void backingMapStateChanged(LifecycleEvent event) {
            switch(event.getState()) {
            case NEW:
            case DESTROYED:
            case DESTROYING:
            case INITIALIZING:
                break;
            case INITIALIZED:
                // Lookup a MapSerializerPlugin using
                // OSGi or directly from the ObjectGrid instance.
                lookupOtherPlugins()
                break;
            case STARTING:
            case PRELOAD:
                break;
            case ONLINE:
                if (event.isWritable()) {
                    startupProcessingForPrimary();
                } else {
                    startupProcessingForReplica();
                }
                break;
            case QUIESCE:
                if (event.isWritable()) {
                    quiesceProcessingForPrimary();
                } else {
                    quiesceProcessingForReplica();
                }
                break;
            case OFFLINE:
                shutdownShardComponents();
                break;
            }
        }
        ...
    }
```

Results

By implementing the ObjectGridPlugin or BackingMapPlugin interface, eXtreme Scale can control the life cycle of your plug-in at the right times.

By implementing the ObjectGridLifecycleListener or BackingMapLifecycleListener interface, the plug-in is automatically registered as a listener of the associated ObjectGrid or BackingMap life cycle events. The INITIALIZING event is used to signal that all of the ObjectGrid and BackingMap plug-ins have been initialized and are available for lookup and use. The ONLINE event is used to signal that the ObjectGrid is online and ready to start processing events.

Configuring eXtreme Scale plug-ins with OSGi Blueprint

All eXtreme Scale ObjectGrid and BackingMap plug-ins can be defined as OSGi beans and services using the OSGi Blueprint Service available with Eclipse Gemini or Apache Aries.

Before you begin

Before you can configure your plug-ins as OSGi services, you must first package your plug-ins in an OSGi bundle, and understand the fundamental principles of the required plug-ins. The bundle must import the WebSphere® eXtreme Scale server or client packages and other dependent packages required by the plug-ins, or create a bundle dependency on the eXtreme Scale server or client bundles This topic describes how to configure the Blueprint XML to create plug-in beans and expose them as OSGi services for eXtreme Scale to use.

About this task

Beans and services are defined in a Blueprint XML file, and the Blueprint container discovers, creates, and wires the beans together and exposes them as services. The process makes the beans available to other OSGi bundles, including the eXtreme Scale server and client bundles.

When creating custom plug-in services for use with eXtreme Scale, the bundle that is to host the plug-ins, must be configured to use Blueprint. In addition, a Blueprint XML file must be created and stored within the bundle. Read about building OSGi applications with the Blueprint Container specification for a general understanding of the specification.

Procedure

1. Create a Blueprint XML file. You can name the file anything. However, you must include the blueprint namespace:

```
<?xml version="1.0" encoding="UTF-8"?>
<blueprint xmlns="http://www.osgi.org/xmlns/blueprint/v1.0.0">
...
</blueprint>
```

2. Create bean definitions in the Blueprint XML file for each eXtreme Scale plug-in.
   Beans are defined using the `<bean>` element and can be wired to other bean references and can include initialization parameters.
   Important: When defining a bean, you must use the correct scope. Blueprint supports the singleton and prototype scopes. eXtreme Scale also supports a custom shard scope.
   Define most eXtreme Scale plug-ins as prototype or shard-scoped beans, since all of the beans must be unique for each ObjectGrid shard or BackingMap instance it is associated with. Shard-scoped beans can be useful when using the beans in other contexts to allow retrieving the correct instance.

   To define a prototype-scoped bean, use the `scope="prototype"` attribute on the bean:

```
<bean
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsblueprintosgi_myPluginBean"
class="com.mycompany.MyBean" scope="prototype">
...
</bean>
```

   To define a shard-scoped bean, you must add the `objectgrid` namespace to the XML schema, and use the `scope="objectgrid:shard"` attribute on the bean:

```
<?xml version="1.0" encoding="UTF-8"?>

<blueprint xmlns="http://www.osgi.org/xmlns/blueprint/v1.0.0"

xmlns:objectgrid="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsblueprintosgi_h
ttp://www.ibm.com/schema/objectgrid"

           xsi:schemaLocation="http://www.ibm.com/schema/objectgrid
                http://www.ibm.com/schema/objectgrid/objectgrid.xsd">

    <bean
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsblueprintosgi_myPluginBean"
class="com.mycompany.MyBean"
                        scope="objectgrid:shard">
    ...
    </bean>

...
```

3. Create PluginServiceFactory bean definitions for each plug-in bean. All eXtreme Scale beans must have a PluginServiceFactory bean defined so that the correct bean scope can be applied. eXtreme Scale includes a BlueprintServiceFactory that you can use. It includes two properties that must be set. You must set the blueprintContainer property to the `blueprintContainer` reference, and the beanId property must be set to the bean identifier name. When eXtreme Scale looks up the service to instantiate the appropriate beans, the server looks up the bean component instance using the Blueprint container.

```
bean
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsblueprintosgi_myPluginBeanFac
tory"
    class="com.ibm.websphere.objectgrid.plugins.osgi.BluePrintServiceFactory">
    <property name="blueprintContainer" ref="blueprintContainer" />
    <property name="beanId" value="myPluginBean" />
</bean>
```

4. Create a service manager for each PluginServiceFactory bean. Each service manager exposes the PluginServiceFactory bean, using the `<service>` element. The service element identifies the name to expose to OSGi, the reference to the PluginServiceFactory bean, the interface to expose, and the ranking of the service. eXtreme Scale uses the service manager ranking to perform service upgrades when the eXtreme Scale grid is active. If the ranking is not specified, the OSGi framework assumes a ranking of 0. Read about updating service rankings for more information.
   Blueprint includes several options for configuring service managers. To define a simple service manager for a PluginServiceFactory bean, create a `<service>` element for each PluginServiceFactory bean:

   ```
   <service ref="myPluginBeanFactory"
       interface="com.ibm.websphere.objectgrid.plugins.osgi.PluginServiceFactory"
       ranking="1">
   </service>
   ```

5. Store the Blueprint XML file in the plug-ins bundle. The Blueprint XML file must be stored in the OSGI-INF/blueprint directory for the Blueprint container to be discovered.
   To store the Blueprint XML file in a different directory, you must specify the following Bundle-Blueprint manifest header:

   ```
   Bundle-Blueprint: OSGI-INF/blueprint.xml
   ```

Results

The eXtreme Scale plug-ins are now configured to be exposed in an OSGi Blueprint container, In addition, the ObjectGrid descriptor XML file is configured to reference the plug-ins using the OSGi Blueprint service.

Installing and starting OSGi-enabled plug-ins

In this task, you install the dynamic plug-in bundle into the OSGi framework. Then, you start the plug-in.

Before you begin

Complete the following tasks before the OSGi-enabled plug-ins are installed and started.

- The eXtreme Scale server or client bundle is installed into the Eclipse Equinox OSGi framework. See Installing eXtreme Scale bundles.
- One or more dynamic BackingMap or ObjectGrid plug-ins are implemented. See Building eXtreme Scale dynamic plug-ins.
- The dynamic plug-ins are packaged as OSGi services in OSGi bundles.
- By default, the JVM continues to run when each eXtreme Scale server in an OSGi framework is stopped in the **xscmd** utility with the **-c teardown** command. If you want eXtreme Scale to exit the JVM after each server is stopped, then set the server property exitJVMOnTeardown to `true`. For more information, see Server properties file.

About this task

Install the bundle with the Eclipse Equinox console. There are several different methods to install the bundle, including a modification of the config.ini configuration file. Products that embed Eclipse Equinox include alternative methods for adding bundles in the config.ini file. For more information, seeEclipse runtime options.

OSGi allows bundles to be started that have duplicate services. WebSphere eXtreme Scale uses the latest service ranking. When multiple OSGi frameworks are started in an eXtreme Scale data grid, you must make sure that the correct service rankings are started on each server. Failure to do so causes the grid to be started with a mixture of different versions.

To see which versions are in-use by the data grid, use the **xscmd** utility to check the current and available rankings. For more information, see Updating OSGi services for eXtreme Scale plug-ins with xscmd.

Procedure

Install the plug-in bundle into the Eclipse Equinox OSGi framework with the OSGi console.

1. Start the Eclipse Equinox framework with the console enabled.

   ```
   <java_home>/bin/java -jar <equinox_root>/plugins/org.eclipse.osgi_3.6.1.R36x_v20100806.jar -console
   ```

2. Install the plug-in bundle in the Equinox console.

   ```
   osgi> install file:///<path to bundle>
   ```

   Equinox lists the bundle ID for the newly installed bundle:

   ```
   Bundle id is 17
   ```

3. Enter the following line to start the bundle in the Equinox console, where <id> is the bundle ID assigned when the bundle was installed:

   ```
   osgi>  start <id>
   ```

4. Retrieve the service status in the Equinox console to verify that the bundle started:

   ```
   osgi> ss
   ```

   When the bundle starts, the bundle lists the ACTIVE state, for example:

   ```
   17      ACTIVE      com.mycompany.plugin.bundle_VRM
   ```

Install the plug-in bundle into the Eclipse Equinox OSGi framework with the config.ini file.

5. Copy the plug-in bundle into the Eclipse Equinox plug-ins directory: For example:

   ```
   <equinox_root>/plugins
   ```

6. Edit the Eclipse Equinox config.ini configuration file, and add the bundle to the osgi.bundles property. For example:

   ```
   osgi.bundles=\
   org.eclipse.osgi.services_3.2.100.v20100503.jar@1:start, \
   org.eclipse.osgi.util_3.2.100.v20100503.jar@1:start, \
   org.eclipse.equinox.cm_1.0.200.v20100520.jar@1:start, \
   com.mycompany.plugin.bundle_VRM.jar@1:start
   ```

   Important: Verify that there is a blank line after the last bundle name. Each bundle is separated by a comma.
7. Start the Eclipse Equinox framework with the console enabled. For example:

   ```
   <java_home>/bin/java -jar <equinox_root>/plugins/org.eclipse.osgi_3.6.1.R36x_v20100806.jar -console
   ```

8. Retrieve the service status in the Equinox console to verify that the bundle started. For example:

   ```
   osgi> ss
   ```

   When the bundle starts, the bundle lists the ACTIVE state; for example:

   ```
   17      ACTIVE      com.mycompany.plugin.bundle_VRM
   ```

Results

The plug-in bundle is now installed and started. The eXtreme Scale container or client can now be started. For more information on developing eXtreme Scale plug-ins, see the System APIs and Plug-ins topic.

Running eXtreme Scale containers with dynamic plug-ins in an OSGi environment

If your application is hosted in the Eclipse Equinox OSGi framework with Eclipse Gemini or Apache Aries, then you can use this task to help you install and configure your WebSphere® eXtreme Scale application in OSGi.

Before you begin

Before you start this task, be sure to complete the following tasks:

- Install the Eclipse Equinox OSGi framework with Eclipse Gemini
- Build and run eXtreme Scale dynamic plug-ins for use in an OSGi environment

About this task

With dynamic plug-ins, you can dynamically upgrade the plug-in while the grid is still active. This allows you to update an application without restarting the grid container processes. For more information about developingeXtreme Scale plug-ins, see System APIs and Plug-ins.

Procedure

1. Configure OSGi-enabled plug-ins using the ObjectGrid descriptor XML file.
2. Start eXtreme Scale container servers using the Eclipse Equinox OSGi framework.

3. Administer OSGi services for eXtreme Scale plug-ins with the xscmd utility.
4. Configure servers with OSGi Blueprint.

- Configuring OSGi-enabled plug-ins using the ObjectGrid descriptor XML file
  In this task, you add existing OSGi services to a descriptor XML file so that WebSphere eXtreme Scale containers can recognize and load the OSGi-enabled plug-ins correctly.
- Starting eXtreme Scale servers using the Eclipse Equinox OSGi framework
  WebSphere eXtreme Scale container servers can be started in an Eclipse Equinox OSGi framework using several methods.
- Administering OSGi-enabled services using the xscmd utility
  You can use the **xscmd** utility to complete administrator tasks, such as viewing services and their rankings that are being used by each container, and updating the runtime environment to use new versions of the bundles.
- Configuring servers with OSGi Blueprint
  You can configure WebSphere eXtreme Scale container servers using an OSGi blueprint XML file, allowing simplified packaging and development of self-contained server bundles.

Previous topic: Building and running eXtreme Scale dynamic plug-ins for use in an OSGi environment

Configuring OSGi-enabled plug-ins using the ObjectGrid descriptor XML file

In this task, you add existing OSGi services to a descriptor XML file so that WebSphere® eXtreme Scale containers can recognize and load the OSGi-enabled plug-ins correctly.

Before you begin

To configure your plug-ins, be sure to:

- Create your package, and enable dynamic plug-ins for OSGi deployment.
- Have the names of the OSGi services that represent your plug-ins available.

About this task

You have created an OSGi service to wrap your plug-in. Now, these services must be defined in the objectgrid.xml file so that eXtreme Scale containers can load and configure the plug-in or plug-ins successfully.

Procedure

1. Any grid-specific plug-ins, such as TransactionCallback, must be specified under the objectGrid element. See the following example from the objectgrid.xml file:

```
<?xml version="1.0" encoding="UTF-8"?>

<objectGridConfig xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://ibm.com/ws/objectgrid/config ../objectGrid.xsd"
    xmlns="http://ibm.com/ws/objectgrid/config">

    <objectGrids>
        <objectGrid name="MyGrid" txTimeout="60">
            <bean
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsconfigosgiplugs_myTranCallbac
k" osgiService="myTranCallbackFactory"/>
            ...
        </objectGrid>
        ...
    </objectGrids>
    ...
/objectGridConfig>
```

   Important: The `osgiService` attribute value must match the `ref` attribute value that is specified in the blueprint XML file, where the service was defined for myTranCallback PluginServiceFactory.
2. Any map-specific plug-ins, such as loaders or serializers, for example, must be specified in the backingMapPluginCollections element and referenced from the backingMap element. See the following example from the objectgrid.xml file:

```
<?xml version="1.0" encoding="UTF-8"?>

objectGridConfig xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://ibm.com/ws/objectgrid/config ../objectGrid.xsd"
    xmlns="http://ibm.com/ws/objectgrid/config">
    <objectGrids>
        <objectGrid name="MyGrid" txTimeout="60">
            <backingMap name="MyMap1" lockStrategy="PESSIMISTIC"
                copyMode="COPY_TO_BYTES" nullValuesSupported="false"
                pluginCollectionRef="myPluginCollectionRef1"/>
            <backingMap name="MyMap2" lockStrategy="PESSIMISTIC"
                copyMode="COPY_TO_BYTES" nullValuesSupported="false"
                pluginCollectionRef="myPluginCollectionRef2"/>
            ...
        </objectGrid>
        ...
```

```
    </objectGrids>
    ...
    <backingMapPluginCollections>
        <backingMapPluginCollection
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsconfigosgiplugs_myPluginColle
ctionRef1">
            <bean
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsconfigosgiplugs_MapSerializer
Plugin" osgiService="mySerializerFactory"/>
        </backingMapPluginCollection>
        <backingMapPluginCollection
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsconfigosgiplugs_myPluginColle
ctionRef2">
            <bean
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsconfigosgiplugs_MapSerializer
Plugin" osgiService="myOtherSerializerFactory"/>
            <bean
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsconfigosgiplugs_Loader"
osgiService="myLoader"/>
        </backingMapPluginCollection>
        ...
    </backingMapPluginCollections>
    ...
</objectGridConfig>
```

Results

The objectgrid.xml file in this example tells eXtreme Scale to create a grid called `MyGrid` with two maps, `MyMap1` and `MyMap2`. The `MyMap1` map uses the serializer wrapped by the OSGi service, mySerializerFactory. The `MyMap2` map uses a serializer from the OSGi service, myOtherSerializerFactory, and a loader from the OSGi service, myLoader.

Starting eXtreme Scale servers using the Eclipse Equinox OSGi framework

WebSphere® eXtreme Scale container servers can be started in an Eclipse Equinox OSGi framework using several methods.

Before you begin

Before you can start an eXtreme Scale container, you must have completed the following tasks:

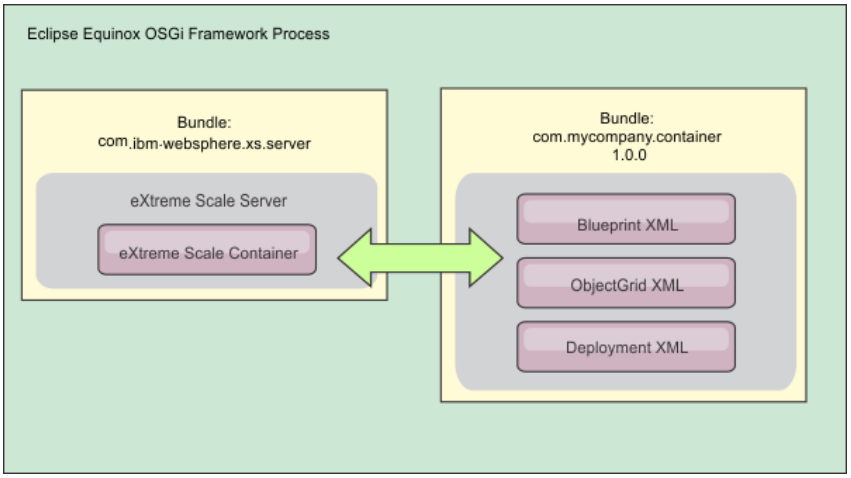
1. The WebSphere eXtreme Scale server bundle must be installed into Eclipse Equinox.
2. Your application must be packaged as an OSGi bundle.
3. Your WebSphere eXtreme Scale plug-ins (if any) must be packaged as an OSGi bundle. They can be bundled in the same bundle as your application or as separate bundles.
4. If your container servers are using IBM® eXtremeMemory, you must first configure the native libraries. For more information, see Configuring IBM eXtremeMemory.

About this task

This task describes how to start an eXtreme Scale container server in an Eclipse Equinox OSGi framework. You can use any of the following methods to start container servers using the Eclipse Equinox implementation:

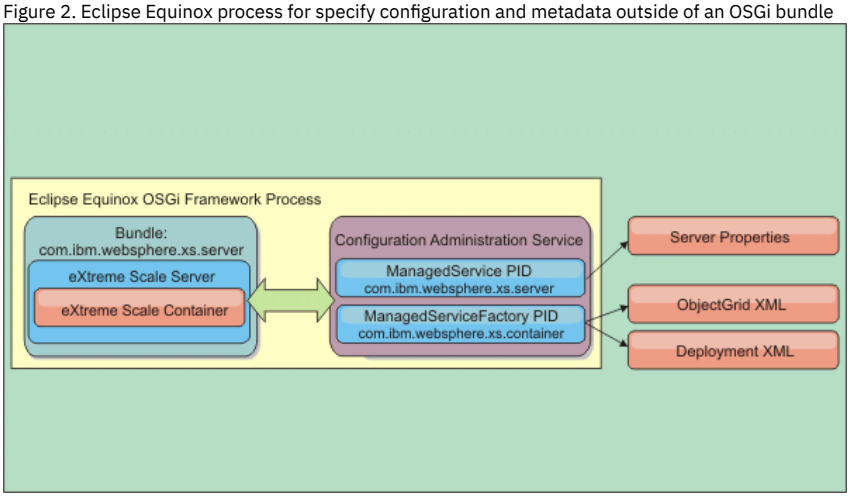
- OSGi Blueprint service
  You can include all configuration and metadata in an OSGi bundle. See the following image to understand the Eclipse Equinox process for this method:

  Figure 1. Eclipse Equinox process for including all configuration and metadata in an OSGi bundle



- OSGi Configuration Admin service
  You can specify configuration and metadata outside of an OSGi bundle. See the following image to understand the Eclipse Equinox process for this method:

  Figure 2. Eclipse Equinox process for specify configuration and metadata outside of an OSGi bundle



- Programmatically
  Supports customized configuration solutions.

In each case, an eXtreme Scale server singleton is configured and one or more containers are configured.

The eXtreme Scale server bundle, objectgrid.jar, includes all of the required libraries to start and run an eXtreme Scale grid container in an OSGi framework. The server runtime environment communicates with user-supplied plug-ins and data objects using the OSGi service manager.
Important: After an eXtreme Scale server bundle is started and the eXtreme Scale server is initialized, it cannot be restarted . The Eclipse Equinox process must be restarted to restart an eXtreme Scale server.
You can use eXtreme Scale support for Spring namespace to configure eXtreme Scale container servers in a Blueprint XML file. When the server and container XML elements are added to the Blueprint XML file, the eXtreme Scale namespace handler automatically starts a container server using the parameters that are defined in the Blueprint XML file when the bundle is started. The handle stops the container when the bundle is stopped.

To configure eXtreme Scale container servers with Blueprint XML, complete the following steps:

Procedure

- Start an eXtreme Scale container server using OSGi blueprint.
  1. Create a container bundle.
  2. Install the container bundle into the Eclipse Equinox OSGi framework. See Installing and starting OSGi-enabled plug-ins.
  3. Start the container bundle.
- Start an eXtreme Scale container server using OSGi configuration admin.
  1. Configure the server and container using config admin.
  2. When the eXtreme Scale server bundle is started, or the persistent identifiers are created with config admin, the server and container automatically start.
- Start an eXtreme Scale container server using the ServerFactory API. See the server API documentation.
  1. Create an OSGi bundle activator class, and use the eXtreme Scale ServerFactory API to start a server.

Related tasks:
Running eXtreme Scale containers with non-dynamic plug-ins in an OSGi environment

Administering OSGi-enabled services using the xscmd utility

You can use the **xscmd** utility to complete administrator tasks, such as viewing services and their rankings that are being used by each container, and updating the runtime environment to use new versions of the bundles.

About this task

With the Eclipse Equinox OSGi framework, you can install multiple versions of the same bundle, and you can update those bundles during run time. WebSphere® eXtreme Scale is a distributed environment that runs the container servers in many OSGi framework instances.
Administrators are responsible for manually copying, installing, and starting bundles into the OSGi framework. eXtreme Scale includes an OSGi ServiceTrackerCustomizer to track any services that have been identified as eXtreme Scale plug-ins in the ObjectGrid descriptor XML file. Use the **xscmd** utility to validate which version of the plug-in is used, which versions are available to be used, and to perform bundle upgrades.

eXtreme Scale uses the service ranking number to identify the version of each service. When two or more services are loaded with the same reference, eXtreme Scale automatically uses the service with the highest ranking.

Procedure

- Run the **osgiCurrent** command, and verify that each eXtreme Scale server is using the correct plug-in service ranking.
  Since eXtreme Scale automatically chooses the service reference with the highest ranking, it is possible that the data grid may start with multiple rankings of a plug-in service.

  If the command detects a mismatch of rankings or if it is unable to find a service, a non-zero error level is set. If the command completed successfully then the error level is set to 0.

  The following example shows the output of the **osgiCurrent** command when two plug-ins are installed in the same grid on four servers. The loaderPlugin plug-in is using ranking 1, and the txCallbackPlugin is using ranking 2.

```
OSGi Service Name Current Ranking ObjectGrid Name MapSet Name Server Name
----------------- --------------- --------------- ----------- -----------
loaderPlugin      1               MyGrid          MapSetA     server1
loaderPlugin      1               MyGrid          MapSetA     server2
loaderPlugin      1               MyGrid          MapSetA     server3
loaderPlugin      1               MyGrid          MapSetA     server4
txCallbackPlugin  2               MyGrid          MapSetA     server1
txCallbackPlugin  2               MyGrid          MapSetA     server2
txCallbackPlugin  2               MyGrid          MapSetA     server3
txCallbackPlugin  2               MyGrid          MapSetA     server4
```

  The following example shows the output of the **osgiCurrent** command when server2 was started with a newer ranking of the loaderPlugin:

```
OSGi Service Name Current Ranking ObjectGrid Name MapSet Name Server Name
----------------- --------------- --------------- ----------- -----------
loaderPlugin      1               MyGrid          MapSetA     server1
loaderPlugin      2               MyGrid          MapSetA     server2
loaderPlugin      1               MyGrid          MapSetA     server3
loaderPlugin      1               MyGrid          MapSetA     server4
txCallbackPlugin  2               MyGrid          MapSetA     server1
txCallbackPlugin  2               MyGrid          MapSetA     server2
txCallbackPlugin  2               MyGrid          MapSetA     server3
txCallbackPlugin  2               MyGrid          MapSetA     server4
```

- Run the **osgiAll** command to verify that the plug-in services have been correctly started on each eXtreme Scale container server.
  When bundles start that contain services that an ObjectGrid configuration is referencing, the eXtreme Scale runtime environment automatically tracks the plug-in, but does not immediately use it. The **osgiAll** command shows which plug-ins are available for each server.

  When run without any parameters, all services are shown for all grids and servers. Additional filters, including the **-serviceName** `<service_name>` filter can be specified to limit the output to a single service or a subset of the data grid.

  The following example shows the output of the **osgiAll** command when two plug-ins are started on two servers. The loaderPlugin has both rankings 1 and 2 started and the txCallbackPlugin has ranking 1 started. The summary message at the end of the output confirms that both servers see the same service rankings:

```
Server: server1
   OSGi Service Name   Available Rankings
   -----------------   ------------------
   loaderPlugin        1, 2
   txCallbackPlugin    1

Server: server2
   OSGi Service Name   Available Rankings
   -----------------   ------------------
   loaderPlugin        1, 2
   txCallbackPlugin    1

Summary - All servers have the same service rankings.
```

  The following example shows the output of the **osgiAll** command when the bundle that includes the loaderPlugin with ranking 1 is stopped on server1. The summary message at the bottom of the output confirms that server1 is now missing the loaderPlugin with ranking 1:

```
Server: server1
   OSGi Service Name   Available Rankings
   -----------------   ------------------
   loaderPlugin        2
   txCallbackPlugin    1
```

```
Server: server2
   OSGi Service Name   Available Rankings
   -----------------   ------------------
   loaderPlugin        1, 2
   txCallbackPlugin    1

Summary - The following servers are missing service rankings:
   Server  OSGi Service Name Missing Rankings
   ------  ---------------- ----------------
   server1 loaderPlugin      1
```

The following example shows the output if the service name is specified with the **-sn** argument, but the service does not exist:

```
Server: server2
   OSGi Service Name Available Rankings
   ----------------- ------------------
   invalidPlugin     No service found

Server: server1
   OSGi Service Name Available Rankings
   ----------------- ------------------
   invalidPlugin     No service found

Summary - All servers have the same service rankings.
```

- Run the **osgiCheck** command to check sets of plug-in services and rankings to see if they are available.
  The **osgiCheck** command accepts one or more sets of service rankings in the form: `-serviceRankings <service name>;<ranking>[,<serviceName>;<ranking>]`

  When the rankings are all available, the method returns with an error level of 0. If one or more rankings are not available, a non-zero error level is set. A table of all of the servers that do not include the specified service rankings is displayed. Additional filters can be used to limit the service check to a subset of the available servers in the eXtreme Scale domain.

  For example, if the specified ranking or service is absent, the following message is displayed:

  ```
  Server  OSGi Service Unavailable Rankings
  ------  ------------ --------------------
  server1 loaderPlugin 3
  server2 loaderPlugin 3
  ```

- Run the **osgiUpdate** command to update the ranking of one or more plug-ins for all servers in a single ObjectGrid and MapSet in a single operation.
  The command accepts one or more sets of service rankings in the form: `-serviceRankings <service name>;<ranking>[,<serviceName>;<ranking>] -g <grid name> -ms <mapset name>`

  With this command, you can complete the following operations:
  - Verify that the specified services are available for updating on each of the servers.
  - Change the state of the grid to offline using the StateManager interface. See Managing ObjectGrid availability for more information. This process quiesces the grid and waits until any running transactions have completed and prevents any new transactions from starting. This process also signals any ObjectGridLifecycleListener and BackingMapLifecycleListener plug-ins to discontinue any transactional activity. See Plug-ins for providing event listeners for information about event listener plug-ins.
  - Update each eXtreme Scale container running in an OSGi framework to use the new service versions.
  - Changes the state of the grid to online, allowing transactions to continue.

  The update process is idempotent so that if a client fails to complete any one task, it results in the operation being rolled back. If a client is unable to perform the rollback or is interrupted during the update process, the same command can be issued again, and it continues at the appropriate step.

  If the client is unable to continue, and the process is restarted from another client, use the -force option to allow the client to perform the update. The **osgiUpdate** command prevents multiple clients from updating the same map set concurrently. For more details about the **osgiUpdate** command, see Updating OSGi services for eXtreme Scale plug-ins with xscmd.

- Updating OSGi services for eXtreme Scale plug-ins with xscmd
  WebSphere eXtreme Scale supports upgrading container server plug-in bundles while the grid is active. This support allows administrators to complete application updates and additions without needing to restart grid processes.

Configuring servers with OSGi Blueprint

You can configure WebSphere® eXtreme Scale container servers using an OSGi blueprint XML file, allowing simplified packaging and development of self-contained server bundles.

Before you begin

This topic assumes that the following tasks have been completed:

- The Eclipse Equinox OSGi framework has been installed and started with either the Eclipse Gemini or Apache Aries blueprint container.
- The eXtreme Scale server bundle has been installed and started.
- The eXtreme Scale dynamic plug-ins bundle has been created.
- The eXtreme Scale ObjectGrid descriptor XML file and deployment policy XML file have been created.

About this task

This task describes how to configure an eXtreme Scale server with a container using a blueprint XML file. The result of the procedure is a container bundle. When the container bundle is started, the eXtreme Scale server bundle will track the bundle, parse the server XML and start a server and container.

A container bundle can optionally be combined with the application and eXtreme Scale plug-ins when dynamic plug-in updates are not required or the plug-ins do not support dynamic updating.

Procedure

1. Create a Blueprint XML file with the `objectgrid` namespace included. You can name the file anything. However, it must include the blueprint namespace:

```
<?xml version="1.0" encoding="UTF-8"?>

<blueprint xmlns="http://www.osgi.org/xmlns/blueprint/v1.0.0"
           xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance

xmlns:objectgrid="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsconfigblue_http
://www.ibm.com/schema/objectgrid"
           xsi:schemaLocation="http://www.ibm.com/schema/objectgrid
                http://www.ibm.com/schema/objectgrid/objectgrid.xsd">
...
</blueprint>
```

2. Add the XML definition for the eXtreme Scale server with the appropriate server properties. See the Spring descriptor XML file for details on all available configuration properties. See the following example of the XML definition:

```
<objectgrid:server
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsconfigblue_xsServer"
tracespec="ObjectGridOSGi=all=enabled"
tracefile="logs/osgi/wxsserver/trace.log" jmxport="1199" listenerPort="2909">
<objectgrid:catalog host="catserver1.mycompany.com" port="2809" />
<objectgrid:catalog host="catserver2.mycompany.com" port="2809" />
</objectgrid:server>
```

3. Add the XML definition for the eXtreme Scale container with the reference to the server definition and the ObjectGrid descriptor XML and ObjectGrid deployment XML files embedded in the bundle; for example:

```
<objectgrid:container
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsconfigblue_container"
    objectgridxml="/META-INF/objectGrid.xml"
    deploymentxml="/META-INF/objectGridDeployment.xml"
    server="xsServer" />
```

4. Store the Blueprint XML file in the container bundle. The Blueprint XML must be stored in the OSGI-INF/blueprint directory for the Blueprint container to be found.
   To store the Blueprint XML in a different directory, you must specify the Bundle-Blueprint manifest header; for example:

```
Bundle-Blueprint: OSGI-INF/blueprint.xml
```

5. Package the files into a single bundle JAR file. See the following example of a bundle directory hierarchy:

```
MyBundle.jar
    /META-INF/manifest.mf
    /META-INF/objectGrid.xml
    /META-INF/objectGridDeployment.xml
    /OSGI-INF/blueprint/blueprint.xml
```

Results

An eXtreme Scale container bundle is now created and can be installed in Eclipse Equinox. When the container bundle is started, the eXtreme Scale server runtime environment in the eXtreme Scale server bundle, will automatically start the singleton eXtreme Scale server using the parameters defined in the bundle, and starts a container server. The bundle can be stopped and started, which results in the container stopping and starting. The server is a singleton and does not stop when the bundle is started the first time.

Scenario: Using JCA to connect transactional applications to eXtreme Scale clients

8.5+ The following scenario is about connecting clients to applications that participate in transactions.

Before you begin

Read the Transaction processing in the Java EE applications overview topic to learn more about transaction support.

About this task

The Java EE Connector Architecture (JCA) provides support for clients that are using Java Transaction API (JTA). Through JTA, client management is simplified and accomplished using Java Platform, Enterprise Edition (Java EE). The JCA specification also supports resource adapters that you can use to connect applications to eXtreme Scale clients. A resource adapter is a system-level software driver that a Java application uses to connect to an enterprise information system (EIS). A resource adapter plugs into an application server and provides connectivity between the EIS, the application server, and the enterprise application. WebSphere eXtreme Scale provides it own resource adapter, which you can install without any required configuration.

As with previous versions of the product, you can use transactions to process a single unit of work to the data grid. With the support of JCA, when you commit those transactions you can enlist resources for that transaction in one-phase commit, which has the following benefits:

- Simplified eXtreme Scale application development. Previously, developers coordinated eXtreme Scale transactions with resources, such as enterprise beans, servlets, and web containers. Because no rollback mechanism existed, developers had no simple way to recover failures.
- Tighter integration exists with WebSphere Application Server, which includes last participant support to enlist in global transactions if necessary.

Scenario goals

After completing this scenario, you will know how to complete the following goals:

- Use Java Transaction API (JTA) support to develop application components that use transactions.
- Connect your applications with eXtreme Scale clients.

1. 8.5+ Transaction processing in Java EE applications
   WebSphere eXtreme Scale provides its own resource adapter that you can use to connect applications to the data grid and process local transactions.
2. Installing an eXtreme Scale resource adapter
   The WebSphere eXtreme Scale resource adapter is Java™ Connector Architecture (JCA) 1.5 compatible and can be installed on a Java 2 Platform, Enterprise Edition (J2EE) 1.5 or later, or on an application server such as WebSphere Application Server.
3. 8.5+ Configuring eXtreme Scale connection factories
   An eXtreme Scale connection factory allows Java EE applications to connect to a remote WebSphere eXtreme Scale data grid. Use custom properties to configure resource adapters.
4. 8.5+ Configuring Eclipse environments to use eXtreme Scale connection factories
   The eXtreme Scale resource adapter includes custom connection factories. To use these interfaces in your eXtreme Scale Java Platform, Enterprise Edition (Java EE) applications, you must import the wxsra.rar file into your workspace and link it to your application project.
5. 8.5+ Configuring applications to connect with eXtreme Scale
   Applications use an eXtreme Scale connection factory to create connection handles to an eXtreme Scale client connection. You can configure resource adapter connection factory references using this task.
6. 8.5+ Securing J2C client connections
   Use the Java 2 Connector (J2C) architecture to secure connections between WebSphere eXtreme Scale clients and your applications.
7. 8.5+ Developing eXtreme Scale client components to use transactions
   The WebSphere eXtreme Scale resource adapter provides client connection management and local transaction support. With this support, Java Platform, Enterprise Edition (Java EE) applications can look up eXtreme Scale client connections and demarcate local transactions with Java EE local transactions or the eXtreme Scale APIs.
8. 8.5+ Administering J2C client connections
   The WebSphere eXtreme Scale connection factory includes an eXtreme Scale client connection that can be shared between applications and persisted through application restarts.

Related tasks:
Scenario: Using an OSGi environment to develop and run eXtreme Scale plug-ins
Scenario: Configuring HTTP session failover in the Liberty profile
8.5+ Scenario: Running grid servers in the Liberty profile using Eclipse tools
Migrating a WebSphere Application Server memory-to-memory replication or database session to use WebSphere eXtreme Scale session management

Transaction processing in Java EE applications

8.5+ WebSphere® eXtreme Scale provides its own resource adapter that you can use to connect applications to the data grid and process local transactions.

Through support from the eXtreme Scale resource adapter, Java™ Platform, Enterprise Edition (Java EE) applications can look up eXtreme Scale client connections and demarcate local transactions using Java EE local transactions or using the eXtreme Scale APIs. When the resource adapter is configured, you can complete the following actions with your Java EE applications:

- Look up or inject eXtreme Scale resource adapter connection factories within a Java EE application component.
- Obtain standard connection handles to the eXtreme Scale client and share them between application components using Java EE conventions.
- Demarcate eXtreme Scale transactions using either the javax.resource.cci.LocalTransaction API or the com.ibm.websphere.objectgrid.Session interface.
- Use the entire eXtreme Scale client API, such as the ObjectMap API and EntityManager API.

The following additional capabilities are available with WebSphere Application Server:

- Enlist eXtreme Scale connections with a global transaction as a last participant with other two-phase commit resources. The eXtreme Scale resource adapter provides local transaction support, with a single-phase commit resource. With WebSphere Application Server, your applications can enlist one, single-phase commit resource into a global transaction through last participant support.

- Automatic resource adapter installation when the profile is augmented.
- Automatic security principal propagation.

Administrator responsibilities

The eXtreme Scale resource adapter is installed into the Java EE application server or embedded with the application. After you install the resource adapter, the administrator creates one or more resource adapter connection factories for each catalog service domain and optionally each data grid instance. The connection factory identifies the properties that are required to communicate with the data grid.

Applications reference the connection factory, which establishes the connection to the remote data grid. Each connection factory hosts a single eXtreme Scale client connection that is reused for all application components.
Important: Because the eXtreme Scale client connection might include a near cache, applications must not share a connection. A connection factory must exist for a single application instance to avoid problems sharing objects between applications.
The connection factory hosts an eXtreme Scale client connection, which is shared between all referencing application components. You can use a managed bean (MBean) to access information about the client connection or to reset the connection when it is no longer needed.

Application developer responsibilities

An application developer creates resource references for managed connection factories in the application deployment descriptor or with annotations. Each resource reference includes a local reference for the eXtreme Scale connection factory, as well as the resource-sharing scope.
Important: Enabling resource sharing is important because it allows the local transaction to be shared between application components.
Applications can inject the connection factory into the Java EE application component, or it can look up the connection factory using Java Naming Directory Interface (JNDI). The connection factory is used to obtain connection handles to the eXtreme Scale client connection. The eXtreme Scale client connection is managed independently from the resource adapter connection and is established on first use, and reused for all subsequent connections.

After finding the connection, the application retrieves an eXtreme Scale session reference. With the eXtreme Scale session reference, the application can use the entire eXtreme Scale client APIs and features.

You can demarcate transactions in one of the following ways:

- Use the com.ibm.websphere.objectgrid.Session transaction demarcation methods.
- Use the javax.resource.cci.LocalTransaction local transaction.
- Use a global transaction, when you use WebSphere Application Server with last participant support enabled. When you select this approach for demarcation, you must:
  - Use an application-managed global transaction with the javax.transaction.UserTransaction.
  - Use a container-managed transaction.

Application deployer responsibilities

The application deployer binds the local reference to the resource adapter connection factory that the application developer defines to the resource adapter connection factories that the administrator defines. The application deployer must assign the correct connection factory type and scope to the application and ensure that the connection factory is not shared between applications to avoid Java object sharing. The application deployer is also responsible for configuring and mapping other appropriate configuration information that is common to all connection factories.

Installing an eXtreme Scale resource adapter

8.5+ The WebSphere® eXtreme Scale resource adapter is Java™ Connector Architecture (JCA) 1.5 compatible and can be installed on a Java 2 Platform, Enterprise Edition (J2EE) 1.5 or later, or on an application server such as WebSphere Application Server.

Before you begin

The resource adapter is in the wxsra.rar resource adapter archive (RAR) file, which is available in all installations of eXtreme Scale. The RAR file is in the following directories:

- For WebSphere Application Server installations: *wxs_install_root*/optionalLibraries/ObjectGrid
- For stand-alone installations: *wxs_install_root*/ObjectGrid/lib directory

The resource adapter is coupled with the eXtreme Scale runtime environment. It requires the eXtreme Scale runtime JAR files in the correct classpath. In general, you can upgrade the eXtreme Scale runtime environment without updating the resource adapter. Upgrading the eXtreme Scale runtime environment also upgrades the resource adapter runtime environment. The resource adapter supports version 8.5 and up to two versions later of the eXtreme Scale runtime environment. Later versions of the resource adapter might require later versions of the eXtreme Scale runtime environment as they become available.

The wxsra.rar file requires one of the eXtreme Scale client runtime JAR files to operate. For details about which client runtime JAR file is appropriate, see Runtime files for WebSphere eXtreme Scale stand-alone installation and Runtime files for WebSphere eXtreme Scale integrated with WebSphere Application Server, which include details about the available runtime JAR files.

About this task

You can install the eXtreme Scale resource adapter using several options that allow for flexible deployment scenarios. The resource adapter can be embedded with the Java Platform, Enterprise Edition (Java EE) application, or it can be installed as a stand-alone RAR file that is shared between applications.

Embedding the resource adapter with the application simplifies deployment because connection factories are only created within the scope of the application and cannot be shared between applications. With the resource adapter embedded in the application, you can also embed the cache objects and ObjectGrid client plug-in classes within the application. Embedding the resource adapter also protects the application from inadvertently sharing cache objects between applications, which can result in java.lang.ClassCastException exceptions.

By installing the wxsra.rar file as a stand-alone resource adapter, you can create resource manager connection factories at the node scope. This option is useful in the following situations:

- When it is not practical to embed the wxsra.rar file inside the application
- When the version of eXtreme Scale is not known at build time
- When you want to share an eXtreme Scale client connection with multiple applications

Important: In multiple versions of WebSphere Application Server, up to Version 8.0.2, you cannot install the eXtreme Scale resource adapter in an application EAR file and in the stand-alone server simultaneously. The result, when you use the enterprise archive (EAR) file that also has the RAR file installed, is that the application experiences an exception, such as `ClassCastException: com.ibm.websphere.xs.ra.XSConnectionFactory incompatible with com.ibm.websphere.xs.ra.XSConnectionFactory`. The following example WebSphere Application Server message and call stack for this error are displayed when a servlet encounters this exception:

```
SRVE0068E: An exception was thrown by one of the service methods of the servlet [ClientServlet]
in application [JTASampleClientEAR]. Exception created : [java.lang.ClassCastException:
com.ibm.websphere.xs.ra.XSConnectionFactory incompatible with com.ibm.websphere.xs.ra.XSConnectionFactory
at com.ibm.websphere.xs.sample.jtasample.WXSClientServlet.connectClient(WXSClientServlet.java:484)
at com.ibm.websphere.xs.sample.jtasample.WXSClientServlet.doGet(WXSClientServlet.java:200)
at javax.servlet.http.HttpServlet.service(HttpServlet.java:575)
at javax.servlet.http.HttpServlet.service(HttpServlet.java:668)
at com.ibm.ws.webcontainer.servlet.ServletWrapper.service(ServletWrapper.java:1214)
at com.ibm.ws.webcontainer.servlet.ServletWrapper.handleRequest(ServletWrapper.java:774)
at com.ibm.ws.webcontainer.servlet.ServletWrapper.handleRequest(ServletWrapper.java:456)
```

Procedure

- **Install an embedded eXtreme Scale resource adapter.** When the wxsra.rar file is embedded in the application EAR file, the resource adapter must have access to the eXtreme Scale runtime libraries.
  For applications that run in WebSphere Application Server, the following choices and subsequent actions are available:

Option	Description
If eXtreme Scale is integrated with the WebSphere Application Server node	The runtime library files are already available in the system classpath, and no other action is required.
If eXtreme Scale is not integrated with the WebSphere Application Server node	You must include the wsogclient.jar file in the wxsra.rar classpath.

  For applications that do not run in WebSphere Application Server, the client runtime library file, ogclient.jar, or the server runtime library file, objectgrid.jar, must be in the classpath of the RAR file.

- **Install a stand-alone eXtreme Scale resource adapter.** When you install the wxsra.rar file as a stand-alone resource adapter, it must have access to the eXtreme Scale runtime libraries.
  For applications that run in WebSphere Application Server, the following choices and subsequent actions are available:

Option	Description
If eXtreme Scale is integrated with the WebSphere Application Server node	The runtime library files are already available in the system classpath, and no other action is required.
If eXtreme Scale is not integrated with the WebSphere Application Server node	You must include the wsogclient.jar file in the wxsra.rar classpath.

  For applications that do not run in WebSphere Application Server, the client runtime library file, ogclient.jar, or the server runtime library file, objectgrid.jar, must be in the classpath of the RAR file.

  1. Give the resource adapter access to any shared classes. All ObjectGrid plug-in classes and the applications that use them must share a class loader. Since the resource adapter is shared by multiple applications, all classes must be accessible by the same class loader. You can create this access by using a shared library between all applications that interact with the resource adapter.

What to do next

Now that you have installed the eXtreme Scale resource adapter, you can configure connection factories so that your Java EE applications can connect to a remote eXtreme Scale data grid.

Configuring eXtreme Scale connection factories

8.5+ An eXtreme Scale connection factory allows Java™ EE applications to connect to a remote WebSphere® eXtreme Scale data grid. Use custom properties to configure resource adapters.

Before you begin

Before you create the connection factories, you must install the resource adapter.

About this task

After you install the resource adapter, you can create one or more resource adapter connection factories that represent eXtreme Scale client connections to remote data grids. Complete the following steps to configure a resource adapter connection factory and use it within an application.
You can create an eXtreme Scale connection factory at the node scope for stand-alone resource adapters or within the application for embedded resource adapters. See the related topics for information about how to create connection factories in WebSphere Application Server.

Procedure

1. Using the WebSphere Application Server administrative console to create an eXtreme Scale connection factory that represents an eXtreme Scale client connection. See Configuring Java EE Connector connection factories in the administrative console. After you specify properties for the connection factory in the General Properties panel, you must click **Apply** for the Custom properties link to become active.
2. Click **Custom properties** in the administrative console. Set the following custom properties to configure the client connection to the remote data grid.

Table 1. Custom properties for configuring connection factories

Property Name	Type	Description
ConnectionName	String	(Optional) The name of the eXtreme Scale client connection. The ConnectionName helps identify the connection when exposed as a managed bean. This property is optional. If not specified, the ConnectionName is undefined.
CatalogServiceEndpoints	String	(Optional) The catalog service domain end points in the format: `<host>:<port>[,<host><port>]`. For more information, see Catalog service domain settings. This property is required if the catalog service domain is not set.
CatalogServiceDomain	String	(Optional) The catalog service domain name that is defined in WebSphere Application Server. For more information, see Configuring catalog servers and catalog service domains. This property is required if the CatalogServiceEndpoints property is not set.
ObjectGridName	String	(Optional) The name of the data grid that this connection factory connects to. If not specified, then the application must supply the name when obtaining the connection from the connection factory.
ObjectGridURL	String	(Optional) The URL of the client data grid, override XML file. This property is not valid if the ObjectGridResource is also specified. For more information, see Configuring Java clients.
ObjectGridResource	String	The resource path of the client data grid, override XML file. This property is optional and invalid if ObjectGridURL is also specified. For more information, see Configuring Java clients.
ClientPropertiesURL	String	(Optional) The URL of the client properties file. This property is not valid if the ClientPropertiesResource is also specified. For more information, see Client properties file for more information.
ClientPropertiesResource	String	(Optional) The resource path of the client properties file. This property is not valid if the ClientPropertiesURL is also specified. For more information, see Client properties file for more information.

WebSphere Application Server also allows other configuration options for adjusting connection pools and managing security. See the related information for links to WebSphere Application Server Information Center topics.

What to do next

Create an eXtreme Scale connection factory reference in the application. See Configuring applications to connect with eXtreme Scale for more information.

- Configuring Eclipse environments to use eXtreme Scale connection factories
  The eXtreme Scale resource adapter includes custom connection factories. To use these interfaces in your eXtreme Scale Java Platform, Enterprise Edition (Java EE) applications, you must import the wxsra.rar file into your workspace and link it to your application project.

Configuring Eclipse environments to use eXtreme Scale connection factories

8.5+ The eXtreme Scale resource adapter includes custom connection factories. To use these interfaces in your eXtreme Scale Java™ Platform, Enterprise Edition (Java EE) applications, you must import the wxsra.rar file into your workspace and link it to your application project.

Before you begin

- You must install Rational® Application Developer Version 7 or later or Eclipse Java EE IDE for Web Developers Version 1.4 or later.
- A server runtime environment must be configured.

Procedure

1. Import the wxsra.rar file into your project by selecting File > Import. The Import window is displayed.
2. Select Java EE > RAR file. The Connector Import window is displayed.
3. To specify the connector file, click Browse to locate the wxsra.rar file. The wxsra.rar file is installed when you install a resource adapter. You can find the resource adapter archive (RAR) file in the following location:
   - For WebSphere® Application Server installations: *wxs_install_root*/optionalLibraries/ObjectGrid
   - For stand-alone installations: *wxs_install_root*/ObjectGrid/lib directory
4. Create a name for the new connector project in the Connector project field. You can use `wxsra`, which is the default name.
5. Choose a Target runtime, which references a Java EE server runtime environment.
6. Optionally select Add project to EAR to embed the RAR into an existing EAR project.

Results

The RAR file is now imported into your Eclipse workspace.

What to do next

You can reference the RAR project from your other Java EE projects using the following steps:

1. Right click on the project and click Properties.
2. Select Java Build Path.
3. Select the Projects tab.
4. Click Add.
5. Select the wxsra connector project, and click OK.
6. Click OK again to close the Properties window.

The eXtreme Scale resource adapter classes are now in the classpath. To install product runtime JAR files using the Eclipse console, see Setting up a stand-alone development environment in Eclipse for more information.

Configuring applications to connect with eXtreme Scale

8.5+ Applications use an eXtreme Scale connection factory to create connection handles to an eXtreme Scale client connection. You can configure resource adapter connection factory references using this task.

Before you begin

Create a Java™ Platform, Enterprise Edition (Java EE) application component, such as an Enterprise JavaBeans (EJB) container or servlet.

Procedure

Create a javax.resource.cci.ConnectionFactory resource reference in the application component. Resource references are declared in the deployment descriptor by the application provider. The connection factory represents an eXtreme Scale client connection that can be used to communicate with one or more named data grids that are available in the catalog service domain.

Previous topic: 8.5+ Configuring Eclipse environments to use eXtreme Scale connection factories

Securing J2C client connections

8.5+ Use the Java™ 2 Connector (J2C) architecture to secure connections between WebSphere® eXtreme Scale clients and your applications.

About this task

Applications reference the connection factory, which establishes the connection to the remote data grid. Each connection factory hosts a single eXtreme Scale client connection that is reused for all application components.

Important: Since the eXtreme Scale client connection might include a near cache, it is important that applications do not share a connection. A connection factory must exist for a single application instance to avoid problems sharing objects between applications.

You can set the credential generator with the API or in the client properties file. In the client properties file, the securityEnabled and credentialGenerator properties are used.

Attention: In the following example, some lines of code are continued on the next line for publication purposes.

```
securityEnabled=true
credentialGeneratorClass=com.ibm.websphere.objectgrid.security.plugins.builtins.
     UserPasswordCredentialGenerator
credentialGeneratorProps=operator XXXXXX
```

The credential generator and credential in the client properties file are used for the eXtreme Scale connect operation and the default J2C credentials. Therefore, the credentials that are specified with the API are used at J2C connect time for the J2C connection. However, if no credentials are specified at J2C connect time, then the credential generator in the client properties file is used.

Procedure

1. Set up secure access where the J2C connection represents the eXtreme Scale client. Use the ClientPropertiesResource connection factory property or the ClientPropertiesURL connection factory property to configure client authentication.
   If you are using WebSphere eXtreme Scale with WebSphere Application Server, then specify the client properties on the catalog service domain configuration. When the connection factory references the domain, it automatically uses this configuration.

2. Configure the client security properties to use the connection factory that references the appropriate credential generator object for eXtreme Scale. These properties are also compatible with eXtreme Scale server security. For example, use the WSTokenCredentialGenerator credential generator for WebSphere credentials when eXtreme Scale is installed with WebSphere Application Server. Alternatively, use the UserPasswordCredentialGenerator credential generator when you run the eXtreme Scale in a stand-alone environment. In the following example, credentials are passed programmatically using the API call instead of using the configuration in the client properties:

   ```
   XSConnectionSpec spec = new XSConnectionSpec();
   spec.setCredentialGenerator(new UserPasswordCredentialGenerator("operator", "xxxxxx"));
   Connection conn = connectionFactory.getConnection(spec);
   ```

3. (Optional) Disable the near cache, if required.
   All J2C connections from a single connection factory share a single near cache. Grid entry permissions and map permissions are validated on the server, but not on the near cache. When an application uses multiple credentials to create J2C connections, and the configuration uses specific permissions for grid entries and maps for those credentials, then disable the near cache. Disable the near cache using the connection factory property, ObjectGridResource or ObjectGridURL. For more information about disabling the near cache, see Configuring the near cache.

4. (Optional) Set security policy settings, if required.
   If the J2EE application contains the embedded eXtreme Scale resource adapter archive (RAR) file configuration, you might be required to set additional security policy settings in the security policy file for the application. For example, these policies are required:

   ```
   permission com.ibm.websphere.security.WebSphereRuntimePermission "accessRuntimeClasses";
   permission java.lang.RuntimePermission "accessDeclaredMembers";
   permission javax.management.MBeanTrustPermission "register";
   permission java.lang.RuntimePermission "getClassLoader";
   ```

   Additionally, any property or resource files used by connection factories require file or other permissions, such as `permission java.io.FilePermission "filePath";`. For WebSphere Application Server, the policy file is META-INF/was.policy, and it is located in the J2EE EAR file.

Results

The client security properties that you configured on the catalog service domain are used as default values. The values that you specify override any properties that are defined in the client.properties files.

What to do next

Use eXtreme Scale data access APIs to develop client components that you want to use transactions.
Previous topic: 8.5+ Configuring applications to connect with eXtreme Scale
Next topic: 8.5+ Developing eXtreme Scale client components to use transactions

Developing eXtreme Scale client components to use transactions

8.5+ The WebSphere® eXtreme Scale resource adapter provides client connection management and local transaction support. With this support, Java™ Platform, Enterprise Edition (Java EE) applications can look up eXtreme Scale client connections and demarcate local transactions with Java EE local transactions or the eXtreme Scale APIs.

Before you begin

Create an eXtreme Scale connection factory resource reference.

About this task

There are several options for working with eXtreme Scale data access APIs. In all cases, the eXtreme Scale connection factory must be injected into the application component, or looked up in Java Naming Directory Interface (JNDI). After the connection factory is looked up, you can demarcate transactions and create connections to access the eXtreme Scale APIs.
You can optionally cast the javax.resource.cci.ConnectionFactory instance to a com.ibm.websphere.xs.ra.XSConnectionFactory that provides additional options for retrieving connection handles. The resulting connection handles must be cast to the com.ibm.websphere.xs.ra.XSConnection interface, which provides the getSession method. The getSession method returns a com.ibm.websphere.objectgrid.Session object handle that allows applications to use any of the eXtreme Scale data access APIs, such as the ObjectMap API and EntityManager API.

The Session handle and any derived objects are valid for the life of the XSConnection handle.

The following procedures can be used to demarcate eXtreme Scale transactions. You cannot mix each of the procedures. For example, you cannot mix global transaction demarcation and local transaction demarcation in the same application component context.

Procedure

- Use autocommit, local transactions. Use the following steps to automatically commit data access operations or operations that do not support an active transaction:
    1. Retrieve a com.ibm.websphere.xs.ra.XSConnection connection outside of the context of a global transaction.
    2. Retrieve and use the com.ibm.websphere.objectgrid.Session session to interact with the data grid.
    3. Invoke any data access operation that supports autocommit transactions.
    4. Close the connection.
- Use an ObjectGrid session to demarcate a local transaction. Use the following steps to demarcate an ObjectGrid transaction using the Session object:
    1. Retrieve a com.ibm.websphere.xs.ra.XSConnection connection.
    2. Retrieve the com.ibm.websphere.objectgrid.Session session.
    3. Use the Session.begin() method to start the transaction.
    4. Use the session to interact with the data grid.
    5. Use the Session.commit() or rollback() methods to end the transaction.
    6. Close the connection.
- Use a javax.resource.cci.LocalTransction transaction to demarcate a local transaction. Use the following steps to demarcate an ObjectGrid transaction using the javax.resource.cci.LocalTransaction interface:
    1. Retrieve a com.ibm.websphere.xs.ra.XSConnection connection.
    2. Retrieve the javax.resource.cci.LocalTransaction transaction using the XSConnection.getLocalTransaction() method.
    3. Use the LocalTransaction.begin() method to start the transaction.
    4. Retrieve and use the com.ibm.websphere.objectgrid.Session session to interact with the data grid.
    5. Use the LocalTransaction.commit() or rollback() methods to end the transaction.
    6. Close the connection.
- Enlist the connection in a global transaction. This procedure also applies to container-managed transactions:
    1. Begin the global transaction through the javax.transaction.UserTransaction interface or with a container-managed transaction.
    2. Retrieve a com.ibm.websphere.xs.ra.XSConnection connection.
    3. Retrieve and use the com.ibm.websphere.objectgrid.Session session.
    4. Close the connection.
    5. Commit or roll back the global transaction.

Example

See the following code example, which demonstrates the previous steps for demarcating eXtreme Scale transactions.

```

Resource reference benefits

Developing components to use transactions

Administering J2C client connections

8.5+ The WebSphere® eXtreme Scale connection factory includes an eXtreme Scale client connection that can be shared between applications and persisted through application restarts.

About this task

The client connection includes a management bean that provides connection status information and lifecycle management operations.

Procedure

Maintain client connections. When the first connection is obtained from the XSConnectionFactory connection factory object, an eXtreme Scale client connection is established to the remote data grid and the ObjectGridJ2CConnection MBean is created. The client connection is maintained for the life of the process. To end a client connection, invoke one of the following events::

- Stop the resource adapter. A resource adapter can be stopped, for example, when it is embedded in an application and the application is stopped.
- Invoke the resetConnection MBean operation on the ObjectGridJ2CConnection MBean. When the connection is reset, all connections are invalidated, transactions completed, and the ObjectGrid client connection is destroyed. Subsequent calls to the getConnection methods on the connection factory result in a new client connection.

WebSphere Application Server also provides additional management beans for managing J2C connections, monitoring connection pools, and performance.

Scenario: Configuring HTTP session failover in the Liberty profile

8.5+ You can configure a web application server so that, when the web server receives an HTTP request for session replication, the request is forwarded to one or more servers that run in the Liberty profile.

Before you begin

To complete this task, you must install the Liberty profile. For more information, see Installing the Liberty profile.

About this task

The Liberty profile does not include session replication. However, if you use WebSphere® eXtreme Scale with the Liberty profile, then you can replicate sessions. Therefore, if a server fails, then application users do not lose session data.
When you add the web feature to the server definition and configure the session manager, you can use session replication in your eXtreme Scale applications that run in the Liberty profile.

- 8.5 Enabling the eXtreme Scale web feature in the Liberty profile
  You can enable the web feature to use HTTP session failover in the Liberty profile.

8.5+

Enabling the eXtreme Scale web feature in the Liberty profile

8.5+ You can enable the web feature to use HTTP session failover in the Liberty profile.

About this task

The web feature is deprecated. Use the webApp feature instead. When you add the webApp feature to the server definition and configure the session manager, you can use session replication in your WebSphere® eXtreme Scale applications that run in the Liberty profile.

When you install the WebSphere Application Server Liberty profile, it does not include session replication. However, if you use WebSphere eXtreme Scale with the Liberty profile, then you can replicate sessions so that if a server goes down, the application users do not lose session data.

When you add the web feature to the server definition and configure the session manager, you can use session replication in your eXtreme Scale applications that run in the Liberty profile.

Procedure

8.5 Define a web application to run in the Liberty profile.

What to do next

Next, configure a web server plug-in to forward HTTP requests to multiple servers in the Liberty profile.
Related reference:
Liberty profile web feature properties
Liberty profile xsWebGrid feature properties
Liberty profile webApp feature properties

Configuring a web server plug-in to forward requests to multiple servers in the Liberty profile

8.5+ Use this task to configure the web server plug-in to distribute HTTP server requests between multiple servers in the Liberty profile.

Before you begin

Before you configure the web server plug-in to route HTTP requests to multiple server, complete the following task:

- 8.5 Enabling the eXtreme Scale web feature in the Liberty profile

About this task

Configure the web server plug-in so that the web server receives an HTTP request for dynamic resources, the request is forwarded to multiple servers that run in the Liberty profile.

Procedure

See Configuring the Liberty profile with a web server plug-in in the WebSphere® Application Server Information Center to complete this task.

What to do next

Next, merge the plugin-cfg.xml files from multiple application server cells. You must also ensure that unique clone IDs exist for each application server that runs in the Liberty profile.

Merging plug-in configuration files for deployment to the application server plug-in

8.5+ Generate plug-in configuration files after you configure a unique clone ID in the Liberty server.xml configuration file.

Before you begin

If you are generating and merging plug-in configuration files to configure HTTP session failover in a Liberty profile, then you must complete the following tasks:

- Enabling the eXtreme Scale web feature in the Liberty profile
- Configuring a web server plug-in to forward requests to multiple servers in the Liberty profile

About this task

Use the WebSphere® Application Server administrative console to complete this task.

Procedure

1. Merge the plugin-cfg.xml files from multiple application server cells. You can either manually merge the plugin-cfg.xml files or use the pluginCfgMerge tool to automatically merge the plugin-cfg.xml file from multiple application server profiles into a single output file. The pluginCfgMerge.bat and pluginCfgMerge.sh files are in the *install_root*/bin directory.
   For more information about manually merging the plugin-cfg.xml files, see the technote about merging plugin-cfg.xml files from multiple application server profiles.

2. Ensure that the cloneID value for each application server is unique. Examine the cloneID value for each application server in the merged file to ensure that this value is unique for each application server. If the cloneID values in the merged file are not all unique, or if you are running with memory to memory session replication in peer to peer mode, use the administrative console to configure unique HTTP session cloneIDs.
   To configure a unique HTTP session clone ID with the WebSphere Application Server administrative console, complete the following steps:

   a. Click Servers > Server Types > WebSphere application servers > *server_name*.
   b. Under Container Settings, click Web Container Settings > Web container.
   c. Under Additional Properties, click Custom properties > New.
   d. Enter `HttpSessionCloneId` in the Name field, and enter a unique value for the server in the Value field. The unique value must be eight to nine alphanumeric characters in length. For example, test1234 is a valid cloneID value.
   e. Click Apply or OK.
   f. Click Save to save the configuration changes to the master configuration.
3. Copy the merged plugin-cfg.xml file to the *plugin_installation_root*/config/web_server_name directory on the web server host.
4. Ensure that you defined the correct operating system, file access permissions for the merged plugin-cfg.xml file. These file access permissions allow the HTTP server plug-in process to read the file.

Results

When you complete this task, you have one plug-in configuration file for multiple application server cells, and your eXtreme Scale applications that run in the Liberty profile are enabled for session replication.

Scenario: Running grid servers in the Liberty profile using Eclipse tools

8.5+ You can use Eclipse tools to run WebSphere® eXtreme Scale servers in the WebSphere Application Server Liberty profile. The Eclipse tools offer a convenient way of running your servers in the same Eclipse environment where you develop, configure, and deploy your eXtreme Scale applications.

About this task

With the Eclipse tools, you can configure eXtreme Scale servers to run in the Liberty profile. If you complete this task manually, you add the supported Liberty features to the server.xml file. However, when you use the Eclipse tools, you can complete this task and other development tasks using Eclipse Java EE IDE for Web Developers, Version: Indigo Service Release 1.

- 8.5+ Installing the Liberty profile developer tools for WebSphere eXtreme Scale
  Eclipse provides a graphical user interface (GUI) that you can use to run WebSphere eXtreme Scale servers in the Liberty profile. To use this GUI, you must install WebSphere eXtreme Scale Version 8.5 Liberty profile tools.
- 8.5+ Setting up your development environment within Eclipse
  After you install the Liberty profile Eclipse tooling for WebSphere eXtreme Scale, you must configure your eXtreme Scale servers in the Liberty profile and generate an Eclipse project in which you can begin development tasks.

Related tasks:
Scenario: Using an OSGi environment to develop and run eXtreme Scale plug-ins

Installing the Liberty profile developer tools for WebSphere eXtreme Scale

8.5+ Eclipse provides a graphical user interface (GUI) that you can use to run WebSphere® eXtreme Scale servers in the Liberty profile. To use this GUI, you must install WebSphere eXtreme Scale Version 8.5 Liberty profile tools.

About this task

You can install the tools using one of the following methods:

- Install from Eclipse Marketplace. Click Help > Eclipse Marketplace.
- Install by dragging an Install icon to a running workbench. This option is only available for installing the developer tools on Eclipse IDE for Java™ EE Developers 3.7, or later.

You must install IBM® WebSphere Application Server V8.5 Liberty Profile Developer Tools to use IBM WebSphere eXtreme Scale V8.5 Liberty Profile Developer Tools. Therefore, the steps in this task include the installation of both developer tools.

Procedure

- Install from Eclipse Marketplace.
  1. Start your Eclipse workbench.
  2. Click Help > Eclipse Marketplace.
  3. In the Find field, type WebSphere.
  4. In the list of results, locate IBM WebSphere Application Server V8.5 Liberty Profile Developer Tools, and click Install.
  5. The Confirm Selected Features page opens. Continue with the installation procedure in the "Complete the installation procedure" step.
  6. Complete each of the previous steps to install IBM WebSphere eXtreme Scale V8.5 Liberty Profile Developer Tools.
- Complete the installation procedure.
  1. Expand the node for the tooling that you installed.
  2. Select IBM WebSphere Application Server V8.5 Liberty Profile Developer Tools or IBM WebSphere eXtreme Scale V8.5 Liberty Profile Developer Tools.
  3. Select any of the optional features that you want to install. When you are finished, click Next.
     Remember: If you want to install any of the additional optional installation features, such as the WebSphere Application Server tools features for Version 8.5, 8.0, or 7.0, a separate set of installation instructions are available in the Installing the Liberty profile developer tools and (optionally) the Liberty profile topic in the WebSphere Application Server Information Center.
  4. On the Review Licenses page, review the license text.
  5. If you agree to the terms, click I accept the terms of the license agreement and then click Finish. The installation process starts.
  6. When the installation process completes, restart the workbench.

Setting up your development environment within Eclipse

8.5+ After you install the Liberty profile Eclipse tooling for WebSphere® eXtreme Scale, you must configure your eXtreme Scale servers in the Liberty profile and generate an Eclipse project in which you can begin development tasks.

- 8.5+ Configuring eXtreme Scale in the Liberty profile using Eclipse tools
  You must configure your WebSphere eXtreme Scale servers to run in the WebSphere Application Server Liberty profile. Complete this task to configure eXtreme Scale servers with Eclipse tools.
- 8.5+ Creating an OSGi bundle project for eXtreme Scale data grid development
  To use Eclipse as the development environment for your WebSphere eXtreme Scale servers in the Liberty profile, you must create an Eclipse project within the supported Open Services Gateway initiative (OSGi) framework.

Configuring eXtreme Scale in the Liberty profile using Eclipse tools

8.5+ You must configure your WebSphere® eXtreme Scale servers to run in the WebSphere Application Server Liberty profile. Complete this task to configure eXtreme Scale servers with Eclipse tools.

Before you begin

You must define a Liberty profile server in Eclipse. To complete this task, see Creating a Liberty profile server using developer tools.

About this task

Configuring the eXtreme Scale server entails specifying the server properties and including those properties in the Liberty profile server.xml file in the *wlp_home*/usr/servers/*your_server_name* directory. This server definition is required to run eXtreme Scale in the Liberty profile.
This procedure also includes adding the configuration from the eXtreme Scale server properties file, xsServerConfig.xml, to the server.xml file.

Procedure

1. Generate the eXtreme Scale server properties file.
   a. Click File > New > Other.
   b. Expand WebSphere eXtreme Scale, and select Container server configuration file. Click Next. The eXtreme Scale Server Configuration File window is displayed.
   c. Click Browse to specify where the Liberty profile is installed. Then, select the Liberty profile server definition for which you want to configure for your eXtreme Scale servers. Click Next. The General Server Configuration window is displayed.
   d. Complete the server configuration. Click Next. The Container Server Configuration window is displayed.
   e. Complete the container server configuration. Click Next.
   f. If you included the catalog server configuration, then another window is displayed, where you specify the catalog server settings. Click Next. The Server Logging Configuration window is displayed.
   g. Complete the logging information pages, and click Next until the Security Configuration window is displayed.

h. Optional: Specify the location of the objectGridSecurity.xml file, which describes the security properties that are common to all servers, including catalog servers and container servers. An example of the defined security properties is the authenticator configuration, which represents the user registry and authentication mechanism. The file name specified for this property must be in a URL format, such as `file:///tmp/og/objectGridSecurity.xml`.
i. Click Finish.

A configuration file is generated in the Liberty profile.

2. Include the configuration from the eXtreme Scale server properties file in the server.xml file.
   a. Open the Servers view in Eclipse.
   b. Expand Liberty Server to locate your server configuration XML file.
   c. Double-click the entry for your server configuration to open the file.
   d. Click Add, and select Include to add an include statement to the server.xml file. Click OK.
   e. Under Include Details, click Browse. The Browse for Include File window is displayed.
   f. Select xsServerConfig.xml, to include the server configuration settings that you created in step 1. Click OK.

What to do next

The eXtreme Scale server configuration file, xsServerConfig.xml, is now included in the Liberty profile server.xml file. Now, you are ready to start the Liberty profile server, where your eXtreme Scale servers will run.

Creating an OSGi bundle project for eXtreme Scale data grid development

8.5+ To use Eclipse as the development environment for your WebSphere® eXtreme Scale servers in the Liberty profile, you must create an Eclipse project within the supported Open Services Gateway initiative (OSGi) framework.

Procedure

1. Create the OSGi bundle project in Eclipse.
   a. Click File > New > Project. The "Select a wizard" window is displayed.
   b. Expand the WebSphere eXtreme Scale folder, and select the Object grid project. The "Object grid project" window is displayed.
   c. Click Add, and enter a backing map name to add the object grid map for which you want to complete development activities. You can enter multiple maps on this page. Click Next.
   d. Specify object grid parameters for each map that you entered. Click Next.
   e. Specify the deployment parameters, and click Finish.

   The OSGi bundle project is created, and you can access eXtreme Scale APIs to complete development activities in the Liberty profile. The bundle includes the gridBlueprint.xml file. This file includes the location of the eXtreme Scale configuration files, objectGrid.xml and gridDeployment.xml. These configuration files include the map or maps that you created in the step c.
2. Export the bundle project, and place the bundle in the grids folder. You must export the project to deploy eXtreme Scale applications in the Liberty profile. When you export the project, it is exported as a bundle Java™ archive (JAR) file to the *Liberty_profile_Server_Definition*/grids folder, which you must manually create before you export the bundle.
   a. Right-click the project that you just created, and select Export > OSGi Bundle or Fragment. The OSGi Application Export window is displayed.
   b. Specify where you want to export the bundle JAR file. Click Finish.

Samples

Several WebSphere® eXtreme Scale tutorials, examples, and samples are available.

Examples

The following topics illustrate key WebSphere eXtreme Scale features.

- DataGrid API example
- Configuring local deployments

Community samples

The following samples from the IBM Elastic Caching Community Samples illustrate how to use WebSphere eXtreme Scale in various environments to exhibit different features of the product.

Free trial

To get started using WebSphere® eXtreme Scale, download a free trial version. You can develop innovative, high-performance applications by extending the data caching concept using advanced features.

Trial download

You can download a free trial version of WebSphere eXtreme Scale, from Download eXtreme Scale trial.

After downloading and unzipping the trial version of eXtreme Scale, navigate to the gettingstarted directory, and read the GETTINGSTARTED_README.txt file. This tutorial gets you started using eXtreme Scale, create a data grid on several servers, and run some simple applications to store and retrieve data in a grid. Before deploying eXtreme Scale in a production environment, there are several options to consider, including the number of servers to use, the amount of storage on each server, and synchronous or asynchronous replication.

Sample properties files

Server properties files contain settings for running your catalog servers and container servers. You can specify a server properties file for either a stand-alone or WebSphere® Application Server configuration. Client property files contain settings for your client.

You can use the following sample properties files that are in the *wxs_install_root*\properties directory to create your properties file:

- sampleServer.properties
- sampleClient.properties

Related reference:
Server properties file
Client properties file

Sample: xsadmin utility

With the **xsadmin** utility, you can format and display textual information about your WebSphere® eXtreme Scale topology. The sample utility provides a method for parsing and discovering current deployment data, and can be used as a foundation for writing custom utilities.

Before you begin

- The **xsadmin** utility is provided as a sample of how you can create custom utilities for your deployment. The **xscmd** utility is provided as a supported utility for monitoring and administering your environment. For more information, see Administering with the xscmd utility.
- For the **xsadmin** utility to display results, you must have created your data grid topology. Your catalog servers and container servers must be started. See Starting and stopping stand-alone servers for more information.
- Verify that the *JAVA_HOME* environment variable is set to use the runtime environment that installed with the product. If you are using the trial version of the product, you must set the *JAVA_HOME* environment variable.

About this task

The **xsadmin** sample utility uses an implementation of Managed Beans (MBeans). This sample monitoring application enables rapidly integrated monitoring capabilities that you can extend by using the interfaces in the com.ibm.websphere.objectgrid.management package. You can look at the source code of the **xsadmin** sample application in the *wxs_home*/samples/xsadmin.jar file in a stand-alone installation, or in the *wxs_home*/xsadmin.jar file in a WebSphere Application Server installation.

You can use the **xsadmin** sample utility to view the current layout and specific state of the data grid, such as map content. In this example, the layout of the data grid in this task consists of a single *ObjectGridA* data grid with one *MapA* map that belongs to the *MapSetA* map set. This example demonstrates how you can display all active containers within a data grid and print filtered metrics regarding the map size of the *MapA* map. To see all possible command options, run the **xsadmin** utility without any arguments or with the -help option.

Procedure

1. Go to the bin directory.

   ```
   cd wxs_home/bin
   ```

2. Run the **xsadmin** utility.
   - To display the online help, run the following command:

     UNIX

     ```
     xsadmin.sh
     ```

     Windows

     ```
     xsadmin.bat
     ```

     You must pass in only one of the listed options for the utility to work. If no -g or -m option is specified, the **xsadmin** utility prints out information for every grid in the topology.

   - To enable statistics for all of the servers, run the following command:

     UNIX

     ```
     xsadmin.sh ObjectGridA -setstatsspec ALL=enabled
     ```

     Windows

     ```
     xsadmin.bat ObjectGridA -setstatsspec ALL=enabled
     ```

   - To display all online containers for a grid, run the following command:

     UNIX

     ```
     xsadmin.sh -g ObjectGridA -m MapSetA -containers
     ```

     Windows

     ```
     xsadmin.bat -g ObjectGridA -m MapSetA -containers
     ```

     All container information is displayed. An example of the output follows:

     ```
     Connecting to Catalog service at localhost:1099

     *** Show all online containers for grid - ObjectGridA & mapset - MapSetA

     Host: 192.168.0.186
     Container: server1_C-0, Server:server1, Zone:DefaultZone
     Partition Shard Type
     ```

```
        0 Primary

Num containers matching = 1
Total known containers = 1
Total known hosts = 1
```

Attention: To obtain this information when Transport Layer Security/Secure Sockets Layer (TLS/SSL) is enabled, you must start the catalog and container servers with the JMX service port set. To set the JMX service port, you can either use the -JMXServicePort option on the **startOgServer** script or you can call the setJMXServicePort method on the ServerProperties interface.

- To connect to the catalog service and display information about MapA, run the following command:

UNIX

```
xsadmin.sh -g ObjectGridA -m MapSetA -mapsizes -fm MapA
```

Windows

```
xsadmin.bat -g ObjectGridA -m MapSetA -mapsizes -fm MapA
```

The size of the specified map is displayed. An example of the output follows:

```
Connecting to Catalog service at localhost:1099

****Displaying Results for Grid - ObjectGridA, MapSet - MapSetA*****

*** Listing Maps for server1 ***
 Map Name Partition Map Size Used Bytes (B) Shard Type
 MapA     0         0        0              Primary
```

- To connect to the catalog service using a specific JMX port and display information about the MapA map, run the following command: UNIX

```
xsadmin.sh -g ObjectGridA -m MapSetA -mapsizes -fm MapA
               -ch CatalogMachine -p 6645
```

Windows

```
xsadmin.bat -g ObjectGridA -m MapSetA -mapsizes -fm MapA
               -ch CatalogMachine -p 6645
```

The **xsadmin** sample utility connects to the MBean server that is running on a catalog server. A catalog server can run as a stand-alone process, WebSphere Application Server process, or embedded within a custom application process. Use the -ch option to specify the catalog service host name, and the -p option to specify the catalog service naming port.

The size of the specified map is displayed. An example of the output follows:

```
Connecting to Catalog service at CatalogMachine:6645

*****Displaying Results for Grid - ObjectGridA, MapSet - MapSetA*****

*** Listing Maps for server1 ***
Map Name: MapA  Partition #: 0  Map Size: 0  Shard Type: Primary
Server Total: 0
```

- To connect to a catalog service hosted in a WebSphere Application Server process, perform the following steps:
The -dmgr option is required when connecting to a catalog service hosted by any WebSphere Application Server process or cluster of processes. Use the -ch option to specify the host name if not `localhost`, and the -p option to override the catalog service bootstrap port, which uses the process BOOTSTRAP_ADDRESS. The -p option is only needed if the BOOTSTRAP_ADDRESS is not set to the default of `9809`.

  Note: The stand-alone version of WebSphere eXtreme Scale cannot be used to connect to a catalog service hosted by a WebSphere Application Server process. Use the **xsadmin** that is script included in the *was_root*/bin directory, which is available when the installing WebSphere eXtreme Scale on WebSphere Application Server or WebSphere Application Server Network Deployment.

  - Navigate to the WebSphere Application Server bin directory:

    ```
    cd was_root/bin
    ```

  - Launch the **xsadmin** utility using the following command:

    UNIX

    ```
    xsadmin.sh -g ObjectGridA -m MapSetA -mapsizes -fm MapA -dmgr
    ```

    Windows

    ```
    xsadmin.bat -g ObjectGridA -m MapSetA -mapsizes -fm MapA -dmgr
    ```

  The size of the specified map is displayed.

```
Connecting to Catalog service at localhost:9809

****Displaying Results for Grid - ObjectGridA, MapSet - MapSetA*****

*** Listing Maps for server1 ***
Map Name: MapA  Partition #: 0  Map Size: 0  Shard Type: Primary
Server Total: 0
```

- To display the configured and runtime placement of your configuration, run one of the following commands:

```
xsadmin -placementStatus
xsadmin -placementStatus -g myOG -m myMapSet
```

```
xsadmin -placementStatus -m myMapSet
xsadmin -placementStatus -g myOG
```

You can scope the command to display placement information for the entire configuration, a single data grid, a single map set, or a combination of a data grid and map set. An example of the output follows:

```
***********Printing Placement Status for Grid - Grid, MapSet - mapSet**************

<objectGrid name="Grid" mapSetName="mapSet">
  <configuration>
    <attribute name="placementStrategy" value="FIXED_PARTITIONS"/>
    <attribute name="numInitialContainers" value="3"/>
    <attribute name="minSyncReplicas" value="0"/>
    <attribute name="developmentMode" value="true"/>
  </configuration>
  <runtime>
    <attribute name="numContainers" value="3"/>
    <attribute name="numMachines" value="1"/>
    <attribute name="numOutstandingWorkItems" value="0"/>
  </runtime>
</objectGrid>
```

- Creating a configuration profile for the xsadmin utility
  You can save your frequently specified parameters for the **xsadmin** utility in a properties file. As a result, the **xsadmin** utility calls are shorter.
- xsadmin utility reference
  You can pass arguments to the **xsadmin** utility with two different methods: with a command-line argument, or with a properties file.
- Verbose option for the xsadmin utility
  You can use the **xsadmin** verbose option to troubleshoot problems. Run the `xsadmin -v` command to list all configured parameters. The verbose option displays all values in all scopes, including command line arguments, properties file arguments, and environment-specified arguments. The `Effective arguments` section includes the settings that are being used in the environment if you have specified the same property using multiple scopes.

Creating a configuration profile for the xsadmin utility

You can save your frequently specified parameters for the **xsadmin** utility in a properties file. As a result, the **xsadmin** utility calls are shorter.

Before you begin

Create a basic deployment of WebSphere® eXtreme Scale that includes at least one catalog server and at least one container server. For more information, see startOgServer script.

About this task

See xsadmin utility reference for a list of the properties that you can put in a configuration profile for the **xsadmin** utility. If you specify both a properties file and a corresponding parameter as a command line argument, the command line argument overrides the properties file value.

Procedure

1. Create a configuration profile properties file. This properties file should contain any global properties that you want to use in all your **xsadmin** command invocations.
   Save the properties file with any name you choose. For example, you might place the file in the following path:
   /opt/ibm/WebSphere/wxs71/ObjectGrid/security/*<my.properties>*.

   Replace <my.properties> the name of your file.

   For example, you might set the following properties in your file:
   - `XSADMIN_TRUST_TYPE=jks`
   - `XSADMIN_TRUST_PATH=/opt/ibm/WebSphere/wxs71/ObjectGrid/bin/security/key.jks`
   - `XSADMIN_USERNAME=ogadmin`
2. Run the xsadmin utility with the properties file that you created. Use the -profile parameter to indicate the location of your properties file. You can also use the -v parameter to display verbose output.

```
./xsadmin.sh -l -v -password xsadmin -ssl -trustPass ogpass -profile
/opt/ibm/WebSphere/wxs71/ObjectGrid/security/<my.properties>
```

xsadmin utility reference

You can pass arguments to the **xsadmin** utility with two different methods: with a command-line argument, or with a properties file.

xsadmin arguments

Note: The **xsadmin** utility has now been deprecated. Use the **xscmd** utility instead. The **xscmd** utility is provided as a supported utility for monitoring and administering your environment. For more information, see Administering with the xscmd utility.
You can define a properties file for the **xsadmin** utility with Version 7.1 Fix 1 or later. By creating a properties file, you can save some of the frequently used arguments, such as the user name. The properties that you can add to a properties file are in the following table. If you specify both a property in a properties file and the equivalent command-line argument, the command-line argument value overrides the properties file value.

For more information about defining a properties file for the **xsadmin** utility, see Creating a configuration profile for the xsadmin utility.

Table 1. Arguments for the **xsadmin** utility

Command Line Argument	Equivalent Property Name in Properties File	Description and valid values
-bp	n/a	Indicates the listener port. **Default:**`2809`
-ch	n/a	Indicates the JMX host name for the catalog server. **Default:**`localhost`
-clear	n/a	Clears the specified map. **Allows the following filters:** `-fm`
-containers	n/a	For each data grid and map set, displays a list of container servers. **Allows the following filters:** `-fnp`
-continuous	n/a	Specify this flag if you want continuous map size results to monitor the data grid. When you run this command with the -mapsizes argument, the map size is displayed every 20 seconds.
-coregroups	n/a	Displays all core groups for the catalog server. This argument is used for advanced diagnostics.
-dismissLink <*catalog_service_domain*>	n/a	Removes a link between 2 catalog service domains. Provide the name of the foreign catalog service domain to which you previously connected with the -establishLink argument.
-dmgr	n/a	Indicates if you are connecting to a WebSphere® Application Server hosted catalog service. **Default:**`false`
-empties	n/a	Specify this flag if you want to show empty containers in the output.
-establishLink <*foreign_domain_name*> <*host1:port1,host2:port2...*>	n/a	Connects the catalog service domain to a foreign catalog service domain. Use the following format: `-establishLink <foreign_domain_name> <host1:port1,host2:port2...>`. *foreign_domain_name* is the name of the foreign catalog service domain, and *host1:port1,host2:port2...* is a comma-separated list of catalog server host names and Object Request Broker (ORB) ports that are running in this catalog service domain.
-fc	n/a	Filters for only this container. If you are filtering container servers in a WebSphere Application Server Network Deployment environment, use the following format: ***<cell_name>/<node_name>/<serverName_containerSuffix>*** **Use with the following arguments:** -mapsizes, -teardown,-revisions
-fh	n/a	Filters for only this host. **Use with the following arguments:** -mapsizes, -teardown,-revisions,-getTraceSpec,-setTraceSpec,-getStatsSpec,-setStatsSpec,-routetable
-fm	n/a	Filters only for this map. **Use with the following arguments:** -clear, -mapsizes
-fnp	n/a	Filters servers that have no primary shards. **Use with the following arguments:** -containers
-fp	n/a	Filters for only this partition. **Use with the following arguments:** -mapsizes, -teardown,-revisions,-getTraceSpec,-setTraceSpec,-getStatsSpec,-setStatsSpec,-routetable
-fs	n/a	Filters for only this server. If you are filtering application servers in a WebSphere Application Server Network Deployment environment, use the following format: ***<cell_name>/<node_name>/<server_name>*** **Use with the following arguments:** -mapsizes, -teardown,-revisions,-getTraceSpec,-setTraceSpec,-getStatsSpec,-setStatsSpec

Command Line Argument	Equivalent Property Name in Properties File	Description and valid values
-fst	n/a	Filters for only this shard type. Specify P for primary shards only, A for asynchronous replica shards only, and S for synchronous replica shards only. **Use with the following arguments:** -mapsizes, -teardown,-revisions,-getTraceSpec,-setTraceSpec,-getStatsSpec,-setStatsSpec
-fz	n/a	Filters for only this zone. **Use with the following arguments:** -mapsizes, -teardown,-revisions,-getTraceSpec,-setTraceSpec,-getStatsSpec,-setStatsSpec,-routetable
-force	n/a	Forces the action that is in the command, disabling any preemptive prompts. This argument is useful for running batched commands.
-g	n/a	Specifies the ObjectGrid name.
-getstatsspec	n/a	Displays the current statistics specification. You can set the statistics specification with the -setstatsspec argument. **Allows the following filters:** `-fst -fc -fz -fs -fh -fp`
-getTraceSpec	n/a	Displays the current trace specification. You can set the trace specification with the -settracespec argument. **Allows the following filters:** `-fst -fc -fz -fs -fh -fp`
-h	n/a	Displays the help for the **xsadmin** utility, which includes a list of arguments.
-hosts	n/a	Displays all of the hosts in the configuration.
-jmxUrl	XSADMIN_JMX_URL	Specifies the address of a JMX API connector server in the following format: `service:jmx:`*`protocol`*`:`*`sap`*. The *protocol* and *sap* variable definitions follow: *protocol* Specifies the transport protocol to be used to connect to the connector server. *sap* Specifies the address at which the connector server is found. For more information about the format of the JMX service URL, see Class JMXServiceURL (Java™ 2 Platform SE 5.0).
-l	n/a	Displays all known data grids and map sets.
-m	n/a	Specifies the name of the map set.
-mapsizes	n/a	Displays the size of each map on the catalog server to verify that key distribution is uniform over the shards. **Allows the following filters:** `-fm -fst -fc -fz -fs -fh -fp`
-mbeanservers	n/a	Displays a list of all MBean server end points.
-overridequorum	n/a	Overrides the quorum setting so that container server events are not ignored during a data center failure scenario.
-password	XSADMIN_PASSWORD	Specifies the password to log in to the **xsadmin** utility. Do not specify the password in your properties file if you want your password to remain secure.
-p	n/a	Indicates the JMX port for the catalog server host. **Default:** 1099 or 9809 for a WebSphere Application Server host, 1099 for stand-alone configurations.

-placementStatus	n/a	Displays the configured placement and runtime placement of your configuration. You can scope the output to a combination of data grids and map sets, or for the entire configuration:
		
		• Entire configuration:
		`-placementStatus`
		• For a specific data grid:
		`-placementStatus -g my_grid`
		• For a specific map set:
		`-placementStatus -m my_mapset`
		• For a specific data grid and map set:
		`-placementStatus -g my_grid -m my_mapset`

-primaries	n/a	Displays a list of the primary shards.
-profile	n/a	Specifies a fully qualified path to the properties file for the **xsadmin** utility.
-quorumstatus	n/a	Displays the status of quorum for the catalog service.

Command Line Argument	Equivalent Property Name in Properties File	Description and valid values
-releaseShard <*container_server_name*> <*objectgrid_name*> <*map_set_name*> <*partition_name*>	n/a	Used in conjunction with the -reserveShard argument. The -releaseShard argument must be invoked after a shard has been reserved and placed. . The -releaseShard argument invokes the ContainerMBean.release() method.
-reserved	n/a	Used with the -containers argument to display only shards that have been reserved with the -reserveShard argument.
-reserveShard <*container_server_name*> <*objectgrid_name*> <*map_set_name*> <*partition_name*>	n/a	Moves a primary shard to the specified container server. The ContainerMBean.reserve() method is invoked by this argument.
-resumeBalancing <*objectgrid_name*> <*map_set_name*>	n/a	Attempts to balance requests. Enables future rebalancing attempts on the specified ObjectGrid and map set.
-revisions	n/a	Displays revision identifiers for a catalog service domain including: each data grid, partition number, partition type (primary or replica), catalog service domain, lifetime ID, and number of data revisions for each specific shard. You can use this argument to determine if an asynchronous replica or linked domain is caught up. This argument invokes the ObjectGridMBean.getKnownRevisions() method. **Allows the following filters:** `-fst -fc -fz -fs -fh -fp`
-routetable	n/a	Displays the current state of the data grid from a client server perspective. The route table is the information that an ObjectGrid client server uses to communicate with the data grid. Use the route table as a diagnostic aid when you are trying to identify connection problems or `TargetNotAvailable` exceptions. **Required arguments:** In a stand-alone environment, you must specify the -bp and -p parameters with this argument if you are not using the default values for the bootstrap listener port and JMX port for the catalog server host. **Allows the following filters:** `-fz -fh -fp`
-settracespec <*trace_string*>	n/a	Enables trace on servers during run time. See the following example: **`-setTraceSpec "ObjectGridReplication=all=enabled"`** See Collecting trace and Server trace options for more information about the trace strings that you can specify. **Allows the following filters:** `-fst -fc -fz -fs -fh -fp`
-swapShardWithPrimary <*container_server_name*> <*objectgrid_name*> <*map_set_name*> <*partition_name*>	n/a	Swaps the specified replica shard from the specified container server with the primary shard. By running this command, you can manually balance primary shards when needed.
-setstatsspec <*stats_spec*>	n/a	Enables statistics gathering. This argument invokes the DynamicServerMBean.setStatsSpec and DynamicServerMBean.getStatsSpec methods. For more information, see Enabling statistics. **Allows the following filters:** `-fm -fst -fc -fz -fs -fh -fp`
-suspendBalancing <*objectgrid_name*> <*map_set_name*>	n/a	Prevents future attempts to balance the specified ObjectGrid and map set.
-ssl	n/a	Indicates that Secure Sockets Layer (SSL) is enabled.
-teardown	n/a	Stops a list or group of catalog and container servers. **Allows the following filters:** `-fst -fc -fz -fs -fh -fp` Format to provide a list of servers: ***`server_name_1,server_name_2 ...`*** To stop all servers in a zone, include the -fz argument: ***`-fz <zone_name>`*** To stop all servers on a host, include the -fh argument: ***`-fh <host_name>`***
-triggerPlacement	n/a	Forces shard placement to run, ignoring the configured numInitialContainers value in the deployment XML file. You can use this argument when you are performing maintenance on your servers to allow shard placement to continue running, even though the numInitialContainers value is lower than the configured value.

Command Line Argument	Equivalent Property Name in Properties File	Description and valid values
-trustPass	XSADMIN_TRUST_PASS	Specifies the password for the specified truststore.
-trustPath	XSADMIN_TRUST_PATH	Specifies a path to the truststore file. Example: etc/test/security/server.public
-trustType	XSADMIN_TRUST_TYPE	Specifies the type of truststore. Valid values: JKS, JCEK, PKCS12, and so on.
-unassigned	n/a	Displays a list of shards that cannot be placed on the data grid. Shards cannot be placed when the placement service has a constraint that is preventing placement.
-username	XSADMIN_USERNAME	Specifies the user name to log in to the **xsadmin** utility.
-v	n/a	Enables the verbose command-line action. Use this flag if you are using environment variables, a properties file, or both to specify certain command-line arguments, and want to view their values. See Verbose option for the xsadmin utility for more information.
-xml	n/a	Prints the unfiltered output from the PlacementServiceMBean.listObjectGridPlacement() method. The other **xsadmin** arguments filter the output of this method and organize the data into a more consumable format.

Verbose option for the xsadmin utility

You can use the **xsadmin** verbose option to troubleshoot problems. Run the `xsadmin -v` command to list all configured parameters. The verbose option displays all values in all scopes, including command line arguments, properties file arguments, and environment-specified arguments. The `Effective arguments` section includes the settings that are being used in the environment if you have specified the same property using multiple scopes.

Verbose option example

xsadmin command arguments:
The following text is an example of output when using the verbose option from the command line after you run the following command with a properties value specified:

```
./xsadmin -l -v -username xsadmin -password xsadmin -ssl -trustPass ogpass
-profile /opt/ibm/WebSphere/wxs71/ObjectGrid/security/my.properties
```

Properties file arguments:
The contents of the /opt/ibm/WebSphere/wxs71/ObjectGrid/security/my.properties properties file follow:

```
XSADMIN_TRUST_PASS=ogpass
XSADMIN_TRUST_TYPE=jks
XSADMIN_TRUST_PATH=/opt/ibm/WebSphere/wxs71/ObjectGrid/bin/security/key.jks
XSADMIN_USERNAME=ogadmin
XSADMIN_PASSWORD=ogpass
```

Command results:

In the following output from the preceding **xsadmin** command, the text that is in ***bold italics*** indicates properties and values that are specified both on the command line and in the properties file. In the `Effective command line arguments` section, you can see that the command line specified arguments override the values in the properties file.

```

```

Attention: The `XSADMIN_PROFILE` property, although it displays in the verbose output, is not a valid key that you can specify in a properties file. The value of this property in the verbose output indicates the property value that is being used, as indicated in the -profile command line argument.

Output without the verbose option

An example of the same command output without the verbose option enabled follows:

```
./xsadmin -l -username xsadmin -password xsadmin -ssl -trustPass ogpass
-profile /opt/ibm/WebSphere/wxs71/ObjectGrid/security/my.properties

Connecting to Catalog service at localhost:1099
*** Show all 'objectGrid:mapset' names
Grid Name  MapSet Name
accounting defaultMapSet
```

Tutorials

You can use tutorials to help you understand product usage scenarios, including entity manager, queries, and security.

- Tutorial: Querying a local in-memory data grid
  You can develop a local in-memory ObjectGrid that can store order information for a website, and use the ObjectQuery API to query the data grid.
- Tutorial: Storing order information in entities
  The tutorial for the entity manager shows you how to use WebSphere® eXtreme Scale to store order information on a Web site. You can create a simple Java™ Platform, Standard Edition 5 application that uses an in-memory, local data grid. The entities use Java SE 5 annotations and generics.
- Tutorial: Configuring Java SE security
  With the following tutorial, you can create a distributed eXtreme Scale environment in a Java Platform, Standard Edition environment.
- 8.5 Tutorial: Run eXtreme Scale clients and servers in the Liberty profile
  You can run WebSphere eXtreme Scale in the Liberty profile.
- Tutorial: Integrate WebSphere eXtreme Scale security with WebSphere Application Server
  This tutorial demonstrates how to secure a WebSphere eXtreme Scale server deployment in a WebSphere Application Server environment.
- Tutorial: Integrate WebSphere eXtreme Scale security in a mixed environment with an external authenticator
  This tutorial demonstrates how to secure WebSphere eXtreme Scale servers that are partially deployed in a WebSphere Application Server environment.
- Tutorial: Running eXtreme Scale bundles in the OSGi framework
  The OSGi sample builds on the Google Protocol Buffers serializer samples. When you complete this set of lessons, you will have run the serializer sample plug-ins in the OSGi framework.

Tutorial: Querying a local in-memory data grid

You can develop a local in-memory ObjectGrid that can store order information for a website, and use the ObjectQuery API to query the data grid.

Before you begin

Be sure to have objectgrid.jar file in the classpath.

About this task

Each step in the tutorial builds on the previous step. Follow each of the steps to build a simple Java™ Platform, Standard Edition Version 5 or later application that uses an in-memory, local data grid.

1. ObjectQuery tutorial - step 1
   With the following steps, you can continue to develop a local, in-memory ObjectGrid that stores order information for an online retail store using the ObjectMap APIs. You define a schema for the map and run a query against the map.
2. ObjectQuery tutorial - step 2
   With the following steps, you can continue to create an ObjectGrid with one map and an index, along with a schema for the map. Then you can insert an object into the cache and later retrieve it using a simple query.
3. ObjectQuery tutorial - step 3
   With the following step, you can create an ObjectGrid with two maps and a schema for the maps with a relationship, then insert objects into the cache and later retrieve them using a simple query.
4. ObjectQuery tutorial - step 4
   The following step shows how to create an ObjectGrid with four maps and a schema for the maps. Some of the maps maintain a one-to-one (unidirectional) and one-to-many (bidirectional) relationship. After creating the maps, you can then run the sample Application.java program to insert objects into the cache and run queries to retrieve these objects.

ObjectQuery tutorial - step 1

With the following steps, you can continue to develop a local, in-memory ObjectGrid that stores order information for an online retail store using the ObjectMap APIs. You define a schema for the map and run a query against the map.

Procedure

1. Create an ObjectGrid with a map schema.
   Create an ObjectGrid with one map schema for the map, then insert an object into the cache and later retrieve it using a simple query.

   OrderBean.java

   ```
   public class OrderBean implements Serializable {
       String orderNumber;
       java.util.Date date;
       String customerName;
       String itemName;
       int quantity;
       double price;
   }
   ```

2. Define the primary key.
   The previous code shows an OrderBean object. This object implements the java.io.Serializable interface because all objects in the cache must (by default) be Serializable.

   The orderNumber attribute is the primary key of the object. The following example program can be run in stand-alone mode. You should follow this tutorial in an Eclipse Java™ project that has the objectgrid.jar file added to the class path.

   Application.java

   ```
   package querytutorial.basic.step1;

   import java.util.Iterator;

   import com.ibm.websphere.objectgrid.ObjectGrid;
   import com.ibm.websphere.objectgrid.ObjectGridManagerFactory;
   import com.ibm.websphere.objectgrid.ObjectMap;
   import com.ibm.websphere.objectgrid.Session;
   import com.ibm.websphere.objectgrid.config.QueryConfig;
   import com.ibm.websphere.objectgrid.config.QueryMapping;
   import com.ibm.websphere.objectgrid.query.ObjectQuery;

   public class Application
   {

       static public void main(String [] args) throws Exception
       {
           ObjectGrid og = ObjectGridManagerFactory.getObjectGridManager().createObjectGrid();
           og.defineMap("Order");

           // Define the schema
           QueryConfig queryCfg = new QueryConfig();
           queryCfg.addQueryMapping(new QueryMapping("Order", OrderBean.class.getName(),
                                                     "orderNumber", QueryMapping.FIELD_ACCESS));
           og.setQueryConfig(queryCfg);

           Session s = og.getSession();
           ObjectMap orderMap = s.getMap("Order");

           s.begin();
           OrderBean o = new OrderBean();
           o.customerName = "John Smith";
   ```

```
        o.date = new java.util.Date(System.currentTimeMillis());
        o.itemName = "Widget";
        o.orderNumber = "1";
        o.price = 99.99;
        o.quantity = 1;
        orderMap.put(o.orderNumber, o);
        s.commit();

        s.begin();
        ObjectQuery query = s.createObjectQuery("SELECT o FROM Order o WHERE o.itemName='Widget'");
        Iterator result = query.getResultIterator();
        o = (OrderBean) result.next();
        System.out.println("Found order for customer: " + o.customerName);
        s.commit();
        // Close the session (optional in Version 7.1.1 and later) for improved performance
        s.close();
}
}
```

This eXtreme Scale application first initializes a local ObjectGrid with an automatically generated name. Next, the application creates a BackingMap and a QueryConfig that defines what Java type is associated with the map, the name of the field that is the primary key for the map, and how to access the data in the object. You then obtain a Session to get the ObjectMap instance and insert an OrderBean object into the map in a transaction.

After the data is committed into the cache, you can use ObjectQuery to find the OrderBean using any of the persistent fields in the class. Persistent fields are those that do not have the transient modifier. Because you did not define any indexes on the BackingMap, ObjectQuery must scan each object in the map using Java reflection.

What to do next

ObjectQuery tutorial - step 2 demonstrates how an index can be used to optimize the query.

Next topic: ObjectQuery tutorial - step 2

ObjectQuery tutorial - step 2

With the following steps, you can continue to create an ObjectGrid with one map and an index, along with a schema for the map. Then you can insert an object into the cache and later retrieve it using a simple query.

Before you begin

Be sure that you have completed ObjectQuery tutorial - step 1 before proceeding with this step of the tutorial.

Procedure

Schema and index

`Application.java`

```
// Create an index
    HashIndex idx= new HashIndex();
    idx.setName("theItemName");
    idx.setAttributeName("itemName");
    idx.setRangeIndex(true);
    idx.setFieldAccessAttribute(true);
    orderBMap.addMapIndexPlugin(idx);
}
```

The index must be a com.ibm.websphere.objectgrid.plugins.index.HashIndex instance with the following settings:

- The Name is arbitrary, but must be unique for a given BackingMap.
- The AttributeName is the name of the field or bean property which the indexing engine uses to introspect the class. In this case, it is the name of the field for which you will create an index.
- RangeIndex must always be true.
- FieldAccessAttribute should match the value set in the QueryMapping object when the query schema was created. In this case, the Java™ object is accessed using the fields directly.

When a query runs that filters on the itemName field, the query engine automatically uses the defined index. Using the index allows the query to run much faster and a map scan is not needed. The next step demonstrates how an index can be used to optimize the query.

Next step

Previous topic: ObjectQuery tutorial - step 1
Next topic: ObjectQuery tutorial - step 3

ObjectQuery tutorial - step 3

With the following step, you can create an ObjectGrid with two maps and a schema for the maps with a relationship, then insert objects into the cache and later retrieve them using a simple query.

Before you begin

Be sure you have completed ObjectQuery tutorial - step 2 prior to proceeding with this step.

About this task

In this example, there are two maps, each with a single Java™ type mapped to it. The Order map has OrderBean objects and the Customer map has CustomerBean objects in it.

Procedure

Define maps with a relationship.

`OrderBean.java`

```
public class OrderBean implements Serializable {
    String orderNumber;
    java.util.Date date;
    String customerId;
    String itemName;
    int quantity;
    double price;
}
```

The OrderBean no longer has the customerName in it. Instead, it has the customerId, which is the primary key for the CustomerBean object and the Customer map.

`CustomerBean.java`

```
public class CustomerBean implements Serializable{
    private static final long serialVersionUID = 1L;
    String id;
    String firstName;
    String surname;
    String address;
    String phoneNumber;
}
```

The relationship between the two types or Maps follows:

`Application.java`

```
public class Application
{

    static public void main(String [] args)
        throws Exception
    {
        ObjectGrid og = ObjectGridManagerFactory.getObjectGridManager().createObjectGrid();
        og.defineMap("Order");
        og.defineMap("Customer");

        // Define the schema
        QueryConfig queryCfg = new QueryConfig();
        queryCfg.addQueryMapping(new QueryMapping(
            "Order", OrderBean.class.getName(), "orderNumber", QueryMapping.FIELD_ACCESS));
        queryCfg.addQueryMapping(new QueryMapping(
            "Customer", CustomerBean.class.getName(), "id", QueryMapping.FIELD_ACCESS));
        queryCfg.addQueryRelationship(new QueryRelationship(
             OrderBean.class.getName(), CustomerBean.class.getName(), "customerId", null));
        og.setQueryConfig(queryCfg);

        Session s = og.getSession();
        ObjectMap orderMap = s.getMap("Order");
        ObjectMap custMap = s.getMap("Customer");

        s.begin();
        CustomerBean cust = new CustomerBean();
        cust.address = "Main Street";
        cust.firstName = "John";
        cust.surname = "Smith";
        cust.id = "C001";
        cust.phoneNumber = "5555551212";
        custMap.insert(cust.id, cust);

        OrderBean o = new OrderBean();
        o.customerId = cust.id;
        o.date = new java.util.Date();
        o.itemName = "Widget";
        o.orderNumber = "1";
```

```
        o.price = 99.99;
        o.quantity = 1;
        orderMap.insert(o.orderNumber, o);
        s.commit();

        s.begin();
        ObjectQuery query = s.createObjectQuery(
            "SELECT c FROM Order o JOIN o.customerId as c WHERE o.itemName='Widget'");
        Iterator result = query.getResultIterator();
        cust = (CustomerBean) result.next();
        System.out.println("Found order for customer: " + cust.firstName + " " + cust.surname);
        s.commit();
    // Close the session (optional in Version 7.1.1 and later) for improved performance
        s.close();
    }
}
```

The equivalent XML in the ObjectGrid deployment descriptor follows:

```
<?xml version="1.0" encoding="UTF-8"?>
<objectGridConfig xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="http://ibm.com/ws/objectgrid/config ../objectGrid.xsd"
xmlns="http://ibm.com/ws/objectgrid/config">
  <objectGrids>
    <objectGrid name="CompanyGrid">
      <backingMap name="Order"/>
      <backingMap name="Customer"/>

      <querySchema>
         <mapSchemas>
           <mapSchema
             mapName="Order"
             valueClass="com.mycompany.OrderBean"
             primaryKeyField="orderNumber"
             accessType="FIELD"/>
           <mapSchema
             mapName="Customer"
             valueClass="com.mycompany.CustomerBean"
             primaryKeyField="id"
             accessType="FIELD"/>
         </mapSchemas>
         <relationships>
           <relationship
             source="com.mycompany.OrderBean"
             target="com.mycompany.CustomerBean"
             relationField="customerId"/>
         </relationships>
      </querySchema>
    </objectGrid>
  </objectGrids>
</objectGridConfig>
```

What to do next

ObjectQuery tutorial - step 4, expands the current step by including field and property access objects and additional relationships.
Previous topic: ObjectQuery tutorial - step 2
Next topic: ObjectQuery tutorial - step 4

ObjectQuery tutorial - step 4

The following step shows how to create an ObjectGrid with four maps and a schema for the maps. Some of the maps maintain a one-to-one (unidirectional) and one-to-many (bidirectional) relationship. After creating the maps, you can then run the sample Application.java program to insert objects into the cache and run queries to retrieve these objects.

Before you begin

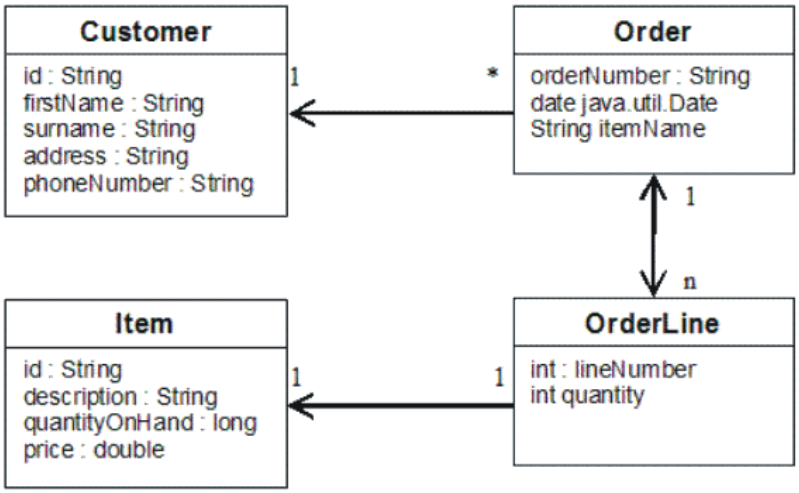
Be sure to have completed ObjectQuery tutorial - step 3 prior to continuing with the current step.

About this task

You are required to create four JAVA classes. These are the maps for the ObjectGrid:

- OrderBean.java
- OrderLineBean.java
- CustomerBean.java
- ItemBean.java

Figure 1. Order Schema. An Order schema has a one-to-one relationship with Customer and a one-to-many relationship with OrderLine. The OrderLine map has a one-to-one relationship with Item and includes the quantity ordered.



After creating these JAVA classes with these relationships, you can then run the sample Application.java program. This program lets you insert objects into the cache and retrieve these using several queries.

Procedure

1. Create the following JAVA classes:

```
OrderBean.java

public class OrderBean implements Serializable {
   String orderNumber;
   java.util.Date date;
   String customerId;
   String itemName;
   List<Integer> orderLines;
}

OrderLineBean.java

public class OrderLineBean implements Serializable {
         int lineNumber;
         int quantity;
         String orderNumber;
         String itemId;
}

CustomerBean.java

public class CustomerBean implements Serializable{
  String id;
  String firstName;
  String surname;
  String address;
  String phoneNumber;
}

ItemBean.java

public class ItemBean implements Serializable {
         String id;
         String description;
         long quantityOnHand;
         double price;
}
```

2. After creating the classes, you can run the sample Application.java:

```
Application.java

                public class Application static public void main(String [] args)throws Exception
        // Configure programatically
                                objectGrid og = ObjectGridManagerFactory.getObjectGridManager().createObjectGrid();
        og.defineMap("Order");
        og.defineMap("Customer");
        og.defineMap("OrderLine");
        og.defineMap("Item");

        // Define the schema
        QueryConfig queryCfg = new QueryConfig();
        queryCfg.addQueryMapping(new QueryMapping("Order", OrderBean.class.getName(), "orderNumber",
QueryMapping.FIELD_ACCESS));
        queryCfg.addQueryMapping(new QueryMapping("Customer", CustomerBean.class.getName(), "id",
```

```
QueryMapping.FIELD_ACCESS));
        queryCfg.addQueryMapping(new QueryMapping("OrderLine", OrderLineBean.class.getName(), "lineNumber",
QueryMapping.FIELD_ACCESS));
        queryCfg.addQueryMapping(new QueryMapping("Item", ItemBean.class.getName(), "id",
QueryMapping.FIELD_ACCESS));
        queryCfg.addQueryRelationship(new QueryRelationship(OrderBean.class.getName(),
CustomerBean.class.getName(), "customerId", null));
        queryCfg.addQueryRelationship(new QueryRelationship(OrderBean.class.getName(),
OrderLineBean.class.getName(),
                                "orderLines", "lineNumber"));
        queryCfg.addQueryRelationship(new QueryRelationship(OrderLineBean.class.getName(),
ItemBean.class.getName(), "itemId", null));
        og.setQueryConfig(queryCfg);

        // Get session and maps;
        Session s = og.getSession();
        ObjectMap orderMap = s.getMap("Order");
        ObjectMap custMap = s.getMap("Customer");
        ObjectMap itemMap = s.getMap("Item");
        ObjectMap orderLineMap = s.getMap("OrderLine");

        // Add data
        s.begin();
        CustomerBean aCustomer = new CustomerBean();
        aCustomer.address = "Main Street";
        aCustomer.firstName = "John";
        aCustomer.surname = "Smith";
        aCustomer.id = "C001";
        aCustomer.phoneNumber = "5555551212";
        custMap.insert(aCustomer.id, aCustomer);

        // Insert an order with a reference to the customer, but without any OrderLines yet.
        // Because we are using CopyMode.COPY_ON_READ_AND_COMMIT, the
        // insert won't be copied into the backing map until commit time, so
        // the reference is still good.

                                OrderBean anOrder = new OrderBean();
                                anOrder.customerId = aCustomer.id;
                                anOrder.date = new java.util.Date();
                                anOrder.itemName = "Widget";
                                anOrder.orderNumber = "1";
                                anOrder.orderLines = new ArrayList();
                                orderMap.insert(anOrder.orderNumber, anOrder);

        ItemBean anItem = new ItemBean();
        anItem.id = "AC0001";
        anItem.description = "Description of widget";
        anItem.quantityOnHand = 100;
        anItem.price = 1000.0;
        itemMap.insert(anItem.id, anItem);

                                // Create the OrderLines and add the reference to the Order
        OrderLineBean anOrderLine = new OrderLineBean();
        anOrderLine.lineNumber = 99;
        anOrderLine.itemId = anItem.id;
        anOrderLine.orderNumber = anOrder.orderNumber;
        anOrderLine.quantity = 500;
        orderLineMap.insert(anOrderLine.lineNumber, anOrderLine);
        anOrder.orderLines.add(Integer.valueOf(anOrderLine.lineNumber));

                                anOrderLine = new OrderLineBean();
        anOrderLine.lineNumber = 100;
        anOrderLine.itemId = anItem.id;
        anOrderLine.orderNumber = anOrder.orderNumber;
        anOrderLine.quantity = 501;
        orderLineMap.insert(anOrderLine.lineNumber, anOrderLine);
        anOrder.orderLines.add(Integer.valueOf(anOrderLine.lineNumber));
        s.commit();

                                s.begin();
        // Find all customers who have ordered a specific item.
        ObjectQuery query = s.createObjectQuery("SELECT c FROM Order o JOIN o.customerId as c WHERE
o.itemName='Widget'");
        Iterator result = query.getResultIterator();
        aCustomer = (CustomerBean) result.next();
        System.out.println("Found order for customer: " + aCustomer.firstName + " " + aCustomer.surname);
        s.commit();

                                s.begin();
        // Find all OrderLines for customer C001.
        // The query joins are expressed on the foreign keys.
        query = s.createObjectQuery("SELECT ol FROM Order o JOIN o.customerId as c JOIN o.orderLines as ol WHERE
c.id='C001'");
        result = query.getResultIterator();
        System.out.println("Found OrderLines:");
        while(result.hasNext()) {
            anOrderLine = (OrderLineBean) result.next();
            System.out.println(anOrderLine.lineNumber + ", qty=" + anOrderLine.quantity);
        }
        // Close the session (optional in Version 7.1.1 and later) for improved performance
        s.close();
```

```
                }
}
```

3. Using the XML configuration below (in the ObjectGrid deployment descriptor) is equivalent to the programmatic approach above.

```
<?xml version="1.0" encoding="UTF-8"?><objectGridConfig xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="http://ibm.com/ws/objectgrid/config
../objectGrid.xsd"xmlns="http://ibm.com/ws/objectgrid/config">
<objectGrids>
        <objectGrid name="CompanyGrid">
  <backingMap name="Order"/>
  <backingMap name="Customer"/>
  <backingMap name="OrderLine"/>
  <backingMap name="Item"/>

<querySchema>
 <mapSchemas>
  <mapSchema
               mapName="Order"
               valueClass="com.mycompany.OrderBean"
               primaryKeyField="orderNumber"
               accessType="FIELD"/>
  <mapSchema
               mapName="Customer"
               valueClass="com.mycompany.CustomerBean"
               primaryKeyField="id"
               accessType="FIELD"/>

Tutorial: Storing order information in entities

The tutorial for the entity manager shows you how to use WebSphere® eXtreme Scale to store order information on a Web site. You can create a simple Java™ Platform, Standard Edition 5 application that uses an in-memory, local data grid. The entities use Java SE 5 annotations and generics.

Before you begin

Ensure that you have met the following requirements before you begin the tutorial:

- You must have Java SE 5.
- You must have the objectgrid.jar file in your classpath.

1. Entity manager tutorial: Creating an entity class
   Create a local ObjectGrid with one entity by creating an Entity class, registering the entity type, and storing an entity instance into the cache.
2. Entity manager tutorial: Forming entity relationships
   Create a simple relationship between entities by creating two entity classes with a relationship, registering the entities with the ObjectGrid, and storing the entity instances into the cache.
3. Entity manager tutorial: Order Entity Schema
   Create four entity classes by using both single and bidirectional relationships, ordered lists, and foreign key relationships. The EntityManager APIs are used to persist and find the entities. Building on the Order and Customer entities that are in the previous parts of the tutorial, this tutorial step adds two more entities: the Item and OrderLine entities.

4. Entity manager tutorial: Updating entries
   If you want to change an entity, you can find the instance, update the instance and any referenced entities, and commit the transaction.
5. Entity manager tutorial: Updating and removing entries with an index
   You can use an index to find, update, and remove entities.
6. Entity manager tutorial: Updating and removing entries by using a query
   You can update and remove entities by using a query.

Entity manager tutorial: Creating an entity class

Create a local ObjectGrid with one entity by creating an Entity class, registering the entity type, and storing an entity instance into the cache.

Procedure

1. Create the Order object. To identify the object as an ObjectGrid entity, add the @Entity annotation. When you add this annotation, all serializable attributes in the object are automatically persisted in eXtreme Scale, unless you use annotations on the attributes to override the attributes. The orderNumber attribute is annotated with `@Id` to indicate that this attribute is the primary key. An example of an Order object follows:

   Order.java

   ```
   @Entity
   public class Order
   {
       @Id String orderNumber;
       Date date;
       String customerName;
       String itemName;
       int quantity;
       double price;
   }
   ```

2. Run the eXtreme Scale Hello World application to demonstrate the entity operations. The following example program can be issued in stand-alone mode to demonstrate the entity operations. Use this program in an Eclipse Java™ project that has the objectgrid.jar file added to the class path. An example of a simple Hello world application that uses eXtreme Scale follows:

   Application.java

   ```
   package emtutorial.basic.step1;

   import com.ibm.websphere.objectgrid.ObjectGrid;
   import com.ibm.websphere.objectgrid.ObjectGridManagerFactory;
   import com.ibm.websphere.objectgrid.Session;
   import com.ibm.websphere.objectgrid.em.EntityManager;

   public class Application
   {

       static public void main(String [] args)
           throws Exception
       {
           ObjectGrid og =
                                   ObjectGridManagerFactory.getObjectGridManager().createObjectGrid();
           og.registerEntities(new Class[] {Order.class});

           Session s = og.getSession();
           EntityManager em = s.getEntityManager();

           em.getTransaction().begin();

           Order o = new Order();
           o.customerName = "John Smith";
           o.date = new java.util.Date(System.currentTimeMillis());
           o.itemName = "Widget";
   ```

```
        o.orderNumber = "1";
        o.price = 99.99;
        o.quantity = 1;

        em.persist(o);
        em.getTransaction().commit();

        em.getTransaction().begin();
        o = (Order)em.find(Order.class, "1");
        System.out.println("Found order for customer: " + o.customerName);
        em.getTransaction().commit();
    }
}
```

This example application performs the following operations:

a. Initializes a local eXtreme Scale with an automatically generated name.
b. Registers the entity classes with the application by using the registerEntities API, although using the registerEntities API is not always necessary.
c. Retrieves a Session and a reference to the entity manager for the Session.
d. Associates each eXtreme Scale Session with a single EntityManager and EntityTransaction. The EntityManager is now used.
e. The registerEntities method creates a BackingMap object that is called Order, and associates the metadata for the Order object with the BackingMap object. This metadata includes the key and non-key attributes, along with the attribute types and names.
f. A transaction starts and creates an Order instance. The transaction is populated with some values. The transaction is then persisted by using the EntityManager.persist method, which identifies the entity as waiting to be included in the associated map.
g. The transaction is then committed, and the entity is included in the ObjectMap instance.
h. Another transaction is made, and the Order object is retrieved by using the key 1. The type cast on the EntityManager.find method is necessary. The Java SE 5 capability is not used to ensure that the objectgrid.jar file works on a Java SE Version 5 and later Java virtual machine.

Next topic: Entity manager tutorial: Forming entity relationships

Entity manager tutorial: Forming entity relationships

Create a simple relationship between entities by creating two entity classes with a relationship, registering the entities with the ObjectGrid, and storing the entity instances into the cache.

Procedure

1. Create the customer entity, which is used to store customer details independently from the Order object. An example of the customer entity follows:

```
Customer.java
@Entity
public class Customer
{
    @Id String id;
    String firstName;
    String surname;
    String address;
    String phoneNumber;
}
```

This class includes information about the customer such as name, address, and phone number.

2. Create the Order object, which is similar to the Order object in the Entity manager tutorial: Creating an entity class topic. An example of the order object follows:

```
Order.java

@Entity
public class Order
{
    @Id String orderNumber;
    Date date;
    @ManyToOne(cascade=CascadeType.PERSIST) Customer customer;
    String itemName;
    int quantity;
    double price;
}
```

In this example, a reference to a Customer object replaces the customerName attribute. The reference has an annotation that indicates a many-to-one relationship. A many-to-one relationship indicates that each order has one customer, but multiple orders might reference the same customer. The cascade annotation modifier indicates that if the entity manager persists the Order object, it must also persist the Customer object. If you choose to not set the cascade persist option, which is the default option, you must manually persist the Customer object with the Order object.

3. Using the entities, define the maps for the ObjectGrid instance. Each map is defined for a specific entity, and one entity is named Order and the other is named Customer. The following example application illustrates how to store and retrieve a customer order:

```
Application.java

public class Application
{
    static public void main(String [] args)
        throws Exception
    {
        ObjectGrid og =
```

```
                                        ObjectGridManagerFactory.getObjectGridManager().createObjectGrid();
        og.registerEntities(new Class[] {Order.class});

        Session s = og.getSession();
        EntityManager em = s.getEntityManager();

        em.getTransaction().begin();

        Customer cust = new Customer();
        cust.address = "Main Street";
        cust.firstName = "John";
        cust.surname = "Smith";
        cust.id = "C001";
        cust.phoneNumber = "5555551212";

        Order o = new Order();
        o.customer = cust;
        o.date = new java.util.Date();
        o.itemName = "Widget";
        o.orderNumber = "1";
        o.price = 99.99;
        o.quantity = 1;

        em.persist(o);
        em.getTransaction().commit();

        em.getTransaction().begin();
        o = (Order)em.find(Order.class, "1");
        System.out.println("Found order for customer: "
                                        + o.customer.firstName + " " + o.customer.surname);
        em.getTransaction().commit();
        // Close the session (optional in Version 7.1.1 and later) for improved performance
        s.close();
    }
}
```

This application is similar to the example application that is in the previous step. In the preceding example, only a single class Order is registered. WebSphere® eXtreme Scale detects and automatically includes the reference to the Customer entity, and a Customer instance for `John Smith` is created and referenced from the new Order object. As a result, the new customer is automatically persisted, because the relationship between two orders includes the cascade modifier, which requires that each object be persisted. When the Order object is found, the entity manager automatically finds the associated Customer object and inserts a reference to the object.

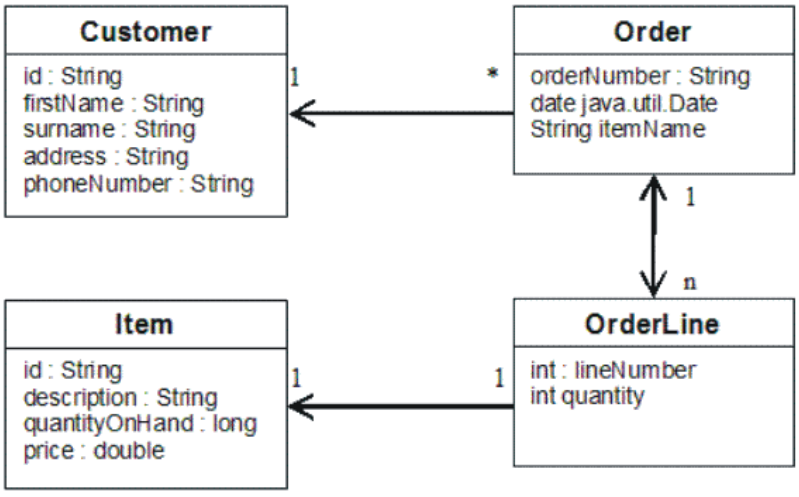
Previous topic: Entity manager tutorial: Creating an entity class
Next topic: Entity manager tutorial: Order Entity Schema

Entity manager tutorial: Order Entity Schema

Create four entity classes by using both single and bidirectional relationships, ordered lists, and foreign key relationships. The EntityManager APIs are used to persist and find the entities. Building on the Order and Customer entities that are in the previous parts of the tutorial, this tutorial step adds two more entities: the Item and OrderLine entities.

About this task

Figure 1. Order Entity Schema. An Order entity has a reference to one customer and zero or more OrderLines. Each OrderLine entity has a reference to a single item and includes the quantity ordered.



Procedure

1. Create the customer entity, which is similar to the previous examples.

```
Customer.java
@Entity
public class Customer
{
    @Id String id;
    String firstName;
    String surname;
    String address;
    String phoneNumber;
}
```

2. Create the Item entity, which holds information about a product that is included in the store's inventory, such as the product description, quantity, and price.

```
Item.java
@Entity
public class Item
{
    @Id String id;
    String description;
    long quantityOnHand;
    double price;
}
```

3. Create the OrderLine entity. Each Order has zero or more OrderLines, which identify the quantity of each item in the order. The key for the OrderLine is a compound key that consists of the Order that owns the OrderLine and an integer that assigns the order line a number. Add the cascade persist modifier to every relationship on your entities.

```
OrderLine.java
@Entity
public class OrderLine
{
    @Id @ManyToOne(cascade=CascadeType.PERSIST) Order order;
    @Id int lineNumber;
    @OneToOne(cascade=CascadeType.PERSIST) Item item;
    int quantity;
    double price;
}
```

4. Create the final Order Object, which has a reference to the Customer for the order and a collection of OrderLine objects.

```
Order.java
@Entity
public class Order
{
    @Id String orderNumber;
    java.util.Date date;
    @ManyToOne(cascade=CascadeType.PERSIST) Customer customer;
    @OneToMany(cascade=CascadeType.ALL, mappedBy="order")
                        @OrderBy("lineNumber") List<OrderLine> lines;
}
```

   The cascade ALL is used as the modifier for lines. This modifier signals the EntityManager to cascade both the PERSIST operation and the REMOVE operation. For example, if the Order entity is persisted or removed, then all OrderLine entities are also persisted or removed.

   If an OrderLine entity is removed from the lines list in the Order object, the reference is then broken. However, the OrderLine entity is not removed from the cache. You must use the EntityManager remove API to remove entities from the cache. The REMOVE operation is not used on the customer entity or the item entity from OrderLine. As a result, the customer entity remains even though the order or item is removed when the OrderLine is removed.

   The mappedBy modifier indicates an inverse relationship with the target entity. The modifier identifies which attribute in the target entity references the source entity, and the owning side of a one-to-one or many-to-many relationship. Typically, you can omit the modifier. However, an error is displayed to indicate that it must be specified if WebSphere® eXtreme Scale cannot discover it automatically. An OrderLine entity that contains two of type Order attributes in a many-to-one relationship typically causes the error.

   The @OrderBy annotation specifies the order in which each OrderLine entity should be in the lines list. If the annotation is not specified, then the lines display in an arbitrary order. Although the lines are added to the Order entity by issuing ArrayList, which preserves the order, the EntityManager does not necessarily recognize the order. When you issue the find method to retrieve the Order object from the cache, the list object is not an ArrayList object.

5. Create the application. The following example illustrates the final Order object, which has a reference to the Customer for the order and a collection of OrderLine objects.
   a. Find the Items to order, which then become Managed entities.
   b. Create the OrderLine and attach it to each Item.
   c. Create the Order and associate it with each OrderLine and the customer.
   d. Persist the order, which automatically persists each OrderLine.
   e. Commit the transaction, which detaches each entity and synchronizes the state of the entities with the cache.
   f. Print the order information. The OrderLine entities are automatically sorted by the OrderLine ID.

```
Application.java

static public void main(String [] args)
        throws Exception
    {
        ...

        // Add some items to our inventory.
```

```
        em.getTransaction().begin();
        createItems(em);
        em.getTransaction().commit();

        // Create a new customer with the items in his cart.
        em.getTransaction().begin();
        Customer cust = createCustomer();
        em.persist(cust);

        // Create a new order and add an order line for each item.
        // Each line item is automatically persisted since the
                                // Cascade=ALL option is set.
        Order order = createOrderFromItems(em, cust, "ORDER_1",
                                        new String[]{"1", "2"}, new int[]{1,3});
        em.persist(order);
        em.getTransaction().commit();

        // Print the order summary
        em.getTransaction().begin();
        order = (Order)em.find(Order.class, "ORDER_1");
        System.out.println(printOrderSummary(order));
        em.getTransaction().commit();
    }

    public static Customer createCustomer() {
        Customer cust = new Customer();
        cust.address = "Main Street";
        cust.firstName = "John";
        cust.surname = "Smith";
        cust.id = "C001";
        cust.phoneNumber = "5555551212";
        return cust;
    }

    public static void createItems(EntityManager em) {
        Item item1 = new Item();
        item1.id = "1";
        item1.price = 9.99;
        item1.description = "Widget 1";
        item1.quantityOnHand = 4000;
        em.persist(item1);

        Item item2 = new Item();
        item2.id = "2";
        item2.price = 15.99;
        item2.description = "Widget 2";
        item2.quantityOnHand = 225;
        em.persist(item2);

    }

    public static Order createOrderFromItems(EntityManager em,
                        Customer cust, String orderId, String[] itemIds, int[] qty) {

        Item[] items = getItems(em, itemIds);

        Order order = new Order();
        order.customer = cust;
        order.date = new java.util.Date();
        order.orderNumber = orderId;
        order.lines = new ArrayList<OrderLine>(items.length);
                        for(int i=0;i<items.length;i++){
                                                OrderLine line = new OrderLine();
            line.lineNumber = i+1;
            line.item = items[i];
            line.price = line.item.price;
            line.quantity = qty[i];
            line.order = order;
            order.lines.add(line);
        }
        return order;
    }

    public static Item[] getItems(EntityManager em, String[] itemIds) {
        Item[] items = new Item[itemIds.length];
        for(int i=0;i<items.length;i++){
                        items[i] = (Item) em.find(Item.class, itemIds[i]);
        }
        return items;
    }
```

The next step is to delete an entity. The EntityManager interface has a remove method that marks an object as deleted. The application should remove the entity from any relationship collections before calling the remove method. Edit the references and issue the remove method, or em.remove(object), as a final step.

Previous topic: Entity manager tutorial: Forming entity relationships
Next topic: Entity manager tutorial: Updating entries

Entity manager tutorial: Updating entries

If you want to change an entity, you can find the instance, update the instance and any referenced entities, and commit the transaction.

Before you begin

Procedure

Update entries. The following example demonstrates how to find the Order instance, change it and any referenced entities, and commit the transaction.

```
public static void updateCustomerOrder(EntityManager em) {
    em.getTransaction().begin();
    Order order = (Order) em.find(Order.class, "ORDER_1");
    processDiscount(order, 10);
    Customer cust = order.customer;
    cust.phoneNumber = "5075551234";
    em.getTransaction().commit();
}

public static void processDiscount(Order order, double discountPct) {
    for(OrderLine line : order.lines) {
        line.price = line.price * ((100-discountPct)/100);
    }
}
```

Flushing the transaction synchronizes all managed entities with the cache. When a transaction is committed, a flush automatically occurs. In this case, the Order becomes a managed entity. Any entities that are referenced from the Order, Customer, and OrderLine also become managed entities. When the transaction is flushed, each of the entities are checked to determine if they have been modified. Those that are modified are updated in the cache. After the transaction completes, by either being committed or rolled back, the entities become detached and any changes that are made in the entities are not reflected in the cache.

Previous topic: Entity manager tutorial: Order Entity Schema
Next topic: Entity manager tutorial: Updating and removing entries with an index

Entity manager tutorial: Updating and removing entries with an index

You can use an index to find, update, and remove entities.

Procedure

Update and remove entities by using an index. Use an index to find, update, and remove entities. In the following examples, the Order entity class is updated to use the @Index annotation. The @Index annotation signalsWebSphere® eXtreme Scale to create a range index for an attribute. The name of the index is the same name as the name of the attribute and is always a MapRangeIndex index type.

```
Order.java
@Entity
public class Order
{
    @Id String orderNumber;
    @Index java.util.Date date;
    @OneToOne(cascade=CascadeType.PERSIST) Customer customer;
    @OneToMany(cascade=CascadeType.ALL, mappedBy="order")
                                @OrderBy("lineNumber") List<OrderLine> lines;  }
```

The following example demonstrates how to cancel all orders that are submitted within the last minute. Find the order by using an index, add the items in the order back into the inventory, and remove the order and the associated line items from the system.

```
public static void cancelOrdersUsingIndex(Session s)
                throws ObjectGridException {
    // Cancel all orders that were submitted 1 minute ago
    java.util.Date cancelTime = new
                        java.util.Date(System.currentTimeMillis() - 60000);
    EntityManager em = s.getEntityManager();
    em.getTransaction().begin();
    MapRangeIndex dateIndex = (MapRangeIndex)
                        s.getMap("Order").getIndex("date");
    Iterator<Tuple> orderKeys = dateIndex.findGreaterEqual(cancelTime);
                while(orderKeys.hasNext()) {
                        Tuple orderKey = orderKeys.next();
                        // Find the Order so we can remove it.
                        Order curOrder = (Order) em.find(Order.class, orderKey);
                        // Verify that the order was not updated by someone else.
                        if(curOrder != null && curOrder.date.getTime() >= cancelTime.getTime()) {
                                for(OrderLine line : curOrder.lines) {
                                        // Add the item back to the inventory.
                                        line.item.quantityOnHand += line.quantity;
                                        line.quantity = 0;
                                }
                        em.remove(curOrder);
```

```
                        }
                    }
            em.getTransaction().commit();
}
```

Previous topic: Entity manager tutorial: Updating entries
Next topic: Entity manager tutorial: Updating and removing entries by using a query

Entity manager tutorial: Updating and removing entries by using a query

You can update and remove entities by using a query.

Procedure

Update and remove entities by using a query.

```
Order.java
@Entity
public class Order
{
    @Id String orderNumber;
    @Index java.util.Date date;
    @OneToOne(cascade=CascadeType.PERSIST) Customer customer;
    @OneToMany(cascade=CascadeType.ALL, mappedBy="order")
                        @OrderBy("lineNumber") List<OrderLine> lines;
}
```

The order entity class is the same as it is in the previous example. The class still provides the @Index annotation, because the query string uses the date to find the entity. The query engine uses indices when they can be used.

```
public static void cancelOrdersUsingQuery(Session s) {
        // Cancel all orders that were submitted 1 minute ago
        java.util.Date cancelTime =
                                        new java.util.Date(System.currentTimeMillis() - 60000);
        EntityManager em = s.getEntityManager();
        em.getTransaction().begin();

        // Create a query that will find the order based on date.  Since
        // we have an index defined on the order date, the query
                                // will automatically use it.
        Query query = em.createQuery("SELECT order FROM Order order
                                        WHERE order.date >= ?1");
        query.setParameter(1, cancelTime);
        Iterator<Order> orderIterator = query.getResultIterator();
                         while(orderIterator.hasNext()) {
                                        Order order = orderIterator.next();
                                        // Verify that the order wasn't updated by someone else.
                                        // Since the query used an index, there was no lock on the row.
                                        if(order != null && order.date.getTime() >= cancelTime.getTime()) {
                                                for(OrderLine line : order.lines) {
                                                        // Add the item back to the inventory.
                                                        line.item.quantityOnHand += line.quantity;
                                                        line.quantity = 0;
                                                }
                                                em.remove(order);
                                        }
                                }
                    em.getTransaction().commit();
}
```

Like the previous example, the cancelOrdersUsingQuery method intends to cancel all orders that were submitted in the past minute. To cancel the order, you find the order using a query, add the items in the order back into the inventory, and remove the order and associated line items from the system.

Tutorial: Configuring Java SE security

With the following tutorial, you can create a distributed eXtreme Scale environment in a Java™ Platform, Standard Edition environment.

Before you begin

Ensure that you are familiar with the basics of a distributed eXtreme Scale configuration.

About this task

Use this tutorial when you have installed eXtreme Scale in a stand-alone environment. Each step in the tutorial builds on the previous one. Follow each of the steps to secure a distributed eXtreme Scale and develop a simple Java SE application to access the secured eXtreme Scale.
Begin tutorial

1. Java SE security tutorial - Step 1
   In order to work with the rest of the tutorial, you need to create and package a simple Java program and two XML files. These set of files defines a simple ObjectGrid configuration with one ObjectGrid instance named `accounting` and a `customer` map. The SimpleDP.xml file features a deployment policy of one map set configured with one partition and zero minimum required replicas.
2. Java SE security tutorial - Step 2
   Before you can verify that the SimpleApp.java sample runs, you need to start a catalog server and a container server. After starting these services successfully, you can then launch the client and run the sample. Additional security features are added incrementally in the steps of the tutorial to increase the amount of integrated security that is available.
3. Java SE security tutorial - Step 3
   The rest of the tutorial demonstrates how to enable client authentication before connecting to an eXtreme Scale server. To prepare for the next step of this tutorial, you need to package the SecureSimpleApp.java program into a JAR and create a set of configuration files, which include a security.xml file, and two JAAS configuration files. The security.xml file lets you write authentication into the environment, and the JAAS configuration files provide the authentication mechanism when connecting to the server.
4. Java SE security tutorial - Step 4
   Building on the previous step, the following topic shows how to implement client authentication in a distributed eXtreme Scale environment.
5. Java SE security tutorial - Step 5
   After authenticating a client, as in the previous step, you can give security privileges through eXtreme Scale authorization mechanisms.
6. Java SE security tutorial - Step 6
   The following step explains how you can enable a security layer for communication between your environment's endpoints.

Java SE security tutorial - Step 1

In order to work with the rest of the tutorial, you need to create and package a simple Java program and two XML files. These set of files defines a simple ObjectGrid configuration with one ObjectGrid instance named `accounting` and a `customer` map. The SimpleDP.xml file features a deployment policy of one map set configured with one partition and zero minimum required replicas.

Procedure

1. In a command line window, go to the *wxs_home* directory.
2. Create a directory called applib.
3. Ensure your development environment contains the ogclient.jar file in the classpath. For more information, see the *Programming Guide*.
4. Create and compile the following SimpleApp.java class:

```
SimpleApp.java
// This sample program is provided AS IS and may be used, executed, copied and modified
// without royalty payment by customer
// (a) for its own instruction and study,
// (b) in order to develop applications designed to run with an IBM WebSphere product,
// either for customer's own internal use or for redistribution by customer, as part of such an
// application, in customer's own products.
// Licensed Materials - Property of IBM
// 5724-J34 (C) COPYRIGHT International Business Machines Corp. 2007-2009
package com.ibm.websphere.objectgrid.security.sample.guide;

import com.ibm.websphere.objectgrid.ClientClusterContext;
import com.ibm.websphere.objectgrid.ObjectGrid;
import com.ibm.websphere.objectgrid.ObjectGridManager;
import com.ibm.websphere.objectgrid.ObjectGridManagerFactory;
import com.ibm.websphere.objectgrid.ObjectMap;
import com.ibm.websphere.objectgrid.Session;

public class SimpleApp {

    public static void main(String[] args) throws Exception {

        SimpleApp app = new SimpleApp();
        app.run(args);
    }

    /**
     * read and write the map
     * @throws Exception
     */
    protected void run(String[] args) throws Exception {
        ObjectGrid og = getObjectGrid(args);

        Session session = og.getSession();

        ObjectMap customerMap = session.getMap("customer");

        String customer = (String) customerMap.get("0001");

        if (customer == null) {
            customerMap.insert("0001", "fName lName");
        } else {
            customerMap.update("0001", "fName lName");
        }
        customer = (String) customerMap.get("0001");
        // Close the session (optional in Version 7.1.1 and later) for improved performance
        session.close();
```

```
        System.out.println("The customer name for ID 0001 is " + customer);
    }

    /**
     * Get the ObjectGrid
     * @return an ObjectGrid instance
     * @throws Exception
     */
    protected ObjectGrid getObjectGrid(String[] args) throws Exception {
        ObjectGridManager ogManager = ObjectGridManagerFactory.getObjectGridManager();

        // Create an ObjectGrid
        ClientClusterContext ccContext = ogManager.connect("localhost:2809", null, null);
        ObjectGrid og = ogManager.getObjectGrid(ccContext, "accounting");

        return og;

    }

}
```

5. Compile the package with this file and name the JAR sec_sample.jar. Put this JAR file in the /applib directory.
6. Go to the *wxs_home* directory, and create a directory called xml
7. In the*wxs_home*/xml directory, create the following configuration files:

```
SimpleApp.xml

<?xml version="1.0" encoding="UTF-8"?>
<objectGridConfig xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
        xsi:schemaLocation="http://ibm.com/ws/objectgrid/config ../objectGrid.xsd"
        xmlns="http://ibm.com/ws/objectgrid/config">
    <objectGrids>
        <objectGrid name="accounting">
            <backingMap name="customer" readOnly="false" copyKey="true"/>
        </objectGrid>
    </objectGrids>
</objectGridConfig>
```

The following XML file configures the deployment environment.

```
SimpleDP.xml

<?xml version="1.0" encoding="UTF-8"?>
<deploymentPolicy xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
        xsi:schemaLocation="http://ibm.com/ws/objectgrid/deploymentPolicy ../deploymentPolicy.xsd"
        xmlns="http://ibm.com/ws/objectgrid/deploymentPolicy">

        <objectgridDeployment objectgridName="accounting">
                <mapSet name="mapSet1" numberOfPartitions="1" minSyncReplicas="0" maxSyncReplicas="2"
                        maxAsyncReplicas="1">
                        <map ref="customer"/>
                </mapSet>
        </objectgridDeployment>
</deploymentPolicy>
```

Results

These files create a simple ObjectGrid configuration with one ObjectGrid an `accounting` instance and a `customer` map.

Next topic: Java SE security tutorial - Step 2

Java SE security tutorial - Step 2

Before you can verify that the SimpleApp.java sample runs, you need to start a catalog server and a container server. After starting these services successfully, you can then launch the client and run the sample. Additional security features are added incrementally in the steps of the tutorial to increase the amount of integrated security that is available.

Before you begin

To successfully complete this step of the tutorial, you should have access to the following files:

- Have access to the compiled sec_sample.jar package. This package contains the SimpleApp.java program.
- Have access to the necessary configuration files SimpleApp.xml and SimpleDP.xml.

You should have created these files in Java SE security tutorial - Step 1 of this tutorial.
You should also know how to:

- Start and stop a catalog servers and container servers. For more information, see Starting and stopping stand-alone servers.
- Run the **xscmd** utility in order verify the map size inserted into the data grid.

Procedure

1. In a command line window, go to the *wxs_home*/bin directory and start the catalog service.
   - UNIX Linux `./startOgServer.sh catalogServer`
   - Windows `startOgServer.bat catalogServer`
2. Start a container service named `c0`:
   - UNIX Linux `./startOgServer.sh c0 -objectGridFile ../xml/SimpleApp.xml -deploymentPolicyFile ../xml/SimpleDP.xml -catalogServiceEndPoints localhost:2809`
   - Windows `startOgServer.bat c0 -objectGridFile ..\xml\SimpleApp.xml - deploymentPolicyFile ..\xml\SimpleDP.xml -catalogServiceEndPoints localhost:2809`
3. After the catalog server and container server have been started, run the sec_sample.jar sample as follows:
   UNIX

   ```
   java -classpath ../lib/objectgrid.jar:../applib/sec_sample.jar
   com.ibm.websphere.objectgrid.security.sample.guide.SimpleApp
   ```

   Windows

   ```
   java -classpath ..\lib\objectgrid.jar;..\applib\sec_sample.jar
   com.ibm.websphere.objectgrid.security.sample.guide.SimpleApp
   ```

   The output of the sample is: `The customer name for ID 0001 is fName lName` The getObjectGrid method in this class obtains an ObjectGrid, and the run method reads a record from the customer map and updates the value in the accounting grid.
4. Verify the size of the "customer" map inserted into the "accounting" grid, by issuing the **xscmd** command utility as follows:
   - UNIX Linux `./xscmd.sh -c showMapSizes -g accounting -ms mapSet1`
   - Windows `xscmd.bat -c showMapSizes -g accounting -ms mapSet1`
5. Stop a container server named `c0` with one of the following scripts:
   - UNIX Linux `./stopOgServer.sh c0 -catalogServiceEndPoints localhost:2809`
   - Windows `stopOgServer.bat c0 -catalogServiceEndPoints localhost:2809`

   If the server stopped successfully, then you will see the following message:
   `CWOBJ2512I: ObjectGrid server c0 stopped.`
6. Stop the catalog server with one of the following scripts:
   - UNIX Linux `./stopOgServer.sh catalogServer -catalogServiceEndPoints localhost:2809`
   - Windows `stopOgServer.bat catalogServer -catalogServiceEndPoints localhost:2809`

   If the server stopped successfully, then you will see the following message:
   `CWOBJ2512I: ObjectGrid server catalogServer stopped.`

Previous topic: Java SE security tutorial - Step 1
Next topic: Java SE security tutorial - Step 3

Java SE security tutorial - Step 3

The rest of the tutorial demonstrates how to enable client authentication before connecting to an eXtreme Scale server. To prepare for the next step of this tutorial, you need to package the SecureSimpleApp.java program into a JAR and create a set of configuration files, which include a security.xml file, and two JAAS configuration files. The security.xml file lets you write authentication into the environment, and the JAAS configuration files provide the authentication mechanism when connecting to the server.

About this task

Procedure

1. In a command line window, go to the *wxs_home*/applib directory you created in Java SE security tutorial - Step 1.
2. Create and compile the following SecureSimpleApp.java class:
   Attention: In the following example, some lines of code are continued on the next line for publication purposes.

   ```
   SecureSimpleApp.java
   package com.ibm.websphere.objectgrid.security.sample.guide;

   import com.ibm.websphere.objectgrid.ClientClusterContext;
   import com.ibm.websphere.objectgrid.ObjectGrid;
   import com.ibm.websphere.objectgrid.ObjectGridManager;
   import com.ibm.websphere.objectgrid.ObjectGridManagerFactory;
   import com.ibm.websphere.objectgrid.security.config.ClientSecurityConfiguration;
   import com.ibm.websphere.objectgrid.security.config.ClientSecurityConfigurationFactory;
   import com.ibm.websphere.objectgrid.security.plugins.CredentialGenerator;
   import com.ibm.websphere.objectgrid.security.plugins.builtins.UserPasswordCredentialGenerator;

   public class SecureSimpleApp extends SimpleApp {

       public static void main(String[] args) throws Exception {

           SecureSimpleApp app = new SecureSimpleApp();
           app.run(args);
   ```

```
    }

    /**
     * Get the ObjectGrid
     * @return an ObjectGrid instance
     * @throws Exception
     */
    protected ObjectGrid getObjectGrid(String[] args) throws Exception {
        ObjectGridManager ogManager = ObjectGridManagerFactory.getObjectGridManager();
        ogManager.setTraceFileName("logs/client.log");
        ogManager.setTraceSpecification("ObjectGrid*=all=enabled:ORBRas=all=enabled");

        // Creates a ClientSecurityConfiguration object using the specified file
        ClientSecurityConfiguration clientSC = ClientSecurityConfigurationFactory
                .getClientSecurityConfiguration(args[0]);

        // Creates a CredentialGenerator using the passed-in user and password.
        CredentialGenerator credGen = new UserPasswordCredentialGenerator(args[1], args[2]);
        clientSC.setCredentialGenerator(credGen);

        // Create an ObjectGrid by connecting to the catalog server
        ClientClusterContext ccContext = ogManager.connect("localhost:2809", clientSC, null);
        ObjectGrid og = ogManager.getObjectGrid(ccContext, "accounting");

        return og;

    }

}
```

3. Ensure your development environment contains the ogclient.jar file in the classpath. For more information, see the *Programming Guide*.
4. Compile the package with these files and name the JAR sec_sample.jar.
5. Change to the *wxs_home* directory.
6. Create a directory called security.
7. Create a configuration file called security.xml. Server security properties are specified in this file. These properties are common for both catalog servers and container servers.

```
security.xml
<?xml version="1.0" encoding="UTF-8"?>
<securityConfig xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://ibm.com/ws/objectgrid/config/security ../objectGridSecurity.xsd"
        xmlns="http://ibm.com/ws/objectgrid/config/security">

        <security securityEnabled="true" loginSessionExpirationTime="300" >

        <authenticator className
="com.ibm.websphere.objectgrid.security.plugins.builtins.KeyStoreLoginAuthenticator">
        </authenticator>
    </security>

</securityConfig>
```

Previous topic: Java SE security tutorial - Step 2
Next topic: Java SE security tutorial - Step 4

Java SE security tutorial - Step 4

Building on the previous step, the following topic shows how to implement client authentication in a distributed eXtreme Scale environment.

Before you begin

Be sure that you have completed Java SE security tutorial - Step 3. You need to have created and complied the SecureSimpleApp.java sample into a sec_sample.jar file, and created a configuration file called security.xml.

About this task

With client authentication enabled, a client is authenticated before connecting to the eXtreme Scale server. This section demonstrates how client authentication can be done in an eXtreme Scale server environment, using the sample SecureSimpleApp.java.
Client credential

The SecureSimpleApp.java sample uses the following two plug-in implementations to obtain client credentials:

`com.ibm.websphere.objectgrid.security.plugins.builtins.UserPasswordCredential`

`com.ibm.websphere.objectgrid.security.plugins.builtins.UserPasswordCredentialGenerator`

For more information about these plug-ins, see Client authentication programming.

Server authenticator

The example uses an eXtreme Scale built-in implementation: `KeyStoreLoginAuthenticator`, which is for testing and sample purposes (a keystore is a simple user registry and should not be used for production). For more information, see the topic on authenticator plug-in under Client authentication programming.

Procedure

1. In a command line window, go to the *wxs_home* directory.
2. Change to the *wxs_home*/security directory you had created in Java SE security tutorial - Step 3.
3. Create a JAAS configuration file that enforces a method of authentication to the server, og_jaas.config. The `KeyStoreLoginAuthenticator` referenced in the security.xml file uses a keystore by using the JAAS login module "KeyStoreLogin". The keystore can be configured as an option to the KeyStoreLoginModule class.

```
og_jaas.config
KeyStoreLogin{
com.ibm.websphere.objectgrid.security.plugins.builtins.KeyStoreLoginModule required
     keyStoreFile="../security/sampleKS.jks" debug = true;
};
```

Windows Important: If you are using Windows, the directory path does not support backslashes. If you have used backslashes, you must escape any backslash (\ ) characters in the path. For example, if you want to use the path C:\opt\ibm, enter C:\\opt\\ibm in the properties file. Windows directories with spaces are not supported.

4. Change to the *java_home*/bin directory and run the keytool.
5. Change to the *wxs_home* /security directory, and create two users, "manager" and "cashier" with their own passwords.
   a. Use the keytool to create a user "manager" with password "manager1" in the keystore sampleKS.jks.
      - UNIX Linux

```
keytool -genkey -v -keystore sampleKS.jks -storepass sampleKS1 \
-alias manager -keypass manager1 \
-dname CN=manager,O=acme,OU=OGSample -validity 10000
```

      - Windows

```
keytool -genkey -v -keystore sampleKS.jks -storepass sampleKS1 ^
-alias manager -keypass manager1 ^
-dname CN=manager,O=acme,OU=OGSample -validity 10000
```

   b. Use the keytool to create a user "cashier" with password "cashier1" in the keystore sampleKS.jks.
      - UNIX Linux

```
keytool -genkey -v -keystore sampleKS.jks -storepass sampleKS1 \
-alias cashier -keypass cashier1 \
-dname CN=cashier,O=acme,OU=OGSample -validity 10000
```

      - Windows

```
keytool -genkey -v -keystore sampleKS.jks -storepass sampleKS1 ^
-alias cashier -keypass cashier1 ^
-dname CN=cashier,O=acme,OU=OGSample -validity 10000
```

6. Make a copy of the sampleClient.properties file located in wxs_home/properties directory to wxs_home/security/client.properties
   - UNIX Linux

```
cp ../properties/sampleClient.properties client.properties
```

   - Windows

```
copy ..\properties\sampleClient.properties client.properties
```

7. In the *wxs_home*/security directory, save it as client.properties
   Make the following changes to the client.properties file:
   a. **securityEnabled:** Set securityEnabled to true (default value) enables the client security, which includes authentication.
   b. **credentialAuthentication:** Set credentialAuthentication to Supported (default value), which means the client supports credential authentication.
   c. **transportType:** Set transportType to TCP/IP, which means no SSL will be used.
8. Copy the sampleServer.properties file into the *wxs_home*/security directory and save it as server.properties.
   - UNIX Linux

```
cp ../properties/sampleServer.properties server.properties
```

   - Windows

```
copy ..\properties\sampleServer.properties server.properties
```

   Make the following changes in the server.properties file:
   a. **securityEnabled:** Set the securityEnabled attribute to true.
   b. **transportType:** Set transportType attribute to TCP/IP, which means no SSL is used.
   c. **secureTokenManagerType:** Set secureTokenManagerType attribute to none to not configure the secure token manager.
9. Go to the *wxs_home*/bin directory and depending on your platform, issue one of the following commands to start a catalog server. You need to issue the **-clusterSecurityFile** and **-serverProps** command line options to pass in security properties:
   - UNIX Linux

```
./startOgServer.sh catalogServer -clusterSecurityFile ../security/security.xml
-serverProps ../security/server.properties -jvmArgs
-Djava.security.auth.login.config="../security/og_jaas.config"
```

   - Windows

```
startOgServer.bat catalogServer -clusterSecurityFile ..\security\security.xml
-serverProps ..\security\server.properties -jvmArgs
-Djava.security.auth.login.config="..\security\og_jaas.config"
```

10. Start a container server named `c0` with one of the following scripts. The server property file is passed by issuing **-serverProps**.
    a.
    - UNIX Linux

      ```
      ./startOgServer.sh c0 -objectgridFile ../xml/SimpleApp.xml
      -deploymentPolicyFile ../xml/SimpleDP.xml
      -catalogServiceEndPoints localhost:2809
      -serverProps ../security/server.properties
      -jvmArgs -Djava.security.auth.login.config="../security/og_jaas.config"
      ```

    - Windows

      ```
      startOgServer.bat c0 -objectgridFile ..\xml\SimpleApp.xml
      -deploymentPolicyFile ..\xml\SimpleDP.xml
      -catalogServiceEndPoints localhost:2809
      -serverProps ..\security\server.properties
      -jvmArgs -Djava.security.auth.login.config="..\security\og_jaas.config"
      ```

11. After the catalog server and container server have been started, run the sec_sample.jar sample as follows:
    - UNIX Linux

      ```
      java -classpath ../lib/objectgrid.jar:../applib/sec_sample.jar
                      com.ibm.websphere.objectgrid.security.sample.guide.SecureSimpleApp
                      ../security/client.properties manager manager1
      ```

    - Windows

      ```
      java -classpath ..\lib\objectgrid.jar;..\applib\sec_sample.jar
                      com.ibm.websphere.objectgrid.security.sample.guide.SecureSimpleApp
                      ..\security\client.properties manager manager1
      ```

    Linux Use a colon (:) for the classpath separator instead of a semicolon (;) as in the previous example.

    After you issue the class, the following output results:

    The customer name for `ID 0001 is fName lName`.

12. Verify the size of the "customer" map inserted into the "accounting" grid, by issuing the **xscmd** command utility as follows:
    - UNIX Linux `./xscmd.sh -c showMapSizes -g accounting -m customer -username manager -password manager1`
    - Windows `xscmd.bat -c showMapSizes -g accounting -m customer -username manager -password manager1`
13. Optional: To stop the container or catalog servers, you can use the **stopOgServer** or **stopXsServer** command. However you need to provide a security configuration file. The sample client property file defines the following two properties to generate a userID/password credential (manager/manager1).

    ```
    credentialGeneratorClass=com.ibm.websphere.objectgrid.security.plugins.builtins.UserPasswordCredentialGenerator
    ```

    ```
    credentialGeneratorProps=manager manager1
    ```

    Stop the container `c0` with the following command.

    - UNIX Linux `./stopOgServer.sh c0 -catalogServiceEndPoints localhost:2809 -clientSecurityFile ../security/client.properties`
    - Windows `stopOgServer.bat c0 -catalogServiceEndPoints localhost:2809 -clientSecurityFile ..\security\client.properties`

    If you do not provide the -clientSecurityFile option, you will see an exception with the following message.

    ```
    >> SERVER (id=39132c79, host=9.10.86.47) TRACE START:

    >> org.omg.CORBA.NO_PERMISSION: Server requires credential authentication but there is no security context from the
    client. This usually happens when the client does not pass a credential the server.

    vmcid: 0x0

    minor code: 0

    completed: No
    ```

    You can also shut down the catalog server using the following command. However, if you want to continue trying the next step tutorial, you can let the catalog server stay running.

    - UNIX Linux `./stopOgServer.sh catalogServer -catalogServiceEndPoints localhost:2809 -clientSecurityFile ../security/client.properties`
    - Windows `stopOgServer.bat catalogServer -catalogServiceEndPoints localhost:2809 -clientSecurityFile ..\security\client.properties`

    If you do shutdown the catalog server, you will see the following output.

    ```
    CWOBJ2512I: ObjectGrid server catalogServer stopped
    ```

    Now, you have successfully made your system partially secure by enabling authentication. You configured the server to plug in the user registry, configured the client to provide client credentials, and changed the client property file and cluster XML file to enable authentication.

    If you provide an invalidate password, you see an exception stating that the user name or password is not correct.

    For more details about client authentication, see Authenticating application clients.

Java SE security tutorial - Step 5

After authenticating a client, as in the previous step, you can give security privileges through eXtreme Scale authorization mechanisms.

Before you begin

Be sure to have completed Java SE security tutorial - Step 4 prior to proceeding with this task.

About this task

The previous step of this tutorial demonstrated how to enable authentication in an eXtreme Scale grid. As a result, no unauthenticated client can connect to your server and submit requests to your system. However, every authenticated client has the same permission or privileges to the server, such as reading, writing, or deleting data that is stored in the ObjectGrid maps. Clients can also issue any type of query. This section demonstrates how to use eXtreme Scale authorization to give various authenticated users varying privileges.
Similar to many other systems, eXtreme Scale adopts a permission-based authorization mechanism. WebSphere® eXtreme Scale has different permission categories that are represented by different permission classes. This topic features MapPermission. For complete category of permissions, see Client authorization programming.

In WebSphere eXtreme Scale, the com.ibm.websphere.objectgrid.security.MapPermission class represents permissions to the eXtreme Scale resources, specifically the methods of ObjectMap or JavaMap interfaces. WebSphere eXtreme Scale defines the following permission strings to access the methods of ObjectMap and JavaMap:

- read: Grants permission to read the data from the map.
- write: Grants permission to update the data in the map.
- insert: Grants permission to insert the data into the map.
- remove: Grants permission to remove the data from the map.
- invalidate: Grants permission to invalidate the data from the map.
- all: Grants all permissions to read, write, insert, remote, and invalidate.

The authorization occurs when a client calls a method of ObjectMap or JavaMap. The eXtreme Scale runtime environment checks different map permissions for different methods. If the required permissions are not granted to the client, an AccessControlException results.

This tutorial demonstrates how to use Java Authentication and Authorization Service (JAAS) authorization to grant authorization map accesses for different users.

Procedure

1. **Enable eXtreme Scale authorization**. To enable authorization on the ObjectGrid, you need to set the securityEnabled attribute to `true` for that particular ObjectGrid in the XML file. Enabling security on the ObjectGrid means that you are enabling authorization. Use the following commands to create a new ObjectGrid XML file with security enabled.
   a. Navigate to the xml directory.

   ```
   cd objectgridRoot/xml
   ```

   b. Copy the SimpleApp.xml file to the SecureSimpleApp.xml file.
   - UNIX Linux

     ```
     cp SimpleApp.xml SecureSimpleApp.xml
     ```

   - Windows

     ```
     copy SimpleApp.xml SecureSimpleApp.xml
     ```

   c. Open the SecureSimpleApp.xml file and add `securityEnabled="true"` on the ObjectGrid level as the following XML shows:

   ```
   <?xml version="1.0" encoding="UTF-8"?>
   <objectGridConfig xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
       xsi:schemaLocation="http://ibm.com/ws/objectgrid/config ../objectGrid.xsd"
                     xmlns="http://ibm.com/ws/objectgrid/config">
       <objectGrids>
           <objectGrid name="accounting" securityEnabled="true">
               <backingMap name="customer" readOnly="false" copyKey="true"/>
           </objectGrid>
       </objectGrids>
   </objectGridConfig>
   ```

2. **Define the authorization policy.** In the previous client authentication topic, you created the users, cashier and manager, in the keystore. In this example, the user "cashier" only has read permissions to all the maps, and the user "manager" has all permissions. JAAS authorization is used in this example. You

must create a JAAS authorization policy file to grant permissions to principals. Create the following og_auth.policy file in the objectgridRoot/security directory:

```
og_auth.policy
grant codebase "http://www.ibm.com/com/ibm/ws/objectgrid/security/PrivilegedAction"
    principal javax.security.auth.x500.X500Principal "CN=cashier,O=acme,OU=OGSample" {
    permission com.ibm.websphere.objectgrid.security.MapPermission "accounting.*", "read";
};

grant codebase "http://www.ibm.com/com/ibm/ws/objectgrid/security/PrivilegedAction"
    principal javax.security.auth.x500.X500Principal "CN=manager,O=acme,OU=OGSample" {
    permission com.ibm.websphere.objectgrid.security.MapPermission "accounting.*", "all";
};
```

Note:

- The `codebase "http://www.ibm.com/com/ibm/ws/objectgridRoot/security/PrivilegedAction"` is a specially-reserved URL for ObjectGrid. All ObjectGrid permissions granted to principals should use this special code base.
- The first grant statement grants "read" map permission to principal `"CN=cashier,O=acme,OU=OGSample"`, so the cashier has only map read permission to all the maps in the ObjectGrid accounting.
- The second grant statement grants "all" map permission to principal `"CN=manager,O=acme,OU=OGSample"`, so the manager has all permissions to maps in the ObjectGrid accounting.

Now you can launch a server with an authorization policy. The JAAS authorization policy file can be set using the standard -D property: -Djava.security.policy=../security/og_auth.policy

3. **Run the application.**

After you create the above files, you can run the application.

Use the following commands to start the catalog server. For more information about starting the catalog service, see Starting a stand-alone catalog service.

a. Navigate to the bin directory: `cd objectgridRoot/bin`

b. Start the catalog server.

- UNIX Linux

```
./startOgServer.sh catalogServer
-clusterSecurityFile ../security/security.xml
-serverProps ../security/server.properties
-jvmArgs -Djava.security.auth.login.config="../security/og_jaas.config"
```

- Windows

```
startOgServer.bat catalogServer
-clusterSecurityFile ..\security\security.xml
-serverProps ..\security\server.properties
-jvmArgs -Djava.security.auth.login.config="..\security\og_jaas.config"
```

The security.xml and server.properties files were created in the previous step of this tutorial.

c. You can then start a secure container server using the following script. Run the following script from the bin directory:

- UNIX Linux

```
./startOgServer.sh c0 -objectGridFile ../xml/SecureSimpleApp.xml
-deploymentPolicyFile ../xml/SimpleDP.xml
-catalogServiceEndPoints localhost:2809
-serverProps ../security/server.properties
-jvmArgs -Djava.security.auth.login.config="../security/og_jaas.config"
-Djava.security.policy="../security/og_auth.policy"
```

- Windows

```
startOgServer.bat c0 -objectGridFile ..\xml\SecureSimpleApp.xml
-deploymentPolicyFile ..\xml\SimpleDP.xml
-catalogServiceEndPoints localhost:2809
-serverProps ..\security\server.properties
-jvmArgs -Djava.security.auth.login.config="..\security\og_jaas.config"
-Djava.security.policy="..\security\og_auth.policy"
```

Notice the following differences from the previous container server start command:

- The SecureSimpleApp.xml file is used instead of SimpleApp.xml file, which is the result of your running the sample sec_sample.jar file to set client authentication.
- Another -Djava.security.policy argument was added to set the JAAS authorization policy file to the container server process.

Use the same command as in the previous step of the tutorial:

a. Navigate to the bin directory.

- UNIX Linux

```
java -classpath ../lib/objectgrid.jar:../applib/sec_sample.jar
com.ibm.websphere.objectgrid.security.sample.guide.SecureSimpleApp
../security/client.properties manager manager1
```

- Windows

```
java -classpath ..\lib\objectgrid.jar;..\applib\sec_sample.jar
com.ibm.websphere.objectgrid.security.sample.guide.SecureSimpleApp
 ..\security\client.properties manager manager1
```

b. Because user "manager" has all permissions to maps in the accounting ObjectGrid, the application runs properly.

Now, instead of using user "manager", use user "cashier" to launch the client application.

c. Navigate to the bin directory.

- UNIX Linux

```
java -classpath ../lib/objectgrid.jar:../applib/sec_sample.jar
com.ibm.ws.objectgrid.security.sample.guide.SecureSimpleApp
../security/client.properties cashier cashier1
```

- Windows

```
java -classpath ..\lib\objectgrid.jar;..\applib\sec_sample.jar
com.ibm.ws.objectgrid.security.sample.guide.SecureSimpleApp
..\security\client.properties cashier cashier1
```

The following exception results:

Attention: In the following example, some lines of code are continued on the next line for publication purposes.

```
Exception in thread "P=387313:O=0:CT" com.ibm.websphere.objectgrid.TransactionException:

        at com.ibm.ws.objectgrid.SessionImpl.processLogSequence(SessionImpl.java:1913)
        at com.ibm.ws.objectgrid.SessionImpl.processLogSequence(SessionImpl.java:1805)
        at com.ibm.ws.objectgrid.ServerCoreEventProcessor.processLogSequence(ServerCoreEventProcessor.java:1011)
        ... 14 more
```

This exception occurs because the user "cashier" does not have write permission, so it cannot update the map customer.

Now your system supports authorization. You can define authorization policies to grant different permissions to different users. For more information about authorization, see Authorizing application clients.

What to do next

Complete the next step of the tutorial. See Java SE security tutorial - Step 6.
Previous topic: Java SE security tutorial - Step 4
Next topic: Java SE security tutorial - Step 6

Java SE security tutorial - Step 6

The following step explains how you can enable a security layer for communication between your environment's endpoints.

Before you begin

Be sure you have completed Java SE security tutorial - Step 5 prior to proceeding with this task.

About this task

The eXtreme Scale topology supports both Transport Layer Security/Secure Sockets Layer (TLS/SSL) for secure communication between ObjectGrid endpoints (client, container servers, and catalog servers). This step of the tutorial builds upon the previous steps to enable transport security.

Procedure

1. **Create TLS/SSL keys and keystores**.
   In order to enable transport security, you must create a keystore and trust store. This exercise only creates one key and trust-store pair. These stores are used for ObjectGrid clients, container servers, and catalog servers, and are created with the JDK keytool.
   - *Create a private key in the keystore*
     ```
     keytool -genkey -alias ogsample -keystore key.jks -storetype JKS -keyalg rsa -dname "CN=ogsample, OU=OGSample,
     O=acme, L=Your City, S=Your State, C=Your Country" -storepass ogpass -keypass ogpass -validity 3650
     ```
     Using this command, a keystore key.jks is created with a key "ogsample" stored in it. This keystore key.jks will be used as the SSL keystore.
   - *Export the public certificate*
     ```
     keytool -export -alias ogsample -keystore key.jks -file temp.key -storepass ogpass
     ```
     Using this command, the public certificate of key "ogsample" is extracted and stored in the file temp.key.
   - *Import the client's public certificate to the trust store*
     ```
     keytool -import -noprompt -alias ogsamplepublic -keystore trust.jks -file temp.key -storepass ogpass
     ```
     Using this command, the public certificate was added to keystore trust.jks. This trust.jks is used as the SSL trust store.
2. **Configure ObjectGrid property files**.
   In this step, you must configure the ObjectGrid property files to enable transport security.

   First, copy the key.jks and trust.jks files into the objectgridRoot/security directory.

   Set the following properties in the client.properties and server.properties file.

   ```
   transportType=SSL-Required

   alias=ogsample
   contextProvider=IBMJSSE2
   protocol=SSL
   keyStoreType=JKS
   keyStore=../security/key.jks
   keyStorePassword=ogpass
   trustStoreType=JKS
   trustStore=../security/trust.jks
   trustStorePassword=ogpass
   ```

   transportType: The value of transportType is set to "SSL-Required", which means the transport requires SSL. So all the ObjectGrid endpoints (clients, catalog servers, and container servers) should have SSL configuration set and all transport communication will be encrypted.

   The other properties are used to set the SSL configurations. See Transport layer security and secure sockets layer for a detailed explanation. Make sure you follow the instructions in this topic to update your orb.properties file.

   Make sure you follow this page to update your orb.properties file.

   In the server.properties file, you must add an additional property clientAuthentication and set it to false. On the server side, you do not need to trust the client.

   ```
   clientAuthentication=false
   ```
3. **Run the application**.
   The commands that you use in this step are the same as the commands in the Java SE security tutorial - Step 3 topic.

   a. Navigate to the `cd objectgridRoot/bin` directory, and use the following commands to start a catalog server:
   - Linux UNIX

     ```
     ./startOgServer.sh catalogServer -clusterSecurityFile ../security/security.xml
     -serverProps ../security/server.properties -JMXServicePort 11001
     -jvmArgs -Djava.security.auth.login.config="../security/og_jaas.config"
     ```
   - Windows

     ```
     startOgServer.bat catalogServer -clusterSecurityFile ..\security\security.xml
     -serverProps ..\security\server.properties -JMXServicePort 11001 -jvmArgs
     ```

```
-Djava.security.auth.login.config="..\security\og_jaas.config"
```

The security.xml and server.properties files were created in the Java SE security tutorial - Step 2 page.

Use the -JMXServicePort option to explicitly specify the JMX port for the server. This option is required to use the **xscmd** utility.

b. From the objectgridRoot/bin directory, start a secure ObjectGrid container server:

- Linux UNIX

```
./startOgServer.sh c0 -objectGridFile ../xml/SecureSimpleApp.xml
-deploymentPolicyFile ../xml/SimpleDP.xml -catalogServiceEndPoints
localhost:2809 -serverProps ../security/server.properties
-JMXServicePort 11002 -jvmArgs
-Djava.security.auth.login.config="../security/og_jaas.config"
-Djava.security.policy="../security/og_auth.policy"
```

- Windows

```
startOgServer.bat c0 -objectGridFile ..\xml\SecureSimpleApp.xml
-deploymentPolicyFile ..\xml\SimpleDP.xml -catalogServiceEndPoints localhost:2809
-serverProps ..\security\server.properties -JMXServicePort 11002
-jvmArgs -Djava.security.auth.login.config="..\security\og_jaas.config"
-Djava.security.policy="..\security\og_auth.policy"
```

c. From the objectgridRoot/bin directory, run the following command to complete client authentication:

- UNIX Linux

```
javaHome/java -classpath ../lib/objectgrid.jar:../applib/sec_sample.jar
com.ibm.websphere.objectgrid.security.sample.guide.SecureSimpleApp
../security/client.properties manager manager1
```

- Windows

```
javaHome\java -classpath ..\lib\objectgrid.jar;..\applib\sec_sample.jar
com.ibm.websphere.objectgrid.security.sample.guide.SecureSimpleApp
..\security\client.properties manager manager1
```

Because user "manager" has permission to all the maps in the accounting ObjectGrid, the application runs successfully.

4. **Use the xscmd utility to show the map sizes of the "accounting" data grid**.

a. From the objectgridRoot/bin directory, use the **xscmd** command to show the map sizes:

- UNIX Linux

```
./xscmd.sh -c showMapsizes -g accounting -m customer -prot SSL
-ts ../security/trust.jks -tsp ogpass -tst jks
-user manager -pwd manager1 -ks ../security/key.jks -ksp ogpass -kst JKS
-cxpv IBMJSSE2 -tt SSL-Required
```

- Windows

```
xscmd.bat -c showMapsizes -g accounting -m customer -prot SSL
-ts ..\security\trust.jks -tsp ogpass -tst jks
-user manager -pwd manager1 -ks ..\security\key.jks -ksp ogpass -kst JKS
-cxpv IBMJSSE2 -tt SSL-Required
```

You see the following output.

```
This administrative utility is provided as a sample only and is not to
be considered a fully supported component of the WebSphere eXtreme Scale product.
Connecting to Catalog service at localhost:1099
*********** Displaying Results for Grid - accounting, MapSet - customer ***********
*** Listing Maps for c0 ***
Map Name: customer Partition #: 0 Map Size: 1 Shard Type: Primary
Server Total: 1
Total Domain Count: 1
```

5. **Troubleshoot running the application with an incorrect keystore**.

If your truststore does not contain the public certificate of the private key in the keystore, an exception that the key cannot be trusted occurs.

To show this exception, create another keystore key2.jks.

```
keytool -genkey -alias ogsample -keystore key2.jks -storetype JKS -keyalg rsa -dname "CN=ogsample, OU=Your
Organizational Unit, O=Your Organization, L=Your City, S=Your State, C=Your Country" -storepass ogpass -keypass
ogpass -validity 3650
```

Then modify the server.properties file to make the keystore point to this new keystore key2.jks:

```
keyStore=../security/key2.jks
```

a. From the `cd objectgridRoot/bin` directory, assume that you run the following commands, which use an incorrect keystore, to start the catalog server:

- Linux UNIX

```
./startOgServer.sh c0 -objectGridFile ../xml/SecureSimpleApp.xml
-deploymentPolicyFile ../xml/SimpleDP.xml -catalogServiceEndPoints localhost:2809
-serverProps ../security/server.properties -JMXServicePort 11002 -jvmArgs
-Djava.security.auth.login.config="../security/og_jaas.config"
-Djava.security.policy="../security/og_auth.policy"
```

- Windows

```
startOgServer.bat c0 -objectGridFile ..\xml\SecureSimpleApp.xml
-deploymentPolicyFile ..\xml/SimpleDP.xml -catalogServiceEndPoints localhost:2809
 -serverProps ..\security\server.properties -JMXServicePort 11002 -jvmArgs
-Djava.security.auth.login.config="..\security\og_jaas.config"
-Djava.security.policy="..\security\og_auth.policy"
```

You receive the following exception:

```
CWPKI0022E: SSL HANDSHAKE FAILURE: A signer with SubjectDN "CN=ogsample,
OU=Your Organizational Unit, O=Your Organization, L=Your City, ST=Your State,
C=Your Country" was sent from target host:port "9.23.39.177:36407". The signer may
need to be added to local trust store
"/opt/IBM/WebSphere/eXtremeScale/ObjectGrid/security/trust.jks"
located in SSL configuration alias "DefaultSystemProperties" loaded from SSL
configuration file "System Properties". The extended error message from the SSL
handshake exception is: "PKIX path building failed: java.security.cert.CertPathBuilderException:
unable to find valid certification path to requested target".

CWPKI0040I: An SSL handshake failure occurred from a secure client. The server's SSL signer
has to be added to the client's trust store. A retrieveSigners utility is provided to download
signers from the server but requires administrative permission. Check with your administrator
to have this utility run to setup the secure environment before running the client. Alternatively,
the com.ibm.ssl.enableSignerExchangePrompt can be enabled in ssl.client.props for "DefaultSSLSettings"
in order to allow acceptance of the signer during the connection attempt.
```

To correct the exception, change the server.properties file back to use the key.jks file.

Previous topic: Java SE security tutorial - Step 5

Tutorial: Run eXtreme Scale clients and servers in the Liberty profile

8.5+ You can run WebSphere® eXtreme Scale in the Liberty profile.

Learning objectives

In this tutorial, you can expect to complete the following learning objectives:

- Install the Liberty profile and eXtreme Scale.
- Create eXtreme Scale servers and an application client for testing in the Liberty profile.
- Deploy WebSphere Application Server applications that run with eXtreme Scale in the Liberty profile.
- Configure session management for eXtreme Scale applications in the Liberty profile.

Time required

This tutorial takes approximately 30 minutes to finish. If you explore other concepts related to this tutorial, it could take longer to complete.

Prerequisites

To complete this tutorial, you must install the following products:

- Java Runtime Environment. For more information about supported Java™ environments, and where to get them, see Minimum supported Java levels in the Liberty profile: Runtime environment known restrictions.
- The Liberty profile
- WebSphere eXtreme Scale

It is also recommended that you have basic Java development knowledge.

- **Liberty profile**

  The Liberty profile is a highly composable, fast-to-start, dynamic application server runtime environment.
- **Module 1: Install the Liberty profile**

  You must install both the WebSphere Application Server Liberty profile and WebSphere eXtreme Scale to complete this tutorial.
- **Module 2: Create a web application server in the Liberty profile**

  You must create a server directory and server.xml file to develop the server definition for the Liberty profile.
- **Module 3: Add the Liberty web feature to the Liberty profile**

  Add the web feature to your server definition to identify web-based applications and add functions, such as session replication.
- **Module 4: Configure clients to use client APIs in the Liberty profile**

  You can configure your WebSphere eXtreme Scale clients to run in the Liberty profile.
- **Module 5: Run the data grid inside the Liberty profile**

  After you add the client and server configurations to the Liberty profile, you can run WebSphere eXtreme Scale in the Liberty profile.

Liberty profile

8.5+ The Liberty profile is a highly composable, fast-to-start, dynamic application server runtime environment.

You install the Liberty profile when you install WebSphere® eXtreme Scale with WebSphere Application Server Version 8.5. Because the Liberty profile does not include a Java™ runtime environment (JRE), you have to install a JRE provided by either Oracle or IBM®.

For more information about supported Java environments and locations, see Minimum supported Java levels in the WebSphere Application Server Information Center.

This server supports two models of application deployment:

- Deploy an application by dropping it into the dropins directory.
- Deploy an application by adding it to the server configuration.

The Liberty profile supports a subset of the following parts of the full WebSphere Application Server programming model:

- Web applications
- OSGi applications
- Java Persistence API (JPA)

Associated services such as transactions and security are only supported as far as is required by these application types and by JPA.
Features are the units of capability by which you control the pieces of the runtime environment that are loaded into a particular server. The Liberty profile includes the following main features:

- Bean validation
- Blueprint
- Java API for RESTful Web Services
- Java Database Connectivity (JDBC)
- Java Naming and Directory Interface
- Java Persistence API (JPA)
- JavaServer Faces (JSF)
- JavaServer Pages (JSP)
- Lightweight Directory Access Protocol (LDAP)
- Local connector (for Java Management Extensions (JMX) clients)
- Monitoring
- OSGi JPA (JPA support for OSGi applications)
- Remote connector (for JMX clients)
- Secure Sockets Layer (SSL)
- Security
- Servlet
- Session persistence
- Transaction
- Web application bundle (WAB)
- z/OS® security
- z/OS transaction management
- z/OS z/OS workload management

You can work with the runtime environment directly, or using the WebSphere Application Server Developer Tools for Eclipse.

On distributed platforms, the Liberty profile provides both a development and an operations environment. On the Mac, it provides a development environment.

z/OS On z/OS systems, the Liberty profile provides an operations environment. You can work natively with this environment using the MVS™ console. For application development, consider using the Eclipse-based developer tools on a separate distributed system, on Mac OS, or in a Linux shell on z/OS.

Running the Liberty profile with a third-party JRE

When you use a JRE that Oracle provides, special considerations must be taken to run WebSphere eXtreme Scale with the Liberty profile.

Classloader deadlock
You might experience a classloader deadlock which has been worked around using the following JVM_ARGS settings. If you experience a deadlock in BundleLoader logic, add the following arguments:

```
export JVM_ARGS="$JVM_ARGS -XX:+UnlockDiagnosticVMOptions -XX:+UnsyncloadClass"
```

- Data caching and the Liberty profile
  You can use data caching products with the WebSphere Application Server Liberty profile to develop HTTP sessions, client-server connections through the REST gateway, and manage other cache integration scenarios.

Server properties file
| | Next >

Module 1: Install the Liberty profile

8.5+ You must install both the WebSphere® Application Server Liberty profile and WebSphere eXtreme Scale to complete this tutorial.

To install the Liberty profile, use IBM® Installation Manager to install WebSphere Application Server Version 8.5 or higher, and then install WebSphere eXtreme Scale for WebSphere Application Server Version 8.5 or higher.
Alternatively, you can install the Liberty profile by running a provided JAR file. However, you still must install WebSphere eXtreme Scale. For more information about downloading and installing the Liberty profile application-serving environment with a JAR file, see Installing the Liberty profile application-serving environment by running a JAR file.

Learning objectives

After completing the lessons in this module, you will know how to:

- Install the Liberty profile as the application serving environment for WebSphere eXtreme Scale. To run eXtreme Scale clients and servers in the Liberty profile, you must install WebSphere eXtreme Scale after you install the Liberty profile.

20 minutes

< Previous | Next >

Module 2: Create a web application server in the Liberty profile

8.5+ You must create a server directory and server.xml file to develop the server definition for the Liberty profile.

Learning objectives

After completing the lesson in this module, you will know how to:

- Define a server to run in the Liberty profile.

Prerequisites

To complete this module, you must:

- Install the Liberty profile.
- Install WebSphere® eXtreme Scale.

Lessons in this module

- **Lesson 2.1: Define a server to run in the Liberty profile**

  Create a server directory and a server.xml server definition file to run in the Liberty profile.

< Previous | Next >
< Previous | Next >

Lesson 2.1: Define a server to run in the Liberty profile

8.5+ Create a server directory and a server.xml server definition file to run in the Liberty profile.

In Module 1, you installed the Liberty profile and WebSphere® eXtreme Scale in the XSWLP/wlp directory. In this lesson, you will create a server directory and a server.xml server definition file in the XSWLP/wlp/bin subdirectory.

1. Open a command prompt from the XSWLP directory where you installed the Liberty profile.
2. Change the directory to the wlp/bin directory; for example, enter `cd wlp/bin`.
3. Enter the following command to create the server, where *defaultServer* is the server name:

   ```
   server create defaultServer
   ```

   If the command was successful, the following response is displayed:

   ```
   Server defaultServer created.
   ```

To verify that you created the server definition file, search for the server.xml file in the directory, XSWLP/wlp/usr/servers/defaultServer, where defaultServer is the server directory that you created in this lesson. The server.xml file contains the server configuration and Liberty profile features that client applications use in the Liberty profile. The defaultServer directory also includes a dropins folder, which you will use in the next lesson to run your eXtreme Scale client applications.

After you verify that the defaultServer directory exists, create a folder in that same directory called grids . In the Lesson 2.3, the grids folder is where you will place the XML descriptor files that eXtreme Scale servers need to run.

Module 3: Add the Liberty web feature to the Liberty profile

8.5+ Add the web feature to your server definition to identify web-based applications and add functions, such as session replication.

Learning objectives

After completing the lesson in this module, you will know how to:

- Define a web application to run in the Liberty profile.

Prerequisites

To complete this module, you must complete the following modules first

- Install the Liberty profile.
- Install WebSphere® eXtreme Scale.
- Create a web application server in the Liberty profile.

.

Lessons in this module

- **Lesson 3.1: Define a web application to run in the Liberty profile**

  Define the web feature to your server definition to enable application functions, such as session replication.

Lesson 3.1: Define a web application to run in the Liberty profile

8.5+ Define the web feature to your server definition to enable application functions, such as session replication.

The web feature is deprecated. Use the webApp feature when you want to replicate HTTP session data for fault tolerance.

The web feature has meta type properties that you can set on the `xsWebAppV85` element of the server.xml file. For more information, see Liberty profile web feature properties

Add the following web feature to the Liberty profile server.xml file. The web feature includes the client feature; however, it does not include the server feature. You likely want to separate your web applications from the data grids. For example, you have one Liberty profile server for your web applications and a different Liberty profile server for hosting the data grid. 8.5+

```
<featureManager>
<feature>eXtremeScale.web-1.0</feature>
</featureManager>
```

Your web applications can now persist its session data in a WebSphere® eXtreme Scale grid.
See the following example of a server.xml file, which contains the web feature that you use when you connect to the data grid remotely. 8.5+

```

Module 4: Configure clients to use client APIs in the Liberty profile

8.5+ You can configure your WebSphere® eXtreme Scale clients to run in the Liberty profile.

Learning objectives

After completing the lesson in this module, you will know how to:

- Configure the Liberty profile to run with eXtreme Scale clients.

Prerequisites

To complete this module, you must complete the following modules first:

- Install the Liberty profile.
- Install WebSphere eXtreme Scale.
- Create a web application server in the Liberty profile.
- Add the Liberty web feature to the web application.

Lessons in this module

- **Lesson 4.1: Configure the Liberty profile to run with eXtreme Scale clients**

  Use the WebSphere eXtreme Scale client feature to run the Liberty profile with eXtreme Scale clients.

< Previous | Next >
< Previous | Next >

Lesson 4.1: Configure the Liberty profile to run with eXtreme Scale clients

8.5+ Use the WebSphere® eXtreme Scale client feature to run the Liberty profile with eXtreme Scale clients.

This configuration provides only the client functionality. In this application, the server function runs in another process. Adding the client feature allows your application to access the eXtreme Scale APIs and connect to a remote grid.

This client configuration provides a single process that includes what you need to unit test a web application using an eXtreme Scale data grid. When you add the client feature, it starts a catalog server and a container server when the configuration is deployed into the grid directory. In addition, after you add the client feature, the application can write to the eXtreme Scale APIs.

1. Add the client feature to the Liberty server. Add the following code to the Liberty server:

   ```
   <server description="eXtreme Scale Container Server">

   <featureManager>
   <feature>eXtremeScale.client-1.0</feature>
   </featureManager>

   </server>
   ```

2. (Optional) Alternatively, you can use the eXtreme Scale server feature to reference the client configuration. When you add the following server configuration, the client functionality is automatically included:

   ```
   <server description="eXtreme Scale Container Server">

   <featureManager>
   <feature>eXtremeScale.server-1.0</feature>
   </featureManager>

   </server>
   ```

3. (Optional) To configure security for your clients, then use the client.xml file to specify the path to the server properties file, which contains all of the security settings. For more information, see Configuring client security on a catalog service domain.

You configured the Liberty profile by adding the client feature to the Liberty server.

Module 5: Run the data grid inside the Liberty profile

8.5+ After you add the client and server configurations to the Liberty profile, you can run WebSphere® eXtreme Scale in the Liberty profile.

Learning objectives

After completing the lessons in this module, you will know how to complete the following tasks:

- Configure eXtreme Scale servers to use the Liberty profile.
- Configure a Liberty profile web application server to use eXtreme Scale for session replication..

Prerequisites

To complete this module, you must complete the following modules in this tutorial:

- Install the Liberty profile.
- Install WebSphere eXtreme Scale.
- Create a web application server in Liberty.
- Add the Liberty profile web feature to the web application.
- Configure clients to use client APIs in the Liberty profile.

Lessons in this module

- **Lesson 5.1: Configure eXtreme Scale servers to use the Liberty profile**

  To run the data grid in a Liberty profile, you must add the server feature to configure WebSphere eXtreme Scale servers that use Liberty profile configuration files.
- **Lesson 5.2: Configuring a Liberty profile web application server to use eXtreme Scale for session replication**

  You can configure a web application server so that when the web server receives an HTTP request for session replication, the request is forwarded to the Liberty profile.

< Previous | Next >
< Previous | Next >

Lesson 5.1: Configure eXtreme Scale servers to use the Liberty profile

8.5+ To run the data grid in a Liberty profile, you must add the server feature to configure WebSphere® eXtreme Scale servers that use Liberty profile configuration files.

1. Configure a catalog server with default settings using the following attributes in the server.xml file, which tells eXtreme Scale to create and start a catalog server:

```
<server description="eXtreme Scale Catalog Server with default settings">

    <!-- Enable features -->
    <featureManager>
        <feature>eXtremeScale.server-1.1</feature>
    </featureManager>

    <xsServer isCatalog="true" listenerPort="${com.ibm.ws.xs.server.listenerPort}" />

    <logging traceSpecification="*=info" maxFileSize="200" maxFiles="10" />

</server>
```

   Notice that the listenerPort element is referenced in the server.xml; however, you configure this value in the bootstrap.properties file. It can be useful to separate elements such as port numbers out of the server.xml file so that multiple processes that run with an identical configuration can share the server.xml file, but still have unique settings.

2. Configure the listenerPort attribute in the bootstrap.properties file.
   In the previous example, tracing is specified in the Liberty profile configuration, and the listenerPort attribute specifies a variable. This variable is configured in the bootstrap.properties file in the server configuration directory, *wlp_install_root*/usr/server/serverName. See the following example of the bootstrap.properties file:

```
# Licensed Materials - Property of IBM
#
# "Restricted Materials of IBM"
#
# Copyright IBM Corp. 2011 All Rights Reserved.
#
```

```
# US Government Users Restricted Rights - Use, duplication or
# disclosure restricted by GSA ADP Schedule Contract with
# IBM Corp.
#
# ------------------------------------------------------------------
#
# port for the OSGi console
# osgi.console=5678

com.ibm.ws.xs.server.listenerPort=2809
```

In this example, the osgi.console port is commented out, which means that the Liberty profile listens on the specified port for telnet clients to connect to an OSGi console. This behavior is useful for diagnosing OSGi-related errors.

3. Configure the server.xml file using the same configuration that you might use for a stand-alone server configuration. In the server.xml file, specify the file path to the properties file in a serverProps attribute inside the com.ibm.ws.xs.server.config element. See the following example from the server.xml file:

```
<server>
...
<com.ibm.ws.xs.server.config ... serverProps="/path/to/myServerProps.properties" ... />
</server>
```

Restriction: The Liberty configuration model has restrictions in the way properties are specified. Therefore, if you require the following properties, you must specify them in the server properties file:

foreignDomain.endpoints
: Specifies the names of catalog service domains to which you want to link in the multimaster replication topology.

xioChannel.xioContainerTCPNonSecure.Port
: Specifies the unsecured listener port number of eXtremeIO on the server. If you do not set the value, an ephemeral port is used. This property is used only when the transportType property is set to `TCP/IP. xioChannel.xioContainerTCPSecure.Port`.

Some properties that were formerly configurable in a stand-alone environment must be configured with the Liberty profile configuration instead of the eXtreme Scale configuration mechanisms.

- Logging and tracing settings must be specified with the logging element in the server.xml file, rather than being specified in the eXtreme Scale server properties file or com.ibm.ws.xs.server.config element. For more information, see Liberty profile: Trace and logging in the WebSphere Application Server Information Center.
- The working directory, like logging and tracing, is a server-wide setting, and therefore, they must be specified in a server-wide way.

If the previous settings are specified incorrectly, eXtreme Scale logs a warning message, which indicates that the settings are ignored.

4. (Optional) To configure security with your servers, then use the server.xml file to specify the path to the server properties file, which contains all of the security settings. When WebSphere eXtreme Scale is deployed in a WebSphere Application Server environment, you can simplify the authentication flow and transport layer security configuration from WebSphere Application Server. For more information, see Security integration with WebSphere Application Server.

Your eXtreme Scale servers are ready to run in the Liberty profile.

< Previous | Next >
< Previous

Lesson 5.2: Configuring a Liberty profile web application server to use eXtreme Scale for session replication

8.5+ You can configure a web application server so that when the web server receives an HTTP request for session replication, the request is forwarded to the Liberty profile.

The Liberty profile does not include session replication. However, if you use WebSphere® eXtreme Scale with the Liberty profile, then you can replicate sessions. Therefore, if a server fails, then application users do not lose session data.
When you add the web feature to the server definition and configure the session manager, you can use session replication in your eXtreme Scale applications that run in the Liberty profile.

1. 8.5 Enable the HTTP session feature in the Liberty profile.
2. Configure a unique clone ID in the Liberty server.xml file.
3. Generate and merge plug-in configuration files for deployment to the application server plug-in.

Your eXtreme Scale applications that run in the Liberty profile are enabled for session replication.

Tutorial: Integrate WebSphere eXtreme Scale security with WebSphere Application Server

This tutorial demonstrates how to secure a WebSphere® eXtreme Scale server deployment in a WebSphere Application Server environment.

Learning objectives

The learning objectives for this tutorial follow:

- Configure WebSphere eXtreme Scale to use WebSphere Application Server authentication plug-ins
- Configure WebSphere eXtreme Scale transport security to use WebSphere Application Server CSIv2 configuration
- Use Java™ Authentication and Authorization Service (JAAS) authorization in WebSphere Application Server
- Use a custom login module for group-based JAAS authorization
- Use WebSphere eXtreme Scale **xscmd** utility in WebSphere Application Server environment

Time required

This tutorial takes approximately 4 hours from start to finish.
< Previous | Next >
< Previous | Next >

Introduction: Integrate WebSphere eXtreme Scale security with WebSphere Application Server using the WebSphere Application Server Authentication plug-ins

In this tutorial, you integrate WebSphere® eXtreme Scale security with WebSphere Application Server. First, you configure authentication with a simple web application that uses authenticated user credentials from the current thread to connect to the ObjectGrid. Then, you investigate the encryption of data that is transferred between the client and server with transport layer security. To give users varying levels of permissions, you can configure Java Authentication and Authorization Service (JAAS). After completing the configuration, you can use the **xscmd** utility to monitor your data grids and maps.

This tutorial assumes that all of your WebSphere eXtreme Scale clients, container servers, and catalog servers are deployed in the WebSphere Application Server environment.

Learning objectives

The learning objectives for this tutorial follow:

- Configure WebSphere eXtreme Scale to use WebSphere Application Server authentication plug-ins
- Configure WebSphere eXtreme Scale transport security to use WebSphere Application Server CSIv2 configuration
- Use Java™ Authentication and Authorization Service (JAAS) authorization in WebSphere Application Server
- Use a custom login module for group-based JAAS authorization
- Use WebSphere eXtreme Scale **xscmd** utility in WebSphere Application Server environment

Time required

This tutorial takes approximately 4 hours from start to finish.

Skill level

Intermediate.

Audience

Developers and administrators that are interested in the security integration between WebSphere eXtreme Scale and WebSphere Application Server.

System requirements and topology

- WebSphere Application Server Version 6.1 or Version 7.0.0.11 or later
- Update the Java runtime to apply the following fix: IZ79819: IBMJDK FAILS TO READ PRINCIPAL STATEMENT WITH WHITESPACE FROM SECURITY FILE

This tutorial uses four WebSphere Application Server application servers and one deployment manager to demonstrate the sample.

Prerequisites

A basic understanding of the following items is helpful before you start this tutorial:

- WebSphere eXtreme Scale programming model
- Basic WebSphere eXtreme Scale security concepts
- Basic WebSphere Application Server security concepts

For a background information about WebSphere eXtreme Scale and WebSphere Application Server security integration, see Security integration with WebSphere Application Server.

Modules in this tutorial

- **Module 1: Prepare WebSphere Application Server**

  Before you start the tutorial to integrate with WebSphere eXtreme Scale, you must create a basic security configuration in WebSphere Application Server.
- **Module 2: Configure WebSphere eXtreme Scale to use WebSphere Application Server Authentication plug-ins**

  After you have created the WebSphere Application Server configuration, you can integrate WebSphere eXtreme Scale authentication with WebSphere Application Server.
- **Module 3: Configure transport security**

  Configure transport security to secure data transfer between the clients and servers in the configuration.
- **Module 4: Use Java Authentication and Authorization Service (JAAS) authorization in WebSphere Application Server**

  Now that you have configured authentication for clients, you can further configure authentication to give different users varying permissions. For example, an operator user might only be able to view data, while an administrator user can perform all operations.

Module 1: Prepare WebSphere Application Server

Before you start the tutorial to integrate with WebSphere® eXtreme Scale, you must create a basic security configuration in WebSphere Application Server.

Learning objectives

With the lessons in this module, you learn how to:

- Configure WebSphere Application Server security to use an internal file-based federated repository as a user account registry.
- Create user groups and users.
- Create clusters for the application and WebSphere eXtreme Scale servers.

Time required

This module takes approximately 60 minutes.

Lessons in this module

- **Lesson 1.1: Understand the topology and get the tutorial files**

  To prepare your environment for the tutorial, you must configure WebSphere Application Server security. You configure administration and application security using internal file-based federated repositories as a user account registry.
- **Lesson 1.2: Configure the WebSphere Application Server environment**

  To prepare your environment for the tutorial, you must configure WebSphere Application Server security. Enable administration and application security using internal file-based federated repositories as a user account registry. Then, you can create server clusters to host the client application and container servers.

< Previous | Next >
< Previous | Next >

Lesson 1.1: Understand the topology and get the tutorial files

To prepare your environment for the tutorial, you must configure WebSphere® Application Server security. You configure administration and application security using internal file-based federated repositories as a user account registry.

This lesson guides you through the sample topology and applications that are used to in the tutorial. To begin running the tutorial, you must download the applications and place the configuration files in the correct locations for your environment. You can download the sample application from the WebSphere eXtreme Scale wiki.

WebSphere Application Server sample topology

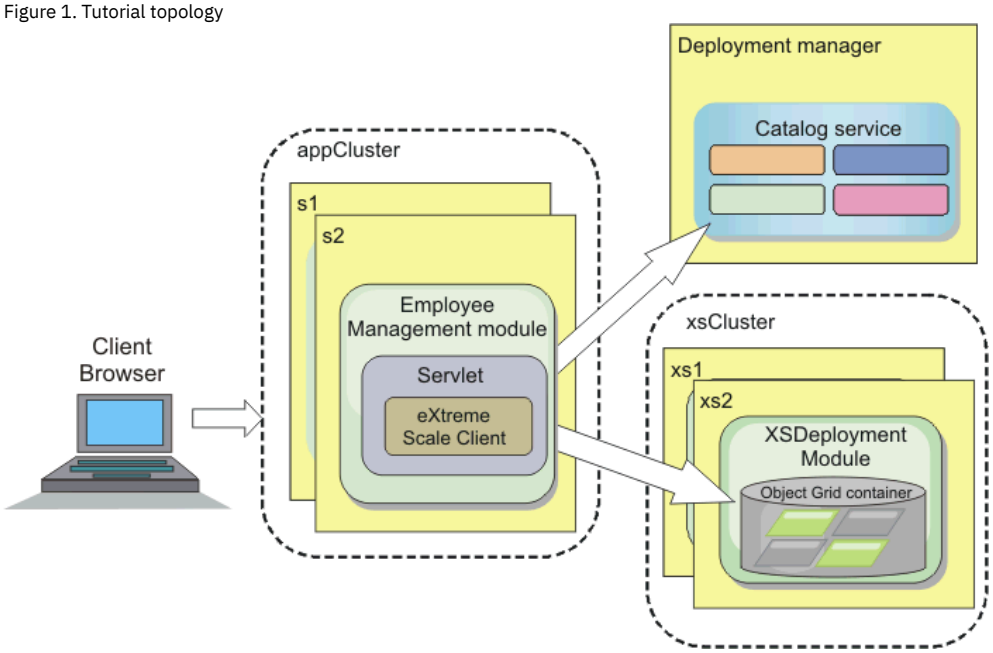
This tutorial guides you through creating four WebSphere Application Server application servers to demonstrate using the sample applications with security enabled. These application servers are grouped into two clusters, each with two servers:

- **appCluster cluster**: Hosts the EmployeeManagement sample enterprise application. This cluster has two application servers: s1 and s2.
- **xsCluster cluster**: Hosts the eXtreme Scale container servers. This cluster has two application servers: xs1 and xs2.

In this deployment topology, the s1 and s2 application servers are the client servers that access data that is being stored in the data grid. The xs1 and xs2 servers are the container servers that host the data grid.
The catalog server is deployed in the deployment manager process by default. This tutorial uses the default behavior. Hosting the catalog server in the deployment manager is not a recommended practice in a production environment. In a production environment, you should create a catalog service domain to define where catalog servers start. See Creating catalog service domains in WebSphere Application Server for more information.

Alternative configuration: You can host all of the application servers in a single cluster, such as in the appCluster cluster. With this configuration, all of the servers in the cluster are both clients and container servers. This tutorial uses two clusters to distinguish between the application servers that are hosting the clients and container servers.

Figure 1. Tutorial topology



Applications

In this tutorial, you are using two applications and one shared library file:

- **EmployeeManagement.ear**: The EmployeeManagement.ear application is a simplified Java™ 2 Platform, Enterprise Edition (J2EE) enterprise application. It contains a web module to manage the employee profiles. The web module contains the management.jsp file to display, insert, update, and delete employee profiles that are stored in the container servers.
- **XSDeployment.ear**: This application contains an enterprise application module with no application artifacts. The cache objects are packaged in the EmployeeData.jar file. The EmployeeData.jar file is deployed as a shared library for the XSDeployment.ear file, so that the XSDeployment.ear file can access the classes. The purpose of this application is to package the eXtreme Scale configuration files. When this enterprise application is started, the eXtreme Scale configuration files are automatically detected by the eXtreme Scale run time, so the container servers are created. These configuration files include the objectGrid.xml and objectGridDeployment.xml files.
- **EmployeeData.jar**: This jar file contains one class: the com.ibm.websphere.sample.xs.data.EmployeeData class. This class represents employee data that is stored in the grid. This Java archive (JAR) file is deployed with the EmployeeManagement.ear and XSDeployment.ear files as a shared library.

Get the tutorial files

1. Download the WASSecurity.zip and security.zip files. You can download the sample application from the WebSphere eXtreme Scale wiki.
2. Extract the WASSecurity.zip file to a directory for viewing the binary and source artifacts, for example the /wxs_samples/ directory. This directory is referred to as *samples_home* for the remainder of the tutorial. For a description of the contents of the WASSecurity.zip file and how to load the source into your Eclipse workspace, see the README.txt file in the package.
3. Extract the security.zip file to the *samples_home* directory. The security.zip file contains the following security configuration files that are used in this tutorial:
   - catServer2.props
   - server2.props
   - client2.props
   - securityWAS2.xml
   - xsAuth2.props

About the configuration files

The objectGrid.xml and objectGridDeployment.xml files create the data grids and maps that store the application data.

These configuration files must be named objectGrid.xml and objectGridDeployment.xml. When the application server starts, eXtreme Scale detects these files in the META-INF directory of the EJB and web modules. If these files are found, it assumed that the Java virtual machine (JVM) acts as a container server for the

defined data grids in the configuration files.

objectGrid.xml file

The objectGrid.xml file defined one ObjectGrid named `Grid`. The `Grid` data grid has one map, the `Map1` map, that stores the employee profile for the application.

```
<?xml version="1.0" encoding="UTF-8"?>
<objectGridConfig xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:schemaLocation="http://ibm.com/ws/objectgrid/config ../objectGrid.xsd"
 xmlns="http://ibm.com/ws/objectgrid/config">

 <objectGrids>
        <objectGrid name="Grid" txTimeout="15">
            <backingMap name="Map1" />
        </objectGrid>
    </objectGrids>

</objectGridConfig>
```

objectGridDeployment.xml file

The objectGridDeployment.xml file specifies how to deploy the `Grid` data grid. When the grid is deployed, it has five partitions and one synchronous replica.

```
<?xml version="1.0" encoding="UTF-8"?>

<deploymentPolicy xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:schemaLocation="http://ibm.com/ws/objectgrid/deploymentPolicy ../deploymentPolicy.xsd"
 xmlns="http://ibm.com/ws/objectgrid/deploymentPolicy">

    <objectgridDeployment objectgridName="Grid">
        <mapSet name="mapSet" numberOfPartitions="5" minSyncReplicas="0" maxSyncReplicas="1" >
            <map ref="Map1"/>
        </mapSet>
    </objectgridDeployment>

</deploymentPolicy>
```

Lesson checkpoint

In this lesson, you learned about the topology for the tutorial and added the configuration files and sample applications to your environment.

If you want to learn more about automatically starting container servers, see Configuring WebSphere Application Server applications to automatically start container servers.

< Previous | Next >

< Previous | Next >

Lesson 1.2: Configure the WebSphere Application Server environment

To prepare your environment for the tutorial, you must configure WebSphere® Application Server security. Enable administration and application security using internal file-based federated repositories as a user account registry. Then, you can create server clusters to host the client application and container servers.

The following steps were written using WebSphere Application Server Version 7.0. However, you can also apply the concepts apply to earlier versions of WebSphere Application Server.

Configure WebSphere Application Server security

1. Configure WebSphere Application Server security.
    a. In the WebSphere Application Server administrative console, click Security > Global Security.
    b. Select Federated repositories as the Available realm definition. Click Set as current.
    c. Click Configure.. to go to the Federated repositories panel.
    d. Enter the Primary administrative user name, for example, `admin`. Click Apply.
    e. When prompted, enter the administrative user password and click OK. Save your changes.
    f. On the Global Security page, verify that Federated repositories setting is set to the current user account registry.
    g. Select the following items: Enable administrative security, Enable application security, and Use Java 2 security to restrict application access to local resources. Click Apply and save your changes.
    h. Restart the deployment manager and any running application servers.

   The WebSphere Application Server administrative security is enabled using the internal file-based federated repositories as the user account registry.
2. Create two user groups: adminGroup and operatorGroup.
    a. Click Users and groups > Manage groups > Create...
    b. Type `adminGroup` as the group name. Enter `Administration group` as the description. Click Create.
    c. Click Create alike. Type `operatorGroup` as the group name. Enter `Operator group` as the description. Click Create.
    d. Click Close.
3. Create users `admin1` and `operator1`.
    a. Click Users and groups > Manage users > Create...
    b. Create a user called `admin1` with the first name `Joe` and last name `Doe` with the password `admin1`. Click Create.
    c. Create a second user. Click Create alike to create a a user called `operator1` with the first name `Jane` and last name `Doe` with the password `operator1`. Click Create. Click Close.
4. Add users to the user groups. Add the `admin1` user to the `adminGroup` and the `operator1` user to the `operatorGroup`.

a. Click Users and groups > Manage users.
b. Search for users to add to groups. Click Search.. and set the search for value to an asterisk (*) to display all the users.
c. From the search result, click the `admin1` user, and click the Groups tab. Click Add to add the group.
d. Search the groups to find the available groups. Click the `adminGroup` and click Add.
e. Repeat these steps to add the `operator1` user to the `operatorGroup` user group.

5. Save your changes, log out of the administrative console, and restart the deployment manager and node agent to enable the security settings.

You enabled security and created users and user groups have administrative and operator access to your WebSphere Application Server configuration.

Create server clusters

Create two server clusters in your WebSphere Application Server configuration: The `appCluster` cluster to host the sample application for the tutorial and the `xsCluster` cluster to host the data grid.

1. In the WebSphere Application Server administrative console, open the clusters panel. Click Servers > Clusters > WebSphere application server clusters > New.
2. Type `appCluster` as the cluster name, leave the Prefer local option selected, and click Next.
3. Create servers in the cluster. Create a server named `s1`, keeping the default options. Add an additional cluster member named `s2`.
4. Complete the remaining steps in the wizard to create the cluster. Save the changes.
5. Repeat these steps to create the `xsCluster` cluster. This cluster has two servers, named `xs1` and `xs2`.

Lesson checkpoint

You enabled global security for the WebSphere Application Server cell, created users and user groups, and created clusters to host the application and data grid.

< Previous | Next >
< Previous | Next >

Module 2: Configure WebSphere eXtreme Scale to use WebSphere Application Server Authentication plug-ins

After you have created the WebSphere® Application Server configuration, you can integrate WebSphere eXtreme Scale authentication with WebSphere Application Server.

When a WebSphere eXtreme Scale client connects to a container server that requires authentication, the client must provide a credential generator represented by the com.ibm.websphere.objectgrid.security.plugins.CredentialGenerator interface. A credential generator is a factory to create a client credential. A client credential can be: a user name and password pair, a Kerberos ticket, a client certificate, or client identification data in any format that the client and server agree upon. See the Credential API documentation for more details. In this sample, the WebSphere eXtreme Scale client is the EmployeeManagment web application that is deployed in the appCluster cluster. The client credential is a WebSphere security token that represents the web user identity.

Learning objectives

With the lessons in this module, you learn how to:

- Configure client server security.
- Configure catalog server security.
- Configure container server security.
- Install and run the sample application.

Time required

This module takes approximately 60 minutes.

Lessons in this module

- **Lesson 2.1: Configure client server security**

  The client properties file indicates the CredentialGenerator implementation class to use.
- **Lesson 2.2: Configure catalog server security**

  A catalog server contains two different levels of security information: The security properties that are common to all the WebSphere eXtreme Scale servers, including the catalog service and container servers, and the security properties that are specific to the catalog server.
- **Lesson 2.3: Configure container server security**

  When a container server connects to the catalog service, the container server gets all the security configurations that are configured in the Object Grid Security XML file, such as authenticator configuration, the login session timeout value, and other configuration information. A container server also has its own server-specific security properties in the server property file.
- **Lesson 2.4: Install and run the sample**

  After authentication is configured, you can install and run the sample application.

Credential API documentation
Lesson 2.2: Configure catalog server security
< Previous | Next >
< Previous | Next >

Lesson 2.1: Configure client server security

The client properties file indicates the CredentialGenerator implementation class to use.

Configure the client properties file with the -Dobjectgrid.client.props JVM property. The file name specified for this property is an absolute file path, such as *samples_home*/security/client2.props. See Client properties file for more information about the client properties file.
Related reference:

Client properties file
Related information:

Module 2: Configure WebSphere eXtreme Scale to use WebSphere Application Server Authentication plug-ins
Credential API documentation

Client properties file contents

This example uses WebSphere Application Server security tokens as the client credential. The client2.props file is in the *samples_home*/security directory. The client2.props file includes the following settings:

securityEnabled
: When set to `true`, indicates that the client must send available security information to the server.

credentialAuthentication
: When set to `Supported`, indicates that the client supports credential authentication.

credentialGeneratorClass
: Indicates the com.ibm.websphere.objectgrid.security.plugins.builtins.WSTokenCredentialGenerator class so the client retrieves the security tokens from the thread. See Security integration with WebSphere Application Server for more information about how security tokens are retrieved.

Setting the client properties file using Java™ virtual machine (JVM) properties

In the administrative console, complete the following steps to both the `s1` and `s2` servers in the `appCluster` cluster. If you are using a different topology, complete the following steps to all of the application servers to which the `EmployeeManagement` application will be deployed.

1. Servers > WebSphere application servers > *server_name* > Java and Process Management > Process definition > Java Virtual Machine.
2. Create the following generic JVM property to set the location of the client properties file:

   ```
   -Dobjectgrid.client.props=samples_home/security/client2.props
   ```

3. Click OK and save your changes.

Lesson checkpoint

You edited the client properties file and configured the servers in the `appCluster` cluster to use the client properties file. This properties file indicates the CredentialGenerator implementation class to use.

< Previous | Next >
< Previous | Next >

Lesson 2.2: Configure catalog server security

A catalog server contains two different levels of security information: The security properties that are common to all the WebSphere® eXtreme Scale servers, including the catalog service and container servers, and the security properties that are specific to the catalog server.

The security properties that are common to the catalog servers and container servers are configured in the security XML descriptor file. An example of common properties is the authenticator configuration, which represents the user registry and authentication mechanism. See Security descriptor XML file for more information about the security properties.
To configure the security XML descriptor file, create a -Dobjectgrid.cluster.security.xml.url property in the Java™ virtual machine (JVM) argument. The file name specified for this property is in an URL format, such as `file:///samples_home/security/securityWAS2.xml`.

Related reference:

Server properties file
Related information:

Module 2: Configure WebSphere eXtreme Scale to use WebSphere Application Server Authentication plug-ins

securityWAS2.xml file

In this tutorial, the securityWAS2.xml file is in the *samples_home*/security directory. The content of the securityWAS2.xml file with the comments removed follows:

```
<securityConfig xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
        xsi:schemaLocation="http://ibm.com/ws/objectgrid/config/security ../objectGridSecurity.xsd"
        xmlns="http://ibm.com/ws/objectgrid/config/security">

        <security securityEnabled="true">
                <authenticator
        className="com.ibm.websphere.objectgrid.security.plugins.builtins.WSTokenAuthenticator">
                </authenticator>
        </security>
</securityConfig>
```

The following properties are defined in the securityWAS2.xml file:

securityEnabled
: The securityEnabled property is set to `true`, which indicates to the catalog server that the WebSphere eXtreme Scale global security is enabled.

authenticator
: The authenticator is configured as the com.ibm.websphere.objectgrid.security.plugins.builtins.WSTokenAuthenticator class. With this built-in implementation of the Authenticator plug-in, the WebSphere eXtreme Scale server can convert the security tokens to a Subject object. See Security integration with WebSphere Application Server for more information about how the security tokens are converted.

catServer2.props file

The server property file stores the server-specific properties, which include the server-specific security properties. See Server properties file for more information. You can configure the server property file with the `-Dobjectgrid.server.props` property in the JVM argument. Specify the file name value for this property is an absolute path, such as *samples_home*`/security/catServer2.props`. For this tutorial, a catServer2.props file is included in the *samples_home*/security directory. The content of the catServer2.props file with comments removed follows:

securityEnabled
: The securityEnabled property is set to `true` to indicate that this catalog server is a secure server.

credentialAuthentication
: The credentialAuthentication property is set to `Required`, so any client that is connecting to the server is required to provide a credential.

secureTokenManagerType
: The secureTokenManagerType is set to `none` to indicate that the authentication secret is not encrypted when joining the existing servers.

authenticationSecret
: The authenticationSecret property is set to `ObjectGridDefaultSecret`. This secret string is used to join the eXtreme Scale server cluster. When a server joins the data grid, it is challenged to present the secret string. If the secret string of the joining server matches the string in the catalog server, the joining server is accepted. If the string does not match, the join request is rejected.

transportType
: The transportType property is set to `TCP/IP` initially. Later in the tutorial, transport security is enabled.

Setting the server properties file with JVM properties

Set the server properties file on the deployment manager server. If you are using a different topology than the topology for this tutorial, set the server properties file on all of the application servers that you are using to host catalog servers.

1. Open the Java virtual machine configuration for the server. In the administrative console, click System administration > Deployment manager > Java and Process Management > Process definition > Java Virtual Machine.
2. Add the following generic JVM arguments:

   ```
   -Dobjectgrid.cluster.security.xml.url=file:///samples_home/security/securityWAS2.xml
   -Dobjectgrid.server.props=samples_home/security/catServer2.props
   ```

3. Click OK and save your changes.

Lesson checkpoint

You configured catalog server security by associating the securityWAS2.xml and catServer2.props files with the deployment manager, which hosts the catalog server process in the WebSphere Application Server configuration.

< Previous | Next >
< Previous | Next >

Lesson 2.3: Configure container server security

When a container server connects to the catalog service, the container server gets all the security configurations that are configured in the Object Grid Security XML file, such as authenticator configuration, the login session timeout value, and other configuration information. A container server also has its own server-specific security properties in the server property file.

Configure the server property file with the `-Dobjectgrid.server.props` Java virtual machine (JVM) property. The file name for this property is an absolute file path, such as *samples_home*/security/server2.props.
In this tutorial, the container servers are hosted in the `xs1` and `xs2` servers in the `xsCluster` cluster.

server2.props file

The server2.props file is in the *samples_home*/security directory under the WASSecurity directory. The properties that are defined in the server2.props file follow:

securityEnabled
: The securityEnabled property is set to `true` to indicate that this container server is a secure server.

credentialAuthentication
: The credentialAuthentication property is set to `Required`, so any client that is connecting to the server is required to provide a credential.

secureTokenManagerType
: The secureTokenManagerType is set to `none` to indicate that the authentication secret is not encrypted when joining the existing servers.

authenticationSecret
: The authenticationSecret property is set to `ObjectGridDefaultSecret`. This secret string is used to join the eXtreme Scale server cluster. When a server joins the data grid, it is challenged to present the secret string. If the secret string of the joining server matches the string in the catalog server, the joining server is accepted. If the string does not match, the join request is rejected.

Setting the server properties file with JVM properties

Set the server properties file on the xs1 and xs2 servers. If you are not using the topology for this tutorial, set the server properties file on all of the application servers that you are using to host container servers.

1. Open the Java™ virtual machine page for the server. Servers > Application servers > *server_name* > Java and Process Management > Process definition > Java Virtual Machine
2. Add the generic JVM arguments:

   `-Dobjectgrid.server.props=`*`samples_home`*`/security/server2.props`

3. Click OK and save your changes.

Lesson checkpoint

Now the WebSphere eXtreme Scale server authentication is secured. By configuring this security, all the applications that try to connect to the WebSphere eXtreme Scale servers are required to provide a credential. In this tutorial, the WSTokenAuthenticator is the authenticator. As a result, the client is required to provide a WebSphere Application Server security token.

< Previous | Next >
< Previous | Next >

Lesson 2.4: Install and run the sample

After authentication is configured, you can install and run the sample application.

Creating a shared library for the EmployeeData.jar file

1. In the WebSphere Application Server administrative console, open the Shared Libraries page. Click Environment > Shared libraries.
2. Choose the cell scope.
3. Create the shared library. Click New. Enter `EmployeeManagementLIB` as the Name. Enter the path to the EmployeeData.jar in the classpath, for example, *samples_home*/WASSecurity/EmployeeData.jar.
4. Click Apply.

Installing the sample

1. Install the EmployeeManagement.ear file.
   a. To begin the installation, click Applications > New application > New Enterprise Application. Choose the detailed path for installing the application.
   b. On the Map modules to servers step, specify the `appCluster` cluster to install the EmployeeManagementWeb module.
   c. On the Map shared libraries step, select the `EmployeeManagementWeb` module.
   d. Click Reference shared libraries. Select the `EmployeeManagementLIB` library.
   e. Map the `webUser` role to All Authenticated in Application's Realm.
   f. Click OK.

   The clients run in the `s1` and `s2` servers in this cluster.
2. Install the sample XSDeployment.ear file.
   a. To begin the installation, click Applications > New application > New Enterprise Application. Choose the detailed path for installing the application.
   b. On the Map modules to servers step, specify the `xsCluster` cluster to install the `XSDeploymentWeb` web module.

c. On the Map shared libraries step, select the `XSDeploymentWeb` module.
d. Click Reference shared libraries. Select the `EmployeeManagementLIB` library.
e. Click OK.

The `xs1` and `xs2` servers in this cluster host the container servers.

3. Restart the deployment manager. When the deployment manager starts, the catalog server also starts. If you look at the SystemOut.log file of the deployment manager, you can see the following message that indicates that the eXtreme Scale server properties file is loaded.

```
CWOBJ0913I: Server property files have been loaded:
/wxs_samples/security/catServer2.props.
```

4. Restart the xsCluster cluster. When the xsCluster starts, the XSDeployment application starts, and a container server is started on the xs1 and xs2 servers respectively. If you look at the SystemOut.log file of the xs1 and xs2 servers, the following message that indicates the server properties file is loaded is displayed:

```
CWOBJ0913I: Server property files have been loaded:
/wxs_samples/security/server2.props.
```

5. Restart the appClusters cluster. When the cluster appCluster starts, the EmployeeManagement application also starts. If you look at the SystemOut.log file of the s1 and s2 servers, you can see the following message that indicates that the client properties file is loaded.

```
CWOBJ0924I: The client property file {0} has been loaded.
```

You can ignore the warning messages regarding the authenticationRetryCount, transportType, and clientCertificateAuthentication properties. The default values are be used because the values were not specified in the properties file.

If you are using WebSphere eXtreme Scale Version 7.0, the English-only CWOBJ9000I message displays to indicate that the client property file has been loaded. If you do not see the expected message, verify that you configured the -Dobjectgrid.server.props or -Dobjectgrid.client.props property in the JVM argument. If you do have the properties configured, make sure the dash (-) is a UTF character.

Running the sample application

1. Run the management.jsp file. In a web browser, access `http://<your_servername>:<port>/EmployeeManagementWeb/management.jsp`. For example, you might use the following URL: `http://localhost:9080/EmployeeManagementWeb/management.jsp`.
2. Provide authentication to the application. Enter the credentials of the user that you mapped to the webUser role. By default, this user role is mapped to all authenticated users. Type `admin1` as your user ID and `admin1` as your password. A page to display, add, update, and delete employees displays.
3. Display employees. Click Display an Employee. Enter `emp1@acme.com` as the email address, and click Submit. A message displays that the employee cannot be found.
4. Add an employee. click Add an Employee. Enter `emp1@acme.com` as the email address, enter `Joe` as the first name, and `Doe` as the last name. Click Submit. A message displays that an employee with the `emp1@acme.com` address has been added.
5. Display the new employee. Click Display an Employee. Enter `emp1@acme.com` as the email address with empty fields for the first and last names, and click Submit. A message displays that the employee has been found, and the correct names are displayed in the first name and last name fields.
6. Delete the employee. Click Delete an employee. Enter `emp1@acme.com` and click Submit. A message is displayed that the employee has been deleted.

Lesson checkpoint

You installed and ran the sample application. Because this tutorial uses WebSphere Application Server integration, you cannot see the scenario when a client fails to authenticate to the eXtreme Scale server. If the user authenticates to the WebSphere Application Server successfully, eXtreme Scale is also successfully authenticated.

< Previous | Next >
< Previous | Next >

Module 3: Configure transport security

Configure transport security to secure data transfer between the clients and servers in the configuration.

In the previous module in the tutorial, you enabled WebSphere® eXtreme Scale authentication. With authentication, any application that tries to connect to the WebSphere eXtreme Scale server is required to provide a credential. Therefore, no unauthenticated client can connect to the WebSphere eXtreme Scale server. The clients must be an authenticated application that is running in a WebSphere Application Server cell.

With the configuration up to this module, the data transfer between the clients in the appCluster cluster and servers in the xsCluster cluster is not encrypted. This configuration might be acceptable if your WebSphere Application Server clusters are installed on servers behind a firewall. However, in some scenarios, non-encrypted traffic is not accepted for some reasons even though the topology is protected by firewall. For example, a government policy might enforce encrypted traffic. WebSphere eXtreme Scale supports Transport Layer Security/Secure Sockets Layer (TLS/SSL) for secure communication between ObjectGrid endpoints, which include client servers, container servers, and catalog servers.

In this sample deployment, the eXtreme Scale clients and container servers are all running in the WebSphere Application Server environment. Client or server properties are not necessary to configure the SSL settings because the eXtreme Scale transport security is managed by the Application Server Common Secure Interoperability Protocol Version 2 (CSIV2) transport settings. WebSphere eXtreme Scale servers use the same Object Request Broker (ORB) instance as the application servers in which they run. Specify all the SSL settings for client and container servers in the WebSphere Application Server configuration using these CSIv2 transport settings. The catalog server has its own proprietary transport paths that do not use Internet Inter-ORB Protocol (IIOP) or Remote Method Invocation (RMI). Because of these proprietary transport paths, the catalog server cannot be managed by the WebSphere Application Server CSIV2 transport settings. Therefore, you must configure the SSL properties in the server properties file for the catalog server.

Learning objectives

After completing the lessons in this module, you know how to:

- Configure CSIv2 inbound and outbound transport.
- Add SSL properties to the catalog server properties file.
- Check the ORB properties file.
- Run the sample.

Time required

This module takes approximately 60 minutes.

Prerequisites

This step of the tutorial builds upon the previous modules. Complete the previous modules in this tutorial before you configure transport security.

Lessons in this module

- **Lesson 3.1: Configure CSIv2 inbound and outbound transport**

  To configure Transport Layer Security/Secure Sockets Layer (TLS/SSL) for the server transport, set the Common Secure Interoperability Protocol Version 2 (CSIv2) inbound transport and CSIv2 outbound transport to `SSL-Required` for all the WebSphere Application Server servers that host clients, catalog servers, and container servers.
- **Lesson 3.2: Add SSL properties to the catalog server properties file**

  The catalog server has its own proprietary transport paths that cannot be managed by the WebSphere Application Server Common Secure Interoperability Protocol Version 2 (CSIV2) transport settings. Therefore, you must configure the Secure Sockets Layer (SSL) properties in the server properties file for the catalog server.
- **Lesson 3.3: Run the sample**

  Restart all the servers and run the sample application again. You should be able to run through the steps without any problems.

< Previous | Next >
< Previous | Next >
< Previous | Next >

Lesson 3.1: Configure CSIv2 inbound and outbound transport

To configure Transport Layer Security/Secure Sockets Layer (TLS/SSL) for the server transport, set the Common Secure Interoperability Protocol Version 2 (CSIv2) inbound transport and CSIv2 outbound transport to `SSL-Required` for all the WebSphere® Application Server servers that host clients, catalog servers, and container servers.

In the tutorial example topology, you must set these properties for the, s1, s2, xs1, and xs2 application servers. The following steps configure the inbound and outbound transports for all the servers in the configuration.

Set the inbound and outbound transports in the administrative console. Make sure that administrative security is enabled.

- **WebSphere Application Server Version 6.1**: Click Security > Secure Administration > Application.. > RMI/IIOP Security and change the transport type to SSL-Required.
- **WebSphere Application Server Version 7.0**: Click Security > Global Security > RMI/IIOP Security > CSIv2 inbound communications. Change the transport type under the CSIv2 Transport Layer to SSL-Required. Repeat this step to configure CSIv2 outbound communications.

You can use centrally managed endpoint security settings, or you can configure SSL repositories. See Common Secure Interoperability Version 2 transport inbound settings for more information.

< Previous | Next >
< Previous | Next >
< Previous | Next >

Lesson 3.2: Add SSL properties to the catalog server properties file

The catalog server has its own proprietary transport paths that cannot be managed by the WebSphere® Application Server Common Secure Interoperability Protocol Version 2 (CSIV2) transport settings. Therefore, you must configure the Secure Sockets Layer (SSL) properties in the server properties file for the catalog server.

To configure catalog server security, additional steps are necessary because the catalog server has its own proprietary transport paths. These transport paths cannot be managed by the Application Server CSIV2 transport settings.

1. Edit the SSL properties in the catServer2.props file. To configure catalog server security, uncomment the following SSL properties in the catalog server properties file. For this tutorial, the catalog server properties are in the catServer2.props file. Update the keyStore and trustStore properties to refer to the

proper location in your environment.

```
#alias=default
#contextProvider=IBMJSSE2
#protocol=SSL
#keyStoreType=PKCS12
#keyStore=/<WAS_HOME>/IBM/WebSphere/AppServer/profiles/<DMGR_NAME>/config/
cells/<CELL_NAME>/nodes/<NODE_NAME>/key.p12
#keyStorePassword=WebAS
#trustStoreType=PKCS12
#trustStore=/<WAS_HOME>/IBM/WebSphere/AppServer/profiles/<DMGR_NAME>/config/
cells/<CELL_NAME>/nodes/<NODE_NAME>/trust.p12
#trustStorePassword=WebAS
#clientAuthentication=false
```

The catServer2.props file is using the default WebSphere Application Server node level keystore and truststore. If you are deploying a more complex deployment environment, you must choose the correct keystore and truststore. In some cases, you must create a keystore and truststore and import the keys from keystores from the other servers. Notice that the `WebAS` string is the default password of the WebSphere Application Server keystore and truststore. See Default self-signed certificate configuration for more details.

2. In the catServer2.props file, update the value of the transportType property. For previous steps of the tutorial, the value was set to `TCP/IP`. Change the value to `SSL-Required`.
3. Restart the deployment manager to activate the changes to the catalog server security settings.

Lesson checkpoint

You configured the SSL properties for the catalog server.

< Previous | Next >
< Previous | Next >

Lesson 3.3: Run the sample

Restart all the servers and run the sample application again. You should be able to run through the steps without any problems.

See Lesson 2.4: Install and run the sample for more information about running and installing the sample application.

Lesson checkpoint

You ran the sample application with transport security enabled.

< Previous | Next >
< Previous | Next >

Module 4: Use Java Authentication and Authorization Service (JAAS) authorization in WebSphere Application Server

Now that you have configured authentication for clients, you can further configure authentication to give different users varying permissions. For example, an operator user might only be able to view data, while an administrator user can perform all operations.

After authenticating a client, as in the previous module in this tutorial, you can give security privileges through eXtreme Scale authorization mechanisms. The previous module of this tutorial demonstrated how to enable authentication for a data grid using integration with WebSphere® Application Server. As a result, no unauthenticated client can connect to the eXtreme Scale servers or submit requests to your system. However, every authenticated client has the same permission or privileges to the server, such as reading, writing, or deleting data that is stored in the ObjectGrid maps. Clients can also issue any type of query. This part of the tutorial demonstrates how to use eXtreme Scale authorization to give authenticated users varying privileges. WebSphere eXtreme Scale uses a permission-based authorization mechanism. You can assign different permission categories that are represented by different permission classes. This module features the MapPermission class. For a list of all possible permissions, see Client authorization programming.

In WebSphere eXtreme Scale, the com.ibm.websphere.objectgrid.security.MapPermission class represents permissions to the eXtreme Scale resources, specifically the methods of the ObjectMap or JavaMap interfaces. WebSphere eXtreme Scale defines the following permission strings to access the methods of ObjectMap and JavaMap:

- **read**: Grants permission to read the data from the map.
- **write**: Grants permission to update the data in the map.
- **insert**: Grants permission to insert the data into the map.
- **remove**: Grants permission to remove the data from the map.
- **invalidate**: Grants permission to invalidate the data from the map.
- **all**: Grants all permissions to read, write, insert, remote, and invalidate.

The authorization occurs when an eXtreme Scale client uses a data access API, such as the ObjectMap ,JavaMap, or EntityManager APIs. The run time checks corresponding map permissions when the method is called. If the required permissions are not granted to the client, an AccessControlException exception results. This tutorial demonstrates how to use Java Authentication and Authorization Service (JAAS) authorization to grant authorization map access for different users.

Learning objectives

After completing the lessons in this module, you know how to:

- Enable authorization for WebSphere eXtreme Scale.
- Enable user-based authorization.
- Configure group-based authorization.

Time required

This module takes approximately 60 minutes.

Prerequisites

You must complete the prior modules in this tutorial before configuring authentication.

Lessons in this module

- **Lesson 4.1: Enable WebSphere eXtreme Scale authorization**

  To enable authorization in WebSphere eXtreme Scale, you must enable security on a specific ObjectGrid.
- **Lesson 4.2: Enable user-based authorization**

  In the authentication module of this tutorial, you created two users: `operator1` and `admin1`. You can assign varying permissions to these users with Java Authentication and Authorization Service (JAAS) authorization.
- **Lesson 4.3: Configure group-based authorization**

  In the previous lesson, you assigned individual user-based authorization with user principals in the Java Authentication and Authorization Service. (JAAS) authorization policy. However, when you have hundreds or thousands of users, use group-based authorization, which authorizes access based on groups instead of individual users.

Related concepts:

Client authorization programming
< Previous | Next >
< Previous | Next >

Lesson 4.1: Enable WebSphere eXtreme Scale authorization

To enable authorization in WebSphere® eXtreme Scale, you must enable security on a specific ObjectGrid.

To enable authorization on the ObjectGrid, you must set the securityEnabled attribute to true for that particular ObjectGrid in the XML file. For this tutorial, you can either use the XSDeployment_sec.ear file in the *samples_home*/WASSecurity directory, which has already has security set in the objectGrid.xml file, or you can edit the existing objectGrid.xml file to enable security. This lesson demonstrates how to edit the file to enable security.

1. Extract the files in the XSDeployment.ear file, and then unzip the XSDeploymentWeb.war file.
2. Open the objectGrid.xml file and set the securityEnabled attribute to `true` on the ObjectGrid level. See an example of this attribute in the following example:

```
<?xml version="1.0" encoding="UTF-8"?>

<objectGridConfig xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:schemaLocation="http://ibm.com/ws/objectgrid/config ../objectGrid.xsd"
 xmlns="http://ibm.com/ws/objectgrid/config">

    <objectGrids>
        <objectGrid name="Grid" securityEnabled="true">
            <backingMap name="Map1" />
        </objectGrid>
    </objectGrids>

</objectGridConfig>
```

   If you have multiple ObjectGrids defined, then you must set this attribute on each data grid.
3. Repackage the XSDeploymentWeb.war and XSDeployment.ear files to include your changes. Name the file XSDeployment_sec.ear so you do not overwrite the original package.
4. Uninstall the existing XSDeployment application and install the XSDeployment_sec.ear file. See Lesson 2.4: Install and run the sample for more information about deploying applications.

Lesson checkpoint

You enabled security on the ObjectGrid, which also enables authorization on the data grid.

< Previous | Next >

Lesson 4.2: Enable user-based authorization

In the authentication module of this tutorial, you created two users: `operator1` and `admin1`. You can assign varying permissions to these users with Java™ Authentication and Authorization Service (JAAS) authorization.

Defining the Java Authentication and Authorization Service (JAAS) authorization policy using user principals

You can assign permissions to the users that you previously created. Assign the `operator1` user read permissions only to all maps. Assign the `admin1` user all permissions. Use the JAAS authorization policy file to grant permissions to principals.
Edit the JAAS authorization file. The xsAuth2.policy file is in the *samples_home*/security directory:

```
grant codebase http://www.ibm.com/com/ibm/ws/objectgrid/security/PrivilegedAction
Principal com.ibm.ws.security.common.auth.WSPrincipalImpl "defaultWIMFileBasedRealm/operator1" {
    permission com.ibm.websphere.objectgrid.security.MapPermission "Grid.Map1", "read";
};

grant codebase http://www.ibm.com/com/ibm/ws/objectgrid/security/PrivilegedAction
Principal com.ibm.ws.security.common.auth.WSPrincipalImpl "defaultWIMFileBasedRealm/admin1" {
    permission com.ibm.websphere.objectgrid.security.MapPermission "Grid.Map1", "all";
};
```

In this file, the `http://www.ibm.com/com/ibm/ws/objectgrid/security/PrivilegedAction` codebase is a specially reserved URL for ObjectGrid. All ObjectGrid permissions that are granted to principals should use this special code base. The following permissions are assigned in this file:

- The first grant statement grants `read` map permission to the `operator1` principal. The `operator1` user has only map read permission to the Map1 map the Grid ObjectGrid instance.
- The second grant statement grants all map permission to the admin1 principal. The `admin1` user has all permissions to the Map1 map in the Grid ObjectGrid instance.
- The principal name is `defaultWIMFileBasedRealm/operator1`, but not `Operator1`. WebSphere Application Server automatically adds the realm name to the principal name when federated repositories are used as the user account registry. Adjust this value if needed.

Setting the JAAS authorization policy file using JVM properties

Use the following steps to set JVM properties for the xs1 and xs2 servers, which are in the xsCluster cluster. If you are using a topology that is different from the sample topology that is used in this tutorial, set the file on all of your container servers.

1. In the administrative console, click Servers > Application servers > *server_name* > Java and Process Management > Process definition > Java Virtual Machine.
2. Add generic JVM arguments.
   Note: When containers are running in WebSphere Application Server, you cannot use the -Djava.security.policy argument because this file overrides the WebSphere Application Server administrative access authorization. Therefore, use -Djava.security.auth.policy to set the JAAS authorization policy.
   Enter the following generic JVM arguments or replace the `-Djava.security.auth.policy` entry with the following text:

   ```
   -Djava.security.auth.policy=samples_home/security/xsAuth2.policy
   ```

3. Click OK and save your changes.

Running the sample application to test authorization

You can use the sample application to test the authorization settings. The administrator user continues to have all permissions in the Map1 map, including displaying and adding employees. The operator user should only be able to view employees because that user was assigned read permission only.

1. Restart all of the application servers that are running container servers.
2. Open the `EmployeeManagementWeb` application. In a web browser, open `http://<host>:<port>/EmployeeManagementWeb/management.jsp`.
3. Log in to the application as an administrator. Use the user name `admin1` and password `admin1`.
4. Attempt to display an employee. Click Display an Employee and search for the `authemp1@acme.com` email address. A message displays that the user cannot be found.
5. Add an employee. Click Add an Employee. Add the email `authemp1@acme.com`, the first name `Joe`, and the last name `Doe`. Click Submit. A message displays that the employee has been added.
6. Log in as the operator user. Open a second Web browser window and open `http://<host>:<port>/EmployeeManagermentWeb/management.jsp`. Use the user name `operator1` and password `operator1`.
7. Attempt to display an employee. Click Display an Employee and search for the `authemp1@acme.com` email address. The employee is displayed.
8. Add an employee. Click Add an Employee. Add the email `authemp2@acme.com`, the first name `Joe`, and the last name `Doe`. Click Submit. The following message displays:

   ```
   An exception occurs when Add the employee. See below for detailed exception messages.
   ```

   The following exception is in the exception chain:

   ```
   java.security.AccessControlException: Access denied
   (com.ibm.websphere.objectgrid.security.MapPermission Grid.Map1 insert)
   ```

This message displays because the `operator1` user does not have permission to insert data into the Map1 map.

If you are running with a version of WebSphere Application Server that is earlier than Version 7.0.0.11, you might see a java.lang.StackOverflowError error on the container server. This error is caused by a problem with the IBM Developer Kit. The problem is fixed in the IBM Developer Kit that is shipped with WebSphere Application Server Version 7.0.0.11 and later.

Lesson checkpoint

In this lesson, you configured authorization by assigning permissions to specific users.

< Previous | Next >
< Previous | Next >

Lesson 4.3: Configure group-based authorization

In the previous lesson, you assigned individual user-based authorization with user principals in the Java™ Authentication and Authorization Service. (JAAS) authorization policy. However, when you have hundreds or thousands of users, use group-based authorization, which authorizes access based on groups instead of individual users.

Unfortunately, the Subject object that is authenticated from the WebSphere® Application Server only contains a user principal. This object does not contain a group principal. You can add a custom login module to populate the group principal into the Subject object.

For this tutorial, the custom login module is named com.ibm.websphere.samples.objectgrid.security.lm.WASAddGroupLoginModule. The module is in the groupLM.jar file. Place this JAR file in the WAS-INSTALL/lib/ext directory.

The WASAddGroupLoginModule retrieves the public group credential from the WebSphere Application Server subject and creates a Group principal, com.ibm.websphere.samples.objectgrid.security.WSGroupPrincipal, to represent the group. This group principal can then be used for group authorization. The groups are defined in the xsAuthGroup2.policy file:

```
grant codebase "http://www.ibm.com/com/ibm/ws/objectgrid/security/PrivilegedAction"
principal com.ibm.websphere.sample.xs.security.WSGroupPrincipal
                "defaultWIMFileBasedRealm/cn=operatorGroup,o=defaultWIMFileBasedRealm" {
    permission com.ibm.websphere.objectgrid.security.MapPermission "Grid.Map1", "read";
};

grant codebase "http://www.ibm.com/com/ibm/ws/objectgrid/security/PrivilegedAction"
principal com.ibm.websphere.sample.xs.security.WSGroupPrincipal
        "defaultWIMFileBasedRealm/cn=adminGroup,o=defaultWIMFileBasedRealm" {
    permission com.ibm.websphere.objectgrid.security.MapPermission "Grid.Map1", "all";
};
```

The principal name is the `WSGroupPrincipal`, which represents the group.

Adding the custom login module

The custom login module must be added to each of the following system login module entries: If you are using Lightweight Third Party Authentication (LTPA), add the entry to the RMI_INBOUND login modules. LTPA is the default authentication mechanism for WebSphere Application Server Version 7.0. For a WebSphere Application Server Network Deployment configuration, you only need to configure the LTPA authentication mechanism configuration entries.
Use the following steps to configure the supplied com.ibm.websphere.samples.objectgrid.security.lm.WASAddGroupLoginModule login module:

1. In the administrative console, click Security > Global Security > Java Authentication and Authorization Service > System logins > *login_module_name* > JAAS login modules > New.
2. Enter the class name as `com.ibm.websphere.sample.xs.security.lm.WASAddGroupLoginModule`.
3. Optional: Add a property `debug` and set the value to `true`.
4. Click Apply to add the new module to the login module list.

Setting the JAAS Authorization Policy file using JVM Properties

In the administrative console, perform the following steps to xs1 and xs2 servers in the xsCluster. If a different deployment topology is used, perform the following steps to the application servers that host the container servers.

1. In the administrative console, click Servers > Application servers > *server_name* > Java and Process management > Process definition > Java virtual machine
2. Add generic JVM arguments.
   Note: When containers are running in WebSphere Application Server, you cannot use the -Djava.security.policy argument because this file overrides the WebSphere Application Server administrative access authorization. Therefore, use -Djava.security.auth.policy to set the JAAS authorization policy.
   Enter the following generic JVM arguments or replace the `-Djava.security.auth.policy` entry with the following text:

   ```
   -Djava.security.auth.policy=samples_home/security/xsAuthGroup2.policy
   ```

3. Click OK and save your changes.

Testing group authorization with the sample application

You can test that group authorization is configured by the login module with the sample application.

1. Restart the container servers. For this tutorial, the container servers are the xs1 and xs2 servers.
2. Log in to the sample application. In a web browser, open `http://<host>:<port>/EmployeeManagementWeb/management.jsp` and login with the user name `admin1` and password `admin1`.
3. Display an employee. Click Display an Employee and search for the `authemp2@acme.com` email address. A message displays that the user cannot be found.
4. Add an employee. Click Add an Employee. Add the email `authemp2@acme.com`, the first name `Joe`, and the last name `Doe`. Click Submit. A message displays that the employee has been added.
5. Log in as the operator user. Open a second web browser window and open the following URL: `http://<host>:<port>/EmployeeManagermentWeb/management.jsp`. Use the user name `operator1` and password `operator1`.
6. Attempt to display an employee. Click Display an Employee and search for the `authemp2@acme.com` email address. The employee is displayed.
7. Add an employee. Click Add an Employee. Add the email `authemp3@acme.com`, the first name `Joe`, and the last name `Doe`. Click Submit. The following message displays:

   ```
   An exception occurs when Add the employee. See below for detailed exception messages.
   ```

   The following exception is in the exception chain:

   ```
   java.security.AccessControlException: Access denied
   (com.ibm.websphere.objectgrid.security.MapPermission Grid.Map1 insert)
   ```

   This message displays because the operator user does not have permission to insert data into the Map1 map.

Lesson checkpoint

You configured groups to simplify the assignment of permission to the users of your application.

< Previous | Next >
< Previous

Module 5: Use the xscmd tool to monitor data grids and maps

You can use the **xscmd** tool to show the primary data grids and map sizes of the `Grid` data grid. The **xscmd** tool uses the MBean to query all of the data grid artifacts, such as primary shards, replica shards, container servers, map sizes, and so on.

In this tutorial, the container and catalog servers are running in WebSphere® Application Server application servers. The WebSphere eXtreme Scale run time registers the Managed Beans (MBean) with the MBean server that is created by the WebSphere Application Server run time. The security that is used by the **xscmd** tool is provided by the WebSphere Application Server MBean security. Therefore, WebSphere eXtreme Scale specific security configuration is not necessary.

1. Using a command-line tool, open the *DMGR_PROFILE*/bin directory.
2. Run the **xscmd** tool.
   Use the **-c showPlacement -sf P** command to list the placement of the primary shards. Linux UNIX

   ```
   xscmd.sh -g Grid -ms mapSet -c showPlacement -sf P
   ```

   Windows

   ```
   xscmd.bat -g Grid -ms mapSet -c showPlacement -sf P
   ```

   Before you can view the output, you are prompted to log in with your WebSphere Application Server ID and password.

Related tasks:

Monitoring with the xscmd utility
Administering with the xscmd utility

Lesson checkpoint

You used the **xscmd** tool in WebSphere Application Server.

Tutorial: Integrate WebSphere eXtreme Scale security in a mixed environment with an external authenticator

This tutorial demonstrates how to secure WebSphere® eXtreme Scale servers that are partially deployed in a WebSphere Application Server environment.

In the deployment for this tutorial, the container servers are deployed in WebSphere Application Server. The catalog server is deployed as stand-alone server, and is started in a Java Standard Edition (Java SE) environment.
Because the catalog server is not deployed in WebSphere Application Server, you cannot use the WebSphere Application Server Authentication plug-ins. For more information about the process of configuring WebSphere Application Server Authentication plug-ins, see Tutorial: Integrate WebSphere eXtreme Scale

security with WebSphere Application Server. In this tutorial, a different authenticator is required for catalog server authentication. You configure a keystore authenticator to authenticate the clients.

Learning objectives

The learning objectives for this tutorial follow:

- Configure WebSphere eXtreme Scale to use the KeyStoreLoginAuthenticator plug-in
- Configure WebSphere eXtreme Scale transport security to use WebSphere Application Server CSIv2 configuration and the WebSphere eXtreme Scale properties file
- Use Java™ Authentication and Authorization Service (JAAS) authorization in WebSphere Application Server
- Use the **xscmd** utility to monitor the data grids and maps that you created in the tutorial.

Time required

This tutorial takes approximately 4 hours from start to finish.
< Previous | Next >
< Previous | Next >

Introduction: Security in a mixed environment

In this tutorial, you integrate WebSphere® eXtreme Scale security in a mixed environment. The container servers run within WebSphere Application Server, and the catalog service runs in stand-alone mode. Because the catalog server is in stand-alone mode, you must configure an external authenticator.

Important: If both your container servers and catalog server are running within WebSphere Application Server, you can use the WebSphere Application Server Authentication plug-ins or an external authenticator. For more information about using the WebSphere Application Server Authentication plug-ins, see Tutorial: Integrate WebSphere eXtreme Scale security with WebSphere Application Server.

Learning objectives

The learning objectives for this tutorial follow:

- Configure WebSphere eXtreme Scale to use the KeyStoreLoginAuthenticator plug-in
- Configure WebSphere eXtreme Scale transport security to use WebSphere Application Server CSIv2 configuration and the WebSphere eXtreme Scale properties file
- Use Java™ Authentication and Authorization Service (JAAS) authorization in WebSphere Application Server
- Use the **xscmd** utility to monitor the data grids and maps that you created in the tutorial.

Time required

This tutorial takes approximately 4 hours from start to finish.

Skill level

Intermediate.

Audience

Developers and administrators that are interested in the security integration between WebSphere eXtreme Scale and WebSphere Application Server and configuring external authenticators.

System requirements

- WebSphere Application Server Version 6.1 or Version 7.0.0.11 or later with the following fixes applied:interim fix PM20613 and interim fix PM15818.
- The catalog server must be running on a stand-alone installation, not an installation that is integrated with WebSphere Application Server.
- Update the Java runtime to apply the following fix: IZ79819: IBMJDK FAILS TO READ PRINCIPAL STATEMENT WITH WHITESPACE FROM SECURITY FILE
- The stand-alone node that runs the catalog service must use the IBM Software Development Kit Version 1.6 J9. This Software Development Kit is included in the WebSphere Application Server installation. The catalog server node must be a stand-alone installation because you cannot run the **startOgServer** command within an installation of WebSphere eXtreme Scale on WebSphere Application Server.

This tutorial uses four WebSphere Application Server application servers and one deployment manager to demonstrate the sample.

Prerequisites

A basic understanding of the following items is helpful before you start this tutorial:

- WebSphere eXtreme Scale programming model
- Basic WebSphere eXtreme Scale security concepts
- Basic WebSphere Application Server security concepts

For a background information about WebSphere eXtreme Scale and WebSphere Application Server security integration, see Security integration with WebSphere Application Server.

Modules in this tutorial

- **Module 1: Prepare the mixed WebSphere Application Server and stand-alone environment**

  Before you start the tutorial, you must create a basic topology that includes container servers that run within WebSphere Application Server. In this tutorial, the catalog servers run in stand-alone mode.
- **Module 2: Configure WebSphere eXtreme Scale authentication in a mixed environment**

  By configuring authentication, you can reliably determine the identity of the requester. WebSphere eXtreme Scale supports both client-to-server and server-to-server authentication.
- **Module 3: Configure transport security**

  Configure transport security to secure data transfer between the clients and servers in the configuration.
- **Module 4: Use Java Authentication and Authorization Service (JAAS) authorization in WebSphere Application Server**

  Now that you have configured authentication for clients, you can further configure authorization to give different users varying permissions. For example, an "operator" user might only be able to view data, while a "manager" user can perform all operations.

< Previous | Next >
< Previous | Next >

Module 1: Prepare the mixed WebSphere Application Server and stand-alone environment

Before you start the tutorial, you must create a basic topology that includes container servers that run within WebSphere® Application Server. In this tutorial, the catalog servers run in stand-alone mode.

Learning objectives

With the lessons in this module, you learn how to:

- Understand the mixed topology and the files that are necessary for the tutorial
- Configure WebSphere Application Server to run the container servers

Time required

This module takes approximately 60 minutes.

Lessons in this module

- **Lesson 1.1: Understand the topology and get the tutorial files**

  To prepare your environment for the tutorial, you must configure the catalog and container servers for the topology.
- **Lesson 1.2: Configure the WebSphere Application Server environment**

  To prepare your environment for the tutorial, you must configure WebSphere Application Server security. Enable administration and application security using internal file-based federated repositories as a user account registry. Then, you can create server clusters to host the client application and container servers. You also must create and start the catalog servers.

< Previous | Next >
< Previous | Next >

Lesson 1.1: Understand the topology and get the tutorial files

To prepare your environment for the tutorial, you must configure the catalog and container servers for the topology.

This lesson guides you through the sample topology and applications that are used to in the tutorial. To begin running the tutorial, you must download the applications and place the configuration files in the correct locations for your environment. You can download the sample application from the IBM elastic caching community.

Topology

In this tutorial, you create the following clusters in the WebSphere Application Server cell:

- **appCluster cluster**: Hosts the EmployeeManagement sample enterprise application. This cluster has two application servers: s1 and s2.

- **xsCluster cluster**: Hosts the eXtreme Scale container servers. This cluster has two application servers: xs1 and xs2.

In this deployment topology, the s1 and s2 application servers are the client servers that access data that is being stored in the data grid. The xs1 and xs2 servers are the container servers that host the data grid.
Alternative configuration: You can host all of the application servers in a single cluster, such as in the appCluster cluster. With this configuration, all of the servers in the cluster are both clients and container servers. This tutorial uses two clusters to distinguish between the application servers that are hosting the clients and container servers.

In this tutorial, you configure a catalog service domain that consists of a remote server that is not in the WebSphere Application Server cell. This configuration is not the default, which results in the catalog servers running on the deployment manager and other processes in the WebSphere Application Server cell. See Creating catalog service domains in WebSphere Application Server for more information about creating a catalog service domain that consists of remote servers.

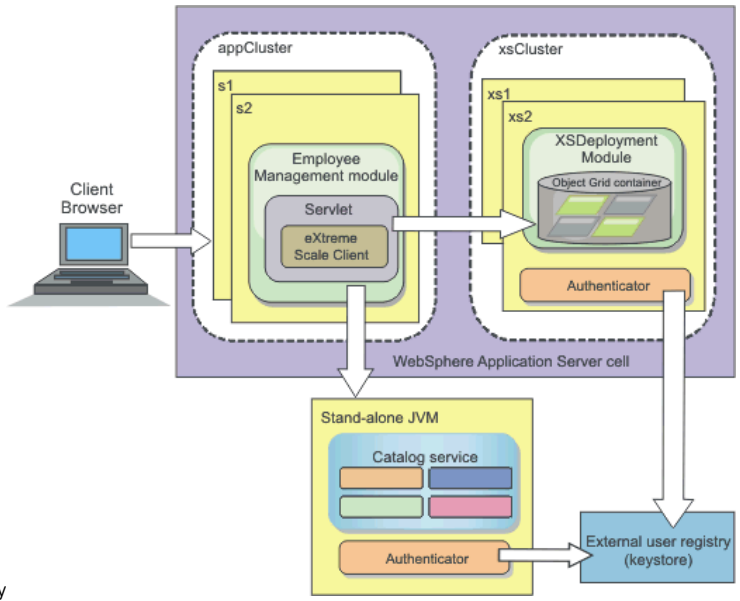

Figure 1. Tutorial topology

Applications

In this tutorial, you are using two applications and one shared library file:

- **EmployeeManagement.ear**: The EmployeeManagement.ear application is a simplified Java™ 2 Platform, Enterprise Edition (J2EE) enterprise application. It contains a web module to manage the employee profiles. The web module contains the management.jsp file to display, insert, update, and delete employee profiles that are stored in the container servers.
- **XSDeployment.ear**: This application contains an enterprise application module with no application artifacts. The cache objects are packaged in the EmployeeData.jar file. The EmployeeData.jar file is deployed as a shared library for the XSDeployment.ear file, so that the XSDeployment.ear file can access the classes. The purpose of this application is to package the eXtreme Scale configuration file and property file. When this enterprise application is started, the eXtreme Scale configuration files are automatically detected by the eXtreme Scale run time, so the container servers are created. These configuration files include the objectGrid.xml and objectGridDeployment.xml files.
- **EmployeeData.jar**: This jar file contains one class: the com.ibm.websphere.sample.xs.data.EmployeeData class. This class represents employee data that is stored in the grid. This Java archive (JAR) file is deployed with the EmployeeManagement.ear and XSDeployment.ear files as a shared library.

Get the tutorial files

1. Download the WASSecurity.zip and security_extauth.zip files from the WebSphere eXtreme Scale wiki.
2. Extract the WASSecurity.zip file to a directory for viewing the binary and source artifacts, for example a wxs_samples/ directory. This directory is referred to as *samples_home* for the remainder of the tutorial. Refer to the README.txt file in the package for a description of the contents and how to load the source into your Eclipse workspace. The following ObjectGrid configuration files are in the META-INF directory:
   - objectGrid.xml
   - objectGridDeployment.xml
3. Create a directory to store the property files that are used to secure this environment. For example, you might create the /opt/wxs/security directory.
4. Extract the security_extauth.zip file to *samples_home*. The security_extauth.zip file contains the following security configuration files that are used in this tutorial:. These configuration files follow:
   - catServer3.props
   - server3.props
   - client3.props
   - security3.xml
   - xsAuth3.props
   - xsjaas3.config
   - sampleKS3.jks

About the configuration files

The objectGrid.xml and objectGridDeployment.xml files create the data grids and maps that store the application data.

These configuration files must be named objectGrid.xml and objectGridDeployment.xml. When the application server starts, eXtreme Scale detects these files in the META-INF directory of the EJB and web modules. If these files are found, it assumed that the Java virtual machine (JVM) acts as a container server for the defined data grids in the configuration files.

objectGrid.xml file

The objectGrid.xml file defined one ObjectGrid named `Grid`. The `Grid` data grid has one map, the `Map1` map, that stores the employee profile for the application.

```
<?xml version="1.0" encoding="UTF-8"?>
<objectGridConfig xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:schemaLocation="http://ibm.com/ws/objectgrid/config ../objectGrid.xsd"
 xmlns="http://ibm.com/ws/objectgrid/config">

 <objectGrids>
        <objectGrid name="Grid" txTimeout="15">
            <backingMap name="Map1" />
        </objectGrid>
    </objectGrids>

</objectGridConfig>
```

objectGridDeployment.xml file

The objectGridDeployment.xml file specifies how to deploy the `Grid` data grid. When the grid is deployed, it has five partitions and one synchronous replica.

```
<?xml version="1.0" encoding="UTF-8"?>

<deploymentPolicy xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:schemaLocation="http://ibm.com/ws/objectgrid/deploymentPolicy ../deploymentPolicy.xsd"
 xmlns="http://ibm.com/ws/objectgrid/deploymentPolicy">

    <objectgridDeployment objectgridName="Grid">
        <mapSet name="mapSet" numberOfPartitions="5" minSyncReplicas="0" maxSyncReplicas="1" >
            <map ref="Map1"/>
        </mapSet>
    </objectgridDeployment>

</deploymentPolicy>
```

Lesson checkpoint

In this lesson, you learned about the topology for the tutorial and added the configuration files and sample applications to your environment.

< Previous | Next >
< Previous | Next >

Lesson 1.2: Configure the WebSphere Application Server environment

To prepare your environment for the tutorial, you must configure WebSphere® Application Server security. Enable administration and application security using internal file-based federated repositories as a user account registry. Then, you can create server clusters to host the client application and container servers. You also must create and start the catalog servers.

The following steps were written using WebSphere Application Server Version 7.0. However, you can also apply the concepts apply to earlier versions of WebSphere Application Server.

Configure WebSphere Application Server security

Create and augment profiles for the deployment manager and nodes with WebSphere eXtreme Scale. See Installing WebSphere eXtreme Scale or WebSphere eXtreme Scale Client with WebSphere Application Server for more information.
Configure WebSphere Application Server security.

a. In the WebSphere Application Server administrative console, click Security > Global Security.
b. Select Federated repositories as the Available realm definition. Click Set as current.
c. Click Configure.. to go to the Federated repositories panel.
d. Enter the Primary administrative user name, for example, `admin`. Click Apply.
e. When prompted, enter the administrative user password and click OK. Save your changes.
f. On the Global Security page, verify that Federated repositories setting is set to the current user account registry.
g. Select the following items: Enable administrative security, Enable application security, and Use Java 2 security to restrict application access to local resources. Click Apply and save your changes.
h. Restart the deployment manager and any running application servers.

The WebSphere Application Server administrative security is enabled using the internal file-based federated repositories as the user account registry.

Create server clusters

Create two server clusters in your WebSphere Application Server configuration: The `appCluster` cluster to host the sample application for the tutorial and the `xsCluster` cluster to host the data grid.

1. In the WebSphere Application Server administrative console, open the clusters panel. Click Servers > Clusters > WebSphere application server clusters > New.
2. Type `appCluster` as the cluster name, leave the Prefer local option selected, and click Next.
3. Create servers in the cluster. Create a server named `s1`, keeping the default options. Add an additional cluster member named `s2`.
4. Complete the remaining steps in the wizard to create the cluster. Save the changes.
5. Repeat these steps to create the `xsCluster` cluster. This cluster has two servers, named `xs1` and `xs2`.

Create a catalog service domain

After configuring the server cluster and security, you must define where catalog servers start.

Define a catalog service domain in WebSphere eXtreme Scale

1. In the WebSphere Application Server administrative console, click System administration > WebSphere eXtreme Scale > Catalog service domains.
2. Create the catalog service domain. Click New. Create the catalog service domain with the name `catalogService1`, and enable the catalog service domain as the default.
3. Add remote servers to the catalog service domain. Select Remote server. Provide the host name where the catalog server is running. Use the listener port value of `16809` for this example.
4. Click OK and save your changes.

Lesson checkpoint

You enabled security in WebSphere Application Server, and created the server topolgy for WebSphere eXtreme Scale.

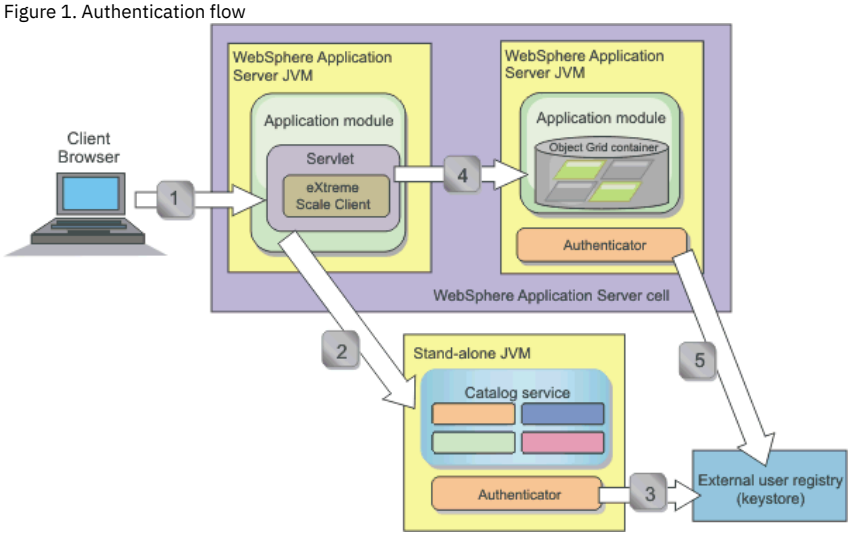
< Previous | Next >
< Previous | Next >

Module 2: Configure WebSphere eXtreme Scale authentication in a mixed environment

By configuring authentication, you can reliably determine the identity of the requester. WebSphere® eXtreme Scale supports both client-to-server and server-to-server authentication.

Authentication flow

Figure 1. Authentication flow



The previous diagram shows two application servers. The first application server hosts the web application, which is also a WebSphere eXtreme Scale client. The second application server hosts a container server. The catalog server is running in a stand-alone Java virtual machine (JVM) instead of WebSphere Application Server.

The arrows marked with numbers in the diagram indicate the authentication flow:

1. An enterprise application user accesses the web browser, and logs in to the first application server with a user name and password. The first application server sends the client user name and password to the security infrastructure to authenticate to the user registry. This user registry is a keystore. As a result, the security information is stored on the WebSphere Application Server thread.
2. The JavaServer Pages (JSP) file acts as a WebSphere eXtreme Scale client to retrieve the security information from the client property file. The JSP application that is acting as the WebSphere eXtreme Scale client sends the WebSphere eXtreme Scale client security credential along with the request to the catalog server. Sending the security credential with the request is considered a *runAs* model. In a runAs model, the web browser client runs as a WebSphere eXtreme Scale client to access the data stored in the container server. The client uses a Java virtual machine (JVM)-wide client credential to connect to the WebSphere eXtreme Scale servers. Using the runAs model is like connecting to a database with a data source level user ID and password.
3. The catalog server receives the WebSphere eXtreme Scale client credential, which includes the WebSphere Application Server security tokens. Then, the catalog server calls the authenticator plug-in to authenticate the client credential. The authenticator connects to the external user registry and sends the

client credential to the user registry for authentication.
4. The client sends the user ID and password to the container server that is hosted in the application server.
5. The container service, hosted in the application server, receives the WebSphere eXtreme Scale client credential, which is the user id and password pair. Then, the container server calls the authenticator plug-in to authenticate the client credential. The authenticator connects to the keystore user registry and sends the client credential to the user registry for authentication

Learning objectives

With the lessons in this module, you learn how to:

- Configure WebSphere eXtreme Scale client security.
- Configure WebSphere eXtreme Scale catalog server security.
- Configure WebSphere eXtreme Scale container server security.
- Install and run the sample application.

Time required

This module takes approximately 60 minutes.

Lessons in this module

- **Lesson 2.1: Configure WebSphere eXtreme Scale client security**

  You configure the client properties with a properties file. The client properties file indicates the CredentialGenerator implementation class to use.
- **Lesson 2.2: Configure catalog server security**

  A catalog server contains two different levels of security information: The first level contains the security properties that are common to all the WebSphere eXtreme Scale servers, including the catalog service and container servers. The second level contains the security properties that are specific to the catalog server.
- **Lesson 2.3: Configure container server security**

  When a container server connects to the catalog service, the container server gets all the security configurations that are configured in the Object Grid Security XML file. The ObjectGrid Security XML file defines authenticator configuration, the login session timeout value, and other configuration information. A container server also has its own server-specific security properties in the server property file.
- **Lesson 2.4: Install and run the sample**

  After authentication is configured, you can install and run the sample application.

< Previous | Next >
< Previous | Next >

Lesson 2.1: Configure WebSphere eXtreme Scale client security

You configure the client properties with a properties file. The client properties file indicates the CredentialGenerator implementation class to use.

Client properties file contents

The tutorial uses WebSphere Application Server security tokens for the client credential. The *samples_home*/security_extauth directory contains the client3.props file.

The client3.props file includes the following settings:

securityEnabled
: Enables WebSphere eXtreme Scale client security. The value is set to `true` to indicate that the client must send available security information to the server.

credentialAuthentication
: Specifies the client credential authentication support. The value is set to `Supported` to indicate that the client supports credential authentication.

credentialGeneratorClass
: Specifies the name of the class that implements the com.ibm.websphere.objectgrid.security.plugins.CredentialGenerator interface. The value is set to the com.ibm.websphere.objectgrid.security.plugins.builtins. UserPasswordCredentialGenerator class so that the client retrieves the security information from the UserPasswordCredentialGenerator class.

credentialGeneratorProps
: Specifies the user name and password: `manager manager1`. The user name is `manager`, and the password is `manager1`. You can also use the **FilePasswordEncoder.bat|sh** command to encode this property using an exclusive or (xor) algorithm.

Setting the client properties file using Java™ virtual machine (JVM) properties

In the administrative console, complete the following steps to both the `s1` and `s2` servers in the `appCluster` cluster. If you are using a different topology, complete the following steps to all of the application servers to which the `EmployeeManagement` application is deployed.

1. Click Servers > WebSphere application servers > *server_name* > Java and Process Management > Process definition > Java Virtual Machine.

2. Create the following generic JVM property to set the location of the client properties file:

   ```
   -Dobjectgrid.client.props=samples_home/security_extauth/client3.props
   ```

   When you connect to a secure data grid, you must configure the client application to provide a valid client security configuration. You can configure the client security configuration through the client application, or you can defined the configuration in a client properties file that has the same value of the JVM property, objectgrid.client.props. When you use the objectgrid.client.props property, the ObjectGridManager obtains the client security configuration from the client properties file and uses this information to connect to the data grid.

3. Click OK and save your changes.

Lesson checkpoint

You edited the client properties file and configured the servers in the `appCluster` cluster to use the client properties file. This properties file indicates the CredentialGenerator implementation class to use.

< Previous | Next >
< Previous | Next >

Lesson 2.2: Configure catalog server security

A catalog server contains two different levels of security information: The first level contains the security properties that are common to all the WebSphere® eXtreme Scale servers, including the catalog service and container servers. The second level contains the security properties that are specific to the catalog server.

The security properties that are common to the catalog servers and container servers are configured in the security XML descriptor file. An example of common properties is the authenticator configuration, which represents the user registry and authentication mechanism. See Security descriptor XML file for more information about the security properties.
To configure the security XML descriptor file in a Java SE environment, use a -clusterSecurityFile option when you run the **startOgServer** command. Specify a value in a file format, such as *samples_home*/security_extauth/security3.xml.

security3.xml file

In this tutorial, the security3.xml file is in the *samples_home*/security_extauth directory. The content of the security3.xml file with the comments removed follows:

```
<securityConfig xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
        xsi:schemaLocation="http://ibm.com/ws/objectgrid/config/security ../objectGridSecurity.xsd"
        xmlns="http://ibm.com/ws/objectgrid/config/security">

        <security securityEnabled="true">
                <authenticator
        className="com.ibm.websphere.objectgrid.security.plugins.builtins.KeyStoreLoginAuthenticator">
                </authenticator>
        </security>
</securityConfig>
```

The following properties are defined in the security3.xml file:

securityEnabled
: The securityEnabled property is set to `true`, which indicates to the catalog server that the WebSphere eXtreme Scale global security is enabled.

authenticator
: The authenticator is configured as the com.ibm.websphere.objectgrid.security.plugins.builtins.KeyStoreLoginAuthenticator class. With this built-in implementation of the Authenticator plug-in, the user ID and password is passed to verify that it is configured in the keystore file. The KeyStoreLoginAuthenticator class uses a `KeyStoreLogin` login module alias, so a Java Authentication and Authorization Service (JAAS) login configuration is required.

catServer3.props file

The server property file stores the server-specific properties, which include the server-specific security properties. See Server properties file for more information. You can use -serverProps option to specify the catalog server property when you run the **startOgServer** command. For this tutorial, a catServer3.props file is in the c directory. The content of the catServer3.props file with the comments removed follows:

```
securityEnabled=true
credentialAuthentication=Required
transportType=TCP/IP
secureTokenManagerType=none
authenticationSecret=ObjectGridDefaultSecret
```

securityEnabled
: The securityEnabled property is set to `true` to indicate that this catalog server is a secure server.

credentialAuthentication
: The credentialAuthentication property is set to `Required`, so any client that is connecting to the server is required to provide a credential. Iin the client property file, the credentialAuthentication value is set to `Supported`, so the server receives the credentials that are sent by the client.

secureTokenManagerType
: The secureTokenManagerType is set to `none` to indicate that the authentication secret is not encrypted when joining the existing servers.

authenticationSecret
: The authenticationSecret property is set to `ObjectGridDefaultSecret`. This secret string is used to join the eXtreme Scale server cluster. When a server joins the data grid, it is challenged to present the secret string. If the secret string of the joining server matches the string in the catalog server, the joining server is accepted. If the string does not match, the join request is rejected.

transportType
: The transportType property is set to `TCP/IP` initially. Later in the tutorial, transport security is enabled.

xsjaas3.config file

Because the KeyStoreLoginAuthenticator implementation uses a login module, you must configure the login model with a JAAS authentication login configuration file. The contents of the xsjaas3.config file follows:

```
KeyStoreLogin{
com.ibm.websphere.objectgrid.security.plugins.builtins.KeyStoreLoginModule required
     keyStoreFile="samples_home/security_extauth/sampleKS3.jks" debug = true;
};
```

If you used a location for *samples_home* other than /wxs_samples/, you need to update the location of the keyStoreFile. This login configuration indicates that the com.ibm.websphere.objectgrid.security.plugins.builtins.KeyStoreLoginModule module is used as the login module. The keystore file is set to the sampleKS3.jks file.

Windows Important: If you are using Windows, the directory path does not support backslashes. If you have used backslashes, you must escape any backslash (\ ) characters in the path. For example, if you want to use the path C:\opt\ibm, enter C:\\opt\\ibm in the properties file. Windows directories with spaces are not supported.

The sampleKS3.jks sample keystore file stores two user IDs and the passwords: manager/manager1 and cashier/cashier1.

You can use the following **keytool** commands to create this keystore:

- `keytool -genkey -v -keystore ./sampleKS3.jks -storepass sampleKS1 -alias manager -keypass manager1 -dname CN=manager,O=acme,OU=OGSample -validity 10000`
- `keytool -genkey -v -keystore ./sampleKS3.jks -storepass sampleKS1 -alias operator -keypass operator1 -dname CN=operator,O=acme,OU=OGSample -validity 10000`

Start the catalog server with security enabled

To start the catalog server, issue the **startOgServer** command with the -clusterSecurityFile and -serverProps parameters to pass in the security properties.

Use a stand-alone installation of WebSphere eXtreme Scale to run the catalog server. When using the stand-alone installation image, you must use the IBM SDK. You can use the SDK that is included with WebSphere Application Server by setting the *JAVA_HOME* variable to point to the IBM SDK. For example, `set JAVA_HOME=was_root/IBM/WebSphere/AppServer/java/`

1. Go to the bin directory.

   ```
   cd wxs_home/bin
   ```

2. Run the **startOgServer** command.

   Linux UNIX

   ```
   ./startOgServer.sh cs1 -listenerPort 16809 -JMXServicePort 16099 -catalogServiceEndPoints
   cs1:[HOST_NAME]:16601:16602 -clusterSecurityFile samples_home/security_extauth/security3.xml
   -serverProps samples_home/security_extauth/catServer3.props -jvmArgs
   -Djava.security.auth.login.config="samples_home/security_extauth/xsjaas3.config"
   ```

   Windows

   ```
   startOgServer.bat cs1 -listenerPort 16809 -JMXServicePort 16099 -catalogServiceEndPoints
   cs1:[HOST_NAME]:16601:16602 -clusterSecurityFile samples_home/security_extauth/security3.xml
   -serverProps samples_home/security_extauth/catServer3.props -jvmArgs
   -Djava.security.auth.login.config="samples_home/security_extauth/xsjaas3.config"
   ```

After you run the **startOgServer** command, a secure server starts with listener port 16809, client port 16601, peer port 16602, and JMX port 16099. If a port conflict exists, change the port number to an unused port number.

Stop a catalog server that has security enabled

You can use the **stopOgServer** command to stop the catalog server.

1. Go to the bin directory.

   ```
   cd wxs_home/bin
   ```

2. Run the **stopOgServer** command. Linux UNIX

   ```
   stopOgServer.sh cs1 -catalogServiceEndPoints localhost:16809 -clientSecurityFile
   samples_home/security_extauth/client3.props
   ```

   Windows

   ```
   stopOgServer.bat cs1 -catalogServiceEndPoints localhost:16809 -clientSecurityFile
   samples_home/security_extauth/client3.props
   ```

Lesson checkpoint

You configured catalog server security by associating the security3.xml, catServer3.props, xsjaas3.config files with the catalog service.

< Previous | Next >
< Previous | Next >

Lesson 2.3: Configure container server security

When a container server connects to the catalog service, the container server gets all the security configurations that are configured in the Object Grid Security XML file. The ObjectGrid Security XML file defines authenticator configuration, the login session timeout value, and other configuration information. A container server also has its own server-specific security properties in the server property file.

Configure the server property file with the -Dobjectgrid.server.props Java virtual machine (JVM) property. The file name specified for this property is an absolute file path, such as *samples_home*/security_extauth/server3.props.
In this tutorial, the container servers are hosted in the `xs1` and `xs2` servers in the `xsCluster` cluster.

server3.props file

The server3.props file is in the *samples_home*/security_extauth/ directory. The content of the server3.props file follows:

```
securityEnabled=true
credentialAuthentication=Required
secureTokenManagerType=none
authenticationSecret=ObjectGridDefaultSecret
```

securityEnabled
: The securityEnabled property is set to `true` to indicate that this container server is a secure server.

credentialAuthentication
: The credentialAuthentication property is set to `Required`, so any client that is connecting to the server is required to provide a credential. In the client property file, the credentialAuthentication property is set to `Supported`, so the server receives the credential that is sent by the client.

secureTokenManagerType
: The secureTokenManagerType is set to `none` to indicate that the authentication secret is not encrypted when joining the existing servers.

authenticationSecret
: The authenticationSecret property is set to `ObjectGridDefaultSecret`. This secret string is used to join the eXtreme Scale server cluster. When a server joins the data grid, it is challenged to present the secret string. If the secret string of the joining server matches the string in the catalog server, the joining server is accepted. If the string does not match, the join request is rejected.

Setting the server properties file with JVM properties

Set the server properties file on the xs1 and xs2 servers. If you are not using the topology for this tutorial, set the server properties file on all of the application servers that you are using to host container servers.

1. Open the Java™ virtual machine page for the server. Servers > WebSphere application servers > *server_name* > Java and Process Management > Process definition > Java Virtual Machine.
2. Add the generic JVM argument:

   ```
   -Dobjectgrid.server.props=samples_home/security_extauth/server3.props
   ```

3. Click OK and save your changes.

Adding the custom login module

The container server uses the same KeyStoreAuthenticator implementation as the catalog server. The KeyStoreAuthenticator implementation uses a KeyStoreLogin login module alias, so you must add a custom login module to the application login model entries.

1. In the WebSphere Application Server administrative console, click Security > Global security > Java Authentication and Authorization Service.
2. Click Application logins.
3. Click New, add an alias `KeyStoreLogin`. Click Apply.
4. Under JAAS login modules, click New.
5. Enter `com.ibm.websphere.objectgrid.security.plugins.builtins.KeyStoreLoginModule` as the module class name, and choose SUFFICIENT as the authentication strategy. Click Apply.
6. Add the `keyStoreFile` custom property with value *samples_home*`/security_extauth/sampleKS.jks`.
   Windows Important: If you are using Windows, the directory path does not support backslashes. If you have used backslashes, you must escape any backslash (\ ) characters in the path. For example, if you want to use the path C:\opt\ibm, enter C:\\opt\\ibm in the properties file. Windows directories with spaces are not supported.
7. Optional: Add the `debug` custom property with value `true`.
8. Save the configuration.

Lesson checkpoint

Now the WebSphere eXtreme Scale server authentication is secured. By configuring this security, all the applications that try to connect to the WebSphere eXtreme Scale servers are required to provide a credential. In this tutorial, the KeyStoreLoginAuthenticator is the authenticator. As a result, the client is required

to provide a user name and password.

< Previous | Next >
< Previous | Next >

Lesson 2.4: Install and run the sample

After authentication is configured, you can install and run the sample application.

Creating a shared library for the EmployeeData.jar file

1. In the WebSphere Application Server administrative console, open the Shared Libraries page. Click Environment > Shared libraries.
2. Choose the cell scope.
3. Create the shared library. Click New. Enter `EmployeeManagementLIB` as the Name. Enter the path to the EmployeeData.jar in the classpath, for example, *samples_home*/WASSecurity/EmployeeData.jar.
4. Click Apply.

Installing the sample

1. Install the EmployeeManagement_extauth.ear file under the *samples_home*/security_extauth directory.
   Important: The EmployeeManagement_extauth.ear file is different from the *samples_home*/WASSecurity/EmployeeManagement.ear file. The manner in which the ObjectGrid session is retrieved has been updated to use the credential that is cached in the client property file in the EmployeeManagement_extauth.ear application. See the comments in the com.ibm.websphere.sample.xs.DataAccessor class in the *samples_home*/WASSecurity/EmployeeManagementWeb project to see the code that was updated for this change.
   a. To begin the installation, click Applications > New application > New Enterprise Application. Choose the detailed path for installing the application.
   b. On the Map modules to servers step, specify the `appCluster` cluster to install the EmployeeManagementWeb module.
   c. On the Map shared libraries step, select the `EmployeeManagementWeb` module.
   d. Click Reference shared libraries. Select the `EmployeeManagementLIB` library.
   e. Map the `webUser` role to All Authenticated in Application's Realm.
   f. Click OK.
   The clients run in the `s1` and `s2` servers in this cluster.
2. Install the sample XSDeployment.ear file that is in the *samples_home*/WASSecurity directory.
   a. To begin the installation, click Applications > New application > New Enterprise Application. Choose the detailed path for installing the application.
   b. On the Map modules to servers step, specify the `xsCluster` cluster to install the `XSDeploymentWeb` web module.
   c. On the Map shared libraries step, select the `XSDeploymentWeb` module.
   d. Click Reference shared libraries. Select the `EmployeeManagementLIB` library.
   e. Click OK.
   The `xs1` and `xs2` servers in this cluster host the container servers.
3. Verify that the catalog server is started. For more information about starting a catalog server for this tutorial, see Start the catalog server with security enabled.
4. Restart the xsCluster cluster. When the xsCluster starts, the XSDeployment application starts, and a container server is started on the xs1 and xs2 servers respectively. If you look at the SystemOut.log file of the xs1 and xs2 servers, the following message that indicates the server properties file is loaded is displayed:

   ```
   CWOBJ0913I: Server property files have been loaded:
   samples_home/security_extauth/server3.props.
   ```

5. Restart the appClusters cluster. When the cluster appCluster starts, the EmployeeManagement application also starts. If you look at the SystemOut.log file of the s1 and s2 servers, you can see the following message that indicates that the client properties file is loaded.

   ```
   CWOBJ0924I: The client property file {0} has been loaded.
   ```

   If you are using WebSphere eXtreme Scale Version 7.0, the English-only CWOBJ9000I message displays to indicate that the client property file has been loaded. If you do not see the expected message, verify that you configured the -Dobjectgrid.server.props or -Dobjectgrid.client.props property in the JVM argument. If you do have the properties configured, make sure the dash (-) is a UTF character.

Running the sample application

1. Run the management.jsp file. In a web browser, access `http://<your_servername>:<port>/EmployeeManagementWeb/management.jsp`. For example, you might use the following URL: `http://localhost:9080/EmployeeManagementWeb/management.jsp`.
2. Provide authentication to the application. Enter the credentials of the user that you mapped to the webUser role. By default, this user role is mapped to all authenticated users. Type any valid user name and password, such as the administrative user name and password. A page to display, add, update, and delete employees displays.
3. Display employees. Click Display an Employee. Enter `emp1@acme.com` as the email address, and click Submit. A message displays that the employee cannot be found.
4. Add an employee. click Add an Employee. Enter `emp1@acme.com` as the email address, enter `Joe` as the given name, and `Doe` as the surname. Click Submit. A message displays that an employee with the `emp1@acme.com` address has been added.
5. Display the new employee. Click Display an Employee. Enter `emp1@acme.com` as the email address with empty fields for the first and surnames, and click Submit. A message displays that the employee has been found, and the correct names are displayed in the given name and surname fields.
6. Delete the employee. Click Delete an employee. Enter `emp1@acme.com` and click Submit. A message is displayed that the employee has been deleted.

Because the catalog server transport type is set to `TCP/IP`, verify that the server s1 and s2 outbound transport setting is not set to `SSL-Required`. Otherwise, an exception occurs. If you look at the system out file of the catalog server, logs/cs1/SystemOut.log file, the following debug output to indicates the key store

authentication:

```
SystemOut     O [KeyStoreLoginModule] initialize: Successfully loaded key store
SystemOut     O [KeyStoreLoginModule] login: entry
SystemOut     O [KeyStoreLoginModule] login: user entered user name: manager
SystemOut     O   Print out the certificates:
...
```

Lesson checkpoint

You installed and ran the sample application.

< Previous | Next >
< Previous | Next >

Module 3: Configure transport security

Configure transport security to secure data transfer between the clients and servers in the configuration.

In the previous module in the tutorial, you enabled WebSphere® eXtreme Scale authentication. With authentication, any application that tries to connect to the WebSphere eXtreme Scale server is required to provide a credential. Therefore, no unauthenticated client can connect to the WebSphere eXtreme Scale server. The clients must be an authenticated application that is running in a WebSphere Application Server cell.

With the configuration up to this module, the data transfer between the clients in the appCluster cluster and servers in the xsCluster cluster is not encrypted. This configuration might be acceptable if your WebSphere Application Server clusters are installed on servers behind a firewall. However, in some scenarios, non-encrypted traffic is not accepted for some reasons even though the topology is protected by firewall. For example, a government policy might enforce encrypted traffic. WebSphere eXtreme Scale supports Transport Layer Security/Secure Sockets Layer (TLS/SSL) for secure communication between ObjectGrid endpoints, which include client servers, container servers, and catalog servers.

In this sample deployment, the eXtreme Scale clients and container servers are all running in the WebSphere Application Server environment. Client or server properties are not necessary to configure the SSL settings because the eXtreme Scale transport security is managed by the Application Server Common Secure Interoperability Protocol Version 2 (CSIV2) transport settings. WebSphere eXtreme Scale servers use the same Object Request Broker (ORB) instance as the application servers in which they run. Specify all the SSL settings for client and container servers in the WebSphere Application Server configuration using these CSIv2 transport settings. You must configure the SSL properties in the server properties file for the catalog server.

Learning objectives

After completing the lessons in this module, you know how to:

- Configure CSIv2 inbound and outbound transport.
- Add SSL properties to the catalog server properties file.
- Check the ORB properties file.
- Run the sample.

Time required

This module takes approximately 60 minutes.

Prerequisites

This step of the tutorial builds upon the previous modules. Complete the previous modules in this tutorial before you configure transport security.

Lessons in this module

- **Lesson 3.1: Configure CSIv2 inbound and outbound transport**

  To configure Transport Layer Security/Secure Sockets Layer (TLS/SSL) for the server transport, set the Common Secure Interoperability Protocol Version 2 (CSIv2) inbound transport and CSIv2 outbound transport to `SSL-Required` for all the WebSphere Application Server servers that host clients, catalog servers, and container servers.
- **Lesson 3.2: Add SSL properties to the catalog server properties file**

  The catalog server is running outside of WebSphere Application Server, so you must configure the SSL properties in the server properties file.
- **Lesson 3.3: Run the sample**

  Restart all the servers and run the sample application again. You should be able to run through the steps without any problems.

< Previous | Next >
< Previous | Next >
< Previous | Next >

Lesson 3.1: Configure CSIv2 inbound and outbound transport

To configure Transport Layer Security/Secure Sockets Layer (TLS/SSL) for the server transport, set the Common Secure Interoperability Protocol Version 2 (CSIv2) inbound transport and CSIv2 outbound transport to `SSL-Required` for all the WebSphere® Application Server servers that host clients, catalog servers, and container servers.

In the tutorial example topology, you must set these properties for the, s1, s2, xs1, and xs2 application servers. The following steps configure the inbound and outbound transports for all the servers in the configuration.

Set the inbound and outbound transports in the administrative console. Make sure that administrative security is enabled.

- **WebSphere Application Server Version 6.1**: Click Security > Secure Administration > Application.. > RMI/IIOP Security and change the transport type to SSL-Required.
- **WebSphere Application Server Version 7.0**: Click Security > Global Security > RMI/IIOP Security > CSIv2 inbound communications. Change the transport type under the CSIv2 Transport Layer to SSL-Required. Repeat this step to configure CSIv2 outbound communications.

You can use centrally managed endpoint security settings, or you can configure SSL repositories. See Common Secure Interoperability Version 2 transport inbound settings for more information.
< Previous | Next >
< Previous | Next >
< Previous | Next >

Lesson 3.2: Add SSL properties to the catalog server properties file

The catalog server is running outside of WebSphere® Application Server, so you must configure the SSL properties in the server properties file.

The other reason to configure the SSL properties in the server properties file is because the catalog server has its own proprietary transport paths that cannot be managed by the WebSphere Application Server Common Secure Interoperability Protocol Version 2 (CSIV2) transport settings. Therefore, you must configure the Secure Sockets Layer (SSL) properties in the server properties file for the catalog server.

SSL properties in the catServer3.props file

```
alias=default
contextProvider=IBMJSSE2
protocol=SSL
keyStoreType=PKCS12
keyStore=/was_root/IBM/WebSphere/AppServer/profiles/
<deployment_manager_name>/config/cells/<cell_name>/nodes/
<node_name>/key.p12
keyStorePassword=WebAS
trustStoreType=PKCS12
trustStore=/was_root/IBM/WebSphere/AppServer/profiles/
<deployment_manager_name>/config/cells/<cell_name>/nodes/
<node_name>/trust.p12
trustStorePassword=WebAS
clientAuthentication=false
```

The catServer3.props file is using the default WebSphere Application Server node level keystore and truststore. If you are deploying a more complex deployment environment, you must choose the correct keystore and truststore. In some cases, you must create a keystore and truststore and import the keys from keystores from the other servers. Notice that the `WebAS` string is the default password of the WebSphere Application Server keystore and truststore. See Default self-signed certificate configuration for more details.
These entries are already included in the *samples_home*/security_extauth/catServer3.props file as comments. You can uncomment the entries and make the appropriate updates for your installation to the *was_root*, <*deployment_manager_name*>, <*cell_name*>, and <*node_name*> variables.

After configuring the SSL properties, change the transportType property value from `TCP/IP` to `SSL-Required`.

SSL properties in the client3.props file

You must also configure the SSL properties in the client3.props file because this file is used when you stop the catalog server that is running outside of WebSphere Application Server.

These properties have no effect on the client servers that are running in WebSphere Application Server because they are using the WebSphere Application Server Common Security Interoperability Protocol Version 2 (CSIV2) transport settings. However, when you stop the catalog server you must provide a client properties file on the **stopOgServer** command. Set the following properties in the <SAMPLES_HOME>/security_extauth/client3.props file to match the values specified above in the catServer3.props file:

```
#contextProvider=IBMJSSE2
#protocol=SSL
#keyStoreType=PKCS12
#keyStore=/was_root/IBM/WebSphere/AppServer/profiles/
<deployment_manager_name>/config/cells/<cell_name>/nodes/
<node_name>/key.p12
#keyStorePassword=WebAS
#trustStoreType=PKCS12
#trustStore=/was_root/IBM/WebSphere/AppServer/profiles/
<deployment_manager_name>/config/cells/<cell_name>/nodes/
<node_name>/trust.p12
#trustStorePassword=WebAS
```

As with the catServer3.props file, you can use the comments that are already provided in the *samples_home*/security_extauth/client3.props file with appropriate updates to *was_root*, <*deployment_manager_name*>, <*cell_name*>, and <*node_name*> variables to match your environment.

Lesson checkpoint

You configured the SSL properties for the catalog server.

< Previous | Next >
< Previous | Next >

Lesson 3.3: Run the sample

Restart all the servers and run the sample application again. You should be able to run through the steps without any problems.

See Lesson 2.4: Install and run the sample for more information about running and installing the sample application.

< Previous | Next >

Module 4: Use Java Authentication and Authorization Service (JAAS) authorization in WebSphere Application Server

Now that you have configured authentication for clients, you can further configure authorization to give different users varying permissions. For example, an "operator" user might only be able to view data, while a "manager" user can perform all operations.

After authenticating a client, as in the previous module in this tutorial, you can give security privileges through eXtreme Scale authorization mechanisms. The previous module of this tutorial demonstrated how to enable authentication for a data grid using integration with WebSphere® Application Server. As a result, no unauthenticated client can connect to the eXtreme Scale servers or submit requests to your system. However, every authenticated client has the same permission or privileges to the server, such as reading, writing, or deleting data that is stored in the ObjectGrid maps. Clients can also issue any type of query. This part of the tutorial demonstrates how to use eXtreme Scale authorization to give authenticated users varying privileges. WebSphere eXtreme Scale uses a permission-based authorization mechanism. You can assign different permission categories that are represented by different permission classes. This module features the MapPermission class. For a list of all possible permissions, see Client authorization programming.

In WebSphere eXtreme Scale, the com.ibm.websphere.objectgrid.security.MapPermission class represents permissions to the eXtreme Scale resources, specifically the methods of the ObjectMap or JavaMap interfaces. WebSphere eXtreme Scale defines the following permission strings to access the methods of ObjectMap and JavaMap:

- **read**: Grants permission to read the data from the map.
- **write**: Grants permission to update the data in the map.
- **insert**: Grants permission to insert the data into the map.
- **remove**: Grants permission to remove the data from the map.
- **invalidate**: Grants permission to invalidate the data from the map.
- **all**: Grants all permissions to read, write, insert, remote, and invalidate.

The authorization occurs when an eXtreme Scale client uses a data access API, such as the ObjectMap ,JavaMap, or EntityManager APIs. The run time checks corresponding map permissions when the method is called. If the required permissions are not granted to the client, an AccessControlException exception results. This tutorial demonstrates how to use Java Authentication and Authorization Service (JAAS) authorization to grant authorization map access for different users.

Learning objectives

After completing the lessons in this module, you know how to:

- Enable authorization for WebSphere eXtreme Scale.
- Enable user-based authorization.

Time required

This module takes approximately 60 minutes.

Lessons in this module

- **Lession 4.1: Enable WebSphere eXtreme Scale authorization**

  To enable authorization in WebSphere eXtreme Scale, you must enable security on a specific ObjectGrid.
- **Lesson 4.2: Enable user-based authorization**

  In the authentication module of this tutorial, you created two users: `operator` and `manager`. You can assign varying permissions to these users with Java Authentication and Authorization Service (JAAS) authorization.

Lession 4.1: Enable WebSphere eXtreme Scale authorization

To enable authorization in WebSphere® eXtreme Scale, you must enable security on a specific ObjectGrid.

To enable authorization on the ObjectGrid, you must set the securityEnabled attribute to true for that particular ObjectGrid in the XML file. For this tutorial, you can either use the XSDeployment_sec.ear file from the *samples_home*/WASSecurity directory, which has already has security set in the objectGrid.xml file, or you can edit the existing objectGrid.xml file to enable security. This lesson demonstrates how to edit the file to enable security.

1. Optional: Extract the files in the XSDeployment.ear file, and then unzip the XSDeploymentWeb.war file.
2. Optional: Open the objectGrid.xml file and set the securityEnabled attribute to `true` on the ObjectGrid level. See an example of this attribute in the following example:

```
<objectGridConfig xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:schemaLocation="http://ibm.com/ws/objectgrid/config ../objectGrid.xsd"
 xmlns="http://ibm.com/ws/objectgrid/config">

    <objectGrids>
        <objectGrid name="Grid" txTimeout="15" securityEnabled="true">
                                    <backingMap name="Map1" />
        </objectGrid>
    </objectGrids>

</objectGridConfig>
```

   If you have multiple ObjectGrids defined, then you must set this attribute on each grid.
3. Optional: Repackage the XSDeploymentWeb.war and XSDeployment.ear files to include your changes.
4. Required: Uninstall the XSDeployment.ear file and then install the updated XSDeployment.ear. You can either use the file you modified in the previous steps, or you can install the XSDeployment_sec.ear file that is provided in the *samples_home*/WASSecurity directory. See Lesson 2.4: Install and run the sample for more information about installing the application.
5. Restart all of the application servers to enable WebSphere eXtreme Scale authorization.

Lesson checkpoint

You enabled security on the ObjectGrid, which also enables authorization on the data grid.

< Previous | Next >
< Previous | Next >

Lesson 4.2: Enable user-based authorization

In the authentication module of this tutorial, you created two users: `operator` and `manager`. You can assign varying permissions to these users with Java™ Authentication and Authorization Service (JAAS) authorization.

Defining the Java Authentication and Authorization Service (JAAS) authorization policy using user principals

You can assign permissions to the users that you previously created. Assign the `operator` user only read permissions to all maps. Assign the `manager` user all permissions. Use the JAAS authorization policy file to grant permissions to principals.
Edit the JAAS authorization file. The xsAuth3.policy file is in the *samples_home*/security_extauth directory.

```
grant codebase "http://www.ibm.com/com/ibm/ws/objectgrid/security/PrivilegedAction"
    principal javax.security.auth.x500.X500Principal
    "CN=operator,O=acme,OU=OGSample" {
    permission com.ibm.websphere.objectgrid.security.MapPermission "Grid.Map1", "read";
};

grant codebase "http://www.ibm.com/com/ibm/ws/objectgrid/security/PrivilegedAction"
    principal javax.security.auth.x500.X500Principal
    "CN=manager,O=acme,OU=OGSample" {
    permission com.ibm.websphere.objectgrid.security.MapPermission "Grid.Map1", "all";
};
```

In this file, the `http://www.ibm.com/com/ibm/ws/objectgrid/security/PrivilegedAction` codebase is a specially reserved URL for ObjectGrid. All ObjectGrid permissions that are granted to principals should use this special code base. The following permissions are assigned in this file:

- The first grant statement grants `read` map permission to the `"CN=operator,O=acme,OU=OGSample"` principal. The `"CN=operator,O=acme,OU=OGSample"` user has only map read permission to the Map1 map the Grid ObjectGrid instance.
- The second grant statement grants all map permission to the `"CN=manager,O=acme,OU=OGSample"` principal. The `"CN=manager,O=acme,OU=OGSample"` user has all permissions to the Map1 map in the Grid ObjectGrid instance.

Setting the JAAS authorization policy file using JVM properties

Use the following steps to set JVM properties for the xs1 and xs2 servers, which are in the xsCluster cluster. If you are using a topology that is different from the sample topology that is used in this tutorial, set the file on all of your container servers.

1. In the administrative console, click Servers > Application servers > *server_name* > Java and process management > Process definition > Java virtual machine.
2. Add the following generic JVM arguments:

   ```
   -Djava.security.policy=samples_home/security_extauth/xsAuth3.policy
   ```

3. Click OK and save your changes.

Running the sample application to test authorization

You can use the sample application to test the authorization settings. The manager user continues to have all permissions in the Map1 map, including displaying and adding employees. The operator user should only be able to view employees because that user was assigned read permission only.

1. Restart all of the application servers that are running container servers. For this tutorial, restart the `xs1` and `xs2` servers.
2. Open the `EmployeeManagementWeb` application. In a web browser, open `http://<host>:<port>/EmployeeManagermentWeb/management.jsp`.
3. Log in to the application using any valid user name and password.
4. Attempt to display an employee. Click Display an Employee and search for the `authemp1@acme.com` email address. A message displays that the user cannot be found.
5. Add an employee. Click Add an Employee. Add the email `authemp1@acme.com`, the given name `Joe`, and the surname `Doe`. Click Submit. A message displays that the employee has been added.
6. Edit the *samples_home*/security_extauth/client3.props file. Change the value of credentialGeneratorProps property from `manager manager1` to `operator operator1`. After you edit the file, the servlet uses user name "operator" and password "operator1" to authenticate to the WebSphere eXtreme Scale servers.
7. Restart the appCluster cluster to pick up the changes in the *samples_home*/security_extauth/client3.props file.
8. Attempt to display an employee. Click Display an Employee and search for the `authemp1@acme.com` email address. The employee is displayed.
9. Add an employee. Click Add an Employee. Add the email `authemp2@acme.com`, the given name `Joe`, and the surname `Doe`. Click Submit. The following message displays:

   ```
   An exception occurs when Add the employee. See below for detailed exception messages.
   ```

   The detailed exception text follows:

   ```
   java.security.AccessControlException: Access denied
   (com.ibm.websphere.objectgrid.security.MapPermission Grid.Map1 insert)
   ```

   This message displays because the `operator` user does not have permission to insert data into the Map1 map.

If you are running with a version of WebSphere Application Server that is earlier than Version 7.0.0.11, you might see a java.lang.StackOverflowError error on the container server. This error is caused by a problem with the IBM Developer Kit. The problem is fixed in the IBM Developer Kit that is shipped with WebSphere Application Server Version 7.0.0.11 and later.

Lesson checkpoint

In this lesson, you configured authorization by assigning permissions to specific users.

< Previous | Next >
< Previous | Next >

Module 5: Use the xscmd utility to monitor data grids and maps

You can use the **xscmd** utility to show the primary data grids and map sizes of the `Grid` data grid. The **xscmd** tool uses the MBean to query all of the data grid artifacts, such as primary shards, replica shards, container servers, map sizes, and other data.

In this tutorial, the catalog server is running as a stand-alone Java SE server. The container servers are running in WebSphere® Application Server application servers.
For the catalog server, a MBean server is created in the stand-alone Java virtual machine (JVM). When you use the **xscmd** tool on the catalog server, WebSphere eXtreme Scale security is used.

For the container servers, the WebSphere eXtreme Scale run time registers the Managed Beans (MBean) with the MBean server that is created by the WebSphere Application Server run time. The security that is used by the **xscmd** tool is provided by the WebSphere Application Server MBean security.

1. Using a command-line tool, open the *DMGR_PROFILE*/bin directory.
2. Run the **xscmd** tool. Use the -c showPlacement -st P parameters as in the following examples:

   Linux UNIX

   ```
   xscmd.sh -c showPlacement -cep localhost:16099 -g Grid -ms mapSet -sf P
   -user manager -pwd manager1
   ```

   Windows

   ```
   xscmd.bat -c showPlacement -cep localhost:16099 -g Grid -m mapSet -sf P
   -user manager -pwd manager1
   ```

8.5+ Attention:
If you use the following command to access the data grid, you might also be authorized to perform administrative actions, such as listAllJMXAddresses:

```
./xscmd.sh -user <user> -password <password> <other_parameters>
```

If this operation works for this user, then any **xscmd** operation might also be performed by the same user. For more information, see Troubleshooting security
The user name and password are passed to the catalog server for authentication.

3. View the command results.

```
*** Showing all primaries for grid - Grid & mapset - mapSet
Partition Container Host Server
0 myCell02\myNode04\xs2_C-1 myhost.mycompany.com myCell02\myNode04\xs2
1 myCell02\myNode04\xs2_C-1 myhost.mycompany.com myCell02\myNode04\xs2
2 myCell02\myNode04\xs2_C-1 myhost.mycompany.com myCell02\myNode04\xs2
3 myCell02\myNode04\xs2_C-1 myhost.mycompany.com myCell02\myNode04\xs2
4 myCell02\myNode04\xs2_C-1 myhost.mycompany.com myCell02\myNode04\xs2
```

4. Run the **xscmd** tool. Use the -c showMapSizes parameter as in the following examples:
Linux UNIX

```
xscmd.sh -c showMapSizes -cep localhost:16099 -g Grid -ms mapSet  -user manager -pwd manager1
```

Windows

```
xscmd.bat -c showMapSizes -cep localhost:16099 -g Grid -ms mapSet -user manager -pwd manager1
```

The user name and password are passed to the catalog server for authentication. After you run the command, you are prompted for the WebSphere Application Server user ID and password to authenticate to WebSphere Application Server. You must provide this login information because the -c showMapSizes option gets the map size from each container server, which requires the WebSphere Application Server security.

5. Optional: You can change the PROFILE/properties/sas.client.props file to run the command without the user ID and password being required. Change the com.ibm.CORBA.loginSource property from `prompt` to `properties` and then provide the user ID and password. An example of the properties in the PROFILE/properties/sas.client.props file follows:

```
com.ibm.CORBA.loginSource=properties
# RMI/IIOP user identity
com.ibm.CORBA.loginUserid=Admin
com.ibm.CORBA.loginPassword=xxxxxx
```

6. Optional: If you are using the **xscmd** command on a WebSphere eXtreme Scale stand-alone installation, then you must add the following options:
   - If you are using WebSphere eXtreme Scale security:

     ```
     -user
     -pwd
     ```

   - If you are using WebSphere eXtreme Scale security with custom credential generation:

     ```
     -user
     -pwd
     -cgc
     -cgp
     ```

   - If SSL is enabled:

     ```
     -tt
     -cxpv
     -prot
     -ks
     -ksp
     -kst
     -ts
     -tsp
     -tst
     ```

If WebSphere eXtreme Scale security and SSL are both enabled, then both set of parameters are required.

Related tasks:

Monitoring with the xscmd utility
Administering with the xscmd utility

Lesson checkpoint

You used the **xscmd** tool to monitor data grids and maps in your configuration.

< Previous | Next >
< Previous | Next >

Tutorial: Running eXtreme Scale bundles in the OSGi framework

The OSGi sample builds on the Google Protocol Buffers serializer samples. When you complete this set of lessons, you will have run the serializer sample plug-ins in the OSGi framework.

Learning objectives

This sample demonstrates the OSGi bundles. The serializer plug-in is incidental and is not required. The OSGi sample is available on the WebSphere eXtreme Scale samples gallery. You must download the sample, and extract it into the *wxs_home*/samples directory. The root directory for the OSGi sample is wxs_home/samples/OSGiProto.

The command examples in this tutorial assume that you are running on the UNIX operating system. You must adjust the command example to run on a Windows operating system.

After completing the lessons in this tutorial, you will understand the OSGi sample concepts and know how to complete the following objectives:

- Install the WebSphere® eXtreme Scale server bundle into the OSGi container to start the eXtreme Scale server.
- Set up your eXtreme Scale development environment to run the sample client.
- Use the xscmd command to query the service ranking of the sample bundle, upgrade it to a new service ranking, and verify the new service ranking.

Time required

This module takes approximately 60 minutes to complete.

Prerequisites

In addition to downloading and extracting the serializer samples, this tutorial also has the following prerequisites:

- Install and extract the eXtreme Scale product
- Set up the Eclipse Equinox Environment
- **Introduction: Starting and configuring the eXtreme Scale server and container to run plug-ins in the OSGi framework**

  In this tutorial you start an eXtreme Scale server in the OSGi framework, start an eXtreme Scale container, and wire the sample plug-ins with eXtreme Scale runtime environment.
- **Module 1: Preparing to install and configure eXtreme Scale server bundles**

  Complete this module to explore OSGi sample bundles and examine configuration files that you use to configure the eXtreme Scale server.
- **Module 2: Installing and starting eXtreme Scale bundles in the OSGi framework**

  Use the lessons in this module to install the eXtreme Scale server bundle into the OSGi container, and start the WebSphere eXtreme Scale server.
- **Module 3: Running the eXtreme Scale sample client**

  The WebSphere eXtreme Scale server is now running in an OSGi environment. Complete the steps in this module to run an WebSphere eXtreme Scale client that inserts data into the grid.
- **Module 4: Querying and upgrading the sample bundle**

  Complete the lessons in this module to use the **xscmd** command to query the service ranking of the sample bundle, upgrade it to a new service ranking, and verify the new service ranking.

< Previous | Next >
< Previous | Next >

Introduction: Starting and configuring the eXtreme Scale server and container to run plug-ins in the OSGi framework

In this tutorial you start an eXtreme Scale server in the OSGi framework, start an eXtreme Scale container, and wire the sample plug-ins with eXtreme Scale runtime environment.

Learning objectives

After completing the lessons in this tutorial you will understand the OSGi sample concepts and know how to complete the following objectives:

- Install the WebSphere® eXtreme Scale server bundle into the OSGi container to start the eXtreme Scale server.
- Set up your eXtreme Scale development environment to run the sample client.
- Use the xscmd command to query the service ranking of the sample bundle, upgrade it to a new service ranking, and verify the new service ranking.

Time required

This tutorial takes approximately 60 minutes to finish. If you explore other concepts related to this tutorial, it might take longer to complete.

Skill level

Intermediate.

Audience

Developers and administrators who want to build, install, and run eXtreme Scale bundles into the OSGi framework.

System requirements

- Luminis OSGi Configuration Admin command line client, version 0.2.5
- Apache Felix File Install, version 3.0.2
- When using Eclipse Gemini as the Blueprint container provider, the following are required:
  - Eclipse Gemini Blueprint, version 1.0.0
  - Spring Framework, version 3.0.5
  - SpringSource AOP Alliance API, version 1.0.0
  - SpringSource Apache Commons Logging, version 1.1.1
- When using Apache Aries as the Blueprint Container provider, you must have the following requirements:
  - Apache Aries, latest snapshot
  - ASM library
  - PAX logging

Prerequisites

To complete this tutorial, you must download the sample, and extracted it into the wxs_home/samples directory. The root directory for the OSGi sample is wxs_home/samples/OSGiProto.

Expected results

When you complete this tutorial, you will have installed the sample bundles and run an eXtreme Scale client to insert data into the grid. You can also expect to query and update those sample bundles using the dynamic capabilities that the OSGi container provides.

Modules in this tutorial

- **Module 1: Preparing to install and configure eXtreme Scale server bundles**

  Complete this module to explore OSGi sample bundles and examine configuration files that you use to configure the eXtreme Scale server.
- **Module 2: Installing and starting eXtreme Scale bundles in the OSGi framework**

  Use the lessons in this module to install the eXtreme Scale server bundle into the OSGi container, and start the WebSphere eXtreme Scale server.
- **Module 3: Running the eXtreme Scale sample client**

  The WebSphere eXtreme Scale server is now running in an OSGi environment. Complete the steps in this module to run an WebSphere eXtreme Scale client that inserts data into the grid.
- **Module 4: Querying and upgrading the sample bundle**

  Complete the lessons in this module to use the **xscmd** command to query the service ranking of the sample bundle, upgrade it to a new service ranking, and verify the new service ranking.

Module 1: Preparing to install and configure eXtreme Scale server bundles

Complete this module to explore OSGi sample bundles and examine configuration files that you use to configure the eXtreme Scale server.

Learning objectives

After completing the lessons in this module, you will understand the concepts and know how to complete the following objectives:

- Locate and explore the bundles that are included in the OSGi sample.
- Examine configuration files that are used to configure the eXtreme Scale grid and server.

Lessons in this module

- **Lesson 1.1: Understand the OSGi sample bundles**

  Complete this lesson to locate and explore the bundles that are provided in the OSGi sample.
- **Lesson 1.2: Understand the OSGi configuration files**

  The OSGi sample includes configuration files that you use to start and configure the WebSphere® eXtreme Scale grid and server.

< Previous | Next >
< Previous | Next >

Lesson 1.1: Understand the OSGi sample bundles

Complete this lesson to locate and explore the bundles that are provided in the OSGi sample.

OSGi sample bundles

Other than the bundles that are configured in the config.ini file, which is shown in the topic about setting up the Eclipse Equinox environment, the following additional bundles are used in the OSGi sample:

objectgrid.jar
: The WebSphere eXtreme Scale server runtime bundle. This bundle is located in the *wxs_home*/lib directory.

com.google.protobuf_2.4.0a.jar
: The Google Protocol Buffers, version 2.4.0a bundle. This bundle is located in the *wxs_sample_osgi_root*/lib directory.

ProtoBufSamplePlugins-1.0.0.jar
: Version 1.0.0 of the user plug-in bundle with sample ObjectGridEventListener and MapSerializerPlugin plug-in implementations. This bundle is located in the *wxs_sample_osgi_root*/lib directory. The services are configured with service ranking 1.
This version uses the standard Blueprint XML to configure the eXtreme Scale plug-in services. The service class is a user-implemented class for WebSphere eXtreme Scale interface, com.ibm.websphere.objectgrid.plugins.osgi.PluginServiceFactory. The user-implemented class creates a bean for each request and works similar to a prototype-scoped bean.

ProtoBufSamplePlugins-2.0.0.jar
: Version 2.0.0 of the user plug-in bundle with sample ObjectGridEventListener and MapSerializerPlugin plug-in implementations. This bundle is located in the *wxs_sample_osgi_root*/lib directory. The services are configured with service ranking 2.
This version uses the standard Blueprint XML to configure the eXtreme Scale plug-in services. The service class is using a WebSphere eXtreme Scale, built-in class, com.ibm.websphere.objectgrid.plugins.osgi.PluginServiceFactoryImpl, which uses the BlueprintContainer service. Using the standard Blueprint XML configuration, the beans can be configured either as a prototype scope or singleton scope. The bean is not configured as a shard scope.

ProtoBufSamplePlugins-Gemini-3.0.0.jar
: Version 3.0.0 of the user plug-in bundle with sample ObjectGridEventListener and MapSerializerPlugin plug-in implementations. This bundle is located in the *wxs_sample_osgi_root*/lib directory. The services are configured with service ranking 3.
This version uses the Eclipse Gemini-specific Blueprint XML to configure the eXtreme Scale plug-in services. The service class is using a WebSphere eXtreme Scale built-in class, com.ibm.websphere.objectgrid.plugins.osgi.PluginServiceFactoryImpl, which uses the BlueprintContainer service. The way to configure a shard scope bean is using a Gemini-specific approach. This version configures the myShardListener bean as a shard scope bean by providing {http://www.ibm.com/schema/objectgrid}shard as the scope value, and configuring a dummy attribute so that the custom scope is recognized by Gemini. This is due to the following Eclipse issue: https://bugs.eclipse.org/bugs/show_bug.cgi?id=348776

ProtoBufSamplePlugins-Aries-4.0.0.jar
: Version 4.0.0 of the user plug-in bundle with sample ObjectGridEventListener and MapSerializerPlugin plug-in implementations. This bundle is located in the *wxs_sample_osgi_root*/lib directory. The services are configured with service ranking 4.
This version uses standard Blueprint XML to configure the eXtreme Scale plug-in services. The service class is using a WebSphere eXtreme Scale, built-in class, com.ibm.websphere.objectgrid.plugins.osgi.PluginServiceFactoryImpl, which uses the BlueprintContainer service. Using the standard Blueprint XML configuration, the beans can be configured using a custom scope. This version configures the myShardListenerbean as a shard scoped bean by providing {http://www.ibm.com/schema/objectgrid}shard as the scope value.

ProtoBufSamplePlugins-Activator-5.0.0.jar
: Version 5.0.0 of the user plug-in bundle with sample ObjectGridEventListener and MapSerializerPlugin plug-in implementations. This bundle is located in the *wxs_sample_osgi_root*/lib directory. The services are configured with service ranking 5.
This version does not use Blueprint container at all. In this version, the services are registered using OSGi service registration. The service class is a user-implemented class for the WebSphere eXtreme Scale interface, com.ibm.websphere.objectgrid.plugins.osgi.PluginServiceFactory. The user-implemented class creates a bean for each request. It works similar to a prototype-scoped bean.

Lesson checkpoint

By exploring the bundles that are provided with the OSGi sample, you can better understand how to develop your own implementations that will run in the OSGi container.

You learned:

- About bundles that included with the OSGi sample
- The location of those bundles
- The service ranking that each bundle has been configured with

< Previous | Next >
< Previous | Next >

Lesson 1.2: Understand the OSGi configuration files

The OSGi sample includes configuration files that you use to start and configure the WebSphere® eXtreme Scale grid and server.

OSGi configuration files

In this lesson, you will explore the following configuration files that are included with the OSGI sample:

- collocated.server.properties
- protoBufObjectGrid.xml
- protoBufDeployment.xml
- blueprint.xml

collocated.server.properties

A server configuration is required to start a server. When the eXtreme Scale server bundle is started, it does not start a server. It waits for the configuration PID, `com.ibm.websphere.xs.server`, to be created with a server property file. This server property file specifies the server name, port number, and other server properties.
In most cases, you create a configuration to set the server property file. In rare cases, you might want only to start a server, with every property set to a default value. In that case, you can create a configuration called `com.ibm.websphere.xs.server` with value set to default.

For more details about the server property file, see the Server properties file topic.

The OSGi sample server properties file starts a single catalog. This sample property file starts a single catalog service and a container server in the OSGi framework process. eXtreme Scale clients connect to port 2809 and JMX clients connect to port 1099. The content of the sample server property file is:

```
serverName=collocatedServer
isCatalog=true
catalogClusterEndPoints=collocatedServer:localhost:6601:6602
traceSpec=ObjectGridOSGi=all=enabled
traceFile=logs/trace.log
listenerPort=2809
JMXServicePort=1099
```

protoBufObjectGrid.xml

The sample protoBufObjectGrid.xml ObjectGrid descriptor XML file contains the following content, with comments removed.

```
<objectGridConfig
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://ibm.com/ws/objectgrid/config ../objectGrid.xsd"
    xmlns="http://ibm.com/ws/objectgrid/config">

    <objectGrids>
        <objectGrid name="Grid" txTimeout="15">

            <bean
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsosgiconfigfiles_ObjectGridEventLis
tener"
                osgiService="myShardListener"/>

            <backingMap name="Map" readOnly="false"
                lockStrategy="PESSIMISTIC" lockTimeout="5"
                copyMode="COPY_TO_BYTES"
                pluginCollectionRef="serializer"/>

        </objectGrid>
    </objectGrids>

    <backingMapPluginCollections>
        <backingMapPluginCollection
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsosgiconfigfiles_serializer">
            <bean
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsosgiconfigfiles_MapSerializerPlugi
n"
                osgiService="myProtoBufSerializer"/>"/>
        </backingMapPluginCollection>
    </backingMapPluginCollections>
        </objectGridConfig>
```

There are two plug-ins configured in this ObjectGrid descriptor XML file:

ObjectGridEventListener
: The shard-level plug-in. For each ObjectGrid instance, there is an instance of ObjectGridEventListener. It is configured to use the OSGi service myShardListener. That means when the grid is created, the ObjectGridEventListener plug-in uses the OSGi service myShardListener with the highest service ranking available.

MapSerializerPlugin
: The map-level plug-in. For the backing map named`Map`, there is a MapSerializerPlugin plug-in configured. It is configured to use the OSGI service myProtoBufSerializer. That means when the map is created, the MapSerializerPlugin plug-in uses the service, myProtoBufSerializer, with the highest ranked service ranking available.

protoBufDeployment.xml

The deployment descriptor XML file describes the deployment policy for the grid named `Grid`, which uses five partitions. See the following code example of the XML file:

```
<deploymentPolicy
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="http://ibm.com/ws/objectgrid/deploymentPolicy ../deploymentPolicy.xsd"
        xmlns="http://ibm.com/ws/objectgrid/deploymentPolicy">

  <objectgridDeployment objectgridName="Grid">
    <mapSet name="MapSet" numberOfPartitions="5">
      <map ref="Map"/>
    </mapSet>
  </objectgridDeployment>
</deploymentPolicy>
```

blueprint.xml

As an alternative to using the collocated.server.properties file in conjunction with configuration PID, `com.ibm.websphere.xs.server`, you can include the ObjectGrid XML and deployment XML files in an OSGi bundle, along with a Blueprint XML file as shown in the following example:

```
<blueprint
         xmlns="http://www.osgi.org/xmlns/blueprint/v1.0.0"

xmlns:objectgrid="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsosgiconfigfiles_http
://www.ibm.com/schema/objectgrid"
       default-activation="lazy">

    <objectgrid:server
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsosgiconfigfiles_server"
isCatalog="true"
                name="server"
                tracespec="ObjectGridOSGi=all=enabled"
                tracefile="C:/Temp/logs/trace.log"
                workingDirectory="C:/Temp/working"
                jmxport="1099">
        <objectgrid:catalog host="localhost" port="2809"/>
    </objectgrid:server>

    <objectgrid:container
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsosgiconfigfiles_container"
        objectgridxml="/META-INF/objectgrid.xml"
       deploymentxml="/META-INF/deployment.xml"
         server="server"/>
</blueprint>
```

Lesson checkpoint

In this lesson, you learned about the configuration files that are used in the OSGi sample. Now, when you start and configure the eXtreme Scale grid and server, you will understand which files are being used in these processes and how these files interact with your plug-ins in the OSGi framework.

< Previous | Next >
< Previous | Next >

Module 2: Installing and starting eXtreme Scale bundles in the OSGi framework

Use the lessons in this module to install the eXtreme Scale server bundle into the OSGi container, and start the WebSphere® eXtreme Scale server.

Starting the server in the OSGi framework does not mean that your OSGi bundles are ready to run. You must configure the server properties and containers so that the OSGi bundles that you install are recognized and can run correctly.

Learning objectives

After completing the lessons in this module, you will understand the concepts and know how to complete the following tasks:

- Install eXtreme Scale bundles using the Equinox OSGi console.
- Configure the eXtreme Scale server.
- Configure the eXtreme Scale container.
- Install and start eXtreme Scale sample bundles.

Prerequisites

To complete this module, the following tasks are required before you begin:

- Install and extract the eXtreme Scale product
- Set up the Eclipse Equinox Environment

You must also prepare to access the following files to complete the lessons in this module:

- objectgrid.jar bundle. You install this eXtreme Scale bundle.

- collocated.server.properties file. You add the server properties to this configuration file.

You can expect to install and start the following bundles:

- protobuf-java-2.4.0a-bundle.jar bundle
- ProtoBufSamplePlugins-1.0.0.jar bundle

Lessons in this module

- **Lesson 2.1: Start the console and install the eXtreme Scale server bundle**

  In this lesson, you use the Equinox OSGi console to install the WebSphere eXtreme Scale server bundle.
- **Lesson 2.2: Customize and configure the eXtreme Scale server**

  Use this lesson to customize and add the server properties to the WebSphere eXtreme Scale server.
- **Lesson 2.3: Configure the eXtreme Scale container**

  Complete this lesson to configure a container, which includes the WebSphere eXtreme Scale ObjectGrid descriptor XML file and ObjectGrid deployment XML file. These files include the configuration for the grid and its topology.
- **Lesson 2.4: Install the Google Protocol Buffers and sample plug-in bundles**

  Complete this tutorial to install the protobuf-java-2.4.0a-bundle.jar bundle and the ProtoBufSamplePlugins-1.0.0.jar plug-in bundle using the Equinox OSGi console.
- **Lesson 2.5: Start the OSGi bundles**

  The WebSphere eXtreme Scale server is packaged as an OSGi server bundle. Complete this lesson to install the eXtreme Scale server bundle as well as other OSGi bundles that you have installed.

< Previous | Next >
< Previous | Next >

Lesson 2.1: Start the console and install the eXtreme Scale server bundle

In this lesson, you use the Equinox OSGi console to install the WebSphere® eXtreme Scale server bundle.

1. Use the following command to start the Equinox OSGi console:

   ```
   cd equinox_root
   java -jar plugins\org.eclipse.osgi_3.6.1.R36x_v20100806.jar -console
   ```

2. After the OSGi console is started, issue the `ss` command in the console, and the following bundles are started:
   Attention: If you completed the task, Installing eXtreme Scale bundles, then the bundle has already been activated. If the bundle is started, then stop the bundle before you complete this step.

   ```
    Eclipse Gemini output:
   osgi> ss
   Framework is launched.
   id State Bundle
   0 ACTIVE org.eclipse.osgi_3.6.1.R36x_v20100806
   1 ACTIVE org.eclipse.osgi.services_3.2.100.v20100503

   ```

```
10 ACTIVE org.apache.felix.fileinstall_3.0.2
11 ACTIVE net.luminis.cmc_0.2.5
```

3. Install the objectgrid.jar bundle. To start a server in the Java™ virtual machine (JVM), you need to install an eXtreme Scale server bundle. This eXtreme Scale server bundle can start a server and create containers. Use the following command to install the objectgrid.jar file:

   ```
   osgi> install file:///wxs_home/lib/objectgrid.jar
   ```

   See the following example:

   ```
   osgi> install file:///opt/wxs/ObjectGrid/lib/objectgrid.jar
   ```

   Equinox displays its bundle ID; for example:

   ```
   Bundle id is 19
   ```

   Remember: Your bundle ID might be different. The file path must be an absolute URL to the bundle path. Relative paths are not supported.

Lesson checkpoint

In this lesson, you used the Equinox OSGi console to install the objectgrid.jar bundle, which you will use to start a server and create a container later in this tutorial.

< Previous | Next >
< Previous | Next >

Lesson 2.2: Customize and configure the eXtreme Scale server

Use this lesson to customize and add the server properties to the WebSphere® eXtreme Scale server.

1. Edit the wxs_sample_osgi_root/projects/server/properties/collocated.server.properties file.
   a. Change the traceFile property to `equinox_root/logs/trace.log`.
2. Save the file.
3. Enter the following lines of code in the OSGI console to create the server configuration from the file. The following example is displayed on multiple lines for publication purposes.

   ```
   osgi> cm create com.ibm.websphere.xs.server
   osgi> cm put com.ibm.websphere.xs.server objectgrid.server.props
   wxs_sample_osgi_root/projects/server/properties/collocated.server.properties
   ```

4. To view the configuration, run the following command:

   ```
   osgi> cm get com.ibm.websphere.xs.server
   Configuration for service (pid) "com.ibm.websphere.xs.server"
   (bundle location = null)
   key                    value
   ----                   ----
   objectgrid.server.props  wxs_sample_osgi_root/projects/server/properties/collocated.server.properties
   service.pid              com.ibm.websphere.xs.server
   ```

Lesson checkpoint

In this lesson, you edited the wxs_sample_osgi_root/projects/server/properties/collocated.server.properties file to specify server settings, such as the working directory and the location for the trace log files.

< Previous | Next >
< Previous | Next >

Lesson 2.3: Configure the eXtreme Scale container

Complete this lesson to configure a container, which includes the WebSphere® eXtreme Scale ObjectGrid descriptor XML file and ObjectGrid deployment XML file. These files include the configuration for the grid and its topology.

To create a container, first create a configuration service using the managed service factory process identification number (PID), com.ibm.websphere.xs.container. The service configuration is a managed service factory, so you can create multiple service PIDs from the factory PID. Then, to start the container service, set the objectgridFile and deploymentPolicyFile PIDs to each service PID.

Complete the following steps to customize and add the server properties to the OSGi framework:

1. In the OSGI console, enter the following command to create the container from the file:

   ```
   osgi> cm createf com.ibm.websphere.xs.container
   PID: com.ibm.websphere.xs.container-1291179621421-0
   ```

2. Enter the following commands to bind the newly created PID to the ObjectGrid XML files.
   Remember: The PID number will be different from what is included in this example.

```
osgi> cm put com.ibm.websphere.xs.container-1291179621421-0 objectgridFile
wxs_sample_osgi_root/projects/server/META-INF/protoBufObjectgrid.xml

osgi> cm put com.ibm.websphere.xs.container-1291179621421-0 deploymentPolicyFile
wxs_sample_osgi_root/projects/server/META-INF/protoBufDeployment.xml
```

3. Use the following command to display the configuration:

```
osgi> cm get com.ibm.websphere.xs.container-1291760127968-0
Configuration for service (pid) "com.ibm.websphere.xs.container-1291760127968-0"
(bundle location = null)

key                    value
------                 ------
deploymentPolicyFile   /opt/wxs/ObjectGrid/samples/OSGiProto/server/META-INF/protoBufDeployment.xml
objectgridFile         /opt/wxs/ObjectGrid/samples/OSGiProto/server/META-INF/protoBufObjectgrid.xml
service.factoryPid     com.ibm.websphere.xs.container
service.pid            com.ibm.websphere.xs.container-1291760127968-0
```

Lesson checkpoint

In this lesson, you created a configuration service, which you used to create an eXtreme Scale container. Since the ObjectGrid XML files contain the configuration for the grid and its topology, you had to bind the container that you created to those ObjectGrid XML files. With this configuration, the eXtreme Scale container can recognize the OSGi bundles that you will run later in this tutorial.

< Previous | Next >
< Previous | Next >

Lesson 2.4: Install the Google Protocol Buffers and sample plug-in bundles

Complete this tutorial to install the protobuf-java-2.4.0a-bundle.jar bundle and the ProtoBufSamplePlugins-1.0.0.jar plug-in bundle using the Equinox OSGi console.

Install the Google Protocol Buffers plug-in

Complete the following steps to install the Google Protocol Buffers plug-in.
In the OSGI console, enter the following command to install the plug-in:

```
osgi> install file:///wxs_sample_osgi_root/lib/com.google.protobuf_2.4.0a.jar
```

The following output is displayed:

```
Bundle ID is 21
```

Sample plug-in bundles overview

The OSGi sample includes five sample bundles that include eXtreme Scale plug-ins, including a custom ObjectGridEventListener and MapSerializerPlugin plug-in. The MapSerializerPlugin plug-in uses the Google Protocol Buffers sample and messages provided by the MapSerializerPlugin sample.

The following bundles are located in *wxs_sample_osgi_root*/lib directory: ProtoBufSamplePlugins-1.0.0.jar and the ProtoBufSamplePlugins-2.0.0.jar.

The blueprint.xml file has the following content with comments removed:

```
<blueprint xmlns="http://www.osgi.org/xmlns/blueprint/v1.0.0">
        <bean
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsinstallgoogleOSGi_myShardListener"
class="com.ibm.websphere.samples.xs.proto.osgi.MyShardListenerFactory"/>
        <service ref="myShardListener" interface="com.ibm.websphere.objectgrid.plugins.osgi.PluginServiceFactory"
ranking="1">
        </service>

        <bean
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsinstallgoogleOSGi_myProtoBufSerial
izer" class="com.ibm.websphere.samples.xs.proto.osgi.ProtoMapSerializerFactory">
                <property name="keyType" value="com.ibm.websphere.samples.xs.serializer.app.proto.DataObjects1$OrderKey"
/>
                <property name="valueType" value="com.ibm.websphere.samples.xs.serializer.app.proto.DataObjects1$Order"
/>
        </bean>

        <service ref="myProtoBufSerializer" interface="com.ibm.websphere.objectgrid.plugins.osgi.PluginServiceFactory"
                ranking="1">
        </service>
</blueprint>
```

The Blueprint XML file exports two services, myShardListener and myProtoBufSerializer. These two services are referenced in the protoBufObjectgrid.xml file.

Install the sample plug-in bundle

Complete the following steps to install the ProtoBufSamplePlugins-1.0.0.jar bundle.

Run the following command in the Equinox OSGi console to install the ProtoBufSamplePlugins-1.0.0.jar plugin bundle:

```
osgi> install file:///wxs_sample_osgi_root/lib/ProtoBufSamplePlugins-1.0.0.jar
```

The following output is displayed:

```
Bundle ID is 22
```

Lesson checkpoint

In this lesson, you installed the protobuf-java-2.4.0a-bundle.jar bundle and the ProtoBufSamplePlugins-1.0.0.jar plug-in bundle.

< Previous | Next >
< Previous | Next >

Lesson 2.5: Start the OSGi bundles

The WebSphere® eXtreme Scale server is packaged as an OSGi server bundle. Complete this lesson to install the eXtreme Scale server bundle as well as other OSGi bundles that you have installed.

1. Run the **ss** command to view the IDs for each bundle.

   ```
   osgi> ss

   Framework is launched.

   id State Bundle
   0 ACTIVE org.eclipse.osgi_3.6.1.R36x_v20100806
   1 ACTIVE org.eclipse.osgi.services_3.2.100.v20100503
   2 ACTIVE org.eclipse.osgi.util_3.2.100.v20100503
   3 ACTIVE org.eclipse.equinox.cm_1.0.200.v20100520
   4 ACTIVE com.springsource.org.apache.commons.logging_1.1.1
   5 ACTIVE com.springsource.org.aopalliance_1.0.0
   6 ACTIVE org.springframework.aop_3.0.5.RELEASE
   7 ACTIVE org.springframework.asm_3.0.5.RELEASE
   8 ACTIVE org.springframework.beans_3.0.5.RELEASE
   9 ACTIVE org.springframework.context_3.0.5.RELEASE
   10 ACTIVE org.springframework.core_3.0.5.RELEASE
   11 ACTIVE org.springframework.expression_3.0.5.RELEASE
   12 ACTIVE org.apache.felix.fileinstall_3.0.2
   13 ACTIVE net.luminis.cmc_0.2.5
   15 ACTIVE org.eclipse.gemini.blueprint.core_1.0.0.RELEASE
   16 ACTIVE org.eclipse.gemini.blueprint.extender_1.0.0.RELEASE
   17 ACTIVE org.eclipse.gemini.blueprint.io_1.0.0.RELEASE
   19 RESOLVED com.ibm.websphere.xs.server_7.1.1
   21 RESOLVED Google_ProtoBuf_2.4.0
   22 RESOLVED ProtoBufPlugins_1.0.0
   ```

2. Start each bundle that you have installed. You must start the bundles in a specific order. See the order of the bundle IDs from the previous example.
   a. Start the sample plug-in bundle, ProtoBufPlugins_1.0.0. Run the following command in the Equinox OSGi console to start the bundle. In this example, the bundle ID of the sample plug-in is 22.

      ```
      osgi> start 22
      ```

   b. Start the Google Protocol Buffers bundle, Google_ProtoBuf_2.4.0. Run the following command in the Equinox OSGi console to start the bundle. In this example, the bundle ID of the Google Protocol Buffers plug-in is 21.

      ```
      osgi> start 21
      ```

   c. Start the server bundle, com.ibm.websphere.xs.server_7.1.1. Run the following command in the OSGi console to start the server. In this example, the bundle ID of the eXtreme Scale server bundle is 19.

      ```
      osgi> start 19
      ```

After you start the server, the MyShardListener event listener is started and ready to insert or update records. You can see the following output on the OSGi console to confirm that the plug-in bundle has started successfully:

```
SystemOut O MyShardListener@1253853884(version=1.0.0) order
com.ibm.websphere.samples.xs.serializer.proto.DataObjects1$Order$Builder
@1aba1aba(22) inserted
```

Lesson checkpoint

In this lesson, you started two plug-in bundles and the server bundle in the eXtreme Scale container that you configured for the OSGi framework.

< Previous | Next >
< Previous | Next >

Module 3: Running the eXtreme Scale sample client

The WebSphere® eXtreme Scale server is now running in an OSGi environment. Complete the steps in this module to run an WebSphere eXtreme Scale client that inserts data into the grid.

Learning objectives

After completing the lessons in this module you will know how to complete the following tasks:

- Run a client application that connects to the grid and inserts and retrieves some data from it.
- Start an order using a non-OSGi client application.

Prerequisites

Complete Module 2: Installing and starting eXtreme Scale bundles in the OSGi framework.

Lessons in this module

- **Lesson 3.1: Set up Eclipse to run the client and build the samples**

  Complete this lesson to import the Eclipse project that you will use to run the client and build the sample plug-ins.
- **Lesson 3.2: Start a client and insert data into the grid**

  Complete this lesson to start a non-OSGi client and run a client application.

< Previous | Next >
< Previous | Next >

Lesson 3.1: Set up Eclipse to run the client and build the samples

Complete this lesson to import the Eclipse project that you will use to run the client and build the sample plug-ins.

The sample includes a Java™ SE client program that connects to the grid and inserts and retrieves data from it. It also includes projects that you can use to build and redeploy the OSGi bundles.
The provided project has been tested with Eclipse 3.x and later, and requires only the standard Java development project perspective. Complete the following steps to set up of your WebSphere® eXtreme Scale development environment.

1. Open Eclipse to a new or existing workspace.
2. From the File menu, select Import.
3. Expand the General folder. Select Existing Projects into Workspace, and click Next.
4. In the Select root directory field, type or browse to the *wxs_sample_osgi_root* directory. Click Finish. Several new projects are displayed in your workspace. Build errors will be fixed by defining two user libraries. Complete the next steps to define the user libraries.
5. From the Window menu, select Preferences.
6. Expand the Java > Build Path branch, and select User Libraries.
7. Define the eXtreme Scale user library.
   a. Click New.
   b. Type `eXtremeScale` in the User Library Name field, and click OK.
   c. Select the new user library, and click Add JARs.
      i. Browse and select the objectgrid.jar file from the *wxs_install_root*/lib directory. Click OK.
      ii. To include API documentation for the ObjectGrid APIs, select the API documentation location for the objectgrid.jar file that you added in the previous step. Click Edit.
      iii. In the location path box for the API documentation, select the Javadoc.zip file that is included in the following directory: *wxs_install_root*/docs/javadoc.zip.
8. Define the Google Protocol Buffers user library.
   a. Click New.
   b. Type `com.google.protobuf` in the User Library Name field, and click OK.
   c. Select the new user library, and click Add JARs.
      i. Browse and select the com.google.protobuf_2.4.0.a.jar file from the *wxs_sample_osgi_root*/lib directory. Click OK.

Lesson checkpoint

In this lesson, you imported the sample Eclipse project and defined the user libraries that fixed any build errors.

< Previous | Next >

Lesson 3.2: Start a client and insert data into the grid

Complete this lesson to start a non-OSGi client and run a client application.

The Java™ client application is com.ibm.websphere.samples.xs.proto.client.Client. The Eclipse project, wxs.sample.osgi.protobuf.client, contains the Java client application. The main class file is com.ibm.websphere.samples.xs.proto.client.Client.
This client uses a client override, ObjectGrid descriptor XML file to override the OSGi configuration, so that the client can run in a non-OSGi environment. See the following content of the file with comments and headers removed.

```
<objectGridConfig xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://ibm.com/ws/objectgrid/config ../objectGrid.xsd"
    xmlns="http://ibm.com/ws/objectgrid/config">

    <objectGrids>
        <objectGrid name="Grid" txTimeout="15">
            <bean
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsstartclientgridOSGi_ObjectGridEven
tListener" className="" osgiService=""/>
            <backingMap name="Map" readOnly="false"
                lockStrategy="PESSIMISTIC" lockTimeout="5"
                copyMode="COPY_TO_BYTES" pluginCollectionRef="serializer"/>

        </objectGrid>
    </objectGrids>

    <backingMapPluginCollections>
        <backingMapPluginCollection
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsstartclientgridOSGi_serializer">

                        <bean
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsstartclientgridOSGi_MapSerializer"
                        className="com.ibm.websphere.samples.xs.serializer.proto.ProtoMapSerializer"
       osgiService="">
                                <property name="keyType" type="java.lang.String"
                                    value="com.ibm.websphere.samples.xs.serializer.proto.DataObjects2$OrderKey" />
                        <property name="valueType" type="java.lang.String"
                            value="com.ibm.websphere.samples.xs.serializer.proto.DataObjects2$Order" />
                        </bean>
                </backingMapPluginCollection>
    </backingMapPluginCollections>
</objectGridConfig>
```

Click Run As > Java Application to run the client application.
When you run the application, the following message is displayed. The message indicates that an order was inserted:

```
order
com.ibm.websphere.samples.xs.serializer.proto.DataObjects1$Order$Builder@5d165d16(5000000) inserted
```

Lesson checkpoint

In this lesson, you started the com.ibm.websphere.samples.xs.proto.client.Client application, which produced an order.

Module 4: Querying and upgrading the sample bundle

Complete the lessons in this module to use the **xscmd** command to query the service ranking of the sample bundle, upgrade it to a new service ranking, and verify the new service ranking.

Learning objectives

After completing the lessons in this module you will know how to complete the tasks:

- Query the current service ranking for a service.
- Query the current ranking for all services.
- Query all available rankings for a service.
- Query all available service rankings.
- Use the xscmd tool to verify whether specific service rankings are available.
- Update service rankings for sample OSGi services.

Prerequisites

Complete Module 3: Running the eXtreme Scale sample client.

Lessons in this module

- **Lesson 4.1: Query service rankings**

  Complete this lesson to query current service rankings as well as those service rankings that are available for upgrade.

- **Lesson 4.2: Determine whether specific service rankings are available**

  Complete this lesson to determine whether specific service rankings are available for the service names that you specify.
- **Lesson 4.3: Update the service rankings**

  Complete this lesson to update current service rankings that you queried.

< Previous | Next >
< Previous | Next >

Lesson 4.1: Query service rankings

Complete this lesson to query current service rankings as well as those service rankings that are available for upgrade.

- Query the current service ranking for a service. Enter the following command to query the current service ranking being used for service, myShardListener, which is used by the ObjectGrid named `Grid` and map set named `MapSet`.
  1. Switch to the following directory:

     ```
     cd wxs_home/bin
     ```

  2. Enter the following command to query the current service ranking for the service, myShardListener.

     ```
     ./xscmd.sh -c osgiCurrent -g Grid -ms MapSet -sn myShardListener
     ```

     The following output is displayed:

     ```
     OSGi Service Name: myShardListener
     ObjectGrid Name MapSet Name Server Name        Current Ranking
     --------------- ----------- -----------        ---------------
     Grid            MapSet      collocatedServer   1

     CWXSI0040I: The command osgiCurrent has completed successfully.
     ```

- Query the current ranking for all services. Enter the following command to query the current service ranking for all services that are used by the ObjectGrid named `Grid` and map set named `MapSet`.
  1. Switch to the following directory:

     ```
     cd wxs_home/bin
     ```

  2. Enter the following command to query the current service ranking for all services.

     ```
     ./xscmd.sh -c osgiCurrent -g Grid -ms MapSet
     ```

     The following output is displayed:

     ```
     OSGi Service Name    Current Ranking ObjectGrid Name MapSet Name Server Name
     -----------------    --------------- --------------- ----------- -----------
     myProtoBufSerializer 1               Grid            MapSet      collocatedServer
     myShardListener      1               Grid            MapSet      collocatedServer

     CWXSI0040I: The command osgiCurrent has completed successfully.
     ```

- Query all available rankings for a service. Enter the following command to query all of the available service rankings for the service named myShardListener.
  1. Switch to the following directory:

     ```
     cd wxs_home/bin
     ```

  2. Enter the following command to query all available rankings for a service.

     ```
     ./xscmd.sh -c osgiAll -sn myShardListener
     ```

     The following output is displayed:

     ```
     Server: collocatedServer
        OSGi Service Name Available Rankings
        ----------------- ------------------
        myShardListener   1

        Summary - All servers have the same service rankings.

     CWXSI0040I: The command osgiAll has completed successfully.
     ```

     The output is grouped by the server. In this example, only the following server exists: collocatedServer.
- Query all available service rankings. Enter the following command to query all of the available service rankings for all services.
  1. Switch to the following directory:

     ```
     cd wxs_home/bin
     ```

  2. Enter the following command to query all available service rankings.

     ```
     ./xscmd.sh -c osgiAll
     ```

     The following output is displayed:

```
Server: collocatedServer
   OSGi Service Name    Available Rankings
   -----------------    ------------------
   myProtoBufSerializer 1
   myShardListener      1

Summary - All servers have the same service rankings.
```

- Install and start Version 2 of the plug-in bundle. In the server OSGi console, install a new bundle that contains a new version of the Order class and the MapSerializerPlugin plug-in. See Lesson 2.4: Install the Google Protocol Buffers and sample plug-in bundles for details about how to install the ProtoBufSamplePlugins-2.0.0.jar bundle.
    1. After the installation, start the new bundle. The services for your new bundle are available, but they are not used by the eXtreme Scale server yet. You must run a service update request to use a service with a specific version.
- Now when you query all the available service rankings again, the service ranking 2 is added in the output.
    1. Switch to the following directory:

       ```
       cd wxs_home/bin
       ```

    2. Enter the following command to query all available service rankings.

       ```
       ./xscmd.sh -c osgiAll
       ```

       The following output is displayed:

       ```
       Server: collocatedServer
          OSGi Service Name    Available Rankings
          -----------------    ------------------
          myProtoBufSerializer 1, 2
          myShardListener      1, 2

       Summary - All servers have the same service rankings.
       ```

Lesson checkpoint

In this tutorial, you queried currently specified and all available service rankings. You also displayed the service ranking for a new bundle that you installed and started.

< Previous | Next >
< Previous | Next >

Lesson 4.2: Determine whether specific service rankings are available

Complete this lesson to determine whether specific service rankings are available for the service names that you specify.

1. Enter the following command to determine whether the service named myShardListener, with service ranking 2 and service named myProtoBufSerializer, with service ranking 2 are available. The service ranking list is passed in using -sr option.
    a. Switch to the following directory:

       ```
       cd wxs_home/bin
       ```

    b. Enter the following command to determine whether the services are available:

       ```
       ./xscmd.sh -c osgiCheck -sr "myShardListener;2,myProtoBufSerializer;2"
       ```

       The following output is displayed:

       ```
       CWXSI0040I: The command osgiCheck has completed successfully.
       ```

2. Enter the following command to determine whether the service named myShardListener, with service ranking 2 and the service named myProtoBufSerializer, with service ranking 3 are available.
    a. Switch to the following directory:

       ```
       cd wxs_home/bin
       ```

    b. Enter the following command to determine whether the services are available:

       ```
       ./xscmd.sh -c osgiCheck -sr "myShardListener;2,myProtoBufSerializer;3"
       ```

       The following output is displayed:

       ```
       Server           OSGi Service         Unavailable Rankings
       ------           ------------         --------------------
       collocatedServer myProtoBufSerializer          3
       ```

Lesson checkpoint

In this lesson, you specified the services myShardListener and myProtoBufSerializer, along with specific service rankings to determine whether those rankings were available.

< Previous | Next >
< Previous

Lesson 4.3: Update the service rankings

Complete this lesson to update current service rankings that you queried.

1. Update the service rankings of the services, myShardListener and myProtoBufSerializer, to service ranking 2. The service ranking list is passed in using -sr option.
   a. Switch to the following directory:

      ```
      cd wxs_home/bin
      ```

   b. Enter the following command to update the service rankings:

      ```
      ./xscmd.sh -c osgiUpdate -g Grid -ms MapSet -sr "myShardListener;2,myProtoBufSerializer;2"
      ```

      The following output is displayed:

      ```
      Update succeeded for the following service rankings:
      Service              Ranking
      -------              -------
      myProtoBufSerializer 2
      myShardListener      2

      CWXSI0040I: The command osgiUpdate has completed successfully.
      ```

      The following output is displayed on the OSGi console:

      ```
      SystemOut O MyShardListener@326505334(version=2.0.0) order
      com.ibm.websphere.samples.xs.serializer.proto.DataObjects2$Order$Builder@
      22342234(34) updated
      ```

      Notice that the MyShardListener service is now version 2.0.0, which has service ranking 2.
2. Run the **xscmd** command to query the current service ranking for all services that are used by the ObjectGrid named `Grid` and the map set named `MapSet`.
   a. Switch to the following directory:

      ```
      cd wxs_home/bin
      ```

   b. Enter the following command to query the service rankings for all services that are used by `Grid` and `MapSet`:

      ```
      ./xscmd.sh -c osgiCurrent -g Grid -ms MapSet
      ```

      The following output is displayed:

      ```
      OSGi Service Name    Current Ranking ObjectGrid Name MapSet Name Server Name
      -----------------    --------------- --------------- ----------- -----------
      myProtoBufSerializer 2               Grid            MapSet      collocatedServer
      myShardListener      2               Grid            MapSet      collocatedServer

      CWXSI0040I: The command osgiCurrent has completed successfully.
      ```

Lesson checkpoint

In this lesson, you updated the service rankings for services myShardListener and myProtoBufSerializer.

.

Tutorial: Getting started with WebSphere eXtreme Scale

After you install WebSphere® eXtreme Scale in a stand-alone environment, you can use the getting started sample application to verify your installation. The getting started sample application is an introduction to in-memory data grids. The getting started sample application is only included in full (client and server) installations of WebSphere eXtreme Scale.You can use the getting started sample application to verify the connection between your client installation and the appliance. The getting started sample application is an introduction to enterprise data grids.

Learning objectives

- Learn about the ObjectGrid descriptor XML file and deployment policy descriptor XML files that you use to configure your environment.
- Start catalog and container servers with the configuration files.
- Learn about developing a client application
- Run the client application to insert data into the data grid.
- Monitor your data grids with the web console.

Time required

60 minutes
| Next >
< Previous | Next >

Getting started tutorial lesson 1.1: Defining data grids with configuration files

The objectgrid.xml and deployment.xml files are required to start container servers.

The sample uses the objectgrid.xml and deployment.xml files that are in the *wxs_install_root*/ObjectGrid/gettingstarted/xml directory. These files are passed to the start commands to start container servers and a catalog server. The objectgrid.xml file is the ObjectGrid descriptor XML file. The deployment.xml file is the ObjectGrid deployment policy descriptor XML file. These files together define a distributed topology.

Related reference:

ObjectGrid descriptor XML file
Deployment policy descriptor XML file

ObjectGrid descriptor XML file

An ObjectGrid descriptor XML file is used to define the structure of the ObjectGrid that is used by the application. It includes a list of backing map configurations. These backing maps store the cache data. The following example is a sample objectgrid.xml file. The first few lines of the file include the required header for each ObjectGrid XML file. This example file defines the `Grid` ObjectGrid with `Map1` and `Map2` backing maps.

```
<objectGridConfig xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:schemaLocation="http://ibm.com/ws/objectgrid/config ../objectGrid.xsd"
 xmlns="http://ibm.com/ws/objectgrid/config">

    <objectGrids>
        <objectGrid name="Grid">
            <backingMap name="Map1" />
            <backingMap name="Map2" />
        </objectGrid>
    </objectGrids>

</objectGridConfig>
```

Deployment policy descriptor XML file

The deployment policy descriptor XML file is intended to be paired with the corresponding ObjectGrid XML, the objectgrid.xml file. In the following example, the first few lines of the deployment.xml file include the required header for each deployment policy XML file. The file defines the objectgridDeployment element for the `Grid` ObjectGrid that is defined in the objectgrid.xml file. The `Map1` and `Map2` BackingMaps that are defined within the `Grid` ObjectGrid are included in the `mapSet` mapSet.

```
<deploymentPolicy xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="http://ibm.com/ws/objectgrid/deploymentPolicy
 ../deploymentPolicy.xsd"
xmlns="http://ibm.com/ws/objectgrid/deploymentPolicy">
<objectgridDeployment objectgridName="Grid">
       <mapSet name="mapSet" numberOfPartitions="13" minSyncReplicas="0"
                  maxSyncReplicas="1" >
            <map ref="Map1"/>
            <map ref="Map2"/>
        </mapSet>
    </objectgridDeployment>
</deploymentPolicy>
```

The numberOfPartitions attribute of the mapSet element specifies the number of partitions for the map set. This attribute is optional; the default value is `1`. The attribute value must be appropriate for the anticipated capacity of the data grid.

The minSyncReplicas attribute of the mapSet element specifies the minimum number of synchronous replicas for each partition in the map set. This attribute is optional; the default is `0`. Primary and replica shards are not placed until the catalog service domain can support the minimum number of synchronous replicas. To support the minSyncReplicas value, you need one more container server than the value of the minSyncReplicas attribute. If the number of synchronous replicas falls below the value of the minSyncReplicas attribute, write transactions are no longer allowed for that partition.

The maxSyncReplicas attribute of the mapSet element is to specify the maximum number of synchronous replicas for each partition in the map set. This attribute is optional; the default is `0`. No other synchronous replicas are placed for a partition after a catalog service domain reaches this number of synchronous replicas for that specific partition. Adding container servers that can support this ObjectGrid can result in an increased number of synchronous replicas if your maxSyncReplicas value is not already met. The sample set the maxSyncReplicas to `1`, which means the catalog service domain places one synchronous replica at most. If you start more than one container server, only one synchronous replica is placed in one of the container server instances.

Lesson checkpoint

In this lesson, you learned:

- How to use the ObjectGrid descriptor XML file to define maps that store the cache data.
- How to use the deployment descriptor XML file to define the number of partitions and replicas for the data grid.

< Previous | Next >
< Previous | Next >

Getting started tutorial lesson 2.1: Creating a client application

To insert, delete, update, and retrieve data from your data grid, you must write a client application. The getting started sample includes a client application that you can use to learn about creating your own client application.

The Client.java file in the *wxs_install_root*/ObjectGrid/gettingstarted/client/src/ directory is the client program that demonstrates how to connect to a catalog server, obtain the ObjectGrid instance, and use the ObjectMap API. The ObjectMap API stores data as key-value pairs and is ideal for caching objects that have no relationships involved. The following steps discuss the contents of the Client.java file.

If you need to cache objects that have relationships, use the EntityManager API.

1. Connect to the catalog service by obtaining a ClientClusterContext instance.
   To connect to the catalog server, use the connect method of ObjectGridManager API. The connect method that is used requires only the catalog server endpoint in the format of *`hostname`*`:`*`port`*. You can indicate multiple catalog server endpoints by separating the list of *`hostname`*`:`*`port`* values with commas. The following code snippet demonstrates how to connect to a catalog server and obtain a ClientClusterContext instance:

   ```
   ClientClusterContext ccc = ObjectGridManagerFactory.getObjectGridManager().connect("localhost:2809", null, null);
   ```

   If the connections to the catalog servers succeed, the connect method returns a ClientClusterContext instance. The ClientClusterContext instance is required to obtain the ObjectGrid from the ObjectGridManager API.
2. Obtain an ObjectGrid instance.
   To obtain ObjectGrid instance, use the getObjectGrid method of the ObjectGridManager API. The getObjectGrid method requires both the ClientClusterContext instance and the name of the data grid instance. The ClientClusterContext instance is obtained during the connection to catalog server. The name of ObjectGrid instance is `Grid` that is specified in the objectgrid.xml file. The following code snippet demonstrates how to obtain the data grid by calling the getObjectGrid method of the ObjectGridManager API.

   ```
   ObjectGrid grid = ObjectGridManagerFactory.getObjectGridManager().getObjectGrid(ccc, "Grid");
   ```

3. Get a Session instance.
   You can get a Session from the obtained ObjectGrid instance. A Session instance is required to get the ObjectMap instance, and perform transaction demarcation. The following code snippet demonstrates how to get a Session instance by calling the getSession method of the ObjectGrid API.

   ```
   Session sess = grid.getSession();
   ```

4. Get an ObjectMap instance.
   After getting a Session, you can get an ObjectMap instance from a Session instance by calling getMap method of the Session API. You must pass the name of map as parameter to getMap method to get the ObjectMap instance. The following code snippet demonstrates how to obtain ObjectMap by calling the getMap method of the Session API.

   ```
   ObjectMap map1 = sess.getMap("Map1");
   ```

5. Use the ObjectMap methods.
   After an ObjectMap instance is obtained, you can use the ObjectMap API. Remember that the ObjectMap interface is a transactional map and requires transaction demarcation by using the begin and commit methods of the Session API. If there is no explicit transaction demarcation in the application, the ObjectMap operations run with auto-commit transactions.

   - The following code snippet demonstrates how to use the ObjectMap API with an auto-commit transaction.

     ```
     map1.insert(k, v);
     ```

   - The following code snippet demonstrates how to use the ObjectMap API with explicit transaction demarcation.

     ```
     sess.begin();
     map1.insert(key1, value1);
     ```

```
sess.commit();
```

6. Optional: Close the Session. After all of the Session and ObjectMap operations are complete, close the session with the Session.close() method. Running this method returns the resources that were being used by the session.

   ```
   sess.close();
   ```

   As a result, subsequent getSession() method calls return faster, and fewer Session objects are in the heap.

Lesson checkpoint

In this lesson, you learned how to create a simple client application for performing data grid operations.
< Previous | Next >
< Previous | Next >

Getting started tutorial lesson 3.2: Running the getting started sample client application

Use the following steps to run a client to interact with the data grid. The catalog server, container server, and client all run on a single server in this example.

Open a terminal session or command-line window to run client commands.
The `runclient.sh|bat` script runs the simple create, retrieve, update, and delete (CRUD) client and starts the specified operation. The `runclient.sh|bat` script is run with the following parameters:

- UNIX Linux `./runclient.sh command value1 value2`
- Windows `runclient.bat command value1 value2`

For *command*, use one of the following options:

- Specify as `i` to insert *value2* into data grid with key *value1*
- Specify as `u` to update object that is keyed by *value1* to *value2*
- Specify as `d` to delete object that is keyed by *value1*
- Specify as `g` to retrieve and display object that is keyed by *value1*

1. Add data to the data grid.
   Important: If your system is using double byte character sets (DBCS), you might see garbled or corrupted text when you insert data into the data grid with the **runClient** script. This text can display in the output or in the cache. To work around this issue, update the Java call in the **runClient** script to include the -Xargencoding argument, and then specify the DBCS as a Unicode character set. For example, use the command: `\u runClient i key\u2e81 Hello\2e84World`
   - UNIX Linux `./runclient.sh i key1 helloWorld`
   - Windows `runclient.bat i key1 helloWorld`
2. Search and display the value:
   - UNIX Linux `./runclient.sh g key1`
   - Windows `runclient.bat g key1`
3. Update the value:
   - UNIX Linux `./runclient.sh u key1 goodbyeWorld`
   - Windows `runclient.bat u key1 goodbyeWorld`
4. Delete the value:
   - UNIX Linux `./runclient.sh d key1`
   - Windows `runclient.bat d key1`

Lesson checkpoint

Lessons learned

In this lesson, you learned:

- How to run the sample client application to insert, get, update, and delete data from the data grid.

Web console statistics
stopOgServer script

Monitoring with the web console

With the web console, you can chart current and historical statistics. This console provides some preconfigured charts for high-level overviews, and has a custom reports page that you can use to build charts from the available statistics. You can use the charting capabilities in the monitoring console of WebSphere eXtreme Scale to view the overall performance of the data grids in your environment.

Install the web console as an optional feature when you run the installation wizard.

1. Start the console server. The **startConsoleServer.bat|sh** script for starting the console server is in the *wxs_install_root*/ObjectGrid/bin directory of your installation.
2. Log on to the console.
    a. From your web browser, go to `https://your.console.host:7443`, replacing `your.console.host` with the host name of the server onto which you installed the console. If you had changed the port number, remember to update the port number in the URL.
    b. Log on to the console.
        - **User ID:** `admin`
        - **Password:** `admin`

    The console welcome page is displayed.
3. Edit the console configuration. Click Settings > Configuration to review the console configuration. The console configuration includes information such as:
    - Trace string for the WebSphere eXtreme Scale client, such as `*=all=disabled`
    - The Administrator name and password
    - The Administrator e-mail address
4. Establish and maintain connections to catalog servers that you want to monitor. Repeat the following steps to add each catalog server to the configuration.
    a. Click Settings > eXtreme Scale Catalog Servers.
    b. Add a new catalog server.
        i. Click the add icon () to register an existing catalog server.
        ii. Provide information, such as the host name and listener port. See Planning for network ports for more information about port configuration and defaults.
        iii. Click OK.
        iv. Verify that the catalog server has been added to the navigation tree.
5. Group the catalog servers that you created into a catalog service domain. You must create a catalog service domain when security is enabled in your catalog servers because security settings are configured in the catalog service domain.
    a. Click Settings > eXtreme Scale Domains page.
    b. Add a new catalog service domain.
        i. Click the add icon () to register a catalog service domain. Enter a name for the catalog service domain.
        ii. After you create the catalog service domain, you can edit the properties. The catalog service domain properties follow:

            Name
                Indicates the host name of the domain, as assigned by the administrator.
            Catalog servers
                Lists one or more catalog servers that belong to the selected domain. You can add the catalog servers that you created in the previous step.
            Generator class
                Specifies the name of the class that implements the CredentialGenerator interface. This class is used to get credentials for clients. If you specify a value in this field, the value overrides the crendentialGeneratorClass property in the client.properties file.
            Generator properties
                Specifies the properties for the CredentialGenerator implementation class. The properties are set to the object with the setProperties(String) method. The credentialGeneratorprops value is used only if the value of the credentialGeneratorClass property is not null. If you specify a value in this field, the value overrides the credentialGeneratorProps property in the client.properties file.
            eXtreme Scale client properties path
                Specifies the path to the client properties file that you edited to include SSL properties. For example, you might indicate the /ObjectGridProperties/sampleclient.properties file. If you want to stop the console from trying to use SSL connections, you can delete the value in this field. After you set the path, the console uses an unsecured connection.

        iii. Click OK.
        iv. Verify that the domain has been added to the navigation tree.

    To view information about an existing catalog service domain, click the name of the catalog service domain in the navigation tree on the Settings > eXtreme Scale Domains page.

6. View the connection status. The Current domain field indicates the name of the catalog service domain that is currently being used to display information in the web console. The connection status displays next to the name of the catalog service domain.
7. View statistics for the data grids and servers, or create a custom report.

Monitoring with the xscmd utility

1. Optional: If client authentication is enabled: Open a command-line window. On the command line, set appropriate environment variables.
2. Go to the *wxs_home*/bin directory.
   `cd wxs_home/bin`
3. Run various commands to display information about your environment.
   - Show all the online container servers for the Grid data grid and the mapSet map set:

     ```
     xscmd -c showPlacement -g Grid -ms mapSet
     ```

   - Display the routing information for the data grid.

     ```
     xscmd -c routetable -g Grid
     ```

   - Display the number of map entries in the data grid.

     ```
     xscmd -c showMapSizes -g Grid -ms mapSet
     ```

Stopping the servers

After you are done using the client application and monitoring the getting started sample environment, you can stop the servers.

- If you used the script files to start the servers, use <ctrl+c> to stop the catalog service process and container servers in the respective windows.
  Note: You can only use <ctrl+c> to stop command scripts that start with "run". For example, **runcat.bat**.
- If you used the **startOgServer** command to start your servers, use the **stopOgServer** command to stop the servers.

  Stop the container server:
  - UNIX Linux `stopOgServer.sh c0 -catalogServiceEndPoints localhost:2809`
  - Windows `stopOgServer.bat c0 -catalogServiceEndPoints localhost:2809`

  Stop the catalog server:
  - UNIX Linux `stopOgServer.sh cs1 -catalogServiceEndPoints localhost:2809`
  - Windows `stopOgServer.bat cs1 -catalogServiceEndPoints localhost:2809`

Lesson checkpoint

In this lesson, you learned:

- How to start the web console and connect it to the catalog server.
- How to monitor data grid and server statistics.
- How to stop the servers.

< Previous

Getting started with developing applications

To begin developing WebSphere® eXtreme Scale applications, you must set up your development environment, learn about APIs that you can use, then develop and test your application.

Before you begin

About this task

When you are developing WebSphere eXtreme Scale applications, you can use the embedded server APIs to create and start servers, ObjectGrid instances, and to insert data into the data grid. You can unit test your application and the associated configuration directly in the Eclipse environment. When you are ready to move your application to a broader environment, you can create configuration XML files that you import to create your deployment.

Procedure

1. Set up a development environment and access the API documentation.
   You can begin to use the APIs to develop your applications. You can also use the API documentation within the development environment.

   More information: Setting up a stand-alone development environment in Eclipse

   More information: Accessing API documentation

2. Create a simple application that starts servers, creates an ObjectGrid instance, and inserts data into the data grid.
   a. Use the ServerFactory API to start and stop servers.
   More information: Using the embedded server API to start and stop servers

b. Use the ObjectGridManager API to retrieve the ObjectGrid instance that you created.
More information: Interacting with an ObjectGrid using the ObjectGridManager interface

c. Use the ObjectMap API to insert data into the data grid.
More information: Caching objects with no relationships involved (ObjectMap API)

The ObjectMap API is the simplest way to access and write data to the data grid. If your objects have complex relationships, you can use the following APIs to read, write, and update data:

- Accessing data with indexes (Index API)
- Caching objects and their relationships (EntityManager API)
- Retrieving entities and objects (Query API)
- Accessing data with the REST data service

For more information about choosing between the different APIs, see Developing applications.

3. Unit test your application.
You can also use the **xscmd** utility to display information about the running servers, replicas, and so on. See Administering with the xscmd utility for more information.

4. When you are satisfied with your application within the development environment, create XML configuration files and update your application to use the configuration. The Getting Started sample application provides examples of these configuration files and a simple application that uses the configuration files.
More information: Tutorial: Getting started with WebSphere eXtreme Scale

5. Run your application using the XML configuration files. How you start your servers depends on the environment that you are using.
You can run your application in one of the following containers:

- Stand-alone Java virtual machine (JVM)
- Tomcat
- WebSphere Application Server
- OSGi

Planning

Before you install WebSphere® eXtreme Scale and deploy your data grid applications, you must decide on your caching topology, complete capacity planning, review the hardware and software requirements, networking and tuning settings, and so on. You can also use the operational checklist to ensure that your environment is ready to have an application deployed.

For a discussion of the best practices that you can use when you are designing your WebSphere eXtreme Scale applications, read the following article on developerWorks®: Principles and best practices for building high performing and highly resilient WebSphere eXtreme Scale applications.

- Planning overview
Before using WebSphere eXtreme Scale in a production environment, consider the following issues to optimize your deployment.
- Planning the topology
With WebSphere eXtreme Scale, your architecture can use local in-memory data caching or distributed client-server data caching. The architecture can have varied relationships with your databases. You can also configure the topology to span multiple data centers.
- Interoperability with other products
You can integrate WebSphere eXtreme Scale with other products, such as WebSphere Application Server and WebSphere Application Server Community Edition.
- Planning for configuration
Before configuring the hardware or software, understand the following considerations.
- Planning for installation
Before you install the product, you must consider software and hardware requirements and Java environment settings.
- Planning environment capacity
If you have an initial data set size and a projected data set size, you can plan the capacity that you need to run WebSphere eXtreme Scale. By using these planning exercises, you can deploy WebSphere eXtreme Scale efficiently for future changes and maximize the elasticity of the data grid, which you would not have with a different scenario such as an in-memory database or other type of database.
- Planning to develop WebSphere eXtreme Scale applications
Set up your development environment and learn where to find details about available programming interfaces.

Planning overview

Before using WebSphere® eXtreme Scale in a production environment, consider the following issues to optimize your deployment.

Caching topology considerations

Each type of cache topology has advantages and disadvantages. The caching topology you implement depends on the requirements of your environment and application. For more information about the different caching topologies, see Planning the topology.

Data capacity considerations

The following list includes items to consider:

- **Number of systems and processors**: How many physical machines and processors are needed in the environment?
- **Number of servers**: How many eXtreme Scale servers to host eXtreme Scale maps?
- **Number of partitions**: The amount of data stored in the maps is one factor in determining the number of partitions needed.
- **Number of replicas**: How many replicas are required for each primary in the domain?
- **Synchronous or asynchronous replication**: Is the data vital so that synchronous replication is required? Or is performance a higher priority, making asynchronous replication the correct choice?
- **Heap sizes**: How much data will be stored on each server?

For a detailed discussion of each of these considerations, see Planning environment capacity..

Installation considerations

You can install WebSphere eXtreme Scale in a stand-alone environment, or you can integrate the installation with WebSphere Application Server. To ensure that you are able to seamlessly upgrade your servers in the future, you must plan your environment accordingly. For the best performance, catalog servers should run on different machines than the container servers. If you must run your catalog servers and container servers on the same machine, then use separate installations of WebSphere eXtreme Scale for the catalog and container servers. By using two installations, you can upgrade the installation that is running the catalog server first. See Updating eXtreme Scale servers.

Planning for installation
Planning to develop WebSphere eXtreme Scale applications

Planning the topology

With WebSphere® eXtreme Scale, your architecture can use local in-memory data caching or distributed client-server data caching. The architecture can have varied relationships with your databases. You can also configure the topology to span multiple data centers.

WebSphere eXtreme Scale requires minimal additional infrastructure to operate. The infrastructure consists of scripts to install, start, and stop a Java™ Platform, Enterprise Edition application on a server. Cached data is stored in the container servers, and clients remotely connect to the server.

In-memory environments

When you deploy in a local, in-memory environment, WebSphere eXtreme Scale runs within a single Java virtual machine and is not replicated. To configure a local environment you can use an ObjectGrid XML file or the ObjectGrid APIs.

Distributed environments

When you deploy in a distributed environment, WebSphere eXtreme Scale runs across a set of Java virtual machines, increasing the performance, availability and scalability. With this configuration, you can use data replication and partitioning. You can also add additional servers without restarting your existing eXtreme Scale servers. As with a local environment, an ObjectGrid XML file, or an equivalent programmatic configuration, is needed in a distributed environment. You must also provide a deployment policy XML file with configuration details
You can create either simple deployments or large, terabyte-sized deployments in which thousands of servers are needed.

- Local in-memory cache
  In the simplest case, WebSphere eXtreme Scale can be used as a local (non-distributed) in-memory data grid cache. The local case can especially benefit high-concurrency applications where multiple threads need to access and modify transient data. The data kept in a local data grid can be indexed and retrieved using queries. Queries help you to work with large in memory data sets. The support provided with the Java virtual machine (JVM), although it is ready to use, has a limited data structure.
- Peer-replicated local cache
  You must ensure the cache is synchronized if multiple processes with independent cache instances exist. To ensure that the cache instances are synchronized, enable a peer-replicated cache with Java Message Service (JMS).
- Embedded cache
  WebSphere eXtreme Scale grids can run within existing processes as embedded eXtreme Scale servers or you can manage them as external processes.
- Distributed cache
  WebSphere eXtreme Scale is most often used as a shared cache, to provide transactional access to data to multiple components where a traditional database would otherwise be used. The shared cache eliminates the need configure a database.
- Database integration: Write-behind, in-line, and side caching
  WebSphere eXtreme Scale is used to front a traditional database and eliminate read activity that is normally pushed to the database. A coherent cache can

be used with an application directly or indirectly using an object relational mapper. The coherent cache can then offload the database or backend from reads. In a slightly more complex scenario, such as transactional access to a data set where only some of the data requires traditional persistence guarantees, filtering can be used to offload even write transactions.

- Planning multiple data center topologies
  Using multi-master asynchronous replication, two or more data grids can become exact copies of each other. Each data grid is hosted in an independent catalog service domain, with its own catalog service, container servers, and a unique name. With multi-master asynchronous replication, you can use links to connect a collection of catalog service domains. The catalog service domains are then synchronized using replication over the links. You can construct almost any topology through the definition of links between the catalog service domains.

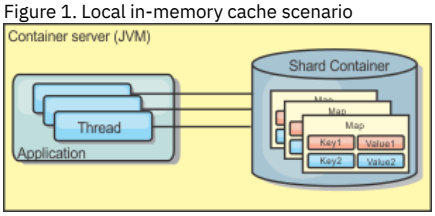
Local in-memory cache

In the simplest case, WebSphere® eXtreme Scale can be used as a local (non-distributed) in-memory data grid cache. The local case can especially benefit high-concurrency applications where multiple threads need to access and modify transient data. The data kept in a local data grid can be indexed and retrieved using queries. Queries help you to work with large in memory data sets. The support provided with the Java™ virtual machine (JVM), although it is ready to use, has a limited data structure.

The local in-memory cache topology for WebSphere eXtreme Scale is used to provide consistent, transactional access to temporary data within a single Java virtual machine.

Figure 1. Local in-memory cache scenario



Advantages

- Simple setup: An ObjectGrid can be created programmatically or declaratively with the ObjectGrid deployment descriptor XML file or with other frameworks such as Spring.
- Fast: Each BackingMap can be independently tuned for optimal memory utilization and concurrency.
- Ideal for single-Java virtual machine topologies with small dataset or for caching frequently accessed data.
- Transactional. BackingMap updates can be grouped into a single unit of work and can be integrated as a last participant in 2-phase transactions such as Java Transaction Architecture (JTA) transactions.

Disadvantages

- Not fault tolerant.
- The data is not replicated. In-memory caches are best for read-only reference data.
- Not scalable. The amount of memory required by the database might overwhelm the Java virtual machine.
- Problems occur when adding Java virtual machines:
  - Data cannot easily be partitioned
  - Must manually replicate state between Java virtual machines or each cache instance could have different versions of the same data.
  - Invalidation is expensive.
  - Each cache must be warmed up independently. The warm-up is the period of loading a set of data so that the cache gets populated with valid data.

When to use

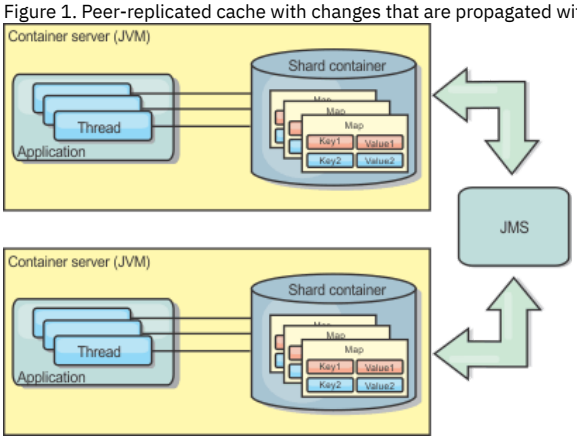
The local, in-memory cache deployment topology should only be used when the amount of data to be cached is small (can fit into a single Java virtual machine) and is relatively stable. Stale data must be tolerated with this approach. Using evictors to keep most frequently or recently used data in the cache can help keep the cache size low and increase relevance of the data.

Related concepts:
Peer-replicated local cache
Embedded cache
Distributed cache
Database integration: Write-behind, in-line, and side caching
Planning multiple data center topologies

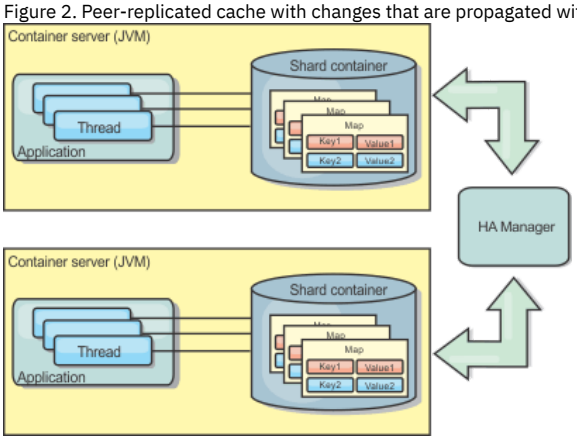
Peer-replicated local cache

You must ensure the cache is synchronized if multiple processes with independent cache instances exist. To ensure that the cache instances are synchronized, enable a peer-replicated cache with Java™ Message Service (JMS).

WebSphere® eXtreme Scale includes two plug-ins that automatically propagate transaction changes between peer ObjectGrid instances. The JMSObjectGridEventListener plug-in automatically propagates eXtreme Scale changes using JMS.
Figure 1. Peer-replicated cache with changes that are propagated with JMS



If you are running a WebSphere Application Server environment, the TranPropListener plug-in is also available. The TranPropListener plug-in uses the high availability (HA) manager to propagate the changes to each peer cache instance.
Figure 2. Peer-replicated cache with changes that are propagated with the high availability manager



Advantages

- The data is more valid because the data is updated more often.
- With the TranPropListener plug-in, like the local environment, the eXtreme Scale can be created programmatically or declaratively with the eXtreme Scale deployment descriptor XML file or with other frameworks such as Spring. Integration with the high availability manager is done automatically.
- Each BackingMap can be independently tuned for optimal memory utilization and concurrency.
- BackingMap updates can be grouped into a single unit of work and can be integrated as a last participant in 2-phase transactions such as Java Transaction Architecture (JTA) transactions.
- Ideal for few-JVM topologies with a reasonably small dataset or for caching frequently accessed data.
- Changes to the eXtreme Scale are replicated to all peer eXtreme Scale instances. The changes are consistent as long as a durable subscription is used.

Disadvantages

- Configuration and maintenance for the JMSObjectGridEventListener can be complex. eXtreme Scale can be created programmatically or declaratively with the eXtreme Scale deployment descriptor XML file or with other frameworks such as Spring.
- Not scalable: The amount of memory required by the database may overwhelm the JVM.
- Functions improperly when adding Java virtual machines:
  - Data cannot easily be partitioned
  - Invalidation is expensive.
  - Each cache must be warmed-up independently

When to use

Use deployment topology only when the amount of data to be cached is small, can fit into a single JVM, and is relatively stable.

Related concepts:
Local in-memory cache

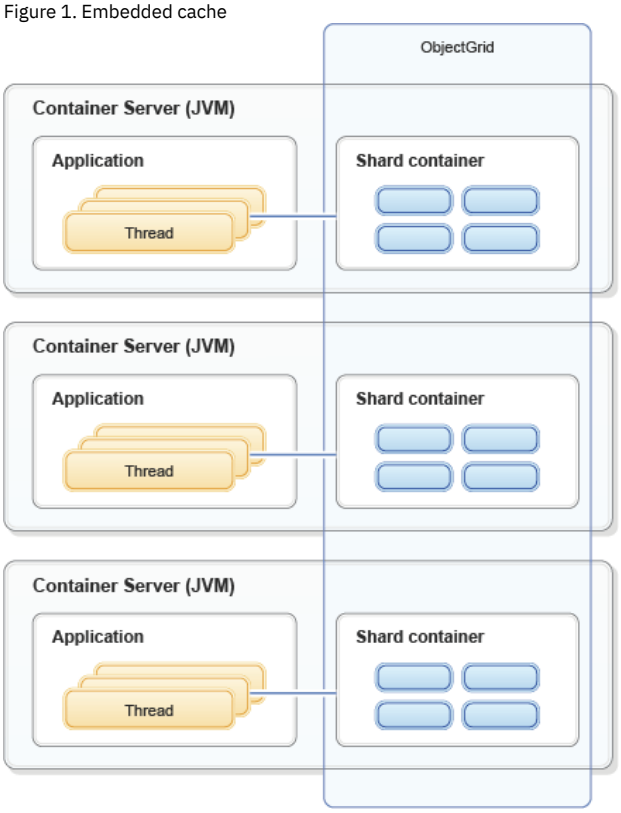
Embedded cache
Distributed cache
Database integration: Write-behind, in-line, and side caching
Planning multiple data center topologies

Embedded cache

WebSphere eXtreme Scale grids can run within existing processes as embedded eXtreme Scale servers or you can manage them as external processes.

Embedded grids are useful when you are running in an application server, such as WebSphere® Application Server. You can start eXtreme Scale servers that are not embedded by using command line scripts and run in a Java™ process.

Figure 1. Embedded cache



Advantages

- Simplified administration since there are less processes to manage.
- Simplified application deployment since the grid is using the client application classloader.
- Supports partitioning and high availability.

Disadvantages

- Increased the memory footprint in client process since all of the data is collocated in the process.
- Increase CPU utilization for servicing client requests.
- More difficult to handle application upgrades since clients are using the same application Java archive files as the servers.
- Less flexible. Scaling of clients and grid servers cannot increase at the same rate. When servers are externally defined, you can have more flexibility in managing the number of processes.

When to use

Use embedded grids when there is plenty of memory free in the client process for grid data and potential failover data.

For more information, see Configuring Java Message Service (JMS)-based client synchronization.

Related concepts:
Local in-memory cache
Peer-replicated local cache
Distributed cache
Database integration: Write-behind, in-line, and side caching
Planning multiple data center topologies

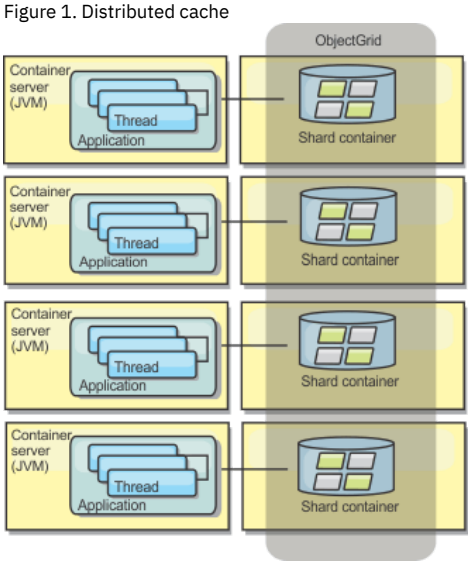
Distributed cache

WebSphere® eXtreme Scale is most often used as a shared cache, to provide transactional access to data to multiple components where a traditional database would otherwise be used. The shared cache eliminates the need configure a database.

Coherency of the cache

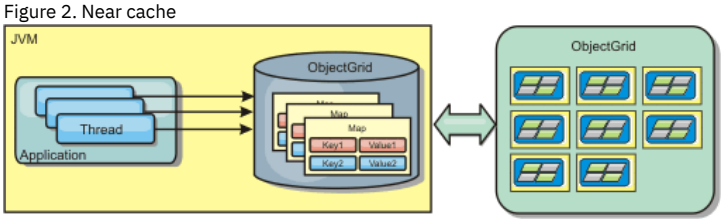
The cache is coherent because all of the clients see the same data in the cache. Each piece of data is stored on exactly one server in the cache, preventing wasteful copies of records that could potentially contain different versions of the data. A coherent cache can also hold more data as more servers are added to the data grid, and scales linearly as the grid grows in size. Because clients access data from this data grid with remote procedural calls, it can also be known as a remote cache, or far cache. Through data partitioning, each process holds a unique subset of the total data set. Larger data grids can both hold more data and service more requests for that data. Coherency also eliminates the need to push invalidation data around the data grid because no stale data exists. The coherent cache only holds the latest copy of each piece of data.

If you are running a WebSphere Application Server environment, the TranPropListener plug-in is also available. The TranPropListener plug-in uses the high availability component (HA Manager) of WebSphere Application Server to propagate the changes to each peer ObjectGrid cache instance.
Figure 1. Distributed cache



Near cache

Clients can optionally have a local, in-line cache when eXtreme Scale is used in a distributed topology. This optional cache is called a near cache, an independent ObjectGrid on each client, serving as a cache for the remote, server-side cache. The near cache is enabled by default when locking is configured as optimistic or none and cannot be used when configured as pessimistic.
Figure 2. Near cache



A near cache is very fast because it provides in-memory access to a subset of the entire cached data set that is stored remotely in the eXtreme Scale servers. The near cache is not partitioned and contains data from any of the remote eXtreme Scale partitions.WebSphere eXtreme Scale can have up to three cache tiers as follows.

1. The transaction tier cache contains all changes for a single transaction. The transaction cache contains a working copy of the data until the transaction is committed. When a client transaction requests data from an ObjectMap, the transaction is checked first.
2. The near cache in the client tier contains a subset of the data from the server tier. When the transaction tier does not have the data, the data is fetched from the client tier, if available and inserted into the transaction cache
3. The data grid in the server tier contains the majority of the data and is shared among all clients. The server tier can be partitioned, which allows a large amount of data to be cached. When the client near cache does not have the data, it is fetched from the server tier and inserted into the client cache. The server tier can also have a Loader plug-in. When the data grid does not have the requested data, the Loader is invoked and the resulting data is inserted from the backend data store into the grid.

To disable the near cache, see Configuring the near cache.

Advantage

- Fast response time because all access to the data is local. Looking for the data in the near cache first saves a trip to the grid of servers, thus making even the remote data locally accessible.

Disadvantages

- Increases duration of stale data because the near cache at each tier may be out of synch with the current data in the data grid.
- Relies on an evictor to invalidate data to avoid running out of memory.

When to use

Use when response time is important and stale data can be tolerated.

Related concepts:

ObjectGrid descriptor XML file

Database integration: Write-behind, in-line, and side caching

WebSphere® eXtreme Scale is used to front a traditional database and eliminate read activity that is normally pushed to the database. A coherent cache can be used with an application directly or indirectly using an object relational mapper. The coherent cache can then offload the database or backend from reads. In a slightly more complex scenario, such as transactional access to a data set where only some of the data requires traditional persistence guarantees, filtering can be used to offload even write transactions.

You can configure WebSphere eXtreme Scale to function as a highly flexible in-memory database processing space. However, WebSphere eXtreme Scale is not an object relational mapper (ORM). It does not know where the data in the data grid came from. An application or an ORM can place data in an eXtreme Scale server. It is the responsibility of the source of the data to make sure that it stays consistent with the database where data originated. This means eXtreme Scale cannot invalidate data that is pulled from a database automatically. The application or mapper must provide this function and manage the data stored in eXtreme Scale.
Figure 1. ObjectGrid as a database buffer

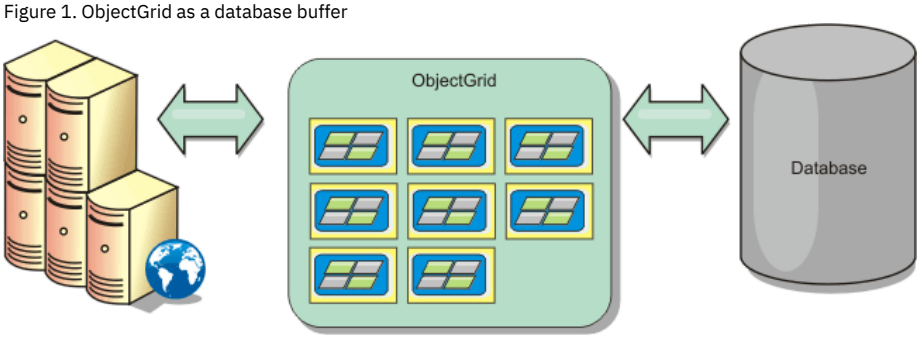

Figure 2. ObjectGrid as a side cache

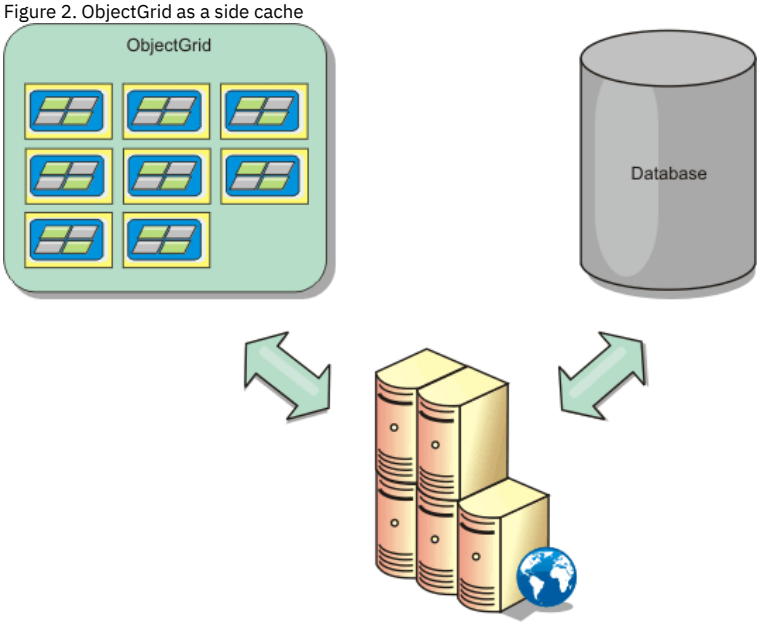

- Sparse and complete cache
  WebSphere eXtreme Scale can be used as a sparse cache or a complete cache. A sparse cache only keeps a subset of the total data, while a complete cache keeps all of the data. and can be populated lazily, as the data is needed. Sparse caches are normally accessed using keys (instead of indexes or queries) because the data is only partially available.
- Side cache
  When WebSphere eXtreme Scale is used as a side cache, the back end is used with the data grid.
- In-line cache
  You can configure in-line caching for a database back end or as a side cache for a database. In-line caching uses eXtreme Scale as the primary means for interacting with the data. When eXtreme Scale is used as an in-line cache, the application interacts with the back end using a Loader plug-in.

- Write-behind caching
  You can use write-behind caching to reduce the overhead that occurs when updating a database you are using as a back end.
- Loaders
  With a Loader plug-in, a data grid map can behave as a memory cache for data that is typically kept in a persistent store on either the same system or another system. Typically, a database or file system is used as the persistent store. A remote Java™ virtual machine (JVM) can also be used as the source of data, allowing hub-based caches to be built using eXtreme Scale. A loader has the logic for reading and writing data to and from a persistent store.
- Data preloading and warm-up
  In many scenarios that incorporate the use of a loader, you can prepare your data grid by preloading it with data.
- Database synchronization techniques
  When WebSphere eXtreme Scale is used as a cache, applications must be written to tolerate stale data if the database can be updated independently from an eXtreme Scale transaction. To serve as a synchronized in-memory database processing space, eXtreme Scale provides several ways of keeping the cache updated.
- Data invalidation
  To remove stale cache data, you can use invalidation mechanisms.
- Indexing
  Use the MapIndexPlugin plug-in to build an index or several indexes on a BackingMap to support non-key data access.
- JPA Loaders
  The Java Persistence API (JPA) is a specification that allows mapping Java objects to relational databases. JPA contains a full object-relational mapping (ORM) specification using Java language metadata annotations, XML descriptors, or both to define the mapping between Java objects and a relational database. A number of open-source and commercial implementations are available.

Plug-ins for communicating with databases

Sparse and complete cache

WebSphere® eXtreme Scale can be used as a sparse cache or a complete cache. A sparse cache only keeps a subset of the total data, while a complete cache keeps all of the data. and can be populated lazily, as the data is needed. Sparse caches are normally accessed using keys (instead of indexes or queries) because the data is only partially available.

Sparse cache

When a key is not present in a sparse cache, or the data is not available and a cache miss occurs, the next tier is invoked. The data is fetched, from a database for example, and is inserted into the data grid cache tier. If you are using a query or index, only the currently loaded values are accessed and the requests are not forwarded to the other tiers.

Complete cache

A complete cache contains all of the required data and can be accessed using non-key attributes with indexes or queries. A complete cache is preloaded with data from the database before the application tries to access the data. A complete cache can function as a database replacement after data is loaded. Because all of the data is available, queries and indexes can be used to find and aggregate data.

Side cache

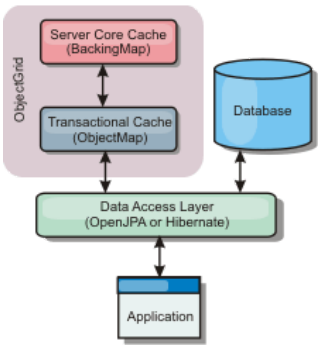
When WebSphere® eXtreme Scale is used as a side cache, the back end is used with the data grid.

Side cache

You can configure the product as a side cache for the data access layer of an application. In this scenario, WebSphere eXtreme Scale is used to temporarily store objects that would normally be retrieved from a back-end database. Applications check to see if the data grid contains the data. If the data is in the data grid, the data is returned to the caller. If the data does not exist, the data is retrieved from the back-end database. The data is then inserted into the data grid so that the next request can use the cached copy. The following diagram illustrates how WebSphere eXtreme Scale can be used as a side-cache with an arbitrary data access layer such as OpenJPA or Hibernate.

Side cache plug-ins for Hibernate and OpenJPA

Figure 1. Side cache



Cache plug-ins for both OpenJPA and Hibernate are included in WebSphere eXtreme Scale, so you can use the product as an automatic side-cache. Using WebSphere eXtreme Scale as a cache provider increases performance when reading and querying data and reduces load to the database. There are advantages that WebSphere eXtreme Scale has over built-in cache implementations because the cache is automatically replicated between all processes. When one client caches a value, all other clients can use the cached value.

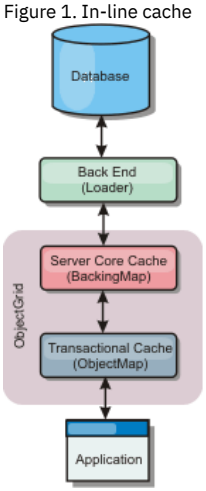
In-line cache

You can configure in-line caching for a database back end or as a side cache for a database. In-line caching uses eXtreme Scale as the primary means for interacting with the data. When eXtreme Scale is used as an in-line cache, the application interacts with the back end using a Loader plug-in.

In-line cache

When used as an in-line cache, WebSphere® eXtreme Scale interacts with the back end using a Loader plug-in. This scenario can simplify data access because applications can access the eXtreme Scale APIs directly. Several different caching scenarios are supported in eXtreme Scale to make sure the data in the cache and the data in the back end are synchronized. The following diagram illustrates how an in-line cache interacts with the application and back end.

Figure 1. In-line cache



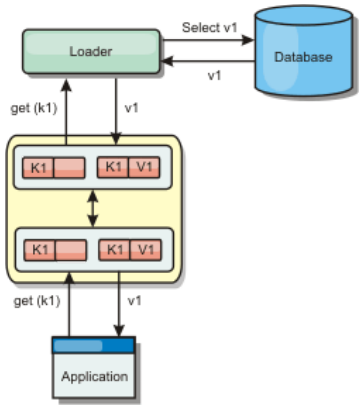
The in-line caching option simplifies data access because it allows applications to access the eXtreme Scale APIs directly. WebSphere eXtreme Scale supports several in-line caching scenarios, as follows.

- Read-through
- Write-through
- Write-behind

Read-through caching scenario

A read-through cache is a sparse cache that lazily loads data entries by key as they are requested. This is done without requiring the caller to know how the entries are populated. If the data cannot be found in the eXtreme Scale cache, eXtreme Scale will retrieve the missing data from the Loader plug-in, which loads the data from the back-end database and inserts the data into the cache. Subsequent requests for the same data key will be found in the cache until it is removed, invalidated or evicted.

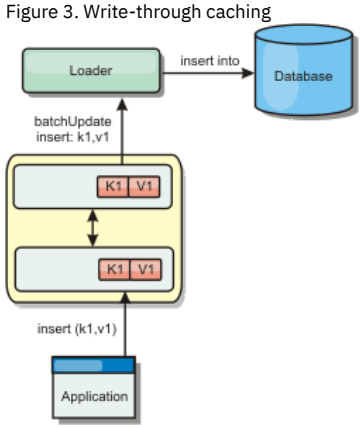
Figure 2. Read-through caching



Write-through caching scenario

In a write-through cache, every write to the cache synchronously writes to the database using the Loader. This method provides consistency with the back end, but decreases write performance since the database operation is synchronous. Since the cache and database are both updated, subsequent reads for the same data will be found in the cache, avoiding the database call. A write-through cache is often used in conjunction with a read-through cache.

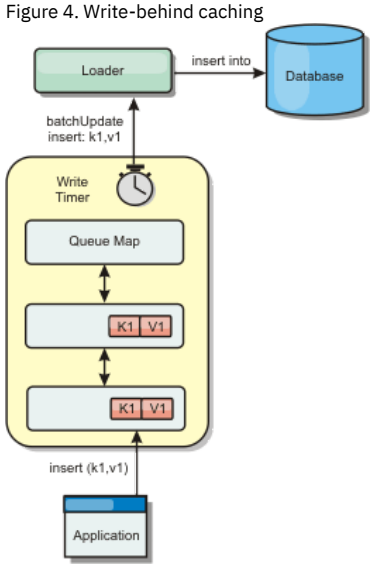
Figure 3. Write-through caching



Write-behind caching scenario

Database synchronization can be improved by writing changes asynchronously. This is known as a write-behind or write-back cache. Changes that would normally be written synchronously to the loader are instead buffered in eXtreme Scale and written to the database using a background thread. Write performance is significantly improved because the database operation is removed from the client transaction and the database writes can be compressed.

Figure 4. Write-behind caching



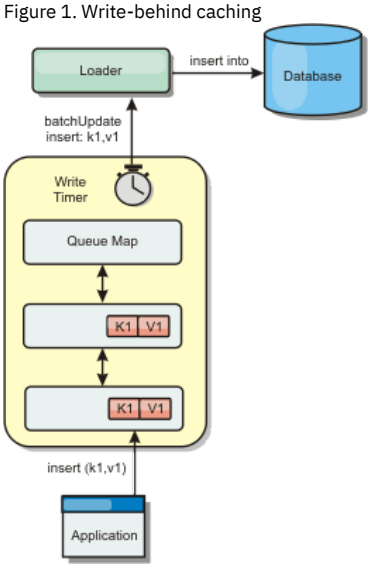
Write-behind caching

You can use write-behind caching to reduce the overhead that occurs when updating a database you are using as a back end.

Write-behind caching overview

Write-behind caching asynchronously queues updates to the Loader plug-in. You can improve performance by disconnecting updates, inserts, and removes for a map, the overhead of updating the back-end database. The asynchronous update is performed after a time-based delay (for example, five minutes) or an entry-based delay (1000 entries).

Figure 1. Write-behind caching



The write-behind configuration on a BackingMap creates a thread between the loader and the map. The loader then delegates data requests through the thread according to the configuration settings in the BackingMap.setWriteBehind method. When an eXtreme Scale transaction inserts, updates, or removes an entry from a map, a LogElement object is created for each of these records. These elements are sent to the write-behind loader and queued in a special ObjectMap called a queue map. Each backing map with the write-behind setting enabled has its own queue maps. A write-behind thread periodically removes the queued data from the queue maps and pushes them to the real back-end loader.

The write-behind loader only sends insert, update, and delete types of LogElement objects to the real loader. All other types of LogElement objects, for example, EVICT type, are ignored.

Write-behind support *is* an extension of the Loader plug-in, which you use to integrate eXtreme Scale with the database. For example, consult the Configuring JPA loaders information about configuring a JPA loader.

Benefits

Enabling write-behind support has the following benefits:

- **Back end failure isolation:** Write-behind caching provides an isolation layer from back end failures. When the back-end database fails, updates are queued in the queue map. The applications can continue driving transactions to eXtreme Scale. When the back end recovers, the data in the queue map is pushed to the back-end.
- **Reduced back end load:** The write-behind loader merges the updates on a key basis so only one merged update per key exists in the queue map. This merge decreases the number of updates to the back-end database.
- **Improved transaction performance:** Individual eXtreme Scale transaction times are reduced because the transaction does not need to wait for the data to be synchronized with the back-end.

Loaders

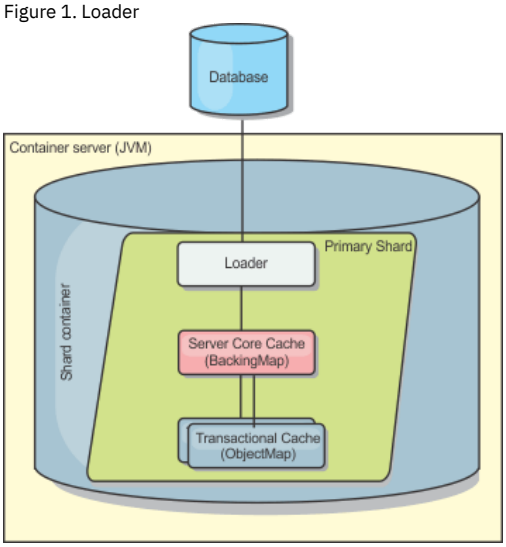
With a Loader plug-in, a data grid map can behave as a memory cache for data that is typically kept in a persistent store on either the same system or another system. Typically, a database or file system is used as the persistent store. A remote Java™ virtual machine (JVM) can also be used as the source of data, allowing hub-based caches to be built using eXtreme Scale. A loader has the logic for reading and writing data to and from a persistent store.

Overview

Loaders are backing map plug-ins that are invoked when changes are made to the backing map or when the backing map is unable to satisfy a data request (a cache miss). The Loader is invoked when the cache is unable to satisfy a request for a key. The Loader logic provides a read-through capability for the cache, which means that data is populated into the cache on demand. Since the entire data set does not need to be loaded upon startup, the cache can be populated lazily. A loader also allows updates to the database when cache values change. All changes within a transaction are grouped together to allow the number of database interactions to be minimized. A TransactionCallback plug-in is used in conjunction with the loader to trigger the demarcation of the backend

transaction. Using this plug-in is important when multiple maps are included in a single transaction or when transaction data is flushed to the cache without committing.

Figure 1. Loader



In order to avoid database locking on the row that requires updating, the loader can also perform optimistic transaction locking. In this scenario, no locking is required on a row. The update is overqualified to ensure that only rows that are in the same state as those originally read are changed. By storing a version attribute in the cache value, the loader can also see the before and after image of the value as it is updated in the cache. This value can then be used when updating the database or back end to verify that the data has not been updated. A Loader can also be configured to preload the data grid when it is started. When partitioned, a Loader instance is associated with each partition. If the "Company" Map has ten partitions, there are ten Loader instances, one per primary partition. When the primary shard for the Map is activated, the preloadMap method for the loader is invoked synchronously or asynchronously which allows loading the map partition with data from the back-end to occur automatically. When invoked synchronously, all client transactions are blocked, preventing inconsistent access to the data grid. Alternatively, a client preloader can be used to load the entire data grid.

Two built-in loaders can greatly simplify integration with relational database back ends. The JPA loaders utilize the Object-Relational Mapping (ORM) capabilities of both the OpenJPA and Hibernate implementations of the Java Persistence API (JPA) specification. See JPA Loaders for more information.

If you are using loaders in a multiple data center configuration, you must consider how revision data and cache consistency is maintained between the data grids. For more information, see Loader considerations in a multi-master topology.

Loader configuration

To add a Loader into the BackingMap configuration, you can use programmatic configuration or XML configuration. A loader has the following relationship with a backing map.

- A backing map can have only one loader.
- A client backing map (near cache) cannot have a loader.
- A loader definition can be applied to multiple backing maps, but each backing map has its own loader instance.

Data preloading and warm-up

In many scenarios that incorporate the use of a loader, you can prepare your data grid by preloading it with data.

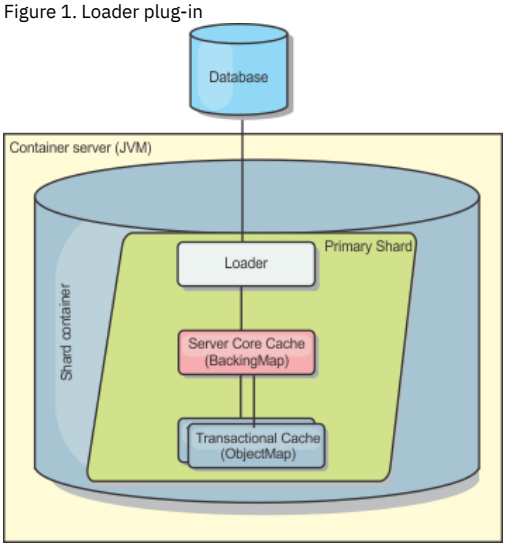
When used as a complete cache, the data grid must hold all of the data and must be loaded before any clients can connect to it. When you are using a sparse cache, you can warm up the cache with data so that clients can have immediate access to data when they connect.

Two approaches exist for preloading data into the data grid: Loader plug-in or client loader.

Loader plug-in

The Loader plug-in is associated with each map and is responsible for synchronizing a single primary partition shard with the database. The preloadMap method of the :Loader plug-in runs automatically when a shard is activated. For example, if you have 100 partitions, 100 loader instances exist, each loading the data for its partition. When run synchronously, all clients are blocked until the preload completes.

Figure 1. Loader plug-in

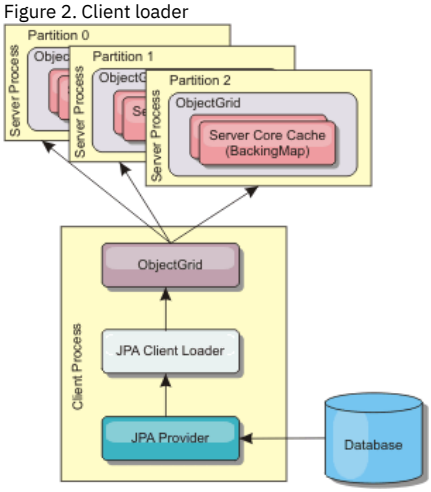


For more information about the Loader plug-in, see Plug-ins for communicating with databases.

Client loader

A client loader is a pattern for using one or more clients to load the data grid with data. Using multiple clients to load grid data can be effective when the partition scheme is not stored in the database. You can invoke client loaders manually or automatically when the data grid starts. Client loaders can optionally use the StateManager to set the state of the data grid to preload mode, so that clients are not able to access the data grid while it is preloading the data. WebSphere® eXtreme Scale includes a Java Persistence API (JPA)-based loader that you can use to automatically load the data grid with either the OpenJPA or Hibernate JPA providers. For more information about cache providers, see JPA level 2 (L2) cache plug-in.

Figure 2. Client loader



Database synchronization techniques

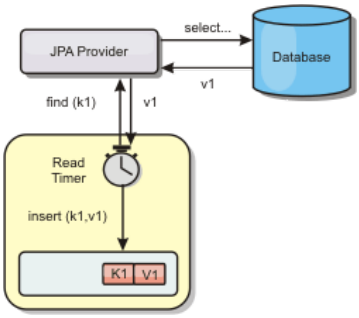
When WebSphere® eXtreme Scale is used as a cache, applications must be written to tolerate stale data if the database can be updated independently from an eXtreme Scale transaction. To serve as a synchronized in-memory database processing space, eXtreme Scale provides several ways of keeping the cache updated.

Database synchronization techniques

Periodic refresh

The cache can be automatically invalidated or updated periodically using the Java™ Persistence API (JPA) time-based database updater.The updater periodically queries the database using a JPA provider for any updates or inserts that have occurred since the previous update. Any changes identified are automatically invalidated or updated when used with a sparse cache. If used with a complete cache, the entries can be discovered and inserted into the cache. Entries are never removed from the cache.

Figure 1. Periodic refresh



Eviction

Sparse caches can utilize eviction policies to automatically remove data from the cache without affecting the database. There are three built-in policies included in eXtreme Scale: time-to-live, least-recently-used, and least-frequently-used. All three policies can optionally evict data more aggressively as memory becomes constrained by enabling the memory-based eviction option. See Plug-ins for evicting cache objects for further details.

Event-based invalidation

Sparse and complete caches can be invalidated or updated using an event generator such as Java Message Service (JMS). Invalidation using JMS can be manually tied to any process that updates the back-end using a database trigger. A JMS ObjectGridEventListener plug-in is provided in eXtreme Scale that can notify clients when the server cache has any changes. This can decrease the amount of time the client can see stale data.

Programmatic invalidation

The eXtreme Scale APIs allow manual interaction of the near and server cache using the Session.beginNoWriteThrough(), ObjectMap.invalidate() and EntityManager.invalidate() API methods. If a client or server process no longer needs a portion of the data, the invalidate methods can be used to remove data from the near or server cache. The beginNoWriteThrough method applies any ObjectMap or EntityManager operation to the local cache without calling the loader. If invoked from a client, the operation applies only to the near cache (the remote loader is not invoked). If invoked on the server, the operation applies only to the server core cache without invoking the loader.

Data invalidation

To remove stale cache data, you can use invalidation mechanisms.

8.5+

Administrative invalidation

You can use the web console or the **xscmd** utility to invalidate data based on the key. You can filter the cache data with a regular expression and then invalidate the data based on the regular expression.

Event-based invalidation

Sparse and complete caches can be invalidated or updated using an event generator such as Java™ Message Service (JMS). Invalidation using JMS can be manually tied to any process that updates the back-end using a database trigger. A JMS ObjectGridEventListener plug-in is provided in eXtreme Scale that can notify clients when the server cache changes. This type of notification decreases the amount of time the client can see stale data.

Event-based invalidation normally consists of the following three components.

- **Event queue:** An event queue stores the data change events. It could be a JMS queue, a database, an in-memory FIFO queue, or any kind of manifest as long as it can manage the data change events.
- **Event publisher:** An event publisher publishes the data change events to the event queue. An event publisher is usually an application you create or an eXtreme Scale plug-in implementation. The event publisher knows when the data is changed or it changes the data itself. When a transaction commits, events are generated for the changed data and the event publisher publishes these events to the event queue.
- **Event consumer:** An event consumer consumes data change events. The event consumer is usually an application to ensure the target grid data is updated with the latest change from other grids. This event consumer interacts with the event queue to get the latest data change and applies the data changes in the target grid. The event consumers can use eXtreme Scale APIs to invalidate stale data or update the grid with the latest data.

For example, JMSObjectGridEventListener has an option for a client-server model, in which the event queue is a designated JMS destination. All server processes are event publishers. When a transaction commits, the server gets the data changes and publishes them to the designated JMS destination. All the client processes are event consumers. They receive the data changes from the designated JMS destination and apply the changes to the client's near cache.

See Configuring Java Message Service (JMS)-based client synchronization for more information.

Programmatic invalidation

The WebSphere® eXtreme Scale APIs allow manual interaction of the near and server cache using the Session.beginNoWriteThrough(), ObjectMap.invalidate() and EntityManager.invalidate() API methods. If a client or server process no longer needs a portion of the data, the invalidate methods can be used to remove data from the near or server cache. The beginNoWriteThrough method applies any ObjectMap or EntityManager operation to the local cache without calling the loader. If invoked from a client, the operation applies only to the near cache (the remote loader is not invoked). If invoked on the server, the operation applies only to the server core cache without invoking the loader.

You can use programmatic invalidation with other techniques to determine when to invalidate the data. For example, this invalidation method uses event-based invalidation mechanisms to receive the data change events, and then uses APIs to invalidate the stale data.

Indexing

Use the MapIndexPlugin plug-in to build an index or several indexes on a BackingMap to support non-key data access.

Index types and configuration

The indexing feature is represented by the MapIndexPlugin plug-in or Index for short. The Index is a BackingMap plug-in. A BackingMap can have multiple Index plug-ins configured, as long as each one follows the Index configuration rules.

You can use the indexing feature to build one or more indexes on a BackingMap. An index is built from an attribute or a list of attributes of an object in the BackingMap. This feature provides a way for applications to find certain objects more quickly. With the indexing feature, applications can find objects with a specific value or within a range of values of indexed attributes.

Two types of indexing are possible: static and dynamic. With static indexing, you must configure the index plug-in on the BackingMap before initializing the ObjectGrid instance. You can do this configuration with XML or programmatic configuration of the BackingMap. Static indexing starts building an index during ObjectGrid initialization. The index is always synchronized with the BackingMap and ready for use. After the static indexing process starts, the maintenance of the index is part of the eXtreme Scale transaction management process. When transactions commit changes, these changes also update the static index, and index changes are rolled back if the transaction is rolled back.

With dynamic indexing, you can create an index on a BackingMap before or after the initialization of the containing ObjectGrid instance. Applications have life cycle control over the dynamic indexing process so that you can remove a dynamic index when it is no longer needed. When an application creates a dynamic index, the index might not be ready for immediate use because of the time it takes to complete the index building process. Because the amount of time depends upon the amount of data indexed, the DynamicIndexCallback interface is provided for applications that want to receive notifications when certain indexing events occur. These events include ready, error, and destroy. Applications can implement this callback interface and register with the dynamic indexing process.

If a BackingMap has an index plug-in configured, you can obtain the application index proxy object from the corresponding ObjectMap. Calling the getIndex method on the ObjectMap and passing in the name of the index plug-in returns the index proxy object. You must cast the index proxy object to an appropriate application index interface, such as MapIndex, MapRangeIndex, or a customized index interface. After obtaining the index proxy object, you can use methods defined in the application index interface to find cached objects.

The steps to use indexing are summarized in the following list:

- Add either static or dynamic index plug-ins into the BackingMap.
- Obtain an application index proxy object by issuing the getIndex method of the ObjectMap.
- Cast the index proxy object to an appropriate application index interface, such as MapIndex, MapRangeIndex, or a customized index interface.
- Use methods that are defined in application index interface to find cached objects.

The HashIndex class is the built-in index plug-in implementation that can support both of the built-in application index interfaces: MapIndex and MapRangeIndex. You also can create your own indexes. You can add HashIndex as either a static or dynamic index into the BackingMap, obtain either MapIndex or MapRangeIndex index proxy object, and use the index proxy object to find cached objects.

Default index

If you want to iterate through the keys in a local map, you can use the default index. This index does not require any configuration, but it must be used against the shard, using an agent or an ObjectGrid instance retrieved from the ShardEvents.shardActivated(ObjectGrid shard) method.

Data quality consideration

The results of index query methods only represent a snapshot of data at a point of time. No locks against data entries are obtained after the results return to the application. Application has to be aware that data updates may occur on a returned data set. For example, the application obtains the key of a cached object by running the findAll method of MapIndex. This returned key object is associated with a data entry in the cache. The application should be able to run the get method on ObjectMap to find an object by providing the key object. If another transaction removes the data object from the cache just before the get method is called, the returned result will be null.

Indexing performance considerations

One of the main objectives of the indexing feature is to improve overall BackingMap performance. If indexing is not used properly, the performance of the application might be compromised. Consider the following factors before using this feature.

- **The number of concurrent write transactions:** Index processing can occur every time a transaction writes data into a BackingMap. Performance degrades if many transactions are writing data into the map concurrently when an application attempts index query operations.
- **The size of the result set that is returned by a query operation:** As the size of the resultset increases, the query performance declines. Performance tends to degrade when the size of the result set is 15% or more of the BackingMap.
- **The number of indexes built over the same BackingMap:** Each index consumes system resources. As the number of the indexes built over the BackingMap increases, performance decreases.

The indexing function can improve BackingMap performance drastically. Ideal cases are when the BackingMap has mostly read operations, the query result set is of a small percentage of the BackingMap entries, and only few indexes are built over the BackingMap.

Planning multiple data center topologies

Using multi-master asynchronous replication, two or more data grids can become exact copies of each other. Each data grid is hosted in an independent catalog service domain, with its own catalog service, container servers, and a unique name. With multi-master asynchronous replication, you can use links to connect a collection of catalog service domains. The catalog service domains are then synchronized using replication over the links. You can construct almost any topology through the definition of links between the catalog service domains.

- Topologies for multi-master replication
  You have several different options when choosing the topology for your deployment that incorporates multi-master replication. Multi-master replication topologies can be implemented in the DataPower® XC10 Appliance by creating multiple collectives and linking them.
- Configuration considerations for multi-master topologies
  Consider the following issues when you are deciding whether and how to use multi-master replication topologies.
- Loader considerations in a multi-master topology
  When you are using loaders in a multi-master topology, you must consider the possible collision and revision information maintenance challenges. The data grid maintains revision information about the items in the data grid so that collisions can be detected when other primary shards in the configuration write entries to the data grid. When entries are added from a loader, this revision information is not included and the entry takes on a new revision. Because the revision of the entry seems to be a new insert, a false collision could occur if another primary shard also changes this state or pulls the same information in from a loader.
- Design considerations for multi-master replication
  When implementing multi-master replication, you must consider aspects in your design such as: arbitration, linking, and performance.

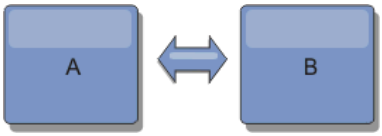
Topologies for multi-master replication

You have several different options when choosing the topology for your deployment that incorporates multi-master replication. Multi-master replication topologies can be implemented in the DataPower® XC10 Appliance by creating multiple collectives and linking them.

Links connecting catalog service domains

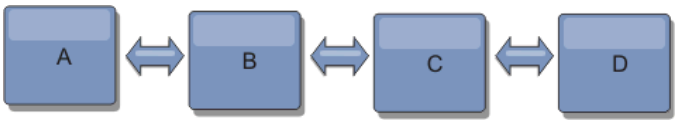
A replication data grid infrastructure is a connected graph of catalog service domains with bidirectional links among them. With a link, two catalog service domains can communicate data changes. For example, the simplest topology is a pair of catalog service domains with a single link between them. The catalog service domains are named alphabetically: A, B, C, and so on, from the left. A link can cross a wide area network (WAN), spanning large distances. Even if the link is interrupted, you can still change data in either catalog service domain. The topology reconciles changes when the link reconnects the catalog service domains. Links automatically try to reconnect if the network connection is interrupted.



After you set up the links, the product first tries to make every catalog service domain identical. Then, eXtreme Scale tries to maintain the identical conditions as changes occur in any catalog service domain. The goal is for each catalog service domain to be an exact mirror of every other catalog service domain connected by the links. The replication links between the catalog service domains help ensure that any changes made in one catalog service domain are copied to the other catalog service domains.

Line topologies

Although it is such a simple deployment, a line topology demonstrates some qualities of the links. First, it is not necessary for a catalog service domain to be connected directly to every other catalog service domain to receive changes. The catalog service domain B pulls changes from catalog service domain A. The catalog service domain C receives changes from catalog service domain A through catalog service domain B, which connects catalog service domains A and C. Similarly, catalog service domain D receives changes from the other catalog service domains through catalog service domain C. This ability spreads the load of distributing changes away from the source of the changes.



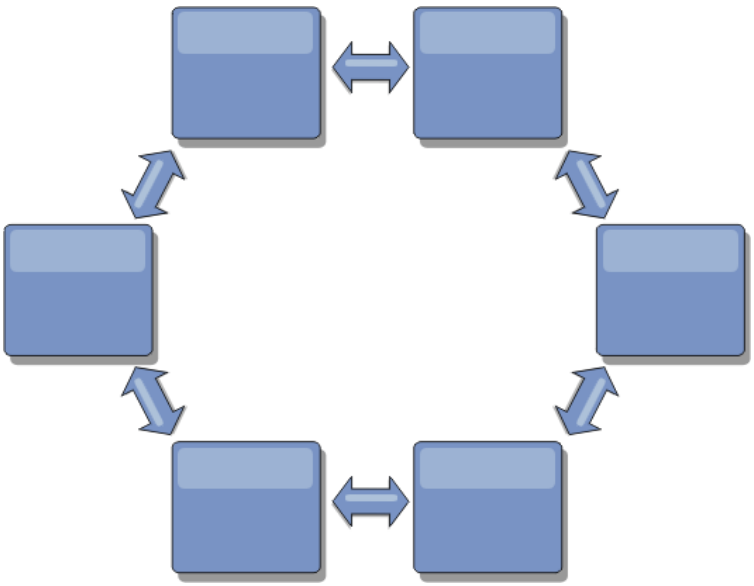
Notice that if catalog service domain C fails, the following actions would occur:

1. catalog service domain D would be orphaned until catalog service domain C was restarted
2. catalog service domain C would synchronize itself with catalog service domain B, which is a copy of catalog service domain A
3. catalog service domain D would use catalog service domain C to synchronize itself with changes on catalog service domain A and B. These changes initially occurred while catalog service domain D was orphaned (while catalog service domain C was down).

Ultimately, catalog service domains A, B, C, and D would all become identical to one other again.

Ring topologies

Ring topologies are an example of a more resilient topology. When a catalog service domain or a single link fails, the surviving catalog service domains can still obtain changes. The catalog service domains travel around the ring, away from the failure. Each catalog service domain has at most two links to other catalog service domains, no matter how large the ring topology. The latency to propagate changes can be large. Changes from a particular catalog service domain might need to travel through several links before all the catalog service domains have the changes. A line topology has the same characteristic.

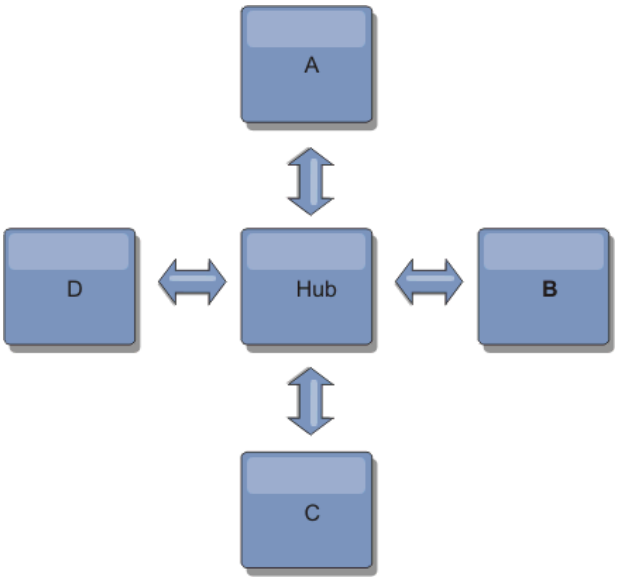


You can also deploy a more sophisticated ring topology, with a root catalog service domain at the center of the ring. The root catalog service domain functions as the central point of reconciliation. The other catalog service domains act as remote points of reconciliation for changes occurring in the root catalog service domain. The root catalog service domain can arbitrate changes among the catalog service domains. If a ring topology contains more than one ring around a root catalog service domain, the catalog service domain can only arbitrate changes among the innermost ring. However, the results of the arbitration spread throughout the catalog service domains in the other rings.

Hub-and-spoke topologies

With a hub-and-spoke topology, changes travel through a hub catalog service domain. Because the hub is the only intermediate catalog service domain that is specified, hub-and-spoke topologies have lower latency. The hub catalog service domain is connected to every spoke catalog service domain through a link. The hub distributes changes among the catalog service domains. The hub acts as a point of reconciliation for collisions. In an environment with a high update rate,

the hub might require run on more hardware than the spokes to remain synchronized. WebSphere® eXtreme Scale is designed to scale linearly, meaning you can make the hub larger, as needed, without difficulty. However, if the hub fails, then changes are not distributed until the hub restarts. Any changes on the spoke catalog service domains will be distributed after the hub is reconnected.



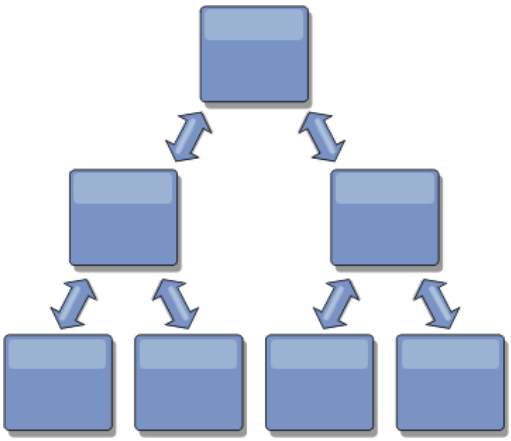
You can also use a strategy with fully replicated clients, a topology variation which uses a pair of servers that are running as a hub. Every client creates a self-contained single container data grid with a catalog in the client JVM. A client uses its data grid to connect to the hub catalog. This connection causes the client to synchronize with the hub as soon as the client obtains a connection to the hub.

Any changes made by the client are local to the client, and are replicated asynchronously to the hub. The hub acts as an arbitration catalog service domain, distributing changes to all connected clients. The fully replicated clients topology provides a reliable L2 cache for an object relational mapper, such as OpenJPA. Changes are distributed quickly among client JVMs through the hub. If the cache size can be contained within the available heap space, the topology is a reliable architecture for this style of L2.

Use multiple partitions to scale the hub catalog service domain on multiple JVMs, if necessary. Because all of the data still must fit in a single client JVM, multiple partitions increase the capacity of the hub to distribute and arbitrate changes. However, having multiple partitions does not change the capacity of a single catalog service domain.

Tree topologies

You can also use an acyclic directed tree. An acyclic tree has no cycles or loops, and a directed setup limits links to existing only between parents and children. This configuration is useful for topologies that have many catalog service domains. In these topologies, it is not practical to have a central hub that is connected to every possible spoke. This type of topology can also be useful when you must add child catalog service domains without updating the root catalog service domain.



A tree topology can still have a central point of reconciliation in the root catalog service domain. The second level can still function as a remote point of reconciliation for changes occurring in the catalog service domain beneath them. The root catalog service domain can arbitrate changes between the catalog service domains on the second level only. You can also use N-ary trees, each of which have N children at each level. Each catalog service domain connects out to *n* links.

Fully replicated clients

This topology variation involves a pair of servers that are running as a hub. Every client creates a self-contained single container data grid with a catalog in the client JVM. A client uses its data grid to connect to the hub catalog, causing the client to synchronize with the hub as soon as the client obtains a connection to the hub.

Any changes made by the client are local to the client, and are replicated asynchronously to the hub. The hub acts as an arbitration catalog service domain, distributing changes to all connected clients. The fully replicated clients topology provides a good L2 cache for an object relational mapper, such as OpenJPA. Changes are distributed quickly among client JVMs through the hub. As long as the cache size can be contained within the available heap space of the clients, this topology is a good architecture for this style of L2.

Use multiple partitions to scale the hub catalog service domain on multiple JVMs, if necessary. Because all of the data still must fit in a single client JVM, using multiple partitions increases the capacity of the hub to distribute and arbitrate changes, but it does not change the capacity of a single catalog service domain.

Configuring multiple data center topologies
Developing custom arbiters for multi-master replication

Configuration considerations for multi-master topologies

Consider the following issues when you are deciding whether and how to use multi-master replication topologies.

- **Map set requirements**
  Map sets must have the following characteristics to replicate changes across catalog service domain links:
  - The ObjectGrid name and map set name within a catalog service domain must match the ObjectGrid name and map set name of other catalog service domains. For example, ObjectGrid "og1" and map set "ms1" must be configured in catalog service domain A and catalog service domain B to replicate the data in the map set between the catalog service domains.
  - Is a data grid that is configured to use the `FIXED_PARTITIONS` placement strategy. `PER_CONTAINER` data grids cannot be replicated.
  - Has the same number of partitions in each catalog service domain. The map set might or might not have the same number and types of replicas.
  - Has the same data types being replicated in each catalog service domain.
  - Contains the same maps and dynamic map templates in each catalog service domain.
  - Does not use entity manager. A map set containing an entity map is not replicated across catalog service domains.
  - Does not use write-behind caching support. A map set containing a map that is configured with write-behind support is not replicated across catalog service domains.

  Any map sets with the preceding characteristics begin to replicate after the catalog service domains in the topology have been started.
- **Class loaders with multiple catalog service domains**
  Catalog service domains must have access to all classes that are used as keys and values. Any dependencies must be reflected in all class paths for data grid container Java virtual machines (JVM) for all domains. If a CollisionArbiter plug-in retrieves the value for a cache entry, then the classes for the values must be present for the domain that is starting the arbiter.

Loader considerations in a multi-master topology

When you are using loaders in a multi-master topology, you must consider the possible collision and revision information maintenance challenges. The data grid maintains revision information about the items in the data grid so that collisions can be detected when other primary shards in the configuration write entries to the data grid. When entries are added from a loader, this revision information is not included and the entry takes on a new revision. Because the revision of the entry seems to be a new insert, a false collision could occur if another primary shard also changes this state or pulls the same information in from a loader.

Replication changes invoke the get method on the loader with a list of the keys that are not already in the data grid but are going to be changed during the replication transaction. When the replication occurs, these entries are collision entries. When the collisions are arbitrated and the revision is applied then a batch update is called on the loader to apply the changes to the database. All of the maps that were changed in the revision window are updated in the same transaction.

Preload conundrum

Consider a two data center topology with data center A and data center B. Both data centers have independent databases, but only data center A is has a data grid that is running. When you establish a link between the data centers for a multi-master configuration, the data grids in data center A begin pushing data to the new data grids in data center B, causing a collision with every entry. Another major issue that occurs is with any data that is in the database in data center B but not in the database in data center A. These rows are not populated and arbitrated, resulting in inconsistencies that are not resolved.

Solution to the preload conundrum

Because data that resides only in the database cannot have revisions, you must always fully preload the data grid from the local database before establishing the multi-master link. Then, both data grids can revision and arbitrate the data, eventually reaching a consistent state.

Sparse cache conundrum

With a sparse cache, the application first attempts to find data in the data grid. If the data is not in the data grid, the data is searched for in the database using the loader. Entries are evicted from the data grid periodically to maintain a small cache size.

This cache type can be problematic in a multi-master configuration scenario because the entries within the data grid have revisioning metadata that help detect when collisions occur and which side has made changes. When links between the data centers are not working, one data center can update an entry and then eventually update the database and invalidate the entry in the data grid. When the link recovers, the data centers attempt to synchronize revisions with each other. However, because the database was updated and the data grid entry was invalidated, the change is lost from the perspective of the data center that went down. As a result, the two sides of the data grid are out of synch and are not consistent.

Solution to the sparse cache conundrum

Hub and spoke topology:
You can run the loader only in the hub of a hub and spoke topology, maintaining consistency of the data while scaling out the data grid. However, if you are considering this deployment, note that the loaders can allow the data grid to be partially loaded, meaning that an evictor has been configured. If the spokes of your configuration are sparse caches but have no loader, then any cache misses have no way to retrieve data from the database. Because of this restriction, you should use a fully populated cache topology with a hub and spoke configuration.

Invalidations and eviction

Invalidation creates inconsistency between the data grid and the database. Data can be removed from the data grid either programmatically or with eviction. When you develop your application, you must be aware that revision handling does not replicate changes that are invalidated, resulting in inconsistencies between primary shards.

Invalidation events are not cache state changes and do not result in replication. Any configured evictors run independently from other evictors in the configuration. For example, you might have one evictor configured for a memory threshold in one catalog service domain, but a different type of less aggressive evictor in your other linked catalog service domain. When data grid entries are removed due to the memory threshold policy, the entries in the other catalog service domain are not affected.

Database updates and data grid invalidation

Problems occur when you update the database directly in the background while calling the invalidation on the data grid for the updated entries in a multi-master configuration. This problem occurs because the data grid cannot replicate the change to the other primary shards until some type of cache access moves the entry into the data grid.

Multiple writers to a single logical database

When you are using a single database with multiple primary shards that are connected through a loader, transactional conflicts result. Your loader implementation must specially handle these types of scenarios.

Mirroring data using multi-master replication

You can configure independent databases that are connected to independent catalog service domains. In this configuration, the loader can push changes from one data center to the other data center.

Configuring multiple data center topologies
Developing custom arbiters for multi-master replication

Design considerations for multi-master replication

When implementing multi-master replication, you must consider aspects in your design such as: arbitration, linking, and performance.

Arbitration considerations in topology design

Change collisions might occur if the same records can be changed simultaneously in two places. Set up each catalog service domain to have about the same amount of processor, memory, network resources. You might observe that catalog service domains performing change collision handling (arbitration) use more resources than other catalog service domains. Collisions are detected automatically. They are handled with one of two mechanisms:

- **Default collision arbiter**: The default protocol is to use the changes from the lexically lowest named catalog service domain. For example, if catalog service domain A and B generate a conflict for a record, then the change from catalog service domain B is ignored. Catalog service domain A keeps its version and the record in catalog service domain B is changed to match the record from catalog service domain A. This behavior applies as well for applications where users or sessions are normally bound or have affinity with one of the data grids.
- **Custom collision arbiter**: Applications can provide a custom arbiter. When a catalog service domain detects a collision, it starts the arbiter. For information about developing a useful custom arbiter, see Developing custom arbiters for multi-master replication.

For topologies in which collisions are possible, consider implementing a hub-and-spoke topology or a tree topology. These two topologies are conducive to avoiding constant collisions, which can happen in the following scenarios:

1. Multiple catalog service domains experience a collision
2. Each catalog service domain handles the collision locally, producing revisions
3. The revisions collide, resulting in revisions of revisions

To avoid collisions, choose a specific catalog service domain, called an *arbitration catalog service domain* as the collision arbiter for a subset of catalog service domains. For example, a hub-and-spoke topology might use the hub as the collision handler. The spoke collision handler ignores any collisions that are detected by the spoke catalog service domains. The hub catalog service domain creates revisions, preventing unexpected collision revisions. The catalog service domain that is assigned to handle collisions must link to all of the domains for which it is responsible for handling collisions. In a tree topology, any internal parent domains handle collisions for their immediate children. In contrast, if you use a ring topology, you cannot designate one catalog service domain in the ring as the arbiter.

The following table summarizes the arbitration approaches that are most compatible with various topologies.

Table 1. Arbitration approaches. This table states whether application arbitration is compatible with various technologies.

Topology	Application Arbitration?	Notes
A line of two catalog service domains	Yes	Choose one catalog service domain as the arbiter.
A line of three catalog service domains	Yes	The middle catalog service domain must be the arbiter. Think of the middle catalog service domain as the hub in a simple hub-and-spoke topology.
A line of more than three catalog service domains	No	Application arbitration is not supported.
A hub with N spokes	Yes	Hub with links to all spokes must be the arbitration catalog service domain.
A ring of N catalog service domains	No	Application arbitration is not supported.
An acyclic, directed tree (n-ary tree)	Yes	All root nodes must rate their direct descendants only.

Linking considerations in topology design

Ideally, a topology includes the minimum number of links while optimizing trade-offs among change latency, fault tolerance, and performance characteristics.

- **Change latency**
  Change latency is determined by the number of intermediate catalog service domains a change must go through before arriving at a specific catalog service domain.

  A topology has the best change latency when it eliminates intermediate catalog service domains by linking every catalog service domain to every other catalog service domain. However, a catalog service domain must perform replication work in proportion to its number of links. For large topologies, the sheer number of links to be defined can cause an administrative burden.

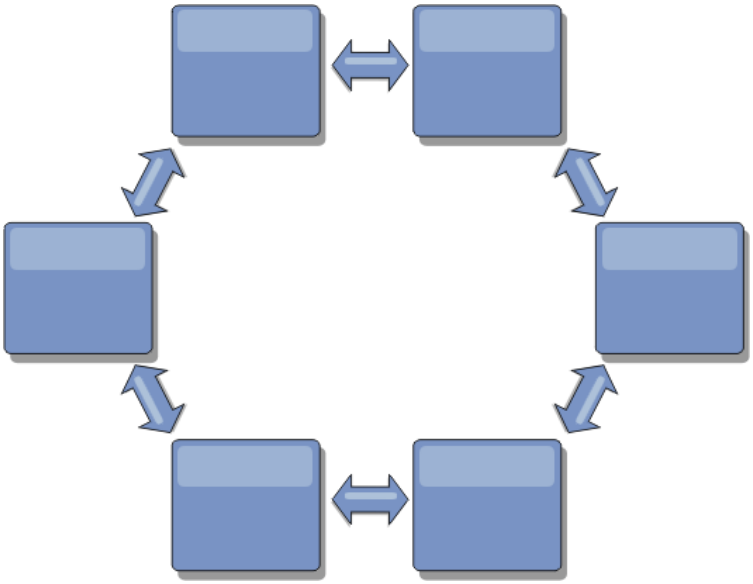
  The speed at which a change is copied to other catalog service domains depends on additional factors, such as:
  - Processor and network bandwidth on the source catalog service domain
  - The number of intermediate catalog service domains and links between the source and target catalog service domain
  - The processor and network resources available to the source, target, and intermediate catalog service domains
- **Fault tolerance**
  Fault tolerance is determined by how many paths exist between two catalog service domains for change replication.

  If you have only one link between a given pair of catalog service domains, a link failure disallows propagation of changes. Similarly, changes are not propagated between catalog service domains if any of the intermediate domains experiences link failure. Your topology could have a single link from one catalog service domain to another such that the link passes through intermediate domains. If so, then changes are not propagated if any of the intermediate catalog service domains is down.

  Consider the line topology with four catalog service domains A, B, C, and D:

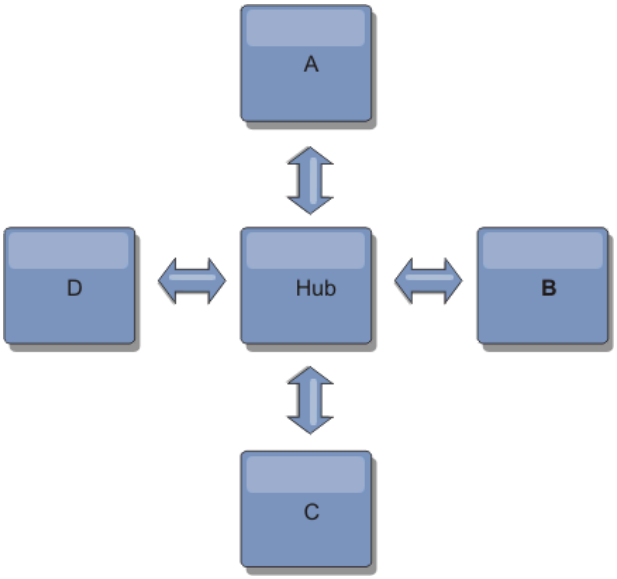
  
  If any of these conditions hold, Domain D does not see any changes from A:
  - Domain A is up and B is down
  - Domains A and B are up and C is down
  - The link between A and B is down
  - The link between B and C is down
  - The link between C and D is down

  In contrast, with a ring topology, each catalog service domain can receive changes from either direction.



For example, if a given catalog service in your ring topology is down, then the two adjacent domains can still pull changes directly from each other.

All changes are propagated through the hub. Thus, as opposed to the line and ring topologies, the hub-and-spoke design is susceptible to break drown if the hub fails.



A single catalog service domain is resilient to a certain amount of service loss. However, larger failures such as wide network outages or loss of links between physical data centers can disrupt any of your catalog service domains.

- **Linking and performance**
  The number of links defined on a catalog service domain affects performance. More links use more resources and replication performance can drop as a result. The ability to retrieve changes for a domain A through other domains effectively offloads domain A from replicating its transactions everywhere. The change distribution load on a domain is limited by the number of links it uses, not how many domains are in the topology. This load property provides scalability, so the domains in the topology can share the burden of change distribution.

  A catalog service domain can retrieve changes indirectly through other catalog service domains. Consider a line topology with five catalog service domains.

  ```
  A <=> B <=> C <=> D <=> E
  ```

  - A pulls changes from B, C, D, and E through B
  - B pulls changes from A and C directly, and changes from D and E through C
  - C pulls changes from B and D directly, and changes from A through B and E through D
  - D pulls changes from C and E directly, and changes from A and B through C
  - E pulls changes from D directly, and changes from A, B, and C through D

  The distribution load on catalog service domains A and E is lowest, because they each have a link only to a single catalog service domain. Domains B, C, and D each have a link to two domains. Thus, the distribution load on domains B, C, and D is double the load on domains A and E. The workload depends on the number of links in each domain, not on the overall number of domains in the topology. Thus, the described distribution of loads would remain constant, even if the line contained 1000 domains.

Multi-master replication performance considerations

Take the following limitations into account when using multi-master replication topologies:

- **Change distribution tuning**, as discussed in the previous section.
- **Replication link performance** WebSphere® eXtreme Scale creates a single TCP/IP socket between any pair of JVMs. All traffic between the JVMs occurs through the single socket, including traffic from multi-master replication. Catalog service domains are hosted on at least *n* container JVMs, providing at least *n* TCP links to peer catalog service domains. Thus, the catalog service domains with larger numbers of containers have higher replication performance levels. More containers require more processor and network resources.
- **TCP sliding window tuning and RFC 1323** RFC 1323 support on both ends of a link yields more data for a round trip. This support results in higher throughput, expanding the capacity of the window by a factor of about 16,000.
  Recall that TCP sockets use a sliding window mechanism to control the flow of bulk data. This mechanism typically limits the socket to 64 KB for a round-trip interval. If the round-trip interval is 100 ms, then the bandwidth is limited to 640 KB/second without additional tuning. Fully using the bandwidth available on a link might require tuning that is specific to an operating system. Most operating systems include tuning parameters, including RFC 1323 options, to enhance throughput over high-latency links.

  Several factors can affect replication performance:
  - The speed at which eXtreme Scale retrieves changes.
  - The speed at which eXtreme Scale can service retrieve replication requests.
  - The sliding window capacity.
  - With network buffer tuning on both sides of a link, eXtreme Scale retrieves changes over the socket efficiently.
- **Object Serialization** All data must be serializable. If a catalog service domain is not using `COPY_TO_BYTES`, then the catalog service domain must use Java™ serialization or ObjectTransformers to optimize serialization performance.
- **Compression** WebSphere eXtreme Scale compresses all data sent between catalog service domains by default. Disabling compression is not currently available.
- **Memory tuning** The memory usage for a multi-master replication topology is largely independent of the number of catalog service domains in the topology.
  Multi-master replication adds a fixed amount of processing per Map entry to handle versioning. Each container also tracks a fixed amount of data for each catalog service domain in the topology. A topology with two catalog service domains uses approximately the same memory as a topology with 50 catalog service domains. WebSphere eXtreme Scale does not use replay logs or similar queues in its implementation. Thus, there is no recovery structure ready in the case that a replication link is unavailable for a substantial period and later restarts.

Interoperability with other products

You can integrate WebSphere® eXtreme Scale with other products, such as WebSphere Application Server and WebSphere Application Server Community Edition.

WebSphere Application Server

You can integrate WebSphere Application Server into various aspects of your WebSphere eXtreme Scale configuration. You can deploy data grid applications and use WebSphere Application Server to host container and catalog servers. Or, you can use a mixed environment that has WebSphere eXtreme Scale Client installed in the WebSphere Application Server environment with stand-alone catalog and container servers. You can also use WebSphere Application Server security in your WebSphere eXtreme Scale environment.

WebSphere Business Process Management and Connectivity products

WebSphere Business Process Management and Connectivity products, including WebSphere Integration Developer, WebSphere Enterprise Service Bus, and WebSphere Process Server, integrate with back end systems, such as CICS®, web services, databases, or JMS topics and queues. You can add WebSphere eXtreme Scale to the configuration to cache the output of these back end systems, increasing the overall performance of your configuration.

WebSphere Commerce

WebSphere Commerce can leverage WebSphere eXtreme Scale caching as a replacement to dynamic cache. By eliminating duplicate dynamic cache entries and the frequent invalidation processing necessary to keep the cache synchronized during high stress situations, you can improve performance, scaling, and high availability.

WebSphere Portal

You can persist HTTP sessions from WebSphere Portal into a data grid in WebSphere eXtreme Scale. In addition, IBM® Web Content Manager in IBM WebSphere Portal can use dynamic cache instances to store rendered content that is retrieved from Web Content Manager when advanced caching is enabled. WebSphere eXtreme Scale offers an implementation of dynamic cache that stores cached content in an elastic data grid instead of using the default dynamic cache implementation.

WebSphere Application Server Community Edition

WebSphere Application Server Community Edition can share session state, but not in an efficient, scalable manner. WebSphere eXtreme Scale provides a high performance, distributed persistence layer that can be used to replicate state, but does not readily integrate with any application server outside of WebSphere Application Server. You can integrate these two products to provide a scalable session management solution.

WebSphere Real Time

With support for WebSphere Real Time, the industry-leading real-time Java™ offering, WebSphere eXtreme Scale enables Extreme Transaction Processing (XTP) applications to have more consistent and predictable response times.

Monitoring

WebSphere eXtreme Scale can be monitored using several popular enterprise monitoring solutions. Plug-in agents are included for IBM Tivoli® Monitoring and Hyperic HQ, which monitor WebSphere eXtreme Scale using publicly accessible management beans. CA Wily Introscope uses Java method instrumentation to capture statistics.

Planning for configuration

Before configuring the hardware or software, understand the following considerations.

- Planning for network ports
  WebSphere eXtreme Scale servers require several ports to operate.
- Planning to use IBM eXtremeMemory
  By configuring eXtremeMemory, you can store objects in native memory instead of on the Java™ heap. When you configure eXtremeMemory, you can either allow the default amount of memory to be used, or you can calculate the amount of memory that you want to dedicate to eXtremeMemory.
- Security overview
  WebSphere eXtreme Scale can secure data access, including allowing for integration with external security providers.

Planning for network ports

WebSphere® eXtreme Scale servers require several ports to operate.

Important: Avoid hard coding port numbers from the ephemeral range of your operating system. If you set a port that belongs in the ephemeral range, port conflicts can occur.

Catalog service domain

A catalog service domain requires the following ports to be defined:

peerPort

Specifies the port for the high availability (HA) manager to communicate between peer catalog servers over a TCP stack. In WebSphere Application Server, this setting is inherited by the high availability manager port configuration.

clientPort
: Specifies the port that peer catalog servers use to access each other's service data. While the value defined for peerPort is used for heartbeat communication between peers that are in the same domain, the clientPort is the port over which actual data gets exchanged. In WebSphere Application Server, this port is set through the catalog service domain configuration.

listenerPort (catalog server)
: Specifies the port number to which the Object Request Broker transport protocol binds for communication.
Default: `2809`

Note: When a data grid server is run inside and the ORB transport protocol is being used, another port ORB_LISTENER_ADDRESS must also be opened. The BOOTSTRAP_ADDRESS port forwards requests to this port.

JMXConnectorPort
: Defines the Secure Sockets Layer (SSL) port to which the Java™ Management Extensions (JMX) service binds. Only required if an SSL transport protocol is needed for JMX data.

SSLPort (optional)
: For secure transport of grid data, the SSL port is used only when the ORB transport protocol is used. If an SSL port is not configured an ephemeral port is chosen at startup, and this can vary each time the catalog server is restarted. When security is enabled, you must use the following argument on the **startOgServer** script to configure the Secure Socket Layer (SSL) port: `-jvmArgs -Dcom.ibm.CSI.SSLPort=<sslPort>`.

Container servers

The WebSphere eXtreme Scale container servers also require several ports to operate. By default, an eXtreme Scale container server generates its HA manager port and listener port automatically. For an environment that has a firewall, it is advantageous for you to plan and control ports. For container servers to start with specific ports, you can use the following options in the **startOgServer** command.

haManagerPort
: Specifies the port that is used by the high availability (HA) manager for heartbeat communication between peer container servers. The haManagerPort port is only used for peer-to-peer communication between container servers that are in same domain. If the haManagerPort property is not defined, then an ephemeral port is used. In WebSphere Application Server, this setting is inherited by the high availability manager port configuration.
Default: `A dynamic port is chosen`.

listenerPort (container server)
: Specifies the port number to which the ORB transport protocol binds for communication.
Default: An ephemeral port is chosen.

Note: When a data grid server is run inside WebSphere Application Server and the ORB transport protocol is being used, another port ORB_LISTENER_ADDRESS must also be opened. The BOOTSTRAP_ADDRESS port forwards requests to this port.

JMXConnectorPort
: Defines the Secure Sockets Layer (SSL) port to which the Java Management Extensions (JMX) service binds. Only required if an SSL transport protocol is needed for JMX data.

JMXServicePort
: Required only for WebSphere eXtreme Scale in a stand-alone environment. Specifies the port number on which the MBean server listens for communication with Java Management Extensions (JMX).
Default: `1099`

SSLPort (optional)
: For secure transport of grid data, the SSL port is used only when the ORB transport protocol is used. If an SSL port is not configured an ephemeral port is chosen at startup, and this can vary each time the container server is restarted. When security is enabled, you must use the following argument on the **startOgServer** script to configure the Secure Socket Layer (SSL) port: `-jvmArgs -Dcom.ibm.CSI.SSLPort=<sslPort>`.

Proper planning of port control is essential when hundreds of Java virtual machines are started in a server. If a port conflict exists, container servers do not start.

Clients

WebSphere eXtreme Scale clients can receive callbacks from servers when you are using the DataGrid API or other multi-partition operations. Use the listenerPort property in the client properties file to specify the port on which the client listens for callbacks from the server.

listenerPort (client)
: Specifies the port number to which the ORB transport protocol binds for communication. This setting configures the client to communicate with the catalog and container service. If a listener is not configured with the ORB transport protocol, an ephemeral port is chosen at startup. This port can vary each time the client application is started.
Default: An ephemeral port is chosen.

Note: When a data grid client is run inside WebSphere Application Server and the ORB transport protocol is being used, another port ORB_LISTENER_ADDRESS must also be opened. The BOOTSTRAP_ADDRESS port forwards requests to this port.

SSLPort (optional)
: For secure transport of grid data, the SSL port is used only when the ORB transport protocol is used. When the ORB transport protocol is used, SSL is an optional configuration. When SSL is enabled with the ORB transport protocol, both sides can initiate traffic. If an SSL port is not configured an ephemeral port is chosen at startup, and this can vary each time the client is restarted. When security is enabled, you must use the following system property when starting the client process: `-Dcom.ibm.CSI.SSLPort=<sslPort>`.

Ports in WebSphere Application Server

- The listenerPort value is inherited from the BOOTSTRAP_ADDRESS value for each WebSphere Application Server application server.

- The listenerPort value is inherited. The value is different depending on the type of transport you are using:
  - If you are using the ORB transport, the BOOTSTRAP_ADDRESS and the ORB_LISTENER_ADDRESS values for each WebSphere Application Server application server are used.
- The haManagerPort and peerPort values are inherited from the DCS_UNICAST_ADDRESS value for each WebSphere Application Server application server.
- The JMXServicePort and JMXConnectorPort values are inherited from the BOOTSTRAP_ADDRESS value for each WebSphere Application Server application server.
- The SSLPort value is inherited from the CSIV2_SSL_SERVERAUTH_LISTENER_ADDRESS value for each WebSphere Application Server application server.

You can define a catalog service domain in the administrative console. For more information, see Creating catalog service domains in WebSphere Application Server.

You can view the ports for a particular server by clicking one of the following paths in the administrative console:

- WebSphere Application Server Network Deployment Version 6.1: Servers > Application Servers > *server_name* > Ports > *end_point_name*.
- WebSphere Application Server Network Deployment Version 7.0 and later: Servers > Server Types > WebSphere Application Servers > *server_name* > Ports > *port_name*.

Security overview

WebSphere® eXtreme Scale can secure data access, including allowing for integration with external security providers.

Note: In an existing non-cached data store such as a database, you likely have built-in security features that you might not need to actively configure or enable. However, after you have cached your data with eXtreme Scale, you must consider the important resulting situation that your backend security features are no longer in effect. You can configureeXtreme Scale security on necessary levels so that your new cached architecture for your data is also secured.
A brief summary of eXtreme Scale security features follows. For more detailed information about configuring security see the *Administration Guide* and the *Programming Guide*.

Distributed security basics

Distributed eXtreme Scale security is based on three key concepts:

Trustable authentication
: The ability to determine the identity of the requester. WebSphere eXtreme Scale supports both client-to-server and server-to-server authentication.

Authorization
: The ability to give permissions to grant access rights to the requester. WebSphere eXtreme Scale supports different authorizations for various operations.

Secure transport
: The safe transmission of data over a network. WebSphere eXtreme Scale supports the Transport Layer Security/Secure Sockets Layer (TLS/SSL) protocols.

Authentication

WebSphere eXtreme Scale supports a distributed client server framework. A client server security infrastructure is in place to secure access to eXtreme Scale servers. For example, when authentication is required by the eXtreme Scale server, an eXtreme Scale client must provide credentials to authenticate to the server. These credentials can be a user name and password pair, a client certificate, a Kerberos ticket, or data that is presented in a format that is agreed upon by client and server.

Authorization

WebSphere eXtreme Scale authorizations are based on subjects and permissions. You can use the Java™ Authentication and Authorization Services (JAAS) to authorize the access, or you can plug in a custom approach, such as Tivoli® Access Manager (TAM), to handle the authorizations. The following authorizations can be given to a client or group:

Map authorization
: Perform insert, read, update, evict, or delete operations on Maps.

ObjectGrid authorization
: Perform object or entity queries on ObjectGrid objects.

DataGrid agent authorization
: Allow DataGrid agents to be deployed to an ObjectGrid.

Server side map authorization
: Replicate a server map to client side or create a dynamic index to the server map.

Administration authorization
: Perform administration tasks.

Transport security

To secure the client server communication, WebSphere eXtreme Scale supports TLS/SSL. These protocols provide transport layer security with authenticity, integrity, and confidentiality for a secure connection between an eXtreme Scale client and server.

Grid security

In a secure environment, a server must be able to check the authenticity of another server. WebSphere eXtreme Scale uses a shared secret key string mechanism for this purpose. This secret key mechanism is similar to a shared password. All the eXtreme Scale servers agree on a shared secret string. When a server joins the data grid, the server is challenged to present the secret string. If the secret string of the joining server matches the one in the master server, then the joining server can join the grid. Otherwise, the join request is rejected.

Sending a clear text secret is not secure. The eXtreme Scale security infrastructure provides a SecureTokenManager plug-in to allow the server to secure this secret before sending it. You can choose how you implement the secure operation. WebSphere eXtreme Scale provides an implementation, in which the secure operation is implemented to encrypt and sign the secret.

Java Management Extensions (JMX) security in a dynamic deployment topology

JMX MBean security is supported in all versions of eXtreme Scale. Clients of catalog server MBeans and container server MBeans can be authenticated, and access to MBean operations can be enforced.

Local eXtreme Scale security

Local eXtreme Scale security is different from the distributed eXtreme Scale model because the application directly instantiates and uses an ObjectGrid instance. Your application and eXtreme Scale instances are in the same Java virtual machine (JVM). Because no client-server concept exists in this model, authentication is not supported. Your applications must manage their own authentication, and then pass the authenticated Subject object to the eXtreme Scale. However, the authorization mechanism that is used for the local eXtreme Scale programming model is the same as what is used for the client-server model.

Configuration and programming

For more information about configuring and programming for security, see Security integration with external providers and Security API.

Planning for installation

Before you install the product, you must consider software and hardware requirements and Java environment settings.

- Hardware and software requirements
  Browse an overview of hardware and operating system requirements. Although you are not required to use a specific level of hardware or operating system for WebSphere eXtreme Scale, formally supported hardware and software options are available on the Systems Requirements page of the product support site. If a conflict exists between the information center and the System Requirements page, the information at the website takes precedence. Prerequisite information in the information center is provided as a convenience only.
- Java SE considerations
  WebSphere eXtreme Scale requires Java™ SE 5, Java SE 6, or Java SE 7. In general, newer versions of Java SE have better functionality and performance.
- Java EE considerations
  As you prepare to integrate WebSphere eXtreme Scale in a Java Platform, Enterprise Edition environment, consider certain items, such as versions, configuration options, requirements and limitations, and application deployment and management.
- Directory conventions
  The following directory conventions are used throughout the documentation to reference special directories such as *wxs_install_root* and *wxs_home*. You access these directories during several different scenarios, including during installation and use of command-line tools.

Hardware and software requirements

Browse an overview of hardware and operating system requirements. Although you are not required to use a specific level of hardware or operating system for WebSphere® eXtreme Scale, formally supported hardware and software options are available on the Systems Requirements page of the product support site. If a

conflict exists between the information center and the System Requirements page, the information at the website takes precedence. Prerequisite information in the information center is provided as a convenience only.

See the System Requirements page for the official set of hardware and software requirements.

You can install and deploy the product in Java™ EE and Java SE environments. You can also bundle the client component with Java EE applications directly without integrating with WebSphere Application Server.

Hardware requirements

WebSphere eXtreme Scale does not require a specific level of hardware. The hardware requirements are dependent on the supported hardware for the Java Platform, Standard Edition installation that you use to run WebSphere eXtreme Scale. If you are using eXtreme Scale with WebSphere Application Server or another Java Platform, Enterprise Edition implementation, the hardware requirements of these platforms are sufficient for WebSphere eXtreme Scale.

Operating system requirements

8.5+ Each Java SE and Java EE implementation requires different operating system levels or fixes for problems that are discovered during the testing of the Java implementation. The levels required by these implementations are sufficient for eXtreme Scale.

8.5+

Installation Manager requirements

Before you can install WebSphere eXtreme Scale, you must install Installation Manager. You can install Installation Manager using the product media, using a file obtained from the Passport Advantage® site, or using a file containing the most current version of Installation Manager from the IBM® Installation Manager download website. See IBM Installation Manager and WebSphere eXtreme Scale product offerings for more information.

Web browser requirements

The web console supports the following Web browsers:

- Mozilla Firefox, version 3.5.x and later
- Microsoft Internet Explorer, version 7 and later

WebSphere Application Server requirements

8.5

- WebSphere Application Server Version 6.1.0.41 or later
- WebSphere Application Server Version 7.0.0.19 or later
- WebSphere Application Server Version 8.0.0.2 or later
- WebSphere Application Server Version 8.5.0.1 or later

See the Recommended fixes for WebSphere Application Server for more information.

Java requirements

8.5 Other Java EE implementations can use the eXtreme Scale run time as a local instance or as a client to eXtreme Scale servers. To implement Java SE, you must use Version 5 or later.

Java SE considerations

WebSphere® eXtreme Scale requires Java™ SE 5, Java SE 6, or Java SE 7. In general, newer versions of Java SE have better functionality and performance.

Supported versions

You can use WebSphere eXtreme Scale with Java SE 5, Java SE 6, and Java SE 7. The version that you use must be currently supported by the Java Runtime Environment (JRE) vendor. If you want to use Secure Sockets Layer (SSL), you must use an IBM® Runtime Environment.
IBM Runtime Environment, Java Technology Edition Version 5, Version 6 , and Version 7 are supported for general use with the product. Version 6 Service Release 9 Fix Pack 2 is a fully supported JRE that is installed as a part of the stand-alone WebSphere eXtreme Scale and WebSphere eXtreme Scale Client installations in the *wxs_install_root*/java directory and is available to be used by both clients and servers. If you are installing WebSphere eXtreme Scale within WebSphere Application Server, you can use the JRE that is included in the WebSphere Application Server installation. For the web console, you must use IBM Runtime Environment, Java Technology Edition Version 6 Service Release 7 and later service releases only.

WebSphere eXtreme Scale takes advantage of Java Development Kit (JDK) Version 5 , Version 6 , and Version 7 functionality as it becomes available. Generally, newer versions of the Java Development Kit (JDK) and Java SE have better performance and functionality.

For more information, see Supported software.

WebSphere eXtreme Scale features that are dependent on Java SE

Table 1. Features that require Java SE 5, Java SE 6, and Java SE 7 . WebSphere eXtreme Scale uses functionality that is introduced in Java SE 5 or Java SE 6 to provide the following product features.

Feature	Supported in Java SE 5 and later service releases	Supported in Java SE Version 6 , Version 7 and later service releases
EntityManager API annotations (Optional: You can also use XML files)	X	X
Java Persistence API (JPA): JPA loader, JPA client loader, and JPA time-based updater	X	X
Memory-based eviction (uses MemoryPoolMXBean)	X	X
Instrumentation agents: • wxssizeagent.jar: Increases the accuracy of the used bytes map metrics. • ogagent.jar: Increases the performance of field-access entities.	X	X
Web console for monitoring		X

Upgrading the JDK in WebSphere eXtreme Scale

Common questions about the upgrade process for releases of WebSphere eXtreme Scale in both stand-alone and WebSphere Application Server environments follow:

- How do I upgrade the JDK that is included in WebSphere eXtreme Scale Version 7.1.0 for a stand-alone environment?
  WebSphere eXtreme Scale Version 7.1.0 included a JRE which is automatically installed to the *wxs_install_root*/java directory. WebSphere eXtreme Scale Version 7.1.0 GA shipped with IBM Java Runtime Environment (JRE) Version 1.6 SR4. To update the JRE shipped with WebSphere eXtreme Scale 7.1.0 requires the application of WebSphere eXtreme Scale 7.1.0 Refresh Pack 0000001 followed by iFIX IFPM56253. For more information, see http://www-304.ibm.com/support/docview.wss?uid=swg1PM56253

  Note: There is currently no interim fix available to upgrade a JRE that was included with WebSphere eXtreme Scale Version 7.0.x.x.
  CAUTION:
  Errors might occur in stand-alone configurations of WebSphere eXtreme Scale that are using the Java 6 runtime and SSL Transport Layer security.
- How do I upgrade the JDK that is included with WebSphere eXtreme Scale for WebSphere Application Server?
  You need to use the JDK upgrade process that is made available by WebSphere Application Server. For more information, see http://www-304.ibm.com/support/docview.wss?uid=swg21427178.

- Which version of the JDK should I use when using WebSphere eXtreme Scale in a WebSphere Application Server environment?
  You can use any level of JDK that is supported by WebSphere Application Server, for the supported version of WebSphere Application Server.

Java EE considerations

As you prepare to integrate WebSphere® eXtreme Scale in a Java™ Platform, Enterprise Edition environment, consider certain items, such as versions, configuration options, requirements and limitations, and application deployment and management.

Running eXtreme Scale applications in a Java EE environment

A Java EE application can connect to a remote eXtreme Scale application. Additionally, the WebSphere Application Server environment supports starting an eXtreme Scale server when an application starts in the application server.

If you use an XML file to create an ObjectGrid instance, and the XML file is in the module of the enterprise archive (EAR) file, access the file by using the getClass().getClassLoader().getResource("META-INF/objGrid.xml") method to obtain a URL object to use to create an ObjectGrid instance. Substitute the name of the XML file that you are using in the method call.

You can use startup beans for an application to bootstrap an ObjectGrid instance when the application starts, and to destroy the instance when the application stops. A startup bean is a stateless session bean with a com.ibm.websphere.startupservice.AppStartUpHome remote location and a com.ibm.websphere.startupservice.AppStartUp remote interface. The remote interface has two methods: the start method and the stop method. Use the start method to bootstrap the instance, and use the stop method to destroy the instance. The application uses the ObjectGridManager.getObjectGrid method to maintain a reference to the instance. See Interacting with an ObjectGrid using the ObjectGridManager interface for more information.

Using class loaders

When application modules that use different class loaders share a single ObjectGrid instance in a Java EE application, verify the objects that are stored in eXtreme Scale and the plug-ins for the product are in a common loader in the application.

Managing the life cycle of ObjectGrid instances in a servlet

To manage the life cycle of an ObjectGrid instance in a servlet, you can use the init method to create the instance and the destroy method to remove the instance. If the instance is cached, it is retrieved and manipulated in the servlet code. See Interacting with an ObjectGrid using the ObjectGridManager interface for more information.

Directory conventions

The following directory conventions are used throughout the documentation to reference special directories such as *wxs_install_root* and *wxs_home*. You access these directories during several different scenarios, including during installation and use of command-line tools.

wxs_install_root
: The *wxs_install_root* directory is the root directory where WebSphere® eXtreme Scale product files are installed. The *wxs_install_root* directory can be the directory in which the trial archive is extracted or the directory in which the WebSphere eXtreme Scale product is installed.

- Example when extracting the trial:
  Example: /opt/IBM/WebSphere/eXtremeScale
- Example when WebSphere eXtreme Scale is installed to a stand-alone directory:
  UNIX **Example:** /opt/IBM/eXtremeScale

  Windows **Example:** C:\Program Files\IBM\WebSphere\eXtremeScale
- Example when WebSphere eXtreme Scale is integrated with WebSphere Application Server:
  Example: /opt/IBM/WebSphere/AppServer

wxs_home
: The *wxs_home* directory is the root directory of the WebSphere eXtreme Scale product libraries, samples, and components. This directory is the same as the *wxs_install_root* directory when the trial is extracted. For stand-alone installations, the *wxs_home* directory is the ObjectGrid subdirectory within the *wxs_install_root* directory. For installations that are integrated with WebSphere Application Server, this directory is the optionalLibraries/ObjectGrid directory within the *wxs_install_root* directory.

- Example when extracting the trial:
  Example: /opt/IBM/WebSphere/eXtremeScale
- Example when WebSphere eXtreme Scale is installed to a stand-alone directory:
  UNIX **Example:** /opt/IBM/eXtremeScale/ObjectGrid

  Windows **Example:** *wxs_install_root*\ObjectGrid
- Example when WebSphere eXtreme Scale is integrated with WebSphere Application Server:
  Example: /opt/IBM/WebSphere/AppServer/optionalLibraries/ObjectGrid

was_root
: The *was_root* directory is the root directory of a WebSphere Application Server installation:
  Example: /opt/IBM/WebSphere/AppServer

restservice_home
: The *restservice_home* directory is the directory in which the WebSphere eXtreme Scale REST data service libraries and samples are located. This directory is named restservice and is a subdirectory under the *wxs_home* directory.

- Example for stand-alone deployments:
  Example: /opt/IBM/WebSphere/eXtremeScale/ObjectGrid/restservice

  Example: *wxs_home*\restservice
- Example for WebSphere Application Server integrated deployments:
  Example: /opt/IBM/WebSphere/AppServer/optionalLibraries/ObjectGrid/restservice

tomcat_root
: The *tomcat_root* is the root directory of the Apache Tomcat installation.
  Example: /opt/tomcat5.5

wasce_root
: The *wasce_root* is the root directory of the WebSphere Application Server Community Edition installation.

Example: /opt/IBM/WebSphere/AppServerCE

java_home
The *java_home* is the root directory of a Java™ Runtime Environment (JRE) installation.
UNIX **Example:** /opt/IBM/WebSphere/eXtremeScale/java

Windows **Example:** *wxs_install_root*\java

samples_home
The *samples_home* is the directory in which you extract the sample files that are used for tutorials.
UNIX **Example:** *wxs_home*/samples

Windows **Example:** *wxs_home*\samples

dvd_root
The *dvd_root* directory is the root directory of the DVD that contains the product.
Example: dvd_root/docs/

equinox_root
The *equinox_root* directory is the root directory of the Eclipse Equinox OSGi framework installation.
Example:/opt/equinox

user_home
The *user_home* directory is the location where user files are stored, such as security profiles.
Windows c:\Documents and Settings*user_name*

UNIX /home/*user_name*

Planning environment capacity

If you have an initial data set size and a projected data set size, you can plan the capacity that you need to run WebSphere® eXtreme Scale. By using these planning exercises, you can deploy WebSphere eXtreme Scale efficiently for future changes and maximize the elasticity of the data grid, which you would not have with a different scenario such as an in-memory database or other type of database.

- Sizing memory and partition count calculation
  You can calculate the amount of memory and partitions needed for your specific configuration.
- Sizing CPU per partition for transactions
  Although a major functionality of eXtreme Scale is its ability for elastic scaling, it is also important to consider sizing and to adjust the ideal number of CPUs to scale up.
- Sizing CPUs for parallel transactions
  Single-partition transactions have throughput scaling linearly as the data grid grows. Parallel transactions are different from single-partition transactions because they touch a set of the servers (this can be all of the servers).
- Dynamic cache capacity planning
  The Dynamic Cache API is available to Java™ EE applications that are deployed in WebSphere Application Server. You can use the dynamic cache to cache business data, generated HTML, or to synchronize the cached data in the cell by using the data replication service (DRS).

Sizing memory and partition count calculation

You can calculate the amount of memory and partitions needed for your specific configuration.

Attention: This topic applies when you are **not** using the COPY_TO_BYTES copy mode. If you are using the COPY_TO_BYTES mode, then the memory size is much less and the calculation procedure is different. For more information about this mode, see Tuning the copy mode.
WebSphere eXtreme Scale stores data within the address space of Java™ virtual machines (JVM). Each JVM provides processor space for servicing create, retrieve, update, and delete calls for the data that is stored in the JVM. In addition, each JVM provides memory space for data entries and replicas. Java objects vary in size, therefore you must make a measurement to make an estimate of how much memory you need.
To size the memory that you need, load your application data into a single JVM. When the heap usage reaches 60%, note the number of objects that are used. This number is the maximum recommended object count for each of your Java virtual machines. To get the most accurate sizing, use realistic data and include any defined indexes in your sizing because indexes also consume memory. The best way to size memory use is to run garbage collection **verbosegc** output because this output gives you the numbers after garbage collection. You can query the heap usage at any given point through MBeans or programmatically, but those queries give you only a current snapshot of the heap. This snapshot might include uncollected garbage, so using that method is not an accurate indication of the consumed memory.

Scaling up the configuration

Number of shards per partition (numShardsPerPartition value)
To calculate the number of shards per partition, or the numShardsPerPartition value, add `1` for the primary shard plus the total number of replica shards you want. For more information about partitioning, see Partitioning.

```
numShardsPerPartition = 1 + total_number_of_replicas
```

Number of Java virtual machines (minNumJVMs value)

To scale up your configuration, first decide on the maximum number of objects that need to be stored in total. To determine the number of Java virtual machines you need, use the following formula:

```
minNumJVMS=(numShardsPerPartition * numObjs) / numObjsPerJVM
```

Round this value up to the nearest integer value.
Number of shards (numShards value)

At the final growth size, use 10 shards for each JVM. As described before, each JVM has one primary shard and (N-1) shards for the replicas, or in this case, nine replicas. Because you already have a number of Java virtual machines to store the data, you can multiply the number of Java virtual machines by 10 to determine the number of shards:

```
numShards = minNumJVMs * 10 shards/JVM
```

Number of partitions If a partition has one primary shard and one replica shard, then the partition has two shards (primary and replica). The number of partitions is the shard count divided by 2, rounded up to the nearest prime number. If the partition has a primary and two replicas, then the number of partitions is the shard count divided by 3, rounded up to the nearest prime number.

```
numPartitions = numShards / numShardsPerPartition
```

Example of scaling

In this example, the number of entries begins at 250 million. Each year, the number of entries grows about 14%. After seven years, the total number of entries is 500 million, so you must plan your capacity accordingly. For high availability, a single replica is needed. With a replica, the number of entries doubles, or 1,000,000,000 entries. As a test, 2 million entries can be stored in each JVM. Using the calculations in this scenario the following configuration is needed:

- 500 Java virtual machines to store the final number of entries.
- 5000 shards, calculated by multiplying 500 Java virtual machines by 10.
- 2500 partitions, or 2503 as the next highest prime number, calculated by taking the 5000 shards, divided by two for primary and replica shards.

Starting configuration

Based on the previous calculations, start with 250 Java virtual machines and grow toward 500 Java virtual machines over five years. With this configuration, you can manage incremental growth until you arrive at the final number of entries.
In this configuration, about 200,000 entries are stored per partition (500 million entries divided by 2503 partitions). Set the numberOfBuckets parameter on the map that holds the entries to the closest higher prime number, in this example 70887, which keeps the ratio around three.

When the maximum number of Java virtual machines is reached

When you reach your maximum number of 500 Java virtual machines, you can still grow your data grid. As the number of Java virtual machines grows beyond 500, the shard count begins to drop below 10 for each JVM, which is below the recommended number. The shards start to become larger, which can cause problems. Repeat the sizing process considering future growth again, and reset the partition count. This practice requires a full data grid restart, or an outage of your data grid.

Number of servers

Attention: Do not use paging on a server under any circumstances.
A single JVM uses more memory than the heap size. For example, 1 GB of heap for a JVM actually uses 1.4 GB of real memory. Determine the available free RAM on the server. Divide the amount of RAM by the memory per JVM to get the maximum number of Java virtual machines on the server.
Related concepts:
Sizing CPU per partition for transactions
Sizing CPUs for parallel transactions
Dynamic cache capacity planning

Sizing CPU per partition for transactions

Although a major functionality of eXtreme Scale is its ability for elastic scaling, it is also important to consider sizing and to adjust the ideal number of CPUs to scale up.

Processor costs include:

- Cost of servicing create, retrieve, update, and delete operations from clients
- Cost of replication from other Java™ virtual machines
- Cost of invalidation
- Cost of eviction policy
- Cost of garbage collection
- Cost of application logic
- Cost of serialization

Java virtual machines per server

Use two servers and start the maximum JVM count per server. Use the calculated partition counts from the previous section. Then, preload the Java virtual machines with enough data to fit on these two computers only. Use a separate server as a client. Run a realistic transaction simulation against this data grid of two servers.
To calculate the baseline, try to saturate the processor usage. If you cannot saturate the processor, then it is likely that the network is saturated. If the network is saturated, add more network cards and round robin the Java virtual machines over the multiple network cards.

Run the computers at 60% processor usage, and measure the create, retrieve, update, and delete transaction rate. This measurement provides the throughput on two servers. This number doubles with four servers, doubles again at 8 servers, and so on. This scaling assumes that the network capacity and client capacity is also able to scale.

As a result, eXtreme Scale response time should be stable as the number of servers is scaled up. The transaction throughput should scale linearly as computers are added to the data grid.
Related concepts:
Sizing memory and partition count calculation
Sizing CPUs for parallel transactions
Dynamic cache capacity planning

Sizing CPUs for parallel transactions

Single-partition transactions have throughput scaling linearly as the data grid grows. Parallel transactions are different from single-partition transactions because they touch a set of the servers (this can be all of the servers).

If a transaction touches all of the servers, then the throughput is limited to the throughput of the client that initiates the transaction or the slowest server touched. Larger data grids spread the data out more and provide more processor space, memory, network, and so on. However, the client must wait for the slowest server to respond, and the client must consume the results of the transaction.

When a transaction touches a subset of the servers, M out of N servers get a request. The throughput is then N divided by M times faster than the throughput of the slowest server. For example, if you have 20 servers and a transaction that touches 5 servers, then the throughput is 4 times the throughput of the slowest server in the data grid.

When a parallel transaction completes, the results are sent to the client thread that started the transaction. This client must then aggregate the results single threaded. This aggregation time increases as the number of servers touched for the transaction grows. However, this time depends on the application because it is possible that each server returns a smaller result as the data grid grows.

Typically, parallel transactions touch all of the servers in the data grid because partitions are uniformly distributed over the grid. In this case, throughput is limited to the first case.

Summary

With this sizing, you have three metrics, as follows.

- Number of partitions.
- Number of servers that are needed for the memory that is required.
- Number of servers that are needed for the required throughput.

If you need 10 servers for memory requirements, but you are getting only 50% of the needed throughput because of the processor saturation, then you need twice as many servers.
For the highest stability, you should run your servers at 60% processor loading and JVM heaps at 60% heap loading. Spikes can then drive the processor usage to 80–90%, but do not regularly run your servers higher than these levels.

Dynamic cache capacity planning

Dynamic cache capacity planning

The Dynamic Cache API is available to Java™ EE applications that are deployed in WebSphere® Application Server. You can use the dynamic cache to cache business data, generated HTML, or to synchronize the cached data in the cell by using the data replication service (DRS).

Overview

All dynamic cache instances created with the WebSphere eXtreme Scale dynamic cache provider are highly available by default. The level and memory cost of high availability depends on the topology used.

When using the embedded topology, the cache size is limited to the amount of free memory in a single server process, and each server process stores a full copy of the cache. As long as a single server process continues to run, the cache survives. The cache data will only be lost if all servers that access the cache are shut down.

For caching using the embedded partitioned topology, the cache size is limited to an aggregate of the free space available in all server processes. By default, the eXtreme Scale dynamic cache provider uses 1 replica for every primary shard, so each piece of cached data is stored twice.

Use the following formula A to determine the capacity of an embedded partitioned cache.

Formula A

F * C / (1 + R) = M

Where:

- F = Free memory per container process
- C = number of containers
- R = number of replicas
- M = Total size of the cache

For a WebSphere Application Server Network Deployment data grid that has 256 MB of available space in each process, with 4 server processes total, a cache instance across all of those servers could store up to 512 megabytes of data. In this mode, the cache can survive one server crashing without losing data. Also, up to two servers could be shut down sequentially without losing any data. So, for the previous example, the formula is as follows:

256mb * 4 containers/ (1 primary + 1 replica) = 512mb.

Caches using the remote topology have similar sizing characteristics as caches using embedded partitioned, but they are limited by the amount of available space in all eXtreme Scale container processes.

In remote topologies, it is possible to increase the number of replicas to provide a higher level of availability at the cost of additional memory overhead. In most dynamic cache applications this should be unnecessary, but you can edit the dynacache-remote-deployment.xml file to increase the number of replicas.

Use the following formulas, B and C, to determine the effect of adding more replicas on the high availability of the cache.

Formula B

N = Minimum(T -1, R)

Where:

- N = the number of processes that can crash simultaneously
- T = the total number of containers
- R = the total number of replicas

Formula C

Ceiling(T/ (1+N)) = m

Where:

- T = Total number containers
- N = Total number of replicas
- m = minimum number of containers needed to support the cache data.

For performance tuning with the dynamic cache provider, see Tuning the dynamic cache provider.

Cache sizing

Before an application using the WebSphere eXtreme Scale dynamic cache provider can be deployed, the general principals described in the previous section should be combined with the environmental data for the production systems. The first figure to establish is the total number of container processes and the amount of available memory in each process to hold cache data. When using the embedded topology, the cache containers will be co-located inside of the WebSphere Application server processes, so there is one container for each server that is sharing the cache. Determining the memory overhead of the application without caching enabled and the WebSphere Application Server is the best way to figure out how much space is available in the process. This can be done by analyzing verbose garbage collection data. When using the remote topology, this information can be found by looking at the verbose garbage collection output of a newly started standalone container that has not yet been populated with cache data. The last thing to keep in mind when figuring out how much space per process is available for cache data, is to reserve some heap space for garbage collection. The overhead of the container, WebSphere Application Server or stand-alone, plus the size reserved for the cache should not be more than 70% of the total heap.

After this information is collected, the values can be plugged into formula A, described previously, to determine the maximum size for the partitioned cache. Once the maximum size is known, the next step is to determine the total number of cache entries that can be supported, which requires determining the average size per cache entry. The simple way of doing this is to add 10% to the size of the customer object. See theTuning guide for dynamic cache and data replication service for more in depth information on sizing cache entries when using dynamic cache.

When compression is enabled it affects the size of the customer object, not the overhead of the caching system. Use the following formula to determine the size of a cached object when using compression:

S = O * C + O * 0.10

Where:

- S = Average size of cached object
- O = Average size of un-compressed customer object
- C = Compression ratio expressed as a fraction.

So, a 2 to 1 compression ratio is 1/2 = 0.50. Smaller is better for this value. If the object being stored is a normal POJO mostly full of primitive types, then assume a compression ratio of 0.60 to 0.70. If the object cached is a Servlet, JSP, or WebServices object, the optimal method for determining the compression ratio is to compress a representative sample with a ZIP compression utility. If this is not possible, then a compression ratio of 0.2 to 0.35 is common for this type of data. Next, use this information to determine the total number of cache entries that can be supported. Use the following D formula:

Formula D

T = S / A

Where:

- T= Total number of cache entries
- S = Total size available for cache data as computed using formula A
- A = Average size of each cache entry

Finally, you must set the cache size on the dynamic cache instance to enforce this limit. The WebSphere eXtreme Scale dynamic cache provider differs from the default dynamic cache provider in this regard. Use the following formula to determine the value to set for the cache size on the dynamic cache instance. Use the following E formula:
Formula E

Cs = Ts / Np

Where:

- Ts = Total target size for the cache
- Cs = Cache Size setting to set on the dynamic cache instance
- Np = number of partitions. The default is 47.

Set the size of the dynamic cache instance to a value calculated by formula E on each server that shares the cache instance.

Planning to develop Java applications

Before you develop Java applications, you should be familiar with the available APIs, plug-ins, and any considerations that are required.

- Java API overview
  WebSphere® eXtreme Scale provides several features that are accessed programmatically using the Java™ programming language through application programming interfaces (APIs) and system programming interfaces.
- Java plug-ins overview
  A WebSphere eXtreme Scale plug-in is a component that provides a certain type of function to the pluggable components that include ObjectGrid and BackingMap. WebSphere eXtreme Scale provides several plug points to allow applications and cache providers to integrate with various data stores, alternative client APIs and to improve overall performance of the cache. The product ships with several default, prebuilt plug-ins, but you can also build custom plug-ins with the application.
- REST data services overview
  The WebSphere eXtreme Scale REST data service is a Java HTTP service that is compatible with Microsoft WCF Data Services (formally ADO.NET Data Services) and implements the Open Data Protocol (OData). Microsoft WCF Data Services is compatible with this specification when using Visual Studio 2008 SP1 and the .NET Framework 3.5 SP1.
- Spring framework overview
  Spring is a framework for developing Java applications. WebSphere eXtreme Scale provides support to allow Spring to manage transactions and configure the clients and servers comprising your deployed in-memory data grid.

- Java class loader and classpath considerations
  Because WebSphere eXtreme Scale stores Java objects in the cache by default, you must define classes on the classpath wherever the data is accessed.
- Relationship management
  Object-oriented languages such as Java, and relational databases support relationships or associations. Relationships decrease the amount of storage through the use of object references or foreign keys.
- Cache key considerations
  WebSphere eXtreme Scale uses hash maps to store data in the grid, where a Java object is used for the key.
- Data for different time zones
  When inserting data with calendar, java.util.Date, and timestamp attributes into an ObjectGrid, you must ensure these date time attributes are created based on same time zone, especially when deployed into multiple servers in various time zones. Using the same time zone based date time objects can ensure the application is time-zone safe and data can be queried by calendar, java.util.Date and timestamp predicates.

Java API overview

WebSphere® eXtreme Scale provides several features that are accessed programmatically using the Java™ programming language through application programming interfaces (APIs) and system programming interfaces.

WebSphere eXtreme Scale APIs

When you are using eXtreme Scale APIs, you must distinguish between transactional and non-transactional operations. A transactional operation is an operation that is performed within a transaction. ObjectMap, EntityManager, Query, and DataGrid API are transactional APIs that are contained inside the Session that is a transactional container. Non-transactional operations have nothing to do with a transaction, such as configuration operations.

The ObjectGrid, BackingMap, and plug-in APIs are non-transactional. The ObjectGrid, BackingMap, and other configuration APIs are categorized as ObjectGrid Core API. Plug-ins are for customizing the cache to achieve the functions that you want, and are categorized as the System Programming API. A plug-in in eXtreme Scale is a component that provides a certain type of function to the pluggable eXtreme Scale components that include ObjectGrid and BackingMap. A feature represents a specific function or characteristic of an eXtreme Scale component, including ObjectGrid, Session, BackingMap, ObjectMap, and so on. Typically, features are configurable with configuration APIs. Plug-ins can be built-in, but might require that you develop your own plug-ins in some situations.

You can normally configure the ObjectGrid and BackingMap to meet your application requirements. When the application has special requirements, consider using specialized plug-ins. WebSphere eXtreme Scale might have built-in plug-ins that meet your requirements. For example, if you need a peer-to-peer replication model between two local ObjectGrid instances or two distributed eXtreme Scale grids, the built-in JMSObjectGridEventListener is available. If none of the built-in plug-ins can solve your business problems, refer to the System Programming API to provide your own plug-ins.

ObjectMap is a simple map-based API. If the cached objects are simple and no relationship is involved, the ObjectMap API is ideal for your application. If object relationships are involved, use the EntityManager API, which supports graph-like relationships.

Query is a powerful mechanism for finding data in the ObjectGrid. Both Session and EntityManager provide the traditional query capability.

The DataGrid API is a powerful computing capability in a distributed eXtreme Scale environment that involves many machines, replicas, and partitions. Applications can run business logic in parallel in all of the nodes in the distributed eXtreme Scale environment. The application can obtain the DataGrid API through the ObjectMap API.

The WebSphere eXtreme Scale REST data service is a Java HTTP service that is compatible with Microsoft WCF Data Services (formally ADO.NET Data Services) and implements the Open Data Protocol (OData). The REST data service allows any HTTP client to access an eXtreme Scale grid. It is compatible with the WCF Data Services support that is supplied with the Microsoft .NET Framework 3.5 SP1. RESTful applications can be developed with the rich tooling provided by Microsoft Visual Studio 2008 SP1. For more details, refer to the eXtreme Scale REST data service user guide.

Java plug-ins overview

A WebSphere® eXtreme Scale plug-in is a component that provides a certain type of function to the pluggable components that include ObjectGrid and BackingMap. WebSphere eXtreme Scale provides several plug points to allow applications and cache providers to integrate with various data stores, alternative

client APIs and to improve overall performance of the cache. The product ships with several default, prebuilt plug-ins, but you can also build custom plug-ins with the application.

All plug-ins are concrete classes that implement one or more eXtreme Scale plug-in interfaces. These classes are then instantiated and invoked by the ObjectGrid at appropriate times. The ObjectGrid and BackingMaps each allow custom plug-ins to be registered.

ObjectGrid plug-ins

The following plug-ins are available for an ObjectGrid instance. If the plug-in is server side only, the plug-ins are removed on the client ObjectGrid and BackingMap instances. The ObjectGrid and BackingMap instances are only on the server.

- **TransactionCallback**: A TransactionCallback plug-in provides transaction life cycle events. If the TransactionCallback plug-in is the built-in JPATxCallback (com.ibm.websphere.objectgrid.jpa.JPATxCallback) class implementation, then the plug-in is server side only. However, the subclasses of the JPATxCallback class are not server side only.
- **ObjectGridEventListener**: An ObjectGridEventListener plug-in provides ObjectGrid life cycle events for the ObjectGrid, shards, and transactions.
- **ObjectGridLifecycleListener**: An ObjectGridLifecycleListener plug-in provides ObjectGrid life cycle events for the ObjectGrid instance. The ObjectGridLifecycleListener plug-in can be used as an optional mixin interface for all other ObjectGrid plug-ins.
- **ObjectGridPlugin**: An ObjectGridPlugin is an optional mix-in interface that provides extended life cycle management events for all other ObjectGrid plug-ins.
- **SubjectSource, ObjectGridAuthorization, SubjectValidation**: eXtreme Scale provides several security endpoints to allow custom authentication mechanisms to be integrated with eXtreme Scale. (Server side only)

Common ObjectGrid plug-in requirements

The ObjectGrid instantiates and initializes plug-in instances using JavaBeans conventions. All of the previous plug-in implementations have the following requirements:

- The plug-in class must be a top-level public class.
- The plug-in class must provide a public, no-argument constructor.
- The plug-in class must be available in the class path for both servers and clients (as appropriate).
- Attributes must be set using the JavaBeans style property methods.
- Plug-ins, unless specifically noted, are registered before ObjectGrid initializes and cannot be changed after the ObjectGrid is initialized.

BackingMap plug-ins

The following plug-ins are available for a BackingMap:

- **Evictor**: An evictor plug-in is a default mechanism that is provided for evicting cache entries and for creating custom evictors. The built in time-to-live evictor uses a time-based algorithm to decide when an entry in BackingMap must be evicted. Some applications might need to use a different algorithm for deciding when a cache entry needs to be evicted. The Evictor plug-in makes a custom designed Evictor available to the BackingMap to use. The Evictor plug-in is in addition to the built in time-to-live evictor. You can use the provided custom Evictor plug-in that implements well-known algorithms such as "least recently used" or "least frequently used". Applications can either plug-in one of the provided Evictor plug-ins or it can provide its own Evictor plug-in. For more information, see Plug-ins for evicting cache objects.
- **ObjectTransformer**: An ObjectTransformer plug-in allows you to serialize, deserialize, and copy objects in the cache. The ObjectTransformer interface has been replaced by the DataSerializer plug-ins, which you can use to efficiently store arbitrary data in WebSphere eXtreme Scale so that existing product APIs can efficiently interact with your data. For more information, see ObjectTransformer plug-in.
- **OptimisticCallback**: An OptimisticCallback plug-in allows you to customize versioning and comparison operations of cache objects when you are using the optimistic lock strategy. The OptimisticCallback plug-in has been replaced by the ValueDataSerializer.Versionable interface, which you can implement when you use the DataSerializer plug-in with the COPY_TO_BYTES copy mode or when you use the @Version annotation with the EntityManager API. For more information, see Plug-ins for versioning and comparing cache objects.
- **MapEventListener**: A MapEventListener plug-in provides callback notifications and significant cache state changes that occur for a BackingMap. An application might want to know about BackingMap events such as a map entry eviction or a preload of a BackingMap completion. A BackingMap calls methods on the MapEventListener plug-in to notify an application of BackingMap events. An application can receive notification of various BackingMap events by using the setMapEventListener method to provide one or more custom designed MapEventListener plug-ins to the BackingMap. The application can modify the listed MapEventListener objects by using the addMapEventListener method or the removeMapEventListener method. For more information, see MapEventListener plug-in.
- **BackingMapLifecycleListener**: A BackingMapLifecycleListener plug-in provides BackingMap life cycle events for the BackingMap instance. The BackingMapLifecycleListener plug-in can be used as an optional mix-in interface for all other BackingMap plug-ins.
- **BackingMapPlugin**: A BackingMapPlugin is an optional mix-in interface that provides extended life cycle management events for all other BackingMap plug-ins.
- **Indexing**: Use the indexing feature, which is represented by the MapIndexplug-in plug-in, to build an index or several indexes on a BackingMap map to support non-key data access.
- **Loader**: A Loader plug-in on an ObjectGrid map acts as a memory cache for data that is typically kept in a persistent store on either the same system or some other system. (Server side only) For example, a Java™ database connectivity (JDBC) Loader can be used to move data in and out of a BackingMap and one or more relational tables of a relational database. A relational database does not need to be used as the persistent store for a BackingMap. The Loader can also be used to moved data between a BackingMap and a file, between a BackingMap and a Hibernate map, between a BackingMap and a Java 2 Platform, Enterprise Edition (JEE) entity bean, between a BackingMap and another application server, and so on. The application must provide a custom-designed Loader plug-in to move data between the BackingMap and the persistent store for every technology that is used. If a Loader is not provided, the BackingMap becomes a simple in-memory cache. For more information, see Plug-ins for communicating with databases.
- **MapSerializerPlugin**: A MapSerializerPlugin allows you to serialize and inflate Java objects and non-Java data in the cache. It is used with the DataSerializer mix-in interfaces, allowing robust and flexible options for high-performance applications.

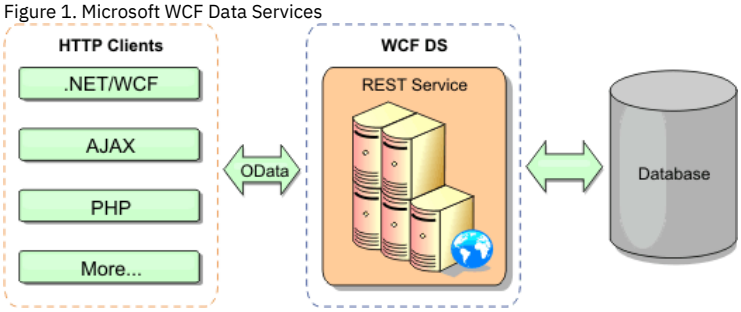
REST data services overview

The WebSphere® eXtreme Scale REST data service is a Java™ HTTP service that is compatible with Microsoft WCF Data Services (formally ADO.NET Data Services) and implements the Open Data Protocol (OData). Microsoft WCF Data Services is compatible with this specification when using Visual Studio 2008 SP1 and the .NET Framework 3.5 SP1.

Compatibility requirements

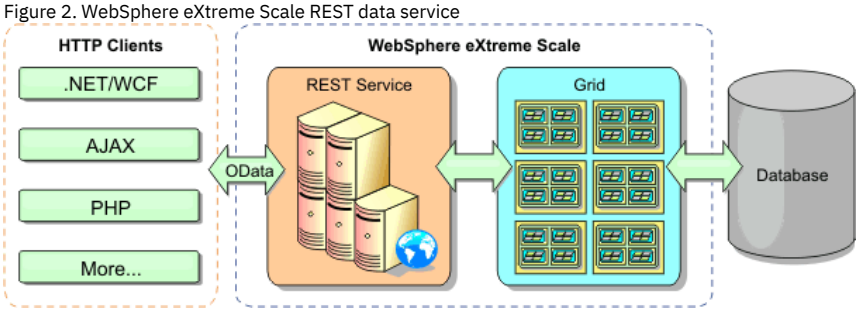
The REST data service allows any HTTP client to access a data grid. The REST data service is compatible with the WCF Data Services support supplied with the Microsoft .NET Framework 3.5 SP1. RESTful applications can be developed with the rich tooling provided by Microsoft Visual Studio 2008 SP1. The figure provides an overview of how WCF Data Services interacts with clients and databases.

Figure 1. Microsoft WCF Data Services



WebSphere eXtreme Scale includes a function-rich API set for Java clients. As shown in the following figure, the REST data service is a gateway between HTTP clients and the WebSphere eXtreme Scale data grid, communicating with the grid through an WebSphere eXtreme Scale client. The REST data service is a Java servlet, which allows flexible deployments for common Java Platform, Enterprise Edition (JEE) platforms, such as WebSphere Application Server. The REST data service communicates with the WebSphere eXtreme Scale data grid using the WebSphere eXtreme Scale Java APIs. It allows WCF Data Services clients or any other client that can communicate with HTTP and XML.

Figure 2. WebSphere eXtreme Scale REST data service



Refer to the Configuring REST data services, or use the following links to learn more about WCF Data Services.

- Open Data Protocol
- Open Data Protocol FAQ

Features

This version of the eXtreme Scale REST data service supports the following features:

- Automatic modeling of eXtreme Scale EntityManager API entities as WCF Data Services entities, which includes the following support:

    - Java data type to Entity Data Model type conversion
    - Entity association support
    - Schema root and key association support, which is required for partitioned data grids

  See Entity model for more information.
- Atom Publish Protocol (AtomPub or APP) XML and JavaScript Object Notation (JSON) data payload format.
- Create, Read, Update and Delete (CRUD) operations using the respective HTTP request methods: POST, GET, PUT and DELETE. In addition, the Microsoft extension: MERGE is supported.
- Simple queries, using filters
- Batch retrieval and change set requests
- Partitioned data grid support for high availability
- Interoperability with eXtreme Scale EntityManager API clients
- Support for standard Java EE Web servers
- Optimistic concurrency
- User authorization and authentication between the REST data service and the eXtreme Scale data grid

Known problems and limitations

- Tunneled requests are not supported.

Spring framework overview

Spring is a framework for developing Java™ applications. WebSphere® eXtreme Scale provides support to allow Spring to manage transactions and configure the clients and servers comprising your deployed in-memory data grid.

8.5+

Spring cache provider

Spring Framework Version 3.1 introduced a new cache abstraction. With this new abstraction, you can transparently add caching to an existing Spring application. You can use WebSphere eXtreme Scale as the cache provider for the cache abstraction. For more information, see Configuring a Spring cache provider.

Spring managed native transactions

Spring provides container-managed transactions that are similar to a Java Platform, Enterprise Edition application server. However, the Spring mechanism can use different implementations. WebSphere eXtreme Scale provides transaction manager integration which allows Spring to manage the ObjectGrid transaction life cycles. For more information, see Managing transactions with Spring.

Spring managed extension beans and namespace support

Also, eXtreme Scale integrates with Spring to allow Spring-style beans defined for extension points or plug-ins. This feature provides more sophisticated configurations and more flexibility for configuring the extension points.

In addition to Spring managed extension beans, eXtreme Scale provides a Spring namespace called "objectgrid". Beans and built-in implementations are pre-defined in this namespace, which makes it easier for users to configure eXtreme Scale. See Spring extension beans and namespace support for more details on these topics and a sample of how to start an eXtreme Scale container server using Spring configurations.

Shard scope support

With the traditional style Spring configuration, an ObjectGrid bean can either be a singleton type or prototype type. ObjectGrid also supports a new scope called the "shard" scope. If a bean is defined as shard scope, then only one bean is created per shard. All requests for beans with an ID or IDs matching that bean definition in the same shard results in that one specific bean instance being returned by the Spring container.

The following example shows that a com.ibm.ws.objectgrid.jpa.plugins.JPAPropFactoryImpl bean is defined with scope set to shard. Therefore, only one instance of the JPAPropFactoryImpl class is created per shard.

```
<bean id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_cxssprgfrmwk_jpaPropFactory"
class="com.ibm.ws.objectgrid.jpa.plugins.JPAPropFactoryImpl" scope="shard" />
```

Spring Web Flow

Spring Web Flow stores its session state in an HTTP session by default. If a web application uses eXtreme Scale for session management, then Spring automatically stores state with eXtreme Scale. Also, fault tolerance is enabled in the same manner as the session.

For more information, see HTTP session management.

Packaging

The eXtreme Scale Spring extensions are in the ogspring.jar file. This Java archive (JAR) file must be on the class path for Spring support to work. If a Java EE application that is running in a WebSphere Extended Deployment augmented WebSphere Application Server Network Deployment, put the spring.jar file and its associated files in the enterprise archive (EAR) modules. You must also place the ogspring.jar file in the same location.

Java class loader and classpath considerations

Because WebSphere® eXtreme Scale stores Java™ objects in the cache by default, you must define classes on the classpath wherever the data is accessed.

Specifically, WebSphere eXtreme Scale client and container processes must include the classes or JAR files in the classpath when starting the process. When you are designing an application for use with eXtreme Scale, separate out any business logic from the persistent data objects.

See Class loading in the WebSphere Application Server information center for more information.

For considerations within a Spring Framework setting, see the packaging section in the Spring framework overview.

For settings related to using the WebSphere eXtreme Scale instrumentation agent, see Entity performance instrumentation agent.

For details on adding your classes or JAR files to the stand-alone container server classpath, see startOgServer script .

Relationship management

Object-oriented languages such as Java™, and relational databases support relationships or associations. Relationships decrease the amount of storage through the use of object references or foreign keys.

When you are using relationships in a data grid, the data must be organized in a constrained tree. One root type must exist in the tree and all children must be associated to only one root. For example: Department can have many Employees and an Employee can have many Projects. But a Project cannot have many Employees that belong to different departments. Once a root is defined, all access to that root object and its descendants are managed through the root. WebSphere® eXtreme Scale uses the hash code of the root object's key to choose a partition. For example:

```
partition = (hashCode MOD numPartitions).
```

When all of the data for a relationship is tied to a single object instance, the entire tree can be collocated in a single partition and can be accessed very efficiently using one transaction. If the data spans multiple relationships, then multiple partitions must be involved which involves additional remote calls, which can lead to performance bottlenecks.

Reference data

Some relationships include look-up or reference data such as: `CountryName`. For look-up or reference data, the data must exist in every partition. The data can be accessed by any root key and the same result is returned. Reference data such as this should only be used in cases where the data is fairly static. Updating this data can be expensive because the data needs to be updated in every partition. The DataGrid API is a common technique to keeping reference data up-to-date.

Costs and benefits of normalization

Normalizing the data using relationships can help reduce the amount of memory used by the data grid since duplication of data is decreased. However, in general, the more relational data that is added, the less it will scale out. When data is grouped together, it becomes more expensive to maintain the relationships

and to keep the sizes manageable. Since the grid partitions data based on the key of the root of the tree, the size of the tree isn't taken into account. Therefore, if you have a lot of relationships for one tree instance, the data grid may become unbalanced, causing one partition to hold more data than the others.

When the data is denormalized or flattened, the data that would normally be shared between two objects is instead duplicated and each table can be partitioned independently, providing a much more balanced data grid. Although this increases the amount of memory used, it allows the application to scale since a single row of data can be accessed that has all of the necessary data. This is ideal for read-mostly grids since maintaining the data becomes more expensive.

For more information, see Classifying XTP systems and scaling.

Managing relationships using the data access APIs

The ObjectMap API is the fastest, most flexible and granular of the data access APIs, providing a transactional, session-based approach at accessing data in the grid of maps. The ObjectMap API allows clients to use common CRUD (create, read, update and delete) operations to manage key-value pairs of objects in the distributed data grid.

When using the ObjectMap API, object relationships must be expressed by embedding the foreign key for all relationships in the parent object.

An example follows.

```
public class Department {
        Collection<String> employeeIds;
}
```

The EntityManager API simplifies relationship management by extracting the persistent data from the objects including the foreign keys. When the object is later retrieved from the data grid, the relationship graph is rebuilt, as in the following example.

```
@Entity
public class Department {
        Collection<String> employees;
}
```

The EntityManager API is very similar to other Java object persistence technologies such as JPA and Hibernate in that it synchronizes a graph of managed Java object instances with the persistent store. In this case, the persistent store is an eXtreme Scale data grid, where each entity is represented as a map and the map contains the entity data rather than the object instances.

Related reference:
Defining an entity schema
EntityTransaction interface

Cache key considerations

WebSphere® eXtreme Scale uses hash maps to store data in the grid, where a Java™ object is used for the key.

Guidelines

When choosing a key, consider the following requirements:

- Keys can never change. If a portion of the key needs to change, then the cache entry should be removed and reinserted.
- Keys should be small. Since keys are used in every data access operation, it's a good idea to keep the key small so that it can be serialized efficiently and use less memory.
- Implement a good hash and equals algorithm. The hashCode and equals(Object o) methods must always be overridden for each key object.
- Cache the key's hashCode. If possible, cache the hash code in the key object instance to speed up hashCode() calculations. Since the key is immutable, the hashCode should be cacheable.
- Avoid duplicating the key in the value. When using the ObjectMap API, it is convenient to store the key inside the value object. When this is done, the key data is duplicated in memory.

Data for different time zones

When inserting data with calendar, java.util.Date, and timestamp attributes into an ObjectGrid, you must ensure these date time attributes are created based on same time zone, especially when deployed into multiple servers in various time zones. Using the same time zone based date time objects can ensure the application is time-zone safe and data can be queried by calendar, java.util.Date and timestamp predicates.

Without explicitly specifying a time zone when creating date time objects, Java™ uses the local time zone and may cause inconsistent date time values in clients and servers.

Consider an example in a distributed deployment in which client1 is in time zone [GMT-0] and client2 is in [GMT-6] and both want to create a java.util.Date object with value '1999-12-31 06:00:00'. Then client1 will create java.util.Date object with value '1999-12-31 06:00:00 [GMT-0]' and client2 will create java.util.Date

object with value '1999-12-31 06:00:00 [GMT-6]'. Both java.util.Date objects are not equal because the time zone is different. A similar problem occurs when preloading data into partitions residing in servers in different time zones if local time zone is used to create date time objects.

To avoid the described problem, the application can choose a time zone such as [GMT-0] as the base time zone for creating calendar, java.util.Date, and timestamp objects.

Installing

WebSphere® eXtreme Scale is an in-memory data grid that you can use to dynamically partition, replicate, and manage application data and business logic across multiple servers. After determining the purposes and requirements of your deployment, install eXtreme Scale on your system.

Before you begin

- Before you begin the installation, you should have an understanding of WebSphere eXtreme Scale caching architectures, cache and database integration, serialization, scalability and availability. See Product overview for more information.
- Plan your WebSphere eXtreme Scale deployment. For more information about the different caching topologies, sizing information, and more, see Planning.
- Verify that your environment meets the prerequisites to install eXtreme Scale. See Hardware and software requirements for more information.
- For more information on environments and other requirements, see Planning for installation.
- If you are installing an upgrade on a previous version of WebSphere eXtreme Scale, follow the steps described in Updating eXtreme Scale servers.

- 8.5+ Installation overview
  You can install WebSphere eXtreme Scale in a stand-alone or WebSphere Application Server environment. To install WebSphere eXtreme Scale , you must first install the IBM Installation Manager and obtain product files. After installing the Installation Manager and setting up access to the appropriate product repositories, you can then choose your installation and environment types. You must install a server and one or more clients. You can also install WebSphere eXtreme Scale as an in-memory data grid for use with both .NET and Java applications with extreme transaction processing (XTP) capabilities.
- 8.5+ Planning for installation
  Before you install the product, you must consider your environment.
- 8.5+ IBM Installation Manager and WebSphere eXtreme Scale product offerings
  WebSphere eXtreme Scale product offerings are available in product repositories. To access these repositories, you must first install IBM® Installation Manager.
- Installing the Eclipse Equinox OSGi framework with Eclipse Gemini for clients and servers
  If you want to deploy WebSphere eXtreme Scale in the OSGi framework, then you must set up the Eclipse Equinox Environment.
- Installing the REST data service
  This topic describes how to install the WebSphere eXtreme Scale REST data service into a Web server.
- 8.5+ Installing WebSphere eXtreme Scale or WebSphere eXtreme Scale Client with WebSphere Application Server
  You can install WebSphere eXtreme Scale or WebSphere eXtreme Scale Client in an environment in which WebSphere Application Server or WebSphere Application Server Network Deployment is installed. You can use the existing features of WebSphere Application Server or WebSphere Application Server Network Deployment to enhance your eXtreme Scale applications.
- 8.5+ Installing the Liberty profile
  You install the Liberty profile application-serving environment by using the Installation Manager, or by running a Java™ archive (JAR) file.
- 8.5+ Uninstalling the product using IBM Installation Manager
  Use IBM Installation Manager to uninstall WebSphere eXtreme Scale product offerings.
- z/OS Customizing WebSphere eXtreme Scale for z/OS
  Using the WebSphere Customization Toolbox, you can generate and run customized jobs to customize WebSphere eXtreme Scale for z/OS®.
- 8.5+ Creating and augmenting profiles for WebSphere eXtreme Scale
  After you install the product, create unique types of profiles and augment existing profiles for WebSphere eXtreme Scale.
- 8.5+ Taking the first steps after installation
  After complete and verify the installation, you can begin to use WebSphere eXtreme Scale to create your data grid.
- 8.5+ Troubleshooting the product installation
  IBM Installation Manager is a common installer for many IBM software products that you use to install this version of WebSphere eXtreme Scale.

Installation overview

You can install WebSphere® eXtreme Scale in a stand-alone or WebSphere Application Server environment. To install WebSphere eXtreme Scale , you must first install the IBM Installation Manager and obtain product files. After installing the Installation Manager and setting up access to the appropriate product repositories, you can then choose your installation and environment types. You must install a server and one or more clients. You can also install WebSphere eXtreme Scale as an in-memory data grid for use with both .NET and Java applications with extreme transaction processing (XTP) capabilities.

WebSphere eXtreme Scale environment types

- **WebSphere Application Server environment:**

By installing WebSphere eXtreme Scale on the nodes in your WebSphere Application Server environment, you can automatically start catalog servers and container servers in the same cell as your deployment manager and other application servers.

- **Stand-alone environment:**
  In a stand-alone installation, you install WebSphere eXtreme Scale in an environment that does not have WebSphere Application Server. With a stand-alone environment, you manually configure and start the catalog server and container server processes.

WebSphere eXtreme Scale installation types

If you have servers that are running client applications that access the data grid, you can use a client-only installation. Or you can choose a full (client and server) installation on nodes that run catalog servers or container servers.

- **Full (Client and Server) installation:**
  - When you are installing on WebSphere Application Server, you can choose to install the client only or both the client and server.
  - When you are installing in a stand-alone environment, you can choose to install the client-only or both the client and server.
- **Client installation:**
  You can use the client-only installation on nodes that are running the client applications.

IBM Installation Manager

Installation Manager is a single installation program that can use remote or local software flat-file repositories to install, modify, or update new WebSphere eXtreme Scale products. It determines and shows available packages—including products, fix packs, interim fixes, and so on—checks prerequisites and interdependencies, and installs the selected packages. You also use Installation Manager to easily uninstall the packages that it installed.

Overview of IBM® Installation Manager: IBM Installation Manager is a general-purpose software installation and update tool that runs on a range of computer systems. Installation Manager can be invoked through a graphical user interface (GUI) or a command-line interface. You can also create response files in XML and use them to direct the performance of Installation Manager tasks in silent mode.

For more information on using Installation Manager, read the IBM Installation Manager Version 1.5 Information Center.

Packages and package groups: Each software product that can be installed with Installation Manager is referred to as a package. An installed package has a product level and an installation location. A package group consists of all of the products that are installed at a single location.

Installation Manager modes: IBM Installation Manager can be installed in one of the following three modes:

- In admin mode, the Installation Manager is installed from an administrator or a root ID and can be invoked by any administrator or root user.
- In nonAdmin mode (also called user mode), the Installation Manager can be invoked only by the user that installed it.
- UNIX Linux In group mode, the Installation Manager can be invoked by any user ID that is connected to the default group of the user that installed it.
  This does not mean that two people can use the single instance of IBM Installation Manager at the same time.

How many Installation Managers do you need: You only need to run Installation Manager on those systems on which you install or update product code. You normally need only one Installation Manager on a system because one Installation Manager can keep track of any number of product installations.

Installing Installation Manager: When the installation kit is available on your system, you can install Installation Manager. Installation Manager consists of a set of binaries that are copied from the installation kit and a set of runtime data that describe the products that have been installed by this particular Installation Manager. Before installing Installation Manager, you must decide in which mode the Installation Manager will run as well as where the binaries and runtime data —called agent data or appdata—will reside. Then, you issue an Installation Manager installation command from the appropriate user ID to install Installation Manager.

Accessing product repositories: All software materials that will be installed with IBM Installation Manager are stored in flat-file repositories. Each repository contains program objects and metadata for one or more packages—that is, software products at a particular level. Repositories can also contain product maintenance, such as fix packs and interim fixes. Whenever you install a new product, you can choose from any of the available product levels in any accessible repository.

Installing the product: After you have installed Installation Manager and have access to all necessary product repositories, you can use the Installation Manager GUI, command-line commands, or response files to perform the actual product installations. When you install a product, you provide the package name, optionally the product level to be installed, the product location, and any other optional properties. For example, some products have optional features that you can select at installation time or a list of optional supported language packs from which you can select.

Working with installed products: You can use Installation Manager commands to list installed products and product levels. You can also obtain this information for installed copies of WebSphere eXtreme Scale products by issuing the **versionInfo** command from the product file system. You can use Installation Manager commands or response files to install a new product level, roll back to a previous level, or modify the product by adding or removing optional features or language packs.

Using the IBM Packaging Utility: With the Packaging Utility, you can create and manage packages for installation repositories. You can copy multiple packages into one repository or copy multiple disks for one product into a repository. You can copy packages from Passport Advantage® into a repository for example. For more information on the Packaging Utility, go to the IBM Installation Manager Version 1.5 Information Center.

Restrictions:

- Windows If a non-administrator installs WebSphere eXtreme Scale Version 8.5 on a Windows Vista, Windows 7, or Windows Server 2008 operating system into the Program Files or Program Files (x86) directory with User Account Control (UAC) enabled, WebSphere eXtreme Scale will not function correctly.
  UAC is an access-control mechanism that allows non-administrative users to install a software product into the Program Files or Program Files (x86) directory; but it then prohibits any write access to that directory after the installation has completed. WebSphere eXtreme Scale requires write access in the *app_server_root* directory in order to function correctly.

To resolve this issue, perform one of the following actions:
    - Install WebSphere eXtreme Scale into a directory other than Program Files or Program Files (x86).
      For example:

      ```
      C:\IBM\WebSphere\AppServer
      ```

    - Disable UAC.
- When you install a product using Installation Manager with local repositories, the installation takes a significantly longer amount of time if you use a compressed repository file directly without extracting it.
  Before you install a product using local repositories, extract the compressed repository file to a location on your local system before using Installation Manager to access it.

- Installation Manager console mode, which is included in Installation Manager Version 1.4.3 and later, does not work with WebSphere eXtreme Scale Version 8.5 offerings on systems other than z/OS®.

Important: Do not transfer the content of a repository in non-binary mode and do not convert any content on extraction.
Tip: Although almost all of the instructions in this section of the information center will work with earlier versions of IBM Installation Manager, the information here is optimized for users who have installed or upgraded to Installation Manager Version 1.5 or later.
8.5+

Available product offerings in Installation Manager

After you have installed Installation Manager and have access to all necessary product repositories, the Installation Manager lists the product offerings that are available to you. When you point to our product repository, you should see the following product offerings:

- WebSphere eXtreme Scale in a stand-alone environment
- WebSphere eXtreme Scale Client in a stand-alone environment
- WebSphere eXtreme Scale for WebSphere Application Server Version 6.1
- WebSphere eXtreme Scale for WebSphere Application Server Version 7.0
- WebSphere eXtreme Scale for WebSphere Application Server Version 8.0
- WebSphere eXtreme Scale Client forWebSphere Application Server Version 6.1
- WebSphere eXtreme Scale Client for WebSphere Application Server Version 7.0
- WebSphere eXtreme Scale Client for WebSphere Application Server Version 8.0

Important: If you want to install WebSphere Application Server and WebSphere eXtreme Scale at the same time, then you need to point to both product repositories. These are installed as two separate products, but can be installed at the same time in Installation Manager.

Planning for installation

Before you install the product, you must consider your environment.

- 8.5+ Installation topologies
  With WebSphere® eXtreme Scale, you can create many installation topologies that include stand-alone servers, WebSphere Application Server, or both.
- 8.5+ Hardware and software requirements
  Browse an overview of hardware and operating system requirements. Although you are not required to use a specific level of hardware or operating system for WebSphere eXtreme Scale, formally supported hardware and software options are available on the Systems Requirements page of the product support site. If a conflict exists between the information center and the System Requirements page, the information at the website takes precedence. Prerequisite information in the information center is provided as a convenience only.
- 8.5+ Offering IDs for WebSphere eXtreme Scale product offerings
  When installing product updates or rolling back fixes with Installation Manager and from the command line, you are required to specify the offering ID. Use the following tables to identify the product offerings and required and optionally installable features.
- 8.5+ Java SE considerations
  WebSphere eXtreme Scale requires Java™ SE 5, Java SE 6, or Java SE 7. In general, newer versions of Java SE have better functionality and performance.
- 8.5+ Java EE considerations
  As you prepare to integrate WebSphere eXtreme Scale in a Java Platform, Enterprise Edition environment, consider certain items, such as versions, configuration options, requirements and limitations, and application deployment and management.
- 8.5+ Directory conventions
  The following directory conventions are used throughout the documentation to reference special directories such as *wxs_install_root* and *wxs_home*. You

access these directories during several different scenarios, including during installation and use of command-line tools.

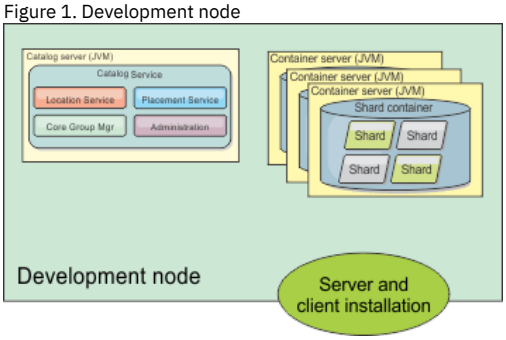
- 8.5+ Runtime files for WebSphere eXtreme Scale stand-alone installation
  Java archive (JAR) files are included in the installation. You can see the JAR files that are included and the location to which they are installed.

Installation topologies

With WebSphere® eXtreme Scale, you can create many installation topologies that include stand-alone servers, WebSphere Application Server, or both.

Development node

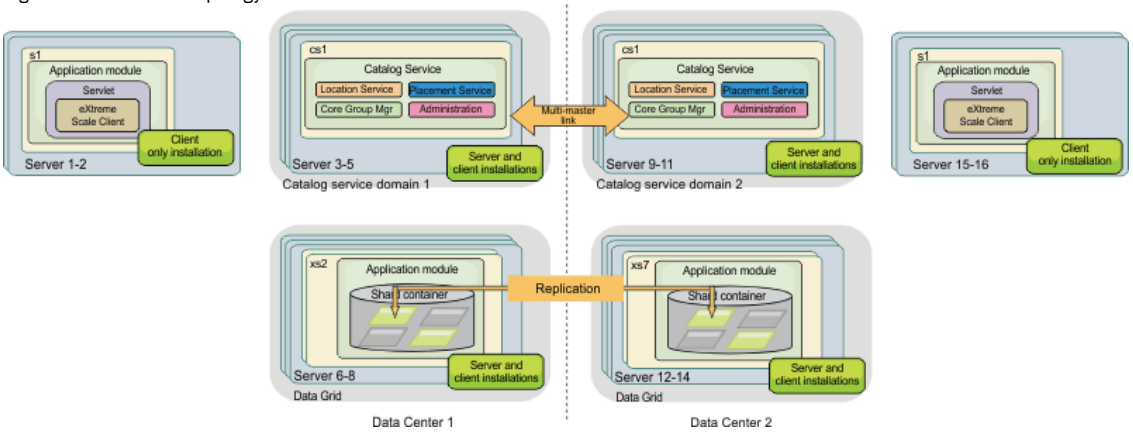
The simplest installation scenario is creating a development node. In this scenario, you install the client and server installation of WebSphere eXtreme Scale one time on the node where you want to develop your application.
Figure 1. Development node



After you complete the installation on your development node, you can configure your development environment and begin writing your applications.

Stand-alone topology

A stand-alone topology consists of servers that are not running on WebSphere Application Server. You can create many different stand-alone topologies, but the following topology is included as an example. In this topology, two data centers are present. In each data center, WebSphere eXtreme Scale full installations (client and server) and client-only installations are installed on the physical servers. The client-only installations are on the nodes that are running the web applications that are using the data grid. These nodes do not run any catalog or container servers, so the server installation is not required. A multi-master link connects the two catalog service domains in the configuration. The multi-master link enables replication between the shards in the container servers in the different data centers.
Figure 2. Stand-alone topology with two data centers

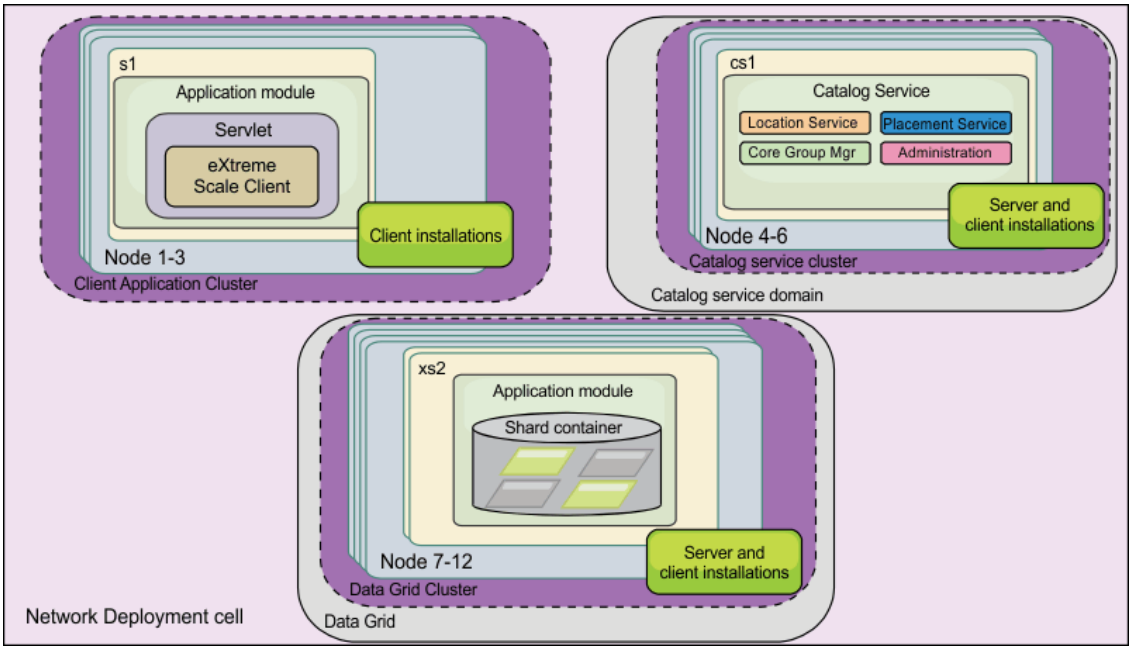


Advantages to using a stand-alone topology:

- Flexible integration options that can be embedded with vendor frameworks and libraries.
- Smaller footprint than a WebSphere Application Server topology.
- Fewer licensing requirements than a WebSphere Application Server topology.
- Expanded Java Runtime Environment (JRE) options.

WebSphere Application Server topology

You can also create an installation that runs entirely in a WebSphere Application Server cell. The clients, catalog servers, and container servers each have an associated cluster. The nodes that run the application have the client-only installation. The other nodes have the client and server installation.
Figure 3. WebSphere Application Server topology example



Advantages of using a WebSphere Application Server topology.

- Centralized and consistent administration and configuration.
- Security integration.
- Java EE application integration.
- Performance monitoring infrastructure (PMI) integration.
- Integration with the following WebSphere Application Server components: OpenJPA L2 cache, dynamic cache, and HTTP session persistence.

Mixed topology

You can create a mixed topology that contains both WebSphere Application Server and stand-alone servers. In the following example, the client applications are running in the WebSphere Application Server cell, while the catalog servers and container servers are running in stand-alone mode.

Figure 4. Mixed topology example

Hardware and software requirements

Browse an overview of hardware and operating system requirements. Although you are not required to use a specific level of hardware or operating system for WebSphere® eXtreme Scale, formally supported hardware and software options are available on the Systems Requirements page of the product support site. If a conflict exists between the information center and the System Requirements page, the information at the website takes precedence. Prerequisite information in the information center is provided as a convenience only.

See the System Requirements page for the official set of hardware and software requirements.

You can install and deploy the product in Java™ EE and Java SE environments. You can also bundle the client component with Java EE applications directly without integrating with WebSphere Application Server.

Hardware requirements

WebSphere eXtreme Scale does not require a specific level of hardware. The hardware requirements are dependent on the supported hardware for the Java Platform, Standard Edition installation that you use to run WebSphere eXtreme Scale. If you are using eXtreme Scale with WebSphere Application Server or another Java Platform, Enterprise Edition implementation, the hardware requirements of these platforms are sufficient for WebSphere eXtreme Scale.

Operating system requirements

8.5+ Each Java SE and Java EE implementation requires different operating system levels or fixes for problems that are discovered during the testing of the Java implementation. The levels required by these implementations are sufficient for eXtreme Scale.

8.5+

Installation Manager requirements

Before you can install WebSphere eXtreme Scale, you must install Installation Manager. You can install Installation Manager using the product media, using a file obtained from the Passport Advantage® site, or using a file containing the most current version of Installation Manager from the IBM® Installation Manager download website. See IBM Installation Manager and WebSphere eXtreme Scale product offerings for more information.

Web browser requirements

The web console supports the following Web browsers:

- Mozilla Firefox, version 3.5.x and later
- Microsoft Internet Explorer, version 7 and later

WebSphere Application Server requirements

8.5

- WebSphere Application Server Version 6.1.0.41 or later
- WebSphere Application Server Version 7.0.0.19 or later
- WebSphere Application Server Version 8.0.0.2 or later
- WebSphere Application Server Version 8.5.0.1 or later

See the Recommended fixes for WebSphere Application Server for more information.

Java requirements

8.5 Other Java EE implementations can use the eXtreme Scale run time as a local instance or as a client to eXtreme Scale servers. To implement Java SE, you must use Version 5 or later.

Offering IDs for WebSphere eXtreme Scale product offerings

When installing product updates or rolling back fixes with Installation Manager and from the command line, you are required to specify the offering ID. Use the following tables to identify the product offerings and required and optionally installable features.

Table 1. Offering IDs for WebSphere eXtreme Scale product offerings

Product name	Offering ID
WebSphere® eXtreme Scale in a stand-alone environment	`com.ibm.websphere.WXS.v85`
WebSphere eXtreme Scale Client in a stand-alone environment	`com.ibm.websphere.WXSCLIENT.v85`
WebSphere eXtreme Scale for WebSphere Application Server Version 6	`com.ibm.websphere.WXS.was6.v85` Note:
WebSphere eXtreme Scale for WebSphere Application Server Version 7	`com.ibm.websphere.WXS.was7.v85`
WebSphere eXtreme Scale for WebSphere Application Server Version 8	`com.ibm.websphere.WXS.was8.v85`
WebSphere eXtreme Scale Client for WebSphere Application Server Version 6	`com.ibm.websphere.WXSCLIENT.was6.v85` Note:
WebSphere eXtreme Scale Client for WebSphere Application Server Version 7	`com.ibm.websphere.WXSCLIENT.was7.v85`
WebSphere eXtreme Scale Client for WebSphere Application Server Version 8	`com.ibm.websphere.WXSCLIENT.was8.v85`

Table 2. Installable features for WebSphere eXtreme Scale; offering ID `com.ibm.websphere.WXS.v85`

Feature name	Feature ID
WebSphere eXtreme Scale	`xs.core.feature`
WebSphere eXtreme Scale Java Runtime Environment	`xs.jre.feature`
WebSphere eXtreme Scale server in a stand-alone environment (Optional)	`xs.server.standalone.feature`
WebSphere eXtreme Scale Client in a stand-alone environment	`xs.client.standalone.feature`
WebSphere eXtreme Scale monitoring console (Optional)	`xs.console.feature`
WebSphere eXtreme Scale Samples (Optional)	`xs.samples.feature`

Table 3. Installable features for WebSphere eXtreme Scale Client; offering ID `com.ibm.websphere.WXSCLIENT.v85`

Feature name	Feature ID
WebSphere eXtreme Scale Client	`xs.client.core.feature`
WebSphere eXtreme Scale Java Runtime Environment	`xs.jre.feature`
WebSphere eXtreme Scale Client in a stand-alone environment	`xs.client.standalone.feature`
WebSphere eXtreme Scale monitoring console (Optional)	`xs.console.feature`
WebSphere eXtreme Scale Samples (Optional)	`xs.samples.feature`

Table 4. Installable features for WebSphere eXtreme Scale for WebSphere Application Server Version 7; offering ID `com.ibm.websphere.WXS.was7.v85`

Feature name	Feature ID
WebSphere eXtreme Scale	`xs.core.feature`
WebSphere eXtreme Scale server	`xs.server.feature`
WebSphere eXtreme Scale Client	`xs.client.feature`
WebSphere eXtreme Scale monitoring console (Optional)	`xs.console.feature`
WebSphere eXtreme Scale Samples (Optional)	`xs.samples.feature`

Table 5. Installable features for WebSphere eXtreme Scale Client for WebSphere Application Server Version 7; offering ID `com.ibm.websphere.WXSCLIENT.was7.v85`

Feature name	Feature ID
WebSphere eXtreme Scale Client	`xs.client.core.feature`
WebSphere eXtreme Scale Client in a stand-alone environment	`xs.client.feature`
WebSphere eXtreme Scale monitoring console (Optional)	`xs.console.feature`
WebSphere eXtreme Scale Samples (Optional)	`xs.samples.feature`

Table 6. Installable features for WebSphere eXtreme Scale for WebSphere Application Server Version 8; offering ID `com.ibm.websphere.WXS.was8.v85`

Feature name	Feature ID

Feature name	Feature ID
WebSphere eXtreme Scale for WebSphere Application Server Version 8.5.5	`xs.core.feature` This feature is required on WebSphere Application Server V8, WebSphere Application Server V8.5 (with or without the WebSphere Application Server Liberty profile), WebSphere Application Server V8.5.5 and the Liberty profile for WebSphere Application Server V8.5.5
WebSphere eXtreme Scale server for WebSphere Application Server (Optional)	`xs.server.feature` You can install this feature with WebSphere Application Server versions 8, 8.5 and 8.5.5. You cannot install this feature with the Liberty profile for WebSphere Application Server V8.5.5 and higher.
WebSphere eXtreme Scale Client for WebSphere Application Server	`xs.client.feature` This feature is required for WebSphere Application Server versions 8, 8.5 and 8.5.5. You cannot install this feature with the Liberty profile.
WebSphere eXtreme Scale monitoring console (Optional)	`xs.console.feature` This feature can be installed on WebSphere Application Server versions 8, 8.5 and 8.5.5. You cannot install this feature with the Liberty profile.
WebSphere eXtreme Scale Samples (Optional)	`xs.samples.feature` This feature can be installed on WebSphere Application Server versions 8, 8.5 and 8.5.5. You cannot install this feature with the Liberty profile.
WebSphere eXtreme Scale Client for WebSphere Application Server Version 8.5 (Optional)	`xs.liberty.feature` You can install this feature with WebSphere Application Server V8.5 with the Liberty profile installed.
WebSphere eXtreme Scale for WebSphere Application Server (Optional; Required for the Liberty profile for WebSphere Application Server Version 8.5.5)	`xs.liberty.standalone.feature` You cannot install this feature with WebSphere Application Server. This feature is the Liberty profile for WebSphere Application Server V8.5.5, and it is intended to be installed by itself.

Table 7. Installable features for WebSphere eXtreme Scale Client for WebSphere Application Server Version 8; offering ID `com.ibm.websphere.WXSCLIENT.was8.v85`

Feature name	Feature ID
WebSphere eXtreme Scale for WebSphere Application Server Version 8.5.5	`xs.client.core.feature` This feature is required on WebSphere Application Server V8, WebSphere Application Server V8.5 (with or without the Liberty profile), WebSphere Application Server V8.5.5 and the Liberty profile for WebSphere Application Server V8.5.5
WebSphere eXtreme Scale Client for WebSphere Application Server	`xs.client.feature` You can install this feature with WebSphere Application Server versions 8, 8.5 and 8.5.5. You cannot install this feature with the Liberty profile.
WebSphere eXtreme Scale monitoring console (Optional)	`xs.console.feature` This feature can be installed on WebSphere Application Server versions 8, 8.5 and 8.5.5. You cannot install this feature with the Liberty profile.
WebSphere eXtreme Scale Samples (Optional)	`xs.samples.feature` This feature can be installed on WebSphere Application Server versions 8, 8.5 and 8.5.5. You cannot install this feature with the Liberty profile.
WebSphere eXtreme Scale for WebSphere Application Server Version 8.5 (Optional)	`xs.liberty.feature` You can install this feature with WebSphere Application Server V8.5 with the Liberty profile installed.
WebSphere eXtreme Scale for WebSphere Application Server (Optional; Required for the Liberty profile for WebSphere Application Server Version 8.5.5)	`xs.liberty.standalone.feature` You cannot install this feature with WebSphere Application Server. This feature is the Liberty profile for WebSphere Application Server V8.5.5, and it is intended to be installed by itself.

Java SE considerations

WebSphere® eXtreme Scale requires Java™ SE 5, Java SE 6, or Java SE 7. In general, newer versions of Java SE have better functionality and performance.

Supported versions

You can use WebSphere eXtreme Scale with Java SE 5, Java SE 6, and Java SE 7. The version that you use must be currently supported by the Java Runtime Environment (JRE) vendor. If you want to use Secure Sockets Layer (SSL), you must use an IBM® Runtime Environment.
IBM Runtime Environment, Java Technology Edition Version 5, Version 6 , and Version 7 are supported for general use with the product. Version 6 Service Release 9 Fix Pack 2 is a fully supported JRE that is installed as a part of the stand-alone WebSphere eXtreme Scale and WebSphere eXtreme Scale Client installations in the *wxs_install_root*/java directory and is available to be used by both clients and servers. If you are installing WebSphere eXtreme Scale within WebSphere Application Server, you can use the JRE that is included in the WebSphere Application Server installation. For the web console, you must use IBM Runtime Environment, Java Technology Edition Version 6 Service Release 7 and later service releases only.

WebSphere eXtreme Scale takes advantage of Java Development Kit (JDK) Version 5 , Version 6 , and Version 7 functionality as it becomes available. Generally, newer versions of the Java Development Kit (JDK) and Java SE have better performance and functionality.

For more information, see Supported software.

WebSphere eXtreme Scale features that are dependent on Java SE

Table 1. Features that require Java SE 5, Java SE 6, and Java SE 7 . WebSphere eXtreme Scale uses functionality that is introduced in Java SE 5 or Java SE 6 to provide the following product features.

Feature	Supported in Java SE 5 and later service releases	Supported in Java SE Version 6 , Version 7 and later service releases
EntityManager API annotations (Optional: You can also use XML files)	X	X
Java Persistence API (JPA): JPA loader, JPA client loader, and JPA time-based updater	X	X
Memory-based eviction (uses MemoryPoolMXBean)	X	X
Instrumentation agents: • wxssizeagent.jar: Increases the accuracy of the used bytes map metrics. • ogagent.jar: Increases the performance of field-access entities.	X	X
Web console for monitoring		X

Upgrading the JDK in WebSphere eXtreme Scale

Common questions about the upgrade process for releases of WebSphere eXtreme Scale in both stand-alone and WebSphere Application Server environments follow:

- How do I upgrade the JDK that is included in WebSphere eXtreme Scale Version 7.1.0 for a stand-alone environment?
  WebSphere eXtreme Scale Version 7.1.0 included a JRE which is automatically installed to the *wxs_install_root*/java directory. WebSphere eXtreme Scale Version 7.1.0 GA shipped with IBM Java Runtime Environment (JRE) Version 1.6 SR4. To update the JRE shipped with WebSphere eXtreme Scale 7.1.0 requires the application of WebSphere eXtreme Scale 7.1.0 Refresh Pack 0000001 followed by iFIX IFPM56253. For more information, see http://www-304.ibm.com/support/docview.wss?uid=swg1PM56253

  Note: There is currently no interim fix available to upgrade a JRE that was included with WebSphere eXtreme Scale Version 7.0.x.x.
  CAUTION:
  Errors might occur in stand-alone configurations of WebSphere eXtreme Scale that are using the Java 6 runtime and SSL Transport Layer security.
- How do I upgrade the JDK that is included with WebSphere eXtreme Scale for WebSphere Application Server?
  You need to use the JDK upgrade process that is made available by WebSphere Application Server. For more information, see http://www-304.ibm.com/support/docview.wss?uid=swg21427178.
- Which version of the JDK should I use when using WebSphere eXtreme Scale in a WebSphere Application Server environment?
  You can use any level of JDK that is supported by WebSphere Application Server, for the supported version of WebSphere Application Server.

Java EE considerations

As you prepare to integrate WebSphere® eXtreme Scale in a Java™ Platform, Enterprise Edition environment, consider certain items, such as versions, configuration options, requirements and limitations, and application deployment and management.

Running eXtreme Scale applications in a Java EE environment

A Java EE application can connect to a remote eXtreme Scale application. Additionally, the WebSphere Application Server environment supports starting an eXtreme Scale server when an application starts in the application server.

If you use an XML file to create an ObjectGrid instance, and the XML file is in the module of the enterprise archive (EAR) file, access the file by using the getClass().getClassLoader().getResource("META-INF/objGrid.xml") method to obtain a URL object to use to create an ObjectGrid instance. Substitute the name of the XML file that you are using in the method call.

You can use startup beans for an application to bootstrap an ObjectGrid instance when the application starts, and to destroy the instance when the application stops. A startup bean is a stateless session bean with a com.ibm.websphere.startupservice.AppStartUpHome remote location and a com.ibm.websphere.startupservice.AppStartUp remote interface. The remote interface has two methods: the start method and the stop method. Use the start method to bootstrap the instance, and use the stop method to destroy the instance. The application uses the ObjectGridManager.getObjectGrid method to maintain a reference to the instance. See Interacting with an ObjectGrid using the ObjectGridManager interface for more information.

Using class loaders

When application modules that use different class loaders share a single ObjectGrid instance in a Java EE application, verify the objects that are stored in eXtreme Scale and the plug-ins for the product are in a common loader in the application.

Managing the life cycle of ObjectGrid instances in a servlet

To manage the life cycle of an ObjectGrid instance in a servlet, you can use the init method to create the instance and the destroy method to remove the instance. If the instance is cached, it is retrieved and manipulated in the servlet code. See Interacting with an ObjectGrid using the ObjectGridManager interface for more information.

Directory conventions

The following directory conventions are used throughout the documentation to reference special directories such as *wxs_install_root* and *wxs_home*. You access these directories during several different scenarios, including during installation and use of command-line tools.

wxs_install_root
: The *wxs_install_root* directory is the root directory where WebSphere® eXtreme Scale product files are installed. The *wxs_install_root* directory can be the directory in which the trial archive is extracted or the directory in which the WebSphere eXtreme Scale product is installed.

- Example when extracting the trial:
  Example: /opt/IBM/WebSphere/eXtremeScale
- Example when WebSphere eXtreme Scale is installed to a stand-alone directory:
  UNIX **Example:** /opt/IBM/eXtremeScale

  Windows **Example:** C:\Program Files\IBM\WebSphere\eXtremeScale
- Example when WebSphere eXtreme Scale is integrated with WebSphere Application Server:
  Example: /opt/IBM/WebSphere/AppServer

wxs_home
: The *wxs_home* directory is the root directory of the WebSphere eXtreme Scale product libraries, samples, and components. This directory is the same as the *wxs_install_root* directory when the trial is extracted. For stand-alone installations, the *wxs_home* directory is the ObjectGrid subdirectory within the *wxs_install_root* directory. For installations that are integrated with WebSphere Application Server, this directory is the optionalLibraries/ObjectGrid directory within the *wxs_install_root* directory.

- Example when extracting the trial:
  Example: /opt/IBM/WebSphere/eXtremeScale
- Example when WebSphere eXtreme Scale is installed to a stand-alone directory:
  UNIX **Example:** /opt/IBM/eXtremeScale/ObjectGrid

  Windows **Example:** *wxs_install_root*\ObjectGrid
- Example when WebSphere eXtreme Scale is integrated with WebSphere Application Server:
  Example: /opt/IBM/WebSphere/AppServer/optionalLibraries/ObjectGrid

was_root
: The *was_root* directory is the root directory of a WebSphere Application Server installation:
  Example: /opt/IBM/WebSphere/AppServer

restservice_home

The *restservice_home* directory is the directory in which the WebSphere eXtreme Scale REST data service libraries and samples are located. This directory is named restservice and is a subdirectory under the *wxs_home* directory.

- Example for stand-alone deployments:
  Example: /opt/IBM/WebSphere/eXtremeScale/ObjectGrid/restservice

  Example: *wxs_home*\restservice

- Example for WebSphere Application Server integrated deployments:
  Example: /opt/IBM/WebSphere/AppServer/optionalLibraries/ObjectGrid/restservice

tomcat_root
The *tomcat_root* is the root directory of the Apache Tomcat installation.
Example: /opt/tomcat5.5

wasce_root
The *wasce_root* is the root directory of the WebSphere Application Server Community Edition installation.
Example: /opt/IBM/WebSphere/AppServerCE

java_home
The *java_home* is the root directory of a Java™ Runtime Environment (JRE) installation.
UNIX **Example:** /opt/IBM/WebSphere/eXtremeScale/java

Windows **Example:** *wxs_install_root*\java

samples_home
The *samples_home* is the directory in which you extract the sample files that are used for tutorials.
UNIX **Example:** *wxs_home*/samples

Windows **Example:** *wxs_home*\samples

dvd_root
The *dvd_root* directory is the root directory of the DVD that contains the product.
Example: dvd_root/docs/

equinox_root
The *equinox_root* directory is the root directory of the Eclipse Equinox OSGi framework installation.
Example:/opt/equinox

user_home
The *user_home* directory is the location where user files are stored, such as security profiles.
Windows c:\Documents and Settings*user_name*

UNIX /home/*user_name*

Runtime files for WebSphere eXtreme Scale integrated with WebSphere Application Server

Java™ archive (JAR) files are included in the installation. You can see the JAR files that are included and the location to which they are installed.

Table 1. Runtime files for WebSphere eXtreme Scale. The following table lists the Java archive (JAR) files that are included in the installation. The installation location is relative to the *wxs_home* directory that you choose during the installation.

File name	Environment	Installation location	Description
wxsdynacache.jar	Client and server	lib	The wxsdynacache.jar file contains the necessary classes to use with the dynamic cache provider.
wsobjectgrid.jar	Local and client	lib	The wsobjectgrid.jar contains the eXtreme Scale local, client, and server run times.
ogagent.jar	Local, client, and server	lib	The ogagent.jar file contains the runtime classes that are required to run the Java instrumentation agent that is used with the EntityManager API.
sessionobjectgrid.jar	Client and server	lib	The sessionobjectgrid.jar file contains the eXtreme Scale HTTP session management runtime.
wsogclient.jar	Local and client	lib	The wsogclient.jar file installed when you use an environment that contains WebSphere® Application Server Version 6.0.2 and later. This file contains only the local and client runtime environments.
wxssizeagent.jar	Local, client, and server	lib	The wxssizeagent.jar file is used to provide more accurate cache entry sizing information when using Java runtime environment (JRE) Version 1.5 or later.
oghibernate-cache.jar	Client and server	optionalLibraries/ObjectGrid	The oghibernate-cache.jar file contains the eXtreme Scale level 2 cache plug-in for JBoss Hibernate.

File name	Environment	Installation location	Description
ogspring.jar	Local, client, and server	optionalLibraries/ObjectGrid	The ogspring.jar file contains support classes for the SpringSource Spring framework integration.
xsadmin.jar	Utility	optionalLibraries/ObjectGrid	The xsadmin.jar file contains the eXtreme Scale administration sample utility.
ibmcfw.jar ibmext.jar ibmorb.jar ibmorbapi.jar	Client and server	optionalLibraries/ObjectGrid/endorsed	This set of files includes the Object Request Broker (ORB) runtime that is used for running applications in Java SE processes.
wxshyperic.jar	Utility	optionalLibraries/ObjectGrid/hyperic/lib	The WebSphere eXtreme Scale server detection plug-in for the SpringSource Hyperic monitoring agent.
restservice.ear	Client	optionalLibraries/ObjectGrid/restservice/lib	The restservice.ear file contains the eXtreme Scale REST data service application enterprise archive for WebSphere Application Server environments.
restservice.war	Client	optionalLibraries/ObjectGrid/restservice/lib	The restservice.war file contains the eXtreme Scale REST data service Web archive for application servers acquired from another vendor.
splicerlistener.jar	Utility	optionalLibraries/ObjectGrid/session/lib	The splicerlistener.jar file contains the splicer utility for the eXtreme Scale HTTP session manager filter.
splicer.jar	Utility	optionalLibraries/ObjectGrid/legacy/session/lib	The splicer.jar contains the Version 7.0 splicer utility for the eXtreme Scale HTTP session manager filter.

Table 2. Runtime files for WebSphere eXtreme Scale Client. The following table lists the Java archive (JAR) files that are included in the installation. The installation location is relative to the *wxs_home* directory that you choose during the installation.

File name	Environment	Installation location	Description
wxsdynacache.jar	Client and server	lib	The wxsdynacache.jar file contains the necessary classes to use with the dynamic cache provider.
ogagent.jar	Local, client, and server	lib	The ogagent.jar file contains the runtime classes that are required to run the Java instrumentation agent that is used with the EntityManager API.
sessionobjectgrid.jar	Client and server	lib	The sessionobjectgrid.jar file contains the eXtreme Scale HTTP session management runtime.
wsogclient.jar	Local and client	lib	The wsogclient.jar file installed when you use an environment that contains WebSphere Application Server Version 6.0.2 and later. This file contains only the local and client runtime environments.
wxssizeagent.jar	Local, client, and server	lib	The wxssizeagent.jar file is used to provide more accurate cache entry sizing information when using Java runtime environment (JRE) Version 1.5 or later.
oghibernate-cache.jar	Client and server	optionalLibraries/ObjectGrid	The oghibernate-cache.jar file contains the eXtreme Scale level 2 cache plug-in for JBoss Hibernate.
ogspring.jar	Local, client, and server	optionalLibraries/ObjectGrid	The ogspring.jar file contains support classes for the SpringSource Spring framework integration.
xsadmin.jar	Utility	optionalLibraries/ObjectGrid	The xsadmin.jar file contains the eXtreme Scale administration sample utility.
ibmcfw.jar ibmext.jar ibmorb.jar ibmorbapi.jar	Client and server	optionalLibraries/ObjectGrid/endorsed	This set of files includes the Object Request Broker (ORB) runtime that is used for running applications in Java SE processes.
wxshyperic.jar	Utility	optionalLibraries/ObjectGrid/hyperic/lib	The WebSphere eXtreme Scale server detection plug-in for the SpringSource Hyperic monitoring agent.
restservice.ear	Client	optionalLibraries/ObjectGrid/restservice/lib	The restservice.ear file contains the eXtreme Scale REST data service application enterprise archive for WebSphere Application Server environments.
restservice.war	Client	optionalLibraries/ObjectGrid/restservice/lib	The restservice.war file contains the eXtreme Scale REST data service Web archive for application servers acquired from another vendor.
splicerlistener.jar	Utility	optionalLibraries/ObjectGrid/session/lib	The splicerlistener.jar file contains the splicer utility for the eXtreme Scale HTTP session manager filter.

File name	Environment	Installation location	Description
splicer.jar	Utility	optionalLibraries/ObjectGrid/legacy/session/lib	The splicer.jar contains the Version 7.0 splicer utility for the eXtreme Scale HTTP session manager filter.

Runtime files for WebSphere eXtreme Scale stand-alone installation

Java™ archive (JAR) files are included in the installation. You can see the JAR files that are included and the location to which they are installed.

Table 1. Runtime files for WebSphere eXtreme Scale full installation. WebSphere® eXtreme Scale relies on ObjectGrid processes and related APIs. The following table lists the JAR files that are included in the installation. The installation location is relative to the *wxs_home* directory that you choose during the installation.

File name	Environment	Installation location	Description
wxsdynacache.jar	Client and server	dynacache/lib	The wxsdynacache.jar file contains the necessary classes to use with the dynamic cache provider. The file is automatically included in the server runtime environment when you use the supplied scripts.
wxshyperic.jar	Utility	hyperic/lib	The WebSphere eXtreme Scale server detection plug-in for the SpringSource Hyperic monitoring agent.
objectgrid.jar	Local, client, and server	lib	The objectgrid.jar file is an OSGi bundle that is used by the server runtime environment of Java SE 1.5 and later. The file is automatically included in the server runtime environment when you use the supplied scripts.
ogagent.jar	Local, client, and server	lib	The ogagent.jar file contains the runtime classes that are required to run the Java instrumentation agent that is used with the EntityManager API.
ogclient.jar	Local and client	lib	The ogclient.jar file is an OSGi bundle that contains only the local and client runtime environments. You can use this file with Java SE 1.5 and later.
ogspring.jar	Local, client, and server	lib	The ogspring.jar file contains support classes for the SpringSource Spring framework integration.
wsogclient.jar	Local and client	lib	The wsogclient.jar file installed when you use an environment that contains WebSphere Application Server Version 6.1 and later. This file contains only the local and client runtime environments.
wxssizeagent.jar	Local, client, and server	lib	The wxssizeagent.jar file is used to provide more accurate cache entry sizing information when using Java runtime environment (JRE) Version 1.5 and later.
ibmcfw.jar ibmorb.jar ibmorbapi.jar	Client and server	lib/endorsed	This set of files includes the Object Request Broker (ORB) runtime that is used for running applications in Java SE processes.
restservice.ear	Client	restservice/lib	The restservice.ear file contains the eXtreme Scale REST data service application enterprise archive for WebSphere Application Server environments.
restservice.war	Client	restservice/lib	The restservice.war file contains the eXtreme Scale REST data service Web archive for application servers acquired from another vendor.
xsadmin.jar	Utility	samples	The xsadmin.jar file contains the eXtreme Scale administration sample utility.
sessionobjectgrid.jar	Client and server	session/lib	The sessionobjectgrid.jar file contains the eXtreme Scale HTTP session management runtime.
splicerlistener.jar	Utility	session/lib	The splicerlistener.jar file contains the splicer utility for the eXtreme Scale Version 7.1 and later HTTP session listener.
xsgbean.jar	Server	wasce/lib	The xsgbean.jar file contains the GBean for embedding eXtreme Scale servers in WebSphere Application Server Community Edition application servers.
splicer.jar	Utility	legacy/session/lib	The splicer utility for the WebSphere eXtreme Scale Version 7.0 HTTP session manager filter.
wxsra.rar	Client and server	session/lib	The wxsra.rar contains the eXtreme Scale resource adapter to connect to the grid using a connection factory.

Table 2. Runtime files for WebSphere eXtreme Scale Client. WebSphere eXtreme Scale Client relies on ObjectGrid processes and related APIs. The following table lists the JAR files that are included in the installation. The installation location is relative to the *wxs_home* directory that you choose during the installation.

File name	Environment	Installation location	Description
wxsdynacache.jar	Client and server	dynacache/lib	The wxsdynacache.jar file contains the necessary classes to use with the dynamic cache provider. The file is automatically included in the server runtime environment when you use the supplied scripts.
wxshyperic.jar	Utility	hyperic/lib	The WebSphere eXtreme Scale server detection plug-in for the SpringSource Hyperic monitoring agent.
ogagent.jar	Local, client, and server	lib	The ogagent.jar file contains the runtime classes that are required to run the Java instrumentation agent that is used with the EntityManager API.
ogclient.jar	Local and client	lib	The ogclient.jar file is an OSGi bundle that contains only the local and client runtime environments. You can use this file with Java SE 1.5 and later.
ogspring.jar	Local, client, and server	lib	The ogspring.jar file contains support classes for the SpringSource Spring framework integration.
wsogclient.jar	Local and client	lib	The wsogclient.jar file installed when you use an environment that containsWebSphere Application Server Version 6.1 and later. This file contains only the local and client runtime environments.
wxssizeagent.jar	Local, client, and server	lib	The wxssizeagent.jar file is used to provide more accurate cache entry sizing information when using Java runtime environment (JRE) Version 1.5 and later.
ibmcfw.jar ibmorb.jar ibmorbapi.jar	Client and server	lib/endorsed	This set of files includes the Object Request Broker (ORB) runtime that is used for running applications in Java SE processes.
restservice.ear	Client	restservice/lib	The restservice.ear file contains the eXtreme Scale REST data service application enterprise archive for WebSphere Application Server environments.
restservice.war	Client	restservice/lib	The restservice.war file contains the eXtreme Scale REST data service Web archive for application servers acquired from another vendor.
xsadmin.jar	Utility	samples	The xsadmin.jar file contains the eXtreme Scale administration sample utility.
sessionobjectgrid.jar	Client and server	session/lib	The sessionobjectgrid.jar file contains the eXtreme Scale HTTP session management runtime.
splicerlistener.jar	Utility	session/lib	The splicerlistener.jar file contains the splicer utility for the eXtreme Scale Version 7.1 and later HTTP session listener.
splicer.jar	Utility	legacy/session/lib	The splicer utility for the WebSphere eXtreme Scale Version 7.0 HTTP session manager filter.
wxsra.rar	Client and server	session/lib	The wxsra.rar contains the eXtreme Scale resource adapter to connect to the grid using a connection factory.

IBM Installation Manager and WebSphere eXtreme Scale product offerings

WebSphere® eXtreme Scale product offerings are available in product repositories. To access these repositories, you must first install IBM® Installation Manager.

You can install Installation Manager with files available on the product media, or with a file obtained from the Passport Advantage® site. You can also download a file from the IBM Installation Manager download website. A file is a compressed file that contains installation images.

Installation Manager gives you access to the necessary product repositories. You must access these repositories to install the WebSphere eXtreme Scale product offerings.

There are two options to access product repositories.
Option 1: Access product repositories on the physical media, and use local installation

1. Install Installation Manager on your system.
2. With Installation Manager, Install the product offering from the product repositories on the media.

Option 2: Download product repositories from Passport Advantage, and use local installation

1. Download the repositories from the Passport Advantage site.
   Note: See see Supported software for a list of the IBM WebSphere eXtreme Scale installation images downloadable from the IBM Passport Advantage Online website and other information.
2. Install Installation Manager on your system.
3. Install the product from downloaded product repositories with Installation Manager.

- 8.5+ Installing IBM Installation Manager using the GUI
  To access the necessary product repositories so that you can install WebSphere eXtreme Scale product offerings, you must install IBM Installation

Manager. You can install Installation Manager using a GUI.

- 8.5+ Installing IBM Installation Manager using the command line
  In order to access the necessary product repositories so that you can install WebSphere eXtreme Scale product offerings, you must install IBM Installation Manager. You can install Installation Manager from the command line.

Installing IBM Installation Manager using the GUI

To access the necessary product repositories so that you can install WebSphere® eXtreme Scale product offerings, you must install IBM® Installation Manager. You can install Installation Manager using a GUI.

Before you begin

You must install IBM Installation Manager and have access to necessary repositories. For more information, see IBM Installation Manager and WebSphere eXtreme Scale product offerings.

Procedure

1. From the location that contains the Installation Manager installation files, run one of the following commands:

   Administrative installation:
   - Windows `install.exe`
   - UNIX Linux `./install`

   Non-administrative installation:
   - Windows `userinst.exe`
   - UNIX Linux `./userinst`

   For more information about administrative and non-administrative installations, see Install as an administrator, nonadministrator, or group

   Group-mode installation:
   UNIX Linux `./groupinst`

   Notes on group mode:
   - With group mode, multiple users can use a single instance of IBM Installation Manager to manage software packages.
     Group mode does not enable two people to use a single instance of IBM Installation Manager at the same time.
   - Windows Group mode is not available on Windows operating systems.
   - If you do not install Installation Manager with group mode, you cannot use group mode to manage any of the products that you install later using this Installation Manager instance.
   - Change the installation location for the current user from the default location to a location that is accessible by all users in the group.
   - Set up your groups, permissions, and environment variables as described in the Group mode road maps in the IBM Installation Manager Version 1.5 Information Center before installing in group mode.
   - For more information about using group mode, read the Group mode road maps in the IBM Installation Manager Version 1.5 Information Center.

2. Verify that the Installation Manager package is selected, and click Next.
3. Accept the terms in the license agreements, and click Next.
4. Click Next.
5. Review the summary information, and click Install. If the installation is successful, the program displays a message indicating that installation is successful. If the installation is not successful, click View Log File to troubleshoot the problem.
6. Add the product repository to your Installation Manager preferences.
   a. Start Installation Manager.
   b. In the top menu, click File > Preferences.
   c. Select Repositories.
   d. Click **Add Repository**.
   e. Enter the path to the `repository.config` file in the location that contains the repository files, for example:

- Windows `C:\repositories\product_name\local-repositories`
- UNIX Linux `/var/repositories/product_name/local-repositories`

f. Click OK.

7. Clear any locations listed in the Repositories window that you are not using.
8. Click Apply.
9. Click OK.
10. Click File > Exit to close Installation Manager.

What to do next

After you successfully install Installation Manager and set up the repository, you can continue to install any WebSphere eXtreme Scale stand-alone or WebSphere eXtreme Scale for WebSphere Application Server for product offering. For more information, see Installing the product with the GUI

- 8.5+ Installing the product with the GUI
  Use the Installation Manager GUI to install WebSphere eXtreme Scale product offerings.

Installing the product with the GUI

Use the Installation Manager GUI to install WebSphere® eXtreme Scale product offerings.

Before you begin

- You must install the necessary product files for the Installation Manager and have access to necessary repositories. For more information, see IBM Installation Manager and WebSphere eXtreme Scale product offerings.

Procedure

1. Start Installation Manager.
   UNIX Linux Tip: You can start Installation Manager in group mode with the **./IBMIM** command.
   - Group mode allows multiple users to use a single instance of IBM Installation Manager to manage software packages.
   - For more information about using group mode, read the Group mode roadmaps in the IBM Installation Manager Version 1.5 Information Center.
2. Click Install.
   Note: If you are prompted to authenticate, use the IBM ID and password that you registered with on the program website.
   Installation Manager searches its defined repositories for available packages.
3. Select one of the following product offerings and the appropriate version.
   - WebSphere eXtreme Scale in a stand-alone environment
   - WebSphere eXtreme Scale Client in a stand-alone environment
   - WebSphere eXtreme Scale for WebSphere Application Server Version 6.1
   - WebSphere eXtreme Scale for WebSphere Application Server Version 7
   - WebSphere eXtreme Scale for WebSphere Application Server Version 8
   - WebSphere eXtreme Scale Client for WebSphere Application Server Version 6.1
   - WebSphere eXtreme Scale Client for WebSphere Application Server Version 7
   - WebSphere eXtreme Scale Client for WebSphere Application Server Version 8

   If you already have the product that is installed on your system, a message indicates that the product is already installed. To create another installation of the product in another location, click Continue.

   Tip: If **Search service repositories during installation and updates** option is selected on the Installation Manager Repository preference page and you are connected to the Internet, you can click **Check for Other Versions and Extensions**. By doing so, you can search for updates in the default update repositories for the selected packages. In this case, you do not need to add the specific service-repository URL to the Installation Manager Repository preference page.
   a. Select the fixes to install.
      Any suggested fixes are selected by default.

      If there are suggested fixes, you can select the option to show only suggested fixes and hide non-recommended fixes.

   b. Click Next.

   Note: Installation Manager might prompt you to update to the latest level of Installation Manager when it connects to the repository. If you are prompted, update to the newer version before you continue. Read the IBM Installation Manager Version 1.5 Information Center for information about automatic updates.
4. Accept the terms in the license agreements, and click Next.
5. Specify the installation root directory for the product.
   The panel also specifies the shared resources directory and disk-space information.
   Note: The first time that you install a package with Installation Manager, specify the shared resources directory. The shared resources directory is where installation artifacts are located that can be used by one or more package groups. Use your largest drive for this installation. You cannot change the

directory location until after you uninstall all packages.
Restrictions:

- Deleting the default target location and leaving an installation-directory field empty prevents you from continuing.
- Do not use symbolic links as the destination directory.
  Symbolic links are not supported.
- Do not use a semicolon in the directory name.
  If the target directory includes a semicolon, the WebSphere eXtreme Scale does not install as expected.

  Windows A semicolon is the character that is used to construct the class path on Windows systems.
- Windows The maximum path length on the Windows Server 2008, Windows Vista, and Windows 7 operating systems is 60 characters.

6. Click Next.
7. Select the features that you want to install.
   Depending on which product offering you selected, you can choose from the following features:
   - Client
     Available as a required feature if you install either WebSphere eXtreme Scale in a stand-alone environment or WebSphere eXtreme Scale for WebSphere Application Server product offerings. The client must be installed for these product offerings.
   - Server
     Available if you to install either WebSphere eXtreme Scale in a stand-alone environment or WebSphere eXtreme Scale for WebSphere Application Server. You can choose not to install the server for these product offerings.
   - Console
     Available for all WebSphere eXtreme Scale product offerings. You can choose to install the monitoring console. With the web console, you can chart current and historical statistics. This console provides some charts for high-level overviews, and has a custom reports page that you can use to build charts from the available statistics. You can use the charting capabilities in the monitoring console of WebSphere eXtreme Scale to view the overall performance of the data grids in your environment.
   - Samples
     Available for all WebSphere eXtreme Scale product offerings.
8. Click Next.
9. Review the summary information, and click Install.
   - If the installation is successful, the program gives you a message to indicate that installation is successful.
     Note: The program might also specify important post-installation instructions as well.
   - If the installation is not successful, click View Log File to troubleshoot the problem.
10. Select which tool you want to start when this installation is finished.
    - Select Profile Management Tool to create a profile if you want to create a new application server profile with settings appropriate for a production environment.
    - Select Profile Management Tool to create an application server profile for a development environment if you want to create an application server profile with settings appropriate for a development environment.
      Note: The development settings are appropriate for a development environment where frequent application updates are done and system resources are at a minimum. Do not use the development settings for production servers.
    - Select None if you do not want to create a new profile when this installation is finished.

    Restriction: The option to start the Profile Management tool is only available when a version of WebSphere Application Server containing the Profile Management tool is installed.
11. Click Finish.
12. Click File > Exit to close Installation Manager.

Installing IBM Installation Manager using the command line

In order to access the necessary product repositories so that you can install WebSphere® eXtreme Scale product offerings, you must install IBM® Installation Manager. You can install Installation Manager from the command line.

Before you begin

You must install the necessary product files for the Installation Manager and have access to necessary repositories. For more information, see IBM Installation Manager and WebSphere eXtreme Scale product offerings.

Procedure

1. Change to the location containing the Installation Manager installation files, and run one of the following commands:

   Administrative installation:
   - Windows `installc.exe -acceptLicense -log` *`log_file_path_and_name`*
   - UNIX Linux `./installc -acceptLicense -log` *`log_file_path_and_name`*

Non-administrative installation:

- Windows `userinstc.exe -acceptLicense -log log_file_path_and_name`
- UNIX Linux `./userinstc -acceptLicense -log log_file_path_and_name`

Group-mode installation:

UNIX Linux `./groupinstc -acceptLicense -dataLocation application_data_location -log log_file_path_and_name -installationDirectory Installation_Manager_home`

Notes on group mode:

- Group mode allows multiple users to use a single instance of IBM Installation Manager to manage software packages.
- Windows Group mode is not available on Windows operating systems.
- If you do not install Installation Manager using group mode, you will not be able to use group mode to manage any of the products that you install later using this Installation Manager.
- Make sure that you change the installation location from the default location in the current user's home directory to a location that is accessible by all users in the group.
- Set up your groups, permissions, and environment variables as described in the Group mode road maps in the IBM Installation Manager Version 1.5 Information Center before installing in group mode.
- For more information about using group mode, read the Group mode road maps in the IBM Installation Manager Version 1.5 Information Center.

2. Optional: If the repository requires a user name and password, create a keyring file to access this repository.
   For more information about creating a keyring file for Installation Manager, read the IBM Installation Manager Version 1.5 Information Center.

   Tip: When creating a keyring file, append /repository.config at the end of the repository URL location if the **imutilsc** command is unable to find the URL that is specified.

What to do next

After successfully installing Installation Manager and setting up the repository, you can continue to install any WebSphere eXtreme Scale stand-alone or WebSphere eXtreme Scale for WebSphere Application Server product offering. For more information, see Installing the product with the GUI.

- 8.5+ Installing the product using the command line
  Use the Installation Manager from the command line to install WebSphere eXtreme Scale product offerings.

Related concepts:

Installing the product using the command line
Uninstalling the product using the command line

Installing the product using the command line

Use the Installation Manager from the command line to install WebSphere® eXtreme Scale product offerings.

Before you begin

You must install the necessary product files for the Installation Manager and have access to necessary repositories. For more information, seeIBM Installation Manager and WebSphere eXtreme Scale product offerings.

Procedure

1. Log on to your system.
2. Change to the eclipse/tools subdirectory in the directory where you installed Installation Manager.
3. Verify that the product repository is available.
   Windows

   ```
   imcl.exe listAvailablePackages -repositories source_repository
   ```

   UNIX Linux

   ```
   ./imcl listAvailablePackages -repositories source_repository
   ```

   You should see one or more levels of the offering.
4. Use the **imcl** command to install the product.
   Windows

   ```
   imcl install offeringID_version,optionalFeatureID
     -repositories source_repository
     -installationDirectory installation_directory
     -sharedResourcesDirectory shared_directory
     -accessRights access_mode
     -preferences preference_key=value
     -properties property_key=value
     -keyring keyring_file -password password
     -acceptLicense
   ```

   For example: `imcl install com.ibm.websphere.WXS.v86_8.6.0.20110503_0200,xs.console.feature`

UNIX Linux

```
./imcl install offeringID_version,optionalFeatureID
  -repositories source_repository
  -installationDirectory installation_directory
  -sharedResourcesDirectory shared_directory
  -accessRights access_mode
  -preferences preference_key=value
  -properties property_key=value
  -keyring keyring_file -password password
  -acceptLicense
```

Tips:

- The *offeringID* is the offering ID that is listed in Offering IDs for WebSphere eXtreme Scale product offerings.
- The *version*, which optionally can be attached to the offering ID with an underscore, is a specific version of the offering to install (`8.5.0.20110503_0200` for example).
  - If *version* is **not** specified, the latest version of the offering and **all** interim fixes for that version are installed.
  - If *version* is specified, the specified version of the offering and **no** interim fixes for that version are installed.

  The version can be found attached to the end of the offering ID with an underscore when you run the following command against the repository:

  ```
  imcl listAvailablePackages -repositories source_repository
  ```

- You can also specify `none`, `recommended` or `all` with the `-installFixes` argument to indicate which interim fixes you want installed with the offering.
  - If the offering version is **not** specified, the `-installFixes` option defaults to `all`.
  - If the offering version is specified, the `-installFixes` option defaults to `none`.
- You can add a list of features that are separated by commas. An example follows:

  ```
  imcl -acceptLicense install com.ibm.websphere.WXS.v85,xs.console.feature,xs.samples.feature
  ```

  ```
  imcl -acceptLicense install com.ibm.websphere.WXS.v86,xs.console.feature,xs.samples.feature
  ```

  - `xs.client.standalone.feature` Available as a required feature if you install WebSphere eXtreme Scale in a stand-alone environment.
  - `xs.server.standalone.feature` Depending on which product offering you want to install, you can choose to install the server. The server is a selectable feature in the following product offerings:
    - WebSphere eXtreme Scale in a stand-alone environment
  - `xs.console.feature` Available for all product offerings. You can choose to install the monitoring console. With the web console, you can chart current and historical statistics. This console provides some preconfigured charts for high-level overviews, and has a custom reports page that you can use to build charts from the available statistics. You can use the charting capabilities in the monitoring console of WebSphere eXtreme Scale to view the overall performance of the data grids in your environment
  - `xs.samples.feature` Available for all product offerings. You can choose to install samples.

  Notes:
- If you previously specified the mode in which to install Installation Manager, the -accessRights parameter is not required
- If you experience issues later, Installation Manager can save earlier versions of a package to roll back to. When Installation Manager rolls back a package to a previous version, the current version of the files is uninstalled and the earlier versions are reinstalled. If you choose not to save the files for rollback, you can prevent the files from being saved by specifying a preference:

  ```
  -preference com.ibm.cic.common.core.preferences.preserveDownloadedArtifacts=False
  ```

  For more information about setting your Installation Manager preferences, see the IBM Installation Manager Version 1.5 Information Center.

  Tip: Even if you choose not to save files for rollback, you can still access product files for rollback from the repository.
- The program might write important post-installation instructions to standard output.

For more information about using the **imcl** command to install the product, see the IBM Installation Manager Version 1.5 Information Center.

Installing IBM Installation Manager using response files

In order to access the necessary product repositories so that you can install WebSphere® eXtreme Scale product offerings, you must install IBM® Installation Manager. You can install Installation Manager using response files.

Before you begin

You must install the necessary product files for the Installation Manager and have access to necessary repositories. For more information, see IBM Installation Manager and WebSphere eXtreme Scale product offerings.

Procedure

Change to the location containing the Installation Manager installation files, and run one of the following commands to install Installation Manager.

Administrative installation:

- Windows `installc.exe -acceptLicense -log log_file_path_and_name`
- UNIX Linux `./installc -acceptLicense -log log_file_path_and_name`

Non-administrative installation:

- Windows `userinstc.exe -acceptLicense -log log_file_path_and_name`
- UNIX Linux `./userinstc -acceptLicense -log log_file_path_and_name`

Group-mode installation:

UNIX Linux `./groupinstc -acceptLicense -dataLocation application_data_location -log log_file_path_and_name -installationDirectory Installation_Manager_home`

Notes on group mode:

- Group mode allows multiple users to use a single instance of IBM Installation Manager to manage software packages. Group mode does not mean that two people can use the single instance of IBM Installation Manager at the same time.
- Windows Group mode is not available on Windows operating systems.
- If you do not install Installation Manager using group mode, you will not be able to use group mode to manage any of the products that you install later using this Installation Manager.
- Make sure that you change the installation location from the default location in the current user's home directory to a location that is accessible by all users in the group.
- Set up your groups, permissions, and environment variables as described in the Group mode road maps in the IBM Installation Manager Version 1.5 Information Center before installing in group mode.
- For more information about using group mode, read the Group mode road maps in the IBM Installation Manager Version 1.5 Information Center.

What to do next

After successfully installing Installation Manager and setting up the repository, you can continue to install any WebSphere eXtreme Scale stand-alone or WebSphere eXtreme Scale for WebSphere Application Server for product offering. For more information, see Installing the product with the GUI.

- 8.5+ Installing the product using a response file
  Use the Installation Manager with a response file to install WebSphere eXtreme Scale product offerings.

Related concepts:
Installation overview
IBM Installation Manager and WebSphere eXtreme Scale product offerings
Related tasks:
Installing the product using a response file
Uninstalling the product using response files

Installing the product using a response file

Use the Installation Manager with a response file to install WebSphere® eXtreme Scale product offerings.

Before you begin

You must install the necessary product files for the Installation Manager and have access to necessary repositories. For more information, seeIBM Installation Manager and WebSphere eXtreme Scale product offerings.

About this task

Using Installation Manager, you can record a response file using the GUI.

Procedure

1. From a command line, change to the Eclipse subdirectory in the directory where you installed Installation Manager.
2. Start Installation Manager from the command line using the -record option.
   For example:
   - Windows **Administrator or non-administrator:**

     ```
     IBMIM.exe -skipInstall "C:\temp\imRegistry"
       -record C:\temp\install_response_file.xml
     ```

   - UNIX Linux **Administrator:**

     ```
     ./IBMIM -skipInstall /var/temp/imRegistry
       -record /var/temp/install_response_file.xml
     ```

   - UNIX Linux **Non-administrator:**

     ```
     ./IBMIM -skipInstall user_home/var/temp/imRegistry
       -record user_home/var/temp/install_response_file.xml
     ```

   Tip: When you record a new response file, you can specify the -skipInstall parameter. Using this parameter has the following benefits:
   - No files are installed, and this speeds up the recording.

- If you use a temporary data location with the -skipInstall parameter, Installation Manager writes the installation registry to the specified data location while recording. When you start Installation Manager again without the -skipInstall parameter, you then can use your response file to install against the real installation registry.
  The -skipInstall operation should not be used on the actual agent data location used by Installation Manager. This operation is unsupported. Use a clean writable location, and reuse that location for future recording sessions.

For more information, read the IBM Installation Manager Version 1.5 Information Center.

3. Add the appropriate repositories to your Installation Manager preferences.
   a. In the top menu, click File > Preferences
   b. Select Repositories
   c. Perform the following actions for each repository:
      i. Click **Add Repository**.
      ii.
      iii. Enter the path to the `repository.config` file in the remote web-based repository or the local directory into which you unpacked the repository files.
      For example:
      - Remote repositories:

        ```
        https://downloads.mycorp.com:8080/WXS_85_repository
        ```

      - Local repositories:
        - Windows `C:\repositories\wxs85\local-repositories`
        - UNIX Linux `/var/repositories/wxs85/local-repositories`

      iv. Click OK.
      v. Click Apply.
      vi. Click OK.
   d. Click **Install**.
   Note: If you are prompted to authenticate, use the IBM ID and password that you registered with on the program website.
   Installation Manager searches its defined repositories for available packages.

4. Select one the following product offerings and the appropriate version:
   - WebSphere eXtreme Scale in a stand-alone environment
   - WebSphere eXtreme Scale Client in a stand-alone environment
   - WebSphere eXtreme Scale for WebSphere Application Server Version 6.1
   - WebSphere eXtreme Scale for WebSphere Application Server Version 7
   - WebSphere eXtreme Scale for WebSphere Application Server Version 8
   - WebSphere eXtreme Scale Client for WebSphere Application Server Version 6.1
   - WebSphere eXtreme Scale Client for WebSphere Application Server Version 7
   - WebSphere eXtreme Scale Client for WebSphere Application Server Version 8

   If you already have the product installed on your system, a message indicates that the product is already installed. To create another installation of the product in another location, click Continue.

   Tip: If **Search service repositories during installation and updates** option is selected on the Installation Manager Repository preference page and you are connected to the Internet, you can click **Check for Other Versions and Extensions**. By doing so, you can search for updates in the default update repositories for the selected packages. In this case, you do not need to add the specific service-repository URL to the Installation Manager Repository preference page.
5. Select the fixes to install.
   Any recommended fixes are selected by default.

   If there are recommended fixes, you can select the option to show only recommended fixes and hide non-recommended fixes.

6. Click Next.
7. Accept the terms in the license agreements, and click Next.
8. Specify the installation root directory for the product.
   The panel also specifies the shared resources directory and disk-space information.
   Note: The first time that you install a package using Installation Manager, specify the shared resources directory. The shared resources directory is where installation artifacts are located that can be used by one or more package groups. Use your largest drive for this installation. You cannot change the directory location until after you uninstall all packages.
   Restrictions:
   - Deleting the default target location and leaving an installation-directory field empty prevents you from continuing.
   - Do not use symbolic links as the destination directory.
     Symbolic links are not supported.

   - Windows The maximum path length on the Windows Server 2008, Windows Vista, and Windows 7 operating systems is 60 characters.
9. Click Next.
10. Select the features that you want to install.
    - Client
      Available as a required feature if you install either WebSphere eXtreme Scale in a stand-alone environment or WebSphere eXtreme Scale for WebSphere Application Server product offerings. The client must be installed for these product offerings.

    - Server
      Available if you to install either WebSphere eXtreme Scale in a stand-alone environment or WebSphere eXtreme Scale for WebSphere Application Server. You can choose not to install the server for these product offerings.

    - Console
      Available for all WebSphere eXtreme Scale product offerings. You can choose to install the monitoring console. With the web console, you can chart current and historical statistics. This console provides some charts for high-level overviews, and has a custom reports page that you can use to

build charts from the available statistics. You can use the charting capabilities in the monitoring console of WebSphere eXtreme Scale to view the overall performance of the data grids in your environment.

- Samples
  Available for all WebSphere eXtreme Scale product offerings.

11. Click Next.
12. Review the summary information, and click **Install**.
    - If the installation is successful, the program gives you a message to indicate that installation is successful.
      Note: The program might also specify important post-installation instructions as well.
    - If the installation is not successful, click View Log File to troubleshoot the problem.
13. Click **Finish**.
14. Click **File > Exit** to close Installation Manager.

- 8.5+ Creating a keyring
  After using the Installation Manager to record a response file to install WebSphere eXtreme Scale product offerings, you can choose to create a keyring file. If you are using a remote repository that requires authentication, then you can create a keyring for installation.

Related concepts:
Installation overview
IBM Installation Manager and WebSphere eXtreme Scale product offerings

Installing IBM Installation Manager using response files
Uninstalling the product using response files

Creating a keyring

After using the Installation Manager to record a response file to install WebSphere® eXtreme Scale product offerings, you can choose to create a keyring file. If you are using a remote repository that requires authentication, then you can create a keyring for installation.

Before you begin

You must record a response file. For more information, see Installing the product using a response file.

Procedure

1. From a command line, change to the Eclipse subdirectory in the directory where you installed Installation Manager.
2. Start Installation Manager from the command line using the -record option.
   For example:
   - Windows **Administrator or non-administrator:**

     ```
     IBMIM.exe -skipInstall "C:\temp\imRegistry"
       -keyring C:\IM\im.keyring
       -record C:\temp\keyring_response_file.xml
     ```

   - UNIX Linux **Administrator:**

     ```
     ./IBMIM -skipInstall /var/temp/imRegistry
       -keyring /var/IM/im.keyring
       -record /var/temp/keyring_response_file.xml
     ```

   - UNIX Linux **Non-administrator:**

     ```
     ./IBMIM -skipInstall user_home/var/temp/imRegistry
       -keyring user_home/var/IM/im.keyring
       -record user_home/var/temp/keyring_response_file.xml
     ```

3. When a window opens that requests your credentials for the authenticated remote repository, enter the correct credentials and **save** them.
4. Click **File > Exit** to close Installation Manager.
   For more information, read the IBM® Installation Manager Version 1.5 Information Center.

Installing the Eclipse Equinox OSGi framework with Eclipse Gemini for clients and servers

If you want to deploy WebSphere® eXtreme Scale in the OSGi framework, then you must set up the Eclipse Equinox Environment.

About this task

The task requires that you download and install the Blueprint framework, which allows you to later configure JavaBeans and expose them as services. The use of services is important because you can expose plug-ins as OSGi services so they can be used by the eXtreme Scale run time environment. The product supports

two blueprint containers within the Eclipse Equinox core OSGi framework: Eclipse Gemini and Apache Aries. Use this procedure to set up the Eclipse Gemini container.

Procedure

1. Download Eclipse Equinox SDK Version 3.6.1 or later from the Eclipse website. Create a directory for the Equinox framework, for example: /opt/equinox. These instructions refer to this directory as equinox_root. Extract the compressed file in the equinox_root directory.
2. Download the gemini-blueprint incubation 1.0.0 compressed file from the Eclipse website. Extract the file contents into a temporary directory, and copy the following extracted files to the equinox_root/plugins directory:

   ```
   dist/gemini-blueprint-core-1.0.0.jar
   dist/gemini-blueprint-extender-1.0.0.jar
   dist/gemini-blueprint-io-1.0.0.jar
   ```

   Attention: Depending on the location where you download the compressed Blueprint file, the extracted files might have the extension, RELEASE.jar, much like the Spring framework JAR files in the next step. You must verify that the file names match the file references in the config.ini file.
3. Download the Spring Framework Version 3.0.5 from the following SpringSource web page: http://www.springsource.com/download/community. Extract it into a temporary directory, and copy the following extracted files to the equinox_root/plugins directory:

   ```
   org.springframework.aop-3.0.5.RELEASE.jar
   org.springframework.asm-3.0.5.RELEASE.jar
   org.springframework.beans-3.0.5.RELEASE.jar
   org.springframework.context-3.0.5.RELEASE.jar
   org.springframework.core-3.0.5.RELEASE.jar
   org.springframework.expression-3.0.5.RELEASE.jar
   ```

4. Download the AOP Alliance Java™ archive (JAR) file from the SpringSource web page. Copy the com.springsource.org.aopalliance-1.0.0.jar to the equinox_root/plugins directory.
5. Download the Apache commons logging 1.1.1 JAR file from the SpringSource web page. Copy the com.springsource.org.apache.commons.logging-1.1.1.jar file to the equinox_root/plugins directory.
6. Download the Luminis OSGi Configuration Admin command-line client. Use this JAR file bundle to manage OSGi administrative configurations. Copy the net.luminis.cmc-0.2.5.jar to the equinox_root/plugins directory.
7. Download the Apache Felix file installation Version 3.0.2 bundle from the following web page: http://felix.apache.org/site/index.html. Copy the org.apache.felix.fileinstall-3.0.2.jar file to the equinox_root/plugins directory.
8. Create a configuration directory inside equinox_root/plugins directory; for example:

   ```
   mkdir equinox_root/plugins/configuration
   ```

9. Create the following config.ini file in the equinox_root/plugins/configuration directory, replacing *equinox_root* with the absolute path to your equinox_root directory and removing all trailing spaces after the backslash on each line. You must include a blank line at the end of the file; for example:

   ```
   osgi.noShutdown=true
   osgi.java.profile.bootdelegation=none
   org.osgi.framework.bootdelegation=none
   eclipse.ignoreApp=true
   osgi.bundles=\
   org.eclipse.osgi.services_3.2.100.v20100503.jar@1:start, \
   org.eclipse.osgi.util_3.2.100.v20100503.jar@1:start, \
   org.eclipse.equinox.cm_1.0.200.v20100520.jar@1:start, \
   com.springsource.org.apache.commons.logging-1.1.1.jar@1:start, \
   com.springsource.org.aopalliance-1.0.0.jar@1:start, \
   org.springframework.aop-3.0.5.RELEASE.jar@1:start, \
   org.springframework.asm-3.0.5.RELEASE.jar@1:start, \
   org.springframework.beans-3.0.5.RELEASE.jar@1:start, \
   org.springframework.context-3.0.5.RELEASE.jar@1:start, \
   org.springframework.core-3.0.5.RELEASE.jar@1:start, \
   org.springframework.expression-3.0.5.RELEASE.jar@1:start, \
   org.apache.felix.fileinstall-3.0.2.jar@1:start, \
   net.luminis.cmc-0.2.5.jar@1:start, \
   gemini-blueprint-core-1.0.0.jar@1:start, \
   gemini-blueprint-extender-1.0.0.jar@1:start, \
   gemini-blueprint-io-1.0.0.jar@1:start
   ```

   If you have already set up the environment, you can clean up the Equinox plug-in repository by removing the following directory: equinox_root\plugins\configuration\org.eclipse.osgi.

10. Run the following commands to start equinox console.
    If you are running a different version of Equinox, then your JAR file name is different from the one in the following example:

    ```
    java -jar plugins\org.eclipse.osgi_3.6.1.R36x_v20100806.jar -console
    ```

- Installing eXtreme Scale bundles
  WebSphere eXtreme Scale includes bundles that can be installed into an Eclipse Equinox OSGi framework. These bundles are required to start eXtreme Scale servers or use eXtreme Scale clients in OSGi. You can install the eXtreme Scale bundles using the Equinox console or using the config.ini configuration file.

Installing the REST data service

This topic describes how to install the WebSphere® eXtreme Scale REST data service into a Web server.

Before you begin

Software requirements
The WebSphere eXtreme Scale REST data service is a Java™ Web application that can be deployed to any application server that supports Java servlet specification, Version 2.3 and a Java runtime environment, Version 5 or later.

The following software is required:

- Java Standard Edition 5 or later
- Web servlet container, Version 2.3 or later, which includes one of the following:
  - WebSphere Application Server Version 6.1.0.25 or later
  - WebSphere Application Server Version 7.0.0.5 or later
  - WebSphere Community Edition Version 2.1.1.3 or later
  - Apache Tomcat Version 5.5 or later

  WebSphere eXtreme Scale, Version 7.1 or later, including the trial.

About this task

The WebSphere eXtreme Scale REST data service includes a single wxsrestservice.war file. The wxsrestservice.war file includes a single servlet that acts as a gateway between your WCF Data Services client applications or any other HTTP REST client and a data grid.

The REST data service includes a sample that allows you to quickly create a data grid and interact with it using an eXtreme Scale client or the REST data service. See Configuring REST data services for details on using the sample.

When WebSphere eXtreme Scale 7.1 is installed or the eXtreme Scale Version 7.1 trial is extracted, the following directories and files are included:

- restservice_home/lib
  The lib directory contains these files:
  - wxsrestservice.ear – The REST data service enterprise application archive for use with WebSphere Application Server and WebSphere Application Server CE.
  - wxsrestservice.war – The REST data service web module for use with Apache Tomcat.

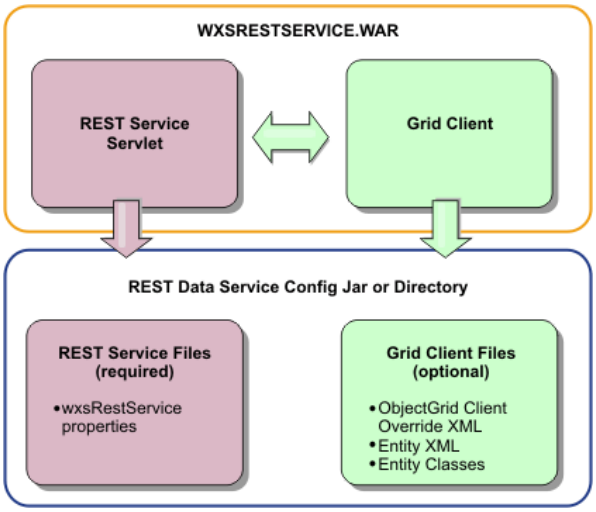
  The wxsrestservice.ear file includes the wxsrestservice.war file and are both tightly coupled with the WebSphere WebSphere eXtreme Scale runtime. If WebSphere eXtreme Scale is upgraded to a new version or a fix pack applied, the wxsrestservice.war file or wxsrestservice.ear file will need to be manually upgraded to the version installed in this directory.

- restservice_home/gettingstarted
  The gettingstarted directory contains a simple sample that demonstrates how to use the WebSphere eXtreme Scale REST data service with a data grid.

Procedure

Package and deploy the REST data service.
The REST data service is designed as a self-contained WAR module. To configure the REST data service, you must first package the REST data service configuration and optional WebSphere eXtreme Scale configuration files into a JAR file or directory. This application packaging is then referenced by the web container server runtime. The following diagram illustrates files used by the eXtreme Scale REST data service.

Figure 1. WebSphere eXtreme Scale REST Data Service Files



The REST service configuration JAR or directory must contain the following file:

wxsRestService.properties: The wxsRestService.properties file includes the configuration options for the REST data service. This includes the catalog service endpoints, ObjectGrid names to expose, trace options and more. See REST data service properties file.

The following ObjectGrid client files are optional:

- META-INF/objectGridClient.xml: The ObjectGrid client override XML file is used to connect to the remote data grid. By default this file is not required. If this file is not present, the REST service uses the server configuration, disabling the near cache.
  The name of the file can be overridden using the objectGridClientXML REST data service configuration property. If provided, this XML file should include:
  a. Any ObjectGrids that you want to expose to the REST data service.
  b. Any reference to the entity descriptor XML file associated with each ObjectGrid configuration.
- META-INF/*entity descriptor XML files*: One or more entity descriptor XML files are required only if the client needs to override the entity definition of the client. The entity descriptor XML file must be used in conjunction with the ObjectGrid client override XML descriptor file.
- **Entity classes** Annotated entity classes or an entity descriptor XML file can be used to describe the entity metadata. The REST service only requires entity classes in the classpath if the eXtreme Scale servers are configured with entity metadata classes and a client override entity XML descriptor is not used.
  An example with the minimum required configuration file, where the entities are defined in XML on the servers:

  ```
  restserviceconfig.jar:
  wxsRestService.properties
  ```

  The property file contains:

  ```
  catalogServiceEndPoints=localhost:2809
  objectGridNames=NorthwindGrid
  ```

  An example with one entity, override XML files and entity classes:

  ```
  restserviceconfig.jar:
  wxsRestService.properties
  ```

  The property file contains:

  ```
  catalogServiceEndPoints=localhost:2809
  objectGridNames=NorthwindGrid

  com/acme/entities/Customer.class
  META-INF/objectGridClient.xml
  ```

  The client ObjectGrid descriptor XML file contains:

  ```
  <objectGrid name="CustomerGrid" entityMetadataXMLFile="emd.xml"/>
  META-INF/emd.xml
  ```

  The entity metadata descriptor XML file contains:

  ```
  <entity class-name="com.acme.entities.Customer" name="Customer"/>
  ```

- Installing eXtreme Scale bundles
  WebSphere eXtreme Scale includes bundles that can be installed into an Eclipse Equinox OSGi framework. These bundles are required to start eXtreme Scale servers or use eXtreme Scale clients in OSGi. You can install the eXtreme Scale bundles using the Equinox console or using the config.ini configuration file.

Installing eXtreme Scale bundles

WebSphere® eXtreme Scale includes bundles that can be installed into an Eclipse Equinox OSGi framework. These bundles are required to start eXtreme Scale servers or use eXtreme Scale clients in OSGi. You can install the eXtreme Scale bundles using the Equinox console or using the config.ini configuration file.

Before you begin

This task assumes that you have installed the following products:

- Eclipse Equinox OSGi framework
- eXtreme Scale stand-alone client or server

About this task

eXtreme Scale includes two bundles. Only one of the following bundles is required in an OSGi framework:

objectgrid.jar
: The server bundle is the objectgrid.jar file and is installed with the eXtreme Scale stand-alone server installation and is required for running eXtreme Scale servers and can also be used for running eXtreme Scale clients, or local, in-memory caches. The bundle ID for the objectgrid.jar file is com.ibm.websphere.xs.server_<version>, where the version is in the format: <Version>.<Release>.<Modification>. For example, the server bundle for this release is com.ibm.websphere.xs.server_8.5.0.

ogclient.jar
: The ogclient.jar bundle is installed with the eXtreme Scale stand-alone and client installations and is used to run eXtreme Scale clients or local, in-memory caches. The bundle ID for ogclient.jar file is com.ibm.websphere.xs.client_<version>, where the version is in the format: <Version>_<Release>_<Modification>. For example, the client bundle for this release is com.ibm.websphere.xs.server_8.5.0.

For more information about developing eXtreme Scale plug-ins, see the System APIs and Plug-ins topic.
Related concepts:
Embedded server API

Install the eXtreme Scale client or server bundle into the Eclipse Equinox OSGi framework using the Equinox console

Procedure

1. Start the Eclipse Equinox framework with the console enabled; for example:
   java_home/bin/java -jar <equinox_root>/plugins/org.eclipse.osgi_3.6.1.R36x_v20100806.jar -console
2. Install the eXtreme Scale client or server bundle in the Equinox console:

   ```
   osgi> install file:///<path to bundle>
   ```

3. Equinox displays the bundle ID for the newly installed bundle:

   ```
   Bundle id is 25
   ```

4. Start the bundle in the Equinox console, where <id> is the bundle ID assigned when the bundle was installed:

   ```
   osgi>  start <id>
   ```

5. Retrieve the service status in the Equinox console to verify that the bundle has started; for example:

   ```
   osgi> ss
   ```

   When the bundle starts successfully, the bundle displays the ACTIVE state; for example:

   ```
   25      ACTIVE      com.ibm.websphere.xs.server_8.5.0
   ```

Install the eXtreme Scale client or server bundle into the Eclipse Equinox OSGi framework using the config.ini file

Procedure

1. Copy the eXtreme Scale client or server (objectgrid.jar or ogclient.jar) bundle from the <wxs_install_root>/ObjectGrid/lib to the Eclipse Equinox plug-ins directory; for example: <equinox_root>/plugins
2. Edit the Eclipse Equinox config.ini configuration file, and add the bundle to the osgi.bundles property; for example:

   ```
   osgi.bundles=\
   org.eclipse.osgi.services_3.2.100.v20100503.jar@1:start, \
   org.eclipse.osgi.util_3.2.100.v20100503.jar@1:start, \
   org.eclipse.equinox.cm_1.0.200.v20100520.jar@1:start, \
   objectgrid.jar@1:start
   ```

   Important: Verify that a blank line exists after the last bundle name. Each bundle is separated by a comma.
3. Start the Eclipse Equinox framework with the console enabled; for example:
   java_home/bin/java -jar <equinox_root>/plugins/org.eclipse.osgi_3.6.1.R36x_v20100806.jar -console
4. Retrieve the service status in the Equinox console to verify that the bundle has started:

   ```
   osgi> ss
   ```

   When the bundle starts successfully, the bundle displays the ACTIVE state; for example:

```
25      ACTIVE      com.ibm.websphere.xs.server_8.5.0
```

Results

The eXtreme Scale server or client bundle is installed and started in your Eclipse Equinox OSGi framework.

Installing WebSphere eXtreme Scale or WebSphere eXtreme Scale Client with WebSphere Application Server

You can install WebSphere® eXtreme Scale or WebSphere eXtreme Scale Client in an environment in which WebSphere Application Server or WebSphere Application Server Network Deployment is installed. You can use the existing features of WebSphere Application Server or WebSphere Application Server Network Deployment to enhance your eXtreme Scale applications.

Before you begin

- Verify that the target installation directory does not contain an existing installation of WebSphere eXtreme Scale or WebSphere eXtreme Scale Client.
- Stop all processes that are running in your WebSphere Application Server or WebSphere Application Server Network Deployment environment. See Command-line utilities for more information about the **stopManager**, **stopNode**, and **stopServer** commands.
  CAUTION:
  Verify that any running processes are stopped. If the running processes are not stopped, the installation proceeds, creating unpredictable results. On some platforms, the installation might be left in an undetermined state.

Important: When you install WebSphere eXtreme Scale or WebSphere eXtreme Scale Client, it should be in the same directory in which you installed WebSphere Application Server. For example, if you installed WebSphere Application Server in C:*was_root*, then you should also choose C:*was_root* as the target directory for your WebSphere eXtreme Scale or WebSphere eXtreme Scale Client installation.

About this task

Integrate eXtreme Scale with WebSphere Application Server or WebSphere Application Server Network Deployment to apply the features of eXtreme Scale to your Java™ Platform, Enterprise Edition applications. Java EE applications host data grids and access the data grids using a client connection.

You can also run the grid as a client inside a Liberty profile that serves systems. To obtain the Liberty profile, you must install WebSphere Application Server .

Procedure

- If you want to install WebSphere eXtreme Scale or WebSphere eXtreme Scale Client within a WebSphere Application Server Version 8 environment, then complete the following steps:
  1. Install IBM Installation Manager. For more information, see Installing IBM Installation Manager using the GUI.
  2. Using Installation Manager, install the appropriate eXtreme Scale product offering:
     - WebSphere eXtreme Scale for WebSphere Application Server Version 8
     - WebSphere eXtreme Scale Client for WebSphere Application Server Version 8

     For more information, see Installing the product with the GUI.
  3. Download the necessary WebSphere Application Server Version 8 repositories from the Passport Advantage® site. For more information, see How to download WebSphere Application Server - Express V8.0 from Passport Advantage.
  4. Install WebSphere Application Server Version 8 For more information, see Installing the product using distributed operating systems using the GUI.
- If you want to install WebSphere eXtreme Scale or WebSphere eXtreme Scale Client within a WebSphere Application Server Version 7 environment, then complete the following steps:
  1. Install IBM Installation Manager. For more information, see Installing IBM Installation Manager using the GUI.
  2. Install WebSphere Application Server Version 7 using InstallShield MultiPlatform (ISMP) installer. For more information, see Installing your application serving environment.
  3. After installation, you must import WebSphere Application Server Version 7 into Installation Manager to complete the installation. Importing WebSphere Application Server Version 7 into the Installation Manager allows you to manage and install fix packs for the product from one location. You must ensure you have the necessary repositories set up within Installation Manager for access to fix packs and updates. For more information on how to import an existing installation of WebSphere Application Server 7 into Installation Manager, see Importing IBM WebSphere Application Server product information into the IBM Installation Manager registry.
  4. Using Installation Manager, install the appropriate eXtreme Scale product offering:
     - WebSphere eXtreme Scale for WebSphere Application Server Version 7
     - WebSphere eXtreme Scale Client for WebSphere Application Server Version 7

     For more information, see Installing the product with the GUI.
- If you want to install WebSphere eXtreme Scale or WebSphere eXtreme Scale Client within a WebSphere Application Server Version 6 environment, then complete the following steps:
  1. Install IBM Installation Manager. For more information, see Installing IBM Installation Manager using the GUI.
  2. Using Installation Manager, install the appropriate eXtreme Scale product offering:
     - WebSphere eXtreme Scale for WebSphere Application Server Version 6.1
     - WebSphere eXtreme Scale Client for WebSphere Application Server Version 6.1

     For more information, see Installing the product with the GUI.
  3. Install WebSphere Application Server Version 6 using the ISMP installer. For more information, see Installing your application serving environment

What to do next

- Start configuring your WebSphere eXtreme Scale or WebSphere eXtreme Scale Client installation. For more information, see Taking the first steps after installation.

8.5+

Installing the Liberty profile

8.5+ You install the Liberty profile application-serving environment by using the Installation Manager, or by running a Java™ archive (JAR) file.

About this task

To install the Liberty profile, you can use IBM® Installation Manager to install WebSphere® Application Server Version 8.5 or higher with WebSphere eXtreme Scale, or you can install the Liberty profile by running a provided JAR file. If you install the WebSphere Application ServerLiberty profile using Installation Manager, then you must also install WebSphere eXtreme Scale Version 8.5 or higher using Installation Manager. Likewise, if you install the WebSphere Application ServerLiberty profile by running a JAR file, then you must also install the WebSphere eXtreme Scale Version 8.5 or higher product image by running a JAR file.
On z/OS® operating systems, the Liberty profile provides an operations environment. You can work natively with this environment using the MVS™ console. For application development, consider using the Eclipse-based developer tools on a separate distributed system, on Mac OS, or in a Linux shell on z/OS.

Procedure

- Install the WebSphere Application Server Liberty profile:
  - Install the Liberty profile by using Installation Manager. For more information about installing WebSphere Application Server Version 8.5 or higher with WebSphere eXtreme Scale, see IBM Installation Manager and WebSphere eXtreme Scale product offerings.
  - Install the Liberty profile application-serving environment by running a Java archive (JAR) file.
- Install WebSphere eXtreme Scale Version 8.5 or higher. For more information, see IBM Installation Manager and WebSphere eXtreme Scale product offerings.
- Migrate your Liberty profile environment. When you migrate from one major release of the Liberty profile to a higher major release, you must change the feature version numbers in your Liberty profile server.xml file.
  For example, in the initial version of the Liberty profile that the product supported, feature version numbers were at the `1.0` level. In WebSphere eXtreme Scale Version 8.6 and higher, feature version numbers are at the `1.1` level.

  Note: When you upgrade to WebSphere Application Server V8.5.5, the Liberty profile is removed. WebSphere eXtreme Scale supports the removal of the feature. However, if you roll back to WebSphere Application Server V8.5, the Liberty profile is added again, which causes problems in WebSphere eXtreme Scale.

- Installing the Liberty profile application-serving environment by running a JAR file
  By running the Java archive (JAR) file that contains the distribution image, you install the application-serving environment, and you are ready to create a Liberty server.

Related concepts:
Liberty profile
Related reference:
Server properties file

Installing the Liberty profile application-serving environment by running a JAR file

By running the Java archive (JAR) file that contains the distribution image, you install the application-serving environment, and you are ready to create a Liberty server.

About this task

You can install the Liberty profile application-serving environment by running a JAR file as described in this topic, or by using the Installation Manager.

When you run the JAR file for WebSphere® Application Server to install the Liberty profile, you must extract the JAR file first. Then, extract the Liberty profile JAR file for WebSphere eXtreme Scale. If you use IBM Installation Manager to install WebSphere Application Server Version 8.5 and obtain the Liberty profile, then you must use Installation Manager to also install WebSphere eXtreme Scale.

This task supports the following editions:

- WebSphere Application Server Liberty Core
- WebSphere Application Server, Base and Developer editions
- WebSphere Application Server, Network Deployment
- WebSphere Application Server for z/OS

For download information for the Liberty profile application-serving and data caching environments, see the WASdev community downloads page.

Procedure

1. Extract the WebSphere Application Server Liberty profile distribution image to your preferred directory.
   This image is packaged as a JAR file; for example, `wlp-edition-8.5.0.0.jar`. Use one of the following actions to extract this JAR file:
   - To extract the distribution image by using the wizard, run `java -jar wlp-edition-8.5.0.0.jar`.
   - To extract the distribution image by accepting the license terms and conditions silently, run `java -jar wlp-edition-8.5.0.0.jar -acceptLicense`.
   - To view all available options, run `java -jar wlp-edition-8.5.0.0.jar -help`.
   - After you run the command to extract the JAR file, follow the steps that are documented through the command-line utility to complete the installation.

   All the application server files are now stored in subdirectories of the wlp directory.

2. Optional: Set the `JAVA_HOME` property for your environment.
   The Liberty profile requires a JRE in which to run. It does not share the JDK or JRE that the WebSphere Application Server full profile uses. You can specify the JDK or JRE location using the JAVA_HOME property in the server.env file, as described in Customizing the Liberty profile environment. On Linux or UNIX systems, you can instead set JAVA_HOME in the user .bashrc file, or append the JDK or JRE path to the PATH environment variable. On Windows systems, you can instead set JAVA_HOME as a system environment variable, or append the JDK or JRE path to the PATH system variable.

   Windows For example, on Windows systems you can use the following commands to set the JAVA_HOME property, and to add the Java™ /bin directory to the path:

   ```
   set JAVA_HOME=C:\Progra~1\Java\JDK16
   set PATH=%JAVA_HOME%\bin;%PATH%
   ```

   Notes:
   - The Liberty profile runtime environment searches for the **java** command in this order: JAVA_HOME property, JRE_HOME property, and system PATH property.
   - For more information about supported Java environments, and where to get them, see Minimum supported Java levels in the Liberty profile: Runtime environment known restrictions.

3. Download WebSphere eXtreme Scale for Developers -Liberty profile. Extract the WebSphere eXtreme Scale distribution image to the directory where you extracted the `wlp-edition-8.5.0.0.jar` file.
   This image is packaged as a JAR file called `wxs-wlp_8.5.0.1.jar`. To extract the distribution image, run the JAR file; for example, run the following command, depending on your version of eXtreme Scale: 8.5

   ```
   java -jar wxs-wlp_8.5.0.1.jar -acceptLicense
   ```

   ```
   java -jar wxs-wlp_8.6.0.4.jar
   ```

Results

If you extract the `wxs-wlp_8.5.0.1.jar` file , eXtreme Scale is installed on top of the WebSphere Application Server Liberty profile when you extract both JAR files to the same directory.

Installing fix packs using IBM Installation Manager

You can use IBM® Installation Manager to update the product with the fix packs that are available for WebSphere® eXtreme Scale product offerings. Fix packs can be installed from the GUI, the command line, or using response files.

- Installing fix packs using the GUI
  You can update this product to a later version using the IBM Installation Manager wizard.
- 8.5+ Installing fix packs using the command line
  You can use the IBM Installation Manager from the command line to update the product with the fix packs that are available for WebSphere eXtreme Scale product offerings.
- Installing fix packs using a response file
  You can update this product to a later version using IBM Installation Manager with a response file.

Installing fix packs using the GUI

You can update this product to a later version using the IBM® Installation Manager wizard.

Before you begin

Contact the IBM Software Support Center for information about upgrades for WebSphere® eXtreme Scale stand-alone or WebSphere eXtreme Scale for WebSphere Application Server product offerings. The most current information is available from the IBM Software Support Center and Fix Central.

IBM Installation Manager is used to apply product maintenance to the following product offerings:

- WebSphere eXtreme Scale in a stand-alone environment
- WebSphere eXtreme Scale Client in a stand-alone environment
- WebSphere eXtreme Scale for WebSphere Application Server Version 6.1
- WebSphere eXtreme Scale for WebSphere Application Server Version 7
- WebSphere eXtreme Scale for WebSphere Application Server Version 8
- WebSphere eXtreme Scale Client forWebSphere Application Server Version 6.1
- WebSphere eXtreme Scale Client for WebSphere Application Server Version 7
- WebSphere eXtreme Scale Client for WebSphere Application Server Version 8

Make sure that the web-based or local service repository location is listed and checked or that the **Search service repositories during installation and updates** option is selected on the Repositories panel in your Installation Manager preferences. For more information on using service repositories with Installation Manager, read the IBM Installation Manager Version 1.5 Information Center.

About this task

Restriction: You cannot use the Installation Manager to upgrade an installation and add or remove the full WebSphere Application Server profile feature or the Liberty profile feature.

Procedure

1. Stop all processes that are running in your environment.
   - To stop all processes that are running in your stand-alone eXtreme Scale environment, see Stopping stand-alone servers.
   - To stop all processes that are running in your WebSphere Application Server environment, see Command-line utilities.
2. Log on to your system.
3. Stop all servers and applications on the WebSphere Application Server installation that is being updated.
4. Start Installation Manager.
5. Click Update.
   Note: If you are prompted to authenticate, use the IBM ID and password that you use to access protected IBM software websites.
6. Select the package group to update.
   Tip: If you select **Update all**, Installation Manager will search all of the added and predefined repositories for updates to all of the package groups that it has installed. Use this feature only if you have full control over which fixes are contained in the targeted repositories. If you create and point to a set of custom repositories that include only the specific fixes that you want to install, you should be able to use this feature confidently. If you enable searching service repositories or install fixes directly from other live web-based repositories, then you might not want to select this option so that you can select only the fixes that you want to install for each offering on subsequent panels.
7. Click Next.
8. Select the version to which you want to update under:
   - WebSphere eXtreme Scale in a stand-alone environment
   - WebSphere eXtreme Scale Client in a stand-alone environment
   - WebSphere eXtreme Scale for WebSphere Application Server Version 6
   - WebSphere eXtreme Scale for WebSphere Application Server Version 7
   - WebSphere eXtreme Scale for WebSphere Application Server Version 8
   - WebSphere eXtreme Scale Client forWebSphere Application Server Version 6
   - WebSphere eXtreme Scale Client for WebSphere Application Server Version 7
   - WebSphere eXtreme Scale Client for WebSphere Application Server Version 8
9. Select any fixes that you want to install.
   Any recommended fixes are selected by default.

   If there are recommended fixes, you can select the option to show only recommended fixes and hide non-recommended fixes.

10. Click Next.
11. Accept the terms in the license agreements, and click Next.
12. Select the optional features that you want in your updated installation.
13. Review the summary information, and click Update.
    - If the installation is successful, the program displays a message indicating that installation is successful.
    - If the installation is not successful, click View Log File to troubleshoot the problem.
14. Click Finish.
15. Click File > Exit to close Installation Manager.

Related tasks:
Uninstalling fix packs using the GUI

Installing fix packs using the command line

You can use the IBM® Installation Manager from the command line to update the product with the fix packs that are available for WebSphere® eXtreme Scale product offerings.

Before you begin

. Contact the IBM Software Support Center for information about upgrades for WebSphere eXtreme Scale stand-alone or WebSphere eXtreme Scale for WebSphere Application Server product offerings. The most current information is available from the IBM Software Support Center and Fix Central.

IBM Installation Manager is used to apply product maintenance to the following product offerings:

- WebSphere eXtreme Scale in a stand-alone environment
- WebSphere eXtreme Scale Client in a stand-alone environment
- WebSphere eXtreme Scale for WebSphere Application Server Version 6.1
- WebSphere eXtreme Scale for WebSphere Application Server Version 7
- WebSphere eXtreme Scale for WebSphere Application Server Version 8
- WebSphere eXtreme Scale Client forWebSphere Application Server Version 6.1
- WebSphere eXtreme Scale Client for WebSphere Application Server Version 7
- WebSphere eXtreme Scale Client for WebSphere Application Server Version 8

About this task

Restriction: You cannot use the Installation Manager to upgrade an installation and add or remove the full WebSphere Application Server profile feature or the Liberty profile feature.

Procedure

1. For a list of interim fixes and fix packs that are available forWebSphere eXtreme Scale 8.5 and specific information about each fix, perform the following actions.
    a. Go to Fix Central.
    b. Select **WebSphere** as the product group.
    c. Select WebSphere eXtreme Scale as the product.
    d. Select **8.5** as the installed version.
    e. Select your operating system as the platform, and click **Continue**.
    f. Select **Browse for fixes**, and click **Continue**.
    g. Click **More Information** under each fix to view information about the fix.
    h. **Recommendation:** Make a note of the name of the fix pack that you would like to install.
2. Update WebSphere eXtreme Scale Version 8.5 with the fix pack using the following procedure.
    - Download the file that contains the fix pack from Fix Central, and use local updating.
      You can download a compressed file that contains the fix pack from Fix Central. Each compressed fix-pack file contains an Installation Manager repository for the fix pack and usually has a .zip extension. After downloading and extracting the fix-pack file, use Installation Manager to update WebSphere Application Server Version 8.x with the fix pack.
        - To download the fix pack, perform the following actions:
            - Go to Fix Central.
            - Select **WebSphere** as the product group.
            - Select **WebSphere eXtreme Scale** as the product.
            - Select **8.x** as the installed version.
            - Select your operating system as the platform, and click **Continue**.
            - Select **Browse for fixes**, and click **Continue**.
            - Select the fix pack that you want to download, and click **Continue**.
            - Select your download options, and click **Continue**.
            - Click **I agree** to agree to the terms and conditions.
            - Click **Download now** to download the fix pack.
            - Transfer the compressed file in binary format to the system on which it will be installed.
            - Extract the compressed repository files to a directory on your system.
        - To install a fix pack from a downloaded file, perform the following actions:
            - Log on to your system.
            - Stop all processes that are running in your environment. To stop all processes that are running in your WebSphere Application Server environment, see Command-line utilities.
            - Change to the *Installation_Manager_binaries*/eclipse/tools directory, where *Installation_Manager_binaries* is the installation root directory for the Installation Manager.
            - Install the fix pack.

              UNIX Linux

              ```
              ./imcl install offering_ID_offering_version,optional_feature_ID
                -installationDirectory product_installation_location
                -repositories location_of_expanded_files
                -acceptLicense
              ```

              Windows

              ```
              imcl.exe install offering_ID_offering_version,optional_feature_ID
                -installationDirectory product_installation_location
                -repositories location_of_expanded_files
                -acceptLicense
              ```

              Tips:
                - The *offering_ID* is the offering ID that is listed in Offering IDs for WebSphere eXtreme Scale product offerings.

- The *offering_version*, which optionally can be attached to the offering ID with an underscore, is a specific version of the offering to install (`8.5.0.20110503_0200` for example).
  - If *offering_version* is **not** specified, the latest version of the offering and **all** interim fixes for that version are installed.
  - If *offering_version* is specified, the specified version of the offering and **no** interim fixes for that version are installed.

  The offering version can be found attached to the end of the offering ID with an underscore when you run the following command against the repository:

  ```
  imcl listAvailablePackages -repositories source_repository
  ```

- You can also specify `none`, `recommended` or `all` with the `-installFixes` argument to indicate which interim fixes you want installed with the offering.
  - If the offering version is **not** specified, the `-installFixes` option defaults to `all`.
  - If the offering version is specified, the `-installFixes` option defaults to `none`.
- You can add a list of features that are separated by commas. If a list of features is not specified, the default features are installed.

- **Optional:** List all installed packages to verify the installation:

  UNIX Linux

  ```
  ./imcl listInstalledPackages -long
  ```

  Windows

  ```
  imcl.exe listInstalledPackages -long
  ```

Related tasks:
Uninstalling fix packs using the command line

Installing fix packs using a response file

You can update this product to a later version using IBM® Installation Manager with a response file.

Before you begin

Tip: As an alterative to the procedure that is described in this article, Installation Manager allows you to use the **updateAll** command in a response file or on the command line to search for and update all installed packages. Use this command only if you have full control over which fixes are contained in the targeted repositories. If you create and point to a set of custom repositories that include only the specific fixes that you want to install, you should be able to use this command confidently. If you enable searching service repositories or install fixes directly from other live web-based repositories, then you might not want to select this option so that you can select only the fixes that you want to install using the -installFixes option with the **install** command on the command line or the installFixes attribute in a response file.

Procedure

1. For a list of interim fixes and fix packs that are available for WebSphere® eXtreme Scale and specific information about each fix, perform the following actions.
   a. Go to Fix Central.
   b. Select **WebSphere** as the product group.
   c. Select WebSphere eXtreme Scale as the product.
   d. Select **8.x** as the installed version.
   e. Select your operating system as the platform, and click **Continue**.
   f. Select **Browse for fixes**, and click **Continue**.
   g. Click **More Information** under each fix to view information about the fix.
   h. **Recommendation:** Make a note of the name of the fix pack that you would like to install.
2. Update WebSphere eXtreme Scale with the fix pack using the following procedure.
   - Download the file that contains the fix pack from Fix Central, and use local updating.
     You can download a compressed file that contains the fix pack from Fix Central. Each compressed fix-pack file contains an Installation Manager repository for the fix pack and usually has a .zip extension. After downloading and extracting the fix-pack file, use Installation Manager to update WebSphere eXtreme Scale with the fix pack.
     - To download the fix pack, perform the following actions:
       - Go to Fix Central.
       - Select **WebSphere** as the product group.
       - Select **WebSphere eXtreme Scale** as the product.
       - Select **8.6** as the installed version.
       - Select your operating system as the platform, and click **Continue**.
       - Select **Browse for fixes**, and click **Continue**.
       - Select the fix pack that you want to download, and click **Continue**.
       - Select your download options, and click **Continue**.
       - Click **I agree** to agree to the terms and conditions.
       - Click **Download now** to download the fix pack.
       - Transfer the compressed file in binary format to the system on which it will be installed.
       - Extract the compressed repository files to a directory on your system.
     - Perform the following actions:

- Log on to your system.
- If the repository requires a user name and password, create a keyring file to access this repository.
  For more information on creating a keyring file for Installation Manager, read the IBM Installation Manager Version 1.5 Information Center.

  Tip: When creating a keyring file, append /repository.config at the end of the repository URL location if the **imutilsc** command is unable to find the URL that is specified.
- To stop all processes that are running in your stand-alone eXtreme Scale environment, see Stopping stand-alone serversTo stop all processes that are running in your WebSphere Application Server environment, see Command-line utilities.
- Change to the *Installation_Manager_binaries*/eclipse/tools directory, where *Installation_Manager_binaries* is the installation root directory for the Installation Manager.
- Install the fix pack using a response file.
  For example:
  - Windows **Administrator or non-administrator:**

    ```
    imcl.exe -acceptLicense
      input C:\temp\update_response_file.xml
      -log C:\temp\update_log.xml
      -keyring C:\IM\im.keyring
    ```

  - UNIX Linux **Administrator:**

    ```
    ./imcl -acceptLicense
      input /var/temp/update_response_file.xml
      -log /var/temp/update_log.xml
      -keyring /var/IM/im.keyring
    ```

  - UNIX Linux **Non-administrator:**

    ```
    ./imcl -acceptLicense
      input user_home/var/temp/update_response_file.xml
      -log user_home/var/temp/update_log.xml
      -keyring user_home/var/IM/im.keyring
    ```

Uninstalling fix packs using IBM Installation Manager

You can use IBM® Installation Manager to rollback WebSphere® eXtreme Scale product offerings to an earlier version. You can uninstall fix packs from the GUI, the command line, or using response files.

- 8.5+ Uninstalling fix packs using the GUI
  You can roll back this product to an earlier version using the IBM Installation Manager GUI.
- 8.5+ Uninstalling fix packs using the command line
  You can roll back this product to an earlier version using IBM Installation Manager from the command line.
- 8.5+ Uninstalling fix packs using response files
  You can roll back this product to an earlier version using IBM Installation Manager with a response file.

Uninstalling fix packs using the GUI

You can roll back this product to an earlier version using the IBM® Installation Manager GUI.

Before you begin

During the rollback process, Installation Manager must access files from the earlier version of the package. By default, these files are stored on your computer when you install a package. If you change the default setting or delete the saved files, Installation Manager requires access to the repository that was used to install the earlier version.

About this task

Restriction: You cannot use the Installation Manager to roll back an installation and add or remove a feature.

Procedure

1. Stop all processes that are running in your environment.
   - To stop all processes that are running in your stand-alone eXtreme Scale environment, see Stopping stand-alone servers.
   - To stop all processes that are running in your WebSphere® Application Server environment, see Command-line utilities.
2. Start Installation Manager.

3. Click Roll Back.
4. Select the package group to roll back.
5. Click Next.
6. Select the version to which you want to roll back under.
7. Click Next.
8. Review the summary information, and click Roll Back.
   - If the rollback is successful, the program displays a message indicating that the rollback is successful.
   - If the rollback is not successful, click View Log File to troubleshoot the problem.
9. Click Finish.
10. Click File > Exit to close Installation Manager.

Installing fix packs using the GUI

Uninstalling fix packs using the command line

You can roll back this product to an earlier version using IBM® Installation Manager from the command line.

Before you begin

Restriction: In order to use this procedure, you must have Installation Manager Version 1.5 or later installed on your system.
During the rollback process, Installation Manager must access files from the earlier version of the package. By default, these files are stored on your computer when you install a package. If you change the default setting or delete the saved files, Installation Manager requires access to the repository that was used to install the earlier version.

About this task

Restriction: You cannot use the Installation Manager to roll back an installation and add or remove the full WebSphere® Application Server profile feature or the Liberty profile feature.

Procedure

1. Optional: If the repository requires a user name and password, create a keyring file to access this repository.
   For more information on creating a keyring file for Installation Manager, read the IBM Installation Manager Version 1.5 Information Center.

   Tip: When creating a keyring file, append /repository.config at the end of the repository URL location if the **imutilsc** command is unable to find the URL that is specified.
2. Log on to your system.
3. Stop all processes that are running in your environment.
   - To stop all processes that are running in your stand-alone eXtreme Scale environment, see Stopping stand-alone servers.
   - To stop all processes that are running in your WebSphere Application Server environment, see Command-line utilities.
4. Change to the eclipse/tools subdirectory in the directory where you installed Installation Manager.
5. Use the **imcl** command to roll back the product.

   UNIX Linux

   ```
   ./imcl rollback offering_ID_offering_version
     -repositories source_repository
     -installationDirectory installation_directory
     -preferences preference_key=value
     -properties property_key=value
     -keyring keyring_file -password password
     -acceptLicense
   ```

   Windows

   ```
   imcl.exe rollback offering_ID_offering_version
     -repositories source_repository
     -installationDirectory installation_directory
     -preferences preference_key=value
     -properties property_key=value
     -keyring keyring_file -password password
     -acceptLicense
   ```

   Tips:
   - The *offering_ID* is the offering ID that is listed in Offering IDs for WebSphere eXtreme Scale product offerings.
   - The *offering_version*, which optionally can be attached to the offering ID with an underscore, is a specific version of the offering to which to roll back (`8.5.0.20110503_0200` for example).
     - If *offering_version* is **not** specified, the installation rolls back to the previously installed version of the offering and **all** interim fixes for that version are installed.
     - If *offering_version* is specified, the installation rolls back to the specified earlier version of the offering and **no** interim fixes for that version are installed.

The offering version can be found attached to the end of the offering ID with an underscore in the Package section of the report that is generated when you run the **historyInfo** or **genHistoryReport** command from the *app_server_root*/bin directory.

For more information on using Installation Manager, read the IBM Installation Manager Version 1.5 Information Center.

6. Optional: List all installed packages to verify the roll back.
   UNIX Linux

   ```
   ./imcl listInstalledPackages -long
   ```

   Windows

   ```
   imcl.exe listInstalledPackages -long
   ```

4. Use a response file to roll back the product.
   Change to the eclipse/tools subdirectory in the directory where you installed Installation Manager, and roll back the product.

   For example:
   - Windows **Administrator or non-administrator:**

     ```
     imcl.exe
       input C:\temp\rollback_response_file.xml
       -log C:\temp\rollback_log.xml
       -keyring C:\IM\im.keyring
     ```

   - UNIX Linux **Administrator:**

     ```
     ./imcl
       input /var/temp/rollback_response_file.xml
       -log /var/temp/rollback_log.xml
       -keyring /var/IM/im.keyring
     ```

   - UNIX Linux **Non-administrator:**

     ```
     ./imcl
       input user_home/var/temp/rollback_response_file.xml
       -log user_home/var/temp/rollback_log.xml
       -keyring user_home/var/IM/im.keyring
     ```

   Note: The program might write important post-installation instructions to standard output.
   For more information on using Installation Manager, read the IBM Installation Manager Version 1.5 Information Center.
5. Optional: List all installed packages to verify the roll back.
   UNIX Linux

   ```
   ./imcl listInstalledPackages -long
   ```

Windows

```
imcl.exe listInstalledPackages -long
```

Uninstalling the product using IBM Installation Manager

Use IBM® Installation Manager to uninstall WebSphere® eXtreme Scale product offerings.

- 8.5+ Uninstalling the product using the GUI
  You can use IBM Installation Manager GUI to uninstall the product .
- 8.5+ Uninstalling the product using the command line
  You can uninstall the product using IBM Installation Manager from the command line.
- 8.5+ Uninstalling the product using response files
  You can uninstall the product using IBM Installation Manager with response files.

Uninstalling the product using the GUI

You can use IBM® Installation Manager GUI to uninstall the product .

Before you begin

You must remove the WebSphere® eXtreme Scale augment from all WebSphere Application Server profiles before uninstalling WebSphere eXtreme Scale. You will be unable to perform the unaugment after uninstalling WebSphere eXtreme Scale. Use the manageprofiles command to unaugment existing profiles in a WebSphere eXtreme Scale environment. .

Procedure

1. Uninstall the product.
   a. Stop all processes that are running in your environment.
      - To stop all processes that are running in your stand-alone eXtreme Scale environment, see Stopping stand-alone servers.
      - To stop all processes that are running in your WebSphere Application Server environment, see Command-line utilities.
   b. Start Installation Manager.
   c. Click **Uninstall**.
   d. In the **Uninstall Packages** window, perform the following actions.
      i. Select one of the following and the appropriate version:
         - WebSphere eXtreme Scale in a stand-alone environment
         - WebSphere eXtreme Scale Client in a stand-alone environment
         - WebSphere eXtreme Scale for WebSphere Application Server Version 6
         - WebSphere eXtreme Scale for WebSphere Application Server Version 7
         - WebSphere eXtreme Scale for WebSphere Application Server Version 8
         - WebSphere eXtreme Scale Client forWebSphere Application Server Version 6
         - WebSphere eXtreme Scale Client for WebSphere Application Server Version 7
         - WebSphere eXtreme Scale Client for WebSphere Application Server Version 8
      ii. Click **Next**.
   e. If the uninstallation wizard displays a list of augmented WebSphere Application Server profiles, then you must unaugment these profiles in order to proceed with the uninstallation.
   f. Review the summary information.
   g. Click **Uninstall**.
      - If the uninstallation is successful, the program displays a message that indicates success.
      - If the uninstallation is not successful, click **View log** to troubleshoot the problem.
   h. Click **Finish**.
   i. Click **File > Exit** to close Installation Manager.
2. Optional: Uninstall IBM Installation Manager.
   Important: Before you can uninstall IBM Installation Manager, you must uninstall all of the packages that were installed by Installation Manager.
   Read the IBM Installation Manager Version 1.5 Information Center for information about performing this procedure.

You can uninstall the product using IBM® Installation Manager from the command line.

Before you begin

You must remove the WebSphere® eXtreme Scale augment from all WebSphere Application Server profiles before uninstalling WebSphere eXtreme Scale. You will be unable to perform the unaugment after uninstalling WebSphere eXtreme Scale. Use the manageprofiles command to unaugment existing profiles in a WebSphere eXtreme Scale environment.

Procedure

1. Log on to your system.
2. Stop all processes that are running in your environment.
   - To stop all processes that are running in your stand-alone eXtreme Scale environment, see Stopping stand-alone servers.
   - To stop all processes that are running in your WebSphere Application Server environment, see Command-line utilities.
   - To stop Liberty servers that are running in your WebSphere Application Server, see the Liberty profile server command.
3. Change to the eclipse/tools subdirectory in the directory where you installed Installation Manager.
4. Use the **imcl** command to uninstall the product.

   Windows

   ```
   imcl.exe uninstall com.ibm.websphere.v85,optional_feature_ID
     -installationDirectory installation_directory
   ```

   UNIX Linux

   ```
   ./imcl uninstall com.ibm.websphere.v85,optional_feature_ID
     -installationDirectory installation_directory
   ```

   Tips:
   - The *offering_ID* is the offering ID that is listed in Offering IDs for WebSphere eXtreme Scale product offerings.
   - You can remove a list of features that are separated by commas—the feature ID. For example,

     ```
     imcl uninstall com.ibm.websphere.WXS.v85,xs.console.feature,xs.samples.feature
     ```

     - `client` indicates the stand-alone client feature
     - `server` indicates the stand-alone server feature
     - `console` indicates the web based monitoring console
     - `samples` indicates the samples
   - If a list of features is not specified, the entire product is uninstalled.

   Go to the IBM Installation Manager Version 1.5 Information Center for more information.
5. If the uninstallation process displays a list of augmented WebSphere Application Server profiles, then you must unaugment these profiles in order to proceed with the uninstallation.
6. Optional: Uninstall IBM Installation Manager.
   Important: Before you can uninstall IBM Installation Manager, you must uninstall all of the packages that were installed by Installation Manager. Read the IBM Installation Manager Version 1.5 Information Center for information about using the uninstall script to perform this procedure.

Uninstalling the product using response files

You can uninstall the product using IBM® Installation Manager with response files.

Before you begin

You must remove the WebSphere® eXtreme Scale augment from all WebSphere Application Server profiles before uninstalling WebSphere eXtreme Scale. You will be unable to perform the unaugment after uninstalling WebSphere eXtreme Scale. Use the manageprofiles command to unaugment existing profiles in a WebSphere eXtreme Scale environment.
Optional: Perform or record the installation of Installation Manager and installation of the product to a temporary installation registry on one of your systems so that you can use this temporary registry to record the uninstallation without using the standard registry where Installation Manager is installed.

About this task

Using Installation Manager, you can work with response files to uninstall the product in a variety of ways. You can record a response file using the GUI as described in the following procedure, or you can generate a new response file by hand or by taking an example and modifying it.

Procedure

1. Stop all processes that are running in your environment.
   - To stop all processes that are running in your stand-alone eXtreme Scale environment, see Stopping stand-alone servers.
   - To stop all processes that are running in your WebSphere Application Server environment, see Command-line utilities.
   - To stop Liberty servers that are running in your WebSphere Application Server, see the Liberty profile server command.
2. Optional: **Record a response file to uninstall the product:** On one of your systems, perform the following actions to record a response file that will uninstall the product:
   a. From a command line, change to the eclipse subdirectory in the directory where you installed Installation Manager.
   b. Start Installation Manager from the command line using the -record option.
   For example:
   - Windows **Administrator or non-administrator:**

     ```
     IBMIM.exe -skipInstall "C:\temp\imRegistry"
       -record C:\temp\uninstall_response_file.xml
     ```

   - UNIX Linux **Administrator:**

     ```
     ./IBMIM -skipInstall /var/temp/imRegistry
       -record /var/temp/uninstall_response_file.xml
     ```

   - UNIX Linux **Non-administrator:**

     ```
     ./IBMIM -skipInstall user_home/var/temp/imRegistry
       -record user_home/var/temp/uninstall_response_file.xml
     ```

   Tip: If you choose to use the -skipInstall parameter with a temporary installation registry created as described in *Before you begin*, Installation Manager uses the temporary installation registry while recording the response file. It is important to note that when the -skipInstall parameter is specified, no product packages are installed or uninstalled. All of the actions that you perform in Installation Manager simply update the installation data that is stored in the specified temporary registry. After the response file is generated, it can be used to uninstall the product, removing the product files and updating the standard installation registry.
   The -skipInstall operation should not be used on the actual agent data location used by Installation Manager. This is unsupported. Use a clean writable location, and re-use that location for future recording sessions.

   For more information, read the IBM Installation Manager Version 1.5 Information Center.

   c. Click Uninstall.
   d. In the Uninstall Packages window, perform the following actions.
      i. Select one of the following and the appropriate version:
         - WebSphere eXtreme Scale in a stand-alone environment
         - WebSphere eXtreme Scale Client in a stand-alone environment
         - 8.5 WebSphere eXtreme Scale for WebSphere Application Server Version 6
         - WebSphere eXtreme Scale for WebSphere Application Server Version 7
         - WebSphere eXtreme Scale for WebSphere Application Server Version 8
         - 8.5 WebSphere eXtreme Scale Client forWebSphere Application Server Version 6
         - WebSphere eXtreme Scale Client for WebSphere Application Server Version 7
         - WebSphere eXtreme Scale Client for WebSphere Application Server Version 8

      ii. Click **Next**.
      iii. Click Next.
   e. Review the summary information.
   f. Click Uninstall.
      - If the uninstallation is successful, the program displays a message that indicates success.
      - If the uninstallation is not successful, click **View log** to troubleshoot the problem.
   g. Click Finish.
   h. Click File > Exit to close Installation Manager.
3. **Use the response file to uninstall the product:** From a command line on each of the systems from which you want to uninstall the product, change to the eclipse/tools subdirectory in the directory where you installed Installation Manager and use the response file that you created to uninstall the product.
   For example:
   - Windows **Administrator or non-administrator:**

     ```
     imcl.exe
       input C:\temp\uninstall_response_file.xml
       -log C:\temp\uninstall_log.xml
     ```

   - UNIX Linux **Administrator:**

     ```
     ./imcl
       input /var/temp/uninstall_response_file.xml
       -log /var/temp/uninstall_log.xml
     ```

   - UNIX Linux **Non-administrator:**

     ```
     ./imcl
       input user_home/var/temp/uninstall_response_file.xml
       -log user_home/var/temp/uninstall_log.xml
     ```

   Go to the IBM Installation Manager Version 1.5 Information Center for more information.

4. Optional: List all installed packages to verify the uninstallation.
   UNIX Linux

   ```
   ./imcl listInstalledPackages
   ```

Windows

```
imcl listInstalledPackages
```

5. If the uninstallation process displays a list of augmented WebSphere Application Server profiles, then you must unaugment these profiles in order to proceed with the uninstallation.
6. Optional: Uninstall IBM Installation Manager.
   Important: Before you can uninstall IBM Installation Manager, you must uninstall all of the packages that were installed by Installation Manager.
   Read the IBM Installation Manager Version 1.5 Information Center for information about using the uninstall script to perform this procedure.

Customizing WebSphere eXtreme Scale for z/OS

Using the WebSphere® Customization Toolbox, you can generate and run customized jobs to customize WebSphere eXtreme Scale for z/OS®.

Before you begin

- Verify that your system contains the latest level of WebSphere Application Server Network Deployment:
  - If you are running Version 7.0, your system must contain fix pack 21 at a minimum. See Installing your Version 7.0 application serving environment for more information.
  - If you are running Version 8.0, your system must contain fix pack 4 at minimum. See Installing your Version 8.0 application serving environment for more information.
- Install WebSphere eXtreme Scale for z/OS. See the *WebSphere eXtreme Scale Program Directory* on the Library Page for more information.

About this task

Using the WebSphere Customization Toolbox, generate customization definitions and upload and run customized jobs to customize WebSphere eXtreme Scale for z/OS.

- z/OS Installing the WebSphere Customization Toolbox
  Install the WebSphere Customization Toolbox to customize your WebSphere eXtreme Scale for z/OS environment.
- z/OS Generating customization definitions
  Use the Profile Management Tool function within the WebSphere Customization Toolbox to generate customization definitions and create customized jobs for WebSphere eXtreme Scale for z/OS.
- z/OS Uploading and running customized jobs
  After you generate the customization definitions, you can upload and run the customized jobs that are associated with the definitions to your WebSphere eXtreme Scale for z/OS system.

Installing the WebSphere Customization Toolbox

Install the WebSphere® Customization Toolbox to customize your WebSphere eXtreme Scale for z/OS® environment.

Before you begin

- Install WebSphere eXtreme Scale for z/OS. See the *WebSphere eXtreme Scale Program Directory* on the Library Page for more information.
- You must use the latest version of the WebSphere Customization Toolbox to successfully install the product extension files.
  8.5 Attention: You can use WebSphere Customization Toolbox Version 8.5 to customize WebSphere Application Server Version 7, Version 8, and Version 8.5.

About this task

The WebSphere Customization Tools is a workstation-based graphical tool you use to create customized jobs that build WebSphere eXtreme Scale for z/OS runtime environments.

Procedure

1. Use FTP to copy the xs.wct extension file from your z/OS system to the workstation on which you are installing the WebSphere Customization Tools. The extension files are in the /usr/lpp/zWebSphere/util/WCT directory on your z/OS operating system.
2. Download and install the latest version of the WebSphere Customization Toolbox.
3. Upload the xs.wct file to the WebSphere Customization Toolbox application.
   a. Start the WebSphere Customization Toolbox application on your workstation.
   b. Click Help > Software Updates > Manage Extension.

c. From the WebSphere Customization Toolbox Extension panel, click Install.
d. From the Source Archive File panel, click Browse, navigate to the directory in which you copied the xs.wct file in step 1, and click Open.
e. Click Next on the Source Archive panel.
f. Click Next on the Extension summary panel, and click Finish on the WebSphere Customization Toolbox Extension panel.
4. From the WebSphere Customization Toolbox Extension panel, click Install.
5. From the Source Archive File panel, click Browse, navigate to the directory in which you copied the xspf.wct file in step 1, and click Open.
6. Click Next on the Summary panel.
7. Click Next on the Extension summary panel, and click Finish on the WebSphere Customization Toolbox Extension panel

What to do next

After you upload both extension files and restart the WebSphere Customization Toolbox, you can use the Profile Management Tool to generate customization definitions for WebSphere eXtreme Scale for z/OS. See Generating customization definitions for more information.

Generating customization definitions

Use the Profile Management Tool function within the WebSphere® Customization Toolbox to generate customization definitions and create customized jobs for WebSphere eXtreme Scale for z/OS®.

Before you begin

- Verify that your system contains the latest level of WebSphere Application Server Network Deployment. See Customizing WebSphere eXtreme Scale for z/OS.

About this task

You can generate customization definitions using the Profile Management Tool, which is provided in the WebSphere Customization Tools. A *customization definition* is a set of files used to create customized jobs for configuring WebSphere eXtreme Scale for z/OS.

Procedure

1. Start the Profile Management Tool.
   - Windows Click Start > Programs > IBM WebSphere > WebSphere Customization Toolbox > WebSphere Customization Toolbox. After the application starts, click the Profile Management Tool tab.
   - Linux Run the shell script, `wct.sh`, which is in the /opt/IBM/WebSphere/Toolbox/ directory. After the application starts, click the Profile Management Tool tab.
2. Using the customization locations that you have added or created for WebSphere Application Server for z/OS, select the profile that you want to augment from the Customization Locations list of the existing WebSphere Application Server product version that is installed on your z/OS operating system.
   Note: Do not use the same location that you are using for other WebSphere eXtreme Scale customization definitions.
3. Select an environment from the Customization Definitions list for WebSphere Application Server for z/OS. Click Augment to create the response file and list of instructions for augmenting the WebSphere Application Server for z/OS runtime environment. The Profile Management Tool Environment Selection panel is displayed.
4. Select the environment to augment from the Environments list, and click Next.
   - Management
   - Application server
   - Managed (custom) node

   The Profile Management Tool Augment Selection panel is displayed.
5. Select the type of augmentation to apply from the list of Augment types, and click Next.
6. Complete the fields on the panels. Specify the values for the parameters that are used to create your WebSphere Application Server for z/OS runtime environment.
7. Click Augment to generate the customization definition.
8. Click Finish to close the dialog, and continue.

What to do next

Upload the customized job to your target z/OS system. See Uploading and running customized jobs for more information.

Uploading and running customized jobs

After you generate the customization definitions, you can upload and run the customized jobs that are associated with the definitions to your WebSphere® eXtreme Scale for z/OS® system.

Before you begin

Generate the customization definitions for the jobs that you want to upload to your z/OS system. For more information, see Generating customization definitions.

About this task

Upload and run the customized jobs that you created using the WebSphere Customization Tools to administer and monitor your WebSphere eXtreme Scale for z/OS environment.

Procedure

1. Upload the customized jobs. On the Customization Definitions tab, select the jobs that you want to upload and click Process. The Profile Management Tool Select Process Type panel is displayed.
2. Select the FTP upload type for the target z/OS operating system, and click Next. Specify the required information on the Upload Customization Definition panel.
3. Click Finish.
4. Run the customized jobs. Click the Customization Instructions tab, and follow the customization instructions for each job.

Creating and augmenting profiles for WebSphere eXtreme Scale

After you install the product, create unique types of profiles and augment existing profiles for WebSphere® eXtreme Scale.

Before you begin

Install WebSphere eXtreme Scale. See Installation overview for more information.

About this task

Augmenting profiles for use with WebSphere eXtreme Scale is optional, but is required in the following usage scenarios:

- To automatically start a catalog service or container in a WebSphere Application Server process. Without augmenting the server profiles, servers can only be started programmatically using the ServerFactory API or as separate processes with the **startOgServer** script.
- To use Performance Monitoring Infrastructure (PMI) to monitor WebSphere eXtreme Scale metrics.
- To display the version of WebSphere eXtreme Scale in the WebSphere Application Server administrative console.

If you are running WebSphere eXtreme Scale within WebSphere Application Server Version 6.1 , you can use the Profile Management Tool plug-in or the **manageprofiles** command to create and augment profiles.

- 8.5+ Using the graphical user interface to create profiles
  Use the graphical user interface (GUI), which is provided by the Profile Management Tool plug-in, to create profiles for WebSphere eXtreme Scale. A profile is a set of files that define the runtime environment.
- 8.5+ Using the graphical user interface to augment profiles
  After you install the product, you can augment an existing profile to make it compatible with WebSphere eXtreme Scale.
- 8.5+ manageprofiles command
  You can use the **manageprofiles** utility to create profiles with the WebSphere eXtreme Scale template, and augment and unaugment existing application server profiles with the eXtreme Scale augment templates. To use the features of the product, your environment must contain at least one profile augmented for the product.
- 8.5+ Non-root profiles
  Give a non-root user permissions for files and directories so that the non-root user can create a profile for the product. The non-root user can also augment a profile that was created by a root user, a different non-root user, or the same non-root user.

What to do next

Depending on which task you choose to complete, launch the First steps console for assistance with configuring and testing your product environment. The First steps console is in the following directory:

- *wxs_install_root*\firststeps\wxs\firststeps.bat
- *wxs_install_root*/firststeps/wxs/firststeps.sh

You can also create or augment additional profiles by repeating any of the preceding tasks.

Using the graphical user interface to create profiles

Use the graphical user interface (GUI), which is provided by the Profile Management Tool plug-in, to create profiles for WebSphere® eXtreme Scale. A profile is a set of files that define the runtime environment.

Before you begin

You cannot use the GUI to augment profiles in the following scenario:

- **64-bit installations of WebSphere Application Server**:

The profile management tool does not exist for 64-bit installations of WebSphere Application Server. Use the **manageprofiles** script from the command line for these installations.

About this task

To use the product features, the Profile Management Tool plug-in enables the GUI to assist you in setting up profiles, such as a WebSphere Application Server profile, a deployment manager profile, a cell profile, and a custom profile. You can augment profiles during or after the installation of WebSphere eXtreme Scale.

Procedure

Use the Profile Management Tool GUI to create profiles. Choose one of the following options to start the wizard:

- Select Profile Management Tool from the First steps console.
- Access the Profile Management Tool from the Start menu.
- Run the ./pmt.sh|bat script from the *install_root*/bin/ProfileManagement directory.

What to do next

You can create additional profiles or augment existing profiles. To restart the Profile Management tool, run the **./pmt.sh|bat** command from the *was_root*/bin/ProfileManagement directory, or select Profile Management Tool in the First steps console.

Start a catalog service, start containers, and configure TCP ports in your WebSphere Application Server environment. See Configuring WebSphere eXtreme Scale with WebSphere Application Server for more information.

Using the graphical user interface to augment profiles

After you install the product, you can augment an existing profile to make it compatible with WebSphere® eXtreme Scale.

About this task

When you augment an existing profile, you change the profile by applying a product-specific augmentation template. For example, WebSphere eXtreme Scale servers do not start automatically unless the server profile is augmented with the xs_augment template.

- Augment the profile with the xs_augment template if you installed the eXtreme Scale client or the client and server.

Procedure

Use the Profile Management Tool GUI to augment profiles for eXtreme Scale. Choose one of the following options to start the wizard:

- Select Profile Management Tool from the First steps console.
- Access the Profile Management Tool from the Start menu.
- Run the ./pmt.sh|bat script from the *was_root*/bin/ProfileManagement directory.

What to do next

You can augment additional profiles. To restart the Profile Management tool, run the **./pmt.sh|bat** command from the *was_root*/bin/ProfileManagement directory, or select Profile Management Tool in the First steps console.

Start a catalog service, start containers, and configure TCP ports in your WebSphere Application Server environment. See Configuring WebSphere eXtreme Scale with WebSphere Application Server for more information.

manageprofiles command

You can use the **manageprofiles** utility to create profiles with the WebSphere® eXtreme Scale template, and augment and unaugment existing application server profiles with the eXtreme Scale augment templates. To use the features of the product, your environment must contain at least one profile augmented for the product.

- Before you can create and augment profiles, you must install eXtreme Scale . See Installing WebSphere eXtreme Scale or WebSphere eXtreme Scale Client with WebSphere Application Server for more information.

Purpose

The **manageprofiles** command creates the runtime environment for a product process in a set of files called a profile. The profile defines the runtime environment. You can perform the following actions with the **manageprofiles** command:

- Create and augment a deployment manager profile
- Create and augment a custom profile
- Create and augment stand-alone application server profile

- Create and augment a cell profile
- Unaugment any type of profile

When you augment an existing profile, you change the profile by applying a product-specific augmentation template.

- Augment the profile with the xs_augment template if you installed the eXtreme Scale client or both the client and server.

Location

The command file is in the *install_root*/bin directory.

Usage

For detailed help, use the -help parameter:

```
./manageprofiles.sh|bat -create -templatePath install_root/profileTemplates/xs_augment/dmgr -help
```

In the following sections, each task that you can perform using the **manageprofiles** command, along with a list of required parameters, is described. For details on the optional parameters to specify for each task, see the **manageprofiles** command in the WebSphere Application Server Information Center.

Create a deployment manager profile

You can use the **manageprofiles** command to create a deployment manager profile. The deployment manager administers the application servers that are federated into the cell.

Parameters

-create
: Creates a profile. (Required)

-templatePath *template_path*
: Specifies the file path to the template. (Required)
Use the following format:

```
-templatePath install_root/profileTemplates/template_type/dmgr
```

Example

- Using the xs_augment template:

```
./manageprofiles.sh|bat -create -templatePath install_root/profileTemplates/xs_augment/dmgr
```

Create a custom profile

You can use the **manageprofiles** command to create a custom profile. A custom profile is an empty node that you customize through the deployment manager to include application servers, clusters, or other Java™ processes.

Parameters

-create
: Creates a profile. (Required)

-templatePath *template_path*
: Specifies the file path to the template. (Required)
Use the following format:

```
-templatePath install_root/profileTemplates/template_type/managed
```

Example

- Using the xs_augment template:

```
./manageprofiles.sh|bat -create -templatePath install_root/profileTemplates/xs_augment/managed
```

Create a stand-alone application server profile

You can use the **manageprofiles** command to create a stand-alone application server profile.

Parameters

-create
: Creates a profile. (Required)

-templatePath *template_path*
: Specifies the file path to the template. (Required)

Use the following format:

```
-templatePath install_root/profileTemplates/template_type/default
```

Example

- Using the xs_augment template:

```
./manageprofiles.sh|bat -create -templatePath install_root/profileTemplates/xs_augment/default
```

Create a cell profile

You can use the **manageprofiles** command to create a cell profile, which consists of a deployment manager and an application server.

Parameters

Specify the following parameters in the deployment manager template:

-create
Creates a profile. (Required)
-templatePath *template_path*
Specifies the file path to the template. (Required)
Use the following format:

```
-templatePath install_root/profileTemplates/template_type/cell/dmgr
```

Specify the following parameters with the application server template:

-create
Creates a profile. (Required)
-templatePath *template_path*
Specifies the file path to the template. (Required)
Use the following format:

```
-templatePath install_root/profileTemplates/template_type/cell/default
```

Example

- Using the xs_augment template:

```
./manageprofiles.sh|bat -create -templatePath install_root/profileTemplates/xs_augment/cell/dmgr
-nodeProfilePath install_root/profiles/AppSrv01 -cellName cell01dmgr -nodeName node01dmgr
-appServerNodeName node01

./manageprofiles.sh|bat -create -templatePath install_root/profileTemplates/xs_augment/cell/default
-dmgrProfilePath install_root/profiles/Dmgr01 -portsFile
install_root/profiles/Dmgr01/properties/portdef.props -nodePortsFile
install_root/profiles/Dmgr01/properties/nodeportdef.props -cellName cell01dmgr
-nodeName node01dmgr -appServerNodeName node01
```

Augment a deployment manager profile

You can use the **manageprofiles** command to augment a deployment manager profile.

Parameters

-augment
Augments the existing profile. (Required)
-profileName
Specifies the name of the profile. (Required)
-templatePath *template_path*
Specifies the path to the template files that are located in the installation root directory. (Required)
Use the following format:

```
-templatePath install_root/profileTemplates/template_type/dmgr
```

Example

- Using the xs_augment template:

```
./manageprofiles.sh|bat -augment -profileName profile01
-templatePath install_root/profileTemplates/xs_augment/dmgr
```

Augment a custom profile

You can use the **manageprofiles** command to augment a custom profile.

Parameters

-augment
Augments the existing profile. (Required)
-profileName
Specifies the name of the profile. (Required)
-templatePath *template_path*
Specifies the path to the template files that are located in the installation root directory. (Required)
Use the following format:

```
-templatePath install_root/profileTemplates/template_type/managed
```

Example

- Using the xs_augment template:

```
./manageprofiles.sh|bat -augment -profileName profile01
-templatePath install_root/profileTemplates/xs_augment/managed
```

Augment a stand-alone application server profile

You can use the **manageprofiles** command to augment a stand-alone application server profile.

Parameters

-augment
Augments the existing profile. (Required)
-profileName
Specifies the name of the profile. (Required)
-templatePath *template_path*
Specifies the path to the template files that are located in the installation root directory. (Required)
Use the following format:

```
-templatePath install_root/profileTemplates/template_type/default
```

Example

- Using the xs_augment template:

```
./manageprofiles.sh|bat -augment -profileName profile01
-templatePath install_root/profileTemplates/xs_augment/default
```

Augment a cell profile

You can use the **manageprofiles** command to augment a cell profile.

Parameters

Specify the following parameters for the deployment manager profile:

-augment
Augments the existing profile. (Required)
-profileName
Specifies the name of the profile. (Required)
-templatePath *template_path*
Specifies the path to the template files that are located in the installation root directory. (Required)
Use the following format:

```
-templatePath install_root/profileTemplates/template_type/cell/dmgr
```

Specify the following parameters for the application server profile:

-augment
Augments the existing profile. (Required)
-profileName
Specifies the name of the profile. (Required)
-templatePath *template_path*
Specifies the path to the template files that are located in the installation root directory. (Required)
Use the following format:

```
-templatePath install_root/profileTemplates/template_type/cell/default
```

Example

- Using the xs_augment template:

```
./manageprofiles.sh|bat -augment -profileName profile01 -templatePath install_root
                                /profileTemplates/xs_augment/cell/dmgr

./manageprofiles.sh|bat -augment -profileName profile01 -templatePath install_root
                                /profileTemplates/xs_augment/cell/default
```

Unaugment a profile

To unaugment a profile, specify the -ignoreStack parameter with the -templatePath parameter in addition to specifying the required -unaugment and -profileName parameters.

Parameters

-unaugment
: Unaugments a previously augmented profile. (Required)

-profileName
: Specifies the name of the profile. The parameter is issued by default if no values are specified. (Required)

-templatePath *template_path*
: Specifies the path to the template files that are located in the installation root directory. (Optional)
Use the following format:

```
-templatePath install_root/profileTemplates/template_type/profile_type
```

where *template_type* is `xs_augment` or `pf_augment` and *profile_type* is one of four profile types:

- `dmgr`: deployment manager profile
- `managed`: custom profile
- `default`: stand-alone application server profile
- `cell`: cell profile

-ignoreStack
: Used with the -templatePath parameter to unaugment a particular profile that has been augmented. (Optional)

Example

- Using the xs_augment template:

```
./manageprofiles.sh|bat -unaugment -profileName profile01 -ignoreStack
-templatePath install_root/profileTemplates/xs_augment/profile_type
```

Non-root profiles

Give a non-root user permissions for files and directories so that the non-root user can create a profile for the product. The non-root user can also augment a profile that was created by a root user, a different non-root user, or the same non-root user.

In a WebSphere® Application Server environment, non-root (non-administrator) users are limited in being able to create and use profiles in their environment. Within the Profile Management tool plug-in, unique names and port values are disabled for non-root users. The non-root user must change the default field values in the Profile Management tool for the profile name, node name, cell name, and port assignments. Consider assigning non-root users a range of values for each of the fields. You can assign responsibility to the non-root users for adhering to their proper value ranges and for maintaining the integrity of their own definitions.

The term *installer* refers to either a root or non-root user. As an installer, you can grant non-root users permissions to create profiles and establish their own product environments. For example, a non-root user might create a product environment to test application deployment with a profile that the user owns. Specific tasks that you can complete to allow non-root profile creation include the following items:

- Creating a profile and assigning ownership of the profile directory to a non-root user so that the non-root user can start WebSphere Application Server for a specific profile.
- Granting write permission of the appropriate files and directories to a non-root user, which allows the non-root user to then create the profile. With this task, you can create a group for users who are authorized to create profiles, or give individual users the ability to create profiles.
- Installing maintenance packages for the product, which includes required services for existing profiles that are owned by a non- user. As the installer, you are the owner of any new files that the maintenance package creates.

For more information about creating profiles for non-root users, see Creating profiles for non-root users .

As an installer, you can also grant permissions for a non-root user to augment profiles. For example, a non-root user can augment a profile that is created by an installer, or augment a profile that they create. Follow the WebSphere Application Server Network Deployment non-root user augmentation process.

However, when a non-root user augments a profile that is created by the installer, the non-root user does not need to create the following files before augmentation. The following files were established during the profile creation process:

- *was_root*/logs/manageprofiles.xml

- *was_root*/properties/fsdb.xml
- *was_root*/properties/profileRegistry.xml

When a non-root user augments a profile that the user creates, the non-root user must modify the permissions for the documents that are located within the eXtreme Scale profile templates.

Attention: You can also use a non-root (non-administrator) profile for WebSphere eXtreme Scale in a stand-alone environmen, a profile that is not in WebSphere Application Server. You must change the owner of the ObjectGrid directory to the non-root profile. Then you can log in with that non-root profile and operate eXtreme Scale as you normally would for a root (administrator) profile.

Taking the first steps after installation

After complete and verify the installation, you can begin to use WebSphere® eXtreme Scale to create your data grid.

Procedure

1. Update your installation by applying maintenance.
   More information: Updating eXtreme Scale servers.
2. If you are using WebSphere eXtreme Scale for the first time, you can use the Getting started information to learn more about how to use the product.
   More information: Getting started
3. Configure the product. Create properties and XML files to define the configuration for data grids, servers, and clients. You can also configure cache or database integration, REST data services, or OSGi plug-ins.
   More information: Configuring
4. Develop an application that accesses the data grid.
   More information: Developing applications
5. Start and administer container and catalog servers with your configuration files and data grid application.
   More information: Administering
6. Monitor the performance of your configuration with the various monitoring tools.
   More information: Monitoring

Troubleshooting the product installation

IBM® Installation Manager is a common installer for many IBM software products that you use to install this version of WebSphere® eXtreme Scale.

Results

Logging and tracing:

- An easy way to view the logs is to open Installation Manager and go to File > View Log. An individual log file can be opened by selecting it in the table and then clicking the Open log file icon.
- Logs are located in the `logs` directory of Installation Manager's application data location. For example:
  - Windows **Administrative installation:**

    ```
    C:\Documents and Settings\All Users\Application Data\IBM\Installation Manager
    ```

  - Windows **Non-administrative installation:**

    ```
    C:\Documents and Settings\user_name\Application Data\IBM\Installation Manager
    ```

  - UNIX Linux **Administrative installation:**

    ```
    /var/IBM/InstallationManager
    ```

  - UNIX Linux **Non-administrative installation:**

    ```
    user_home/var/ibm/InstallationManager
    ```

- The main log files are time-stamped XML files in the `logs` directory, and they can be viewed using any standard web browser.
- The `log.properties` file in the `logs` directory specifies the level of logging or tracing that Installation Manager uses. To turn on tracing for the WebSphere eXtreme Scale plug-ins, for example, create a `log.properties` file with the following content:

  ```
  com.ibm.ws=DEBUG
  com.ibm.cic.agent.core.Engine=DEBUG
  global=DEBUG
  ```

  Restart Installation Manager as necessary, and Installation Manager outputs traces for theWebSphere eXtreme Scale plug-ins.

Notes on troubleshooting:

- UNIX Linux By default, some HP-UX systems are configured to not use DNS to resolve host names. This could result in Installation Manager not being able to connect to an external repository.
  You can ping the repository, but nslookup does not return anything.

  Work with your system administrator to configure your machine to use DNS, or use the IP address of the repository.

- In some cases, you might need to bypass existing checking mechanisms in Installation Manager.
  - On some network file systems, disk space might not be reported correctly at times; and you might need to bypass disk-space checking and proceed with your installation.
    To disable disk-space checking, specify the following system property in the config.ini file in *IM_install_root*/eclipse/configuration and restart Installation Manager:

    ```
    cic.override.disk.space=sizeunit
    ```

    where *size* is a positive integer and *unit* is blank for bytes, k for kilo, m for megabytes, or g for gigabytes. For example:

    ```
    cic.override.disk.space=120 (120 bytes)
    cic.override.disk.space=130k (130 kilobytes)
    cic.override.disk.space=140m (140 megabytes)
    cic.override.disk.space=150g (150 gigabytes)
    cic.override.disk.space=true
    ```

    Installation Manager will report a disk-space size of Long.MAX_VALUE. Instead of displaying a very large amount of available disk space, N/A is displayed.
  - To bypass operating-system prerequisite checking, add `disableOSPrereqChecking=true` to the config.ini file in *IM_install_root*/eclipse/configuration and restart Installation Manager.

  If you need to use any of these bypass methods, contact IBM Support for assistance in developing a solution that does not involve bypassing the Installation Manager checking mechanisms.
- For more information on using Installation Manager, read the IBM Installation Manager Version 1.5 Information Center.
  Read the release notes to learn more about the latest version of Installation Manager. To access the release notes, complete the following task:
  - Windows Click **Start > Programs > IBM Installation Manager > Release Notes®**.
  - UNIX Linux Go to the documentation subdirectory in the directory where Installation Manager is installed, and open the readme.html file.
- If a fatal error occurs when you try to install the product, take the following steps:
  - Make a backup copy of your current product installation directory in case IBM support needs to review it later.
  - Use Installation Manager to uninstall everything that you have installed under the product installation location (package group). You might run into errors, but they can be safely ignored.
  - Delete everything that remains in the product installation directory.
  - Use Installation Manager to reinstall the product to the same location or to a new one.

Note on version and history information: The **versionInfo** and **historyInfo** commands return version and history information based on all of the installation, uninstallation, update, and rollback activities performed on the system.

Upgrading and migrating WebSphere eXtreme Scale

You can migrate to Version 8.5 from previous versions, or you can apply maintenance packages. To avoid outages, you must consider the order in which you apply the updates to the servers in your configuration.

- Updating eXtreme Scale servers
  You can upgrade WebSphere® eXtreme Scale to a new version, either by applying maintenance or installing a new version, without interrupting service.
- Migrating to WebSphere eXtreme ScaleVersion 8.5
  With the WebSphere eXtreme Scale installer, you cannot upgrade or modify a previous installation. You must uninstall the previous version before you install the new version. You do not need to migrate your configuration files because they are backward compatible. However, if you changed any of the script files that are shipped with the product, you must reapply these changes to the updated script files.
- Installing fix packs using IBM Installation Manager
  You can use IBM® Installation Manager to update the product with the fix packs that are available for WebSphere eXtreme Scale product offerings. Fix packs can be installed from the GUI, the command line, or using response files.
- 8.5+ Uninstalling fix packs using IBM Installation Manager
  You can use IBM Installation Manager to rollback WebSphere eXtreme Scale product offerings to an earlier version. You can uninstall fix packs from the GUI, the command line, or using response files.
- 8.5+ Updating WebSphere eXtreme Scale on WebSphere Application Server
  When you migrate WebSphere Application Server to a new version, you can also migrate the WebSphere eXtreme Scale configuration to the new WebSphere Application Server installation.
- xsadmin tool to xscmd tool migration
  In previous releases, the **xsadmin** tool was a sample command-line utility to monitor the state of the environment. The **xscmd** tool has been introduced as an officially supported administrative and monitoring command-line tool. If you were previously using the **xsadmin** tool, consider migrating your commands to the new **xscmd** tool.
- Deprecated properties and APIs
  The following list of properties and APIs were deprecated in the specified releases. Use the recommended migration action to determine how to update your configuration.

Updating eXtreme Scale servers

You can upgrade WebSphere® eXtreme Scale to a new version, either by applying maintenance or installing a new version, without interrupting service.

Before you begin

You must have the binary file for the major version release or maintenance that you want to apply. You can get the latest information about the available releases and maintenance packages from the IBM support portal for WebSphere eXtreme Scale.

About this task

To upgrade without service interruption, first upgrade catalog servers, then upgrade the container servers and client servers. If you have a server and client installation on the same physical server, you can upgrade the full installations on each physical server. If you have client-only installations, upgrade these installations last.

Procedure

1. Upgrade the catalog service tier, repeating the following steps for each catalog server in the data grid. Upgrade the catalog service tier before upgrading any container servers or clients. Individual catalog servers can interoperate with version compatibility, so you can apply upgrades to one catalog server at a time without interrupting service.
   a. If you are running with quorum mechanism enabled, check for a healthy quorum status. Run the following command:

      ```
      xsadmin -quorumStatus
      ```

      ```
      xscmd -c showQuorumStatus
      ```

      This result indicates that all the catalog servers are connected.
   b. If you are using multi-master replication between two catalog service domains, dismiss the link between the two catalog service domains while you are upgrading the catalog servers.

      ```
      xsadmin -ch host -p 1099 -dismissLink domain_name
      ```

      ```
      xscmd -c dismissLink -cep host:2809 -fd domain_name
      ```

      You only need to run this command from one of the catalog service domains to remove the link between two catalog service domains.
   c. Shut down one of the catalog servers. You can use the **stopOgServer** command, the **xscmd -c teardown** command, or shut down the application server that is running the catalog service in WebSphere Application Server. There are no requirements for the order in which you stop the catalog servers, but shutting down the primary catalog server last reduces turnover. To determine which catalog server is the primary, look for the CWOBJ8106 message in the log files. Under normal conditions when the quorum mechanism is enabled, quorum is maintained when a catalog server is shut down, but it is a best practice to query quorum status after each shutdown with the **xscmd -c showQuorumStatus** command.
      You can provide a specific list of servers to stop to the **stopOgServer** command, or the **xscmd -c teardown** commands:

      ```
      stopOgServer server_name
      ```

      ```
      xsadmin -teardown server_name
      ```

      ```
      xscmd -c teardown -sl server_name
      ```

      With the previous examples, the **stopOgServer** , or **xscmd -c teardown** commands are completing the same shutdown tasks. However, you can filter the servers to stop with the **xscmd -c teardown** command. See Stopping servers gracefully with the xscmd utility for more information about filtering the servers by zone or host name. The teardown command filters out the matching servers and asks if the selected servers are correct.
   d. Install the updates on the catalog server. You can either migrate the catalog server to a new major release of the product or apply a maintenance package. See the following topics for more information:
      - To migrate from a Version 7.1.x installation: Migrating to WebSphere eXtreme ScaleVersion 8.5
   e. Restart the catalog server.
      If you are using a stand-alone environment, see Starting a stand-alone catalog service for more information. If you are using a WebSphere Application Server environment, see Starting and stopping servers in a WebSphere Application Server environment for more information.

      The catalog server runs in compatibility mode until all the catalog servers are moved to the same level. Compatibility mode mostly applies to major release migrations because new functions are not available on the servers that are not migrated. No restrictions exist on how long catalog servers can run in compatibility mode, but the best practice is to migrate all catalog servers to the same level as soon as possible.

   f. Verify that the catalog server started successfully. Ensure that the following **xscmd** commands return valid results:

      ```
      xscmd -c routetable -cep cathost:2809
      xscmd -c showMapSizes -cep cathost:2809
      ```

      Important: These commands must contain the -cep *<catalog_server_host>:<listener_port>* value for the restarted catalog server.
   g. Apply updates to the remaining catalog servers in your configuration.
2. Upgrade the container servers, repeating the following steps for each container server in the data grid. You can upgrade container servers in any order.
   a. Stop the container servers that you want to upgrade. You can stop the container servers that you want to updgrade with the **stopOgserver** command, or with the **xscmd -c teardown** command. For more information, see Stopping stand-alone servers and Stopping servers gracefully with the xscmd utility.
      By running the **xscmd -c teardown** or **stopOgserver** commands to handle multiple servers in parallel, the placement mechanism can move shards in larger groups. However, do not to take down too many servers at the same time. The resources of servers that remain might become overloaded.

b. Verify that the container servers were stopped and removed from the data grid. . Run the following **xscmd** commands and verify that the results do not contain the stopped container servers.

```
xscmd -c routetable
xscmd -c showMapSizes
```

If these commands are run too soon after container servers are stopped, correct results might not be returned. Wait a few minutes and try running the commands again.

c. Install the updates on the container servers. You can either migrate the container servers to a new major release of the product or apply a maintenance package. See the following topics for more information:
   - To migrate from a Version 7.1.x installation: Migrating to WebSphere eXtreme ScaleVersion 8.5

d. Restart your container servers.

e. Verify that the container servers were restarted and added to the data grid. Run the following **xscmd** commands and verify that the results contain the restarted container servers.

```
xscmd -c routetable
xscmd -c showMapSizes
```

If these commands are run too soon after container servers are started, correct results might not be returned. Wait a few minutes and try running the commands again.

f. Upgrade any remaining container servers in your configuration.

3. If you are using multi-master replication, reconnect your catalog service domains. Use the **xscmd -c establishLink** command to reconnect the catalog service domains.

```
xsadmin -ch host -p 1099 -establishLink dname fdHostA:2809,fdHostB:2809
```

```
xscmd -c establishLink -cep host:2809 -fd dname -fe fdHostA:2809,fdHostB:2809
```

4. 8.5+ To check that all servers are using the new version of WebSphere eXtreme Scale, issue the **xscmd -c showinfo** command.

```
xscmd -c showinfo
```

5. Upgrade the client-only installations.

What to do next

- You can also use these steps to revert to an older version or to uninstall maintenance packages. However, if you revert to Version 7.1.0 when you are using multi-master replication, the two-way replication might not function correctly when you re-establish the links. In this situation, restart both catalog service domains and re-link the catalog service domains with the **establishLink** command.

Migrating to WebSphere eXtreme ScaleVersion 8.5

With the WebSphere® eXtreme Scale installer, you cannot upgrade or modify a previous installation. You must uninstall the previous version before you install the new version. You do not need to migrate your configuration files because they are backward compatible. However, if you changed any of the script files that are shipped with the product, you must reapply these changes to the updated script files.

Before you begin

Verify that your systems meet the minimum requirements for the product versions you plan to migrate and install. See Hardware and software requirements for more information.

About this task

Merge any modified product script files with new product script files in the /bin directory to maintain your changes.
Tip: If you did not modify the script files that are installed with the product, you are not required to complete the following migration steps. Instead, you can upgrade to Version 8.5 by uninstalling the previous version and installing the new version in the same directory.

Procedure

1. Stop all processes that are using WebSphere eXtreme Scale.
   - Stop all processes that are running in your stand-alone WebSphere eXtreme Scale environment. For more information, see Stopping stand-alone servers.

- Read about command-line utilities to stop all processes that are running in your WebSphere Application Server or WebSphere Application Server Network Deployment environment.

2. Save any modified scripts from your current installation directory to a temporary directory.
3. Uninstall the product. For more information, see Uninstalling the product using IBM Installation Manager.
4. Install WebSphere eXtreme Scale Version 8.5. See Installing for more information.
5. Merge your changes from the files in the temporary directory to the new product script files in the /bin directory.
6. Start all of your WebSphere eXtreme Scale processes to begin using the product. For more information, see Administering.

Updating WebSphere eXtreme Scale on WebSphere Application Server

8.5+ When you migrate WebSphere® Application Server to a new version, you can also migrate the WebSphere eXtreme Scale configuration to the new WebSphere Application Server installation.

Before you begin

- It is assumed that both WebSphere eXtreme Scale Version 7 and WebSphere eXtreme Scale Version 8 are being installed on the same server.
- Migrate WebSphere Application Server Version 7 to WebSphere Application Server Version 8. For more information, see Migrating product configurations.
- Install WebSphere eXtreme Scale Version 8 on your WebSphere Application Server Version 8 installation. For more information, see Installing WebSphere eXtreme Scale or WebSphere eXtreme Scale Client with WebSphere Application Server. All WebSphere eXtreme Scale migration scripts must be run from WebSphere eXtreme Scale Version 8.5 or later. For example, if you are migrating from Version 7.x to Version 8, run the scripts for migration from the *<WXS_v8_install_root>*/bin directory.

About this task

When you install a new version of WebSphere Application Server that has WebSphere eXtreme Scale integration, you first upgrade WebSphere Application Server with the normal process. Then, install the new version of WebSphere eXtreme Scale on your new installation. Then, you can use the **xsmigration** script to move the WebSphere eXtreme Scale configuration information to the new WebSphere Application Server installation.

Procedure

1. Migrate the deployment manager-related configuration from Version 7 to Version 8.
   a. Run the WebSphere Application Server backup script. For more information, see WASPreUpgrade command.
   b. Stop the deployment manager.
   c. Access the deployment manager server in your WebSphere eXtreme Scale configuration and run the migration script.
      i. Change the directory to: *<WXS_v8_install_root>*/bin
      ii. Run the following command:

```
xsmigration.bat|sh -targetwashome <WAS8x_HOME>
-sourcewashome <WAS7x_HOME> -targetprofilepath <WAS8x_DmgrProfile>
 -sourceprofilepath <WAS7x_DmgrProfile>
```

      where
      - *<WAS8x_HOME>* is the root location of the WebSphere Application Server Version 8.x installation. Example /opt/IBM/WebSphere8
      - *<WAS7x_HOME>* is the root location of the WebSphere Application Server Version 7.x installation Example:/opt/IBM/WebSphere7
      - *<WAS8x_DmgrProfile>* is the location of the WebSphere Application Server Version 8.x deployment manager profile. Example: /opt/IBM/WebSphere8/profiles/DMgr01
      - *<WAS7x_DmgrProfile>* is the location of the WebSphere Application Server Version 7.x deployment manager profile. Example: /opt/IBM/WebSphere7/profiles/DMgr01
2. Migrate the application server related configuration from Version 7 to Version 8.
   a. Change the directory to: *<WXS_v8_install_root>*/bin.
   b. Run the following command:

```
xsmigration.bat|sh -targetwashome <WAS8x_HOME>
-sourcewashome <WAS7x_HOME> -targetprofilepath <WAS8x_AppServerProfile>
 -sourceprofilepath <WAS7x_AppServerProfile>
```

   where
   - *<WAS8x_HOME>* is the root location of the WebSphere Application Server Version 8.x installation. Example /opt/IBM/WebSphere8
   - *<WAS7x_HOME>* is the root location of the WebSphere Application Server Version 7.x installation Example:/opt/IBM/WebSphere7
   - *<WAS8x_AppServerProfile>* is the location of the WebSphere Application Server Version 8.x application server profile. Example: /opt/IBM/WebSphere8/profiles/AppServer01
   - *<WAS7x_AppServerProfile>* is the location of the WebSphere Application Server Version 7.x application server profile. Example: /opt/IBM/WebSphere7/profiles/AppServer01

3. Restart the WebSphere Application Server Version 8 deployment manager and synchronize all the managed nodes.

xsadmin tool to xscmd tool migration

In previous releases, the **xsadmin** tool was a sample command-line utility to monitor the state of the environment. The **xscmd** tool has been introduced as an officially supported administrative and monitoring command-line tool. If you were previously using the **xsadmin** tool, consider migrating your commands to the new **xscmd** tool.

xsadmin and xscmd command equivalents

Important: The **xsadmin** utility has now been deprecated. Use the **xscmd** utility instead. The **xscmd** utility is provided as a supported utility for monitoring and administering your environment. For more information, see Administering with the xscmd utility.

Table 1. Arguments for the **xsadmin** utility and **xscmd** equivalent commands. Some **xscmd** commands have a short form and a long form. The short form commands have one dash (-), and the long form commands have two dashes (--). You can use either form interchangeably.

xsadmin Command Line Argument	xscmd Equivalent Command	xscmd Command Parameters
-bp	• -cep *hostname:listener_port* • --catalogEndpoint *hostname:listener_port*	n/a
-ch	• -cep *hostname:listener_port* • --catalogEndpoint *hostname:listener_port*	n/a
-clear	-c clearGrid	-g, -ms, -v, -m, (-cep)
-containers	• -c showPlacement -container*containerName* • -c showPlacement -server *serverName*	-e, -i, , -st, -snp, -ct, -s, -p, -hf, -z, -g, -m, -ms
-continuous	n/a	n/a
-coregroups	• • -c listCoreGroupMembers -cg *core_group*	n/a
-dismissLink <*catalog_service_domain*>	-c dismissLink	• -fd <*foreignCatalogServiceDomain*> • --foreignCatalogServiceDomain <*foreignCatalogServiceDomain*>
-dmgr	n/a - this argument is automatically determined with **xscmd**	n/a
-empties	arg specific to a new command	n/a
-establishLink <*foreign_domain_name*> <*host1:port1,host2:port2...*>	-c establishLink	• -fd <*foreignCatalogServiceDomain*> -fe <*host1:port1,host2:port2...*> • --foreignCatalogServiceDomain <*foreignCatalogServiceDomain*> -foreignEndPoints <*host1:port1,host2:port2...*>
-fc	• -ct • --container	n/a
-fh	• -hf • --hostFilter	n/a
-fm	• -m • --map	n/a
-fnp	• -snp • --serversWithNoPrimaries	n/a
-fp	• -p • --partitionId	n/a
-fs	• -s • --server	n/a
-fst	• -st <*shard_type*> • --shardType <*shard_type*> Shard values: P=primary A=asyncReplica S=syncReplica	n/a

xsadmin Command Line Argument	xscmd Equivalent Command	xscmd Command Parameters
-fz	• -z • --zone	n/a
-force	arg specific to a new command	
-g	• -g • --objectGrid	n/a
-getstatsspec	-c getStatsSpec	n/a
-getTraceSpec	-c getTraceSpec	n/a
-h	You can run help with or without a specific command name: • -h • --help • -h <*command_name*> • --help <*command_name*>	n/a
-hosts	-c listHosts	-g, -ms, -st, -c, -s, -hf, -z
-jmxUrl	• -cep *hostname*:*listener_port* • --catalogEndpoint *hostname*:*listener_port*	n/a

Deprecated properties and APIs

The following list of properties and APIs were deprecated in the specified releases. Use the recommended migration action to determine how to update your configuration.

8.5+

Deprecated items in Version 8.5

Table 1. Deprecated properties and APIs

Deprecation	Recommended migration action
WebSphereTransactionCallback This plug-in was used to manage data grid transactions with enterprise applications that run in a WebSphere® Application Server environment.	8.5+ The WebSphereTransactionCallback interface has been replaced by the WebSphere eXtreme Scale resource adapter, which enables Java Transaction API (JTA) transaction management. You can install this resource adapter on WebSphere Application Server or other Java Platform, Enterprise Edition (Java EE) application servers. The WebSphereTransactionCallback plug-in is not an enlisted JTA API, and therefore, is not designed to roll back the JTA transaction if the commit fails.

Deprecated items in Version 7.1.1

Table 2. Deprecated properties and APIs

Deprecation	Recommended migration action

Deprecation	Recommended migration action
com.ibm.websphere.objectgrid.plugins.builtins.TranPropListener class This class was used to propagate successful ObjectGrid transaction commit processes to other WebSphere application servers hosting the same ObjectGrid instance, based upon the ObjectGrid name.	The TranPropListener interface has been replaced by the JMSObjectGridEventListener interface, which is a JMS-based implementation of the ObjectGridEventListener interface. It supports client-side, near cache invalidation and peer-to-peer replication.
com.ibm.websphere.objectgrid.plugins.OptimisticCallback class This class was used to provide optimistic comparison operations for the values of a map.	The OptimisticCallback plug-in has been replaced by the ValueDataSerializer.Versionable interface, which you can implement when you use the DataSerializer plug-in with the COPY_TO_BYTES copy mode or when you use the @Version annotation with the EntityManager API. See the API documentation for more information.
com.ibm.websphere.objectgrid.plugins.NoVersioningOptimisticCallback plug-in This plug-in was used for optimistic locking without doing version checking. With this built-in OptimisticCallback handler, the loader handled version checking, but optimistic locking was used to ensure that committed data is always returned on a read.	The NoVersioningOptimisticCallback interface extends the OptimisticCallback interface. Therefore, use the pessimistic locking strategy with a default transaction isolation of READ_COMMITTED or lower. See Tuning locking performance for more information.
com.ibm.websphere.objectgrid.plugins.ObjectTransformer class This plug-iin was used to serialize, deserialize, and copy objects into the cache.	The ObjectTransformer interface has been replaced by the DataSerializer plug-ins, which you can use to efficiently store arbitrary data in WebSphere eXtreme Scale so that existing product APIs can efficiently interact with your data.
com.ibm.websphere.objectgrid.BackingMap.setMapEventListeners method This method was used to set the list of MapEventListener objects.	Use either the addMapEventListener(EventListener) or removeMapEventListener(EventListener) methods to add or remove event listeners from a backing map.
com.ibm.websphere.objectgrid.ObjectGrid.setEventListeners method This method was used to overwrite the current list of ObjectGridEventListener objects and replace it with the supplied list of ObjectGridEventListeners objects.	Use either the addEventListener(EventListener) or removeEventListener(EventListener) methods to add or remove event listeners or life cycle listeners from the data grid.

Stabilized features in Version 7.1.1

If a feature is listed as stabilized, IBM does not currently plan to deprecate or remove this capability in a subsequent release of the product; but future investment will be focused on the alternative function. Users do not need to change any existing applications and scripts that use a stabilized function; but they should consider using the strategic alternative for new applications.

Table 3. Deprecated properties and APIs

Stabilized feature	Recommended migration action
xsadmin The xsadmin utility is provided as a sample of how you can create custom utilities for your deployment.	Use the **xscmd** utility to complete administrative tasks in the environment such as: establishing multi-master replication links, overriding quorum, and stopping groups of servers with the teardown command.

Deprecated items in Version 7.1

Table 4. Deprecated properties and APIs

Deprecation	Recommended migration action
catalog.services.cluster cell and server property: This custom property was used to define a group of catalog servers in the WebSphere Application Server configuration.	This custom property is deprecated starting in the Version 7.1 release. Create a catalog service domain in the WebSphere Application Server administrative console, which creates the same configuration as using the custom property. See Creating catalog service domains in WebSphere Application Server for more information.
CoreGroupServicesMBean MBean and interface	This MBean is deprecated starting in the Version 7.1 release. Use the CatalogServiceManagementMBean instead.
ServerMBean.updateTraceSpec() MBean operation	This operation is deprecated starting in the Version 7.1 release. Use the TraceSpec attribute on the DynamicServerMBean instead.
CoreGroupServicesMBean MBean	This MBean is deprecated starting in the Version 7.1 release. Use the CatalogServiceManagementMbean MBean instead.

Deprecation	Recommended migration action
ServiceUnavailableException exception	This exception is deprecated starting in the Version 7.1 release. Use the TargetNotAvailableException exception instead.
	The capabilities of WPF can be alternatively realized in WebSphere eXtreme Scale.
StreamQuery: A continuous query over in-flight data stored in ObjectGrid maps.	None
Static grid configuration: A static, cluster-based topology using the cluster deployment XML file.	Replaced with the improved, dynamic deployment topology for managing large data grids.
Deprecated system properties: System properties to specify the server and client properties files are deprecated.	You can still use these arguments, but change your system properties to the new values. -Dcom.ibm.websphere.objectgrid.CatalogServerProperties The property was deprecated in WebSphere eXtreme Scale Version 7.0. Use the -Dobjectgrid.server.props property. -Dcom.ibm.websphere.objectgrid.ClientProperties The property was deprecated in WebSphere eXtreme Scale Version 7.0. Use the -Dobjectgrid.client.props property. -Dobjectgrid.security.server.prop The property was deprecated in WebSphere eXtreme Scale Version 6.1.0.3. Use the -Dobjectgrid.server.prop property. -serverSecurityFile This argument was deprecated in WebSphere eXtreme Scale Version 6.1.0.3. This option is passed into the startOgServer script. Use the -serverProps argument.

- Removed properties and APIs
  If you are migrating your configuration from an earlier release of WebSphere eXtreme Scale, some features might be removed from this and earlier releases. Use the recommended migration action to determine how to update your configuration.

What's new in Version 8.5
Removed properties and APIs

Removed properties and APIs

If you are migrating your configuration from an earlier release of WebSphere® eXtreme Scale, some features might be removed from this and earlier releases. Use the recommended migration action to determine how to update your configuration.

If a feature is listed as deprecated in Deprecated features, IBM® might remove this capability in a subsequent release of the product. Future investment will be focused on the strategic function listed under Recommended Migration Actions in Deprecated features. Typically, a feature is not removed until at least two major releases or three full years (whichever time period is longer) after the release in which that feature is deprecated. In rare cases, it might become necessary to remove features sooner; such cases are indicated clearly and explicitly in the descriptions of these deprecated features in Deprecated features.
The following information describes removed features, APIs, scripting interfaces, tools, and publicly exposed configuration data. Where possible, the recommended replacement is identified.

8.5+

Removed items in Version 8.5

Table 1. Removed properties and APIs

Removed item	Recommended migration action
Keyword support: Keywords are string tags that can be applied to cache entries and later queried using ObjectMap API methods.	Use the index or query function to get objects with specific attributes.
MapAuthorization interface: This plug-in was used to authorize ObjectMap and JavaMap to access the principals that were represented by a subject object.	Use ObjectGridAuthorization to plug in authorization implementations. An ObjectGridAuthorization can be used to authorize permissions to ObjectGrid, ObjectMap, and JavaMap accesses.
WebSphere partitioning facility (WPF): The partitioning facility is a set of programming APIs that allowed Java™ EE applications to support asymmetric clustering.	You can configure partitioning with WebSphere eXtreme Scale.
StreamQuery: A continuous query over in-flight data stored in ObjectGrid maps.	None

Configuring

You can configure WebSphere® eXtreme Scale to run in a stand-alone environment, or you can configure eXtreme Scale to run in an environment with WebSphere Application Server or WebSphere Application Server Network Deployment. For a WebSphere eXtreme Scale deployment to pick up configuration changes on the server side of the data grid, you must restart processes to make these changes take effect rather than being applied dynamically. However, on the client side, although you may not alter the configuration settings for an existing client instance, you can create a new client with the settings you require by using an XML file or doing so programmatically. When creating a client, you can override the default settings that come from the current server configuration.

- Configuration methods
  You can configure most aspects of the product with XML files and property files. You can also use programmatic methods, including application and system programming interfaces, plug-ins, and managed beans.
- Operational checklist
  Use the operational checklist to prepare your environment for deploying WebSphere eXtreme Scale.
- Configuring data grids
  Use an ObjectGrid descriptor XML file to configure data grids, backing maps, plug-ins, and so on. To configure WebSphere eXtreme Scale, use an ObjectGrid descriptor XML file and the ObjectGrid API. For a distributed topology, you need an ObjectGrid descriptor XML file and a deployment policy XML file.
- Configuring deployment policies
  Use the deployment policy descriptor XML file and the objectgrid descriptor XML file to manage a distributed topology. The deployment policy is encoded as an XML file that is provided to the container server. The deployment policy provides information about maps, map sets, partitions, replicas, and so on. It also controls shard placement behaviors.
- Configuring catalog and container servers
  WebSphere eXtreme Scale has two types of servers: catalog servers and container servers. Catalog servers control the placement of shards and discover and monitor the container servers. Multiple catalog servers can join a catalog service domain to provide high availability to the environment. A container server is a Java™ virtual machine (JVM) that stores the application data for the data grid.
- Configuring multiple data center topologies
  With the multi-master asynchronous replication, you link a set of catalog service domains. The connected catalog service domains are then synchronized using replication over the links. You can define the links using properties files, at run time with Java Management Extensions (JMX) programs, or with command-line utilities. The set of current links for a domain is stored in the catalog service. You can add and remove links without restarting the catalog service domain that hosts the data grid.
- Configuring ports
  You must open ports to communicate among servers and with remote servers.
- Configuring transports
  Transports enable the exchange of objects and data between different server processes in your configuration.
- Configuring Java clients
  You can configure WebSphere eXtreme Scale to run in a stand-alone environment, or in an environment with WebSphere Application Server. For a WebSphere eXtreme Scale deployment to pick up configuration changes on the server grid side, you must restart processes to make these changes take effect rather than being applied dynamically. However, on the client side, although you cannot alter the configuration settings for an existing client instance, you can create a new client instance with the settings you require by using an XML file or doing so programmatically. When creating a client, you can override the default settings that come from the current server configuration.
- Configuring eXtreme Scale connection factories
  An eXtreme Scale connection factory allows Java EE applications to connect to a remote WebSphere eXtreme Scale data grid. Use custom properties to configure resource adapters.
- Configuring cache integration
  WebSphere eXtreme Scale can integrate with other caching-related products. You can also use the WebSphere eXtreme Scale dynamic cache provider to plug WebSphere eXtreme Scale into the dynamic cache component in WebSphere Application Server. Another extension to WebSphere Application Server is the WebSphere eXtreme Scale HTTP session manager, which can help to cache HTTP sessions.
- Configuring database integration
  You can use WebSphere eXtreme Scale to lower the load on databases. You can use a Java Persistence API (JPA) between WebSphere eXtreme Scale and the database to integrate changes as a loader.
- Configuring REST data services
  You can use WebSphere eXtreme Scale REST data service with WebSphere Application Server version 7.0,WebSphere Application Server Community Edition and Apache Tomcat.
- Configuring OSGi-enabled plug-ins using the ObjectGrid descriptor XML file
  In this task, you add existing OSGi services to a descriptor XML file so that WebSphere eXtreme Scale containers can recognize and load the OSGi-enabled plug-ins correctly.
- Configuring servers for OSGi
  WebSphere eXtreme Scale includes a server OSGi bundle, allowing starting and configuring servers and containers within an OSGi framework. The configuration topics describe how to use the eXtreme Scale server bundle, OSGi Blueprint service and eXtreme Scale configuration to run eXtreme Scale servers in an Eclipse Equinox OSGi framework.
- 8.5+ Configuring eXtreme Scale servers to run in the Liberty profile
  You must create server and catalog service definitions to run WebSphere eXtreme Scale in the Liberty profile.
- 8.5+ Scenario: Configuring HTTP session failover in the Liberty profile
  You can configure a web application server so that, when the web server receives an HTTP request for session replication, the request is forwarded to one or more servers that run in the Liberty profile.

Configuration methods

You can configure most aspects of the product with XML files and property files. You can also use programmatic methods, including application and system programming interfaces, plug-ins, and managed beans.

About this task

Use the following files to create a basic configuration:

Server properties file
: Use the server properties file to define settings for catalog and container servers, such as trace, logging, security, ports, and so on. You can pass a server properties file to the server start script, put the file in your classpath, or define the file with system properties.

Client properties file
: Use the client properties file to set properties on your clients, including ports and security settings. You can specify the client properties file to use with a system property, by placing the file in the classpath, or by using the ClientClusterContext.getClientProperties method.

ObjectGrid descriptor XML file
: The ObjectGrid descriptor XML file describes the data grid and map configuration. Specify the file to use with the server start script for stand-alone configurations, or add the file to the application module for WebSphere® Application Server configurations.

Deployment policy descriptor XML file
: The deployment policy XML file controls shard and placement of data on the various container servers in the configuration. Specify the file to use with the server start script for stand-alone configurations, or add the file to the application module for WebSphere Application Server configurations.

Operational checklist

Use the operational checklist to prepare your environment for deploying WebSphere® eXtreme Scale.

Table 1. Operational checklist

Checklist item	For more information

If you are using AIX®, tune the following operating system settings:
 	
TCP_KEEPINTVL
The TCP_KEEPINTVL setting is part of a socket keep-alive protocol that enables detection of network outage. The property specifies the interval between packets that are sent to validate the connection. When you are using WebSphere eXtreme Scale, set the value to `10`. To check the current setting, run the following command:
`# no -o tcp_keepintvl`
To change the current setting, run the following command:
`# no -o tcp_keepintvl=10`
The TCP_KEEPINTVL setting is in half seconds.
TCP_KEEPINIT
The TCP_KEEPINIT setting is part of a socket keep-alive protocol that enables detection of network outage. The property specifies the initial timeout value for TCP connection. When you are using WebSphere eXtreme Scale, set the value to `40`. To check the current setting, run the following commands:
`# no -o tcp_keepinit`
To change the current setting, run the following command:
`# no -o tcp_keepinit=40`
The TCP_KEEPINIT setting is in half seconds.
	• For AIX tuning information, see Tuning AIX systems.

Checklist item	For more information
Update the orb.properties file to modify the transport behavior of the grid. The orb.properties file is in the java/jre/lib directory.	ORB properties
Use parameters in the **startOgServer** script. In particular, use the following parameters: • Set heap settings with the -jvmArgs parameter. • Set application class path and properties with the -jvmArgs parameter. • Set -jvmArgs parameters for configuring agent monitoring. Port settings WebSphere eXtreme Scale has to open ports for communications for some transports. These ports are all dynamically defined. However, if a firewall is in use between containers then you must specify the ports. Use the following information about the ports: Listener port You can use the -listenerPort argument to specify the port that is used for communication between processes. Core group port You can use the -haManagerPort argument to specify the port that is used for failure detection. This argument is the same as peerPort. Note that core groups do not need to communicate across zones, so you might not need to set this port if the firewall is open to all the members of a single zone. JMX service port You can use the -JMXServicePort argument to specify the port that the JMX service should use. SSL port Passing `-Dcom.ibm.CSI.SSLPort=1234` as a -jvmArgs argument sets the SSL port to `1234`. The SSL port is the secure port peer to the listener port. Client port Used in the catalog service only. You can specify this value with the -catalogServiceEndPoints argument. The format of the value of this parameter is in the format: `serverName:hostName:clientPort:peerPort`	startOgServer script
Verify that security settings are configured correctly: • Transport (SSL) • Application (Authentication and Authorization) To verify your security settings, you can try to use a malicious client to connect to your configuration. For example, when the SSL-Required setting is configured, a client that has a TCP_IP setting with or a client with the wrong trust store should not be able to connect to the server. When authentication is required, a client with no credential, such as a user ID and password, should not be able to connect to the sever. When authorization is enforced, a client with no access authorization should not be granted the access to the server resources.	Security integration with external providers
Choose how you are going to monitor your environment. • **xscmd** tool: ◦ The JMX ports of the catalog servers need to be visible to the**xscmd** tool. The container server ports also need to be accessible for some commands that gather information from the containers. • Monitoring console: With the monitoring console, you can chart current and historical statistics. • Vendor monitoring tools: ◦ Tivoli® Enterprise Monitoring Agent ◦ CA Wily Introscope ◦ Hyperic HQ	• Monitoring with the xscmd utility • Java Management Extensions (JMX) security • Monitoring with the web console • Monitoring with the WebSphere eXtreme Scale Agent for IBM Tivoli Monitoring • Monitoring eXtreme Scale with Hyperic HQ • Monitoring eXtreme Scale applications with CA Wily Introscope

Configuring data grids

Use an ObjectGrid descriptor XML file to configure data grids, backing maps, plug-ins, and so on. To configure WebSphere® eXtreme Scale, use an ObjectGrid descriptor XML file and the ObjectGrid API. For a distributed topology, you need an ObjectGrid descriptor XML file and a deployment policy XML file.

- Configuring local deployments
  A local in-memory eXtreme Scale configuration can be created by using an ObjectGrid descriptor XML file or APIs.
- Configuring evictors with XML files
  In addition to programmatically setting a time-to-live (TTL) evictor with the BackingMap interface, you can use an XML file to configure an evictor on each BackingMap instance.
- Configuring a locking strategy in the ObjectGrid descriptor XML file
  You can define an optimistic, a pessimistic, or no locking strategy on each BackingMap in the WebSphere eXtreme Scale configuration.
- Configuring the lock timeout value in the ObjectGrid descriptor XML file
  The lock timeout value on a BackingMap instance is used to ensure that an application does not wait endlessly for a lock mode to be granted because of a deadlock condition that occurs due to an application error.
- Configuring peer-to-peer replication with JMS
  The Java™ Message Service (JMS) based peer-to-peer replication mechanism is used in both the distributed and local WebSphere eXtreme Scale environment. JMS is a core-to-core replication process and allows data updates to flow among local ObjectGrids and distributed ObjectGrids. For example, with this mechanism you can move data updates from a distributed eXtreme Scale data grid to a local eXtreme Scale grid, or from a grid to another grid in a different system domain.
- Configuring dynamic maps
  You can dynamically create maps that are based on a set of map templates. You can create your own map templates.

Configuring local deployments

A local in-memory eXtreme Scale configuration can be created by using an ObjectGrid descriptor XML file or APIs.

About this task

To create a local deployment, you create an ObjectGrid descriptor XML file and then pass the file to the createObjectGrid methods in the ObjectGridManager interface.
As an alternative, you can also create the entire deployment programmatically with the ObjectGridManager interface.

Procedure

1. Create an ObjectGrid descriptor XML file.
   The following companyGrid.xml file is an example of an ObjectGrid descriptor XML. The first few lines of the file include the required header for each ObjectGrid XML file. The file defines an ObjectGrid instance named "CompanyGrid" and several BackingMaps named "Customer," "Item," "OrderLine," and "Order."

```
companyGrid.xml file
<?xml version="1.0" encoding="UTF-8"?>
<objectGridConfig xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
        xsi:schemaLocation="http://ibm.com/ws/objectgrid/config ../objectGrid.xsd"
        xmlns="http://ibm.com/ws/objectgrid/config">

        <objectGrids>
                <objectGrid name="CompanyGrid">
                        <backingMap name="Customer" />
                        <backingMap name="Item" />
                        <backingMap name="OrderLine" />
                        <backingMap name="Order" />
                </objectGrid>
        </objectGrids>

</objectGridConfig>
```

2. Pass the XML file to one of the createObjectGrid methods in the ObjectGridManager interface.
   The following code sample validates the companyGrid.xml file against the XML schema, and creates the ObjectGrid instance named "CompanyGrid." The newly created ObjectGrid instance is not cached.

```
ObjectGridManager objectGridManager = ObjectGridManagerFactory.getObjectGridManager();
ObjectGrid companyGrid = objectGridManager.createObjectGrid("CompanyGrid",
        new URL("file:etc/test/companyGrid.xml"), true, false);
```

What to do next

See Creating ObjectGrid instances with the ObjectGridManager interface for more information about defining all of the maps programmatically with the createObjectGrid methods on the ObjectGridManager interface.

Configuring evictors with XML files

In addition to programmatically setting a time-to-live (TTL) evictor with the BackingMap interface, you can use an XML file to configure an evictor on each BackingMap instance.

Before you begin

Before you begin, decide on the type of evictor you are going to use:

- **The default time-based TTL evictor:** The default evictor uses a time-to-live (TTL) eviction policy for each BackingMap instance.
- **A pluggable evictor mechanism:** Pluggable evictors typically use an eviction policy that is based on the number of entries instead of on time.

Set the evictor settings before you start your container servers.

Procedure

- To set the default TTL evictor, add the ttlEvictorType attribute to the ObjectGrid descriptor XML file.
  The following example shows that the map1 BackingMap instance uses a NONE TTL evictor type. The map2 BackingMap instance uses either a LAST_ACCESS_TIME or LAST_UPDATE_TIME TTL evictor type. Specify only one or the other of these settings. The map2 BackingMap instance has a time-to-live value of 1800 seconds, or 30 minutes. The map3 BackingMap instance is defined to use a CREATION_TIME TTL evictor type and has a time-to-live value of 1200 seconds, or 20 minutes.

  Figure 1. Enable TimeToLive evictor with XML

```
<?xml version="1.0" encoding="UTF-8"?>
<objectGridConfig xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:schemaLocation="http://ibm.com/ws/objectgrid/config ../objectGrid.xsd"
 xmlns="http://ibm.com/ws/objectgrid/config">
<objectGrids>
    <objectGrid name="grid1">
        <backingMap name="map1" ttlEvictorType="NONE" />
        <backingMap name="map2" ttlEvictorType="LAST_ACCESS_TIME|LAST_UPDATE_TIME"
                                        timeToLive="1800" />
        <backingMap name="map3" ttlEvictorType="CREATION_TIME"
                                        timeToLive="1200" />
    </objectgrid>
</objectGrids>
```

- To set a pluggable evictor, use the following example.
  Figure 2. Plugging in an evictor using XML

```

Configuring a locking strategy in the ObjectGrid descriptor XML file

You can define an optimistic, a pessimistic, or no locking strategy on each BackingMap in the WebSphere® eXtreme Scale configuration.

Before you begin

Decide which locking strategy you want to use. For more information, see Locking strategies.

About this task

You can configure each BackingMap instance to use one of the following locking strategies:

- Optimistic locking mode (default)
- Pessimistic locking mode
- None

Procedure

- **Configure a pessimistic locking strategy**
  - With the lockStrategy attribute in the ObjectGrid descriptor XML file:

```
<?xml version="1.0" encoding="UTF-8"?>
<objectGridConfig xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://ibm.com/ws/objectgrid/config ../objectGrid.xsd"
    xmlns="http://ibm.com/ws/objectgrid/config">

    <objectGrids>
        <objectGrid name="test">
            <backingMap name="pessimisticMap"
                lockStrategy="PESSIMISTIC"/>
        </objectGrid>
    </objectGrids>
</objectGridConfig>
```

- **Configure an optimistic locking strategy**
  - With the lockStrategy attribute in the ObjectGrid descriptor XML file:

```
<?xml version="1.0" encoding="UTF-8"?>
<objectGridConfig xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://ibm.com/ws/objectgrid/config ../objectGrid.xsd"
    xmlns="http://ibm.com/ws/objectgrid/config">
    <objectGrids>
        <objectGrid name="test">
            <backingMap name="optimisticMap"
                lockStrategy="OPTIMISTIC"/>
        </objectGrid>
    </objectGrids>
</objectGridConfig>
```

- **Configure a no locking strategy**

- With the lockStrategy attribute in the ObjectGrid descriptor XML file:

```
<?xml version="1.0" encoding="UTF-8"?>
<objectGridConfig xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"

Configuring peer-to-peer replication with JMS

The Java™ Message Service (JMS) based peer-to-peer replication mechanism is used in both the distributed and local WebSphere® eXtreme Scale environment. JMS is a core-to-core replication process and allows data updates to flow among local ObjectGrids and distributed ObjectGrids. For example, with this mechanism you can move data updates from a distributed eXtreme Scale data grid to a local eXtreme Scale grid, or from a grid to another grid in a different system domain.

Before you begin

The JMS-based peer-to-peer replication mechanism is based on the built-in JMS-based ObjectGridEventListener, com.ibm.websphere.objectgrid.plugins.builtins.JMSObjectGridEventListener. For detailed information regarding enabling peer-to-peer replication mechanism, see JMS event listener.

See Configuring Java Message Service (JMS)-based client synchronization for more information.

The following is an XML configuration example to enable a peer-to-peer replication mechanism on an eXtreme Scale configuration:

```
peer-to-peer replication configuration - XML example
<bean
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txspeerrepl_ObjectGridEventListener"
className="com.ibm.websphere.objectgrid.plugins.JMSObjectGridEventListener">
        <property name="replicationRole" type="java.lang.String" value="DUAL_ROLES" description="" />
  <property name="replicationStrategy" type="java.lang.String" value="PUSH" description="" />
  <property name="jms_topicConnectionFactoryJndiName" type="java.lang.String"
              value="defaultTCF" description="" />
  <property name="jms_topicJndiName" type="java.lang.String" value="defaultTopic" description="" />
  <property name="jms_topicName" type="java.lang.String" value="defaultTopic" description="" />
  <property name="jms_userid" type="java.lang.String" value="" description="" />
  <property name="jms_password" type="java.lang.String" value="" description="" />
  <property name="jndi_properties" type="java.lang.String"
        value="java.naming.factory.initial=org.apache.activemq.jndi.ActiveMQInitialContextFactory;
        java.naming.provider.url=tcp://localhost:61616;connectionFactoryNames=defaultTCF;
        topic.defaultTopic=defaultTopic"
        description="jndi properties" />
     </bean>
```

Distributing changes between peer JVMs

The LogSequence and LogElement objects distribute changes between peer JVMs and communicate the changes that have occurred in an eXtreme Scale transaction with an ObjectGridEventListener plug-in.

For more information about how Java™ Message Service (JMS) can be used to distribute transactional changes, see JMS for distributed transaction changes.

A prerequisite is that the ObjectGrid instance must be cached by the ObjectGridManager. See createObjectGrid methods for more information. The cacheInstance boolean value must be set to true.

It is not necessary for you to implement this mechanism. There is a built-in peer-to-peer replication mechanism for you to use this function. See Configuring peer-to-peer replication with JMS.

The objects provide a means for an application to easily publish changes that have occurred in an ObjectGrid using a message transport to peer ObjectGrids in remote Java virtual machines and then apply those changes on that JVM. The LogSequenceTransformer class is critical to enabling this support. This article examines how to write a listener using a Java Message Service (JMS) messaging system for propagating the messages. To that end, eXtreme Scale supports transmitting LogSequences that result from an eXtreme Scale transaction commit across WebSphere Application Server cluster members with an IBM-provided plug-in. This function is not enabled by default, but can be configured to be operational. However, when either the consumer or producer is not a WebSphere Application Server, using an external JMS messaging system might be required.

Implementing the mechanism

The LogSequenceTransformer class, and the ObjectGridEventListener, LogSequence and LogElement APIs allow any reliable publish-and-subscribe to be used to distribute the changes and filter the maps you want to distribute. The snippets in this topic show how to use these APIs with JMS to build a peer-to-peer ObjectGrid shared by applications that are hosted on a diverse set of platforms sharing a common message transport.

Initialize the plug-in

The ObjectGrid calls the initialize method of the plug-in, part of the ObjectGridEventListener interface contract, when the ObjectGrid starts. The initialize method must obtain its JMS resources, including connections, sessions, and publishers, and start the thread that is the JMS listener.

The following examples show the initialize method:

```
initialize method example
public void initialize(Session session) {
        mySession = session;
        myGrid = session.getObjectGrid();
        try {
            if (mode == null) {
                throw new ObjectGridRuntimeException("No mode specified");
            }
            if (userid != null) {
                connection = topicConnectionFactory.createTopicConnection(userid,
                                                                  password);
            } else
                connection = topicConnectionFactory.createTopicConnection();

            // need to start the connection to receive messages.
            connection.start();

            // the jms session is not transactional (false).
            jmsSession = connection.createTopicSession(false,
                                                       javax.jms.Session.AUTO_ACKNOWLEDGE);
            if (topic == null)
                if (topicName == null) {
                    throw new ObjectGridRuntimeException("Topic not specified");
                } else {
                    topic = jmsSession.createTopic(topicName);
                }
            publisher = jmsSession.createPublisher(topic);
            // start the listener thread.
            listenerRunning = true;
            listenerThread = new Thread(this);
            listenerThread.start();
        } catch (Throwable e) {
            throw new ObjectGridRuntimeException("Cannot initialize", e);
        }
    }
```

The code to start the thread uses a Java 2 Platform, Standard Edition (Java SE) thread. If you are running a WebSphere Application Server Version 6.x or a WebSphere Application Server Version 5.x Enterprise server, use the asynchronous bean application programming interface (API) to start this daemon thread. You can also use the common APIs. Following is an example replacement snippet showing the same action using a work manager:

```
// start the listener thread.
listenerRunning = true;
workManager.startWork(this, true);
```

The plug-in must also implement the Work interface instead of the Runnable interface. You also need to add a release method to set the listenerRunning variable to false. The plug-in must be provided with a WorkManager instance in its constructor or by injection if using an Inversion of Control (IoC) container.

Transmit the changes

The following is a sample transactionEnd method for publishing the local changes that are made to an ObjectGrid. This sample uses JMS, although you can use any message transport that is capable of reliable publish-and subscribe-messaging.

```
transactionEnd method example
// This method is synchronized to make sure the
```

```
    // messages are published in the order the transaction
    // were committed. If we started publishing the messages
    // in parallel then the receivers could corrupt the Map
    // as deletes may arrive before inserts etc.
    public synchronized void transactionEnd(String txid, boolean isWriteThroughEnabled,
                               boolean committed,
            Collection changes) {
        try {
            // must be write through and commited.
            if (isWriteThroughEnabled && committed) {
                // write the sequences to a byte []
                ByteArrayOutputStream bos = new ByteArrayOutputStream();
                ObjectOutputStream oos = new ObjectOutputStream(bos);
                if (publishMaps.isEmpty()) {
                    // serialize the whole collection
                    LogSequenceTransformer.serialize(changes, oos, this, mode);
                } else {
                    // filter LogSequences based on publishMaps contents
                    Collection publishChanges = new ArrayList();
                    Iterator iter = changes.iterator();
                    while (iter.hasNext()) {
                        LogSequence ls = (LogSequence) iter.next();
                        if (publishMaps.contains(ls.getMapName())) {
                            publishChanges.add(ls);
                        }
                    }
                    LogSequenceTransformer.serialize(publishChanges, oos, this, mode);
                }
                // make an object message for the changes
                oos.flush();
                ObjectMessage om = jmsSession.createObjectMessage(bos.toByteArray());
                // set properties
                om.setStringProperty(PROP_TX, txid);
                om.setStringProperty(PROP_GRIDNAME, myGrid.getName());
                // transmit it.
                publisher.publish(om);
            }
        } catch (Throwable e) {
            throw new ObjectGridRuntimeException("Cannot push changes", e);
        }
    }
```

This method uses several instance variables:

- `jmsSession` variable: A JMS session that is used to publish messages. It is created when the plug-in initializes.
- `mode` variable: The distribution mode.
- `publishMaps` variable: A set that contains the name of each map with changes to publish. If the variable is empty, then all the maps are published.
- `publisher` variable: A TopicPublisher object that is created during the plug-in initialize method

Receive and apply update messages

Following is the run method. This method runs in a loop until the application stops the loop. Each loop iteration attempts to receive a JMS message and apply it to the ObjectGrid.

```
JMS message run method example
private synchronized boolean isListenerRunning() {
        return listenerRunning;
    }

    public void run() {
        try {
            System.out.println("Listener starting");
            // get a jms session for receiving the messages.
            // Non transactional.
            TopicSession myTopicSession;
            myTopicSession = connection.createTopicSession(false, javax.jms.
                                                    Session.AUTO_ACKNOWLEDGE);

            // get a subscriber for the topic, true indicates don't receive
            // messages transmitted using publishers
            // on this connection. Otherwise, we'd receive our own updates.
            TopicSubscriber subscriber = myTopicSession.createSubscriber(topic,
                                                    null, true);
            System.out.println("Listener started");
            while (isListenerRunning()) {
                ObjectMessage om = (ObjectMessage) subscriber.receive(2000);
                if (om != null) {
                    // Use Session that was passed in on the initialize...
                    // very important to use no write through here
                    mySession.beginNoWriteThrough();
                    byte[] raw = (byte[]) om.getObject();
                    ByteArrayInputStream bis = new ByteArrayInputStream(raw);
                    ObjectInputStream ois = new ObjectInputStream(bis);
                    // inflate the LogSequences
                    Collection collection = LogSequenceTransformer.inflate(ois,
                                                                                    myGrid);
                    Iterator iter = collection.iterator();
                    while (iter.hasNext()) {
                        // process each Maps changes according to the mode when
```

```
                    // the LogSequence was serialized
                    LogSequence seq = (LogSequence) iter.next();
                    mySession.processLogSequence(seq);
                }
                mySession.commit();
            } // if there was a message
        } // while loop
        // stop the connection
        connection.close();
    } catch (IOException e) {
        System.out.println("IO Exception: " + e);
    } catch (JMSException e) {
        System.out.println("JMS Exception: " + e);
    } catch (ObjectGridException e) {
        System.out.println("ObjectGrid exception: " + e);
        System.out.println("Caused by: " + e.getCause());
    } catch (Throwable e) {
        System.out.println("Exception : " + e);
    }
    System.out.println("Listener stopped");
}
```

JMS event listener

The JMSObjectGridEventListener is designed to support client-side near cache invalidation and a peer-to-peer replication mechanism. It is a Java™ Message Service (JMS) implementation of the ObjectGridEventListener interface.

The client invalidation mechanism can be used in a distributed eXtreme Scale environment to ensure client near cache data to be synchronized with servers or other clients. Without this function, the client near cache could hold stale data. However, even with this JMS-based client invalidation mechanism, you have to take into consideration the timing window for updating a client near cache because of the delay for the run time in publishing updates.

The peer-to-peer replication mechanism can be used in both distributed and local eXtreme Scale environments. It is an ObjectGrid core-to-core replication process and allows data updates to flow among local ObjectGrids and distributed ObjectGrids. For example, with this mechanism you can move data updates from a distributed grid to a local ObjectGrid, or from any grid to another grid in a different system domain.

The JMSObjectGridEventListener requires the user to configure JMS and Java Naming and Directory Interface (JNDI) information in order to obtain required JMS resources. Additionally, replication-related properties must be set correctly. In a JEE environment, the JNDI should be available in both Web and Enterprise JavaBean (EJB) containers. In this case, the JNDI property is optional unless you want to obtained external JMS resources.

This event listener has properties you can configure with XML or programmatic approaches, which can be used for only client invalidation, only peer-to-peer replication, or both. Most properties are optional for customizing the behavior to achieve your required functionality.

For more information, see JMSObjectGridEventListener API.

For more information see the JMSObjectGridEventListener API.

Extending the JMSObjectGridEventListener plug-in

The JMSObjectGridEventListener plug-in allows peer ObjectGrid instances to receive updates when data in the grid has been changed or evicted. It also allows clients to be notified when entries are updated or evicted from an eXtreme Scale grid. This topic describes how to extend the JMSObjectGridEventListener plug-in to allow applications to be notified when a JMS message is received. This is most useful when using the CLIENT_SERVER_MODEL setting for client invalidation.

When running in the receiver role, the overridden JMSObjectGridEventListener.onMessage method is automatically called by the eXtreme Scale runtime when the JMSObjectGridEventListener instance receives JMS message updates from the grid. These messages wrap a collection of LogSequence. Objects. The LogSequence objects are passed to the onMessage method and the application uses the LogSequence to identify which cache entries have been inserted, deleted, updated or invalidated.

To use the onMessage extension point, applications perform the following steps.

1. Create a new class, extending the JMSObjectGridEventListener class, overriding the onMessage method.
2. Configure the extended JMSObjectGridEventListener the same way as the ObjectGridEventListener for ObjectGrid.

The extended JMSObjectGridEventListener class is a child class of the JMSObjectGridEventListener class and can only override two methods: the initialize (optional) and onMessage methods. If a child class of the JMSObjectGridEventListener class needs to use any ObjectGrid artifacts such as ObjectGrid or Session in the onMessage method, it can get these artifacts in the initialize method and cache them as instance variables. Also, in the onMessage method, cached ObjectGrid artifacts can be used to process a passed collection of LogSequences.

Note: The overridden initialize method has to invoke super.initialize method in order to initialize parent JMSObjectGridEventListener appropriately.
The following is a sample for an extended JMSObjectGridEventListener class.

```
package com.ibm.websphere.samples.objectgrid.jms.price;

import java.util.*;
import com.ibm.websphere.objectgrid.*;
import com.ibm.websphere.objectgrid.plugins.LogElement;
import com.ibm.websphere.objectgrid.plugins.LogSequence;
import com.ibm.websphere.objectgrid.plugins.builtins.JMSObjectGridEventListener;

public class ExtendedJMSObjectGridEventListener extends JMSObjectGridEventListener{
        protected static boolean debug = true;

    /**
     * This is the grid associated with this listener.
     */
    ObjectGrid grid;

    /**
     * This is the session associated with this listener.
     */
    Session session;

    String objectGridType;

    public List receivedLogSequenceList = new ArrayList();

        /* (non-Javadoc)
         * @see com.ibm.websphere.objectgrid.plugins.builtins.JMSObjectGridEventListener
                                #initialize(com.ibm.websphere.objectgrid.Session)
         */
        public void initialize(Session session) {
                // Note: if need to use any ObjectGrid artifact, this class need to get ObjectGrid
                //       from the passed Session instance and get ObjectMap from session instance
                // for any transactional ObjectGrid map operation.

                super.initialize(session);  // must invoke super's initialize method.
                this.session = session; // cache the session instance, in case need to
                //                      use it to perform map operation.
                this.grid = session.getObjectGrid(); // get ObjectGrid, in case need
                //                      to get ObjectGrid information.

                if (grid.getObjectGridType() == ObjectGrid.CLIENT)
                        objectGridType = "CLIENT";
                else if (grid.getObjectGridType() == ObjectGrid.SERVER)
                        objectGridType = "Server";

                if (debug)
                        System.out.println("ExtendedJMSObjectGridEventListener[" +
                                        objectGridType + "].initialize() : grid = "     + this.grid);
        }

        /* (non-Javadoc)
         * @see com.ibm.websphere.objectgrid.plugins.builtins.JMSObjectGridEventListener
                                #onMessage(java.util.Collection)
         */
        protected void onMessage(Collection logSequences) {
                System.out.println("ExtendedJMSObjectGridEventListener[" +
                                objectGridType + "].onMessage(): ");

                Iterator iter = logSequences.iterator();

                while (iter.hasNext()) {
            LogSequence seq = (LogSequence) iter.next();

                StringBuffer buffer = new StringBuffer();
                String mapName = seq.getMapName();
                int size = seq.size();
                buffer.append("\nLogSequence[mapName=" + mapName + ", size=" + size + ",
                                        objectGridType=" + objectGridType
                                + "]: ");

                Iterator logElementIter = seq.getAllChanges();
                for (int i = seq.size() - 1; i >= 0; --i) {
                        LogElement le = (LogElement) logElementIter.next();
                        buffer.append(le.getType() + " -> key=" + le.getCacheEntry().getKey() + ", ");
                }
                buffer.append("\n");

                receivedLogSequenceList.add(buffer.toString());

                if (debug) {
                        System.out.println("ExtendedJMSObjectGridEventListener["
                                                + objectGridType + "].onMessage(): " + buffer.toString());
                }
                }
        }

        public String dumpReceivedLogSequenceList() {
                String result = "";
                int size = receivedLogSequenceList.size();
                result = result + "\nExtendedJMSObjectGridEventListener[" + objectGridType
```

```
                                + "]: receivedLogSequenceList size = " + size + "\n";
                for (int i = 0; i < size; i++) {
                        result = result + receivedLogSequenceList.get(i) + "\n";
                }
                return result;
        }

        public String toString() {
                return "ExtendedJMSObjectGridEventListener["
                                + objectGridType + " - " + this.grid + "]";
        }
}
```

Configuration

The extended JMSObjectGridEventListener class must be configured the same way for both client invalidation and peer-to-peer replication mechanism. The following is the XML configuration example.

```
<objectGrid name="PRICEGRID">
                        <bean
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_cxsjmsevntls_ObjectGridEventListener"
                                className="com.ibm.websphere.samples.objectgrid.jms.

Configuring deployment policies

Use the deployment policy descriptor XML file and the objectgrid descriptor XML file to manage a distributed topology. The deployment policy is encoded as an XML file that is provided to the container server. The deployment policy provides information about maps, map sets, partitions, replicas, and so on. It also controls shard placement behaviors.

- Configuring distributed deployments
  Use the deployment policy descriptor XML file and the ObjectGrid descriptor XML file to manage your topology.
- Controlling shard placement with zones
  Use your deployment policy to define zones. Zones give you control over shard placement in WebSphere® eXtreme Scale. Zones are a logical, user-defined concept used to represent logical groupings of physical servers.

Configuring distributed deployments

Use the deployment policy descriptor XML file and the ObjectGrid descriptor XML file to manage your topology.

The deployment policy is encoded as an XML file that is provided to the eXtreme Scale container server. The XML file specifies the following information:

- The maps that belong to each map set
- The number of partitions
- The number of synchronous and asynchronous replicas

The deployment policy also controls the following placement behaviors.

- The minimum number of active container servers before placement occurs
- Automatic replacement of lost shards
- Placement of each shard from a single partition onto a different machine

Endpoint information is not pre-configured in the dynamic environment. There are no server names or physical topology information found in the deployment policy. All shards in a data grid are automatically placed into container servers by the catalog service. The catalog service uses the constraints that are defined by the deployment policy to automatically manage shard placement. This automatic shard placement leads to easy configuration for large data grids. You can also add servers to your environment as needed.

Restriction: In a WebSphere® Application Server environment, a core group size of more than 50 members is not supported.
A deployment policy XML file is passed to a container server during startup. A deployment policy must be used along with an ObjectGrid XML file. The deployment policy is not required to start a container server, but is recommended. The deployment policy must be compatible with the ObjectGrid XML file that is used with it. For each objectgridDeployment element in the deployment policy, you must include a corresponding objectGrid element in your ObjectGrid XML file. The maps in the objectgridDeployment must be consistent with the backingMap elements found in the ObjectGrid XML. Every backingMap must be referenced within only one mapSet element.

In the following example, the companyGridDpReplication.xml file is intended to be paired with the corresponding companyGrid.xml file.

```
companyGridDpReplication.xml
<?xml version="1.0" encoding="UTF-8"?>
<deploymentPolicy xmlns:xsi="http://www.w3.org./2001/XMLSchema-instance"
        xsi:schemaLocation="http://ibm.com/ws/objectgrid/deploymentPolicy ../deploymentPolicy.xsd"
        xmlns="http://ibm.com/ws/objectgrid/deploymentPolicy">

        <objectgridDeployment objectgridName="CompanyGrid">
                <mapSet name="mapSet1" numberOfPartitions="11"
                        minSyncReplicas="1" maxSyncReplicas="1"
                        maxAsyncReplicas="0" numInitialContainers="4">
                        <map ref="Customer" />
                        <map ref="Item" />
                        <map ref="OrderLine" />
                        <map ref="Order" />
                </mapSet>
        </objectgridDeployment>

</deploymentPolicy>

companyGrid.xml
<?xml version="1.0" encoding="UTF-8"?>
<objectGridConfig xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
        xsi:schemaLocation="http://ibm.com/ws/objectgrid/config ../objectGrid.xsd"
        xmlns="http://ibm.com/ws/objectgrid/config">

        <objectGrids>
                <objectGrid name="CompanyGrid">
                        <backingMap name="Customer" />
                        <backingMap name="Item" />
                        <backingMap name="OrderLine" />
                        <backingMap name="Order" />
                </objectGrid>
        </objectGrids>

</objectGridConfig>
```

The companyGridDpReplication.xml file has one mapSet element that is divided into 11 partitions. Each partition must have exactly one synchronous replica. The number of synchronous replicas is specified by the minSyncReplicas and maxSyncReplicas attributes. Because the minSyncReplicas attribute is set to `1`, each partition in the mapSet element must have at least one synchronous replica available to process write transactions. Because the maxSyncReplicas attribute is set to `1`, each partition cannot exceed one synchronous replica. The partitions in this mapSet element have no asynchronous replicas.

The numInitialContainers attribute instructs the catalog service to defer placement until four container servers are available to support this ObjectGrid instance. The numInitialContainers attribute is ignored after the specified number of container servers has been reached.

You can also use the placementDeferralInterval property and **xscmd -c suspendBalancing** command to delay the placement of shards on the container servers.

Although the companyGridDpReplication.xml file is a basic example, a deployment policy can offer you full control over your environment.

Distributed topology

Distributed coherent caches offer increased performance, availability, and scalability, which you can configure.
WebSphere eXtreme Scale automatically balances servers. You can include additional servers without restarting WebSphere eXtreme Scale. Adding additional servers without having to restart eXtreme Scale allows you to have simple deployments and also large, terabyte-sized deployments in which thousands of servers are needed.

This deployment topology is flexible. Using the catalog service, you can add and remove servers to better use resources without removing the entire cache. You can use the **startOgServer** and **stopOgServer** commands to start and stop container servers. Both of these commands require you to specify the -catalogServiceEndPoints option. All distributed topology clients communicate to the catalog service through the Internet Interoperability Object Protocol (IIOP). All clients use the ObjectGrid interface to communicate with servers.

The dynamic configuration capability of WebSphere eXtreme Scale makes it easy to add resources to the system. Containers host the data and the catalog service allows clients to communicate with the grid of container servers. The catalog service forwards requests, allocates space in host container servers, and manages the health and availability of the overall system. Clients connect to a catalog service, retrieve a description of the container server topology, and then communicate directly to each server as needed. When the server topology changes due to the addition of new servers, or due to the failure of others, the catalog service automatically routes client requests to the appropriate server that hosts the data.

A catalog service typically exists in its own grid of Java™ virtual machines. A single catalog server can manage multiple servers. You can start a container server in a JVM by itself or load the container server into an arbitrary JVM with other container servers for different servers. A client can exist in any JVM and communicate with one or more servers. A client can also exist in the same JVM as a container server.

You can also create a deployment policy programmatically when you are embedding a container server in an existing Java process or application. For more information, see the DeploymentPolicy API documentation.

Controlling placement

Controlling shard placement with zones

Use your deployment policy to define zones. Zones give you control over shard placement in WebSphere® eXtreme Scale. Zones are a logical, user-defined concept used to represent logical groupings of physical servers.

- Zones for replica placement
  With zones, you can place replicas across data centers. A zone can be defined as different floors of a building, different buildings, or even different cities or other distinctions as configured with zone rules. With this capability, data grids of thousands of partitions can be managed with optional placement rules.
- Zone-preferred routing
  With zone-preferred routing, you can define how WebSphere eXtreme Scale directs transactions to zones.
- Defining zones for container servers
  Zones are collections of container servers. A container server can belong only one zone. A container server is assigned to a zone when it starts.
- Example: Zone definitions in the deployment policy descriptor XML file
  You can specify zones and zone rules with the deployment policy descriptor XML file.
- Viewing zone information with the xscmd utility
  You can use the **xscmd** utility to view information about your current zone deployment, including shard placement data.

Zones for replica placement

With zones, you can place replicas across data centers. A zone can be defined as different floors of a building, different buildings, or even different cities or other distinctions as configured with zone rules. With this capability, data grids of thousands of partitions can be managed with optional placement rules.

Zone rules

An eXtreme Scale partition has one primary shard and zero or more replica shards. For this example, consider the following naming convention for these shards. `P` is the primary shard, `S` is a synchronous replica and `A` is an asynchronous replica. A zone rule has three components:

- A rule name
- A list of zones
- An inclusive or exclusive flag

For more information about defining a zone name for a container server, see Defining zones for container servers. A zone rule specifies the possible set of zones in which a shard can be placed. The inclusive flag indicates that after a shard is placed in a zone from the list, then all other shards are also placed in that zone. An exclusive setting indicates that each shard for a partition is placed in a different zone in the zone list. For example, using an exclusive setting means that if there are three shards (primary, and two synchronous replicas), then the zone list must have three zones.
Each shard can be associated with one zone rule. A zone rule can be shared between two shards. When a rule is shared then the inclusive or exclusive flag extends across shards of all types sharing a single rule.

Examples

A set of examples showing various scenarios and the deployment configuration to implement the scenarios follows.

Striping primaries and replicas across zones

You have three blade chassis, and want primaries that are distributed across all three, with a single synchronous replica placed in a different chassis than the primary. Define each chassis as a zone with chassis names `ALPHA`, `BETA`, and `GAMMA`. An example deployment XML follows:

```
<?xml version="1.0" encoding="UTF-8"?>
<deploymentPolicy xmlns:xsi=http://www.w3.org/2001/XMLSchema-instance
        xsi:schemaLocation=
        "http://ibm.com/ws/objectgrid/deploymentPolicy ../deploymentPolicy.xsd"
                        xmlns="http://ibm.com/ws/objectgrid/deploymentPolicy">
                <objectgridDeployment objectgridName="library">
                        <mapSet name="ms1" numberOfPartitions="37" minSyncReplicas="1"
                                maxSyncReplicas="1" maxAsyncReplicas="0">
                        <map ref="book" />
                        <zoneMetadata>
                                <shardMapping shard="P" zoneRuleRef="stripeZone"/>
                                <shardMapping shard="S" zoneRuleRef="stripeZone"/>
                                <zoneRule name ="stripeZone" exclusivePlacement="true" >
                                        <zone name="ALPHA" />
                                        <zone name="BETA" />
                                        <zone name="GAMMA" />
                                </zoneRule>
                        </zoneMetadata>
                </mapSet>
        </objectgridDeployment>
</deploymentPolicy>
```

This deployment XML contains a grid called library with a single Map called book. It uses four partitions with a single synchronous replica. The zone metadata clause shows the definition of a single zone rule and the association of zone rules with shards. The primary and synchronous shards are both associated with the zone rule "stripeZone". The zone rule has all three zones in it and it uses exclusive placement. This rule means that if the primary for partition 0 is placed in `ALPHA` then the replica for partition 0 is placed in either `BETA` or `GAMMA`. Similarly, primaries for other partitions are placed in other zones and the replicas are placed in another zone.

Asynchronous replica in a different zone than primary and synchronous replica

In this example, two buildings exist with a high latency connection between them. You want no data loss high availability for all scenarios. However, the performance impact of synchronous replication between buildings leads you to a trade-off. You want a primary with synchronous replica in one building and an asynchronous replica in the other building. Normally, the failures are JVM crashes or computer failures rather than large-scale issues. With this topology, you can survive normal failures with no data loss. The loss of a building is rare enough that some data loss is acceptable in that case. You can make two zones, one for each building. The deployment XML file follows:

```
<?xml version="1.0" encoding="UTF-8"?>
<deploymentPolicy xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
                xsi:schemaLocation="http://ibm.com/ws/objectgrid/deploymentPolicy ../deploymentPolicy.xsd"
                xmlns="http://ibm.com/ws/objectgrid/deploymentPolicy">

        <objectgridDeployment objectgridName="library">
                <mapSet name="ms1" numberOfPartitions="13" minSyncReplicas="1"
                        maxSyncReplicas="1" maxAsyncReplicas="1">
                        <map ref="book" />
                        <zoneMetadata>
                                <shardMapping shard="P" zoneRuleRef="primarySync"/>
                                <shardMapping shard="S" zoneRuleRef="primarySync"/>
                                <shardMapping shard="A" zoneRuleRef="aysnc"/>
                                <zoneRule name ="primarySync" exclusivePlacement="false" >
                                        <zone name="BldA" />
                                        <zone name="BldB" />
                                </zoneRule>
                                <zoneRule name="aysnc" exclusivePlacement="true">
                                        <zone name="BldA" />
                                        <zone name="BldB" />
                                </zoneRule>
                        </zoneMetadata>
                </mapSet>
        </objectgridDeployment>
</deploymentPolicy>
```

The primary and synchronous replica share a primaySync zone rule with an exclusive flag setting of false. So, after the primary or sync gets placed in a zone, then the other is also placed in the same zone. The asynchronous replica uses a second zone rule with the same zones as the primarySync zone rule but it uses the

exclusivePlacement attribute set to true. This attribute indicates that means a shard cannot be placed in a zone with another shard from the same partition. As a result, the asynchronous replica does not get placed in the same zone as the primary or synchronous replicas.

Placing all primaries in one zone and all replicas in another zone

Here, all primaries are in one specific zone and all replicas in a different zone, a primary and a single asynchronous replica. All replicas are in zone A and primaries in B.

```
<?xml version="1.0" encoding="UTF-8"?>

<deploymentPolicy xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
        xsi:schemaLocation=
                "http://ibm.com/ws/objectgrid/deploymentPolicy ../deploymentPolicy.xsd"
        xmlns="http://ibm.com/ws/objectgrid/deploymentPolicy">

        <objectgridDeployment objectgridName="library">
                <mapSet name="ms1" numberOfPartitions="13" minSyncReplicas="0"
                        maxSyncReplicas="0" maxAsyncReplicas="1">
                        <map ref="book" />
                        <zoneMetadata>
                                <shardMapping shard="P" zoneRuleRef="primaryRule"/>
                                <shardMapping shard="A" zoneRuleRef="replicaRule"/>
                                <zoneRule name ="primaryRule">
                                        <zone name="A" />
                                </zoneRule>
                                <zoneRule name="replicaRule">
                                        <zone name="B" />
                                                </zoneRule>
                                        </zoneMetadata>
                                </mapSet>
                </objectgridDeployment>
</deploymentPolicy>
```

Here, you can see two rules, one for the primaries (P) and another for the replica (A).

Zones over wide area networks (WAN)

You might want to deploy a single data grid over multiple buildings or data centers with slower network interconnections. Slower network connections lead to lower bandwidth and higher latency connections. The possibility of network partitions also increases in this mode due to network congestion and other factors. eXtreme Scale approaches this harsh environment by limiting heartbeating between zones.

Java™ virtual machines grouped into core groups do heartbeat each other. When the catalog service organizes Java virtual machines into core groups, those groups do not span zones. A leader within that group pushes membership information to the catalog service. The catalog service verifies any reported failures before taking action. It does this by attempting to connect to the suspect Java virtual machines. If the catalog service sees a false failure detection, then it takes no action as the core group partition heals in a short time.

The catalog service also heartbeats core group leaders periodically at a slow rate to handle the case of core group isolation.

Zone-preferred routing

With zone-preferred routing, you can define how WebSphere® eXtreme Scale directs transactions to zones.

You have control over where the shards of a data grid are placed. See Zones for replica placement to get more information about some basic scenarios and how to configure your deployment policy accordingly.

Zone-preferred routing givesWebSphere eXtreme Scale clients the capability to specify a preference for a particular zone or set of zones. As a result, client transactions are routed to preferred zones before attempting to route to any other zone.

Requirements for zone-preferred routing

Before attempting zone-preferred routing, ensure that the application is able to satisfy the requirements of your scenario.

Per-container partition placement is necessary to use zone-preferred routing. This placement strategy is a good fit for applications that are storing session data in the ObjectGrid. The default partition placement strategy for WebSphere eXtreme Scale is `fixed-partition`. Keys are hashed at transaction commit time to determine which partition houses the key-value pair of the map when using fixed-partition placement.

Per-container placement assigns your data to a random partition when the transaction commits time through the SessionHandle object. You must be able to reconstruct the SessionHandle object to retrieve your data from the data grid.

You can use zones to have more control over where primary shards and replica shards are placed in your domain. Using multiple zones in your deployment is advantageous when your data is in multiple physical locations. Geographically separating primaries and replicas is a way to ensure that catastrophic loss of one data center does not affect the availability of the data.

When data is spread across multiple zones, it is likely that clients are also spread across the topology. Routing clients to their local zone or data center has the obvious performance benefit of reduced network latency. Route clients to local zones or data centers when possible.

Configuring your topology for zone-preferred routing

Consider the following scenario. You have two data centers: Chicago and London. To minimize response time of clients, you want clients to read and write data to their local data center.

Primary shards must be placed in each data center so that transactions can be written locally from each location. Clients must be aware of zones to route to the local zone.

Per-container placement locates new primary shards on each container that is started. Replicas are placed according to zone and placement rules that are specified by the deployment policy. By default, a replica is placed in a different zone than its primary shard. Consider the following deployment policy for this scenario.

```
<?xml version="1.0" encoding="UTF-8"?>
<deploymentPolicy xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
        xsi:schemaLocation="http://ibm.com/ws/objectgrid/deploymentPolicy ../deploymentPolicy.xsd"
        xmlns="http://ibm.com/ws/objectgrid/deploymentPolicy">
        <objectgridDeployment objectgridName="universe">
                <mapSet name="mapSet1" placementStrategy="PER_CONTAINER"
                        numberOfPartitions="3" maxAsyncReplicas="1">
                        <map ref="planet" />
                </mapSet>
        </objectgridDeployment>
</deploymentPolicy>
```

Each container that starts with the deployment policy receives three new primaries. Each primary has one asynchronous replica. Start each container with the appropriate zone name. Use the -zone parameter if you are starting your containers with the **startOgServer** script.

For a Chicago container server:

- UNIX Linux

  ```
  startOgServer.sh s1 -objectGridFile ../xml/universeGrid.xml
  -deploymentPolicyFile ../xml/universeDp.xml
  -catalogServiceEndPoints MyServer1.company.com:2809
  -zone Chicago
  ```

- Windows

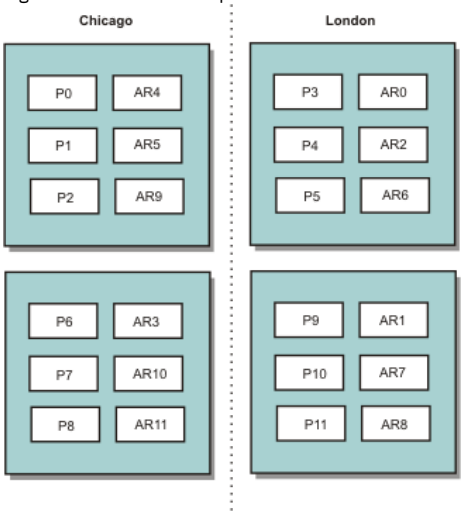
  ```
  startOgServer.bat s1 -objectGridFile ../xml/universeGrid.xml
  -deploymentPolicyFile ../xml/universeDp.xml
  -catalogServiceEndPoints MyServer1.company.com:2809
  -zone Chicago
  ```

If your containers are running in WebSphere Application Server, you must create a node group and name it with the prefix `ReplicationZone`. Servers that are running on the nodes in these node groups are placed in the appropriate zone. For example, servers running on a Chicago node might be in a node group named `ReplicationZoneChicago`.

See Zones for replica placement for more information.

Primary shards for the Chicago zone have replicas in the London zone. Primary shards for the London zone have replicas in the Chicago zone.

Figure 1. Primaries and replicas in zones



Set the preferred zones for the clients. Provide a client properties file to your client Java virtual machine (JVM). Create a file named objectGridClient.properties and ensure that this file is in your classpath.

Include the preferZones property in the file. Set the property value to the appropriate zone. Clients in Chicago must have the following value in the objectGridClient.properties file:

```
preferZones=Chicago
```

The property file for London clients must contain the following value:

```
preferZones=London
```

This property instructs each client to route transactions to its local zone if possible. The topology asynchronously replicates data that is inserted into a primary shard in the local zone into the foreign zone.

Using the SessionHandle interface to route to the local zone

The per-container placement strategy does not use a hash-based algorithm to determine the location of your key-value pairs in the data grid. You must use SessionHandle objects to ensure that transactions are routed to the correct location when you are using this placement strategy. When a transaction is committed, a SessionHandle object is bound to the session if one has not already been set. The SessionHandle object can also be bound to the Session by calling the Session.getSessionHandle method before committing the transaction. The following code snippet shows a SessionHandle being bound before committing the transaction.

```
Session ogSession = objectGrid.getSession();

// binding the SessionHandle
SessionHandle sessionHandle = ogSession.getSessionHandle();

ogSession.begin();
ObjectMap map = ogSession.getMap("planet");
map.insert("planet1", "mercury");

// tran is routed to partition specified by SessionHandle
ogSession.commit();
```

Assume that the prior code was running on a client in your Chicago data center. The preferZones attribute is set to `Chicago` for this client. As a result, your deployment would route transactions to one of the primary partitions in the Chicago zone: partition 0, 1, 2, 6, 7, or 8.

The SessionHandle object provides a path back to the partition that is storing this committed data. The SessionHandle object must be reused or reconstructed and set on the Session to get back to the partition containing the committed data.

```
ogSession.setSessionHandle(sessionHandle);
ogSession.begin();

// value returned will be "mercury"
String value = map.get("planet1");
ogSession.commit();
```

The transaction in this code reuses the SessionHandle object that was created during the insert transaction. The get transaction then routes to the partition that holds the inserted data. Without the SessionHandle object, the transaction cannot retrieve the inserted data.

How container and zone failures affect zone-based routing

Generally, a client with the preferZones property set routes all transactions to the specified zone or zones. However, the loss of a container results in the promotion of a replica shard to a primary shard. A client that was previously routing to partitions in the local zone must retrieve previously inserted data from the remote zone.

Consider the following scenario. A container in the Chicago zone is lost. It previously contained primaries for partitions 0, 1, and 2. The new primary shards for these partitions are then placed in the London zone because the London zone hosted the replicas for these partitions.

Any Chicago client that is using a SessionHandle object that points to one of the failed-over partitions now reroutes to London. Chicago clients that are using new SessionHandle objects route to Chicago-based primaries.

Similarly, if the entire Chicago zone is lost, all replicas in the London zone are promoted to primaries. In this scenario, all Chicago clients route their transactions to London.

Defining zones for container servers

Zones are collections of container servers. A container server can belong only one zone. A container server is assigned to a zone when it starts.

About this task

You must plan your zones before you start your container servers because container servers define their zone membership at startup. If you want to change the zone membership of a container server, you must restart the server with the new zone information.

Procedure

How you define zones depends on if you are using stand-alone container servers or container servers that are running within WebSphere® Application Server:

- Define zones for stand-alone container servers.
    1. Use the -zone parameter of the **startOgServer** script to specify the zone for all the containers in the started server. For more information about starting servers, see Starting and stopping stand-alone servers.

2. You can also zone names when you are starting container servers programmatically with the embedded server API. For more information, see Using the embedded server API to start and stop servers.

- Define zones for container servers that are running within WebSphere Application Server.
  You can use node groups to place container servers in specific zones. Use the following syntax to name your node group to assign it a zone: `ReplicationZone<identifier>`. When you define zones in the deployment policy, you must name the zones exactly as you named the node groups. The node group name and the zone name in the deployment policy descriptor XML file must be identical

  Important: WebSphere Application Server does not prohibit nodes from being in multiple node groups. Because container servers can be only one zone, ensure that your nodes are in exactly one ReplicationZone node group.
  For example, divide four nodes into two zones, A and B.

  1. Configure four nodes: node1, node2, node3, and node4, each node having two servers.
  2. Create a node group named ReplicationZoneA and a node group named ReplicationZoneB.
  3. Add node1 and node2 to ReplicationZoneA and add node3 and node4 to ReplicationZoneB.
  4. Define ReplicationZoneA and ReplicationZoneB in your deployment policy descriptor XML file. See Example: Zones in a WebSphere Application Server environment for an example.
  5. When the servers on node1 and node2 are started, they join ReplicationZoneA, or zone A in the WebSphere eXtreme Scale configuration. The servers on node3 and node4 join ReplicationZoneB, as zone B in the WebSphere eXtreme Scale configuration.

Example: Zone definitions in the deployment policy descriptor XML file

You can specify zones and zone rules with the deployment policy descriptor XML file.

Example: Primary and replica shards in different zones

This example places primary shards in one zone, and replica shards in a different zone, with a single asynchronous replica. All primary shards start in the DC1 zone. Replica shards start in zone DC2.

```
<?xml version="1.0" encoding="UTF-8"?>
<deploymentPolicy xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
        xsi:schemaLocation="http://ibm.com/ws/objectgrid/deploymentPolicy
        ../deploymentPolicy.xsd"        xmlns="http://ibm.com/ws/objectgrid/deploymentPolicy">
 <objectgridDeployment objectgridName="library">
        <mapSet name="ms1" numberOfPartitions="13" minSyncReplicas="0"
                maxSyncReplicas="0" maxAsyncReplicas="1">
                <map ref="book" />
                <zoneMetadata>
                                <shardMapping shard="P" zoneRuleRef="primaryRule"/>
                                <shardMapping shard="A" zoneRuleRef="replicaRule"/>
                                <zoneRule name="primaryRule">
                                        <zone name="DC1" />
                                </zoneRule>
                                <zoneRule name="replicaRule">
                                </zoneRule>
                </zoneMetadata>
        </mapSet>
  </objectgridDeployment>
 </deploymentPolicy>
```

One asynchronous replica is defined in the ms1 mapSet element. Therefore, two shards exist for each partition: a primary and one asynchronous replica. In the zoneMetadata element, a shardMapping element is defined for each shard: P for the primary, and DC1 for the asynchronous replica. The primaryRule attribute defines the zone set for the primary shards, which is just zone DC1, and this rule is to be used for primary shard placement. Asynchronous replicas are placed in the DC2 zone.

However, if the DC2 zone is lost, the replica shards become unavailable. The loss or failure of a container server in the DC1 zone can result in data loss, even though a replica has been specified.

To address this possibility, you can either add a zone or add a replica, as described in the following sections.

Example: Add a zone, striping shards

The following code configures a new zone:

```
<?xml version="1.0" encoding="UTF-8"?>
<deploymentPolicy xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
        xsi:schemaLocation="http://ibm.com/ws/objectgrid/deploymentPolicy
        ../deploymentPolicy.xsd" xmlns="http://ibm.com/ws/objectgrid/deploymentPolicy">
        <objectgridDeployment objectgridName="library">
                <mapSet name="ms1" numberOfPartitions="13" minSyncReplicas="0"
                        maxSyncReplicas="0" maxAsyncReplicas="1">
                                <map ref="book" />
```

```
                                <zoneMetadata>
                                        <shardMapping shard="P" zoneRuleRef="stripeRule"/>
                                        <shardMapping shard="A" zoneRuleRef="stripeRule"/>
                                        <zoneRule name="stripeRule" exclusivePlacement="true">
                                                <zone name="A" />
                                                <zone name="B" />
                                                <zone name="C" />
                                        </zoneRule>
                                </zoneMetadata>
                        </mapSet>
                </objectgridDeployment>
</deploymentPolicy>
```

Three total zones have been defined in this code: A, B, and C. Instead of separate primary and replica zone rules, a shared zone rule named stripeRule is defined. This rule includes all of the zones, with the exclusivePlacement attribute set to `true`. The eXtreme Scale placement policy ensures that primary and replica shards are in separate zones. This striping of placement causes primary and replica shards to spread across both zones to conform to this policy. Adding a third zone C ensures that losing any one zone does not result in data loss, and still leaves primary and replica shards for each partition. A zone failure results in the loss of either the primary shard, the replica shard, or neither. Any lost shard is replaced from the surviving shard in a surviving zone, placing it in the other surviving zone.

Example: Add a replica and define multiple data centers

The classic two data-center scenario has high speed, low latency networks in each data center, but high latency between the data centers. Synchronous replicas are used in each data center where the low latency minimizes the impact of replication on response times. Asynchronous replication is used between data centers, so the high latency network has no impact on response time.

```
<?xml version="1.0" encoding="UTF-8"?>
 <deploymentPolicy xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
        xsi:schemaLocation="http://ibm.com/ws/objectgrid/deploymentPolicy
        ../deploymentPolicy.xsd" xmlns="http://ibm.com/ws/objectgrid/deploymentPolicy">
        <objectgridDeployment objectgridName="library">
                <mapSet name="ms1" numberOfPartitions="13" minSyncReplicas="1"
                        maxSyncReplicas="1" maxAsyncReplicas="1">
                        <map ref="book" />
                        <zoneMetadata>
                                <shardMapping shard="P" zoneRuleRef="primarySync"/>
                                <shardMapping shard="S" zoneRuleRef="primarySync"/>
                                <shardMapping shard="A" zoneRuleRef="async"/>
                                <zoneRule name="primarySync" exclusivePlacement="false">
                                        <zone name="DC1" />
                                        <zone name="DC2" />
                                </zoneRule>
                                <zoneRule name="async" exclusivePlacement="true">
                                        <zone name="DC1" />
                                        <zone name="DC2" />
                                </zoneRule>
                        </zoneMetadata>
                </mapSet>
  </objectgridDeployment>
 </deploymentPolicy>
```

The primary and synchronous replica share the primarySync rule with an exclusivePlacement attribute setting of `false`. The exclusivePlacement attribute set to false creates a configuration with the primary and synchronous replica shards of each partition placed in the same zone. The asynchronous replica shard uses a second zone rule with mostly the same zones as the primarySync zone rule. However the asynchronous replica uses the exclusivePlacement attribute set to `true`. The exclusivePlacement attribute, when set to true, means that a shard cannot be placed in a zone with another shard from the same partition. As a result, the asynchronous replica shard does not get placed in the same zone as the primary or synchronous replica shard. There are three shards per partition in this mapSet: a primary, and both a synchronous and asynchronous replica, so there are three shardMapping elements, one for each shard.

If a zone is lost, any asynchronous replicas are lost, and not regenerated, because they have no separate zone. If the primary and replica shards are lost, then the surviving asynchronous replica is promoted to primary, and a new synchronous replica is created in the zone. The primaries and replicas are striped across each zone.

With exclusive placement, each shard has its own zone: You must have enough zones for all the shards you want to place in their own zones. If a rule has one zone, only one shard can be placed in the zone. With two zones, you can have up to two shards in the zone.

Example: Zones in a WebSphere Application Server environment

The following code configures a new zone:

```
<?xml version="1.0" encoding="UTF-8"?>
<deploymentPolicy xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
        xsi:schemaLocation="http://ibm.com/ws/objectgrid/deploymentPolicy
        ../deploymentPolicy.xsd" xmlns="http://ibm.com/ws/objectgrid/deploymentPolicy">
        <objectgridDeployment objectgridName="library">
                <mapSet name="ms1" numberOfPartitions="13" minSyncReplicas="0"
                        maxSyncReplicas="0" maxAsyncReplicas="1">
                                <map ref="book" />
                                <zoneMetadata>
                                        <shardMapping shard="P" zoneRuleRef="stripeRule"/>
                                        <shardMapping shard="A" zoneRuleRef="stripeRule"/>
                                        <zoneRule name="stripeRule" exclusivePlacement="true">
                                                <zone name="ReplicationZoneA" />
                                                <zone name="ReplicationZoneB" />
                                                <zone name="ReplicationZoneC" />
```

```
                                        </zoneRule>
                                    </zoneMetadata>
                </mapSet>
            </objectgridDeployment>
</deploymentPolicy>
```

For this example, three node groups are defined in the WebSphere® Application Server environment: ReplicationZoneA, ReplicationZoneB, and ReplicationZoneC. The node group name and the zone name in the deployment policy descriptor XML file must be identical, and must contain the text `ReplicationZone<identifier>`. This file defines a similar configuration to the striping shards example, but shows the required naming for a WebSphere Application Server configuration.

Related tasks:
Controlling shard placement with zones
Defining zones for container servers
Viewing zone information with the xscmd utility
Administering with the xscmd utility

Viewing zone information with the xscmd utility

You can use the **xscmd** utility to view information about your current zone deployment, including shard placement data.

Before you begin

- Deploy a distributed data grid with multiple data centers. See Zone-preferred routing for more information.

About this task

You can determine information about your configuration related to zone settings by using the **xscmd** utility that ships with the product.

Procedure

Use the **xscmd** utility to determine information about the shards of data. Run the following command:

```
xscmd -c showPlacement -z zone_name
```

Example

You can also run a simpler scenario by using the getting started sample: *wxs_install_root*/ObjectGrid/gettingstarted. See Tutorial: Getting started with WebSphere eXtreme Scale for more information.

1. Start a catalog server:

   ```
   runcat.bat
   ```

2. Determine your required number of replicas, zone rules, containers, and other settings such as with the following command:

   ```
   startOgServer.bat serverA0 -objectgridFile xml\objectgrid.xml
   -deploymentPolicyFile xml\deployment.xml -zone zoneA
   ```

3. You can stop container processes to simulate failure in the data grid:

   ```
   stopOgServer.bat serverA0,serverA1,serverB0 -catalogServiceEndPoints localhost:2809
   ```

   .
   If the server that contains the last shard of a partition is stopped, eXtreme Scale allocates a new primary shard. You can check for data loss:
   - The **runclient** script inserts and reads item in your data grid.
   - The **xscmd -c showMapSizes** command shows the number of items in the data grid.
4. Show active container servers with the following command:

   ```
   xscmd -c showPlacement -z zone_name
   ```

Configuring catalog and container servers

WebSphere® eXtreme Scale has two types of servers: catalog servers and container servers. Catalog servers control the placement of shards and discover and monitor the container servers. Multiple catalog servers can join a catalog service domain to provide high availability to the environment. A container server is a Java™ virtual machine (JVM) that stores the application data for the data grid.

- Configuring catalog servers and catalog service domains
  The catalog service hosts logic that is typically idle during steady states. As a result, the catalog service minimally influences scalability. The service is built to service hundreds of container servers that become available simultaneously. For high availability, configure the catalog service into a catalog service domain.
- Configuring container servers
  The container server stores application data for the data grid. This data is generally broken into parts, which are called partitions, which are hosted across multiple container servers. Each container server in turn hosts a subset of the complete data.
- Configuring eXtreme Scale servers to run in the Liberty profile
  You must create server and catalog service definitions to run WebSphere eXtreme Scale in the Liberty profile.

Related concepts:

Configuring eXtreme Scale servers to run in the Liberty profile

8.5+ You must create server and catalog service definitions to run WebSphere® eXtreme Scale in the Liberty profile.

Before you begin

Install the WebSphere Application Server Liberty profile and WebSphere eXtreme Scale. For more information, see Installing the Liberty profile.

Procedure

1. Create a server definition; for example:

   ```
   <wlp install_root>/bin/server create <your server name>
   ```

2. Find the server.xml file under your server definition and open it in an editor. A commented feature manager stanza already exists. You can find the server definition in the following directory:

   ```
   <wlp install_root>/usr/servers/<your server name>
   ```

3. Create a catalog service definition. To define a catalog service in a server, you need the WebSphere eXtreme Scale server feature and the server configuration file.
   a. Add the server feature to the server definition: 8.5

   ```
   <featureManager>
        <feature>eXtremeScale_server-1.0</feature>
   </featureManager>
   ```

   b. Add the configuration to tell the server feature that this server is a catalog service; for example:

   ```
   <com.ibm.ws.xs.server.config isCatalog="true"/>
   ```

What to do next

After you configure eXtreme Scale servers, you can start yours servers in the Liberty profile. For more information, see Starting and stopping servers in the Liberty profile.

Configuring catalog servers and catalog service domains

The catalog service hosts logic that is typically idle during steady states. As a result, the catalog service minimally influences scalability. The service is built to service hundreds of container servers that become available simultaneously. For high availability, configure the catalog service into a catalog service domain.

Before you begin

After a catalog service domain is started, the members of the data grid bind together. Carefully plan your catalog service domain topology, because you cannot modify your catalog service domain configuration at run time. Spread out the data grid as diversely as possible to prevent errors.

The best practice to avoid a single point of failure for your catalog service domain is to start a minimum of three catalog servers on three different nodes.

If you are using only two nodes, configure two catalog servers on each of the two nodes for a total of four catalog server processes. Creating this configuration ensures that when only one of the nodes is started, the required two catalog servers are running. You must start at least two catalog servers at the same time. When catalog servers start, they look for other catalog servers in the configuration, and do not start successfully until at least one other catalog sever is found.

Procedure

- Configure stand-alone catalog servers and catalog service domains.
  You configure stand-alone catalog server and catalog service domains with parameters and property files that you pass to the start server command or to the embedded server API.
  - Example: Configuring catalog service domains
  - Starting and stopping stand-alone servers
  - Catalog server properties
- Configure catalog servers and catalog service domains in WebSphere® Application Server
  Configure catalog servers that run in WebSphere Application Server with the WebSphere Application Server administrative console, administrative tasks, and the server properties file. The server life cycle is controlled by the process life cycle within WebSphere Application Server. When processes start or stop in WebSphere Application Server, the catalog servers that are running on these processes also start or stop.
  - Creating catalog service domains in WebSphere Application Server
  - Configuring the catalog service in WebSphere Application Server

- Example: Configuring catalog service domains
  When you are using the catalog service, a minimum of two catalog servers are required to avoid a single point of failure. Depending on the number of nodes in your environment, you can create different configurations to ensure that at least two catalog servers are always running.
- Configuring WebSphere eXtreme Scale with WebSphere Application Server
  You can run catalog service and container server processes in WebSphere Application Server. The process to configure these servers is different than a stand-alone configuration. The catalog service can automatically start in WebSphere Application Server servers or deployment managers. Container process start when an eXtreme Scale application is deployed and started in the WebSphere Application Server environment.
- Configuring the quorum mechanism
  Configure the quorum mechanism for each catalog server. You must enable the quorum mechanism on all of the catalog servers in the catalog service domain. Changing the quorum configuration requires a restart.
- Tuning the heartbeat interval setting for failover detection
  You can configure the amount of time between system checks for failed servers with the heartbeat interval setting. This setting applies to catalog servers only.

startOgServer script
Related information:
Catalog service domain settings

Example: Configuring catalog service domains

When you are using the catalog service, a minimum of two catalog servers are required to avoid a single point of failure. Depending on the number of nodes in your environment, you can create different configurations to ensure that at least two catalog servers are always running.

Example: Starting four catalog servers on two nodes in a stand-alone environment

The following script starts catalog servers cs0 and cs1 on the host1 node, and starts catalog servers cs2 and cs3 on the host2 node.

```
./startOgServer.sh|bat cs0 -listenerPort 2809 -catalogServiceEndPoints
cs0:host1:6601:6602,cs1:host1:6603:6604,cs2:host2:6601:6602,cs3:host2:6603:6604
-quorum true -jvmArgs -Xmx256m

./startOgServer.sh|bat cs1 -listenerPort 2810 -catalogServiceEndPoints
cs0:host1:6601:6602,cs1:host1:6603:6604,cs2:host2:6601:6602,cs3:host2:6603:6604
-quorum true -jvmArgs -Xmx256m

./startOgServer.sh|bat cs2 -listenerPort 2809 -catalogServiceEndPoints
cs0:host1:6601:6602,cs1:host1:6603:6604,cs2:host2:6601:6602,cs3:host2:6603:6604
-quorum true -jvmArgs -Xmx256m

./startOgServer.sh|bat cs3 -listenerPort 2810 -catalogServiceEndPoints
cs0:host1:6601:6602,cs1:host1:6603:6604,cs2:host2:6601:6602,cs3:host2:6603:6604
-quorum true -jvmArgs -Xmx256m
```

Remember: You must use the -listenerPort option because the catalog servers that are running on a node each require a unique port number.

Example: Starting multiple catalog servers in a WebSphere Application Server environment

Catalog servers start automatically in a WebSphere® Application Server environment. You can define multiple catalog servers to start by creating a catalog service domain. After you specify multiple endpoints in the catalog service domain, restart the included application servers so that the catalog servers start in parallel.

- **WebSphere Application Server Network Deployment**: You can choose multiple existing application servers from the cell to be members of your catalog service domain. Since, you can only start a cluster of catalog servers that are in the same core group, verify that any application servers in a catalog service domain are in the same core group.
- **Base WebSphere Application Server**: You can only start a single catalog server in a base application server using the **startServer** command . To start a cluster, use the **startXsServer** command.

Configuring WebSphere eXtreme Scale with WebSphere Application Server

You can run catalog service and container server processes in WebSphere® Application Server. The process to configure these servers is different than a stand-alone configuration. The catalog service can automatically start in WebSphere Application Server servers or deployment managers. Container process start when an eXtreme Scale application is deployed and started in the WebSphere Application Server environment.

About this task

Attention: Do not collocate your container servers with catalog servers in a production environment. Include the catalog service in multiple node agent processes or in an application server that is not hosting an eXtreme Scale application.

- Configuring the catalog service in WebSphere Application Server
  Catalog service processes can run in WebSphere Application Server. The server life cycle in WebSphere Application Server determines when the catalog service starts and stops.

Configuring the catalog service in WebSphere Application Server

Catalog service processes can run in WebSphere® Application Server. The server life cycle in WebSphere Application Server determines when the catalog service starts and stops.

Procedure

1. Choose one or more WebSphere Application Server processes to augment with the WebSphere eXtreme Scale profile. See Creating and augmenting profiles for WebSphere eXtreme Scale for more information. If you want the catalog service to start automatically in WebSphere Application Server Network Deployment on the deployment manager, install WebSphere eXtreme Scale on the deployment manager node and augment the deployment manager profile.

2. Configure server properties files for the WebSphere Application Server processes and add to the class path for the node. See Server properties file for more information.
3. Configure a catalog service domain. The catalog service domain is a group of catalog servers within your environment. See Creating catalog service domains in WebSphere Application Server for more information.
4. Start the WebSphere Application Server processes that are hosting the catalog servers. See Starting and stopping servers in a WebSphere Application Server environment for more information.

- Creating catalog service domains in WebSphere Application Server
  Catalog service domains define a group of catalog servers that manage the placement of shards and monitor the health of container servers in your data grid.

Creating catalog service domains in WebSphere Application Server

Catalog service domains define a group of catalog servers that manage the placement of shards and monitor the health of container servers in your data grid.

Before you begin

- Install WebSphere® eXtreme Scale on WebSphere Application Server. See Installing WebSphere eXtreme Scale or WebSphere eXtreme Scale Client with WebSphere Application Server for more information.

About this task

By creating a catalog service domain, you are defining a highly available collection of catalog servers.
These catalog servers can run in WebSphere Application Server within a single cell and core group. The catalog service domain can also define a remote group of servers that run in different Java™ SE processes or other WebSphere Application Server cells.

For catalog servers that run on existing application servers within the cell: When you define a catalog service domain that places catalog servers on the application servers within the cell, the core group mechanisms of WebSphere Application Server are used. The catalog service automatically starts on the application servers in the cell. As a result, the members of a single catalog service domain cannot span the boundaries of a core group, and a catalog service domain therefore cannot span cells. However, WebSphere eXtreme Scale container servers and clients can span cells by connecting to a catalog server across cell boundaries, such as a stand-alone catalog service domain or a catalog service domain embedded in another cell.

For remote catalog servers: You can connect WebSphere eXtreme Scale containers and clients to a catalog service domain that is running in another WebSphere Application Server cell or that are running as stand-alone processes. Because remotely configured catalog servers do not automatically start in the cell, you must manually start any remotely configured catalog servers. When you configure a remote catalog service domain, the domain name should match the domain name that you specified when you start the remote catalog servers. The default catalog service domain name for stand-alone catalog servers is `DefaultDomain`. Specify a catalog service domain name with the **startOgServer** command -domain parameter, a server properties file, or with the embedded server API. You must start each remote catalog server process in the remote domain with the same domain name. See Starting a stand-alone catalog service for more information about starting catalog servers.

Attention: Do not collocate the catalog services with WebSphere eXtreme Scale container servers in a production environment. Include the catalog service in multiple node agent processes or in an application server that is not hosting a WebSphere eXtreme Scale application.

Procedure

1. Create the catalog service domain.
   a. In the WebSphere Application Server administrative console, click System administration > WebSphere eXtreme Scale > Catalog service domains > New.
   b. Define a name, default value, and JMX authentication credentials for your catalog service domain. If you are configuring remote endpoints for the catalog service domain, the name of the catalog service domain should match the name of the catalog service domain that you specify when you start the catalog servers.
   c. Add catalog server endpoints. You can either select existing application servers or add remote servers that are running a catalog service.
2. Test the connection to the catalog servers within your catalog service domain. For existing application servers, catalog servers start when the associated application server is started. For remote application servers, you must start the servers manually using the **startOgServer** command or embedded server API.
   a. In the WebSphere Application Server administrative console, click System administration > WebSphere eXtreme Scale > Catalog service domains.

b. Select the catalog service domain that you want to test and click Test connection. When you click this button, all of the defined catalog service domain end points are queried one by one, if any one end point is available, returns a message that indicates that the connection to the catalog service domain was successful.

- Catalog service domain administrative tasks
  You can use the Jacl or Jython scripting languages to manage catalog service domains in your WebSphere Application Server configuration.
- Catalog service domain collection
  Use this page to manage catalog service domains. Catalog service domains define a group of catalog servers that manage the placement of shards and monitors the health of container servers in your data grid.
- Catalog service domain settings
  Use this page to manage the settings for a specific catalog service domain. Catalog service domains define a group of catalog servers that manage the placement of shards and monitors the health of container servers in your data grid. You can define a catalog service domain that is in the same cell as your deployment manager. You can also define remote catalog service domains if your WebSphere eXtreme Scale configuration is in a different cell or your data grid is made up of Java SE processes.
- Client security properties
  Use this page to configure client security for a catalog service domain. These settings apply to all the servers in your catalog service domain. These properties can be overridden by specifying a splicer.properties file with the com.ibm.websphere.xs.sessionFilterProps custom property or by splicing the application EAR file.
- Catalog service domain custom properties
  You can further edit the configuration of the catalog service domain by defining custom properties.

Catalog service domain administrative tasks

You can use the Jacl or Jython scripting languages to manage catalog service domains in your WebSphere® Application Server configuration.

Requirements

You must have the WebSphere eXtreme Scale Client installed in your WebSphere Application Server environment.

List all administrative tasks

To get a list of all of the administrative tasks that are associated with catalog service domains, run the following command with **wsadmin**:

- Using Jacl:

```
wsadmin>$AdminTask help XSDomainManagement
```

- Using a Jython string:

```
wsadmin>print AdminTask.help ('XSDomainManagement')
```

Commands

The administrative tasks for catalog service domains include the following commands:

- createXSDomain
- deleteXSDomain
- getDefaultXSDomain
- listXSDomains
- modifyXSDomain
- testXSDomainConnection
- testXSServerConnection

List all administrative task command arguments

To get a list of all of the command arguments associated with catalog service domain administrative tasks, run the following command with **wsadmin**:

- Using Jacl:

```
wsadmin>$AdminTask help <command>
wsadmin>$AdminTask help <command> <commandStep>
Example: wsadmin>$AdminTask help createXSDomain defineDomainServers
```

- Using a Jython string:

```
wsadmin>print AdminTask.help ('<command>')
Example: wsadmin>print AdminTask.help ('createXSDomain')
```

createXSDomain

The **createXSDomain** command registers a new catalog service domain.

Table 1. createXSDomain command arguments

Argument	Description
-name (required)	Specifies the name of the catalog service domain that you want to create.
-default	Specifies whether the catalog service domain is the default for the cell. The default value is `true`. (Boolean: set to `true` or `false`)

Table 2. defineDomainServers step arguments

Argument	Description
name_of_endpoint	Specifies the name of the catalog service domain endpoint. • **For existing application servers**: Specifies the name of the endpoint must be in the following format, using backslashes: *cell_name\node_name\server_name* • **For remote servers**: Specifies the host name of the remote server. You can have the same name for multiple endpoints, but the client port values must be unique for each endpoint.
custom_properties	Specifies custom properties for the catalog service domain endpoint. If you do not have any custom properties, use a set of double quotation marks (`""`) for this argument.
endpoint_ports	Specifies the port numbers for the catalog service domain endpoint. The ports must be specified in the following order: *<client_port>*, *<listener_port>* For existing application servers where only a client port is required, enter the client port value as either `"2809"` or `"2809,"`. For remote servers where only a listener port is required, enter the listener port value as: `",9810"` Client Port Specifies the port that is used for communication between the catalog servers in the catalog service domain. This value is only required for existing application servers (catalog servers that are running in WebSphere Application Server processes) and can be set to any port that is not being used elsewhere. Listener Port Specifies the port that is used for communication with clients. This value is required for remote endpoints and must match the value used when the catalog service was started. The listener port is used by clients and containers to communicate with the catalog service. **For WebSphere eXtreme Scale remote endpoints**: Defines the Object Request Broker (ORB) listener port for containers and clients to communicate with the catalog service through the ORB. For WebSphere Application Server endpoints, the listener port value is optional because the value is inherited from the BOOTSTRAP_ADDRESS port configuration.

Table 3. configureClientSecurity step arguments

Argument	Description
-securityEnabled	Specifies that client security is enabled for the catalog server. The server properties file that is associated with the selected catalog server must have a matching securityEnabled setting in the server properties file. If these settings do not match, an exception results. (Boolean: set to `true` or `false`)
-credentialAuthentication (optional)	Indicates if credential authentication is enforced or supported. Never No client certificate authentication is enforced. Required Credential authentication is always enforced. If the server does not support credential authentication, the client cannot to connect to the server. Supported (Default) Credential authentication is enforced only if both the client and server support credential authentication.
-authenticationRetryCount (optional)	Specifies the number of times that authentication gets tried again if the credential is expired. If you do not want to try authentication again, set the value to `0`. The default value is `0`.
-credentialGeneratorClass	Indicates the com.ibm.websphere.objectgrid.security.plugins.builtins. WSTokenCredentialGenerator implementation class, so the client retrieves the security tokens from the thread.

Argument	Description
-credentialGeneratorProps	Specifies the properties for the CredentialGenerator implementation class. The properties are sent to the object with the setProperties(String) method. The credential generator properties value is used only when a value is specified for the Credential generator class field. Properties for **com.ibm.websphere.objectgrid.security.plugins.UserPasswordCredentialGenerator** includes userid_password which can be defined as “userid password”. Note: Because parsing of the userid_password property depends upon the space character as the value separator, userids and passwords which contain spaces must use the “\20” escape character to represent a space. For example: If the userid is “Test User Id” and the password is “Test Password”, the userid_password property should be entered as: “Test\20User\20Id Test\20Password”. Properties for **com.ibm.websphere.objectgrid.security.plugins.builtins.WSTokenCredentialGenerator** includes the property subject_type, which can be defined as either“runAs” or “caller”.

Return value:

Batch mode example usage

Batch mode requires correct formatting of the command entry. Consider using interactive mode to ensure the values that you enter are processed correctly. When you use batch mode, you must define the -defineDomainServers step arguments using a specific array of properties. This array of properties is in the format *name_of_endpoint custom_properties endpoint_ports*. The *endpoint_ports* value is a list of ports that must be specified in the following order: *<client_port>,<listener_port>*.

- Create a catalog service domain of remote endpoints using Jacl:

```
$AdminTask createXSDomain {-name TestDomain -default true -defineDomainServers
{{xhost1.ibm.com "" ,2809}} -configureClientSecurity {-securityEnabled false
-credentialAuthentication Required -authenticationRetryCount 0 -credentialGeneratorClass
com.ibm.websphere.objectgrid.security.plugins.builtins.UserPasswordCredentialGenerator
-credentialGeneratorProps "manager manager1"}}
```

- Create a catalog service domain of remote endpoints using Jython string:

```
AdminTask.createXSDomain('[-name TestDomain -default true
-defineDomainServers [[xhost1.ibm.com "" ,2809]
[xhost2.ibm.com "" ,2809]] -configureClientSecurity [-securityEnabled false
-credentialAuthentication Required -authenticationRetryCount 0 -credentialGeneratorClass
com.ibm.websphere.objectgrid.security.plugins.builtins.UserPasswordCredentialGenerator
-credentialGeneratorProps "manager manager1"] ]')
```

- Create a catalog service domain of existing application server endpoints using Jacl:

```
$AdminTask createXSDomain {-name TestDomain -default true -defineDomainServers
 {{cellName/nodeName/serverName "" 1109}}}
```

Interactive mode example usage

- Using Jacl:

```
$AdminTask createXSDomain {-interactive}
```

- Using Jython string:

```
AdminTask.createXSDomain ('[-interactive]')
```

deleteXSDomain

The **deleteXSDomain** command deletes a catalog service domain.

Required parameters:

-name
Specifies the name of the catalog service domain to delete.

Return value:

Batch mode example usage

- Using Jacl:

```
$AdminTask deleteXSDomain {-name TestDomain }
```

- Using Jython string:

```
AdminTask.deleteXSDomain('[-name TestDomain ]')
```

Interactive mode example usage

- Using Jacl:

```
$AdminTask deleteXSDomain {-interactive}
```

- Using Jython string:

```
AdminTask.deleteXSDomain ('[-interactive]')
```

getDefaultXSDomain

The **getDefaultXSDomain** command returns the default catalog service domain for the cell.

Required parameters: None

Return value: The name of the default catalog service domain.

Batch mode example usage

- Using Jacl:

```
$AdminTask getDefaultXSDomain
```

- Using Jython string:

```
AdminTask.getDefaultXSDomain
```

Interactive mode example usage

- Using Jacl:

```
$AdminTask getDefaultXSDomain {-interactive}
```

- Using Jython string:

```
AdminTask.getDefaultXSDomain ('[-interactive]')
```

listXSDomains

The **listXSDomains** command returns a list of the existing catalog service domains.

Required parameters: None

Return value: A list of all of the catalog service domains in the cell.

Batch mode example usage

- Using Jacl:

```
$AdminTask listXSDomains
```

- Using Jython string:

```
AdminTask.listXSDomains
```

Interactive mode example usage

- Using Jacl:

```
$AdminTask listXSDomains {-interactive}
```

- Using Jython string:

```
AdminTask.listXSDomains ('[-interactive]')
```

modifyXSDomain

The **modifyXSDomain** command modifies an existing catalog service domain.

Batch mode requires correct formatting of the command entry. Consider using interactive mode to ensure the values that you enter are processed correctly. When you use batch mode, you must define the -modifyEndpoints, -addEndpoints and -removeEndpoints step arguments using a specific array of properties. This array of properties is in the format *name_of_endpoint host_name custom_properties endpoint_ports*. The *endpoint_ports* value is a list of ports that must be specified in the following order: *<client_port>,<listener_port>*.

Table 4. modifyXSDomain command arguments

Argument	Description
-name (required)	Specifies the name of the catalog service domain that you want to edit.
-default	If set to `true`, specifies that the selected catalog service domain is the default for the cell. (Boolean)

Table 5. modifyEndpoints step arguments

Argument	Description

Argument	Description
name_of_endpoint	Specifies the name of the catalog service domain endpoint. • **For existing application servers**: Specifies the name of the endpoint in the following format, using backslashes: *cell_name\node_name\server_name* • **For remote servers**: Specifies the host name of the remote server. You can have the same name for multiple endpoints, but the listener port values must be unique for each endpoint.
endpoint_ports	Specifies the port numbers for the catalog service domain endpoint. The endpoints must be specified in the following order: *<client_port>,<listener_port>* For existing application servers where only a client port is required, enter the client port value as either: "2809" or "2809,". For remote servers where only a listener port is required, enter the listener port value as: ",9810". Client Port Specifies the port that is used for communication between the catalog servers in the catalog service domain. This value is only required for existing application servers (catalog servers that are running in WebSphere Application Server processes) and can be set to any port that is not being used elsewhere. Listener Port Specifies the port that is used for communication with clients. This value is required for remote endpoints and must match the value used when the catalog service was started. The listener port is used by clients and containers to communicate with the catalog service. **For WebSphere eXtreme Scale remote endpoints**: Defines the Object Request Broker (ORB) listener port for containers and clients to communicate with the catalog service. For WebSphere Application Server endpoints, specifying the listener port value is optional. The value is inherited from the BOOTSTRAP_ADDRESS port configuration.

Table 6. addEndpoints step arguments

Argument	Description
name_of_endpoint	Specifies the name of the catalog service domain endpoint. • **For existing application servers**: Specifies the name of the endpoint in the following format, using backslashes: *cell_name\node_name\server_name* • **For remote servers**: Specifies the host name of the remote server. You can have the same name for multiple endpoints, but the listener port values must be unique for each endpoint.
custom_properties	Specifies custom properties for the catalog service domain endpoint. If you do not have any custom properties, use a set of double quotation marks ("") for this argument.
endpoint_ports	Specifies the port numbers for the catalog service domain endpoint. The endpoints must be specified in the following order: *<client_port>,<listener_port>* For existing application servers where only a client port is required, enter the client port value as either: "2809" or "2809,". For remote servers where only a listener port is required, enter the listener port value as : ",9810". Client Port Specifies the port that is used for communication between the catalog servers in the catalog service domain. This value is only required for existing application servers (catalog servers that are running in WebSphere Application Server processes) and can be set to any port that is not being used elsewhere. Listener Port Specifies the port that is used for communication with clients. This value is required for remote endpoints and must match the value used when the catalog service was started. The listener port is used by clients and containers to communicate with the catalog service. **For WebSphere eXtreme Scale remote endpoints**: Defines the Object Request Broker (ORB) listener port for containers and clients to communicate with the catalog service through the ORB. For WebSphere Application Server endpoints, specifying the listener port value is optional because the value is inherited from the BOOTSTRAP_ADDRESS port configuration.

Table 7. removeEndpoints step arguments

Argument	Description
name_of_endpoint	Specifies the name of the catalog service endpoint to delete.

Table 8. configureClientSecurity step arguments

Argument	Description
-securityEnabled	Specifies that client security is enabled for the catalog server. The server properties file that is associated with the selected catalog server must have a matching securityEnabled setting in the server properties file. If these settings do not match, an exception results. (Boolean: set to `true` or `false`)

Argument	Description
-credentialAuthentication (optional)	Indicates whether credential authentication is enforced or supported. Never No client certificate authentication is enforced. Required Credential authentication is always enforced. If the server does not support credential authentication, the client cannot to connect to the server. Supported (Default) Credential authentication is enforced only if both the client and server support credential authentication.
-authenticationRetryCount (optional)	Specifies the number of times that authentication gets tried again if the credential is expired. If you do not want to try authentication again, set the value to `0`. The default value is `0`.
-credentialGeneratorClass	Indicates the com.ibm.websphere.objectgrid.security.plugins.builtins. WSTokenCredentialGenerator implementation class, so the client retrieves the security tokens from the thread.
-credentialGeneratorProps	Specifies the properties for the CredentialGenerator implementation class. The properties are sent to the object with the setProperties(String) method. The credential generator properties value is used only when a value is specified for the Credential generator class field. Properties for **`com.ibm.websphere.objectgrid.security.plugins.UserPasswordCredentialGenerator`** includes userid_password which can be defined as “userid password”. Note: Because parsing of the userid_password property depends upon the space character as the value separator, userids and passwords which contain spaces must use the “`\20`” escape character to represent a space. For example: If the userid is “`Test User Id`” and the password is “`Test Password`”, the userid_password property should be entered as: “`Test\20User\20Id Test\20Password`”. Properties for **`com.ibm.websphere.objectgrid.security.plugins.builtins.WSTokenCredentialGenerator`** includes the property subject_type, which can be defined as either“`runAs`” or “`caller`”.

Return value:

Batch mode example usage

- Using Jacl:

```
$AdminTask modifyXSDomain {-name TestDomain -default true -modifyEndpoints
{{xhost1.ibm.com "" ,2809}} -addEndpoints {{xhost2.ibm.com "" ,2809}}}
-removeEndpoints {{xhost3.ibm.com}}}
```

- Using Jython string:

```
AdminTask.modifyXSDomain('[-name TestDomain
-default false -modifyEndpoints [[xhost1.ibm.com "" ,2809]]
-addEndpoints [[xhost3.ibm.com "" ,2809]]
-removeEndpoints [[xhost2.ibm.com]]]')
```

- Using the client security specification during the modify command:

```
$AdminTask modifyXSDomain {-name myDomain -default false
-configureClientSecurity {-securityEnabled true -
Supported -authenticationRetryCount 1 -credentialGeneratorClass
com.ibm.websphere.objectgrid.security.plugins.builtins.UserPasswordCredentialGenerator
 -credentialGeneratorProps "manager manager1"}}
```

Interactive mode example usage

- Using Jacl:

```
$AdminTask modifyXSDomain {-interactive}
```

- Using Jython string:

```
AdminTask.modifyXSDomain ('[-interactive]')
```

testXSDomainConnection

The **testXSDomainConnection** command tests the connection to a catalog service domain.

Required parameters:

-name
Specifies the name of the catalog service domain to which to test the connection.

Optional parameters

-timeout
Specifies the maximum amount of time to wait for the connection, in seconds.

Return value: If a connection can be made, returns `started`, otherwise, returns `stopped`.

Batch mode example usage

- Using Jacl:

```
$Admintask testXSDomainConnection
```

- Using Jython string:

```
AdminTask.testXSDomainConnection
```

Interactive mode example usage

- Using Jacl:

```
$AdminTask testXSDomainConnection {-interactive}
```

- Using Jython string:

```
AdminTask.testXSDomainConnection ('[-interactive]')
```

testXSServerConnection

The **testXSServerConnection** command tests the connection to a catalog server. This command works for both stand-alone servers and servers that are a part of a catalog service domain.

Required parameters:

host
Specifies the host on which the catalog server resides.
listenerPort
Specifies the listener port for the catalog server.

Optional parameters

timeout
Specifies the maximum amount of time to wait for a connection to the catalog server, in seconds.
domain
Specifies the name of a catalog service domain. If you define a value for this parameter, the client security properties for the specified catalog service domain are used to test the connection. Otherwise, a search occurs to find the catalog service domain for the specified host and listener port. If a catalog service domain is found, the client security properties that are defined for the catalog service domain are used to test the server. Otherwise, no client security properties are used during the test.

Return value: If a connection can be made, returns `started`, otherwise returns `stopped`.

Batch mode example usage

- Using Jacl:

```
$Admintask testXSServerConnection {-host xhost1.ibm.com -listenerPort 2809}
```

- Using Jython string:

```
AdminTask.testXSServerConnection('[-host xshost3.ibm.com -listenerPort 2809]')
```

Interactive mode example usage

- Using Jacl:

```
$AdminTask testXSServerConnection {-interactive}
```

- Using Jython string:

```
AdminTask.testXSServerConnection ('[-interactive]')
```

Catalog service domain collection

Use this page to manage catalog service domains. Catalog service domains define a group of catalog servers that manage the placement of shards and monitors the health of container servers in your data grid.

To view this administrative console page, click System administration > WebSphere eXtreme Scale > Catalog service domains. To create a new catalog service domain, click New. To delete a catalog service domain, select the catalog service domain you want to remove and click Delete.

Test Connection

When you click the Test connection button, all of the defined catalog service domain end points are queried one by one, if any one end point is available, returns a message that indicates that the connection to the catalog service domain was successful. You can use this button to test that you have configured the connection and security information correctly.

Set Default

Defines the catalog service domain that is used as the default. Select one catalog service domain as the default and click Set default. Only one catalog service domain can be selected as the default.

Name

Specifies the name for the catalog service domain.

Default

Specifies which catalog service domain in the list is the default. The default catalog service domain is indicated with the following icon:  .

Catalog service domain settings

Use this page to manage the settings for a specific catalog service domain. Catalog service domains define a group of catalog servers that manage the placement of shards and monitors the health of container servers in your data grid. You can define a catalog service domain that is in the same cell as your deployment manager. You can also define remote catalog service domains if your WebSphere® eXtreme Scale configuration is in a different cell or your data grid is made up of Java™ SE processes.

To view this administrative console page, click System administration > WebSphere eXtreme Scale > Catalog service domains > *catalog_service_domain_name*.

Test connection

When you click the Test connection button, all of the defined catalog service domain end points are queried one by one, if any one end point is available, returns a message that indicates that the connection to the catalog service domain was successful. You can use this button to test that you have configured the connection and security information correctly.

Name

Specifies the name of the catalog service domain.

Enable this catalog service domain as the default unless another catalog service domain is explicitly specified

If you select this check box, the selected catalog service domain becomes the default catalog service domain for the cell. Each server profile in the cell that is augmented with the WebSphere eXtreme Scale profile belongs to the selected catalog service domain.

For WebSphere eXtreme Scale, all eXtreme Scale containers that are embedded in Java EE application modules connect to the default domain. Clients can connect to the default domain using the ServerFactory.getServerProperties().getCatalogServiceBootstrap() API to retrieve the catalog service endpoints to use when calling the ObjectGridManager.connect() API.

If you change the default domain to point to a different set of catalog servers, then all containers and clients refer to the new domain after they are restarted.

Catalog servers

Specifies a list of catalog servers that belong to this catalog service domain.

Click New to add a catalog server to the list. This catalog server must already exist in the eXtreme Scale configuration. You can also edit or delete a server from the list by selecting the endpoint and then clicking Edit or Delete. Define the following properties for each catalog server endpoint:

Catalog server endpoint
: Specifies the name of the existing application server or remote server on which the catalog service is running. A catalog service domain cannot contain a mix of existing application servers and remote server endpoints.

  - Existing application server: Specifies the path of an application server, node agent, or deployment manager in the cell. A catalog service starts automatically in the selected server. Select from the list of the existing application servers. All of the application servers that you define within the catalog service domain must be in the same core group.
  - Remote server: Specifies the host name of the remote catalog server.
    For WebSphere eXtreme Scale remote endpoints: Specifies the host name of the remote catalog server process. You must start the remote servers with the **startOgServer** script or the embedded server API.

Client Port
: Specifies the port that is used for communication between the catalog servers in the catalog service domain. This value is required for catalog servers that are running in WebSphere Application Server processes. You can set the value to any port that is not being used by another process.

Listener Port
: Specifies the port that is used for communication with clients. This value is required for remote endpoints and must match the value used when the catalog service was started. The listener port is used by clients and containers to communicate with the catalog service.
For WebSphere eXtreme Scale remote endpoints: Defines the Object Request Broker (ORB) listener port for containers and clients to communicate with the catalog service through the ORB. For WebSphere Application Server endpoints, the listener port value is inherited from the BOOTSTRAP_ADDRESS port configuration.

Status

Table 1. Catalog server endpoint status

Icon	Definition
	Unknown
	Started
	Stopped

Client security properties

Use this page to configure client security for a catalog service domain. These settings apply to all the servers in your catalog service domain. These properties can be overridden by specifying a splicer.properties file with the com.ibm.websphere.xs.sessionFilterProps custom property or by splicing the application EAR file.

To view this administrative console page, click System administration > WebSphere eXtreme Scale > Catalog service domains > *catalog_service_domain_name* > Client security properties.

Enable client security

Specifies that client security is enabled for the catalog server. The server properties file that is associated with the selected catalog server must have a matching securityEnabled setting in the server properties file. If these settings do not match, an exception results.

Credential authentication

Indicates if credential authentication is enforced or supported.

Never
: No client credential authentication is enforced.

Required
: Credential authentication is always enforced. If the server does not support credential authentication, the client cannot to connect to the server.

Supported
: Credential authentication is enforced only if both the client and server support credential authentication.

Authentication retry count

Specifies the number of times that authentication gets tried again if the credential is expired.

If you do not want to try authentication again, set the value to `0`.

Credential generator class

Indicates the com.ibm.websphere.objectgrid.security.plugins.CredentialGenerator implementation class, so the client retrieves the credential from the CredentialGenerator object.

You can choose from two predefined credential generator classes, or you can specify a custom credential generator. If you choose a custom credential generator, you must indicate the name of the credential generator class.

- com.ibm.websphere.objectgrid.security.plugins.builtins.UserPasswordCredentialGenerator
- com.ibm.websphere.objectgrid.security.plugins.builtins.WSTokenCredentialGenerator
- Custom credential generator

Subject type

Specifies if you are using the J2EE caller or the J2EE runAs subject type. You must specify this value when you choose the WSTokenCredentialGenerator credential generator.

- **runAs**: The subject contains the principal of the J2EE run as identity and the J2EE run as credential.
- **caller**: The subject contains the principal of the J2EE caller and the J2EE caller credential.

User ID

Specify a user ID when you are using the UserPasswordCredentialGenerator credential generator implementation.

Password

Specify a password when you are using the UserPasswordCredentialGenerator credential generator implementation.

Credential generator properties

Specifies the properties for a custom CredentialGenerator implementation class. The properties are set in the object with the setProperties(String) method. The credential generator properties value is used only when a value is specified for the Credential generator class field.

Catalog service domain custom properties

You can further edit the configuration of the catalog service domain by defining custom properties.

To view this administrative console page, click System administration > WebSphere eXtreme Scale > Catalog service domains > Custom properties. To create a new custom property, click New.

Name

Specifies the name of the custom property for the catalog service domain.

Value

Specifies a value for the custom property for the catalog service domain.

Configuring the quorum mechanism

Configure the quorum mechanism for each catalog server. You must enable the quorum mechanism on all of the catalog servers in the catalog service domain. Changing the quorum configuration requires a restart.

Before you begin

The configuration must support the following requirements:

- **IP configuration:** Any addressable element on the network must be able to connect to any other addressable element on the network unimpeded. All the firewalls in the configuration must allow all traffic to flow between the IP addresses and ports that are being used to host catalog servers and container servers.

About this task

For more information about the quorum mechanism, see Catalog server quorums.

Changing the quorum configuration requires that you restart the catalog server. You can choose one of the following processes to enable the quorum configuration on the catalog servers in your catalog service domain:

- Stop the entire catalog service domain, change the setting, and restart the catalog service domain.
- Stop and start one catalog service at a time. With this process, some catalog servers have quorum enabled while other catalog servers do not. If container server outages occur during this process, container server lifecycle events occur only if the primary catalog server does not have quorum yet, or when you override quorum.

Procedure

Enable quorum on the catalog servers. In WebSphere® Application Server, you must configure quorum with the server properties file. In a stand-alone environment you can either use the properties method or enable quorum when you start the server:

- **Set the `enableQuorum=true` property in the server properties file.**
  You can use this configuration in a WebSphere Application Server or stand-alone environment. See the following example objectGridServer.properties file:

  ```
  catalogClusterEndPoints=cat0:cat0.domain.com:6600:6601,
  cat1:cat1.domain.com:6600:6601
  catalogServiceEndPoints= cat0.domain.com:2809, cat1.domain.com:2809
  enableQuorum=true
  ```

  For more information about configuring the properties file, see Server properties file.
- **Pass the `-quorum` enabled flag on thestartOgServer command.**
  You can use this configuration method when you start stand-alone servers only.

  ```
  # bin/startOgServer cat0 -serverProps objectGridServer.properties -quorum true
  ```

  For more information about the **startOgServer** command, see Starting and stopping stand-alone servers.

Results

By enabling the quorum mechanism on the catalog servers within a catalog service domain, all the catalog servers must be available for data grid placement operations to occur. If a short network brownout occurs, placement operations are temporarily stopped until all the catalog servers in the quorum are available. To verify the quorum settings, run the xscmd command **showQuorumStatus**.
You can add catalog servers to the quorum by repeating these steps.

What to do next

For more information about dealing with outages and overriding the quorum mechanism, see Managing data center failures when quorum is enabled.

Tuning the heartbeat interval setting for failover detection

You can configure the amount of time between system checks for failed servers with the heartbeat interval setting. This setting applies to catalog servers only.

About this task

Configuring failover depends on the type of environment you are using. If you are using a stand-alone environment, you can configure failover with the command line. If you are using a WebSphere® Application Server Network Deployment environment, you must configure failover in the WebSphere Application Server Network Deployment administrative console.

Procedure

- Configure failover for stand-alone environments.
  - With the -heartbeat parameter in the **startOgServer** script when you start the catalog server.
  - With the heartBeatFrequencyLevel property in the server properties file for the catalog server.

  Use one of the following values:

Table 1. Valid heartbeat values

Value	Action	Description
-1	Aggressive	Specifies an aggressive heartbeat level. With this value, failures are detected more quickly, but more processor and network resources are used. This level is more sensitive to missing heartbeats when the server is busy. Failovers are typically detected within 5 seconds.

Value	Action	Description
0	Typical (default)	Specifies a heartbeat level at a typical rate. With this value, failover detection occurs at a reasonable rate without overusing resources. Failovers are typically detected within 30 seconds.
1	Relaxed	Specifies a relaxed heartbeat level. With this value, a decreased heartbeat frequency increases the time to detect failures, but also decreases processor and network use. Failovers are typically detected within 180 seconds.

An aggressive heartbeat interval can be useful when the processes and network are stable. If the network or processes are not optimally configured, heartbeats might be missed, which can result in a false failure detection.

- Configure failover for WebSphere Application Server environments.
  You can configure WebSphere Application Server Network Deployment Version 6.1 and later to allow WebSphere eXtreme Scale to fail over very quickly. The default failover time for hard failures is approximately 200 seconds. A hard failure is a physical computer or server crash, network cable disconnection or operating system error. Failures because of process crashes or soft failures typically fail over in less than one second. Failure detection for soft failures occurs when the network sockets from the dead process are closed automatically by the operating system for the server hosting the process.

  Core group heartbeat configuration

  WebSphere eXtreme Scale running in a WebSphere Application Server process inherits the failover characteristics from the core group settings of the application server. The following sections describe how to configure the core group heartbeat settings for different versions of WebSphere Application Server Network Deployment:

  - **Update the core group settings for WebSphere Application Server Network Deployment Version 6.1 and 7.0:**
    Specify the heartbeat interval in seconds on WebSphere Application Server versions from Version 6.0 through Version 6.1.0.12 or in milliseconds starting with Version 6.1.0.13. You must also specify the number of missed heartbeats. This value indicates how many heartbeats can be missed before a peer Java™ virtual machine (JVM) is considered as failed. The hard failure detection time is approximately the product of the heartbeat interval and the number of missed heartbeats.

    These properties are specified using custom properties on the core group using the WebSphere administrative console. See Core group custom properties for configuration details. These properties must be specified for all core groups used by the application:
    - The heartbeat interval is specified using either the IBM_CS_FD_PERIOD_SEC custom property for seconds or the IBM_CS_FD_PERIOD_MILLIS custom property for milliseconds (requires Version 6.1.0.13 or later).
    - The number of missed heartbeats is specified using the IBM_CS_FD_CONSECUTIVE_MISSED custom property.

    The default value for the IBM_CS_FD_PERIOD_SEC property is 20 and for the IBM_CS_FD_CONSECUTIVE_MISSED property is 10. If the IBM_CS_FD_PERIOD_MILLIS property is specified, then it overrides any of the set IBM_CS_FD_PERIOD_SEC custom properties. The values of these properties are positive integer values.

    Use the following settings to achieve a 1500 ms failure detection time for WebSphere Application Server Network Deployment Version 6.x servers:
    - Set `IBM_CS_FD_PERIOD_MILLIS = 750` (WebSphere Application Server Network Deployment V6.1.0.13 and later)
    - Set `IBM_CS_FD_CONSECUTIVE_MISSED = 2`
  - **Update the core group settings for WebSphere Application Server Network Deployment Version 7.0**

    WebSphere Application Server Network Deployment Version 7.0 provides two core group settings that can be adjusted to increase or decrease failover detection:

    - **Heartbeat transmission period.** The default is 30000 milliseconds.
    - **Heartbeat timeout period.** The default is 180000 milliseconds.

    For more details on how change these settings, see the WebSphere Application Server Network Deployment Information center: Discovery and failure detection settings.

    Use the following settings to achieve a 1500 ms failure detection time for WebSphere Application Server Network Deployment Version 7 servers:

    - Set the heartbeat transmission period to 750 milliseconds.
    - Set the heartbeat timeout period to 1500 milliseconds.

What to do next

When these settings are modified to provide short failover times, there are some system-tuning issues to be aware of. First, Java is not a real-time environment. It is possible for threads to be delayed if the JVM is experiencing long garbage collection times. Threads might also be delayed if the machine hosting the JVM is heavily loaded (due to the JVM itself or other processes running on the machine). If threads are delayed, heartbeats might not be sent on time. In the worst case, they might be delayed by the required failover time. If threads are delayed, false failure detections occur. The system must be tuned and sized to ensure that false failure detections do not happen in production. Adequate load testing is the best way to ensure this.

Note: The current version of eXtreme Scale supports WebSphere Real Time.

Configuring container servers

The container server stores application data for the data grid. This data is generally broken into parts, which are called partitions, which are hosted across multiple container servers. Each container server in turn hosts a subset of the complete data.

About this task

- **Stand-alone container servers**:
  Configure stand-alone container servers with a server properties file and a deployment policy XML file. Control the life cycle of a container server with the start and stop scripts or with the embedded server API.
- **Container servers that start in WebSphere® Application Server:**
  Configure container servers in WebSphere Application Server with a server properties file and deployment policy XML file that is embedded into a Java EE application module. The life cycle of the container servers is controlled by the application. Container servers start and stop with the application.
- Container server reconnect properties
  Use Java virtual machine (JVM) properties to configure how your container server reconnects to the data grid if the container server becomes disconnected.
- Configuring container servers in WebSphere Application Server
  Configure container servers in WebSphere Application Server by using a server properties file and deployment policy XML file that is embedded into a Java EE application module. Container servers stop and start when the application is stopped and started.

Container server reconnect properties

Use Java™ virtual machine (JVM) properties to configure how your container server reconnects to the data grid if the container server becomes disconnected.

JVM system properties

If a container server becomes disconnected from the data grid, WebSphere® eXtreme Scale attempts to reconnect those container servers. By setting system properties, you can control how the container reconnects. You can set these properties when you start a container server. Some properties are applicable to WebSphere eXtreme Scale in a stand-alone environment, while others are only applicable in an integrated WebSphere Application Server environment. For example, when a container server is started in a stand-alone environment, you can set these properties as an option from a command console:

```
startOgServer.sh server01 -objectgridFile objectgrid.xml -deploymentPolicyFile deployment.xml -
Dcom.ibm.websphere.objectgrid.container.reconnect.restart=false
```

For more information, see Starting and stopping stand-alone servers. If you want to set the appropriate property for WebSphere eXtreme Scale for WebSphere Application Server, you can use the WebSphere Integrated Solutions Console tool. This tool is a graphical user interface that is accessible from the WebSphere Application Server environment, and is installed as an extension to the WebSphere ISC.

`com.ibm.websphere.objectgrid.container.reconnect.block.reconnect.time`
: Defines the amount of time (in milliseconds) to block another container reconnect call. Only valid when a container server is started for the product offering:WebSphere eXtreme Scale for WebSphere Application Server.
  Default: 30000 milliseconds

`com.ibm.websphere.objectgrid.container.reconnect.min.successful.heartbeats`
: Defines the minimum number of successful heartbeats before a container can be stopped. Only valid when a container server is started for the product offering: WebSphere eXtreme Scale for WebSphere Application Server.
  Default: 10

`com.ibm.websphere.objectgrid.container.reconnect.restart`
: Defines whether container reconnect can restart the JVM. Only valid when a container server is started for WebSphere eXtreme Scale in a stand-alone environment.
  Default: true

`com.ibm.websphere.objectgrid.container.reconnect.restart.command`
: Defines the command that is used to restart the container. This command overrides the dynamically generated command if this property is not specified. Each argument in the command is delimited by the value that is defined in the property 'com.ibm.websphere.objectgrid.container.reconnect.restart.delimiter'. Only for use with OSGi container servers. The following is an example of a valid command that uses the `','` as a delimiter.
  Default: `" "` An empty string identifies not to restart a container server on OSGi.

  Example: `/usr/bin/java,-Dprop=value,SomeClass,arg1,arg2`

  You must specify this property if you want OSGi containers to restart when the conditions for container restart be met. Otherwise, the container server is stopped and the JVM continues to run, including any other OSGi services within that JVM.

`com.ibm.websphere.objectgrid.container.reconnect.restart.delimiter`
: Defines the delimiter that is used for tokenizing the command that is specified in the property 'com.ibm.websphere.objectgrid.container.reconnect.restart.command'. A blank space is not to be used as a delimiter as parsing issues can result. Only for use with OSGi container servers.
  Default: `","` A comma is the default delimiter.

`com.ibm.websphere.objectgrid.container.reconnect.restart.delay`

Defines the time (in milliseconds) to delay before you proceed with the startup on the newly created child container when the JVM is restarted. Only valid when a container server is started for the product offering: WebSphere eXtreme Scale in a stand-alone environment.
Default: 2000 milliseconds

`com.ibm.websphere.objectgrid.container.reconnect.restart.parent.timeout`
Defines the time (in milliseconds) for the newly created child container to wait for its parent to disconnect before timing out when the JVM is restarted. Only valid when a container server is started for the product offering: WebSphere eXtreme Scale in a stand-alone environment.
Default: 180000 milliseconds

`com.ibm.websphere.objectgrid.container.reconnect.retry.forever`
Defines whether the container attempts to reconnect to the container server forever. Only valid when a container server is started for the product offering:WebSphere eXtreme Scale for WebSphere Application Server.
Default: false

Configuring container servers in WebSphere Application Server

Configure container servers in WebSphere® Application Server by using a server properties file and deployment policy XML file that is embedded into a Java™ EE application module. Container servers stop and start when the application is stopped and started.

Before you begin

Configure a catalog service domain. See Creating catalog service domains in WebSphere Application Server for more information.

About this task

To create container servers in WebSphere Application Server, you must embed the WebSphere eXtreme Scale configuration XML files to create the container servers within the application module.

Procedure

1. Identify the application servers on which you want to deploy the Java EE application that contains the WebSphere eXtreme Scale container server definitions. Verify that the target application server profiles have been augmented with the WebSphere eXtreme Scale profile. In a production environment, do not collocate the servers that you use for container servers with the catalog servers. See Creating and augmenting profiles for WebSphere eXtreme Scale for more information.
2. Configure a server properties file and add the server properties file to the class path for each target application server node. See Server properties file for more information.
3. Add the ObjectGrid descriptor XML file and deployment policy XML file to the application module. See Configuring WebSphere Application Server applications to automatically start container servers for more information.

- Configuring WebSphere Application Server applications to automatically start container servers
  Container servers in a WebSphere Application Server environment start automatically when a module starts that has the eXtreme Scale XML files included.

Configuring WebSphere Application Server applications to automatically start container servers

Container servers in a WebSphere® Application Server environment start automatically when a module starts that has the eXtreme Scale XML files included.

Before you begin

WebSphere Application Server and WebSphere eXtreme Scale must be installed, and you must be able to access the WebSphere Application Server administrative console.

About this task

Java™ Platform, Enterprise Edition applications have complex class loader rules that greatly complicate loading classes when using a shared data grid within a Java EE server. A Java EE application is typically a single Enterprise Archive (EAR) file. The EAR file contains one or more deployed Enterprise JavaBeans (EJB) or web archive (WAR) modules.

WebSphere eXtreme Scale watches for each module start and looks for eXtreme Scale XML files. If the catalog service detects that a module starts with the XML files, the application server is registered as a container server Java virtual machine (JVM). By registering the container servers with the catalog service, the same application can be deployed in different data grids, but used as a single data grid by the catalog service. The catalog service is not concerned with cells, grids, or dynamic grids. A single data grid can span multiple cells if required.

Procedure

1. Package your EAR file to have modules that include the eXtreme Scale XML files in the META-INF folder. WebSphere eXtreme Scale detects the presence of the objectGrid.xml and objectGridDeployment.xml files in the META-INF folder of EJB and WEB modules when they start. If only an objectGrid.xml file is found, then the JVM is assumed to be client. Otherwise, it is assumed this JVM acts as a container for the data grid that is defined in the objectGridDeployment.xml file.
   You must use the correct names for these XML files. The file names are case-sensitive. If the files are not present, then the container does not start. You can check the systemout.log file for messages that indicate that shards are being placed. An EJB module or WAR module using eXtreme Scale must have eXtreme Scale XML files in its META-INF directory.

   The eXtreme Scale XML files include:
   - An ObjectGrid descriptor XML file, named objectGrid.xml. See ObjectGrid descriptor XML file for more information.
   - A deployment descriptor XML file named objectGridDeployment.xml. See Deployment policy descriptor XML file for more information.
   - (Optional) An entity metadata descriptor XML file, if entities are used. The entity.xml file name must match the name that is specified in the objectGrid.xml file. See Entity metadata descriptor XML file for more information.

   The run time detects these files, then contacts the catalog service to inform it that another container is available to host shards for that eXtreme Scale.
   Tip: If your application has entities and you are planning to use one container server, set the minSyncReplicas value to `0` in the deployment descriptor XML file. Otherwise, you might see one of the following messages in the SystemOut.log file because placement cannot occur until another server starts to meet the minSyncReplica policy:

   ```
   CWPRJ1005E: Error resolving entity association. Entity=entity_name,
   association=association_name.
   ```

   ```
   CWOBJ3013E: The EntityMetadata repository is not available.  Timeout
   threshold reached when trying to register the entity: entity_name.
   ```

2. Deploy and start your application.
   The container starts automatically when the module is started. The catalog service starts to place partition primaries and replicas (shards) as soon as possible. This placement occurs immediately unless you configure the environment to delay placement. For more information, see Controlling placement.

What to do next

Applications within the same cell as the containers can connect to these data grids by using a ObjectGridManager.connect(null, null) method and then call the getObjectGrid(ccc, "object grid name") method. The connect or getObjectGrid methods might be blocked until the containers have placed the shards, but this blocking is only an issue when the data grid is starting.

ClassLoaders

Any plug-ins or objects stored in an eXtreme Scale are loaded on a certain class loader. Two EJB modules in the same EAR can include these objects. The objects are the same but are loaded with different ClassLoaders. If application A stores a Person object in a map that is local to the server, application B receives a `ClassCastException` if it tries to read that object. This exception occurs because application B loaded the Person object on a different class loader.

One approach to resolve this problem is to have a root module contain the necessary plug-ins and objects that are stored in the eXtreme Scale. Each module that uses eXtreme Scale must reference that module for its classes. Another resolution is to place these shared objects in a utility JAR file that is on a common class loader shared by both modules and applications. The objects can also be placed in the WebSphere classes or lib/ext directory, however this placement complicates the deployment.

EJB modules in an EAR file typically share the same ClassLoader and are not affected by this problem. Each WAR module has its own ClassLoader and is affected by this problem.

Connecting to a data grid client-only

If the catalog.services.cluster property is defined in the cell, node or server custom properties, any module in the EAR file can call the ObjectGridManager.connect (ServerFactory.getServerProperties().getCatalogServiceBootstrap(), null, null) method to get a ClientClusterContext. The module can also call the ObjectGridManager.getObjectGrid(ccc, "grid name") method to gain a reference to the data grid. If any application objects are stored in Maps, verify that those objects are present in a common ClassLoader.

Java clients or clients outside the cell can connect with the bootstrap IIOP port of the catalog service. In WebSphere Application Server, the deployment manager hosts the catalog service by default. The client can then obtain a ClientClusterContext and the named data grid.

Entity manager

With the entity manager, the tuples are stored in the maps instead of application objects, resulting in fewer class loader problems. Plug-ins can be a problem, however. Also note that a client override ObjectGrid descriptor XML file is always required when connecting to a data grid that has entities defined: ObjectGridManager.connect("host:port[,host:port], null, objectGridOverride) or ObjectGridManager.connect(null, objectGridOverride).

Configuring multiple data center topologies

With the multi-master asynchronous replication, you link a set of catalog service domains. The connected catalog service domains are then synchronized using replication over the links. You can define the links using properties files, at run time with Java Management Extensions (JMX) programs, or with command-line utilities. The set of current links for a domain is stored in the catalog service. You can add and remove links without restarting the catalog service domain that hosts the data grid.

Before you begin

- See Planning multiple data center topologies for more information about multi-master replication topologies and design considerations. You can configure links among catalog service domains with the server properties file to form the topology during server startup. You can also configure links at run time.
- If you are using loaders in your multi-master replication topology, you must plan how you are going to maintain accurate data between the data centers. The approaches that you can use vary depending on the topology you are using. For more information, see Loader considerations in a multi-master topology.

Procedure

- Define links in the server properties file for the catalog server of each catalog service domain in the topology, for bootstrap purposes.
  See Server properties file for more information about defining this file for the catalog server.

  Important: Property names are case-sensitive.

  Local Domain name:
  Specify the name of the catalog service domain for the current catalog server:

  ```
  domainName=domain1
  ```

  An optional list of foreign domain names:
  Specify the names of catalog service domains to which you want to link in the multi-master replication topology:

  ```
  foreignDomains=domain2,domain3,domain4
  ```

  An optional list of endpoints for the foreign domain names:
  Specifies the connection information for the catalog servers of the foreign domains:

  ```
  domain2.endPoints=hostB1:2809, hostB2:2809
  ```

  If a foreign domain has multiple catalog servers, specify all of them.

- Use the **xscmd** utility or JMX programming to add or remove links at run time.
  The links for a domain are kept in the catalog service in replicated memory. This set of links can be changed at any time by the administrator without requiring a restart of this domain or any other domain. The **xscmd** utility includes several options for working with links.

  The **xscmd** utility connects to a catalog service and thus a single catalog service domain. Therefore, the **xscmd** utility can be used to create and destroy links between the domain it attaches to and any other domain.

  Use the command line to create a link, for example:

  ```
  xscmd -c establishLink -cep host:2809 -fd dname -fe fdHostA:2809,fdHostB:2809
  ```

  The command establishes a new link between the local domain and the foreign domain named `dname`. The `dname` catalog service is running at `fdHostA:2809` and `fdHostB:2809`. The local catalog service domain has a catalog service listener host and port of `host:2809`. Specify all catalog service endpoints from the foreign domain so that fault tolerance connectivity to the domain is possible. Do not use a single `host:port` pair for the catalog service of the foreign catalog service domain.

  You can use any local catalog service JVM with **xscmd** and the using the -cep option. If the catalog server is hosted in a WebSphere Application Server deployment manager, then the port is usually 9809.

  The ports specified for the foreign domain are not JMX ports. They are the usual ports you would use for eXtreme Scale clients.

  After the command to add a new link is issued, the catalog service instructs all containers under its management to begin replicating to the foreign domain. A link is not needed on both sides. It is only necessary to create a link on one side.

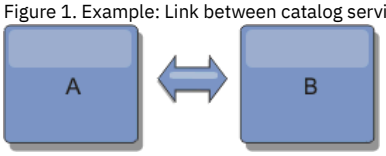
  Use the command line to remove a link, for example:

  ```
  xscmd -c dismissLink -cep host:2809 -fd dname
  ```

The command connects to the catalog service for a domain and instructs it to stop replicating to a specific domain. A link needs to be dismissed from one side only.
Attention: You can run the establish or dismiss link commands multiple times. If the link does not enter the correct status or is disjoint, run the command again.

Examples

Figure 1. Example: Link between catalog service domains



Suppose that you want to configure a two-domain setup involving catalog service domains A and B.
Here is the server properties file for the catalog server in domain A:

```
domainName=A
foreignDomains=B
B.endPoints=hostB1:2809, hostB2:2809
```

Here is the server properties file for the catalog server in domain B. Notice the similarity between the two property files.

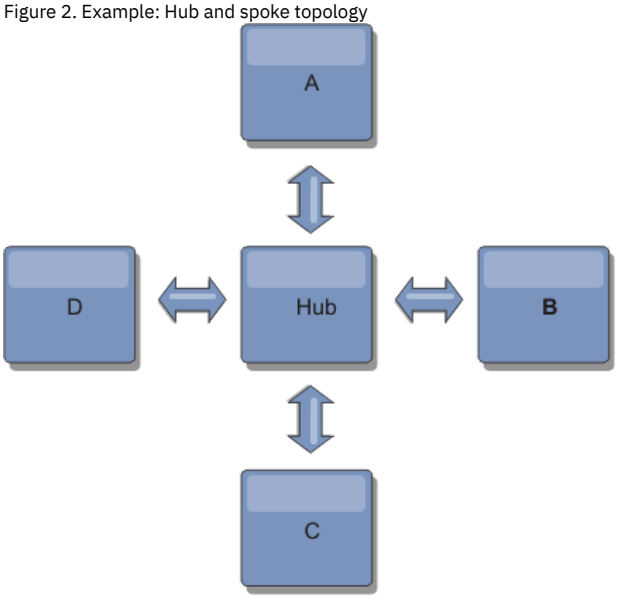
```
domainName=B
foreignDomains=A
A.endPoints=hostA1:2809,hostA2:2809
```

After the two domains are started, then any data grids with the following characteristics are replicated between the domains.

- Has a private catalog service with a unique domain name
- Has the same data grid name as other grids in the domain
- Has the same number of partitions as other data grids in the domain
- Has a data grid that uses the fixed partition placement strategy. A data grid that is configured to use a per container placement strategy cannot be replicated.
- Has the same number of partitions (it might or might not have the same number and types of replicas)
- Has the same data types being replicated as other data grids in the domain
- Has the same map set name, map names, and dynamic map templates as other data grids in the domain

The replication policy of a catalog service domain is ignored.
The preceding example shows how to configure each domain to have a link to the other domain, but it is necessary only to define a link in one direction. This fact is especially useful in hub and spoke topologies, allowing a much simpler configuration. The hub property file does not require updates as spokes are added, and each spoke file needs only to include hub information. Similarly, a ring topology requires each domain to have only a link to the previous and next domain in the ring.

Figure 2. Example: Hub and spoke topology



The hub and four spokes (domains A, B, C, and D) has server property files like the following examples.

```
domainName=Hub
```

Spoke A has the following server properties:

```
domainName=A
foreignDomains=Hub
Hub.endPoints=hostH1:2809, hostH2:2809
```

Spoke B has the following server properties:

```
domainName=B
foreignDomains=Hub
Hub.endPoints=hostH1:2809, hostH2:2809
```

Spoke C has the following server properties:

```
domainName=C
foreignDomains=Hub
Hub.endPoints=hostH1:2809, hostH2:2809
```

Spoke D has the following properties:

```
domainName=D
foreignDomains=Hub
Hub.endPoints=hostH1:2809, hostH2:2809
```

What to do next

- If you need to check or troubleshoot problems with the links between your catalog service domains, you can use the **xscmd** utility. For more information about commands to help you troubleshoot your multiple data center configuration, see Troubleshooting multiple data center configurations.
- You can provide a custom collision arbiter to resolve collisions between the catalog service domains. See Developing custom arbiters for multi-master replication for more information.

Configuring ports

You must open ports to communicate among servers and with remote servers.

- Configuring ports in stand-alone mode
  You can configure the necessary ports for servers and clients in an eXtreme scale deployment by using command-line parameters, property files or programmatically. Most examples included in the following sections describe command-line parameters to the **startOgServer** script. Equivalent configuration options can also be set in properties files, using the embedded server API or the client API.
- Configuring ports in a WebSphere Application Server environment
  WebSphere eXtreme Scale catalog services, container servers and clients, when running in WebSphere Application Server processes, utilize ports and services already defined for the process.
- Servers with multiple network cards
  You can run eXtreme Scale processes on a server that has more than one network card.

Configuring ports in stand-alone mode

You can configure the necessary ports for servers and clients in an eXtreme scale deployment by using command-line parameters, property files or programmatically. Most examples included in the following sections describe command-line parameters to the **startOgServer** script. Equivalent configuration options can also be set in properties files, using the embedded server API or the client API.

Procedure

1. Start catalog service endpoints.
   WebSphere® eXtreme Scale uses IIOP to communicate between Java™ virtual machines. The catalog service JVMs are the only processes that require the explicit configuration of ports for the IIOP services and group services ports. Other processes dynamically allocate ports.

a. Specify client and peer ports. The client port and peer port are used for communication between catalog services in a catalog service domain. To specify the client port and peer port, use the following command-line option:

-catalogServiceEndPoints <serverName:hostName:clientPort:peerPort>
Specifies a list of catalog servers to link together into a catalog service domain. Each attribute is defined as follows:

serverName
Specifies the name of the catalog server.
hostName
Specifies the host name for the computer where the server is launched.
clientPort
Specifies the port that is used for peer catalog service communication.
peerPort
This value is the same as the haManagerPort. Specifies the port that is used for peer catalog service communication.

The following example starts the cs1 catalog server, which is in the same catalog service domain as the cs2 and cs3 servers:

```
startOgServer.bat|sh cs1 -catalogServiceEndPoints
cs1:MyServer1.company.com:6601:6602,cs2:MyServer2.company.com:6601:6602,cs3:MyServer3.company.com:6601:66
02
```

If you start additional catalog servers, they must include the same servers in the -catalogServiceEndPoints argument. The order of the list can be different, but the servers contained in the list must be the same for each catalog server. Do not put any spaces in the list.

You can also set the catalog service end points with the catalogClusterEndPoints server property.

b. Set the listener host and port. The listener port is used for communication between catalog services in a catalog service domain, and for communication between catalog services and container servers and clients. To specify the listener port and listener host, use the following command-line options:

-listenerHost <host name>
Specifies the host name to which the Object Request Broker (ORB) transport protocol binds for communication. The value must be a fully qualified domain name or IP address. If your configuration involves multiple network cards, set the listener host and port to the IP address for which to bind. By setting the listener and host port, it allows the transport mechanism in the JVM know which IP address to use. If you do not specify which IP address to use, symptoms such as connection timeouts, unusual API failures, and clients that seem to hang can occur.

Default: `localhost`
-listenerPort <port>
Specifies the port number to which the ORB transport protocol binds for communication. **Default:** `2809`

You can also set the listener port and listener host with the listenerHost and listenerPort server properties.

c. Optional: Set the JMX service port.
The JMX service port is used for communication from JMX clients. To specify the JMX service port, use the following command-line option:

-JMXServicePort <port>
Required only for WebSphere eXtreme Scale in a stand-alone environment. Specifies the port number on which the MBean server listens for communication with Java Management Extensions (JMX).
Default: `1099` for catalog servers

You can also set the JMX service port with the JMXServicePort server property.

d. Optional: Set the JMX connector port.
The JMX connector port is used for communication from JMX clients. To specify the JMX connector port, use the following command-line option:

-JMXConnectorPort <port>
Defines the Secure Sockets Layer (SSL) port to which the Java Management Extensions (JMX) service binds. Only required if an SSL transport protocol is needed for JMX data.

You can also set the JMX connector port with the JMXConnectorPort server property.

e. Set the Secure Socket Layer (SSL) port.
When security is enabled, an SSL port is also required. To specify the SSL port, use the following command-line option:

```
-jvmArgs -Dcom.ibm.CSI.SSLPort=<sslPort>
```

Figure 1. Example using the command line. Start the first catalog server on hostA.
An example of the command follows:

```
./startOgServer.sh cs1 -listenerHost hostA -listenerPort 2809
-catalogServiceEndPoints cs1:hostA:6601:6611,cs2:hostB:6601:6611
```

Start the second catalog server on hostB. An example of the command follows:

```
./startOgServer.sh cs2 -listenerHost hostB -listenerPort 2809
-catalogServiceEndPoints cs1:hostA:6601:6611,cs2:hostB:6601:6611
```

2. Start container server endpoints.
The following command starts a container server to use with the example catalog service:

```
./startOgServer.sh c0 -catalogServiceEndPoints hostA:2809,hostB:2809
```

The container server Java virtual machines use two ports. The HA manager port is used for internal communication between peer container servers and catalog servers. The listener port is used for IIOP communication between peer container servers, catalog servers, and clients. The listener host is used to

bind the ORB to a specific network adapter. If you do not specify, both ports are dynamically selected. However, if you want to explicitly configure ports, such as in a firewall environment, you can use a command-line options to specify the ORB port.

a. Specify the listener host and port. To specify the listener port and listener host, use the following command-line options:

-listenerHost <host name>
Specifies the host name to which the Object Request Broker (ORB) transport protocol binds for communication. The value must be a fully qualified domain name or IP address. If your configuration involves multiple network cards, set the listener host and port to the IP address for which to bind. By setting the listener and host port, it allows the transport mechanism in the JVM know which IP address to use. If you do not specify which IP address to use, symptoms such as connection timeouts, unusual API failures, and clients that seem to hang can occur.

Default: `localhost`

-listenerPort <port>
Specifies the port number to which the ORB transport protocol binds for communication. **Default:** `2809`

You can also set listener port and listener host with the listenerHost and listenerPort server properties.

b. Specify the HA manager port. To specify the HA manager port, use the following command-line option:

-haManagerPort <port>
Specifies the port that is used by the high availability (HA) manager for heartbeat communication between peer container servers. The haManagerPort port is only used for peer-to-peer communication between container servers that are in same domain. If the haManagerPort property is not defined, then an ephemeral port is used. In WebSphere Application Server, this setting is inherited by the high availability manager port configuration.

You can also set the HA manager port with the HAManagerPort server property.

c. Optional: Specify the SSL port.
When security is enabled, a Secure Socket Layer (SSL) port is also required. To specify the SSL port, use the following command-line option:

```
-jvmArgs -Dcom.ibm.CSI.SSLPort=<sslPort>
```

d. Optional: Specify the JMX service port.

-JMXServicePort <port>
Required only for WebSphere eXtreme Scale in a stand-alone environment. Specifies the port number on which the MBean server listens for communication with Java Management Extensions (JMX).
Default: `1099` for catalog servers

You can also set the JMX service port with the JMXServicePort server property.

e. Optional: Set the JMX connector port.
The JMX connector port is used for communication from JMX clients. To specify the JMX connector port, use the following command-line option:

-JMXConnectorPort <port>
Defines the Secure Sockets Layer (SSL) port to which the Java Management Extensions (JMX) service binds. Only required if an SSL transport protocol is needed for JMX data.

You can also set the JMX connector port with the JMXConnectorPort server property.

3. Start client endpoints.
Clients must know the catalog service listener end points only. Clients retrieve end points for container server Java virtual machines, which are the Java virtual machines that hold the data, automatically from the catalog service. To connect to the catalog service in the previous example, the client must pass the following list of `host:port` pairs to the connect API:

```
hostA:2809,hostB:2809
```

The client can also receive callbacks from container servers when using the DataGrid API. These callbacks communicate using IIOP with the ORB listener port. To specify the port and network adapter to receive callbacks, set the listenerHost and listenerPort properties in the client properties file.

When security is enabled, a Secure Socket Layer (SSL) port is also required. To specify the SSL port, use the following system property when starting the client process:

```
-jvmArgs -Dcom.ibm.CSI.SSLPort=<sslPort>
```

Related concepts:
Planning for network ports
Servers with multiple network cards

Configuring ports in a WebSphere Application Server environment

WebSphere eXtreme Scale catalog services, container servers and clients, when running in WebSphere Application Server processes, utilize ports and services already defined for the process.

About this task

The following sections explain details relating to using ports in your deployment.

1. Catalog service endpoints
   WebSphere eXtreme Scale catalog services run in any WebSphere Application Server process and are configured using the administrative console or using administrative tasks. All ports are inherited by the process except for the client port, which is explicitly configured. For details on which ports are used by the catalog service, see Planning for network ports. For details on configuring a catalog service domain, see High availability catalog service.

2. Container server endpoints
   WebSphere eXtreme Scale container servers are hosted within Java EE modules. The container servers use the ports defined for the application server process. For details on which ports are used by the container service, see Planning for network ports. For details on starting a container within a Java EE module such as an Enterprise JavaBeans™ (EJB) or Web module, see Configuring WebSphere Application Server applications to automatically start container servers.

3. Client endpoints
   WebSphere eXtreme Scale clients are hosted within Java EE web or EJB modules.

   Clients programmatically connect to the catalog service domain using the ObjectGridManager.connect() API. When connecting to a catalog service domain hosted within the same cell, the client connection will automatically find the default catalog service domain by using the following API call on the ObjectGridManager:

   ```
   connect(securityProps, overRideObjectGridXML)
   ```

   If the default catalog service domain is hosted remotely (external to the cell), the catalog service endpoints must be specified using the following method on the ObjectGridManager API:

   ```
   connect(catalogServerEndpoints, securityProps, overRideObjectGridXml)
   ```

   If the default catalog service domain is defined in the cell, then the CatalogServerProperties API can be used to retrieve the catalog server addresses. The XSDomainManagement administrative task can also be used to retrieve any configured catalog service domain endpoints.

Related concepts:
Planning for network ports
Servers with multiple network cards

Servers with multiple network cards

You can run eXtreme Scale processes on a server that has more than one network card.

If a server or client is running on a server that contains more than one network card, then you must specify the network port and host name in your eXtreme Scale configuration to bind to a specified card. If this configuration is not specified, then the eXtreme Scale runtime automatically chooses a network post and host name, which may result in connection failures or slower performance.

When you are setting the host name for eXtreme Scale processes that are embedded in WebSphere® Application Server, you might need to consider the WebSphere Application Server or other stack products in your configuration. For an example, see Technote: Configuring the node agent on one NIC and its application server on another NIC, which is on a different subnet, can lead to ORB errors .

For catalog or container servers, you must set the listener host and listener port in one of the following ways:

- In the server properties file.
- Command-line parameter on the **startOgServer** script.

For clients, you cannot use the command line, and must use client properties.

Configuring ports in stand-alone mode
Configuring ports in a WebSphere Application Server environment

Configuring transports

Transports enable the exchange of objects and data between different server processes in your configuration.

About this task

8.5+ The main transport mechanism is the Object Request Broker (ORB). This mechanism stores cache entries on the Java™ heap. Using the ORB as the transport mechanism is required in the following configuration scenarios:

- When you are using a system other than x86 64-bit Linux.
- When you are using container servers that are running in a WebSphere® Application Server environment.
- When you are using evictor plug-ins or composite indexes.

ORB
When you use the ORB transport, communication between clients and servers, and between servers within the environment, is handled by the ORB.

- Configuring Object Request Brokers
  The Object Request Broker (ORB) is used by WebSphere eXtreme Scale to communicate over a TCP stack. Use the orb.properties file to pass the

properties that are used by the ORB to modify the transport behavior of the data grid. No action is required to use the ORB provided by WebSphere eXtreme Scale or WebSphere Application Server for your WebSphere eXtreme Scale servers.

Configuring Object Request Brokers

The Object Request Broker (ORB) is used by WebSphere® eXtreme Scale to communicate over a TCP stack. Use the orb.properties file to pass the properties that are used by the ORB to modify the transport behavior of the data grid. No action is required to use the ORB provided by WebSphere eXtreme Scale or WebSphere Application Server for your WebSphere eXtreme Scale servers.

- Configuring the Object Request Broker in a WebSphere Application Server environment
  You can use WebSphere eXtreme Scale with applications that use the Object Request Broker (ORB) directly in WebSphere Application Server or WebSphere Application Server Network Deployment environments.
- Configuring the Object Request Broker with stand-alone WebSphere eXtreme Scale processes
  You can use WebSphere eXtreme Scale with applications that use the Object Request Broker (ORB) directly in environments that do not contain WebSphere Application Server or WebSphere Application Server Network Deployment.
- Configuring a custom Object Request Broker
  WebSphere eXtreme Scale uses the Object Request Broker (ORB) to enable communication among processes. No action is required to use the Object Request Broker (ORB) provided by WebSphere eXtreme Scale or WebSphere Application Server for your WebSphere eXtreme Scale servers. Little effort is required to use the same ORBs for your WebSphere eXtreme Scale clients. If instead you must use a custom ORB, the ORB supplied with the IBM® SDK is a good choice, although you must configure the ORB. ORBs from other vendors can be used, also with configuration.

Related reference:
ORB properties

Configuring the Object Request Broker in a WebSphere Application Server environment

You can use WebSphere® eXtreme Scale with applications that use the Object Request Broker (ORB) directly in WebSphere Application Server or WebSphere Application Server Network Deployment environments.

Procedure

1. Name your application servers appropriately.
   You cannot have servers in a WebSphere Application Server environment with the same name when the servers are using the ORB to communicate with each other. You can resolve this restriction by specifying the system property -Dcom.ibm.websphere.orb.uniqueServerName=true for the processes that have the same name. For example, when servers with the name `server1` on each node are used as a catalog service domain, or where multiple node agents are used to form a catalog service domain.

2. Tune the ORB properties within the WebSphere Application Server configuration.
   See ORB properties for more information about the properties that you can tune. Depending on the property, you might change a setting in the administrative console or in the *was_root*properties/orb.properties file.

3. If you are using multiple network interface cards, you must set the ORB_LISTENER_ADDRESS value in the ports panel in the WebSphere Application Server administrative console. Repeat this step for each application server in the configuration.
   a. For an application server, click Servers > Application servers > *server_name*. Under Communications, click Ports. The Ports panel is displayed for the specified server.
   b. Click Details and edit the ORB_LISTENER_ADDRESS value.
   c. Enter the IP address in the Host field. This value must be a private address for a multiple network interface environment.
   Note: DNS host names are not supported for the ORB_LISTENER_ADDRESS value.
   d. Enter the port number in the Port field. The port number specifies the port for which the service is configured to accept client requests. The port value is used with the host name.

What to do next

You can use the **wxsLogAnalyzer** tool to verify the ORB settings across your environment. See Analyzing log and trace data for more information.

Configuring the Object Request Broker with stand-alone WebSphere eXtreme Scale processes

You can use WebSphere® eXtreme Scale with applications that use the Object Request Broker (ORB) directly in environments that do not contain WebSphere Application Server or WebSphere Application Server Network Deployment.

Before you begin

If you use the ORB within the same process as eXtreme Scale when you are running applications, or other components and frameworks, that are not included with eXtreme Scale, you might need to complete additional tasks to ensure that eXtreme Scale runs correctly in your environment.

About this task

Add the ObjectGridInitializer property to the orb.properties file to initialize the use of the ORB in your environment. Use the ORB to enable communication between eXtreme Scale processes and other processes that are in your environment.

Procedure

1. The stand-alone installation does not include an orb.properties file. You must put an orb.properties file is in the java/jre/lib directory. For descriptions of the properties and settings, see ORB properties.
2. In the orb.properties file, type the following line, and save your changes:

```
org.omg.PortableInterceptor.ORBInitializerClass.com.ibm.ws.objectgrid.corba.ObjectGridInitializer
```

Results

eXtreme Scale correctly initializes the ORB and coexists with other applications for which the ORB is enabled.

To use a custom version of the ORB with eXtreme Scale, see Configuring a custom Object Request Broker.

What to do next

You can use the **xsLogAnalyzer** tool to verify the ORB settings across your environment. See Analyzing log and trace data for more information.

ORB properties

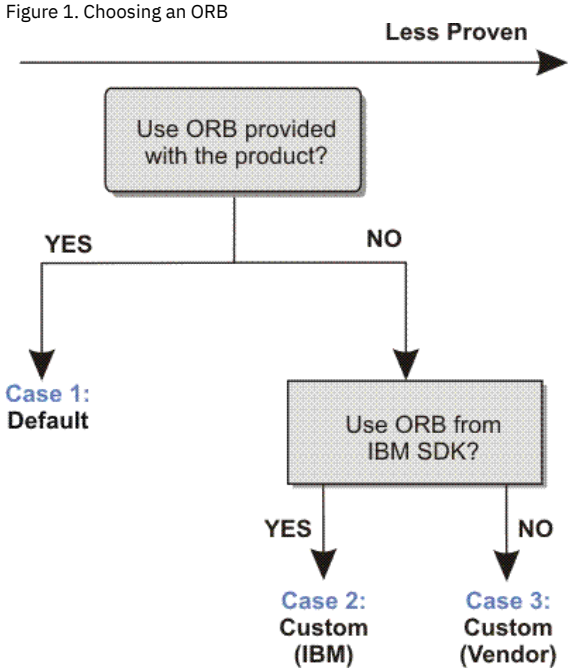
Configuring a custom Object Request Broker

WebSphere® eXtreme Scale uses the Object Request Broker (ORB) to enable communication among processes. No action is required to use the Object Request Broker (ORB) provided by WebSphere eXtreme Scale or WebSphere Application Server for your WebSphere eXtreme Scale servers. Little effort is required to use the same ORBs for your WebSphere eXtreme Scale clients. If instead you must use a custom ORB, the ORB supplied with the IBM® SDK is a good choice, although you must configure the ORB. ORBs from other vendors can be used, also with configuration.

Before you begin

Determine if you are using the ORB provided with WebSphere eXtreme Scale or WebSphere Application Server, the ORB provided with the IBM SDK, or an external vendor ORB.

Figure 1. Choosing an ORB



You can make separate decisions for the WebSphere eXtreme Scale server processes and WebSphere eXtreme Scale client processes. While eXtreme Scale supports developer kits from most vendors, it is recommended you use the ORB that is supplied with eXtreme Scale for both your server and client processes. eXtreme Scale does not support the ORB that is supplied with the Oracle Java™ Development Kit (JDK).

About this task

Become familiar with the configuration that is required to use the ORB of your choice.

Case 1: Default ORB

- For your WebSphere eXtreme Scale server processes, no configuration is required to use the ORB provided with WebSphere eXtreme Scale or WebSphere Application Server.
- For your WebSphere eXtreme Scale client processes, minimal classpath configuration is required to use the ORB provided with WebSphere eXtreme Scale or WebSphere Application Server.

Case 2: Custom ORB (IBM)
To configure your WebSphere eXtreme Scale client processes to use the ORB provided with the IBM SDK, see the instructions later in this topic. You can use the IBM ORB whether you are using the IBM SDK or another development kit. You can use IBM SDK Version 5 or later.

Case 3: Custom ORB (supplied by an external vendor)
Using a vendor ORB for your WebSphere eXtreme Scale client processes is the least tested option. Any problems that you encounter when you use ORBs from independent software vendors must be reproducible with the IBM ORB and compatible JRE before you contact support.
The ORB supplied with the Oracle Java Development Kit (JDK) is not supported.

Procedure

- Configure your client processes to use one of the default ORBs (**Case 1**). Use the following JVM argument :

  ```
  -jvmArgs -Djava.endorsed.dirs=default_ORB_directory${pathSeparator}JRE_HOME/lib/endorsed
  ```

  The default ORB directory is: *wxs_home*/lib/endorsed. Updating the following properties in the orb.properties file might also be necessary:

  ```
  org.omg.CORBA.ORBClass=com.ibm.CORBA.iiop.ORB
  org.omg.CORBA.ORBSingletonClass=com.ibm.rmi.corba.ORBSingleton
  ```

- Configure client or server processes to use IBM SDK Version 5 **(Case 2)**.
  1. Copy the ORB Java archive (JAR) files into an empty directory, or the *custom_ORB_directory*.
     - ibmorb.jar
     - ibmorbapi.jar
  2. Specify the *custom_ORB_directory* directory as an endorsed directory in the scripts that start the Java command.
     Tip: If your Java commands already specify an endorsed directory, another option is to place the *custom_ORB_directory* directory under the existing endorsed directory. By placing the *custom_ORB_directory* directory under the existing endorsed directory, updating the scripts is not necessary. If you decide to update the scripts anyway, be sure to add the *custom_ORB_directory* directory as a prefix to your existing `-Djava.endorsed.dirs=` argument, rather than completely replacing the existing argument.
     - Update scripts for a stand-alone eXtreme Scale environment.
       Edit the path for the *OBJECTGRID_ENDORSED_DIRS* variable in the setupCmdLine.bat|sh file to specify the *custom_ORB_directory*. Save your changes.
     - Update scripts when eXtreme Scale is embedded in a WebSphere Application Server environment.
       Add the following system property and parameters to the startOgServer script:

       ```
       -jvmArgs -Djava.endorsed.dirs=custom_ORB_directory
       ```

     - Update custom scripts that you use to start a client application process or a server process.

       ```
       -Djava.endorsed.dirs=custom_ORB_directory
       ```

Related reference:
ORB properties

Configuring Java clients

You can configure WebSphere® eXtreme Scale to run in a stand-alone environment, or in an environment with WebSphere Application Server. For a WebSphere eXtreme Scale deployment to pick up configuration changes on the server grid side, you must restart processes to make these changes take effect rather than being applied dynamically. However, on the client side, although you cannot alter the configuration settings for an existing client instance, you can create a new client instance with the settings you require by using an XML file or doing so programmatically. When creating a client, you can override the default settings that come from the current server configuration.

You can configure an eXtreme Scale client (Java client only) in the following ways, each of which can be done with a client override XML file or programmatically:

- XML configuration
- Programmatic configuration
- Spring Framework configuration
- Disabling the near cache

- Java client overrides
  You can configure a WebSphere eXtreme Scale client based on your requirements by overriding the server settings. You can override several plug-ins and attributes.
- Configuring Java clients with an XML configuration
  You can use an ObjectGrid configuration XML file to override settings on the client side.

- Configuring the REST gateway with an XML configuration
  You can use a wxsRestGateway.properties file to override data grid settings on the client side.
- Configuring Java clients programmatically
  You can override client-side settings programmatically. Create an ObjectGridConfiguration object that is similar in structure to the server-side ObjectGrid instance.
- Configuring the near cache
  Clients can optionally have a local, in-line cache when eXtreme Scale is used in a distributed topology. This optional cache is called a near cache, an independent data grid on each client, serving as a cache for the remote, server-side cache. The near cache is enabled by default when locking is disabled, or is configured as optimistic, and cannot be used when configured as pessimistic.
- Configuring an evictor for the near cache
  To control the size of the near cache, configure a client-side override that enables an evictor on the client.
- Configuring Java Message Service (JMS)-based client synchronization
  You can use JMS-based client synchronization to keep data from the client near cache synchronized with other severs and clients.

Configuring Java clients with an XML configuration

You can use an ObjectGrid configuration XML file to override settings on the client side.

About this task

To change the settings on a WebSphere® eXtreme Scale client, create an ObjectGrid XML file that is similar in structure to the file that was used for the container server.

For a list of the plug-ins and attributes that you can override on the client, see Java client overrides.

Procedure

1. Create an ObjectGrid configuration XML file for the client. This file is similar in structure to the file for the container server.
   Assume that the following XML file was paired with a deployment policy XML file, and these files were used to start a container server.

```
companyGridServerSide.xml

<?xml version="1.0" encoding="UTF-8"?>
<objectGridConfig xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://ibm.com/ws/objectgrid/config ../objectGrid.xsd"
    xmlns="http://ibm.com/ws/objectgrid/config">

    <objectGrids>
        <objectGrid name="CompanyGrid">
            <bean
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsconfigclixml_TransactionCallb
ack"
                className="com.company.MyTxCallback" />
            <bean
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsconfigclixml_ObjectGridEventL
istener"
                className="com.company.MyOgEventListener" />
            <backingMap name="Customer"
                pluginCollectionRef="customerPlugins" />
            <backingMap name="Item" />
            <backingMap name="OrderLine" numberOfBuckets="1049"
                timeToLive="1600" ttlEvictorType="LAST_ACCESS_TIME" />
            <backingMap name="Order" lockStrategy="PESSIMISTIC"
                pluginCollectionRef="orderPlugins" />
        </objectGrid>
    </objectGrids>

    <backingMapPluginCollections>
        <backingMapPluginCollection
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsconfigclixml_customerPlugins"
>
            <bean
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsconfigclixml_Evictor"
                className="com.ibm.websphere.objectGrid.plugins.builtins.LRUEvictor" />
            <bean
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsconfigclixml_MapEventListener
"
                className="com.company.MyMapEventListener" />
        </backingMapPluginCollection>
        <backingMapPluginCollection
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsconfigclixml_orderPlugins">
            <bean
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsconfigclixml_MapIndexPlugin"
                className="com.company.MyMapIndexPlugin" />
        </backingMapPluginCollection>
    </backingMapPluginCollections>
</objectGridConfig>
```

   On a container server, the ObjectGrid instance named CompanyGrid behaves as defined by the companyGridServerSide.xml file. By default, the CompanyGrid client has the same settings as the CompanyGrid instance that is running on the server. The following ObjectGrid XML file can be used to

specify some of the attributes and plug-ins on the CompanyGrid client:

companyGridClientSide.xml

```
<?xml version="1.0" encoding="UTF-8"?>
<objectGridConfig xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://ibm.com/ws/objectgrid/config ../objectGrid.xsd"
    xmlns="http://ibm.com/ws/objectgrid/config">

    <objectGrids>
        <objectGrid name="CompanyGrid">
            <bean
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsconfigclixml_TransactionCallb
ack"
                classname="com.company.MyClientTxCallback" />
            <bean
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsconfigclixml_ObjectGridEventL
istener" classname="" />
                        <backingMap name="Customer" numberOfBuckets="1429"
            pluginCollectionRef="customerPlugins" />
            <backingMap name="Item" />
            <backingMap name="OrderLine" numberOfBuckets="701"
                timeToLive="800" ttlEvictorType="LAST_ACCESS_TIME" />
            <backingMap name="Order" lockStrategy="PESSIMISTIC"
                pluginCollectionRef="orderPlugins" />
        </objectGrid>
    </objectGrids>

    <backingMapPluginCollections>
        <backingMapPluginCollection
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsconfigclixml_customerPlugins"
>
            <bean
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsconfigclixml_Evictor"
                classname="com.ibm.websphere.objectGrid.plugins.builtins.LRUEvictor" />
            <bean
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsconfigclixml_MapEventListener
" classname="" />
        </backingMapPluginCollection>
        <backingMapPluginCollection
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsconfigclixml_orderPlugins">
            <bean
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsconfigclixml_MapIndexPlugin"
                classname="com.company.MyMapIndexPlugin" />
        </backingMapPluginCollection>
    </backingMapPluginCollections>
</objectGridConfig>
```

The XML file defines the following overrides:

- The TransactionCallback bean on the client is com.company.MyClientTxCallback instead of the server-side setting of com.company.MyTxCallback.
- The client does not have an ObjectGridEventListener plug-in because the className value is the empty string.
- The client sets the numberOfBuckets to 1429 for the Customer backingMap, retains its Evictor plug-in, and removes the MapEventListener plug-in.
- The numberOfBuckets and timeToLive attributes of the OrderLine backingMap changed.
- Although a different lockStrategy attribute is specified, there is no effect because the lockStrategy attribute is not supported for a client override.

2. Create the client with the XML file.
To create the CompanyGrid client with the companyGridClientSide.xml file, pass the ObjectGrid XML file as a URL to one of the connect methods on the ObjectGridManager interface:

```
ObjectGridManager ogManager =
        ObjectGridManagerFactory.ObjectGridManager();
ClientClusterContext clientClusterContext =
        ogManager.connect("MyServer1.company.com:2809", null, new URL(
                "file:xml/companyGridClientSide.xml"));
```

Configuring Java Message Service (JMS)-based client synchronization

You can use JMS-based client synchronization to keep data from the client near cache synchronized with other severs and clients.

Near cache

You can use the built-in Java™ Message Service (JMS)-based com.ibm.websphere.objectgrid.plugins.builtins.JMSObjectGridEventListener class to enable the client invalidation mechanism within a distributed eXtreme Scale environment.

The client invalidation mechanism is the solution for the issue of stale data in client near cache in distributed eXtreme Scale environment. This mechanism ensures that the client near cache is synchronized with servers or other clients. However, even with this JMS-based client invalidation mechanism, the client near cache does not immediately update. A delay occurs when the run time publishes updates.

Two models are available for the client invalidation mechanism in a distributed eXtreme Scale environment:

- Client-server model: In this model, all server processes are in a publisher role that publishes all the transaction changes to the designated JMS destination. All client processes are in receiver roles and receive all transactional changes from the designated JMS destination.
- Client as dual roles model: In this model, all server processes have nothing to do with the JMS destination. All client processes are both JMS publisher and receiver roles. Transactional changes that occur on the client are published to the JMS destination and all the clients receive these transactional changes.

For more information, see JMS event listener.

Client-server model

In a client-server model, the servers are in a JMS publisher role and the client is in JMS receiver role.

Configuring request and retry timeout values

About this task

You can configure settings for the eXtreme Scale client that control how long the client attempts to create network connections, how long the client attempts to process a data grid request to a partition, and how long it attempts to retry that request to the partition, before it returns an exception to your application.

Factors for tuning request and retry timeout values in IBM eXtremeIO (XIO) and Object Request Broker (ORB)

For some tuning options, where you set the values depends on which transport you are using, either XIO or ORB. These transport-level tuning options have the initial impact on interactions with your client because they govern how long the transport attempts network socket connections and how long an individual remote procedure call (RPC) analogous to a data grid operation is given to complete.

When you tune these values, consider what your environment can tolerate under peak load conditions as well as steady state conditions. If you tune the intervals too far under the default values (30 seconds for request timeout, for example), your operations might fail prematurely. Consider the following factors:

- Network latencies
- Coupling of grid interactions with external resources like databases
- Garbage collection pauses resulting from your combination of heap size, heap usage, and garbage collection tuning policies

ORB settings for tuning request and retry timeout values

The following timeout settings exist for the ORB:

com.ibm.CORBA.ConnectionTimeout
: Specifies the amount of time that the ORB attempts to create a socket connection with the remote location before the attempts time out. The ORB caches these connections, and therefore, this operation is not done on every request.

com.ibm.CORBA.RequestTimeout
: Specifies the amount of time that the ORB waits for an RPC to complete before timing out.

com.ibm.CORBA.FragmentTimeout
: Reference the IBM ORB documentation for precise details. The product provides default settings for this value.

com.ibm.CORBA.LocateRequestTimeout
: Reference the IBM ORB documentation for precise details. The product provides default settings for this value.

com.ibm.CORBA.SocketWriteTimeout
: Specifies how many seconds a socket write waits before giving up.

As you tune the RequestTimeout and ConnectionTimeout settings, adjusting them based on the default recommendations can be appropriate. You can also set these settings with the same value, where you define these settings that are based on how long you want the request timeout to be.

XIO settings for tuning request and retry timeout values

With XIO, the following consolidated settings exist:

- The xioTimeout setting determines how long the XIO transport attempts to establish a network socket connection.
- There is no equivalent to the LocateRequest setting and the FragmentTimeout setting in the ORB.
- The xioRequestTimeout value specifies how many seconds any request waits for a response before giving up. This property influences the amount of time a client takes to fail over if a network outage failure occurs. If you set this property too low, requests might time out inadvertently. Carefully consider the value of this property to prevent inadvertent timeouts.

Common settings for tuning request and retry timeout values

The next level of tuning is the requestRetryTimeout. With each transport type, after it throws a system exception because an RPC did not complete in time, the eXtreme Scale client can use the additional time that is defined by the requestRetryTimeout setting (for example, the request timeout is 10 seconds, and the retry request timeout is 20 seconds) to specify how long it takes to complete the following actions:

- Asynchronously asks the catalog server for the latest routing table in case partitions are located elsewhere because of a failover.
- Takes new routes and retries the request, or stops trying and throws an exception to your application.

The requestRetryTimeout property is set in milliseconds. Set the value greater than zero for the request to be retried on exceptions for which retry is available. Set the value to `0` to fail without retries on exceptions. To use the default behavior, remove the property or set the value to `-1`.

XIO failture detection

The properties, xioRequestTimeout, xioTimeout, and requestRetryTimeout have an impact on the XIO failure detection system, in that the clients will be quicker to tell the catalog that a container might be failing, and therefore, trigger the catalog to attempt communication with the container. Where a failure exists, shard failure recovery is initiated for the container shards. Similarly, catalog calls to containers over XIO are governed by the xioRequestTimeout and xioTimeout properties.

Ways to set request retry timeout

You can configure the request retry timeout value on the client properties file or in a session. The session value overrides the client properties setting. If the value is set to greater than zero, the request is tried until either the timeout condition is met or a permanent failure occurs. A permanent failure might be a `DuplicateKeyException` exception. A value of zero indicates the fail-fast mode setting and the data grid does not attempt to try the transaction again after any type of transaction.

Transaction timeout and request retry timeout

During run time, the transaction timeout value is used with the request retry timeout value, ensuring that the request retry timeout does not exceed the transaction timeout.

Two types of transactions exist: Autocommit transactions, and transactions that use explicit begin and commit methods. The valid exceptions for retry differ between these two types of transactions:

- For transactions that are called within a session, transactions are tried again for ORB CORBA SystemException (TransportException for XIO) and eXtreme Scale client TargetNotAvailable exceptions.
- Autocommit transactions are tried again for CORBA SystemException and eXtreme Scale client availability exceptions. These exceptions include the ReplicationVotedToRollbackTransactionException, TargetNotAvailable, and AvailabilityException exceptions.

Application or other permanent failures return immediately and the client does not try the transaction again. These permanent failures include the DuplicateKeyException and KeyNotFoundException exceptions. Use the fail-fast setting to return all exceptions without trying transactions again after any exceptions.

Exceptions where the client tries the transaction again:

- ReplicationVotedToRollbackTransactionException (only on autocommit)
- TargetNotAvailable
- org.omg.CORBA.SystemException (TransportException is the XIO equivalent of this ORB system exception.)
- AvailabilityException (only on autocommit)
- LockTimeoutException (only on autocommit)
- UnavailableServiceException (only on autocommit)

Permanent exceptions, where the transaction is not tried again:

- DuplicateKeyException
- KeyNotFoundException
- LoaderException
- TransactionAffinityException
- LockDeadlockException
- OptimisticCollisionException

Procedure

- Set the request retry timeout value in a client property file.
  To set the requestRetryTimeout value on a client, add or modify the requestRetryTimeout property in the Client properties file. The client properties is the objectGridClient.properties file by default. The requestRetryTimeout property is set in milliseconds. Set the value greater than zero for the request to be retried on exceptions for which retry is available. Set the value to `0` to fail without retries on exceptions. To use the default behavior, remove the property or set the value to `-1`. An example of the value in the objectGridClient.properties file follows:

  ```
  requestRetryTimeout = 30000
  ```

  The requestRetryTimeout value is specified in milliseconds. In the example, if the value is used on an ObjectGrid instance, the requestRetryTimeout value is 30 seconds.

- Set the request retry timeout value programmatically.
  To set the client properties programmatically, first create a client properties file in an appropriate <location> for your application. In the following example, the client properties file refers to the objectGridClient.properties snippet in the previous section. After you connect to ObjectGridManager instance, set the client properties as described. Then, when you have an ObjectGrid instance, the instance has the client properties that you defined in the file. If you change the client properties file, you must explicitly get a new ObjectGrid instance each time.

  ```
  ObjectGridManager manager = ObjectGridManagerFactory.getObjectGridManager();
  String objectGridName = "testObjectGrid";
  URL clientXML = null;
  ClientClusterContext ccc = manager.connect("localhost:2809", null, clientXML);
  File file = new File("<location>/objectGridClient.properties");
  URL url = file.toURI().toURL();
  ccc.setClientProperties(objectGridName, url);
  ObjectGrid objectGrid = ogManager.getObjectGrid(ccc, objectGridName);
  ```

- Set the override file during a session commit.
  To set the request retry timeout on a session or to override the requestRetryTimeout client property, call the setRequestRetryTimeout(long) method on the Session interface.

  ```
  Session sessionA = objectGrid.getSession();
  sessionA.setRequestRetryTimeout(30000);
  ObjectMap mapA = sessionA.getMap("payroll");
  String key = "key:" + j;
  mapA.insert(key, "valueA");
  ```

  This session now uses a requestRetryTimeout value of 30000 ms or 30 seconds, regardless of the value that is set in the client properties file. For more information about the session interface, see Using Sessions to access data in the grid.

Example

Consider the following example, where the client can handle network latency, garbage collection, general contention on the server as a result of setting short timeout values. The requestRetryTimeout property is `10` seconds, and the xioTimeout property matches the ORB ConnectionTimeout value, which is `5` seconds.

Table 1. Data grid configurations for ORB and eXtremeIO transport types

Grid Type	ORB	XIO

Grid Type	ORB	XIO

A Java™ or .NET client application that accesses an eXtreme Scale API directly	• Modify the orb.properties file for your client application. Set the following values:
	  ◦ com.ibm.CORBA.RequestTimeout=5
	  ◦ com.ibm.CORBA.ConnectTimeout=5
	  ◦ com.ibm.CORBA.FragmentTimeout=5
	  ◦ com.ibm.CORBA.LocateRequestTimeout=5
	  ◦ com.ibm.CORBA.SocketWriteTimeout=5
	Note: With WebSphere Application Server, you control the ORB settings through the deployment manager, and not through an orb.properties file.
	• Modify the objectGridClient.properties file for the client application with requestRetryTimeout=10000.
		Modify the objectGridClient.properties file for your client application with the following values:
		• xioRequestTimeout=5000. This value is in milliseconds and is equivalent to com.ibm.CORBA.RequestTimeout.
		• xioTimeout=5. This value is in seconds and is equivalent to com.ibm.CORBA.ConnectTimeout.
		• requestRetryTimeout=10000. This value is in milliseconds and is also used for the ORB transport.
		• ORB FragmentTimeout and LocateRequestTimeout have no XIO equivalent values.

HTTP session	Same ORB configuration as a Java or .NET client application that accesses an eXtreme Scale API directly	Same XIO configuration as a Java or .NET client application that accesses an eXtreme Scale API directly
Dynamic cache	Same ORB configuration as a Java or .NET client application that accesses an eXtreme Scale API directly. For dynamic cache instances, you can set the following additional property on the cache instance: • `com.ibm.websphere.xs.dynacache.request_retry_timeout_override=10000` You can use the requestRetryTimeout setting with the client properties in the class path instead of this cache instance property, if you want it to be the same for every dynamic cache instance.	Same XIO configuration as a Java or .NET client application that accesses an eXtreme Scale API directly. Configuring eXtreme Scale connection factories

8.5+ An eXtreme Scale connection factory allows Java™ EE applications to connect to a remote WebSphere® eXtreme Scale data grid. Use custom properties to configure resource adapters.

Before you begin

Before you create the connection factories, you must install the resource adapter.

About this task

After you install the resource adapter, you can create one or more resource adapter connection factories that represent eXtreme Scale client connections to remote data grids. Complete the following steps to configure a resource adapter connection factory and use it within an application.
You can create an eXtreme Scale connection factory at the node scope for stand-alone resource adapters or within the application for embedded resource adapters. See the related topics for information about how to create connection factories in WebSphere Application Server.

Procedure

1. Using the WebSphere Application Server administrative console to create an eXtreme Scale connection factory that represents an eXtreme Scale client connection. See Configuring Java EE Connector connection factories in the administrative console. After you specify properties for the connection factory in the General Properties panel, you must click **Apply** for the Custom properties link to become active.
2. Click **Custom properties** in the administrative console. Set the following custom properties to configure the client connection to the remote data grid.

Table 1. Custom properties for configuring connection factories

Property Name	Type	Description
ConnectionName	String	(Optional) The name of the eXtreme Scale client connection. The ConnectionName helps identify the connection when exposed as a managed bean. This property is optional. If not specified, the ConnectionName is undefined.
CatalogServiceEndpoints	String	(Optional) The catalog service domain end points in the format: `<host>:<port>[,<host><port>]`. For more information, see Catalog service domain settings. This property is required if the catalog service domain is not set.

Property Name	Type	Description
CatalogServiceDomain	String	(Optional) The catalog service domain name that is defined in WebSphere Application Server. For more information, see Configuring catalog servers and catalog service domains. This property is required if the CatalogServiceEndpoints property is not set.
ObjectGridName	String	(Optional) The name of the data grid that this connection factory connects to. If not specified, then the application must supply the name when obtaining the connection from the connection factory.
ObjectGridURL	String	(Optional) The URL of the client data grid, override XML file. This property is not valid if the ObjectGridResource is also specified. For more information, see Configuring Java clients.
ObjectGridResource	String	The resource path of the client data grid, override XML file. This property is optional and invalid if ObjectGridURL is also specified. For more information, see Configuring Java clients.
ClientPropertiesURL	String	(Optional) The URL of the client properties file. This property is not valid if the ClientPropertiesResource is also specified. For more information, see Client properties file for more information.
ClientPropertiesResource	String	(Optional) The resource path of the client properties file. This property is not valid if the ClientPropertiesURL is also specified. For more information, see Client properties file for more information.

WebSphere Application Server also allows other configuration options for adjusting connection pools and managing security. See the related information for links to WebSphere Application Server Information Center topics.

What to do next

Create an eXtreme Scale connection factory reference in the application. See Configuring applications to connect with eXtreme Scale for more information.

- Configuring Eclipse environments to use eXtreme Scale connection factories
  The eXtreme Scale resource adapter includes custom connection factories. To use these interfaces in your eXtreme Scale Java Platform, Enterprise Edition (Java EE) applications, you must import the wxsra.rar file into your workspace and link it to your application project.

Previous topic: Installing an eXtreme Scale resource adapter

Configuring Eclipse environments to use eXtreme Scale connection factories

8.5+ The eXtreme Scale resource adapter includes custom connection factories. To use these interfaces in your eXtreme Scale Java™ Platform, Enterprise Edition (Java EE) applications, you must import the wxsra.rar file into your workspace and link it to your application project.

Before you begin

- You must install Rational® Application Developer Version 7 or later or Eclipse Java EE IDE for Web Developers Version 1.4 or later.
- A server runtime environment must be configured.

Procedure

1. Import the wxsra.rar file into your project by selecting File > Import. The Import window is displayed.
2. Select Java EE > RAR file. The Connector Import window is displayed.
3. To specify the connector file, click Browse to locate the wxsra.rar file. The wxsra.rar file is installed when you install a resource adapter. You can find the resource adapter archive (RAR) file in the following location:
   - For WebSphere® Application Server installations: *wxs_install_root*/optionalLibraries/ObjectGrid
   - For stand-alone installations: *wxs_install_root*/ObjectGrid/lib directory
4. Create a name for the new connector project in the Connector project field. You can use `wxsra`, which is the default name.
5. Choose a Target runtime, which references a Java EE server runtime environment.
6. Optionally select Add project to EAR to embed the RAR into an existing EAR project.

Results

The RAR file is now imported into your Eclipse workspace.

What to do next

You can reference the RAR project from your other Java EE projects using the following steps:

1. Right click on the project and click Properties.
2. Select Java Build Path.
3. Select the Projects tab.
4. Click Add.
5. Select the wxsra connector project, and click OK.
6. Click OK again to close the Properties window.

The eXtreme Scale resource adapter classes are now in the classpath. To install product runtime JAR files using the Eclipse console, see Setting up a stand-alone development environment in Eclipse for more information.

Previous topic: 8.5+ Configuring eXtreme Scale connection factories
Next topic: 8.5+ Configuring applications to connect with eXtreme Scale

Configuring applications to connect with eXtreme Scale

8.5+ Applications use an eXtreme Scale connection factory to create connection handles to an eXtreme Scale client connection. You can configure resource adapter connection factory references using this task.

Before you begin

Create a Java™ Platform, Enterprise Edition (Java EE) application component, such as an Enterprise JavaBeans (EJB) container or servlet.

Procedure

Create a javax.resource.cci.ConnectionFactory resource reference in the application component. Resource references are declared in the deployment descriptor by the application provider. The connection factory represents an eXtreme Scale client connection that can be used to communicate with one or more named data grids that are available in the catalog service domain.

Configuring cache integration

WebSphere® eXtreme Scale can integrate with other caching-related products. You can also use the WebSphere eXtreme Scale dynamic cache provider to plug WebSphere eXtreme Scale into the dynamic cache component in WebSphere Application Server. Another extension to WebSphere Application Server is the WebSphere eXtreme Scale HTTP session manager, which can help to cache HTTP sessions.

- Configuring HTTP session managers
  The HTTP session manager provides session replication capabilities for an associated application. The session manager works with the web container to create and manage the life cycles of HTTP sessions that are associated with the application.
- Configuring the dynamic cache provider for WebSphere eXtreme Scale
  Installing and configuring the dynamic cache provider for eXtreme Scale depends on what your requirements are and the environment you have set up.
- JPA level 2 (L2) cache plug-in
  WebSphere eXtreme Scale includes level 2 (L2) cache plug-ins for both OpenJPA and Hibernate Java™ Persistence API (JPA) providers. When you use one of these plug-ins, your application uses the JPA API. A data grid is introduced between the application and the database, improving response times.
- 8.5+ Configuring a Spring cache provider
  Spring Framework Version 3.1 introduced a new cache abstraction. With this new abstraction, you can transparently add caching to an existing Spring application. You can use WebSphere eXtreme Scale as the cache provider for the cache abstraction.

Configuring JPA loaders

Configuring HTTP session managers

The HTTP session manager provides session replication capabilities for an associated application. The session manager works with the web container to create and manage the life cycles of HTTP sessions that are associated with the application.

About this task

- Configuring the HTTP session manager with WebSphere Application Server
  While WebSphere Application Server provides session management function, the performance degrades as the number of requests increases. WebSphere eXtreme Scale comes bundled with a session management implementation that provides session replication, high availability, better scalability, and more robust configuration options.
- Configuring HTTP session manager with WebSphere Portal
  You can persist HTTP sessions from WebSphere Portal into a data grid.
- Configuring the HTTP session manager for various application servers
  WebSphere eXtreme Scale is bundled with a session management implementation that overrides the default session manager for a web container. This implementation provides session replication, high availability, better scalability, and configuration options. You can enable the WebSphere eXtreme Scale session replication manager and generic embedded ObjectGrid container startup for various application servers such as Tomcat.
- XML files for HTTP session manager configuration
  When you start a container server that stores HTTP session data, you can either use the default XML files or you can specify customized XML files. These files create specific ObjectGrid names, number of replicas, and so on.
- Servlet context initialization parameters
  The following list of servlet context initialization parameters can be specified in the splicer properties file as required in the chosen splicing method.
- splicer.properties file
  The splicer.properties file contains all of the configuration options for configuring a servlet-filter-based session manager.

Configuring the HTTP session manager with WebSphere Application Server

While WebSphere® Application Server provides session management function, the performance degrades as the number of requests increases. WebSphere eXtreme Scale comes bundled with a session management implementation that provides session replication, high availability, better scalability, and more robust configuration options.

Before you begin

- WebSphere eXtreme Scale must be installed on your WebSphere Application Server or WebSphere Application Server Network Deployment cell to use the eXtreme Scale session manager. For more information, see Installing WebSphere eXtreme Scale or WebSphere eXtreme Scale Client with WebSphere Application Server.
- When WebSphere eXtreme Scale for HTTP session replication is used on WebSphere Application Server, the Allow overflow session management setting must be checked for every applicable web application and application server that hosts that web application. For more information, see Session management settings.
- Global security must be enabled in the WebSphere Application Server administrative console, if the catalog servers within your catalog service domain have Secure Sockets Layer (SSL) enabled. It must also be enabled if you want to use SSL for a catalog service domain with SSL supported. You require SSL for a catalog server by setting the transportType attribute to `SSL-Required` in the Server properties file. For more information about configuring global security, see Global security settings.

About this task

The WebSphere eXtreme Scale HTTP session manager supports both embedded and remote servers for caching.

- **Embedded scenario**

  In the embedded scenario, the data grid servers are collocated in the same processes where the servlets run. The session manager can communicate directly with the local ObjectGrid instance, avoiding costly network delays.

  If you are using WebSphere Application Server, place the supplied *wxs_home*/session/samples/objectGrid.xml and *wxs_home*/session/samples/objectGridDeployment.xml files into the META-INF directories of your web archive (WAR) files. eXtreme Scale automatically detects these files when the application starts and automatically starts the eXtreme Scale containers in the same process as the session manager.

  You can modify the objectGridDeployment.xml file. Modifying this file depends on whether you want to use synchronous or asynchronous replication and how many replicas you want configured.

- **Remote servers scenario**

In the remote servers scenario, the container servers that are run are in different processes than the servlets. The session manager communicates with a remote container server. To use a remote, network-attached container server, the session manager must be configured with the host names and port numbers of the catalog service domain. The session manager then uses an eXtreme Scale client connection to communicate with the catalog server and the container servers.

If the container servers are starting in independent, stand-alone processes, start the data grid containers with the objectGridStandAlone.xml and objectGridDeploymentStandAlone.xml files that are supplied in the session manager samples directory.

Procedure

1. Splice your application so that it can use the session manager. To use the session manager, you must add the appropriate filter declarations to the web deployment descriptors for the application. In addition, session manager configuration parameters are passed in to the session manager in the form of servlet context initialization parameters in the deployment descriptors. There are multiple ways in which you can introduce this information into your application:
   - **Auto-splice with WebSphere Application Server**
     You can configure your application to use the HTTP session manager for the data grid when you install your application. You can also edit the application or server configuration to use the WebSphere eXtreme Scale HTTP session manager. For more information, see Configuring WebSphere Application Server HTTP session persistence to a data grid.
   - **Splice the application with the addObjectGridFilter script**
     For more information about running this script, see Splicing a session data grid application with the addObjectGridFilter script.
   - **Auto-splice the application with custom properties**
     You do not need to manually splice your applications when the application is running in WebSphere Application Server or WebSphere Application Server Network Deployment.

     You can use this auto-splice option when your environment meets the following conditions:
     - You are using a deployment manager. The cell, server, and application scope are available scopes and are only available when you are running in a deployment manager. If you require a different scope, manually splice your web applications.
     - The splicer.properties file must be in at the same path on all nodes. The nodes are hosting an application server or applications that are being spliced for session replication. For mixed environments containing Windows and UNIX nodes, this option is not possible, so you must manually splice the application.

     Add the `com.ibm.websphere.xs.sessionFilterProps` custom property to either a cell or a server to set the splicer.properties file location for all of the web applications at that scope. The file exists on the deployment manager. If you want to indicate the splicer.properties file for a specific application with a cell-level custom property, enter the name of the custom property as: `<application_name>,com.ibm.websphere.xs.sessionFilterProps`, where *application_name* indicates the name of the application for which you want to apply the custom property. The value is the location of the splicer.properties file your applications require. An example path for the location of a file follows: /opt/splicer.properties.
   - **Manually splice the application with the Ant build script**
     WebSphere eXtreme Scale ships with a build.xml file that can be used by Apache Ant, which is included in the *was_root*/bin folder of a WebSphere Application Server installation. You can modify the build.xml file to change the session manager configuration properties. The configuration properties are identical to the property names in the splicer.properties file. You modify the build.xml file, start the Ant process by running the following command:
     - UNIX ant.sh, ws_ant.sh
     - Windows ant.bat, ws_ant.bat

     (UNIX) or (Windows).
   - **Manually update the web descriptor**
     Edit the web.xml file that is packaged with the web application to incorporate the filter declaration, its servlet mapping, and servlet context initialization parameters. Do not use this method because it is prone to errors.

   For a list of the parameters that you can use, see Servlet context initialization parameters.
2. Deploy the application. Deploy the application with your normal set of steps for a server or cluster. After you deploy the application, you can start the application.
3. Access the application. You can now access the application, which interacts with the session manager and WebSphere eXtreme Scale.

What to do next

You can change most of the configuration attributes for the session manager when you instrument your application to use the session manager. These attributes include: synchronous or asynchronous replication, in-memory session table size, and so on. Apart from the attributes that can be changed at application instrumentation time, the only other configuration attributes that you can change after the application deployment are the attributes that are related to the WebSphere eXtreme Scale server cluster topology and the way that their clients (session managers) connect to them.
Remote scenario behavior: If the entire data grid that is hosting the application session data is unreachable from the web container client, the client instead uses the base web container in WebSphere Application Server for session management. The data grid might be unreachable in the following scenarios:

- A network problem between the web container and the remote container servers.
- The remote container server processes have been stopped.

The number of session references kept in memory, which is specified by sessionTableSize parameter, is still maintained when the sessions are stored in the base web container. The least recently used sessions are invalidated from the web container session cache when the sessionTableSize value is exceeded. If the remote data grid becomes available, sessions that were invalidated from the web container cache can retrieve data from the remote data grid and load the data into a new session. If the entire remote data grid is not available and the session is invalidated from the session cache, the user session data is lost. Because of this issue, do not shut down the entire production remote data grid when the system is running under load.

- Configuring WebSphere Application Server HTTP session persistence to a data grid
  You can configure your WebSphere Application Server application to persist sessions to a data grid. This data grid can be in an embedded container server

that runs within WebSphere Application Server, or it can be in a remote data grid.

- Splicing a session data grid application with the addObjectGridFilter script
  Use the **addObjectGridFilter** command-line script to splice an application with filter declarations and configuration in the form of servlet context initialization parameters.
- Editing the splicer.properties file
  After you have configured the appliance to store HTTP sessions, you can edit other aspects of the HTTP session configuration with the splicer.properties file.

Configuring WebSphere Application Server HTTP session persistence to a data grid

You can configure your WebSphere® Application Server application to persist sessions to a data grid. This data grid can be in an embedded container server that runs within WebSphere Application Server, or it can be in a remote data grid.

Before you begin

Before you change the configuration in WebSphere Application Server, you must have:

- The name of the session data grid that you want to use. See Configuring the HTTP session manager with WebSphere Application Server for information about creating a session data grid.
- If the catalog service to manage your sessions is outside of the cell in which you are installing your session application, you must create a catalog service domain. For more information, see Creating catalog service domains in WebSphere Application Server.
- If you are configuring a catalog service domain, you might must enable client security on the catalog service domain if the container servers require authentication. These settings inform the run time which CredentialGenerator implementation to use. This implementation generates a credential to pass to the remote data grid. For more information, see Configuring client security on a catalog service domain.
- Enable global security in the WebSphere Application Server administrative console, if you support one of these scenarios:
  - The catalog servers within your catalog service domain have Secure Sockets Layer (SSL) enabled.
  - You want to use SSL for a catalog service domain with SSL supported.

  You require SSL for a catalog server by setting the transportType attribute to `SSL-Required` in the Server properties file. For more information about configuring global security, see Global security settings.
- If you are using Version 7.1.0.3 or later, you can persist sessions that use URL rewriting or cookies as a session tracking mechanism to the data grid. For releases before Version 7.1.0.3, you cannot persist sessions that use URL rewriting as a session tracking mechanism. To enable the persistence of sessions that use URL rewriting, set the useURLEncoding property to `true` in the splicer.properties file after you automatically splice the application.
- When you are automatically splicing applications for HTTP session management in WebSphere Application Server , all of the application servers that host the web application have the HttpSessionIdReuse web container custom property that is set to `true`. This property enables sessions that fail over from one application server to another, or are invalidated from the in-memory session cache in a remote scenario to preserve its session ID across requests. If you do not want this behavior, set the web container custom property to `false` on all of the applicable application servers before you configure session management for the applications. For more information about this custom property, see Troubleshooting cache integration.

Procedure

- **To configure session management when you are installing the application, complete the following steps:**
  1. In the WebSphere Application Server administrative console, click Applications > New application > New Enterprise Application. Choose the Detailed path for creating the application and complete the initial wizard steps.
  2. In the eXtreme Scale session management settings step of the wizard, configure the data grid that you want to use. Choose either the Remote eXtreme Scale data grid or the Embedded eXtreme Scale data grid.
     - For the Remote eXtreme Scale data grid option, choose the catalog service domain that manages the session data grid, and choose a data grid from the list of active session data grids.
     - For the Embedded eXtreme Scale data grid option, choose either the default ObjectGrid configuration or specify the specific location of your ObjectGrid configuration files.
  3. Complete the wizard steps to finish installing your application.

You can also install the application with a wsadmin script. In the following example, the -SessionManagement parameter creates the same configuration that you can in the administrative console:
For the remote eXtreme Scale data grid configuration:

```
AdminApp.install('C:/A.ear', '[  -nopreCompileJSPs -distributeApp
-nouseMetaDataFromBinary -nodeployejb -appname A -edition 8.0
-createMBeansForResources -noreloadEnabled -nodeployws -validateinstall
off -noprocessEmbeddedConfig -filepermission .*\.dll=755#.*\.so=755#.*\.a=755#.*\.sl=755
-buildVersion Unknown -noallowDispatchRemoteInclude -noallowServiceRemoteInclude
-asyncRequestDispatchType DISABLED -nouseAutoLink -SessionManagement [[true
XSRemoteSessionManagement cs0:!:grid0]]
-MapWebModToVH [[MicroWebApp microwebapp.war,WEB-INF/web.xml default_host] [MicroSipApp
microsipapp.war,WEB-INF/web.xml default_host] [MicroDG1App microdg1app.war,WEB-INF/web.xml
default_host] [MicroDG2App microdg2app.war,WEB-INF/web.xml default_host] [MicroSip2App
microsip2app.war,WEB-INF/web.xml default_host]]]')
```

For the eXtreme Scale embedded scenario with default configuration:

```
AdminApp.install('C:/A.ear', '[  -nopreCompileJSPs -distributeApp
-nouseMetaDataFromBinary -nodeployejb -appname A -edition 8.0
-createMBeansForResources -noreloadEnabled -nodeployws -validateinstall
off -noprocessEmbeddedConfig -filepermission .*\.dll=755#.*\.so=755#.*\.a=755#.*\.sl=755
-buildVersion Unknown -noallowDispatchRemoteInclude -noallowServiceRemoteInclude
-asyncRequestDispatchType DISABLED -nouseAutoLink -SessionManagement [[true
XSRemoteSessionManagement  :!: :!:default]]  -MapWebModToVH [[MicroWebApp microwebapp.war,
WEB-INF/web.xml default_host] [MicroSipApp
microsipapp.war,WEB-INF/web.xml default_host] [MicroDG1App microdg1app.war,WEB-INF/web.xml
default_host] [MicroDG2App microdg2app.war,WEB-INF/web.xml default_host] [MicroSip2App
microsip2app.war,WEB-INF/web.xml default_host]]]')
```

For the eXtreme Scale embedded scenario with a custom configuration:

```
AdminApp.install('C:/A.ear', '[  -nopreCompileJSPs -distributeApp
-nouseMetaDataFromBinary -nodeployejb -appname A -edition 8.0
-createMBeansForResources -noreloadEnabled -nodeployws -validateinstall
off -noprocessEmbeddedConfig -filepermission .*\.dll=755#.*\.so=755#.*\.a=755#.*\.sl=755
-buildVersion Unknown -noallowDispatchRemoteInclude -noallowServiceRemoteInclude
-asyncRequestDispatchType DISABLED -nouseAutoLink -SessionManagement [[true
XSRemoteSessionManagement  :!: :!:custom:!:c:\XS\objectgrid.xml:!:c:\XS\objectgriddeployment.xml]]
-MapWebModToVH [[MicroWebApp microwebapp.war,WEB-INF/web.xml default_host] [MicroSipApp
microsipapp.war,WEB-INF/web.xml default_host] [MicroDG1App microdg1app.war,WEB-INF/web.xml
default_host] [MicroDG2App microdg2app.war,WEB-INF/web.xml default_host] [MicroSip2App
microsip2app.war,WEB-INF/web.xml default_host]]]')
```

- **To configure session management on an existing application in the WebSphere Application Server administrative console:**
  Note: The Override session management box is checked when the application is set to use WebSphere eXtreme Scale. This means any server level session settings that were made to WebSphere Application Server configuration are overwritten by the application-level session settings. If you do not want to override settings, you can enable WebSphere eXtreme Scale at the server level.
  1. In the WebSphere Application Server administrative console, click Applications > Application Types > WebSphere enterprise applications > *application_name* > Web Module properties > Session management > eXtreme Scale session management settings.
  2. Update the fields to enable session persistence to a data grid.

  You can also update the application with a wsadmin script. In the following example, the -SessionManagement parameter creates the same configuration that you can in the administrative console:

  For the remote eXtreme Scale data grid configuration:

  ```
  AdminApp.edit('DefaultApplication','[-SessionManagement[[true
  XSRemoteSessionManagement cs0:!:grid0]]]')
  ```

  The `:!:` characters that are passed are used as delimiters. The values that are passed are:

  catalogServiceName*:!:*gridName

  For the eXtreme Scale embedded scenario with default configuration:

  ```
  AdminApp.edit('DefaultApplication','[-SessionManagement[[true
  XSEmbeddedSessionManagement :!:!:!:default]]]')
  ```

  The `:!:` characters that are passed are used as delimiters. The values that are passed are:

  ***catalogServiceName*:!:*gridName*:!:default:!:**
  absolutePath_to_objectGridXmlfile*:!:*absolutePath_to_DeploymentXmlfile

  For the eXtreme Scale embedded scenario with a custom configuration:

  ```
  AdminApp.edit('DefaultApplication','[-SessionManagement[[true
  XSEmbeddedSessionManagement
  :!:!:!:custom:!:c:\XS\objectgrid.xml:!:c:\XS\objectgriddeployment.xml]]]')
  ```

  The `:!:` characters that are passed are used as delimiters. The values that are passed are:

  ***catalogServiceName*:!:*gridName*:!:custom:!:**
  absolutePath_to_objectGridXmlfile*:!:*absolutePath_to_DeploymentXmlfile

  When you save the changes, the application uses the configured data grid for session persistence on the appliance.
- **To configure session management on an existing server:**
  1. In the WebSphere Application Server administrative console, click Servers > Server Types > WebSphere application servers > *server_name* > Session management > eXtreme Scale session management settings.

2. Update the fields to enable session persistence.

You can also configure session management on an existing server with the following wsadmin tool commands:

For the remote eXtreme Scale data grid configuration:

```
AdminTask.configureServerSessionManagement('[-nodeName IBM-C77EE220EB6Node01 -serverName server1
-enableSessionManagement true -sessionManagementType XSRemoteSessionManagement -XSRemoteSessionManagement
[-catalogService cs0 -csGridName grid0]]')
```

For the eXtreme Scale embedded configuration:

- The default configuration, if you are using the default XML files:

```
AdminTask.configureServerSessionManagement('[-nodeName IBM-C77EE220EB6Node01 -serverName server1
-enableSessionManagement true -sessionManagementType XSEmbeddedSessionManagement
-XSEmbeddedSessionManagement [-embeddedGridType default -objectGridXML -objectGridDeploymentXML ]]')
```

- The custom configuration, if you are using customized XML files:

```
AdminTask.configureServerSessionManagement('[-nodeName IBM-C77EE220EB6Node01 -serverName server1
-enableSessionManagement true -sessionManagementType XSEmbeddedSessionManagement
-XSEmbeddedSessionManagement
[-embeddedGridType custom -objectGridXML c:\XS\objectgrid.xml -objectGridDeploymentXML
c:\XS\objectgriddeployment.xml]]')
```

When you save the changes, the server now uses the configured data grid for session persistence with any applications that are running on the server.

Results

You configured HTTP session manager to persist the sessions to a data grid. Entries are removed from the data grid when the sessions time out. See Session management settings for more information about updating the session timeout value in the WebSphere Application Server administrative console.

- eXtreme Scale session management settings
  You can configure your WebSphere Application Server applications to use WebSphere eXtreme Scale or a WebSphere DataPower® XC10 Appliance for session persistence.

eXtreme Scale session management settings

You can configure your WebSphere® Application Server applications to use WebSphere eXtreme Scale or a WebSphere DataPower® XC10 Appliance for session persistence.

You can edit these settings in the enterprise application installation wizard, or on the application or server detail pages:

- Version 6.1: Applications > Install new application
- Version 6.1: Applications > Enterprise Applications > *application_name*
- Version 6.1: Servers > Application servers > *server_name* > Web container settings > Session management
- Version 7.0: Applications > New application > New Enterprise Application, and choose the Detailed path for creating the application.
- Version 7.0: Applications > Application Types > WebSphere enterprise applications > *application_name* > Web Module properties > Session management > Session management settings
- Version 7.0: Servers > Server Types > WebSphere application servers > *server_name* > Container settings > Session management settings

Enable session management

Enables session management to use WebSphere eXtreme Scale embedded or remote data grid or a WebSphere DataPower XC10 Appliance for session persistence.

Manage session persistence by

Specifies how session persistence is managed. You can choose one of the following options:

- WebSphere DataPower XC10 Appliance
- Remote eXtreme Scale data grid
- Embedded eXtreme Scale data grid

The remaining settings that you configure depend on the session persistence mechanism you choose.

WebSphere DataPower XC10 Appliance specific settings

The following settings are specific to configuring the WebSphere DataPower XC10 Appliance for session persistence.

IP or host name of the WebSphere DataPower XC10 Appliance

Specifies the IP or host name of the appliance to use for persisting sessions.

IBM® WebSphere DataPower XC10 Appliance administrative credentials

Specifies the User name and Password that you use to log in to the DataPower XC10 Appliance user interface. Click Test Connection... to test the connection to your appliance.

Session persistence preference

Specifies the data grid on which sessions are persisted. You can choose one of the following options:

- Persist sessions in a new data grid on the IBM WebSphere DataPower XC10 Appliance. You can then specify a Data grid name.
- Persist sessions in an existing data grid on the IBM WebSphere DataPower XC10 Appliance. You can then enter or browse for an Existing data grid name.

Remote eXtreme Scale data grid configuration

The following settings are specific to configuring the remote eXtreme Scale grid for session persistence.

Catalog service domain that manages the remote session data grid

Specifies the catalog service domain that you want to use to manage your sessions.

If no catalog service domains are displayed, or you want to create a new catalog service domain, click System administration > WebSphere eXtreme Scale > Catalog service domains.

Remote data grid in which to store session information

Specifies the name of the data grid in the catalog service domain in which you want to store your session information. The list of active remote grids is populated when you select a catalog service. The remote data grid must already exist in the eXtreme Scale configuration.

Embedded eXtreme Scale data grid configuration

The following settings are specific to configuring an embedded eXtreme Scale configuration. In the embedded eXtreme Scale scenario, the eXtreme Scale processes are hosted by WebSphere Application Server processes.

eXtreme Scale embedded data grid configuration

- Use default ObjectGrid configuration
- Specify custom ObjectGrid configuration files

Full path to objectgrid.xml file to copy into configuration
: Specifies the full path to the objectgrid.xml file for the configuration that you want to use.

Full path to objectgriddeployment.xml file to copy into configuration
: Specifies the full path to the objectgriddeployment.xml file for the configuration that you want to use.

Configuring HTTP session manager with WebSphere Portal

You can persist HTTP sessions from WebSphere® Portal into a data grid.

Before you begin

Your WebSphere eXtreme Scale and WebSphere Portal environment must meet the following requirements:

- How you install WebSphere eXtreme Scale depends on your deployment scenario. You can run the container servers, which host the data grids, either inside or outside of the WebSphere Application Server cell:
  - If you are running container servers in the WebSphere Application Server cell **(embedded scenario)**: Install both the WebSphere eXtreme Scale client and server on your WebSphere Application Server and WebSphere Portal nodes.
  - If you are running container servers outside of the WebSphere Application Server cell **(remote scenario)**: Install WebSphere eXtreme Scale Client on your WebSphere Application Server and WebSphere Portal nodes.

  See Installing WebSphere eXtreme Scale or WebSphere eXtreme Scale Client with WebSphere Application Server for more information.
- WebSphere Portal Version 7 or later.
- Custom portlets must be configured within WebSphere Portal. The administrative portlets that come with WebSphere Portal cannot currently be integrated with data grids.

About this task

Introducing WebSphere eXtreme Scale into a WebSphere Portal environment can be beneficial in the following scenarios:
Important: Although the following scenarios introduce benefits, increased processor usage in the WebSphere Portal tier can result from introducing WebSphere eXtreme Scale into the environment.

- **When session persistence is required.**
  For example, if the session data from your custom portlets must stay available during a WebSphere Portal Server failure, you can persist the HTTP sessions to the WebSphere eXtreme Scale data grid. Data replicates among many servers, increasing data availability.
- **In a multiple data center topology.**
  If your topology spans multiple data centers across different physical locations, you can persist the WebSphere Portal HTTP sessions to the WebSphere eXtreme Scale data grid. The sessions replicate across data grids in the data centers. If a data center fails, the sessions are rolled over to another data center that has a copy of the data grid data.
- **To lower memory requirements on the WebSphere Portal Server tier.**
  By offloading session data to a remote tier of container servers, a subset of sessions are on the WebSphere Portal servers. This offload of data reduces the memory requirements on the WebSphere Portal Server tier.

Procedure

1. Splice the wps WebSphere Portal application and any custom portlets to enable the sessions to be stored in the data grid.
   See Configuring WebSphere Application Server HTTP session persistence to a data grid for more information. This action results in the splicing of the custom portlets to enable session persistance to your data grid.

   You can splice the application by configuring HTTP session management when you deploy the application, or you can use custom properties to automatically splice your applications. See Configuring the HTTP session manager with WebSphere Application Server for more information about splicing the application.

2. If you are using the remote scenario, where your container servers are outside of the WebSphere Application Server, explicitly start remote eXtreme Scale containers for remote HTTP session persistence scenarios. Start the containers with the XS/ObjectGrid/session/samples/objectGridStandAlone.xml and objectGridDeploymentStandAlone.xml configuration files. For example, you might use the following command: UNIX Linux

   ```
   startOgServer.sh xsContainer1 -catalogServiceEndPoints <host>:<port>
   -objectgridFile XS/ObjectGrid/session/samples/objectGridStandAlone.xml -deploymentPolicyFile
   XS/ObjectGrid/session/samples/objectGridDeploymentStandAlone.xml
   ```

   For more information about starting container servers, see Starting container servers . If you are using an embedded scenario, see Configuring container servers in WebSphere Application Server for more information about configuring and starting container servers.
3. Some versions of WebSphere Portal server can have runtime errors when cookies are added to an HTTP response. Since adds cookies for failover and other purposes, these cookies need to be added to WebSphere Portal server cookie ignore list. For more information, see the cookie.ignore.regex parameter section of Caching pages shared by multiple users on the IBM WebSphere Portal wiki. The two cookies that need to be added to the list are IBMID.* and IBMSessionHandle.*. The updated list may look like this for example `"digest\\.ignore.*|LtpaToken|LtpaToken2|JSESSIONID|IBMID.*|IBMSessionHandle.*"`. For more information, see Caching pages shared by multiple users on the IBM WebSphere Portal wiki.
4. Restart the WebSphere Portal servers. See WebSphere Portal Version 7: Starting and stopping servers, deployment managers, and node agents for more information.

Results

You can access the WebSphere Portal Server, and HTTP session data for the configured custom portlets is persisted to the data grid.
If the entire data grid that is hosting the application session data is unreachable from the web container client, the client instead uses the base web container in WebSphere Application Server for session management. The data grid might be unreachable in the following scenarios:

- A network problem between the Web container and the remote container servers.
- The remote container server processes have been stopped.

The number of session references kept in memory, specified by sessionTableSize parameter, is still maintained when the sessions are stored in the base web container. The least recently used sessions are invalidated from the web container session cache when the sessionTableSize value is exceeded. If the remote data grid becomes available, sessions that were invalidated from the web container cache can retrieve data from the remote data grid and load the data into a new session. If the entire remote data grid is not available and the session is invalidated from the session cache, the user's session data is lost. Because of this issue, you should not shut down the entire production remote data grid when the system is running under load.

Configuring the HTTP session manager for various application servers

WebSphere® eXtreme Scale is bundled with a session management implementation that overrides the default session manager for a web container. This implementation provides session replication, high availability, better scalability, and configuration options. You can enable the WebSphere eXtreme Scale session replication manager and generic embedded ObjectGrid container startup for various application servers such as Tomcat.

About this task

You can use the HTTP session manager with other application servers that are not running WebSphere Application Server, such as WebSphere Application Server Community Edition. To configure other application servers to use the data grid, you must splice your application and incorporate WebSphere eXtreme Scale Java archive (JAR) files into your application.

Procedure

1. Splice your application so that it can use the session manager. To use the session manager, you must add the appropriate filter declarations to the web deployment descriptors for the application. In addition, session manager configuration parameters are passed in to the session manager in the form of servlet context initialization parameters in the deployment descriptors. There are three ways in which you can introduce this information into your application:
   - **addObjectGridFilter** script: For more information, see Splicing a session data grid application with the addObjectGridFilter script.
   - Ant build script:
     WebSphere eXtreme Scale ships with a build.xml file that can be used by Apache Ant, which is included in the *was_root*/bin folder of a WebSphere Application Server installation. You can modify the build.xml file to change the session manager configuration properties. The configuration properties are identical to the property names in the splicer.properties file. After the build.xml file has been modified, invoke the Ant process by running ant.sh, ws_ant.sh (UNIX) or ant.bat, ws_ant.bat (Windows).

   - Update the web descriptor manually:
     Edit the web.xml file that is packaged with the web application to incorporate the filter declaration, its servlet mapping, and servlet context initialization parameters. Do not use this method because it is prone to errors.

   For a list of the parameters that you can use, see Servlet context initialization parameters.
2. Incorporate the WebSphere eXtreme Scale session replication manager JAR files into your application. You can embed the files into the application module WEB-INF/lib directory or in the application server classpath. The required JAR files vary depending on the type of containers that you are using:
   - Remote container servers: ogclient.jar and sessionobjectgrid.jar
   - Embedded container servers: objectgrid.jar and sessionobjectgrid.jar
3. Optional: If you use remote container servers, start the container servers. See Starting a stand-alone catalog service for details.
4. Deploy the application. Deploy the application with your normal set of steps for a server or cluster. After you deploy the application, you can start the application.
5. Access the application. You can now access the application, which interacts with the session manager and WebSphere eXtreme Scale.

What to do next

You can change a majority of the configuration attributes for the session manager when you instrument your application to use the session manager. These attributes include variations to the replication type (synchronous or asynchronous), in-memory session table size, and so on. Apart from the attributes that can be changed at application instrumentation time, the only other configuration attributes that you can change after the application deployment are the attributes that are related to the WebSphere eXtreme Scale server cluster topology and the way that their clients (session managers) connect to them.
Remote scenario behavior: If the entire data grid that is hosting the application session data is unreachable from the web container client, the client instead uses the base web container of the application server for session management. The data grid might be unreachable in the following scenarios:

- A network problem between the Web container and the remote container servers.
- The remote container server processes have been stopped.

The number of session references kept in memory, specified by sessionTableSize parameter, is still maintained when the sessions are stored in the base web container. The least recently used sessions are invalidated from the web container session cache when the sessionTableSize value is exceeded. If the remote data grid becomes available, sessions that were invalidated from the web container cache can retrieve data from the remote data grid and load the data into a new session. If the entire remote data grid is not available and the session is invalidated from the session cache, the user session data is lost. Because of this issue, do not shut down the entire production remote data grid when the system is running under load.

XML files for HTTP session manager configuration

When you start a container server that stores HTTP session data, you can either use the default XML files or you can specify customized XML files. These files create specific ObjectGrid names, number of replicas, and so on.

Sample files location

These XML files are packaged in *wxs_install_root*/ObjectGrid/session/samples for a stand-alone installation or *was_root*/optionalLibraries/ObjectGrid/session/samples for WebSphere® eXtreme Scale installed in a WebSphere Application Server cell.

Embedded XML package

If you are configuring an embedded scenario, the container server starts in the web container tier. Use the objectGrid.xml file and objectGridDeployment.xml file, which are provided by default. You can update these files to customize the behavior of the HTTP session manager.
Figure 1. objectGrid.xml file

```
<?xml version="1.0" encoding="UTF-8"?>
<objectGridConfig xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="http://ibm.com/ws/objectgrid/config ../objectGrid.xsd"
xmlns="http://ibm.com/ws/objectgrid/config">
        <objectGrids>
                <objectGrid name="session" txTimeout="30">
                        <bean
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_rxssessxml_ObjectGridEventListener"
className="com.ibm.ws.xs.sessionmanager.SessionHandleManager"/>
                        <backingMap name="objectgridSessionMetadata" pluginCollectionRef="objectgridSessionMetadata"
readOnly="false"
                                    lockStrategy="PESSIMISTIC" ttlEvictorType="LAST_ACCESS_TIME" timeToLive="3600"
copyMode="NO_COPY"/>
                        <backingMap name="objectgridSessionAttribute.*" template="true" readOnly="false"
lockStrategy="PESSIMISTIC"
                                    ttlEvictorType="NONE" copyMode="NO_COPY"/>
       <backingMap name="objectgridSessionTTL.*" template="true" readOnly="false" lockStrategy="PESSIMISTIC"
                                    ttlEvictorType="LAST_ACCESS_TIME" timeToLive="3600" copyMode="NO_COPY"/>
                </objectGrid>
        </objectGrids>
    <backingMapPluginCollections>
        <backingMapPluginCollection
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_rxssessxml_objectgridSessionMetadata"
>
            <bean
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_rxssessxml_MapEventListener"
className="com.ibm.ws.xs.sessionmanager.MetadataMapListener"/>
        </backingMapPluginCollection>
    </backingMapPluginCollections>
</objectGridConfig>
```

Values you can change:

ObjectGrid name attribute
The value must match the following values in other configuration files:

- The objectGridName property in the splicer.properties file that is used to splice the web application.
- The objectgridName attribute in the objectGridDeployment.xml file.

If you have multiple applications, and you want the session data to be stored in different data grids, those applications must have different ObjectGrid name attribute values.

ObjectGrid txTimeout attribute
This value determines how many seconds a transaction can be open before the container server triggers the transaction to time out. The default is 30 seconds, and can be changed depending on the environment. If the HTTP session persistence is configured with the replicationInterval servlet context initialization parameter value set greater than zero, transactions are batched on a thread. If the replicationInterval property is set to `0`, a transaction typically starts when a web application retrieves a valid HttpSession object. The transaction commits at the end of the web application request. If your environment has requests that take longer than 30 seconds, set this value accordingly.

Values you cannot change:

ObjectGridEventListener
The ObjectGridEventListener line cannot be changed and is used internally.
objectgridSessionMetadata

The objectgridSessionMetadata line refers to the map where the HTTP session metadata is stored. There is one entry for every HTTP session stored in the data grid in this map.

objectgridSessionTTL.*

This value cannot be changed and is for future use.

objectgridSessionAttribute.*

The `objectgridSessionAttribute.*` text defines a dynamic map. This value is used to create the map in which HTTP session attributes are stored when the fragmentedSession parameter is set to `true` in the splicer.properties file. This dynamic map is called `objectgridSessionAttribute`. Another map is created based on this template called `objectgridSessionAttributeEvicted`, which stores sessions that have timed out, but the web container has not invalidated.

A time to live policy (TTL) is defined for the objectgridSessionMetadata map definition. The other map, objectgridSessionAttribute is dependant on this map and does not require a TTL parameter. For each active HTTP session, an entry gets created in the objectgridSessionMetadata map, and one entry in the objectgridSessionAttribute map for every session attribute. If an in-memory session does not exist due to an application server failure or a session is removed from the in-memory cache on the application server, the grid must initiate the session invalidation using the TTL eviction policy. At the time of eviction, the attributes are removed from the objectgridSessionAttribute map and inserted into a dynamically created map called objectgridSessionAttributeEvicted map. The data is stored in this map until an application server can remove the session and complete session invalidation. Therefore, the TTL parameter is only required in the objectgridSessionMetadata map definition.

Note: The objectgridSessionTTL is not used by WebSphere eXtreme Scale in the current release.

The MapEventListener line is internal and cannot be modified.

Figure 2. objectGridDeployment.xml file

```
<?xml version="1.0" encoding="UTF-8"?>
<deploymentPolicy xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
        xsi:schemaLocation="http://ibm.com/ws/objectgrid/deploymentPolicy ../deploymentPolicy.xsd"
        xmlns="http://ibm.com/ws/objectgrid/deploymentPolicy">

        <objectgridDeployment objectgridName="session">
                <mapSet name="sessionMapSet" numberOfPartitions="5" minSyncReplicas="0" maxSyncReplicas="0"
                        maxAsyncReplicas="1" developmentMode="false" placementStrategy="PER_CONTAINER">
            <map ref="objectgridSessionMetadata"/>
            <map ref="objectgridSessionAttribute.*"/>
            <map ref="objectgridSessionTTL.*"/>
    </mapSet>
   </objectgridDeployment>
</deploymentPolicy>
```

Values you can change:

ObjectGrid name attribute

The value must match the following values in other configuration files:

- The objectGridName property in the splicer.properties file that is used to splice the web application.
- The ObjectGrid name attribute in the objectGrid.xml file.

If you have multiple applications, and you want the session data to be stored in different data grids, those applications must have different ObjectGrid name attribute values.

mapSet element attributes

You can change all mapSet properties except for the placementStrategy attribute.

Name

Can be updated to any value.

numberOfPartitions

Specifies the number of primary partitions that are started in each server that is hosting the web application. As you add partitions, the data becomes more spread out in the event of a failover. The default value is `5` partitions, and is fine for most applications.

minSyncReplicas, maxSyncReplicas, and maxAsyncReplicas

Specifies the number and type of replicas that store the HTTP session data. The default is `1` asynchronous replica, which is fine for most applications. Synchronous replication occurs during the request path, which can increase the response times for your web application.

developmentMode

Informs the eXtreme Scale placement service whether the replica shards for a partition can be placed on the same node as its primary shard. You can set the value to true in a development environment, but disable this function in a production environment because a node failure could cause the loss of session data.

placementStrategy

Do not change the value of this attribute.

The rest of the file refers to the same map names as in the objectGrid.xml file. These names cannot be changed.

Values you cannot change:

- The placementStrategy attribute on the mapSet element.

Remote XML package

When you are using the remote mode, where the containers run as stand-alone processes, you must use the objectGridStandAlone.xml file and the objectGridDeploymentStandAlone.xml file to start the processes. You can update these files to modify the configuration.

Figure 3. objectGridStandAlone.xml file

```
<?xml version="1.0" encoding="UTF-8"?>
<objectGridConfig xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
        xsi:schemaLocation="http://ibm.com/ws/objectgrid/config ../objectGrid.xsd"
        xmlns="http://ibm.com/ws/objectgrid/config">
        <objectGrids>
                <objectGrid name="session" txTimeout="30">
```

```
                        <bean
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_rxssessxml_ObjectGridEventListener"
className="com.ibm.ws.xs.sessionmanager.SessionHandleManager"/>
            <backingMap name="objectgridSessionMetadata" pluginCollectionRef="objectgridSessionMetadata"
                                                         readOnly="false" lockStrategy="PESSIMISTIC"
ttlEvictorType="LAST_ACCESS_TIME" timeToLive="3600"
                                                         copyMode="COPY_TO_BYTES"/>
            <backingMap name="objectgridSessionAttribute.*" template="true" readOnly="false" lockStrategy="PESSIMISTIC"
                                                         ttlEvictorType="NONE" copyMode="COPY_TO_BYTES"/>
            <backingMap name="objectgridSessionTTL.*" template="true" readOnly="false" lockStrategy="PESSIMISTIC"
                                                         ttlEvictorType="LAST_ACCESS_TIME" timeToLive="3600"
copyMode="COPY_TO_BYTES"/>
                </objectGrid>
        </objectGrids>
    <backingMapPluginCollections>
        <backingMapPluginCollection
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_rxssessxml_objectgridSessionMetadata"
>
            <bean
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_rxssessxml_MapEventListener"
className="com.ibm.ws.xs.sessionmanager.MetadataMapListener"/>
        </backingMapPluginCollection>
    </backingMapPluginCollections>
</objectGridConfig>
```

Values you can change:

ObjectGrid name attribute

The value must match the following values in other configuration files:

- The objectGridName property in the splicer.properties file that is used to splice the web application.
- The objectgridName attribute in the objectGridStandAlone.xml file.

If you have multiple applications, and you want the session data to be stored in different data grids, those applications must have different ObjectGrid name attribute values.

ObjectGrid txTimeout attribute

This value determines how many seconds a transaction can be open before the container server triggers the transaction to time out. The default is 30 seconds, and can be changed depending on the environment. If the HTTP session persistence is configured with the replicationInterval servlet context initialization parameter value set greater than zero, transactions are batched on a thread. If the replicationInterval property is set to `0`, a transaction typically starts when a web application retrieves a valid HttpSession object. The transaction commits at the end of the web application request. If your environment has requests that take longer than 30 seconds, set this value accordingly.

Values you cannot change:

ObjectGridEventListener

The ObjectGridEventListener line cannot be changed and is used internally.

objectgridSessionMetadata

The objectgridSessionMetadata line refers to the map where the HTTP session metadata is stored. There is one entry for every HTTP session stored in the data grid in this map.

objectgridSessionTTL.*

This value cannot be changed and is for future use.

objectgridSessionAttribute.*

The `objectgridSessionAttribute.*` text defines a dynamic map. This value is used to create the map in which HTTP session attributes are stored when the fragmentedSession parameter is set to `true` in the splicer.properties file. This dynamic map is called `objectgridSessionAttribute`. Another map is created based on this template called `objectgridSessionAttributeEvicted`, which stores sessions that have timed out, but the web container has not invalidated.

A time to live policy (TTL) is defined for the objectgridSessionMetadata map definition. The other map, objectgridSessionAttribute is dependant on this map and does not require a TTL parameter. For each active HTTP session, an entry gets created in the objectgridSessionMetadata map, and one entry in the objectgridSessionAttribute map for every session attribute. If an in-memory session does not exist due to an application server failure or a session is removed from the in-memory cache on the application server, the grid must initiate the session invalidation using the TTL eviction policy. At the time of eviction, the attributes are removed from the objectgridSessionAttribute map and inserted into a dynamically created map called objectgridSessionAttributeEvicted map. The data is stored in this map until an application server can remove the session and complete session invalidation. Therefore, the TTL parameter is only required in the objectgridSessionMetadata map definition.

Note: The objectgridSessionTTL is not used by WebSphere eXtreme Scale in the current release.

The MetadataMapListener line is internal and cannot be modified.

Figure 4. objectGridDeploymentStandAlone.xml file

```
<?xml version="1.0" encoding="UTF-8"?>
<deploymentPolicy xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
        xsi:schemaLocation="http://ibm.com/ws/objectgrid/deploymentPolicy ../deploymentPolicy.xsd"
        xmlns="http://ibm.com/ws/objectgrid/deploymentPolicy">

        <objectgridDeployment objectgridName="session">
                <mapSet name="sessionMapSet" numberOfPartitions="47" minSyncReplicas="0" maxSyncReplicas="0"
                        maxAsyncReplicas="1" developmentMode="false" placementStrategy="FIXED_PARTITIONS">
            <map ref="objectgridSessionMetadata"/>
            <map ref="objectgridSessionAttribute.*"/>
            <map ref="objectgridSessionTTL.*"/>
            </mapSet>
    </objectgridDeployment>
</deploymentPolicy>
```

Values you can change:

objectgridName attribute

The value must match the following values in other configuration files:

- The objectGridName property in the splicer.properties file that is used to splice the web application.
- The ObjectGrid name attribute in the objectGrid.xml file.

If you have multiple applications, and you want the session data to be stored in different data grids, those applications must have different ObjectGrid name attribute values.

mapSet element attributes
: You can change all mapSet properties.

Name
: Can be updated to any value.

numberOfPartitions
: The default fixed partition placement strategy is enabled with the FIXED_PARTITIONS setting. This setting specifies the number of total partitions that are spread across all running grid containers. The default value is `47` partitions, and is fine for most applications. If a per container placement strategy is used with the PER_CONTAINER setting, then this specifies the number of primary partitions started in each grid container. As you add partitions, the data becomes more spread out in the event of a failover. The recommended value is `5` for the per container strategy.

minSyncReplicas, maxSyncReplicas, and maxAsyncReplicas
: Specifies the number of primary partitions that are started in each server that is hosting the web application. As you add partitions, the data becomes more spread out in the event of a failover. The default value is `5` partitions, and is fine for most applications.

developmentMode
: Informs the eXtreme Scale placement service whether the replica shards for a partition can be placed on the same node as its primary shard. You can set the value to true in a development environment, but disable this function in a production environment because a node failure could cause the loss of session data.

placementStrategy
: You can change this attribute to one of the following:

- FIXED_PARTITIONS This is the default value and is the preferred approach for using a remote HTTP Session topology. It is required if you are using Multi-Master replication
- PER_CONTAINER This is still a supported configuration in a remote topology.

Servlet context initialization parameters

The following list of servlet context initialization parameters can be specified in the splicer properties file as required in the chosen splicing method.

Parameters

applicationQualifiedCookies
: A string value of either `true` or `false`. Set to `true` if your environment contains multiple applications that use unique cookie names. Default is `false`, which assumes all applications are using the same cookie name.

authenticationRetryCount
: Specifies the retry count for authentication if the credential is expired. If the value is set to 0, there will not be any authentication retry.

catalogHostPort
: The catalog server can be contacted to obtain a client side ObjectGrid instance. The value must be of the form `host:port<,host:port>`. The host is the listener host on which the catalog server is running. The port is the listener port for that catalog server process. This list can be arbitrarily long and is used for bootstrapping only. The first viable address is used. It is optional inside WebSphere® Application Server if the catalog.services.cluster property is configured.

credentialAuthentication
: Specifies the client credential authentication support.The possible values are:

- Never- The client does not support credential authentication.
- Supported - The client supports the credential authentication if and only if the server supports too.
- Required - The client requires the credential authentication. The default value is Supported.

cookieDomain
: Specifies if you require sessions to be accessible across hosts. Set the value to the name of the common domain between the hosts.

cookiePath
: Specifies the name of the class that implements the com.ibm.websphere.objectgrid.security.plugins.CredentialGenerator interface. This class is used to get credentials for clients.

credentialGeneratorClass
: The name of the class that implements the com.ibm.websphere.objectgrid.security.plugins.CredentialGenerator interface. This class is used to obtain credentials for clients.

credentialGeneratorProps
: The properties for the CredentialGenerator implementation class. The properties are set to the object with the setProperties(String) method. The credentialGeneratorProps value is used only if the value of the credentialGeneratorClass property is not null.

enableSessionStats
: A string value of either `true` or `false`. Enables eXtreme Scale client HTTP Sessions statistics tracking.

fragmentedSession
: A string value of either `true` or `false`. The default value is `true`. Use this setting to control whether the product stores session data as a whole entry, or stores each attribute separately.

  Set the fragmentedSession parameter to `true` if the web application session has many attributes or attributes with large sizes. Set fragmentedSession to `false` if a session has few attributes, because all the attributes are stored in the same key in the data grid.

  In the previous, filter-based implementation, this property was referred to as persistenceMechanism, with the possible values of ObjectGridStore (fragmented) and ObjectGridAtomicSessionStore (not fragmented).

objectGridType
: A string value of either `REMOTE` or `EMBEDDED`. The default is `REMOTE`.

  If it is set to `REMOTE`, the session data is stored outside of the server on which the web application is running.

  If it is set to `EMBEDDED`, an embedded eXtreme Scale container starts in the application server process on which the web application is running.

objectGridName
: A string value that defines the name of the ObjectGrid instance used for a particular web application. The default name is session.

  This property must reflect the objectGridName in both the ObjectGrid XML and deployment XML files used to start the eXtreme Scale container servers.

objectGridXML
: The file location of the objectgrid.xml file. The built-in XML file packaged in the eXtreme Scale library is loaded automatically if `objectGridType=EMBEDDED` and the objectGridXML property is not specified.

objectGridDeploymentXML
: Specifies the location of the objectGrid deployment policy XML file. The built-in XML file packaged in the eXtreme Scale library is loaded automatically if `objectGridType=EMBEDDED` and the objectGridDeploymentXML property is not specified.

replicationInterval
: An integer value (in seconds) that defines the time between writing of updated sessions to ObjectGrid. The default is `10` seconds. Possible values are from 0 to 60. 0 means that updated sessions are written to the ObjectGrid at the end of servlet service method call for each request. A higher replicationInterval value improves performance because fewer updates are written to the data grid. However, a higher value makes the configuration less fault tolerant.

  This setting applies only when objectGridType is set to `REMOTE`.

reuseSessionID
: A string value of either `true` or `false`. The default is `false`. Set to `true` if the underlying web container reuses session IDs across requests to different hosts. The value of this property must be the same as the value in the web container. If you are using WebSphere Application Server and configuring eXtreme Scale HTTP session persistence using the administrative console or **wsadmin** tool scripting, the web container custom property `HttpSessionIdReuse=true` is added by default. The reuseSessionID is also set to `true`. If you do not want the session IDs to be reused, set the `HttpSessionIdReuse=false` custom property on the web container custom property before you configure eXtreme Scale session persistence.

sessionIdOverrideClass
: The name of the class that implements the com.ibm.websphere.xs.sessionmanager.SessionIDOverride interface. This class is used to override the unique session identifier retrieved with the HttpSession.getId() method so that all applications have the same ID. The default is to use the user ID derived from the HttpSession.getId().

sessionStatsSpec = session.all = enabled
: A string of eXtreme Scale client HTTP statistics specification.

shareSessionsAcrossWebApps
: A string value of either `true` or `false`. The default is `false`. Specifies if sessions are shared across web applications, specified as a string value of either `true` or `false`. The servlet specification states that HTTP Sessions cannot be shared across web applications. An extension to the servlet specification is provided to allow this sharing.

sessionTableSize
: An integer value that defines the number of session references kept in memory. The default is `1000`.

  This setting pertains only to a `REMOTE` topology because the `EMBEDDED` topology already has the session data in the same tier as the web container.

  Sessions are evicted from the in-memory table based on least recently used (LRU) logic. When a session is evicted from the in-memory table, it is invalidated from the web container. However, the data is not removed from the grid, so subsequent requests for that session can still retrieve the data. This value must be set higher than the web container maximum thread pool value, which reduces contention on the session cache.

securityEnabled
: A string value of either `true` or `false`. The default value is `false`. This setting enables eXtreme Scale client security. It must match the securityEnabled setting in the eXtreme Scale server properties file. If the settings do not match, an exception occurs.

sessionIdOverrideClass
: Overrides the retrieved session ID of an application. The default is to use the ID derived from the HttpSession.getId() method. Enables eXtreme Scale client HTTP Sessions to override the unique session ID of an application so that all applications are retrieved with the same ID. Set to the implementation of the com.ibm.websphere.xs.sessionmanager.SessionIDOverride interface. This interface determines the HttpSession ID based on the HttpServletRequest object.

traceSpec
: Specifies the IBM® WebSphere trace specification as a string value. Use this setting for application servers other than WebSphere Application Server.

traceFile
: Specifies the trace file location as a string value. Use this setting for application servers other than WebSphere Application Server.

useURLEncoding
: A string value of either `true` or `false`. The default is `false`. Set to `true` if you want to enable URL rewriting. The default value is `false`, which indicates that cookies are used to store session data. The value of this parameter must be the same as the web container settings for session management.

useCookies
: A string value of either `true` or `false`. Set to true if the underlying web container will reuse session ID's across requests to different hosts. The default is `false`. The value of this should be the same as what is set in the web container.

splicer.properties file

The splicer.properties file contains all of the configuration options for configuring a servlet-filter-based session manager.

Sample splicer properties

If you choose to use any of the additional properties that are described in this file, be sure to uncomment the lines for the properties that you want to enable.

```
# Properties file that contains all the configuration
# options that the servlet filter based ObjectGrid session
# manager can be configured to use.
#
# This properties file can be made to hold all the default
# values to be assigned to these configuration settings, and
# individual settings can be overridden using ANT Task
# properties, if this properties file is used in conjunction
# with the filtersplicer ANT task.

# A string value of either "REMOTE" or "EMBEDDED".  The default is REMOTE.
# If it is set to "REMOTE", the session data will be stored outside of
# the server on which the web application is running. If it is set to
# "EMBEDDED", an embedded WebSphere eXtreme Scale container will start
# in the application server process on which the web application is running.

objectGridType = REMOTE

# A string value that defines the name of the ObjectGrid
# instance used for a particular web application. The default name
# is session. This property must reflect the objectGridName in both
# the objectgrid xml and deployment xml files used to start the eXtreme
# Scale containers.

objectGridName = session

# Catalog Server can be contacted to obtain a client side
# ObjectGrid instance.  The value needs to be of the
# form "host:port<,host:port>", where the host is the listener host
# on which the catalog server is running, and the port is the listener
# port for that catalog server process.
# This list can be arbitrarily long and is used for bootstrapping only.
# The first viable address will be used.  It is optional inside WebSphere
# if the catalog.services.cluster property is configured.

# catalogHostPort = host:port<,host:port>

# An integer value (in seconds) that defines the time in seconds between
# writing of updated sessions to ObjectGrid. The default is 10. This property
# is only used when objectGridType is set to REMOTE. Possible values are
# from 0 to 60. 0 means updated sessions are written to the ObjectGrid
# at the end of servlet service method call for each request.

replicationInterval = 10

# An integer value that defines the number of session references
# kept in memory. The default is 1000. This property is only used when
# objectGridType is set to REMOTE. When the number of sessions stored
# in memory in the web container exceeds this value, the least recently
# accessed session is invalidated from the web container. If a request
# comes in for that session after it's been invalidated, a new session
```

```
# will be created (with a new session ID if reuseSessionId=false),
# populated with the invalidated session's attributes. This value should
# always be set to be higher than the maximum size of the web container
# thread pool to avoid contention on this session cache.

sessionTableSize = 1000

# A string value of either "true" or "false", default is "true".
# It is to control whether we store session data as a whole entry
# or store each attribute separately.
# This property was referred to as persistenceMechanism in the
# previous filter-based implementation, with the possible values
# of ObjectGridStore (fragmented) and ObjectGridAtomicSessionStore
# (not fragmented).

fragmentedSession = true

# A string value of either "true" or "false", default is "false".
# Enables eXtreme Scale client security. This setting needs to match
# the securityEnabled setting in the eXtreme Scale server properties
# file. If the settings do not match, an exception occurs.

securityEnabled = false

# Specifies the client credential authentication support.
#   The possible values are:
#   Never      - The client does not support credential authentication.
#   Supported* - The client supports the credential authentication if and only if the server
#                supports too.
#   Required   - The client requires the credential authentication.
#   The default value is Supported.

# credentialAuthentication =

# Specifies the retry count for authentication if the credential
# is expired. If the value is set to 0, there will not be
# any authentication retry.

# authenticationRetryCount =

# Specifies the name of the class that implements the
# com.ibm.websphere.objectgrid.security.plugins.CredentialGenerator
# interface. This class is used to get credentials for clients.

# credentialGeneratorClass =

# Specifies the properties for the CredentialGenerator implementation
# class. The properties are set to the object with the setProperties(String)
# method. The credentialGeneratorProps value is used only if the value of the
# credentialGeneratorClass property is not null.

# credentialGeneratorProps =

# The file location of the objectgrid xml file.
# The built-in xml file packaged in the eXtreme Scale library
# will automatically be loaded if this property
# is not specified and if objectGridType=EMBEDDED

# objectGridXML =

# The file location of the objectGrid deployment policy xml file.
# The built-in xml file packaged in the eXtreme Scale library
# will automatically be loaded if this property
# is not specified and if objectGridType=EMBEDDED

# objectGridDeploymentXML =

# A string of IBM WebShere trace specification,
# useful for all other application servers besides WebSphere.

# traceSpec =

# A string of trace file location.
# useful for all other application servers besides WebSphere.

# traceFile=

# This property should be set if you require sessions to be
# accessible across hosts. The value will be the name of the
# common domain between the hosts.

# cookieDomain=

# This property should be set to the same path you have configured
# for your application server cookie settings. The default path
# is /.

# cookiePath

# Set to true if the underlying web container will reuse
# session ID's across requests to different hosts. Default
```

```
# is false. The value of this should be the same as what is
# set in the web container.

# reuseSessionId=

# A string value of either "true" or "false", the default is
# "false". Per the servlet specification, HTTP Sessions cannot
# be shared across web applications. An extension to the servlet
# specification is provided to allow this sharing.

# shareSessionsAcrossWebApps = false

# A string value of either "true" or "false", default is "false".
# Set to true if you want to enable urlRewriting.  Default is
# false. The value of this should reflect what is set in the
# web container settings for session management.

# useURLEncoding = false

# Set to false if you want to disable cookies as the session tracking
# mechanism.  Default is true. The value of this should reflect what
# is set in the web container settings for session management.

# useCookies = true

# A string of eXtreme Scale client Http session statistics specification,

# sessionStatsSpec = session.all=enabled

# Set to true if your environment contains multiple applications that
# use unique cookie names. Default is false, which assumes all applications
# are using the same cookie name.

# applicationQualifiedCookies = false

# The prefix of the two cookies that are added to the HTTP response that
# represent the ID of the session object in the data grid and the session
# handle that contains the session's data. Default is IBM

# cookieNamePrefix = IBM

# When listenerMode = true (default), use the web container to generate sessions.
# if it is set to false, the web container will not be used.
# Setting listenerMode=false is only supported when
# reuseSessionId = true, sessionTableSize > 0, and when installed on WebSphere
# Application Server.
# listenerMode = true

# Only applies when listenerMode=false. When this property is set to true, all
# listeners configured for this web application will get the HttpSessionListener.sessionCreated
# call whenever a session is created, or a session is retrieved from the remote grid.
# Examples of this would be when an application server fails, or the
# sessionTableSize is exceeded and a session has to be brought back into the
# application server from the remote grid. HttpSessionListener.sessionDestroyed will also be
# called when a session is invalidated from the in-memory session cache if the sessionTableSize
# limit is exceeded.

# sessionCreatedOnFailover = false
```

Configuring the dynamic cache provider for WebSphere eXtreme Scale

Installing and configuring the dynamic cache provider for eXtreme Scale depends on what your requirements are and the environment you have set up.

Before you begin

- To use the dynamic cache provider, WebSphere® eXtreme Scale must be installed on top of the WebSphere Application Server node deployments, including the deployment manager node. See Installing WebSphere eXtreme Scale or WebSphere eXtreme Scale Client with WebSphere Application Server for more information.

- Global security must be enabled in the WebSphere Application Server administrative console, if the catalog servers within your catalog service domain have Secure Sockets Layer (SSL) enabled or you want to use SSL for a catalog service domain with SSL supported. You require SSL for a catalog server by setting the transportType attribute to `SSL-Required` in the Server properties file. For more information about configuring global security, see Global security settings.

About this task

For information about using the eXtreme Scale dynamic cache provider with IBM® WebSphere Commerce, see the following topics in the IBM WebSphere Commerce documentation:

- Enabling the dynamic cache service and servlet caching
- Enabling WebSphere Commerce data cache

If you are not specifically directing your caching to a defined Object Cache or Servlet Cache instance, then it is likely that the Dynamic Cache API calls are being serviced by the baseCache. If you want to use the eXtreme Scale dynamic cache provider for JSP, Web services or command caching, then you must set the baseCache instance to use the eXtreme Scale dynamic cache provider. The same configuration properties are used to configure the baseCache instance. Remember that these configuration properties need to be set as Java™ Virtual Machine (JVM) custom properties. This caveat applies to any cache configuration property discussed in this section except for servlet caching. To use eXtreme Scale with the dynamic cache provider for servlet caching, be sure to configure enablement in system properties rather than custom properties.

Procedure

1. Enable the eXtreme Scale dynamic cache provider.
   - **WebSphere Application Server Version 7.0 and later:**
     You can configure the dynamic cache service to use the eXtreme Scale dynamic cache provider with the administrative console. After you install eXtreme Scale, the eXtreme Scale dynamic cache provider is immediately available as a Cache Provider option in the administrative console. For more information, see WebSphere Application Server Version 7.0 information center: Selecting a cache service provider.

   - **WebSphere Application Server Version 6.1:**
     Use a custom property to configure the dynamic cache service to use the eXtreme Scale dynamic cache provider. You can also use these custom properties in WebSphere Application Server Version 7.0 and later. To create a custom property on a cache instance, click Resources > Cache instances > cache_instance_type > cache_instance_name > Custom properties > New. If you are using the base cache instance, create the custom properties on the JVM.

     com.ibm.ws.cache.CacheConfig.cacheProviderName
     To use the eXtreme Scale dynamic cache provider, set the value to `com.ibm.ws.objectgrid.dynacache.CacheProviderImpl`. You can create this custom property on a dynamic cache instance, or the base cache instance. If you choose to set the custom property on the base cache instance, then all other cache instances on the server use the eXtreme Scale provider by default. Any eXtreme Scale dynamic cache provider configuration properties set for the baseCache are the default configuration properties for all cache instances backed by eXtreme Scale. To override the base cache instance and make a particular dynamic cache instance use the default dynamic cache provider, create the com.ibm.ws.cache.CacheConfig.cacheProviderName custom property on the dynamic cache instance and set the value to `default`.

2. Optional: If you are using replicated cache instances, configure the replication setting for the cache.
   With the eXtreme Scale dynamic cache provider, you can have local cache instances or replicated cache instances. If you are only using local cache instances, you can skip this step.

   Use one of the following methods to configure the replicated cache:

   - Enable cache replication with the administrative console. You can enable cache replication at any time in WebSphere Application Server Version 7.0. In WebSphere Application Server Version 6.1, you must create a DRS replication domain.
   - Enable cache replication with the com.ibm.ws.cache.CacheConfig.enableCacheReplication custom property to force the cache to report that it is a replicated cache, even though a DRS replication domain has not been assigned to it. Set the value of this custom property to `true`. Set this custom property on the cache instance if you are using an object cache or servlet cache, or on the JVM if you are using the baseCache instance.
3. Optional: If you are using eXtreme Scale as a JSP fragment cache, set the com.ibm.ws.cache.CacheConfig.disableTemplateInvalidation custom property to `true` to disable template-based invalidations during JSP reloads.
4. Configure the topology for the dynamic cache service.
   The only required configuration parameter for the eXtreme Scale dynamic cache provider is the cache topology. Set the custom property on the cache instance or for the dynamic cache service if you are using baseCache instance. Enter the name of the custom property as: `com.ibm.websphere.xs.dynacache.topology`.

   The three possible values for this property follow. You must use one of the allowed values:
   - `embedded`
   - `embedded_partitioned`
   - `remote`

   If you are using embedded or embedded partitioned topologies, consider setting the `com.ibm.ws.cache.CacheConfig.ignoreValueInInvalidationEvent` custom property to `true` to save some serialization costs. Set this custom property on the cache instance or the JVM if you are using the baseCache instance.

5. Optional: If you are using an embedded partitioned topology, configure the number of initial containers for the dynamic cache service.
   You can maximize the performance of caches that are using the embedded partitioned topology by configuring the number of initial containers. Set the variable as a system property on the WebSphere Application Server Java virtual machine.

   Enter the name of the property as: `com.ibm.websphere.xs.dynacache.num_initial_containers`.

   The recommended value of this configuration property is an integer that is equal to or slightly less than the total number of WebSphere Application Server instances that are accessing this distributed cache instance. For example, if a dynamic cache service is shared between data grid members, then the value should be set to the number of data grid members.

For embedded or embedded_partitioned topologies, you must be using Version 7.0 of WebSphere Application Server. Set the following custom property on the JVM process to ensure that the initial containers are available right away.

```
com.ibm.ws.cache.CacheConfig.createCacheAtServerStartup=true
```

6. Configure the eXtreme Scale catalog service grid.
   When you are using eXtreme Scale as the dynamic cache provider for a distributed cache instance, you must configure an eXtreme Scale catalog service domain.

   A single catalog service domain can service multiple dynamic cache service providers backed by eXtreme Scale.

   A catalog service can run inside or outside of WebSphere Application Server processes. Starting with eXtreme Scale Version 7.1, when you use the administrative console to configure catalog service domains, the dynamic cache uses these settings. It is not necessary to take additional steps to set up a catalog service. For more information, see Creating catalog service domains in WebSphere Application Server.

7. Configure custom key objects.
   When you are using custom objects as keys the objects must implement the Serializable or Externalizable interface. When you are using the embedded or embedded partitioned topologies, you must place objects on the WebSphere shared library path, just like if they were being used with the default dynamic cache provider. See Using the DistributedMap and DistributedObjectCache interfaces for the dynamic cache in the WebSphere Application Server Network Deployment information center for more details.

   If you are using the remote topology, you must place the custom key objects on the CLASSPATH for the standalone eXtreme Scale containers. See Starting container servers for more information.

8. Optional: If you are using a remote topology, configure the eXtreme Scale container servers.
   - **Embedded or embedded partitioned topology:**
     The cached data is stored in WebSphere eXtreme Scale container servers. Container servers can run inside or outside of WebSphere Application Server processes. The eXtreme Scale provider automatically creates containers inside the WebSphere process when you are using embedded or embedded partitioned topologies for a cache instance. No further configuration is needed for these topologies.

   - **Remote topology:**
     When you are using the remote topology, you must start up stand-alone eXtreme Scale container servers before the WebSphere Application Server instances that access the cache instance start. To start stand-alone container servers, see Starting and stopping stand-alone servers. Verify that all the container servers for a specific dynamic cache service point to the same catalog service endpoints.

     The XML configuration files for the stand-alone eXtreme Scale dynamic cache provider containers are in either the *was_root*/optionalLibraries/ObjectGrid/dynacache/etc directory for installations on top of WebSphere Application Server, or the *wxs_install_root*/ObjectGrid/dynacache/etc directory for stand-alone installations. The files are named dynacache-remote-objectgrid.xml and dynacache-remote-definition.xml. Make copies of these files to edit and use when you are starting stand-alone containers for the eXtreme Scale dynamic cache provider. The **numInitialContainers** parameter in the **dynacache-remote-deployment.xml** file must match the number of container processes that are running. Note that the numberOfPartitions attribute in the `dynacache-remote-objectgrid.xml` file has a default value of `47`.

     Note: The set of container server processes must have enough free memory to service all the dynamic cache instances that are configured to use the remote topology. Any WebSphere Application Server process that shares the same or equivalent values for the catalog.services.cluster custom property must use the same set of stand-alone containers. The number of containers and number of servers on which they reside must be sized appropriately. See Dynamic cache capacity planning for additional details.
     A command line entry that starts a stand-alone container for the eXtreme Scale dynamic cache provider follows:

     UNIX

     ```
     startOgServer.sh container1 -objectGridFile
     ../dynacache/etc/dynacache-remote-objectgrid.xml -deploymentPolicyFile
     ../dynacache/etc/dynacache-remote-deployment.xml -catalogServiceEndPoints
     MyServer1.company.com:2809
     ```

9. For distributed or embedded topologies, enable the sizing agent to improve memory consumption estimates.
   The sizing agent estimates memory consumption (usedBytes statistic). The agent requires a Java 5 or higher JVM.

   Load the agent by adding the following argument to the JVM command line:

   ```
   -javaagent:WXS lib directory/wxssizeagent.jar
   ```

   For an embedded topology, add the argument to the command line of the WebSphere Application Server process.

   For a distributed topology, add the argument to command line of the eXtreme Scale processes (containers) and the WebSphere Application Server process.

JPA level 2 (L2) cache plug-in

WebSphere® eXtreme Scale includes level 2 (L2) cache plug-ins for both OpenJPA and Hibernate Java™ Persistence API (JPA) providers. When you use one of these plug-ins, your application uses the JPA API. A data grid is introduced between the application and the database, improving response times.

Using eXtreme Scale as an L2 cache provider increases performance when you are reading and querying data and reduces load to the database. WebSphere eXtreme Scale has advantages over built-in cache implementations because the cache is automatically replicated between all processes. When one client caches a value, all other clients are able to use the cached value that is locally in-memory.

You can configure the topology and properties for the L2 cache provider in the persistence.xml file. For more information about configuring these properties, see JPA cache configuration properties for both OpenJPA and Hibernate Version 3.0.

Tip: The JPA L2 cache plug-in requires an application that uses the JPA APIs. If you want to use WebSphere eXtreme Scale APIs to access a JPA data source, use the JPA loader. For more information, see JPA Loaders.

JPA L2 cache topology considerations

The following factors affect which type of topology to configure:

1. **How much data do you expect to be cached?**
   - If the data can fit into a single JVM heap, use the Embedded topology or Intra-domain topology.
   - If the data cannot fit into a single JVM heap, use the Embedded, partitioned topology, or Remote topology
2. **What is the expected read-to-write ratio?**
   The read-to-write ratio affects the performance of the L2 cache. Each topology handles read and write operations differently.
   - Embedded topology: local read, remote write
   - Intra-domain topology: local read, local write
   - Embedded, partitioned topology: Partitioned: remote read, remote write
   - Remote topology: remote read, remote write.

   Applications that are mostly read-only should use embedded and intra-domain topologies when possible. Applications that do more writing should use intra-domain topologies.
3. **What is percentage of data is queried versus found by a key?**
   When enabled, query operations make use of the JPA query cache. Enable the JPA query cache for applications with high read to write ratios only, for example when you are approaching 99% read operations. If you use JPA query cache, you must use the Embedded topology or Intra-domain topology.

   The find-by-key operation fetches a target entity if the target entity does not have any relationship. If the target entity has relationships with the EAGER fetch type, these relationships are fetched along with the target entity. In JPA data cache, fetching these relationships causes a few cache hits to get all the relationship data.

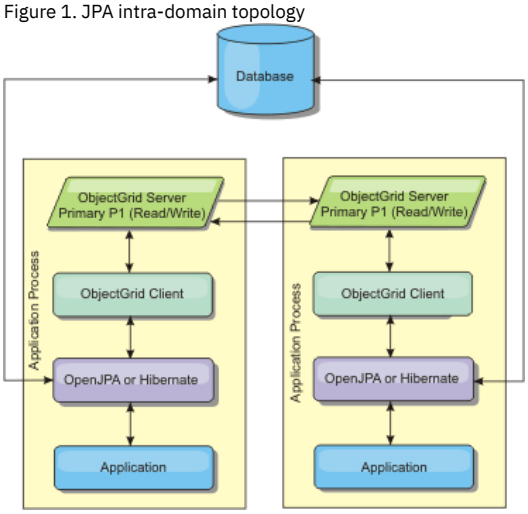
4. **What is the tolerated staleness level of the data?**
   In a system with few JVMs, data replication latency exists for write operations. The goal of the cache is to maintain an ultimate synchronized data view across all JVMs. When you are using the intra-domain topology, a data replication delay exists for write operations. Applications using this topology must be able to tolerate stale reads and simultaneous writes that might overwrite data.

Intra-domain topology

With an intra-domain topology, primary shards are placed on every container server in the topology. These primary shards contain the full set of data for the partition. Any of these primary shards can also complete cache write operations. This configuration eliminates the bottleneck in the embedded topology where all the cache write operations must go through a single primary shard.

In an intra-domain topology, no replica shards are created, even if you have defined replicas in your configuration files. Each redundant primary shard contains a full copy of the data, so each primary shard can also be considered as a replica shard. This configuration uses a single partition, similar to the embedded topology.

Figure 1. JPA intra-domain topology



Related JPA cache configuration properties for the intra-domain topology:

```
ObjectGridName=objectgrid_name,ObjectGridType=EMBEDDED,PlacementScope=CONTAINER_SCOPE,PlacementScopeTopology=HUB | RING
```

Advantages:

- Cache reads and updates are local.
- Simple to configure.

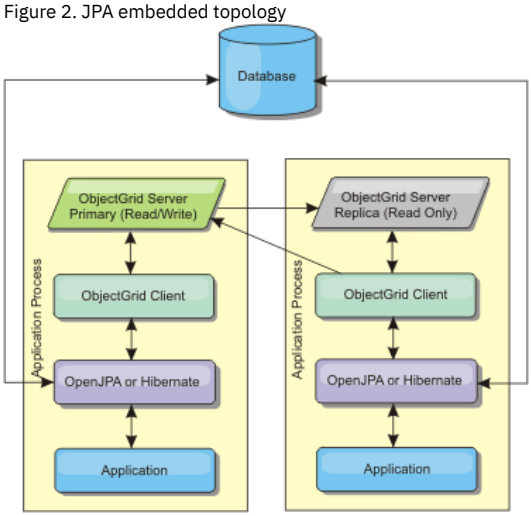
Limitations:

- This topology is best suited for when the container servers can contain the entire set of partition data.
- Replica shards, even if they are configured, are never placed because every container server hosts a primary shard. However, all the primary shards are replicating with the other primary shards, so these primary shards become replicas of each other.

Embedded topology

Tip: Consider using an intra-domain topology for the best performance.
An embedded topology creates a container server within the process space of each application. OpenJPA and Hibernate read the in-memory copy of the cache directly and write to all of the other copies. You can improve the write performance by using asynchronous replication. This default topology performs best when the amount of cached data is small enough to fit in a single process. With an embedded topology, create a single partition for the data.

Figure 2. JPA embedded topology



Related JPA cache configuration properties for the embedded topology:

`ObjectGridName=`*`objectgrid_name`*`,ObjectGridType=EMBEDDED,MaxNumberOfReplicas=`*`num_replicas`*`,ReplicaMode=`*`SYNC`*` | `*`ASYNC`*` | `*`NONE`

Advantages:

- All cache reads are fast, local accesses.
- Simple to configure.

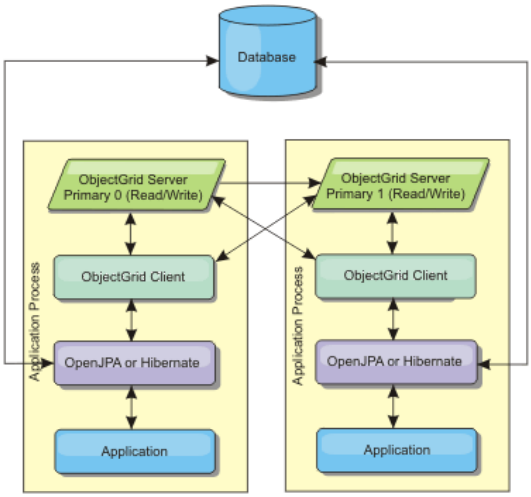
Limitations:

- Amount of data is limited to the size of the process.
- All cache updates are sent through one primary shard, which creates a bottleneck.

Embedded, partitioned topology

Tip: Consider using an intra-domain topology for the best performance.
CAUTION:
Do not use the JPA query cache with an embedded partitioned topology. The query cache stores query results that are a collection of entity keys. The query cache fetches all entity data from the data cache. Because the data cache is divided up between multiple processes, these additional calls can negate the benefits of the L2 cache.
When the cached data is too large to fit in a single process, you can use the embedded, partitioned topology. This topology divides the data over multiple processes. The data is divided between the primary shards, so each primary shard contains a subset of the data. You can still use this option when database latency is high.

Figure 3. JPA embedded, partitioned topology



Related JPA cache configuration properties for the embedded, partitioned topology:

```
ObjectGridName=objectgrid_name,ObjectGridType=EMBEDDED_PARTITION,ReplicaMode=SYNC | ASYNC | NONE,
NumberOfPartitions=num_partitions,ReplicaReadEnabled=TRUE | FALSE
```

Advantages:

- Stores large amounts of data.
- Simple to configure
- Cache updates are spread over multiple processes.

Limitation:

- Most cache reads and updates are remote.

For example, to cache 10 GB of data with a maximum of 1 GB per JVM, 10 Java virtual machines are required. The number of partitions must therefore be set to 10 or more. Ideally, the number of partitions must be set to a prime number where each shard stores a reasonable amount of memory. Usually, the numberOfPartitions setting is equal to the number of Java virtual machines. With this setting, each JVM stores one partition. If you enable replication, you must increase the number of Java virtual machines in the system. Otherwise, each JVM also stores one replica partition, which consumes as much memory as a primary partition.

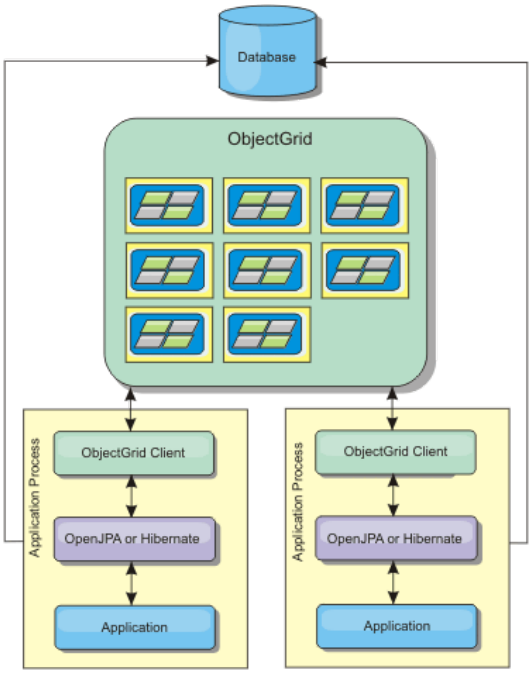
Read about Sizing memory and partition count calculation to maximize the performance of your chosen configuration.

For example, in a system with four Java virtual machines, and the numberOfPartitions setting value of `4`, each JVM hosts a primary partition. A read operation has a 25 percent chance of fetching data from a locally available partition, which is much faster compared to getting data from a remote JVM. If a read operation, such as running a query, needs to fetch a collection of data that involves 4 partitions evenly, 75 percent of the calls are remote and 25 percent of the calls are local. If the ReplicaMode setting is set to either `SYNC` or `ASYNC` and the ReplicaReadEnabled setting is set to `true`, then four replica partitions are created and spread across four Java virtual machines. Each JVM hosts one primary partition and one replica partition. The chance that the read operation runs locally increases to 50 percent. The read operation that fetches a collection of data that involves four partitions evenly has 50 percent remote calls and 50 percent local calls. Local calls are much faster than remote calls. Whenever remote calls occur, the performance drops.

Remote topology

CAUTION:
Do not use the JPA query cache with a remote topology. The query cache stores query results that are a collection of entity keys. The query cache fetches all entity data from the data cache. Because the data cache is remote, these additional calls can negate the benefits of the L2 cache.
Tip: Consider using an intra-domain topology for the best performance.
A remote topology stores all of the cached data in one or more separate processes, reducing memory use of the application processes. You can take advantage of distributing your data over separate processes by deploying a partitioned, replicated eXtreme Scale data grid. As opposed to the embedded and embedded partitioned configurations described in the previous sections, if you want to manage the remote data grid, you must do so independent of the application and JPA provider.

Figure 4. JPA remote topology



Related JPA cache configuration properties for the remote topology:

`ObjectGridName=`*`objectgrid_name`*`,ObjectGridType=REMOTE,AllowNearCache=TRUE`

Note: The AllowNearCache property is optional. If it is not included in the configuration, the default value is FALSE. This property is only used by a remote object grid type as long as the remote object grid server is also enabled for near caching as defined in the ObjectGrid descriptor XML file. To enable the L2 cache provider for near caching, set the property AllowNearCache is set to `TRUE`.
The REMOTE ObjectGrid type does not require any property settings because the ObjectGrid and deployment policy is defined separately from the JPA application. The JPA cache plug-in remotely connects to an existing remote ObjectGrid.

Because all interaction with the ObjectGrid is remote, this topology has the slowest performance among all ObjectGrid types.

Advantages:

- Stores large amounts of data.
- Application process is free of cached data.
- Cache updates are spread over multiple processes.
- Flexible configuration options.

Limitation:

- All cache reads and updates are remote.

- JPA cache configuration properties for both OpenJPA and Hibernate Version 3.0
  WebSphere eXtreme Scale includes level 2 cache plug-ins for both OpenJPA and Hibernate Java Persistence API (JPA) providers. To configure the L2 cache plug-in, you must update properties in the persistence.xml file.
- Configuring the OpenJPA cache plug-in
  You can configure both DataCache and QueryCache implementations for OpenJPA.
- Configuring the Hibernate cache plug-in
  You can enable the cache to use the Hibernate cache plug-in by specifying properties files.

JPA cache configuration properties for both OpenJPA and Hibernate Version 3.0

WebSphere® eXtreme Scale includes level 2 cache plug-ins for both OpenJPA and Hibernate Java™ Persistence API (JPA) providers. To configure the L2 cache plug-in, you must update properties in the persistence.xml file.

Tip: The JPA L2 cache plug-in requires an application that uses the JPA APIs. If you want to use WebSphere eXtreme Scale APIs to access a JPA data source, use the JPA loader. For more information, see Configuring JPA loaders.

Properties location

You can configure these properties in the persistence.xml file. The syntax for specifying the properties in this file varies depending if you are using OpenJPA or Hibernate Version 3.0:

- **OpenJPA:** You can set the properties on the DataCache or QueryCache:

  ```
  <property name="openjpa.DataCache"
   value="<object_grid_datacache_class(<property>=<value>,...)"/>
  ```

  or

  ```
  <property name="openjpa.QueryCache"
   value="<object_grid_querycache_class(<property>=<value>,...)"/>
  ```

- **Hibernate Version 3.0:**

  ```
  <property name="objectgrid.configuration"
   value="<property>=<value>,..." />
  ```

Default topology and properties

The following default property values are used if you do not specify any values in the configuration:

- **ObjectGridName**: persistence unit name
- **ObjectGridType**: `EMBEDDED`
- **NumberOfPartitions**: `1` (cannot be changed when ObjectGrid type is `EMBEDDED`)
- **ReplicaMode**: `SYNC`
- **ReplicaReadEnabled**: `TRUE` (cannot be changed when ObjectGrid type is `EMBEDDED`)
- **MaxUsedMemory**: `TRUE`
- **MaxNumberOfReplicas**: `47` (must be less than or equal to the number of Java virtual machines in a distributed system)

Properties

You can configure JPA cache plug-ins with the following properties.

ObjectGridName
: Specifies the unique ObjectGrid name. The default value is the defined persistence unit name. If the persistence unit name is not available from the JPA provider, a generated name is used.

ObjectGridType
: Specifies the type of ObjectGrid.
Valid values:

  `EMBEDDED`
  : The default and recommended configuration type. Its default settings include: `NumberOfPartitions=1`, `ReplicaMode=SYNC`, `ReplicaReadEnabled=true` and `MaxNumberOfReplicas=47`. Use the ReplicaMode parameter to set the replication mode and the MaxNumberOfReplicas parameter to set the maximum number of replicas. If a system has more than 47 Java virtual machines, set the MaxNumberOfReplicas value to be equal to the number of Java virtual machines.

  `EMBEDDED_PARTITION`
  : The type to use when the system needs to cache a large amount of data in a distributed system. The default number of partitions is `47` with a replica mode of `NONE`. In a small system that has only a few Java virtual machines, set the NumberOfPartitions value to be equal or less than the number of Java virtual machines. You can specify the ReplicaMode, NumberOfPartitions, and ReplicaReadEnabled values to tune the system.

  `REMOTE`
  : The cache tries to connect to a remote, distributed ObjectGrid from the catalog service.

MaxNumberOfReplicas
: Specifies the maximum number of replicas to be used for the cache. This value applies to the `EMBEDDED` type only. This number must be equal to or greater than the number of Java virtual machines in a system. The default value is `47`.
Valid values: greater than or equal to `1`

MaxUsedMemory
: **Valid values:** `TRUE` or `FALSE`

  Enables eviction of cache entries when memory becomes constrained. The default value is `TRUE` and evicts data when the JVM heap utilization threshold exceeds 70 percent. You can modify the default JVM heap utilization threshold percentage by setting the memoryThresholdPercentage property in the objectGridServer.properties file and placing this file in the class path. For more information about evictors, see Plug-ins for evicting cache objectsthe information about evictors in the *Product Overview*. For more information about the server properties file, see Server properties file.

NumberOfPartitions
: **Valid values:** greater than or equal to `1`

  Specifies the number of partitions to be used for the cache. This property applies when the ObjectGridType value is set to `EMBEDDED_PARTITION`. The default value is `47`. For the `EMBEDDED` type, the **NumberOfPartitions** value is always `1`.

PlacementScope
: Indicates the granularity of a single instance of a map set.
Valid values:

DOMAIN_SCOPE
(Default) Places one primary shard for each partition on a container server within the catalog service domain. Replica shards for each partition are placed on the other container servers within the catalog service domain.
CONTAINER_SCOPE
Places a primary shard on each container server in the catalog service domain.

PlacementScopeTopology
Defines the linking topology of the container servers within the catalog service domain. This value is only used when the PlacementScope value is set to something other than `DOMAIN_SCOPE`.
Valid values:

HUB
(Default) If the hub topology is selected, then a single data grid is selected to be the hub. Every other data grid connects to the hub. This topology is fairly scalable because the spokes have a single connection. The hub can become a bottleneck and temporary single point of failure. The hub is relocated to another container server when it fails. The advantage to this configuration is more complex arbitration code can be written that allows a single point, the hub, to handle all collisions.
RING
If the ring topology is selected, each data grid is linked with two other data grids. The ordering of the links is not guaranteed. However, each container that starts is likely linked to the first container and last container to be added to the ring. This topology is the most scalable, but only two links can fail before being temporarily cut off. If the container servers fail, links are established among the survivors after the failure has been discovered.

ReplicaMode
Valid values: `SYNC`/`ASYNC`/`NONE`

Specifies the method that is used to copy the cache to the replicas. This property applies when you have the ObjectGridType value set to `EMBEDDED` or `EMBEDDED_PARTITION`. The default value is `NONE` for the `EMBEDDED_PARTITION` type and `SYNC` for the `EMBEDDED` type. If the **ReplicaMode** value is set to `NONE` for the `EMBEDDED` ObjectGridType, the `EMBEDDED` type still uses a **ReplicaMode** of `SYNC`.
ReplicaReadEnabled
Valid values: `TRUE` or `FALSE`

When enabled, clients read from replicas. This property applies to the `EMBEDDED_PARTITION` type. The default value is FALSE for the `EMBEDDED_PARTITION` type. The `EMBEDDED` type always sets the **ReplicaReadEnabled** value to `TRUE`.
writeBehind
For Hibernate providers only: When writeBehind is enabled, updates are temporarily stored in a JVM scope data storage until either the writeBehindInterval or writeBehindMaxBatchSize conditions are met.

Attention: Unless writeBehind is enabled, the other write behind configuration settings are disregarded.
Important: Take care when using the write behind function. Write behind configurations introduce longer latency of data synchronization across all JVMs and a higher chance of lost updates. In a system that has write behind configuration enabled with four or more JVMs, the update performed on one JVM has an approximate 15 second delay before the update becomes available to other JVMs. If any two JVMs update the same entry, the one that flushes the update first loses its update.
Valid values: TRUE or FALSE

Default value: FALSE

writeBehindInterval
For Hibernate providers only: Specifies the time interval in milliseconds to flush updates to the cache.

Valid values: greater than or equal to 1

Default value: 5000 (5 seconds)

writeBehindPoolSize
For Hibernate providers only: Specifies the maximum size of the thread pool used in flushing updates to the cache.

Valid values: greater than or equal to 1

Default value: 5

writeBehindMaxBatchSize
For Hibernate providers only: Specifies the maximum batch size per region cache in flushing updates to the cache. For example, if the size is set to 1000, and the updates stored in the write behind storage of a region cache exceeds 1000 entries, the updates are flushed to the cache, even the specified writeBehindInterval condition is not met. Updates flush to the cache either approximately at the number of seconds specified by the writeBehindInterval value or whenever the size of write behind storage of each region cache exceeds 1000 entries. Note, in the case of the writeBehindMaxBatchSize condition met; only the region cache that meets this condition flushes its updates in write behind storage to cache. A region cache usually corresponds to an entity or a query.

Valid values: greater than or equal to 1

Default value: 1000

Configuring the OpenJPA cache plug-in

You can configure both DataCache and QueryCache implementations for OpenJPA.

Before you begin

- You must determine the JPA cache plug-in topology that you want to use. See JPA level 2 (L2) cache plug-in for more information about the different configurations and the properties to set for each topology.
- You must have an application that uses the JPA APIs. If you want to use WebSphere eXtreme Scale APIs to access data with JPA, use the JPA loader. For more information, see Configuring JPA loaders.

Procedure

1. Set properties in your persistence.xml file to configure the OpenJPA cache plug-in: You can set these properties on either the DataCache or Query cache implementation.
   DataCache and QueryCache configurations are independent of one another. You can enable either configuration. However, if both configurations are enabled, the QueryCache configuration uses the same configuration as the DataCache configuration, and its configuration properties are discarded.

   ```
   <property name="openjpa.DataCache"
             value="<object_grid_datacache_class(<property>=<value>,...)"/>
   ```

   or

   ```
   <property name="openjpa.QueryCache"
             value="<object_grid_querycache_class(<property>=<value>,...)"/>
   ```

   Note: You can enable the QueryCache configuration for embedded and embedded-intradomain topologies only.
   You can specify the ObjectGridName property, the ObjectGridType property, and other simple deployment policy-related properties in the property list of the ObjectGrid cache class to customize cache configuration. An example follows:

   ```
   <property name="openjpa.DataCache"
             value="com.ibm.websphere.objectgrid.openjpa.ObjectGridDataCache(
             ObjectGridName=BasicTestObjectGrid,ObjectGridType=EMBEDDED,
             maxNumberOfReplicas=4)"/>
   <property name="openjpa.QueryCache"
             value="com.ibm.websphere.objectgrid.openjpa.ObjectGridQueryCache()"/>
   <property name="openjpa.RemoteCommitProvider" value="sjvm"/>
   ```

   See JPA cache configuration properties for both OpenJPA and Hibernate Version 3.0 for a list of the properties that you can set.
2. In the persistence.xml file, you also must set the openjpa.RemoteCommitProvider property to `sjvm`.

   ```
   <property name="openjpa.RemoteCommitProvider" value="sjvm"/>
   ```

3. Optional: To further customize the data grid used by the cache, you can provide additional settings with XML files.
   For most scenarios, setting cache properties should be sufficient. To further customize the ObjectGrid used by the cache, you can provide OpenJPA ObjectGrid configuration XML files in the META-INF directory similarly to the persistence.xml file. During initialization, the cache tries to locate these XML files and process them if found.

   There are three types of OpenJPA ObjectGrid configuration XML files:
   - openjpa-objectGrid.xml (ObjectGrid configuration)
     File path: META-INF/openjpa-objectGrid.xml

     This file is used to customize ObjectGrid configuration for both the EMBEDDED and EMBEDDED_PARTITION type. With the REMOTE type, this file is ignored. By default, each entity class is mapped to its own BackingMap configuration named as an entity class name within the ObjectGrid configuration. For example, com.mycompany.Employee entity class is mapped to com.mycompany.Employee BackingMap. The default BackingMap configuration is `readOnly="false"`, `copyKey="false"`, `lockStrategy="NONE"`, and `copyMode="NO_COPY"`. You can customize some BackingMaps with your chosen configuration. You can use the `ALL_ENTITY_MAPS` reserved keyword to represent all maps excluding other customized maps listed in the openjpa-objectGrid.xml file. BackingMaps that are not listed in this openjpa-objectGrid.xml file use the default configuration. If customized BackingMaps do not specify the BackingMaps attribute or properties and these attributes are specified in the default configuration, the attribute values from the default configuration are applied. For example, if an entity class is annotated with `timeToLive=30`, the default BackingMap configuration for that entity has a `timeToLive=30`. If the custom openjpa-objectGrid.xml file also includes that BackingMap but does not specify timeToLive value, then the customize BackingMap has a `timeToLive=30` value by default. The openjpa-objectGrid.xml file intends to override or extend the default configuration.

   - openjpa-objectGridDeployment.xml (deployment policy)
     File path: META-INF/openjpa-objectGridDeployment.xml

     This file is used to customize deployment policy. When you are customizing deployment policy, if the openjpa-objectGridDeployment.xml file is provided, the default deployment policy is discarded. All deployment policy attribute values are from the provided openjpa-objectGridDeployment.xml file.

   - openjpa-objectGrid-client-override.xml (client ObjectGrid override configuration)
     File path: META-INF/openjpa-objectGrid-client-override.xml

This file is used to customize a client-side ObjectGrid. By default, the ObjectGrid cache applies a default client override ObjectGrid configuration that disables a near cache. You can enable the near cache by providing the openjpa-objectGrid-client-override.xml file that overrides this configuration. For more information about the settings to change in this file to enable near cache, see Configuring the near cache. The way that the openjpa-objectGrid-client-override.xml file works is similar to the openjpa-objectGrid.xml file. It overrides or extends the default client ObjectGrid override configuration.

Depending on the configured eXtreme Scale topology, you can provide any one of these three XML files to customize that topology.
For both the EMBEDDED and EMBEDDED_PARTITION types, you can provide any one of the three XML files to customize the ObjectGrid, deployment policy, and client ObjectGrid override configuration.

For a REMOTE ObjectGrid, the ObjectGrid cache does not create a dynamic ObjectGrid. Instead, the cache only obtains a client-side ObjectGrid from the catalog service. You can only provide the openjpa-objectGrid-client-override.xml file to customize the client ObjectGrid override configuration.

4. Optional: (Remote configurations only) Set up an external eXtreme Scale system if you want to configure a cache with a REMOTE ObjectGrid type.
You must set up an external eXtreme Scale system if you want to configure a cache with a REMOTE ObjectGrid type. You need both ObjectGrid and ObjectGridDeployment configuration XML files that are based on the persistence.xml file to set up an external system. For examples of these configuration files, see Example: OpenJPA ObjectGrid XML files.

Results

EMBEDDED, EMBEDDED_PARTITION, or intra-domain configuration:

When an application starts, the plug-in automatically detects or starts a catalog service, starts a container server, and connect the container servers to the catalog service. The plug-in then communicates with the ObjectGrid container and its peers that are running in other application server processes using the client connection.

REMOTE configuration:

The deployment policy is specified separately from the JPA application. An external ObjectGrid system has both catalog service and container server processes. You must start a catalog service before starting container servers. See Starting stand-alone servers and Starting container servers for more information.

What to do next

- Develop an OpenJPA application that uses the configuration. For more information, see Example: Using the Hibernate plug-in to preload data into the ObjectGrid cache.
- In a production environment, create catalog service domains for your automatically created processes for your EMBEDDED or EMBEDDED_PARTITION configuration.
  - Stand-alone environment:
    If you are not running your servers inside a WebSphere Application Server process, the catalog service domain hosts and ports are specified using properties file named objectGridServer.properties. This file must be stored in the class path of the application and have the **catalogServiceEndPoints** property defined. The catalog service domain is started independently from the application processes and must be started before the application processes are started.

    The format of the objectGridServer.properties file follows:

    ```
    catalogServiceEndPoints=<hostname1>:<port1>,<hostname2>:<port2>
    ```

  - WebSphere Application Server environment:
    If you are running inside a WebSphere Application Server process, the JPA cache plug-in automatically connects to the catalog service or catalog service domain that is defined for the WebSphere Application Server cell.

- When you are using the `EMBEDDED` or `EMBEDDED_PARTITION` ObjectGridType value in a Java SE environment, use the System.exit(0) method at the end of the program to stop the embedded eXtreme Scale server. Otherwise, the program can become unresponsive.

- Example: OpenJPA ObjectGrid XML files
  OpenJPA ObjectGrid XML files should be created based on the configuration of the persistence unit.

Example: OpenJPA ObjectGrid XML files

OpenJPA ObjectGrid XML files should be created based on the configuration of the persistence unit.

persistence.xml file

A persistence.xml file that is an example that represents the configuration of a persistence unit follows:

```
<persistence xmlns="http://java.sun.com/xml/ns/persistence"
             xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  version="1.0">
  <persistence-unit name="AnnuityGrid">
    <provider>org.apache.openjpa.persistence.PersistenceProviderImpl</provider>
    <class>com.ibm.wssvt.acme.annuity.common.bean.jpa.AnnuityPersistebleObject</class>
    <class>com.ibm.wssvt.acme.annuity.common.bean.jpa.Annuity</class>
    <class>com.ibm.wssvt.acme.annuity.common.bean.jpa.FixedAnnuity</class>
    <class>com.ibm.wssvt.acme.annuity.common.bean.jpa.EquityAnnuity</class>
    <class>com.ibm.wssvt.acme.annuity.common.bean.jpa.Payout</class>
    <class>com.ibm.wssvt.acme.annuity.common.bean.jpa.Rider</class>
    <class>com.ibm.wssvt.acme.annuity.common.bean.jpa.Payor</class>
    <class>com.ibm.wssvt.acme.annuity.common.bean.jpa.Person</class>
    <class>com.ibm.wssvt.acme.annuity.common.bean.jpa.AnnuityHolder</class>
    <class>com.ibm.wssvt.acme.annuity.common.bean.jpa.Contact</class>
    <class>com.ibm.wssvt.acme.annuity.common.bean.jpa.Address</class>
    <exclude-unlisted-classes>true</exclude-unlisted-classes>

    <properties>
    <!-- Database setting -->

    <!--  enable cache -->
      <property name="openjpa.DataCache"
        value="com.ibm.websphere.objectgrid.openjpa.ObjectGridDataCache(objectGridName=Annuity,
               objectGridType=EMBEDDED, maxNumberOfReplicas=4)" />
      <property name="openjpa.RemoteCommitProvider" value="sjvm" />
      <property name="openjpa.QueryCache"
                value="com.ibm.websphere.objectgrid.openjpa.ObjectGridQueryCache()" />
    </properties>
  </persistence-unit>
</persistence>
```

openjpa-objectGrid.xml file

The openjpa-objectGrid.xml file is used to customize ObjectGrid configuration for both the EMBEDDED and EMBEDDED_PARTITION type. The openjpa-objectGrid.xml file that matches the persistence.xml file follows:

```
<?xml version="1.0" encoding="UTF-8"?>
<?xml version="1.0" encoding="UTF-8"?>
<objectGridConfig xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://ibm.com/ws/objectgrid/config ../objectGrid.xsd"
  xmlns="http://ibm.com/ws/objectgrid/config">
  <objectGrids>
    <objectGrid name="Annuity">
      <backingMap name="com.ibm.wssvt.acme.annuity.common.bean.jpa.Annuity" readOnly="false" copyKey="false"
                  lockStrategy="NONE" copyMode="NO_COPY" evictionTriggers="MEMORY_USAGE_THRESHOLD"
                  pluginCollectionRef="com.ibm.wssvt.acme.annuity.common.bean.jpa.Annuity" />
      <backingMap name="com.ibm.wssvt.acme.annuity.common.bean.jpa.Address" readOnly="false" copyKey="false"
                  lockStrategy="NONE" copyMode="NO_COPY" evictionTriggers="MEMORY_USAGE_THRESHOLD"
                  pluginCollectionRef="com.ibm.wssvt.acme.annuity.common.bean.jpa.Address" />
      <backingMap name="com.ibm.wssvt.acme.annuity.common.bean.jpa.Payor" readOnly="false" copyKey="false"
                  lockStrategy="NONE" copyMode="NO_COPY" evictionTriggers="MEMORY_USAGE_THRESHOLD"
                  pluginCollectionRef="com.ibm.wssvt.acme.annuity.common.bean.jpa.Payor" />
      <backingMap name="com.ibm.wssvt.acme.annuity.common.bean.jpa.Person" readOnly="false" copyKey="false"
                  lockStrategy="NONE" copyMode="NO_COPY" evictionTriggers="MEMORY_USAGE_THRESHOLD"
                  pluginCollectionRef="com.ibm.wssvt.acme.annuity.common.bean.jpa.Person" />
      <backingMap name="com.ibm.wssvt.acme.annuity.common.bean.jpa.Contact" readOnly="false" copyKey="false"
                  lockStrategy="NONE" copyMode="NO_COPY" evictionTriggers="MEMORY_USAGE_THRESHOLD"
                  pluginCollectionRef="com.ibm.wssvt.acme.annuity.common.bean.jpa.Contact" />
      <backingMap name="com.ibm.wssvt.acme.annuity.common.bean.jpa.AnnuityPersistebleObject"
                  readOnly="false" copyKey="false"
                  lockStrategy="NONE" copyMode="NO_COPY" evictionTriggers="MEMORY_USAGE_THRESHOLD"
                  pluginCollectionRef="com.ibm.wssvt.acme.annuity.common.bean.jpa.AnnuityPersistebleObject" />

    </backingMapPluginCollection>
  </backingMapPluginCollections>
</objectGridConfig>
```

Important:

1. Each entity is mapped to a BackingMap named as the fully qualified entity class name.
   By default, entities are part of the second level cache. In the Entity classes which needs to be excluded from caching, You can include the `@DataCache(enabled=false)` annotation on the entity class that you want to exclude from L2 cache:

```
import org.apache.openjpa.persistence.DataCache;
@Entity
@DataCache(enabled=false)
public class OpenJPACacheTest { ... }
```

2. If entity classes are in an inheritance hierarchy, child classes map to the parent BackingMap. The inheritance hierarchy shares a single BackingMap.
3. The ObjectGridQueryCache map is required to support QueryCache.
4. The backingMapPluginCollection for each entity map must have the ObjectTransformer using the com.ibm.ws.objectgrid.openjpa.ObjectGridPCDataObjectTransformer class.
5. The backingMapPluginCollection for ObjectGridQueryCache map must have the key index named as QueryCacheKeyIndex as shown in the sample.
6. The evictor is optional for each map.

openjpa-objectGridDeployment.xml file

The openjpa-objectGridDeployment.xml file is used to customize deployment policy. The openjpa-objectGridDeployment.xml file that matches the persistence.xml file follows:

```
openjpa-objectGridDeployment.xml

<?xml version="1.0" encoding="UTF-8" ?>
<deploymentPolicy xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://ibm.com/ws/objectgrid/deploymentPolicy ../deploymentPolicy.xsd"
  xmlns="http://ibm.com/ws/objectgrid/deploymentPolicy">
  <objectgridDeployment objectgridName="Annuity">
    <mapSet name="MAPSET_Annuity" numberOfPartitions="1" numInitialContainers="1"
            minSyncReplicas="0" maxSyncReplicas="4" maxAsyncReplicas="0"
            replicaReadEnabled="true">
      <map ref="com.ibm.wssvt.acme.annuity.common.bean.jpa.Annuity" />
      <map ref="com.ibm.wssvt.acme.annuity.common.bean.jpa.Address" />
      <map ref="com.ibm.wssvt.acme.annuity.common.bean.jpa.Payor" />
      <map ref="com.ibm.wssvt.acme.annuity.common.bean.jpa.Person" />
      <map ref="com.ibm.wssvt.acme.annuity.common.bean.jpa.Contact" />
      <map ref="com.ibm.wssvt.acme.annuity.common.bean.jpa.AnnuityPersistebleObject" />
      <map ref="com.ibm.wssvt.acme.annuity.common.bean.jpa.Rider" />
      <map ref="com.ibm.wssvt.acme.annuity.common.bean.jpa.Payout" />
      <map ref="ObjectGridQueryCache" />
    </mapSet>
  </objectgridDeployment>
</deploymentPolicy>
```

Note: The ObjectGridQueryCache map is required to support QueryCache.

Configuring the Hibernate cache plug-in

You can enable the cache to use the Hibernate cache plug-in by specifying properties files.

Before you begin

- You must determine the JPA cache plug-in topology that you want to use. See JPA level 2 (L2) cache plug-in for more information about the different configurations.
- You must have an application that uses the JPA APIs. If you want to use WebSphere eXtreme Scale APIs to access data with JPA, use the JPA loader. For more information, see Configuring JPA loaders.

Procedure

1. If you are using WebSphere Application Server, place the Java Archive (JAR) files in the appropriate locations for your configuration. 8.5
   The Hibernate cache plug-in is packaged in the oghibernate-cache.jar file and is installed in the *was_root*/optionalLibraries/ObjectGrid directory. To use the Hibernate cache plug-in, you have to include the oghibernate-cache.jar file in the Hibernate library. For example, if you include the Hibernate library in your application, also must include the oghibernate-cache.jar file. If you define a shared library to include Hibernate library, you must add the oghibernate-cache.jar file into the shared library directory.

   eXtreme Scale does not install the cglib.jar file in the WebSphere Application Server environment. If you have existing applications or shared libraries, such as hibernate, which depend on the cglib.jar, locate the cglib.jar file and include it in the classpath. For example, if your application includes all hibernate library JAR files, but excludes the cglib.jar file available with hibernate, you must include the cglib.jar file that comes from Hibernate in your application.

2. Set properties in your persistence.xml file to configure the Hibernate cache plug-in
   The syntax for setting properties in the persistence.xml file follows:

```
<property name="hibernate.cache.provider_class"
        value="com.ibm.websphere.objectgrid.hibernate.cache.ObjectGridHibernateCacheProvider" />
<property name="hibernate.cache.use_query_cache" value="true"/>
<property name="objectgrid.configuration" value="<property>=<value>,..." />
<property name="objectgrid.hibernate.regionNames" value="<regionName>,.." />
```

- hibernate.cache.provider_class : The value of the provider_class property is the com.ibm.websphere.objectgrid.hibernate.cache.ObjectGridHibernateCacheProvider class.
- hibernate.cache.use_query_cache: To enable query cache, set the value to `true` on the use_query_cache property.
  Note: You can enable the query cache for embedded and embedded-intradomain topologies only.
- objectgrid.configuration: Use the objectgrid.configuration property to specify eXtreme Scale cache configuration properties, including the ObjectGridType attribute that specifies how to place the shards on the data grid.
  You must specify a unique ObjectGridName property value to avoid potential naming conflicts. The other eXtreme Scale cache configuration properties are optional.

  To enable write-behind caching, use the following write-behind attributes on the objectgrid.configuration property. When write-behind caching is enabled, updates are temporarily stored in a JVM scope data storage until either the writeBehindInterval or writeBehindMaxBatchSize conditions are met, when the data is flushed to the cache.

  ```
  writeBehind=true, writeBehindInterval=5000, writeBehindPoolSize=10, writeBehindMaxBatchSize=1000
  ```

  Attention: Unless writeBehind is enabled, the other write behind configuration settings are disregarded.
  For more information about the values that you can set in the objectgrid.configuration property, see JPA cache configuration properties for both OpenJPA and Hibernate Version 3.0.

- objectgrid.hibernate.regionNames: The objectgrid.hibernate.regionNames property is optional and should be specified when the regionNames values are defined after the eXtreme Scale cache is initialized. Consider the example of an entity class that is mapped to a regionName with the entity class unspecified in the persistence.xml file or not included in the Hibernate mapping file. Further, say it does have Entity annotation. Then, the regionName for this entity class is resolved at class loading time when the eXtreme Scale cache is initialized. Another example is the Query.setCacheRegion(String regionName) method that runs after the eXtreme Scale cache initialization. In these situations, include all possible dynamic determined regionNames in the objectgrid.hibernate.regionNames property so that the eXtreme Scale cache can prepare BackingMaps for all regionNames.

3. Optional: To further customize the data grid used by the cache, you can provide additional settings with XML files.
   For most scenarios, setting cache properties should be sufficient. To further customize the ObjectGrid used by the cache, you can provide Hibernate ObjectGrid configuration XML files in the META-INF directory similarly to the persistence.xml file. During initialization, the cache tries to locate these XML files and process them if found.

   There are three types of Hibernate ObjectGrid configuration XML files:
   - hibernate-objectGrid.xml (ObjectGrid configuration)
     File path: META-INF/hibernate-objectGrid.xml

     By default, each entity class has an associated regionName (default to entity class name) that is mapped to a BackingMap configuration named as regionName within the ObjectGrid configuration. For example, the com.mycompany.Employee entity class has an associated regionName default to com.mycompany.Employee BackingMap. The default BackingMap configuration is readOnly="false", copyKey="false", lockStrategy="NONE", and `copyMode="NO_COPY"`. You can customize some BackingMaps with a chosen configuration. The reserved key word "ALL_ENTITY_MAPS" can be used to represent all maps excluding other customized maps listed in the hibernate-objectGrid.xmlfile. BackingMaps that are not listed in this hibernate-objectGrid.xml file use the default configuration.

   - hibernate-objectGridDeployment.xml (deployment policy)
     File path: META-INF/hibernate-objectGridDeployment.xml

     This file is used to customize deployment policy. When you are customizing deployment policy, if the hibernate-objectGridDeployment.xml is provided, the default deployment policy is discarded. All deployment policy attribute values will come from the provided hibernate-objectGridDeployment.xml file.

   - hibernate-objectGrid-client-override.xml (client ObjectGrid override configuration)
     File path: META-INF/hibernate-objectGrid-client-override.xml

     This file is used to customize a client-side ObjectGrid. By default, the ObjectGrid cache applies a default client override configuration that disables the near cache. You can enable the near cache by providing the hibernate-objectGrid-client-override.xml file that overrides this configuration. For more information about the settings to change in this file to enable near cache, see Configuring the near cache. The way that the hibernate-objectGrid-client-override.xml file works is similar to the hibernate-objectGrid.xml file. It overrides or extends the default client ObjectGrid override configuration.

   Depending on the configured eXtreme Scale topology, you can provide any one of these three XML files to customize that topology.
   For both the EMBEDDED and EMBEDDED_PARTITION type, you can provide any one of the three XML files to customize the ObjectGrid, deployment policy, and client ObjectGrid override configuration.

   For a REMOTE ObjectGrid, the cache does not create a dynamic ObjectGrid. The cache only obtains a client-side ObjectGrid from the catalog service. You can only provide a hibernate-objectGrid-client-override.xml file to customize client ObjectGrid override configuration.

4. Optional: (Remote configurations only) Set up an external eXtreme Scale system if you want to configure a cache with a REMOTE ObjectGrid type. You also need to specify the libraries and their dependencies in the classpath for the eXtreme Scale container servers.
   You must set up an external eXtreme Scale system if you want to configure a cache with a REMOTE ObjectGrid type. You need both ObjectGrid and ObjectGridDeployment configuration XML files that are based on the persistence.xml file to set up an external system. For examples of these configuration files, seeExample: Hibernate ObjectGrid XML files.

Results

EMBEDDED or EMBEDDED_PARTITION configuration:

When an application starts, the plug-in automatically detects or starts a catalog service, starts a container server, and connect the container servers to the catalog service. The plug-in then communicates with the ObjectGrid container and its peers that are running in other application server processes using the client connection.

Each JPA entity has an independent backing map assigned using the class name of the entity. Each BackingMap has the following attributes.

- `readOnly="false"`
- `copyKey="false"`
- `lockStrategy="NONE"`
- `copyMode="NO_COPY"`

REMOTE configuration:

The deployment policy is specified separately from the JPA application. An external ObjectGrid system has both catalog service and container server processes. You must start a catalog service before starting container servers. See Starting stand-alone servers and Starting container servers for more information.

What to do next

- Develop a Hibernate application that uses the configuration. For more information, see Example: Using the Hibernate plug-in to preload data into the ObjectGrid cache.
- In a production environment, create catalog service domains for your automatically created processes for your EMBEDDED or EMBEDDED_PARTITION configuration.
  - Stand-alone environment:
    If you are not running your servers inside a WebSphere Application Server process, the catalog service domain hosts and ports are specified using properties file named objectGridServer.properties. This file must be stored in the class path of the application and have the **catalogServiceEndPoints** property defined. The catalog service domain is started independently from the application processes and must be started before the application processes are started.

    The format of the objectGridServer.properties file follows:

    ```
    catalogServiceEndPoints=<hostname1>:<port1>,<hostname2>:<port2>
    ```

  - WebSphere Application Server environment:
    If you are running inside a WebSphere Application Server process, the JPA cache plug-in automatically connects to the catalog service or catalog service domain that is defined for the WebSphere Application Server cell. However, using an objectGridServer.properties file with defined `catalogServiceEndPoints` will cause problems because it will try to establish a connection to that catalog server instead of the one in WebSphere Application Server.
- When you are using the `EMBEDDED` or `EMBEDDED_PARTITION` ObjectGridType value in a Java SE environment, use the System.exit(0) method at the end of the program to stop the embedded eXtreme Scale server. Otherwise, the program can become unresponsive.
- Example: Hibernate ObjectGrid XML files
  Create Hibernate ObjectGrid XML files based on the configuration of a persistence unit.

Example: Hibernate ObjectGrid XML files

Create Hibernate ObjectGrid XML files based on the configuration of a persistence unit.

persistence.xml file

An example persistence.xml file that represents the configuration of a persistence unit follows:

```
<persistence xmlns="http://java.sun.com/xml/ns/persistence" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  version="1.0">
  <persistence-unit name="AnnuityGrid">
    <provider>org.hibernate.ejb.HibernatePersistence</provider>

    <class>com.ibm.wssvt.acme.annuity.common.bean.jpa.AnnuityPersistebleObject</class>
    <class>com.ibm.wssvt.acme.annuity.common.bean.jpa.Annuity</class>
    <class>com.ibm.wssvt.acme.annuity.common.bean.jpa.FixedAnnuity</class>
    <class>com.ibm.wssvt.acme.annuity.common.bean.jpa.EquityAnnuity</class>
    <class>com.ibm.wssvt.acme.annuity.common.bean.jpa.Payout</class>
    <class>com.ibm.wssvt.acme.annuity.common.bean.jpa.Rider</class>
    <class>com.ibm.wssvt.acme.annuity.common.bean.jpa.Payor</class>
```

```
    <class>com.ibm.wssvt.acme.annuity.common.bean.jpa.Person</class>
    <class>com.ibm.wssvt.acme.annuity.common.bean.jpa.AnnuityHolder</class>
    <class>com.ibm.wssvt.acme.annuity.common.bean.jpa.Contact</class>
    <class>com.ibm.wssvt.acme.annuity.common.bean.jpa.Address</class>

    <exclude-unlisted-classes>true</exclude-unlisted-classes>

    <properties>
      <property name="hibernate.show_sql" value="false" />
      <property name="hibernate.connection.url" value="jdbc:db2:Annuity" />
      <property name="hibernate.connection.driver_class" value="com.ibm.db2.jcc.DB2Driver" />
      <property name="hibernate.default_schema" value="EJB30" />

      <!-- Cache -->
      <property name="hibernate.cache.provider_class"
        value="com.ibm.websphere.objectgrid.hibernate.cache.ObjectGridHibernateCacheProvider" />
      <property name="hibernate.cache.use_query_cache" value="true" />
      <property name="objectgrid.configuration" value="ObjectGridType=EMBEDDED,
                ObjectGridName=Annuity, MaxNumberOfReplicas=4" />
    </properties>
  </persistence-unit>

</persistence>
```

hibernate-objectGridDeployment.xml file

Use the hibernate-objectGridDeployment.xml file to optionally customize the deployment policy. If you provide this file in the META-INF/hibernate-objectGridDeployment.xml directory, the default deployment policy is overridden by the configuration in this file.

```
<?xml version="1.0" encoding="UTF-8" ?>
<deploymentPolicy xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://ibm.com/ws/objectgrid/deploymentPolicy ../deploymentPolicy.xsd"
  xmlns="http://ibm.com/ws/objectgrid/deploymentPolicy">
  <objectgridDeployment objectgridName="Annuity">
    <mapSet name="MAPSET_Annuity" numberOfPartitions="1" numInitialContainers="1" minSyncReplicas="0"
          maxSyncReplicas="4" maxAsyncReplicas="0" replicaReadEnabled="true">
      <map ref="com.ibm.wssvt.acme.annuity.common.bean.jpa.Annuity" />
      <map ref="defaultCacheMap" />
      <map ref="com.ibm.wssvt.acme.annuity.common.bean.jpa.Payor" />
      <map ref="com.ibm.wssvt.acme.annuity.common.bean.jpa.Contact" />
      <map ref="com.ibm.wssvt.acme.annuity.common.bean.jpa.Person" />
      <map ref="com.ibm.wssvt.acme.annuity.common.bean.jpa.Rider" />
      <map ref="com.ibm.wssvt.acme.annuity.common.bean.jpa.Payout" />
      <map ref="org.hibernate.cache.UpdateTimestampsCache" />
      <map ref="org.hibernate.cache.StandardQueryCache" />
    </mapSet>
  </objectgridDeployment>
</deploymentPolicy>
```

hibernate-objectGrid.xml file

If you are not using Hibernate with the Java Persistence API (JPA), use the following example hibernate-objectGrid.xml to create your Hibernate configuration:

```
<?xml version="1.0" encoding="UTF-8"?>
<objectGridConfig xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://ibm.com/ws/objectgrid/config ../objectGrid.xsd"
  xmlns="http://ibm.com/ws/objectgrid/config">
  <objectGrids>
    <objectGrid name="Annuity">
      <backingMap name="com.ibm.wssvt.acme.annuity.common.bean.jpa.Annuity" readOnly="false" copyKey="false"
                  lockStrategy="NONE" copyMode="NO_COPY" evictionTriggers="MEMORY_USAGE_THRESHOLD"
                  pluginCollectionRef="com.ibm.wssvt.acme.annuity.common.bean.jpa.Annuity" />
      <backingMap name="defaultCacheMap" readOnly="false" copyKey="false"
                  lockStrategy="NONE" copyMode="NO_COPY" evictionTriggers="MEMORY_USAGE_THRESHOLD"
                  pluginCollectionRef="defaultCacheMap" />
      <backingMap name="com.ibm.wssvt.acme.annuity.common.bean.jpa.Payor" readOnly="false" copyKey="false"
                  lockStrategy="NONE" copyMode="NO_COPY" evictionTriggers="MEMORY_USAGE_THRESHOLD"
                  pluginCollectionRef="com.ibm.wssvt.acme.annuity.common.bean.jpa.Payor" />
      <backingMap name="com.ibm.wssvt.acme.annuity.common.bean.jpa.Contact" readOnly="false" copyKey="false"
                  lockStrategy="NONE" copyMode="NO_COPY" evictionTriggers="MEMORY_USAGE_THRESHOLD"
                  pluginCollectionRef="com.ibm.wssvt.acme.annuity.common.bean.jpa.Contact" />
      <backingMap name="com.ibm.wssvt.acme.annuity.common.bean.jpa.Person" readOnly="false" copyKey="false"
                  lockStrategy="NONE" copyMode="NO_COPY" evictionTriggers="MEMORY_USAGE_THRESHOLD"
                  pluginCollectionRef="com.ibm.wssvt.acme.annuity.common.bean.jpa.Person" />
      <backingMap name="com.ibm.wssvt.acme.annuity.common.bean.jpa.Rider" readOnly="false" copyKey="false"
                  lockStrategy="NONE" copyMode="NO_COPY" evictionTriggers="MEMORY_USAGE_THRESHOLD"
                  pluginCollectionRef="com.ibm.wssvt.acme.annuity.common.bean.jpa.Rider" />
      <backingMap name="com.ibm.wssvt.acme.annuity.common.bean.jpa.Payout" readOnly="false" copyKey="false"
                  lockStrategy="NONE" copyMode="NO_COPY" evictionTriggers="MEMORY_USAGE_THRESHOLD"
                  pluginCollectionRef="com.ibm.wssvt.acme.annuity.common.bean.jpa.Payout" />
      <backingMap name="org.hibernate.cache.UpdateTimestampsCache" readOnly="false" copyKey="false"
                  lockStrategy="NONE" copyMode="NO_COPY" evictionTriggers="MEMORY_USAGE_THRESHOLD"
                  pluginCollectionRef="org.hibernate.cache.UpdateTimestampsCache" />
      <backingMap name="org.hibernate.cache.StandardQueryCache" readOnly="false" copyKey="false"
                  lockStrategy="NONE" copyMode="NO_COPY" evictionTriggers="MEMORY_USAGE_THRESHOLD"
                  pluginCollectionRef="org.hibernate.cache.StandardQueryCache" />
    </objectGrid>
```

```
  </objectGrids>

Configuring a Spring cache provider

8.5+ Spring Framework Version 3.1 introduced a new cache abstraction. With this new abstraction, you can transparently add caching to an existing Spring application. You can use WebSphere® eXtreme Scale as the cache provider for the cache abstraction.

Before you begin

- You must have an application that is using Spring Framework Version 3.1 or later.
- Your application must declare the methods to cache by using annotations. For more information about updating your application for cache abstraction, see Spring Framework Reference Documentation : Cache abstraction.
- Ensure that the ogclient.jar file is in the classpath for the Spring application.
- If the JVM on which your application is running is not the JVM that is installed by WebSphere eXtreme Scale Client, you must add the following JVM argument so that the IBM Object Request Broker (ORB) is used:

  ```
  -Djava.endorsed.dirs=wxs_root/lib/endorsed
  ```

- You must start a catalog server. For more information, see Starting a stand-alone catalog service.

About this task

By using the cache abstraction in the Spring framework, you can reduce the number of times that your Spring application methods run. When configured, the results of a particular method are placed in the cache. When the method is run again, the abstraction checks the cache to see if the method results are already in the cache. If the results are in the cache, the results are returned from the cache and the method does not run again. Therefore, you can reduce the number of times that expensive methods run, also decreasing the average response time of your application.

Procedure

1. Configure your container servers to use the configuration files for Spring.
   You must start container servers before the Spring application that accesses the cache starts. To start container servers, see Starting stand-alone servers.

   The default XML configuration files for starting a container server for the eXtreme Scale Spring cache provider are in one of the following locations:
   - Stand-alone installations: *wxs_install_root*/ObjectGrid/spring/etc
   - WebSphere Application Server installations: *was_root*/optionalLibraries/ObjectGrid/spring/etc

   The files are named spring-remote-objectgrid.xml and spring-remote-deployment.xml. You can use these files as-is, customize these files, or create your own configuration files.
   Run the following command to start a stand-alone container server for the eXtreme Scale Spring cache provider. Run the following command from the *wxs_home*/ObjectGrid/bin directory: Windows

   ```
   startOgServer.bat container1 -objectGridFile ../spring/etc/spring-remote-objectgrid.xml
   -deploymentPolicyFile ../spring/etc/spring-remote-deployment.xml
   ```

   UNIX

   ```
   startOgServer.sh container1 -objectGridFile ../spring/etc/spring-remote-objectgrid.xml
   -deploymentPolicyFile ../spring/etc/spring-remote-deployment.xml
   ```

2. Configure Spring Inversion of Control (IoC) container to use WebSphere eXtreme Scale as the cache provider. The WebSphere eXtreme Scale cache implementation resides under the com.ibm.websphere.objectgrid.spring package. Define the following beans in your Spring IoC container configuration.

   ```
   <bean
   id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsspringprovide_wxsCSDomain"
   class="com.ibm.websphere.objectgrid.spring.ObjectGridCatalogServiceDomainBean"
     p:catalog-service-endpoints="CATALOG_SERVICE_ENDPOINTS"
     p:client-override-xml="CLIENT_OVERRIDE_XML (optional)"
     p:client-security-config="CLIENT_SECURITY_CONFIG (optional)" />

   <bean
   id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsspringprovide_wxsGridClient"
   class="com.ibm.websphere.objectgrid.spring.ObjectGridClientBean"
     p:object-grid-name="OBJECT_GRID_NAME(optional)"
     p:catalog-service-domain-ref="wxsCSDomain" />

   <bean
   id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsspringprovide_cacheManager"
   class="org.springframework.cache.support.SimpleCacheManager">
     <property name="caches">
       <set>
         <bean class="com.ibm.websphere.objectgrid.spring.ObjectGridCache"
            p:name="CACHE_NAME"
            p:map-name="MAP_NAME (optional)"
                  p:object-grid-client-ref="wxsGridClient" />
       </set>
     </property>
   </bean>
   ```

   CATALOG_SERVICE_ENDPOINTS
   Specifies the Object Request Broker (ORB) host and port number.
   CLIENT_OVERRIDE_XML (optional)
   Specifies an absolute or relative path to an ObjectGrid XML file on which to alter settings on the client side as a Spring resource. For information about specifying resources in Spring, see Spring Framework Reference Documentation: Resources.
   Example:`p:client-override-xml="file:/path/to/objectgrid.xml"`

   Example:`p:client-override-xml="classpath:com/example/app/override-objectgrid.xml"`

   Example:`p:client-override-xml="http://myserver/override-objectgrid.xml"`

   Example:`p:client-override-xml="ftp://myserver/override-objectgrid.xml"`

CLIENT_SECURITY_CONFIG (optional)
Specifies an absolute or relative path to a client.properties file as a Spring resource. For information about specifying resources in Spring, see Spring Framework Reference Documentation: Resources.
Example: `p:client-security-config="file:/path/to/client.properties"`

OBJECT_GRID_NAME (optional)
Specifies the ObjectGrid name. This parameter is not needed if the container servers are started with the provided XML configuration files. This parameter must be consistent with the XML configuration files that are used to start the container servers.

CACHE_NAME
Specifies the name of the cache that is specified in your Spring caching application.

MAP_NAME (optional)
Specifies the name of the backing map for a cache. This parameter is not needed if the container servers are started with the provided XML configuration files. This parameter must be consistent with the XML configuration files that are used to start the container servers. If you use the provided XML configuration files, the *MAP_NAME* value is not needed. The maps for the data grid are created automatically when the Spring application runs. The dynamic map name starts with `IBM_SPRING_PARTITIONED_`. For example: `IBM_SPRING_PARTITIONED_1`, `IBM_SPRING_PARTITIONED_2`, and so on.

Example

The following snippet creates two caches, named `default` and `books` hosted by the catalog service domain at `localhost:2809`.

```
<bean id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsspringprovide_wxsCSDomain"
class="com.ibm.websphere.objectgrid.spring.ObjectGridCatalogServiceDomainBean"
        p:catalog-service-endpoints ="localhost:2809" />
<bean id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsspringprovide_wxsGridClient"
class="com.ibm.websphere.objectgrid.spring.ObjectGridClientBean"
        p:catalog-service-domain-ref="wxsCSDomain" />
<bean id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsspringprovide_cacheManager"
class="org.springframework.cache.support.SimpleCacheManager">
        <property name="caches">
                <set>
                        <bean class="com.ibm.websphere.objectgrid.spring.ObjectGridCache"
                                p:name="default"
                                p:object-grid-client-ref="wxsGridClient" />
                        <bean class="com.ibm.websphere.objectgrid.spring.ObjectGridCache"
                                p:name="books"
                                p:object-grid-client-ref="wxsGridClient" />
                </set>
        </property>
</bean>
```

Configuring database integration

You can use WebSphere® eXtreme Scale to lower the load on databases. You can use a Java Persistence API (JPA) between WebSphere eXtreme Scale and the database to integrate changes as a loader.

Before you begin

For a summary of the various topologies that you can create with a database, see Database integration: Write-behind, in-line, and side caching.

- Configuring JPA loaders
  A Java™ Persistence API (JPA) Loader is a plug-in implementation that uses JPA to interact with the database.

Configuring JPA loaders

A Java™ Persistence API (JPA) Loader is a plug-in implementation that uses JPA to interact with the database.

Before you begin

- You must have a JPA implementation, such as Hibernate or OpenJPA.
- Your database can be any back end that is supported by the chosen JPA provider.
- Decide whether you are going to use the JPALoader plug-in or the JPAEntityLoader plug-in. Use the JPALoader plug-in when you are storing data using the ObjectMap API. Use the JPAEntityLoader plug-in when you are storing data using the EntityManager API.
  Note: If you are using the JPA APIs to access the JPA data source, use the JPA L2 cache plug-in. The cache plug-in introduces the data grid between your application and the JPA data source, while still using a JPA application. For more information, see JPA level 2 (L2) cache plug-in.

About this task

For more information about how the Java Persistence API (JPA) Loader works, see JPA Loaders.

Procedure

1. Configure the necessary parameters that JPA requires to interact with a database.
   The following parameters are required. These parameters are configured in the JPALoader or JPAEntityLoader bean, and JPATxCallback bean.

   - persistenceUnitName: Specifies the persistence unit name. This parameter is required for two purposes: for creating a JPA EntityManagerFactory, and for locating the JPA entity metadata in the persistence.xml file. This attribute is set on the JPATxCallback bean.
   - JPAPropertyFactory: Specifies the factory to create a persistence property map to override the default persistence properties. This attribute is set on the JPATxCallback bean. To set this attribute, Spring style configuration is required.
   - entityClassName: Specifies the entity class name that is required to use JPA methods, such as EntityManager.persist, EntityManager.find, and so on. The JPALoader plug-in requires this parameter, but the parameter is optional for JPAEntityLoader. For the JPAEntityLoader plug-in, if an entityClassName parameter is not configured, the entity class configured in the ObjectGrid entity map is used. You must use the same class for the eXtreme Scale EntityManager and for the JPA provider. This attribute is set on the JPALoader or JPAEntityLoader bean.
   - preloadPartition: Specifies the partition at which the map preload is started. If the preload partition is less than zero, or greater than the total number of partitions minus 1, the map preload is not started. The default value is -1, which means the preload does not start by default. This attribute is set on the JPALoader or JPAEntityLoader bean.

   Other than the four JPA parameters to be configured in eXtreme Scale, JPA metadata are used to retrieve the key from the JPA entities. The JPA metadata can be configured as annotation, or as an orm.xml file specified in the persistence.xml file. It is not part of the eXtreme Scale configuration.

2. Configure XML files for the JPA configuration.
   To configure a JPALoader or JPAEntityLoader, see Plug-ins for communicating with databases.

   Configure a JPATxCallback transaction callback along with the loader configuration. The following example is an ObjectGrid XML descriptor file (objectgrid.xml), that has a JPAEntityLoader and JPATxCallback configured:

```
configuring a loader including callback - XML example
<?xml version="1.0" encoding="UTF-8"?>
<objectGridConfig xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
        xsi:schemaLocation="http://ibm.com/ws/objectgrid/config ../objectGrid.xsd"
        xmlns="http://ibm.com/ws/objectgrid/config">
    <objectGrids>
      <objectGrid name="JPAEM" entityMetadataXMLFile="jpaEMD.xml">
        <bean
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsjpaload_TransactionCallback"
           className="com.ibm.websphere.objectgrid.jpa.JPATxCallback">
           <property
              name="persistenceUnitName"
              type="java.lang.String"
              value="employeeEMPU" />
       </bean>
       <backingMap name="Employee" pluginCollectionRef="Employee" />
    </objectGrid>
  </objectGrids>

  <backingMapPluginCollections>
    <backingMapPluginCollection
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsjpaload_Employee">
        <bean id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsjpaload_Loader"
          className="com.ibm.websphere.objectgrid.jpa.JPAEntityLoader">
            <property
             name="entityClassName"
             type="java.lang.String"
             value="com.ibm.ws.objectgrid.jpa.test.entity.Employee"/>
        </bean>
    </backingMapPluginCollection>
  </backingMapPluginCollections>
</objectGridConfig>
```

   If you want to configure a JPAPropertyFactory, you have to use a Spring style configuration. The following is an XML configuration file sample,JPAEM_spring.xml which configures a Spring bean to be used for eXtreme Scale configurations.

```
configuring a loader including JPA property factory - XML example
<?xml version="1.0" encoding="UTF-8"?>
<beans xmlns="http://www.springframework.org/schema/beans"
       xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
       xmlns:aop="http://www.springframework.org/schema/aop"
       xmlns:tx="http://www.springframework.org/schema/tx"

xmlns:objectgrid="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsjpaload_http://
www.ibm.com/schema/objectgrid"
       xsi:schemaLocation="http://www.springframework.org/schema/beans
           http://www.springframework.org/schema/beans/spring-beans-2.0.xsd">

  <objectgrid:JPAEntityLoader
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsjpaload_jpaLoader"
                entityClassName="com.ibm.ws.objectgrid.jpa.test.entity.Employee"/>
  <objectgrid:JPATxCallback
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsjpaload_jpaTxCallback"
persistenceUnitName="employeeEMPU" />
</beans>
```

The Objectgrid.xml configuration XML file follows. Notice the ObjectGrid name is `JPAEM`, which matches the ObjectGrid name in the JPAEM_spring.xml Spring configuration file.

```
JPAEM loader configuration - XML example
<?xml version="1.0" encoding="UTF-8"?>
<objectGridConfig xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:schemaLocation="http://ibm.com/ws/objectgrid/config ../objectGrid.xsd"
 xmlns="http://ibm.com/ws/objectgrid/config">
  <objectGrids>
    <objectGrid name="JPAEM" entityMetadataXMLFile="jpaEMD.xml">
      <bean
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsjpaload_TransactionCallback"
           className="{spring}jpaTxCallback"/>
       <backingMap name="Employee" pluginCollectionRef="Employee"
                   writeBehind="T4"/>
     </objectGrid>
  </objectGrids>

  <backingMapPluginCollections>
    <backingMapPluginCollection
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsjpaload_Employee">
      <bean id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsjpaload_Loader"
className="{spring}jpaLoader" />
    </backingMapPluginCollection>
  </backingMapPluginCollections>
</objectGridConfig>
```

An entity can be annotated with both the JPA annotations and eXtreme Scale entity manager annotations. Each annotation has an XML equivalent that can be used. Thus, eXtreme Scale added the Spring namespace. You can also configure these using the Spring namespace support. For more information, see Spring framework overview.

- Configuring a JPA time-based data updater
  You can configure a time-based database update using XML for a local or distributed eXtreme Scale configuration. You can also configure a local configuration programmatically.

Troubleshooting loaders

Configuring a JPA time-based data updater

You can configure a time-based database update using XML for a local or distributed eXtreme Scale configuration. You can also configure a local configuration programmatically.

About this task

For more information about how the Java™ Persistence API (JPA) time-based data updater works, see JPA time-based data updater.

Procedure

Create a timeBasedDBUpdate configuration.

- **With an XML file:**
  The following example shows an objectgrid.xml file that contains a timeBasedDBUpdate configuration:

```
JPA time-based updater - XML example
<?xml version="1.0" encoding="UTF-8"?>
<objectGridConfig xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:schemaLocation="http://ibm.com/ws/objectgrid/config ../objectGrid.xsd"
 xmlns="http://ibm.com/ws/objectgrid/config">
    <objectGrids>
        <objectGrid name="changeOG"
            entityMetadataXMLFile="userEMD.xml">
            <backingMap name="user" >
                <timeBasedDBUpdate timestampField="rowChgTs"
                      persistenceUnitName="userderby"
                      entityClass="com.test.UserClass"
                      mode="INVALIDATE_ONLY"
                />
            </backingMap>
        </objectGrid>
    </objectGrids>
    <backingMapPluginCollections>
</objectGridConfig>
```

In this example, the map "user" is configured with time-based database update. The database update mode is INVALIDATE_ONLY, and the timestamp field is rowChgTs.

When the distributed ObjectGrid "changeOG" is started in the container server, a time-based database update thread is automatically started in partition 0.

- **Programmatically:**
  If you create a local ObjectGrid, you can also create a TimeBasedDBUpdateConfig object and set it on the BackingMap instance:

  ```
  public void setTimeBasedDBUpdateConfig(TimeBasedDBUpdateConfig dbUpdateConfig);
  ```

  For more information about setting an object on the BackingMap instance, see BackingMap interface
  Alternatively, you can annotate the timestamp field in the entity class using the com.ibm.websphere.objectgrid.jpa.dbupdate.annotation.Timestamp annotation. By configuring the value in the class, you do not have to configure the timestampField in the XML configuration.

What to do next

Start the JPA time-based data updater. See Starting the JPA time-based updater for more information.

Configuring REST data services

You can use WebSphere® eXtreme Scale REST data service with WebSphere Application Server version 7.0,WebSphere Application Server Community Edition and Apache Tomcat.

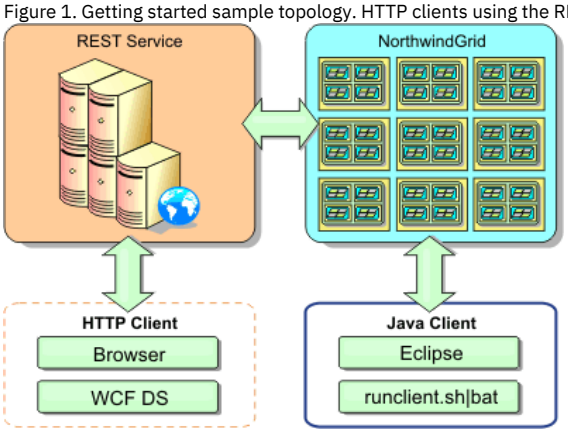
About this task

The included sample has source code and compiled binaries to run a partitioned data grid. This sample demonstrates how to create a simple data grid, model the data using entities and provides two command-line client applications that allow adding and querying entities using Java™ or C#.

The sample Java client uses the Java EntityManager API to persist and query data in the data grid. This client can be run in Eclipse or using a command-line script. Note that the sample Java client does not demonstrate the REST data service, but allows updating data in the grid, so a web browser or other clients can read the data.

The sample Microsoft WCF Data Services C# client communicates with the eXtreme Scale data grid through the REST data service using the .NET framework. The WCF Data Services client can be used to both update and query the data grid.

Figure 1. Getting started sample topology. HTTP clients using the REST data service and Java clients can access the same data grid.



Procedure

1. Configure and start the eXtreme Scale data grid. See Enabling the REST data service.
2. Configure and start the REST data service in a web server. See Configuring application servers for the REST data service.
3. Run a client to interact with the REST data service. Two options are available:
   a. Run the sample Java client to populate the grid with data using the EntityManager API and query the data in the grid using a web browser and the eXtreme Scale REST data service. See Using a Java client with REST data services.
   b. Run the sample WCF Data Services C# client. See Visual Studio 2008 WCF client with REST data service.

- Enabling the REST data service
  The REST data service can represent WebSphere eXtreme Scale entity metadata to represent each entity as an EntitySet.
- Configuring application servers for the REST data service
  You can configure various application servers to use the REST data service.
- Configuring Web browsers to access REST data service ATOM feeds
  The eXtreme Scale REST data service creates ATOM feeds by default when using a web browser. The ATOM feed format may not be compatible with older browsers or may be interpreted such that the data cannot be viewed as XML. You can configure Internet Explorer Version 8 and Firefox Version 3 to display the ATOM feeds and XML within the browser.
- Using a Java client with REST data services
  The Java client application uses the eXtreme Scale EntityManager API to insert data into the grid.
- Visual Studio 2008 WCF client with REST data service
  The eXtreme Scale REST data service getting started sample includes a WCF Data Services client that can interact with the eXtreme Scale REST data service. The sample is written as a command-line application in C#.

Enabling the REST data service

The REST data service can represent WebSphere® eXtreme Scale entity metadata to represent each entity as an EntitySet.

Starting a sample eXtreme Scale data grid

In general , before starting the REST data service, start the eXtreme Scale data grid. The following steps will start a single eXtreme Scale catalog service process and two container server processes.

WebSphere eXtreme Scale can be installed using three different methods:

- Trial install
- Stand-alone deployment
- WebSphere Application Server integrated deployment

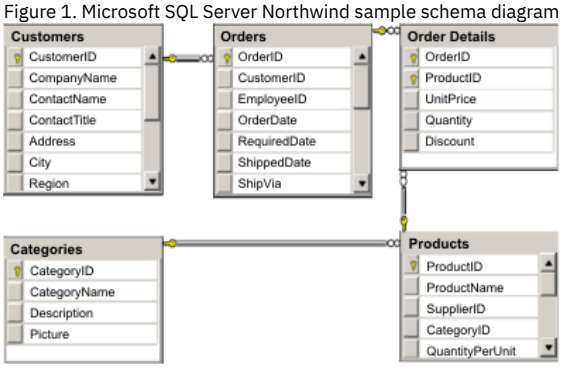
- Scalable data model in eXtreme Scale
  The Microsoft Northwind sample uses the Order Detail table to establish a many-to-many association between Orders and Products.
- Retrieving and updating data with REST
  The OData protocol requires that all entities can be addressed by their canonical form. This means that each entity must include the key of the partitioned, root entity, the schema root.
- Starting a stand-alone data grid for REST data services
  Follow these steps to start the WebSphere eXtreme Scale REST service sample data grid for a stand-alone eXtreme Scale deployment.
- Starting a data grid for REST data services in WebSphere Application Server
  Follow these steps to start a stand-alone WebSphere eXtreme Scale REST service sample data grid for a WebSphere eXtreme Scale deployment that is integrated with WebSphere Application Server. Although WebSphere eXtreme Scale is integrated with WebSphere Application Server, these steps start a stand-alone WebSphere eXtreme Scale catalog service process and container.

Scalable data model in eXtreme Scale

The Microsoft Northwind sample uses the Order Detail table to establish a many-to-many association between Orders and Products.

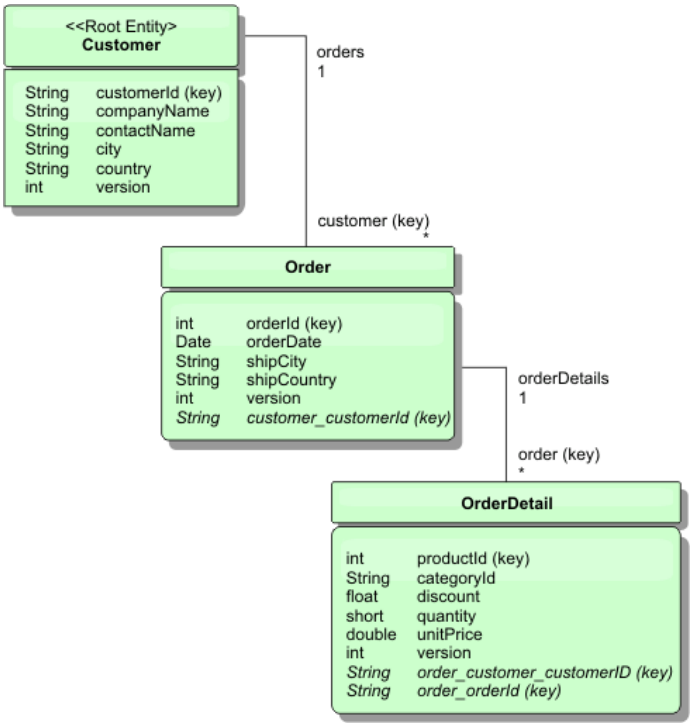
Object to relational mapping specifications (ORMs) such as the ADO.NET Entity Framework and Java™ Persistence API (JPA) can map the tables and relationships using entities. However, this architecture does not scale. Everything must be located on the same machine, or an expensive cluster of machines to perform well.

Figure 1. Microsoft SQL Server Northwind sample schema diagram



To create a scalable version of the sample, the entities must be modeled so each entity or group of related entities can be partitioned based off a single key. By creating partitions on a single key, requests can be spread out among multiple, independent servers. To achieve this configuration, the entities have been divided into two trees: the Customer and Order tree and the Product and Category tree. In this model, each tree can be partitioned independently and therefore can grow at different rates, increasing scalability.

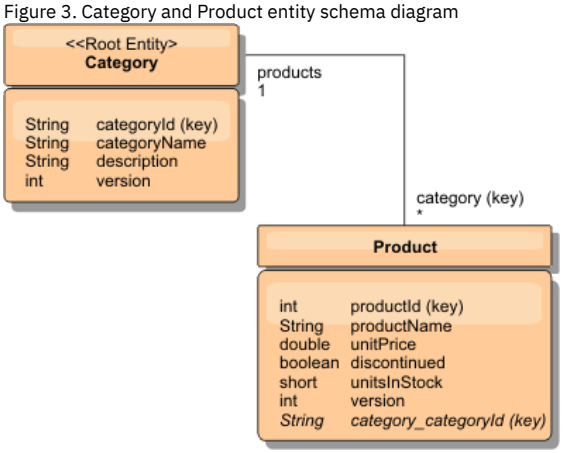
Figure 2. Customer and Order entity schema diagram



For example, both Order and Product have unique, separate integers as keys. In fact, the Order and Product tables are really independent of each other. For example, consider the effect of the size of a catalog, the number of products you sell, with the total number of orders. Intuitively, it might seem that having many products implies also having many orders, but this is not necessarily the case. If this were true, you could easily increase sales by just adding more products to your catalog. Orders and products have their own independent tables. You can further extend this concept so that orders and products each have their own separate, data grids. With independent data grids, you can control the number of partitions and servers, in addition to the size of each data grid separately so that your application can scale. If you double the size of your catalog, you must double the products data grid, but the order grid might be unchanged. The converse is true for an order surge, or expected order surge.

In the schema, a Customer has zero or more Orders, and an Order has line items (OrderDetail), each with one specific product. A Product is identified by ID (the Product key) in each OrderDetail. A single data grid stores Customers, Orders, and OrderDetails with Customer as the root entity of the data grid. You can retrieve Customers by ID, but you must get Orders starting with the Customer ID. So customer ID is added to Order as part of its key. Likewise, the customer ID and order ID are part of the OrderDetail ID.

Figure 3. Category and Product entity schema diagram



In the Category and Product schema, the Category is the schema root. With this schema, customers can query products by category. See Retrieving and updating data with REST for additional details on key associations and their importance.

Retrieving and updating data with REST

The OData protocol requires that all entities can be addressed by their canonical form. This means that each entity must include the key of the partitioned, root entity, the schema root.

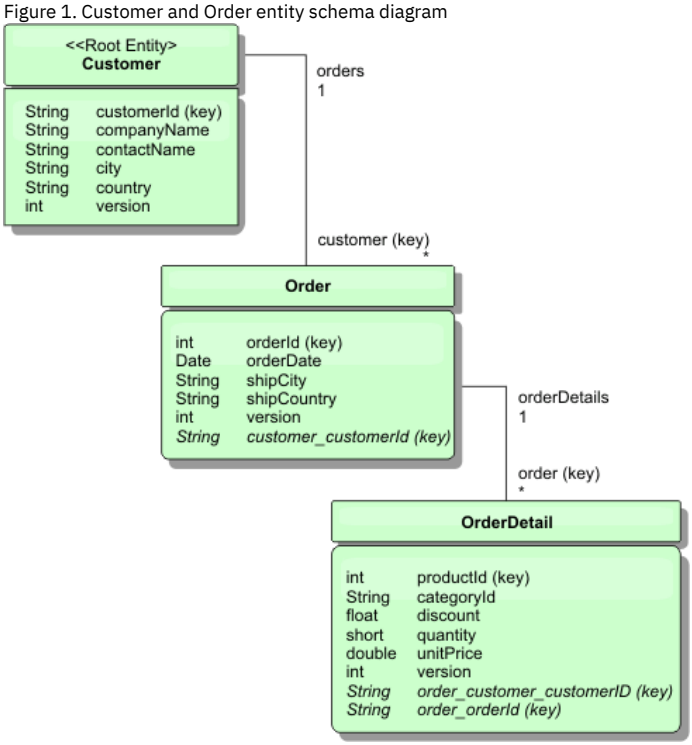
The following is an example of how to use the association from a root entity to address a child in :

```
/Customer('ACME')/order(100)
```

In WCF Data Services, the child entity must be directly addressable, meaning that the key in the schema root must be a part of the key of the child: `/Order(customer_customerId='ACME', orderId=100)`. This is achieved by creating an association to the root entity where the one-to-one or many-to-one

association to the root entity is also identified as a key. When entities are included as part of the key, the attributes of the parent entity are exposed as key properties.

Figure 1. Customer and Order entity schema diagram



The Customer/Order entity schema diagram illustrates how each entity is partitioned using the Customer. The Order entity includes the Customer as part of its key and is therefore directly accessible. The REST data service exposes all key associations as individual properties: Order has customer_customerId and OrderDetail has order_customer_customerId and order_orderId.

Using the EntityManager API, you can find the Order using the Customer and order id:

```
transaction.begin();
// Look-up the Order using the Customer.  We only include the Id
// in the Customer class when building the OrderId key instance.
Order order = (Order) em.find(Order.class,
    new OrderId(100, new Customer('ACME')));
...
transaction.commit();
```

When using the REST data service, the Order can be retrieved with either of the URLs:

- `/Order(orderId=100, customer_customerId='ACME')`
- `/Customer('ACME')/orders?$filter=orderId eq 100`

The customer key is addressed using the attribute name of the Customer entity, an underscore character and the attribute name of the customer id: customer_customerId.

An entity can also include a non-root entity as part of its key if all of the ancestors to the non-root entity have key associations to the root. In this example, OrderDetail has a key-association to Order and Order has a key-association to the root Customer entity. Using the EntityManager API:

```
transaction.begin();
// Construct an OrderDetailId key instance.  It includes
// The Order and Customer with only the keys set.
Customer customerACME = new Customer("ACME");
Order order100 = new Order(100, customerACME);
OrderDetailId orderDetailKey =
    new OrderDetailId(order100, "COMP");
OrderDetail orderDetail = (OrderDetail)
    em.find(OrderDetail.class, orderDetailKey);
...
```

The REST data service allows addressing the OrderDetail directly:

```
/OrderDetail(productId=500, order_customer_customerId='ACME', order_orderId =100)
```

The association from the OrderDetail entity to the Product entity has been broken to allow partitioning the Orders and Product inventory independently. The OrderDetail entity stores the category and product id instead of a hard relationship. By decoupling the two entity schemas, only one partition is accessed at a time.

The Category and Product schema illustrated in the diagram shows that the root entity is Category and each Product has an association to a Category entity. The Category entity is included in the Product identity. The REST data service exposes a key property: category_categoryId which allows directly addressing the Product.

Because Category is the root entity, in a partitioned environment, the Category must be known in order to find the Product. Using the EntityManager API, the transaction must be pinned to the Category entity prior to finding the Product.

Using the EntityManager API:

```
transaction.begin();
// Create the Category root entity with only the key.  This
// allows us to construct a ProductId without needing to find
// The Category first.  The transaction is now pinned to the
// partition where Category "COMP" is stored.
Category cat = new Category("COMP");
Product product = (Product) em.find(Product.class,
    new ProductId(500, cat));
...
```

The REST data service allows addressing the Product directly:

```
/Product(productId=500, category_categoryId='COMP')
```

Starting a stand-alone data grid for REST data services

Follow these steps to start the WebSphere® eXtreme Scale REST service sample data grid for a stand-alone eXtreme Scale deployment.

Before you begin

Install the WebSphere eXtreme Scale Trial or full product:

- Install the stand-alone version of the product and apply any subsequent fixes.
- Download and extract the WebSphere eXtreme Scale Version 7.1 or later trial, which includes the WebSphere eXtreme Scale REST data service.

About this task

Start the WebSphere eXtreme Scale sample data grid.

Procedure

1. Start the catalog service process. Open a command-line or terminal window and set the JAVA_HOME environment variable:
   - Linux UNIX `export JAVA_HOME=java_home`
   - Windows `set JAVA_HOME=java_home`
2. `cd restservice_home/gettingstarted`
3. Start the catalog service process. To start the service *without* eXtreme Scale security, use the following commands.
   - Linux UNIX `./runcat.sh`
   - Windows `runcat.bat`

   To start the service witheXtreme Scale security, use the following commands.
   - Linux UNIX `./runcat_secure.sh`
   - Windows `runcat_secure.bat`
4. Start two container server processes. Open another command-line or terminal window and set the JAVA_HOME environment variable:
   - Linux UNIX `export JAVA_HOME=java_home`
   - Windows `set JAVA_HOME=java_home`
5. `cd restservice_home/gettingstarted`
6. Start a container server process:
   To start the server without eXtreme Scale security, use the following commands:
   - Linux UNIX `./runcontainer.sh container0`
   - Windows `runcontainer.bat container0`

   To start the server witheXtreme Scale security, use the following commands.
   - Linux UNIX `./runcontainer_secure.sh container0`
   - Windows `runcontainer_secure.bat container0`
7. Open another command-line or terminal window and set the JAVA_HOME environment variable:
   - Linux UNIX `export JAVA_HOME=java_home`
   - Windows `set JAVA_HOME=java_home`
8. `cd restservice_home/gettingstarted`
9. Start a second container server process.
   To start the server without eXtreme Scale security, use the following commands.
   - Linux UNIX `./runcontainer.sh container1`
   - Windows `runcontainer.bat container1`

   To start the server with eXtreme Scale security, use the following commands.
   - Linux UNIX `./runcontainer_secure.sh container1`
   - Windows `runcontainer_secure.bat container1`

Results

Wait until the eXtreme Scale containers are ready before proceeding with the next steps. The container servers are ready when the following message is displayed in the terminal window:
`CWOBJ1001I: ObjectGrid Server container_name is ready to process requests.`

Where *container_name* is the name of the container that was started.

Starting a data grid for REST data services in WebSphere Application Server

Follow these steps to start a stand-alone WebSphere® eXtreme Scale REST service sample data grid for a WebSphere eXtreme Scale deployment that is integrated with WebSphere Application Server. Although WebSphere eXtreme Scale is integrated with WebSphere Application Server, these steps start a stand-alone WebSphere eXtreme Scale catalog service process and container.

Before you begin

Install the product into a WebSphere Application Server Version 7.0.0.5 or later installation directory with security disabled. Augment at least one application server profile.

About this task

Start the WebSphere eXtreme Scale sample data grid.

Procedure

1. Start the catalog service process. Open a command-line or terminal window and set the JAVA_HOME environment variable:
   - Linux UNIX `export JAVA_HOME=java_home`
   - Windows `set JAVA_HOME=java_home`

   `cd restservice_home/gettingstarted`
2. Start the catalog service process.
   To start the server without eXtreme Scale security, use the following commands.
   - Linux UNIX `./runcat.sh`
   - Windows `runcat.bat`

   To start the server witheXtreme Scale security, use the following commands.
   - Linux UNIX `./runcat_secure.sh`
   - Windows `runcat_secure.bat`
3. Start two container server processes. Open another command-line or terminal window and set the JAVA_HOME environment variable:
   - Linux UNIX `export JAVA_HOME=java_home`
   - Windows `set JAVA_HOME=java_home`
4. Start a container server process.
   To start the server without eXtreme Scale security, use the following commands.
   a. Open a command-line window.
   b. `cd restservice_home/gettingstarted`
   c. To start the server *without* eXtreme Scale security, use the following commands.
      - Linux UNIX `./runcontainer.sh container0`
      - Windows `runcontainer.bat container0`
   d. To start the server with eXtreme Scale security, use the following commands.
      - Linux UNIX `./runcontainer_secure.sh container0`
      - Windows `runcontainer_secure.bat container0`
5. Start a second container server process.
   a. Open a command-line window.
   b. `cd restservice_home/gettingstarted`
   c. To start the server *without* eXtreme Scale security, use the following commands.
      - Linux UNIX `./runcontainer.sh container1`
      - Windows `runcontainer.bat container1`
   d. To start the server *with* eXtreme Scale security, use the following commands.
      - Linux UNIX `./runcontainer_secure.sh container1`
      - Windows `runcontainer_secure.bat container1`

Results

Wait until the container servers are ready before proceeding with the next steps. The container servers are ready when the following message is displayed:
`CWOBJ1001I: ObjectGrid Server container_name is ready to process requests.`

Where *container_name* is the name of the container that was started in the previous step.

Configuring application servers for the REST data service

You can configure various application servers to use the REST data service.

- Deploying the REST data service on WebSphere Application Server
  This topic describes how to configure the WebSphere eXtreme Scale REST data service on WebSphere Application Server or WebSphere Application Server Network Deployment Version 6.1.0.25 or or later. These instructions also apply to deployments whereWebSphere eXtreme Scale is integrated with the WebSphere Application Server deployment.
- Deploying the REST data service on WebSphere Application Server Community Edition
  You can configure the eXtreme Scale REST data service on WebSphere Application Server Community Edition Version 2.1.1.3 or later.
- Deploying the REST data service on Apache Tomcat
  This topic describes how to configure theWebSphere eXtreme Scale REST data service on Apache Tomcat Version 5.5 or later.

Deploying the REST data service on WebSphere Application Server

This topic describes how to configure the WebSphere® eXtreme Scale REST data service on WebSphere Application Server or WebSphere Application Server Network Deployment Version 6.1.0.25 or or later. These instructions also apply to deployments whereWebSphere eXtreme Scale is integrated with the WebSphere Application Server deployment.

Before you begin

You must have one of the following environments on your system to configure and deploy the REST data service for WebSphere eXtreme Scale.

- WebSphere Application Server with the stand-alone WebSphere eXtreme Scale client:
  - The WebSphere eXtreme Scale Trial Version 7.1 with the REST data service is downloaded and extracted or theWebSphere eXtreme Scale Version 7.1.0.0 with cumulative fix 2 product is installed into a stand-alone directory.
  - WebSphere Application Server Version 6.1.0.25 or 7.0.0.5 or later is installed and running.
- WebSphere Application Server integrated with WebSphere eXtreme Scale:
  WebSphere eXtreme Scale Version 7.1.0.0 with cumulative fix 2 or later is installed on top of WebSphere Application Server Version 6.1.0.25 or 7.0 or later.

  Tip: The WebSphere eXtreme Scale REST data service only requires that the WebSphere eXtreme Scale client option be installed. The profile does not need to be augmented.
  Read about how to enable Java™ 2 security in the WebSphere Application Server information center.

Procedure

1. Configure and start a data grid.
   a. For details on configuring a data grid for use with the REST data service, see Starting a data grid for REST data services in WebSphere Application Server.
   b. Verify that a client can connect to and access entities in the data grid. For an example, see Tutorial: Getting started with WebSphere eXtreme Scale.
2. Build the eXtreme Scale REST service configuration JAR or directory. See the information about packaging and deploying the REST service in Installing the REST data service.
3. Add the REST data service configuration JAR or directory to the application server classpath:
   a. Open the WebSphere Application Server administrative console
   b. Navigate to Environment > Shared libraries
   c. Click **New**
   d. Add the following entries into the appropriate fields:
      - Name: extremescale_rest_configuration
      - Classpath: <REST service configuration jar or directory>
   e. Click **OK**
   f. Save the changes to the master configuration
4. Add the WebSphere eXtreme Scale client runtime JAR, wsogclient.jar, and the REST data service configuration JAR or directory to the application server classpath. This step is not necessary if WebSphere eXtreme Scale is integrated with the WebSphere Application Server installation.

   a. Open theWebSphere Application Server administrative console.
   b. Navigate to Environment > Shared libraries.
   c. Click **New**.
   d. Add the following entries into the fields:
      - Name: extremescale_client_v71
      - Classpath: wxs_home/lib/wsogclient.jar

      Remember: Add each path on a separate line.
   e. Click OK.
   f. Save the changes to the master configuration.
5. Install the REST data service EAR file, wxsrestservice.ear, to the WebSphere Application Server using the administrative console:
   a. Open the WebSphere Application Server administrative console.
   b. Click Applications > New application.
   c. Browse to the /lib/wxsrestservice.ear file on the file system and select it and click **Next**.
      - If using WebSphere Application Server Version 7.0, click Next.
      - If using WebSphere Application Server Version 6.1, enter a Context Root value with the name: /wxsrestservice and continue to the next step.
   d. Choose the detailed installation option, and click Next.
   e. On the application security warnings screen, click Continue.
   f. Choose the default installation options, and click Next.
   g. Choose a server to map the application to, and click Next.
   h. On the JSP reloading page, use the defaults, and click Next.
   i. On the shared libraries page, map the wxsrestservice.war module to the shared libraries that you defined:

- extremescale_rest_configuration
- extremescale_client_v71

Tip: This shared library is required only if WebSphere eXtreme Scale is not integrated with WebSphere Application Server.

j. On the map shared library relationship page, use the defaults, and click Next.
k. On the map virtual hosts page, use the defaults, and click Next.
l. On the map context roots page, set the context root to: wxsrestservice
m. On the Summary screen, click Finish to complete the installation.
n. Save the changes to the master configuration.

6. Start the `wxsrestservice` REST data service application:
   a. Go to the application in the administrative console.
      - WebSphere Application Server Version 7.0: In the administrative console, click Applications > Application Types > WebSphere Applications.
      - WebSphere Application Server Version 6.1: In the administrative console, click Applications > Enterprise Applications.
   b. Check the check box next to the `wxsrestservice` application, and click **Start**.
   c. Review the SystemOut.log file for the application server profile. When the REST data service has started successfully, the following message is displayed in the SystemOut.log file for the server profile:
   `CWOBJ4000I: The WebSphere eXtreme Scale REST data service has been started.`

7. Verify the REST data service is working: The port number can be found in the SystemOut.log file within the application server profile logs directory by looking at the first port displayed for message identifier: SRVE0250I. The default port is 9080.
   For example:`http://localhost:9080/wxsrestservice/restservice/NorthwindGrid/` Result: The AtomPub service document is displayed.

   For example: `http://localhost:9080/wxsrestservice/restservice/NorthwindGrid/$metadata`. The Entity Model Data Extensions (EDMX) document is displayed.

8. To stop the data grid processes, use `CTRL+C` in the respective command window.

- Starting REST data services with WebSphere eXtreme Scale integrated in WebSphere Application Server 7.0
  This topic describes how to configure and start the eXtreme Scale REST data service using WebSphere Application Server version 7.0 that has been integrated and augmented with WebSphere eXtreme Scale.

Starting REST data services with WebSphere eXtreme Scale integrated in WebSphere Application Server 7.0

This topic describes how to configure and start the eXtreme Scale REST data service using WebSphere® Application Server version 7.0 that has been integrated and augmented with WebSphere eXtreme Scale.

Before you begin

Verify that the sample stand-alone eXtreme Scale data grid is started. See Enabling the REST data service for details on how to start the data grid.

About this task

To get started with the WebSphere eXtreme Scale REST data service using WebSphere Application Server, follow these steps:

Procedure

1. Add the WebSphere eXtreme Scale REST data service sample configuration JAR to the classpath:
   a. Open the WebSphere Administration Console
   b. Navigate to Environment -> Shared libraries
   c. Click New
   d. Add the following entries into the appropriate fields:
      i. Name: extremescale_gettingstarted_config
      ii. Classpath
         - restservice_home/gettingstarted/restclient/bin
         - restservice_home/gettingstarted/common/bin

      Remember: Each path must appear on a different line.
   e. Click **OK**
   f. Save the changes to the master configuration
2. Install the REST data service EAR file, wxsrestservice.ear, to the WebSphere Application Server using the WebSphere administration console:
   a. Open the WebSphere administration console
   b. Navigate to Applications -> New Application
   c. Browse to restservice_home/lib/wxsrestservice.ear file on the file system. Select the file and click **Next**.
   d. Choose the detailed installation options, and click **Next**.
   e. On the application security warnings screen, click **Continue**.
   f. Choose the default installation options, and click **Next**.
   g. Choose a server to map the wxsrestservice.war module to, and click **Next**.
   h. On the JSP reloading page, use the defaults, and click **Next**.
   i. On the shared libraries page, map the "wxsrestservice.war" module to the following shared libraries that were defined during step 1: extremescale_ gettingstarted _config
   j. On the map shared library relationship page, use the defaults, and click **Next**.
   k. On the map virtual hosts page, use the defaults, and click **Next**.

l. On the map context roots page, set the context root to: wxsrestservice.
m. On the Summary screen, click **Finish** to complete the installation.
n. Save the changes to the master configuration.

3. If the eXtreme Scale data grid was started with eXtreme Scale security enabled, set the following property in the restservice_home/gettingstarted/restclient/bin/wxsRestService.properties file.

```
ogClientPropertyFile=restservice_home/gettingstarted/security/security.ogclient.properties
```

4. Start the application server and the "wxsrestservice " eXtreme Scale REST data service application.
After the application is started review the SystemOut.log for the application server and verify that the following message appears: `CWOBJ4000I: The WebSphere eXtreme Scale REST data service has been started.`

5. Verify that the REST data service is working:
   a. Open a browser and navigate to:
   http://localhost:9080/wxsrestservice/restservice/NorthwindGrid

   The service document for the NorthwindGrid is displayed.

   b. Navigate to:
   http://localhost:9080/wxsrestservice/restservice/NorthwindGrid/$metadata

   The Entity Model Data Extensions (EDMX) document is displayed

6. To stop the data grid processes, use CTRL+C in the respective command window to stop the process.

Deploying the REST data service on WebSphere Application Server Community Edition

You can configure the eXtreme Scale REST data service on WebSphere® Application Server Community Edition Version 2.1.1.3 or later.

Before you begin

- An IBM® (recommended) or Oracle JRE or JDK, Version 5 or later is installed and the JAVA_HOME environment variable is set.
- Download and install WebSphere Application Server Community Edition Version 2.1.1.3 or later to the wasce_root directory, for example the /opt/IBM/wasce directory. Read the installation instructions for information on version 2.1.1 or other versions.

Procedure

1. Configure and start a data grid.
   a. For details on configuring an eXtreme Scale data grid for use with the REST data service, read about Starting a stand-alone data grid for REST data services.
   b. Verify that an eXtreme Scale client can connect to and access entities in the data grid. For an example, see Tutorial: Getting started with WebSphere eXtreme Scale.
2. Build the eXtreme Scale REST service configuration JAR or directory. See the packaging and deployment information in the Installing the REST data service topic for details.
3. Start the WebSphere Application Server Community Edition server:
   a. To start the server without Java™ SE security enabled, run the following command:
   UNIX Linux `wasce_root/bin/startup.sh`

   Windows `wasce_root/bin/startup.bat`

   b. To start the server with Java SE security enabled, follow these steps: UNIX Linux
      i. Open a command-line or terminal window and run the following copy command (or copy the contents of the specified policy file into your existing policy): `cp restservice_home/gettingstarted/wasce/geronimo.policy wasce_root/bin`
      ii. Edit the `wasce_root/bin/setenv.sh` file
      iii. After the line that contains "`WASCE_JAVA_HOME=`", add the following: `export JAVA_OPTS="-Djava.security.manager -Djava.security.policy=geronimo.policy"`

   Windows
      i. Open a command-line window and run the following copy command or copy the contents of the specified policy file into your existing policy:
      `copy restservice_home\gettingstarted\wasce\geronimo.policy\bin`

      ii. Edit the `wasce_root\bin\setenv.bat` file
      iii. After the line that contains "set WASCE_JAVA_HOME=", add the following:
      `set JAVA_OPTS="-Djava.security.manager -Djava.security.policy=geronimo.policy"`

4. Add the ObjectGrid client runtime JAR to the WebSphere Application Server Community Edition repository:
   a. Open the WebSphere Application Server Community Edition administration console and log in. The default URL is: `http://localhost:8080/console` and the default userid is `system` and password is `manager`.
   b. Click the Repository link on the left side of the console window, in the Services folder.
   c. In the Add Archive to Repository section, fill in the following into the input text boxes:

Table 1. Add Archive to Repository

Text box	Value

Text box	Value
File	wxs_home/lib/ogclient.jar
Group	com.ibm.websphere.xs
Artifact	ogclient
Version	7.1
Type	JAR

d. Click the Install button

See the following tech note for details on different ways class and library dependencies can be configured: Specifying external dependencies to applications running on WebSphere Application Server Community Edition.

5. Deploy and start the REST data service module, the wxsrestservice.war file, to the WebSphere Application Server Community Edition server.
   a. Copy and edit the sample deployment plan XML file: restservice_home/gettingstarted/wasce/geronimo-web.xml to include path dependencies to your REST data service configuration JAR or directory. See section for an example on setting the classpath to include your wxsRestService.properties file and other configuration files and metadata classes.
   b. Open the WebSphere Application Server Community Edition administration console and log in.
   Tip: The default URL is: `http://localhost:8080/console`. The default userid is `system` and password is `manager`.
   c. Click on the Deploy Newlink on the left side of the console window.
   d. On the Install New Applications page, enter the following values into the text boxes:

Table 2. Install New Applications

Text box	Value
Archive	restservice_home/lib/wxsrestservice.war
Plan	restservice_home/gettingstarted/wasce/geronimo-web.xml

   Tip: Use the path to the geronimo-web.xml file that you copied and edited in step 3.
   e. Click on the Install button. The console page then indicates that the application was successfully installed and started.
   f. Examine the WebSphere Application Server Community Edition system output log or console to verify that the REST data service has started successfully. The following message must appear:
   `CWOBJ4000I: The WebSphere eXtreme Scale REST data service has been started.`

6. Start the WebSphere Application Server Community Edition server by running the following command:
   - UNIX Linux `wasce_root/bin/startup.sh`
   - Windows `wasce_root/bin/startup.bat`
7. Install the eXtreme Scale REST data service and the provided sample into the WebSphere Application Server Community Edition server:
   a. Add the ObjectGrid client runtime JAR to the WebSphere Application Server Community Edition repository:
      i. Open the WebSphere Application Server Community Edition administration console and log in. The default URL is: `http://localhost:8080/console`. The default userid is `system` and password is `manager`.
      ii. Click the Repository link on the left side of the console window, in the Services folder.
      iii. In the Add Archive to Repository section, fill in the following into the input text boxes:

Table 3. Add Archive to Repository

Text box	Value
File	wxs_home/lib/ogclient.jar
Group	com.ibm.websphere.xs
Artifact	ogclient
Version	7.1
Type	JAR

      iv. Click the install button.
      Tip: See the following technote for details on different ways class and library dependencies can be configured: Specifying external dependencies to applications running on WebSphere Application Server Community Edition
   b. Deploy the REST data service module: wxsrestservice.war to the WebSphere Application Server Community Edition server.
      i. Edit the sample restservice_home/gettingstarted/wasce/geronimo-web.xml deployment XML file to include path dependencies to the getting started sample classpath directories:
         - Change the "classesDirs" for the two getting started client GBeans:

      The "classesDirs" path for the GettingStarted_Client_SharedLib GBean should be set to: restservice_home/gettingstarted/restclient/bin
      The "classesDirs" path for the GettingStarted_Common_SharedLib GBean should be set to: restservice_home/gettingstarted/common/bin

      ii. Open the WebSphere Application Server Community Edition administration console and log in.
      iii. Click on the Deploy New link on the left side of the console window.
      iv. On the Install New Applications page, enter the following values into the text boxes:

Table 4. Install New Applications

Text box	Value
Archive	*restservice_home*/lib/wxsrestservice.war
Plan	*restservice_home*/gettingstarted/wasce/geronimo-web.xml

      v. Click the Install button.
      The console page then indicates that the application has successfully installed and started.

      vi. Examine the WebSphere Application Server Community Edition system output log to verify that the REST data service has started successfully by verifying that the following message is present:

```
CWOBJ4000I: The WebSphere eXtreme Scale REST data service has been started.
```

8. Verify that the REST data service is working:
   Open a Web browser and navigate to the following URL: `http://<host>:<port>/<context root>/restservice/<Grid Name>`

   The default port for WebSphere Application Server Community Edition is 8080 and is defined using the "HTTPPort" property in the /var/config/config-substitutions.properties file.

   For example: http://localhost:8080/wxsrestservice/restservice/NorthwindGrid/

Results

The AtomPub service document is displayed.

- Starting the REST data service in WebSphere Application Server Community Edition
  This topic describes how to configure and start the eXtreme Scale REST data service using WebSphere Application Server Community Edition.

Starting the REST data service in WebSphere Application Server Community Edition

This topic describes how to configure and start the eXtreme Scale REST data service using WebSphere® Application Server Community Edition.

Before you begin

Verify that the sample data grid is started. See Enabling the REST data service for details on how to start the grid.

Procedure

1. Download and install WebSphere Application Server Community Edition Version 2.1.1.3 or later to wasce_root, such as: /opt/IBM/wasce
2. Start the WebSphere Application Server Community Edition server by running the following command:
   - Linux UNIX wasce_root/bin/startup.sh
   - Windows wasce_root/bin/startup.bat
3. If the eXtreme Scale grid was started with eXtreme Scale security enabled, set the following properties in the restservice_home/gettingstarted/restclient/bin/wxsRestService.properties file.

   ```
   ogClientPropertyFile=restservice_home/gettingstarted/security/security.ogclient.properties
   loginType=none
   ```

4. Install the eXtreme Scale REST data service and the provided sample into the WebSphere Application Server Community Edition server:
   a. Add the ObjectGrid client runtime JAR to the WebSphere Application Server Community Edition repository:
      i. Open the WebSphere Application Server Community Edition administration console and log in.
         Tip: The default URL is: `http://localhost:8080/console`. The default user ID is `system` and password is `manager`.
      ii. Click the Repository, in the Services folder.
      iii. In the Add Archive to Repository section, fill in the following into the input text boxes:

      Table 1. Archive to repository

Text box	Value
File	wxs_home/lib/ogclient.jar
Group	com.ibm.websphere.xs
Artifact	ogclient
Version	7.0
Type	jar

      iv. Click the Install button.
         Tip: See the following tech note for details on different methods of configuration class and library dependencies: Specifying external dependencies to applications running on WebSphere Application Server Community Edition.
   b. Deploy the REST data service module, which is the wxsrestservice.war file, to the WebSphere Application Server Community Edition server.
      i. Edit the sample restservice_home/gettingstarted/wasce/geronimo-web.xml deployment XML file to include path dependencies to the getting started sample classpath directories:
         Change the classesDirs paths for the two getting started client GBeans:
         - The "classesDirs" path for the GettingStarted_Client_SharedLib GBean should be set to: restservice_home/gettingstarted/restclient/bin
         - The "classesDirs" path for the GettingStarted_Common_SharedLib GBean should be set to: restservice_home/gettingstarted/common/bin

      ii. Open the WebSphere Application Server Community Edition administrative console and log in.
         Tip: The default URL is: `http://localhost:8080/console`. The default user ID is `system` and password is `manager`.
      iii. Click Deploy New.
      iv. On the Install New Applications page, enter the following values into the text boxes:

      Table 2. Installation values

Text box	Value
Archive	restservice_home/lib/wxsrestservice.war
Plan	restservice_home/gettingstarted/wasce/geronimo-web.xml

v. Click on the Install button.
The console page should indicate that the application was successfully installed and started.

vi. Examine the WebSphere Application Server Community Edition system output log or console to verify that the REST data service has started successfully by verify that the following message is present:
`CWOBJ4000I: The WebSphere eXtreme Scale REST data service has been started.`

5. Verify that the REST data service is working:
   a. Open the following link in a browser window: `http://localhost:8080/wxsrestservice/restservice/NorthwindGrid`. The service document for the NorthwindGrid grid is displayed.
   b. Open the following link in a browser window: `http://localhost:8080/wxsrestservice/restservice/NorthwindGrid/$metadata`. The Entity Model Data Extensions (EDMX) document is displayed.
6. To stop the grid processes, use `CTRL+C` in the respective command window to stop the process.
7. To stop WebSphere Application Server Community Edition, use the following command:
   - UNIX Linux wasce_root/bin/shutdown.sh
   - Windows wasce_root\bin\shutdown.bat

   Tip: The default user ID is `system` and password is `manager`. If you are using a custom port, use the `-port` option.

Deploying the REST data service on Apache Tomcat

This topic describes how to configure theWebSphere® eXtreme Scale REST data service on Apache Tomcat Version 5.5 or later.

About this task

- An IBM® or Oracle JRE or JDK, Version 5 or later installed and a specified JAVA_HOME environment variable.
- Apache Tomcat Version 5.5 or later is installed. See Apache Tomcat for details on how to install Tomcat.
- A stand-alone installation of WebSphere eXtreme Scale.

Procedure

1. If using an Oracle JRE or JDK, install the IBM ORB into Tomcat:
   a. Tomcat version 5.5:
      Copy all of the JAR files from:

      the *wxs_home*/lib/endorsed directory

      to:

      the *tomcat_root*/common/endorsed directory

   b. Tomcat version 6.0:
      Create an "endorsed" directory:

      UNIX Linux mkdir tomcat_root/endorsed

      Windows md tomcat_root/endorsed

      Copy all of the JAR files from:

      wxs_home/lib/endorsed

      to:

      tomcat_root/common/endorsed

2. Configure and start a data grid.
   a. For details on configuring a data grid for use with the REST data service, see Configuring.
   b. Verify that an eXtreme Scale client can connect to and access entities in the grid. For an example, see Configuring REST data services.
3. Build the eXtreme Scale REST service configuration JAR or directory. See the packaging and deployment information in Installing the REST data service for details.
4. Deploy the REST data service module: wxsrestservice.war to the Tomcat server.
   Copy the wxsrestservice.war file from:

   restservice_home/lib

   to:

   tomcat_root/webapps

5. Add the ObjectGrid client runtime JAR and the application JAR to the shared classpath in Tomcat:
   a. Edit the *tomcat_root*/conf/catalina.properties file

b. Append the following path names to the end of the shared.loader property, separating each path name with a comma:
- *wxs_home*/lib/ogclient.jar
- *restservice_home*/gettingstarted/restclient/bin
- *restservice_home*/gettingstarted/common/bin

6. If you are using Java™ 2 security, add security permissions to the tomcat policy file:
   - If using Tomcat version 5.5:
     Merge the contents of the sample 5.5 catalina policy file found in

     restservice_home/gettingstarted/tomcat/catalina-5_5.policy with the *tomcat_root*/conf/catalina.policy file.

   - If using Tomcat version 6.0:
     Merge the contents of the sample 6.0 catalina policy file found in

     restservice_home/gettingstarted/tomcat/catalina-6_0.policy with the *tomcat_root*/conf/catalina.policy file.

7. Start the Tomcat server:
   - **If using Tomcat 5.5 on UNIX or Windows, or the Tomcat 6.0 ZIP distribution:**
     - `cd tomcat_root/bin`
     - Start the server:
       - Without Java 2 security enabled:
         UNIX Linux `./catalina.sh run`

         Windows `catalina.bat run`

       - With Java 2 security enabled:
         UNIX Linux `./catalina.sh run -security`

         Windows `catalina.bat run -security`

     - The Apache Tomcat logs are displayed to the console. When the REST data service has started successfully, the following message is displayed in the administrative console:
       `CWOBJ4000I: The WebSphere eXtreme Scale REST data service has been started.`

   - **If using Tomcat 6.0 on Windows using the Windows installer distribution:**
     - `cd /bin`
     - Start the Apache Tomcat 6 configuration tool:
       `tomcat6w.exe`

     - To enable Java 2 security (optional):
       Add the following entries to the Java Options in the Java tab in the Apache Tomcat 6 properties window:

       ```
       -Djava.security.manager

       -Djava.security.policy=\conf\catalina.policy
       ```

     - Click on the Start button on the Apache Tomcat 6 properties window to start the Tomcat server.
     - Review the following logs to verify that the Tomcat server has started successfully:
       - *tomcat_root*/bin/catalina.log
         Displays the status of the Tomcat server engine

       - *tomcat_root*/bin/stdout.log
         Displays the system output log

     - When the REST data service has started successfully, the following message is displayed in the system output log:
       `CWOBJ4000I: The WebSphere eXtreme Scale REST data service has been started.`

8. Verify the REST data service is working.
   Open a Web browser and navigate to the following URL:

   `http://host:port/context_root/restservice/grid_name`

   The default port for Tomcat is 8080 and is configured in the *tomcat_root*/conf/server.xml file in the <Connector> element.

   For example:

   `http://localhost:8080/wxsrestservice/restservice/NorthwindGrid/`

Results

The AtomPub service document is displayed.

- Starting REST data services in Apache Tomcat
  This topic describes how to configure and start the eXtreme Scale REST data service using Apache Tomcat, version 5.5 or later.

Starting REST data services in Apache Tomcat

This topic describes how to configure and start the eXtreme Scale REST data service using Apache Tomcat, version 5.5 or later.

Before you begin

Verify that the sample eXtreme Scale data grid is started. See Enabling the REST data service for details on how to start the data grid.

Procedure

1. Download and install Apache Tomcat Version 5.5 or later to tomcat_root. For example: /opt/tomcat
2. Install the eXtreme Scale REST data service and the provided sample into the Tomcat server as follows:
   a. If you are using an Oracle JRE or JDK, you must install the IBM® ORB into Tomcat:
      - For Tomcat version 5.5
        Copy all of the JAR files from:

        wxs_home/lib/endorsed

        to

        tomcat_root/common/endorsed

      - For Tomcat version 6.0
        - Create an "endorsed" directory
          - UNIX Linux `mkdir tomcat_root/endorsed`
          - Windows `md tomcat_root/endorsed`
        - Copy all of the JAR files from:
          wxs_home/lib/endorsed

          to

          tomcat_root/endorsed

   b. Deploy the REST data service module: wxsrestservice.war to the Tomcat server.
      Copy the wxsrestservice.war file from:

      restservice_home/lib

      to:

      tomcat_root/webapps

   c. Add the ObjectGrid client runtime JAR and the application JAR to the shared classpath in Tomcat:
      i. Edit the tomcat_root/conf/catalina.properties file
      ii. Append the following path names to the end of the shared.loader property in the form of a comma-delimited list:
         - wxs_home/lib/ogclient.jar
         - restservice_home/gettingstarted/restclient/bin
         - restservice_home/gettingstarted/common/bin

      Important: The path separator must be a **forward** slash.
3. If the eXtreme Scale data grid was started with eXtreme Scale security enabled, set the following properties in the restservice_home/gettingstarted/restclient/bin/wxsRestService.properties file.

   ```
   ogClientPropertyFile=restservice_home/gettingstarted/security/security.ogclient.properties
   loginType=none
   ```

4. Start the Tomcat server with the REST data service:
   - If using Tomcat 5.5 on UNIX or Windows, or Tomcat 6.0 on UNIX:
     - `cd tomcat_root/bin`
     - Start the server:
       - UNIX Linux `./catalina.sh run`
       - Windows `catalina.bat run`
     - The console then displays the Apache Tomcat logs. When the REST data service has started successfully, the following message is displayed in the administration console:
       `CWOBJ4000I: The WebSphere eXtreme Scale REST data service has been started.`
   - If using Tomcat 6.0 on Windows:
     - `cd tomcat_root/bin`
     - Start the Apache Tomcat 6 configuration tool with the following command: `tomcat6w.exe`
     - Click on the Start button on the Apache Tomcat 6 properties window to start the Tomcat server.
     - Review the following logs to verify that the Tomcat server has started successfully:
       - tomcat_root/bin/catalina.log
         Displays the status of the Tomcat server engine
       - tomcat_root/bin/stdout.log
         Displays the system output log.
     - When the REST data service has started successfully, the following message is displayed in the system output log: `CWOBJ4000I: The WebSphere eXtreme Scale REST data service has been started.`
5. Verify that the REST data service is working:
   a. Open a browser and navigate to:
      http://localhost:8080/wxsrestservice/restservice/NorthwindGrid

The service document for the NorthwindGrid is displayed.

b. Navigate to:
http://localhost:8080/wxsrestservice/restservice/NorthwindGrid/$metadata

The Entity Model Data Extensions (EDMX) document is displayed.

6. To stop the data grid processes, use CTRL+C in the respective command window.
7. To stop Tomcat, use CTRL +C in the window in which you started it.

Configuring Web browsers to access REST data service ATOM feeds

The eXtreme Scale REST data service creates ATOM feeds by default when using a web browser. The ATOM feed format may not be compatible with older browsers or may be interpreted such that the data cannot be viewed as XML. You can configure Internet Explorer Version 8 and Firefox Version 3 to display the ATOM feeds and XML within the browser.

About this task

The eXtreme Scale REST data service creates ATOM feeds by default when using a web browser. The ATOM feed format may not be compatible with older browsers or may be interpreted such that the data cannot be viewed as XML. For older browsers, you will be prompted to save the files to disk. Once the files are downloaded, use your favorite XML reader to look at the files. The generated XML is not formatted to be displayed, so everything will be printed on one line. Most XML reading programs, such as Eclipse, support reformatting the XML into a readable format.
For modern browsers, such as Microsoft Internet Explorer Version 8 and Firefox Version 3, the ATOM XML files can be displayed natively in the browser. The following topics provide details on how to configure Internet Explorer Version 8 and Firefox Version 3 to display the ATOM feeds and XML within the browser.

Procedure

Configure Internet Explorer Version 8

- To enable Internet Explorer to read the ATOM feeds that the REST data service generates use the following steps:
  1. Click Tools > Internet Options
  2. Select the **Content** tab
  3. Click the **Settings** button in the **Feeds and Web Slices** section
  4. Uncheck the box: "Turn on feed reading view"
  5. Click **OK** to return to the browser.
  6. Restart Internet Explorer.

Configure Firefox Version 3

- Firefox does not automatically display pages with content type: application/atom+xml. The first time a page is displayed, Firefox prompts you to save the file. To display the page, open the file itself with Firefox as follows:
  1. From the application chooser dialog box, select the "Open with" radio button and click the **Browse** button.
  2. Navigate to your Firefox installation directory. For example: C:\Program Files\Mozilla Firefox
  3. Select `firefox.exe` and hit the **OK** button.
  4. Check the “Do this automatically for files like this...” check box.
  5. Click the **OK** button.
  6. Next, Firefox displays the ATOM XML page in a new browser window or tab
- Firefox automatically renders ATOM feeds in readable format. However, the feeds that the REST data service creates include XML. Firefox cannot display the XML unless you disable the feed renderer. Unlike Internet Explorer, in Firefox, the ATOM feed rendering plug-in must be explicitly edited. To configure Firefox to read ATOM feeds as XML files, follow these steps:
  1. Open the following file in a text editor: <firefoxInstallRoot>\components\FeedConverter.js. In the path, <firefoxInstallRoot> is the root directory where Firefox is installed.
     For Windows operating systems, the default directory is: C:\Program Files\Mozilla Firefox.
  2. Search for the snippet that looks as follows:

     ```
     // show the feed page if it wasn't sniffed and we have a document,
     // or we have a document, title, and link or id
     if (result.doc && (!this._sniffed ||
         (result.doc.title && (result.doc.link || result.doc.id)))) {
     ```

  3. Comment out the two lines that begin with `if` and `result` by placing `//` (two forward slashes) in front of them.
  4. Append the following statement to the snippet: `if(0) {`.
  5. The resulting text should look as follows:

     ```
     // show the feed page if it wasn't sniffed and we have a document,
     // or we have a document, title, and link or id
     //if (result.doc && (!this._sniffed ||
     //    (result.doc.title && (result.doc.link || result.doc.id)))) {
     if(0) {
     ```

  6. Save the file.
  7. Restart Firefox
  8. Now Firefox can automatically display all feeds in the browser.
- Test your setup by trying some URLs.

Example

This section describes some example URLs that can be used to view the data that was added by the getting started sample provided with the REST data service. Before using the following URLs, add the default data set to the eXtreme Scale sample data grid using either the sample Java™ client or the sample Visual Studio WCF Data Services client.

The following examples assume the port is 8080 which can vary. See section for details on how to configure the REST data service on different application servers.

- View a single customer with the id of "ACME":

  ```
  http://localhost:8080/wxsrestservice/restservice/NorthwindGrid/Customer('ACME')
  ```

- View all of the orders for customer "ACME":

  ```
  http://localhost:8080/wxsrestservice/restservice/NorthwindGrid/Customer('ACME')/orders
  ```

- View the customer "ACME" and the orders:

  ```
  http://localhost:8080/wxsrestservice/restservice/NorthwindGrid/Customer('ACME')?$expand=orders
  ```

- View order 1000 for customer "ACME":

  ```
  http://localhost:8080/wxsrestservice/restservice/NorthwindGrid/Order(orderId=1000,customer_customerId='ACME')
  ```

- View order 1000 for customer "ACME" and its associated Customer:

  ```
  http://localhost:8080/wxsrestservice/restservice/NorthwindGrid/
  Order(orderId=1000,customer_customerId='ACME')?$expand=customer
  ```

- View order 1000 for customer "ACME" and its associated Customer and OrderDetails:

  ```
  http://localhost:8080/wxsrestservice/restservice/NorthwindGrid/
  Order(orderId=1000,customer_customerId='ACME')?$expand=customer,orderDetails
  ```

- View all orders for customer "ACME" for the month of October, 2009 (GMT):

  ```
  http://localhost:8080/wxsrestservice/restservice/NorthwindGrid/
  Customer(customerId='ACME')/orders?$filter=orderDate
  ge datetime'2009-10-01T00:00:00'
  and orderDate lt datetime'2009-11-01T00:00:00'
  ```

- View all the first 3 orders and orderDetails for customer "ACME" for the month of October, 2009 (GMT):

  ```
  http://localhost:8080/wxsrestservice/restservice/NorthwindGrid/
  Customer(customerId='ACME')/orders?$filter=orderDate
  ge datetime'2009-10-01T00:00:00'
  and orderDate lt datetime'2009-11-01T00:00:00'
  &$orderby=orderDate&$top=3&$expand=orderDetails
  ```

Using a Java client with REST data services

The Java™ client application uses the eXtreme Scale EntityManager API to insert data into the grid.

About this task

The previous sections described how to create an eXtreme Scale data grid and configure and start the eXtreme Scale REST data service. The Java client application uses the eXtreme Scale EntityManager API to insert data into the grid. It does not demonstrate how to use the REST interfaces. The purpose of this client is to demonstrate how the EntityManager API is used to interact with the eXtreme Scale data grid, and allow modifying data in the grid. To view data in the grid using the REST data service, use a web browser or use the Visual Studio 2008 client application.

Procedure

To quickly add content to the eXtreme Scale data grid, run the following command:

1. Open a command-line or terminal window and set the JAVA_HOME environment variable:
   - Linux UNIX `export JAVA_HOME=java_home`
   - Windows `set JAVA_HOME=java_home`
2. `cd restservice_home/gettingstarted`
3. Insert some data into the grid. The data that is inserted will be retrieved later using a Web browser and the REST data service.
   If the data grid was started *without*eXtreme Scale security, use the following commands.
   - UNIX Linux `./runclient.sh load default`
   - Windows `runclient.bat load default`

   If the data grid was started *with*eXtreme Scale security, use the following commands.
   - UNIX Linux `./runclient_secure.sh load default`
   - Windows `runclient_secure.bat load default`

   For a Java client, use the following command syntax:

- UNIX Linux `runclient.sh command`
- Windows `runclient.bat command`

The following commands are available:

- `load default`
  Loads a predefined set of Customer, Category and Product entities into the data grid and creates a random set of Orders for each customer.
- `load category categoryId categoryName firstProductId num_products`
  Creates a product Category and a fixed number of Product entities in the data grid. The firstProductId parameter identifies the id number of the the first product and each subsequent product is assigned the next id until the specified number of products is created.
- `load customer companyCode contactNamecompanyName numOrders firstOrderIdshipCity maxItems discountPct`
  Loads a new Customer into the data grid and creates a fixed set of Order entities for any random product currently loaded in the grid. The number of Orders is determined by setting the <numOrders> parameter. Each Order will have a random number of OrderDetail entities up to <maxItems>
- `display customer companyCode`
  Display a Customer entity and the associated Order and OrderDetail entities.
- `display category categoryId`
  Display a product Category entity and the associated Product entities.

Results

- `runclient.bat load default`
- `runclient.bat load customer IBM "John Doe" "IBM Corporation" 5 5000 Rochester 5 0.05`
- `runclient.bat load category 5 "Household Items" 100 5`
- `runclient.bat display customer IBM`
- `runclient.bat display category 5`

Running and building the sample data grid and Java client with Eclipse

The REST data service getting started sample can be updated and enhanced using Eclipse. For details on how to setup your Eclipse environment see the text document: restservice_home/gettingstarted/ECLIPSE_README.txt.

After the WXSRestGettingStarted project is imported into Eclipse and is building successfully, the sample will automatically re-compile and the script files used to start the container server and client will automatically pick up the class files and XML files. The REST data service will also automatically detect any changes since the Web server is configured to read the Eclipse build directories automatically.
Important: When changing source or configuration files, both the eXtreme Scale container server and the REST data service application must be restarted. The eXtreme Scale container server must be started before the REST data service Web application.

Visual Studio 2008 WCF client with REST data service

The eXtreme Scale REST data service getting started sample includes a WCF Data Services client that can interact with the eXtreme Scale REST data service. The sample is written as a command-line application in C#.

Software requirements

The WCF Data Services C# sample client requires the following:

- Operating system
  - Microsoft Windows XP
  - Microsoft Windows Server 2003
  - Microsoft Windows Server 2008
  - Microsoft Windows Vista
- Microsoft Visual Studio 2008 with Service Pack 1

  Tip: See the previous link for additional hardware and software requirements.
- Microsoft .NET Framework 3.5 Service Pack 1
- Microsoft Support: An update for the .NET Framework 3.5 Service Pack 1 is available

Building and running the getting started client

The WCF Data Services sample client includes a Visual Studio 2008 project and solution and the source code for running the sample. The sample must be loaded into Visual Studio 2008 and compiled into a Windows runnable program before it can be run. To build and run the sample, see the text document: restservice_home/gettingstarted/VS2008_README.txt.

WCF Data Services C# client command syntax

Windows `WXSRESTGettingStarted.exe <service URL> <command>`

The <service URL> is the URL of the eXtreme Scale REST data service configured in section .

The following commands are available:

- `load default`
  Loads a predefined set of Customer, Category and Product entities into the data grid and creates a random set of Orders for each customer.
- `load category <categoryId> <categoryName> <firstProductId> <numProducts>`
  Creates a product Category and a fixed number of Product entities in the data grid. The firstProductId parameter identifies the id number of the the first product and each subsequent product is assigned the next id until the specified number of products is created.
- `load customer <companyCode> <contactName> <companyName> <numOrders> <firstOrderId> <shipCity> <maxItems> <discountPct>`
  Loads a new Customer into the data grid and creates a fixed set of Order entities for any random product currently loaded in the data grid. The number of Orders is determined by setting the <numOrders> parameter. Each Order will have a random number of OrderDetail entities up to <maxItems>
- `display customer <companyCode>`
  Display a Customer entity and the associated Order and OrderDetail entities.
- `display category <categoryId>`
  Display a product Category entity and the associated Product entities.
- `unload`
  Remove all entities that were loaded using the "default load" command.

The following examples illustrate various commands.

- `WXSRestGettingStarted.exe http://localhost:8080/wxsrestservice/restservice/NorthwindGrid load default`
- `WXSRestGettingStarted.exe http://localhost:8080/wxsrestservice/restservice/NorthwindGrid load customer`
- `IBM "John Doe" "IBM Corporation" 5 5000 Rochester 5 0.05`
- `WXSRestGettingStarted.exe http://localhost:8080/wxsrestservice/restservice/NorthwindGrid load category 5 "Household Items" 100 5`
- `WXSRestGettingStarted.exe http://localhost:8080/wxsrestservice/restservice/NorthwindGrid display customer IBM`
- `WXSRestGettingStarted.exe http://localhost:8080/wxsrestservice/restservice/NorthwindGrid display category 5`

Configuring OSGi-enabled plug-ins using the ObjectGrid descriptor XML file

In this task, you add existing OSGi services to a descriptor XML file so that WebSphere® eXtreme Scale containers can recognize and load the OSGi-enabled plug-ins correctly.

Before you begin

To configure your plug-ins, be sure to:

- Create your package, and enable dynamic plug-ins for OSGi deployment.
- Have the names of the OSGi services that represent your plug-ins available.

About this task

You have created an OSGi service to wrap your plug-in. Now, these services must be defined in the objectgrid.xml file so that eXtreme Scale containers can load and configure the plug-in or plug-ins successfully.

Procedure

1. Any grid-specific plug-ins, such as TransactionCallback, must be specified under the objectGrid element. See the following example from the objectgrid.xml file:

```
<?xml version="1.0" encoding="UTF-8"?>

<objectGridConfig xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://ibm.com/ws/objectgrid/config ../objectGrid.xsd"
    xmlns="http://ibm.com/ws/objectgrid/config">

    <objectGrids>
        <objectGrid name="MyGrid" txTimeout="60">
            <bean
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsconfigosgiplugs_2_myTranCallb
ack" osgiService="myTranCallbackFactory"/>
            ...
        </objectGrid>
        ...
    </objectGrids>
    ...
/objectGridConfig>
```

   Important: The `osgiService` attribute value must match the `ref` attribute value that is specified in the blueprint XML file, where the service was defined for myTranCallback PluginServiceFactory.
2. Any map-specific plug-ins, such as loaders or serializers, for example, must be specified in the backingMapPluginCollections element and referenced from the backingMap element. See the following example from the objectgrid.xml file:

```
<?xml version="1.0" encoding="UTF-8"?>

objectGridConfig xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://ibm.com/ws/objectgrid/config ../objectGrid.xsd"
    xmlns="http://ibm.com/ws/objectgrid/config">
    <objectGrids>
        <objectGrid name="MyGrid" txTimeout="60">
            <backingMap name="MyMap1" lockStrategy="PESSIMISTIC"
                copyMode="COPY_TO_BYTES" nullValuesSupported="false"
                pluginCollectionRef="myPluginCollectionRef1"/>
            <backingMap name="MyMap2" lockStrategy="PESSIMISTIC"
                copyMode="COPY_TO_BYTES" nullValuesSupported="false"
                pluginCollectionRef="myPluginCollectionRef2"/>
            ...
        </objectGrid>
        ...
    </objectGrids>
    ...
    <backingMapPluginCollections>
        <backingMapPluginCollection
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsconfigosgiplugs_2_myPluginCol
lectionRef1">
            <bean
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsconfigosgiplugs_2_MapSerializ
erPlugin" osgiService="mySerializerFactory"/>
        </backingMapPluginCollection>
        <backingMapPluginCollection
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsconfigosgiplugs_2_myPluginCol
lectionRef2">
            <bean
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsconfigosgiplugs_2_MapSerializ
erPlugin" osgiService="myOtherSerializerFactory"/>
            <bean
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsconfigosgiplugs_2_Loader"
osgiService="myLoader"/>
        </backingMapPluginCollection>
        ...
    </backingMapPluginCollections>
    ...
</objectGridConfig>
```

Results

The objectgrid.xml file in this example tells eXtreme Scale to create a grid called `MyGrid` with two maps, `MyMap1` and `MyMap2`. The `MyMap1` map uses the serializer wrapped by the OSGi service, mySerializerFactory. The `MyMap2` map uses a serializer from the OSGi service, myOtherSerializerFactory, and a loader from the OSGi service, myLoader.

Configuring servers for OSGi

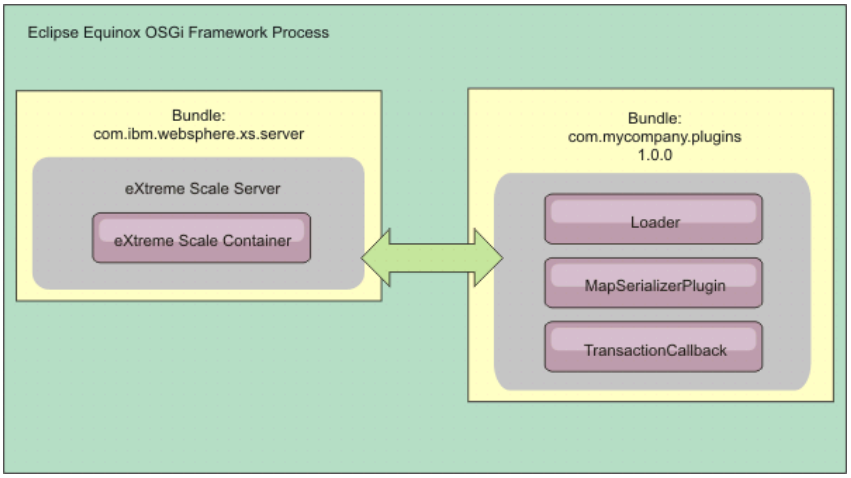
WebSphere® eXtreme Scale includes a server OSGi bundle, allowing starting and configuring servers and containers within an OSGi framework. The configuration topics describe how to use the eXtreme Scale server bundle, OSGi Blueprint service and eXtreme Scale configuration to run eXtreme Scale servers in an Eclipse Equinox OSGi framework.

About this task

the following tasks are required to start an eXtreme Scale server within Eclipse Equinox:

Procedure

1. Create an OSGi bundle that will store the eXtreme Scale plug-ins, exposing them as services and update the ObjectGrid descriptor XML file to reference the services.
2. Configure OSGi to start an eXtreme Scale container server.
3. Install and start the eXtreme Scale server bundle in the OSGi framework.
4. Install and start the OSGi bundle that contains the eXtreme Scale plug-ins.
   Figure 1. Eclipse Equinox process for installing and starting OSGi bundles with eXtreme Scale plug-ins



- Configuring eXtreme Scale plug-ins with OSGi Blueprint
  All eXtreme Scale ObjectGrid and BackingMap plug-ins can be defined as OSGi beans and services using the OSGi Blueprint Service available with Eclipse Gemini or Apache Aries.
- Configuring servers with OSGi Blueprint
  You can configure WebSphere eXtreme Scale container servers using an OSGi blueprint XML file, allowing simplified packaging and development of self-contained server bundles.
- Configuring servers with OSGI config admin
  You can use the OSGi configuration administration (config admin) service to configure WebSphere eXtreme Scale container servers.

Configuring eXtreme Scale plug-ins with OSGi Blueprint

All eXtreme Scale ObjectGrid and BackingMap plug-ins can be defined as OSGi beans and services using the OSGi Blueprint Service available with Eclipse Gemini or Apache Aries.

Before you begin

Before you can configure your plug-ins as OSGi services, you must first package your plug-ins in an OSGi bundle, and understand the fundamental principles of the required plug-ins. The bundle must import the WebSphere® eXtreme Scale server or client packages and other dependent packages required by the plug-ins, or create a bundle dependency on the eXtreme Scale server or client bundles This topic describes how to configure the Blueprint XML to create plug-in beans and expose them as OSGi services for eXtreme Scale to use.

About this task

Beans and services are defined in a Blueprint XML file, and the Blueprint container discovers, creates, and wires the beans together and exposes them as services. The process makes the beans available to other OSGi bundles, including the eXtreme Scale server and client bundles.

When creating custom plug-in services for use with eXtreme Scale, the bundle that is to host the plug-ins, must be configured to use Blueprint. In addition, a Blueprint XML file must be created and stored within the bundle. Read about building OSGi applications with the Blueprint Container specification for a general understanding of the specification.

Procedure

1. Create a Blueprint XML file. You can name the file anything. However, you must include the blueprint namespace:

   ```
   <?xml version="1.0" encoding="UTF-8"?>
   <blueprint xmlns="http://www.osgi.org/xmlns/blueprint/v1.0.0">
   ...
   </blueprint>
   ```

2. Create bean definitions in the Blueprint XML file for each eXtreme Scale plug-in.
   Beans are defined using the `<bean>` element and can be wired to other bean references and can include initialization parameters.
   Important: When defining a bean, you must use the correct scope. Blueprint supports the singleton and prototype scopes. eXtreme Scale also supports a custom shard scope.
   Define most eXtreme Scale plug-ins as prototype or shard-scoped beans, since all of the beans must be unique for each ObjectGrid shard or BackingMap instance it is associated with. Shard-scoped beans can be useful when using the beans in other contexts to allow retrieving the correct instance.

   To define a prototype-scoped bean, use the `scope="prototype"` attribute on the bean:

   ```
   <bean
   id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsblueprintosgi_2_myPluginBean"
   class="com.mycompany.MyBean" scope="prototype">
   ...
   </bean>
   ```

To define a shard-scoped bean, you must add the `objectgrid` namespace to the XML schema, and use the `scope="objectgrid:shard"` attribute on the bean:

```
<?xml version="1.0" encoding="UTF-8"?>

<blueprint xmlns="http://www.osgi.org/xmlns/blueprint/v1.0.0"

xmlns:objectgrid="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsblueprintosgi_2
_http://www.ibm.com/schema/objectgrid"

           xsi:schemaLocation="http://www.ibm.com/schema/objectgrid
                http://www.ibm.com/schema/objectgrid/objectgrid.xsd">

    <bean
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsblueprintosgi_2_myPluginBean"
class="com.mycompany.MyBean"
                        scope="objectgrid:shard">
    ...
    </bean>

...
```

3. Create PluginServiceFactory bean definitions for each plug-in bean. All eXtreme Scale beans must have a PluginServiceFactory bean defined so that the correct bean scope can be applied. eXtreme Scale includes a BlueprintServiceFactory that you can use. It includes two properties that must be set. You must set the blueprintContainer property to the `blueprintContainer` reference, and the beanId property must be set to the bean identifier name. When eXtreme Scale looks up the service to instantiate the appropriate beans, the server looks up the bean component instance using the Blueprint container.

```
bean
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsblueprintosgi_2_myPluginBeanF
actory"
    class="com.ibm.websphere.objectgrid.plugins.osgi.BluePrintServiceFactory">
    <property name="blueprintContainer" ref="blueprintContainer" />
    <property name="beanId" value="myPluginBean" />
</bean>
```

4. Create a service manager for each PluginServiceFactory bean. Each service manager exposes the PluginServiceFactory bean, using the `<service>` element. The service element identifies the name to expose to OSGi, the reference to the PluginServiceFactory bean, the interface to expose, and the ranking of the service. eXtreme Scale uses the service manager ranking to perform service upgrades when the eXtreme Scale grid is active. If the ranking is not specified, the OSGi framework assumes a ranking of 0. Read about updating service rankings for more information.
   Blueprint includes several options for configuring service managers. To define a simple service manager for a PluginServiceFactory bean, create a `<service>` element for each PluginServiceFactory bean:

```
<service ref="myPluginBeanFactory"
    interface="com.ibm.websphere.objectgrid.plugins.osgi.PluginServiceFactory"
    ranking="1">
</service>
```

5. Store the Blueprint XML file in the plug-ins bundle. The Blueprint XML file must be stored in the OSGI-INF/blueprint directory for the Blueprint container to be discovered.
   To store the Blueprint XML file in a different directory, you must specify the following Bundle-Blueprint manifest header:

```
Bundle-Blueprint: OSGI-INF/blueprint.xml
```

Results

The eXtreme Scale plug-ins are now configured to be exposed in an OSGi Blueprint container, In addition, the ObjectGrid descriptor XML file is configured to reference the plug-ins using the OSGi Blueprint service.

Configuring servers with OSGi Blueprint

You can configure WebSphere® eXtreme Scale container servers using an OSGi blueprint XML file, allowing simplified packaging and development of self-contained server bundles.

Before you begin

This topic assumes that the following tasks have been completed:

- The Eclipse Equinox OSGi framework has been installed and started with either the Eclipse Gemini or Apache Aries blueprint container.
- The eXtreme Scale server bundle has been installed and started.
- The eXtreme Scale dynamic plug-ins bundle has been created.
- The eXtreme Scale ObjectGrid descriptor XML file and deployment policy XML file have been created.

About this task

This task describes how to configure an eXtreme Scale server with a container using a blueprint XML file. The result of the procedure is a container bundle. When the container bundle is started, the eXtreme Scale server bundle will track the bundle, parse the server XML and start a server and container.

A container bundle can optionally be combined with the application and eXtreme Scale plug-ins when dynamic plug-in updates are not required or the plug-ins do not support dynamic updating.

Procedure

1. Create a Blueprint XML file with the `objectgrid` namespace included. You can name the file anything. However, it must include the blueprint namespace:

```
<?xml version="1.0" encoding="UTF-8"?>

<blueprint xmlns="http://www.osgi.org/xmlns/blueprint/v1.0.0"
           xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance

xmlns:objectgrid="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsconfigblue_2_ht
tp://www.ibm.com/schema/objectgrid"
           xsi:schemaLocation="http://www.ibm.com/schema/objectgrid
                http://www.ibm.com/schema/objectgrid/objectgrid.xsd">
...
</blueprint>
```

2. Add the XML definition for the eXtreme Scale server with the appropriate server properties. See the Spring descriptor XML file for details on all available configuration properties. See the following example of the XML definition:

```
<objectgrid:server
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsconfigblue_2_xsServer"
tracespec="ObjectGridOSGi=all=enabled"
tracefile="logs/osgi/wxsserver/trace.log" jmxport="1199" listenerPort="2909">
<objectgrid:catalog host="catserver1.mycompany.com" port="2809" />
<objectgrid:catalog host="catserver2.mycompany.com" port="2809" />
</objectgrid:server>
```

3. Add the XML definition for the eXtreme Scale container with the reference to the server definition and the ObjectGrid descriptor XML and ObjectGrid deployment XML files embedded in the bundle; for example:

```
<objectgrid:container
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsconfigblue_2_container"
    objectgridxml="/META-INF/objectGrid.xml"
    deploymentxml="/META-INF/objectGridDeployment.xml"
    server="xsServer" />
```

4. Store the Blueprint XML file in the container bundle. The Blueprint XML must be stored in the OSGI-INF/blueprint directory for the Blueprint container to be found.
   To store the Blueprint XML in a different directory, you must specify the Bundle-Blueprint manifest header; for example:

```
Bundle-Blueprint: OSGI-INF/blueprint.xml
```

5. Package the files into a single bundle JAR file. See the following example of a bundle directory hierarchy:

```
MyBundle.jar
    /META-INF/manifest.mf
    /META-INF/objectGrid.xml
    /META-INF/objectGridDeployment.xml
    /OSGI-INF/blueprint/blueprint.xml
```

Results

An eXtreme Scale container bundle is now created and can be installed in Eclipse Equinox. When the container bundle is started, the eXtreme Scale server runtime environment in the eXtreme Scale server bundle, will automatically start the singleton eXtreme Scale server using the parameters defined in the bundle, and starts a container server. The bundle can be stopped and started, which results in the container stopping and starting. The server is a singleton and does not stop when the bundle is started the first time.

Configuring servers with OSGI config admin

You can use the OSGi configuration administration (config admin) service to configure WebSphere® eXtreme Scale container servers.

About this task

To configure a server, the ManagedService persistent identifier (PID), com.ibm.websphere.xs.server, is set to reference the ObjectGrid server properties file on the file system. To configure a container, the ManagedServiceFactory PID, com.ibm.websphere.xs.container, is set to reference the ObjectGrid deployment XML

file and ObjectGrid deployment policy XML file on the file system.
When the two PIDs are set in the config admin service, the eXtreme Scale server service automatically initializes the server and start the container with the specified configuration files. Config admin PIDs are persisted to the OSGi configuration directory. If the configuration is not cleared, the settings are retained between framework restarts.

Several third-party utilities exist for setting config admin properties. The following utilities are examples of tools that the product supports:

- The Luminis OSGi Configuration Admin command line client allows command line configuration.
- Apache Felix File Install allows specifying config admin PID settings in standard property files.

To configure eXtreme Scale container servers with the OSGi Configuration Administration command-line client for Luminis, complete the following steps

Procedure

1. Create a managed service PID for the ObjectGrid server properties file in the OSGi console, by running the following commands:

```
osgi> cm create com.ibm.websphere.xs.server
osgi> cm put com.ibm.websphere.xs.server objectgrid.server.props /mypath/server.properties
```

2. Create a managed service factory persistence identifier PID for the ObjectGrid container in the OSGi console by running the following commands. Attention: Use the PID that is created with the **createf** config admin command. The PID that is used in the following code snippet is only an example.

```
osgi> cm createf com.ibm.websphere.xs.container
PID: com.ibm.websphere.xs.container-123456789-0
osgi> cm put com.ibm.websphere.xs.container-123456789-0 objectgridFile /mypath/objectGrid.xml
osgi> cm put com.ibm.websphere.xs.container-123456789-0 deploymentPolicyFile /mypath/deployment.xml
```

Results

eXtreme Scale container servers are now configured to start in an Eclipse Equinox OSGi framework.

What to do next

Container servers can also be programmatically created using the ServerFactory API and OSGi bundle activators. For details on using the ServerFactory API, see the API documentation.

Configuring eXtreme Scale servers to run in the Liberty profile

8.5+ You must create server and catalog service definitions to run WebSphere® eXtreme Scale in the Liberty profile.

Before you begin

Install the WebSphere Application Server Liberty profile and WebSphere eXtreme Scale. For more information, see Installing the Liberty profile.

Procedure

1. Create a server definition; for example:

```
<wlp install_root>/bin/server create <your server name>
```

2. Find the server.xml file under your server definition and open it in an editor. A commented feature manager stanza already exists. You can find the server definition in the following directory:

```
<wlp install_root>/usr/servers/<your server name>
```

3. Create a catalog service definition. To define a catalog service in a server, you need the WebSphere eXtreme Scale server feature and the server configuration file.
   a. Add the server feature to the server definition: 8.5

```
<featureManager>
     <feature>eXtremeScale_server-1.0</feature>
</featureManager>
```

   b. Add the configuration to tell the server feature that this server is a catalog service; for example:

```
<com.ibm.ws.xs.server.config isCatalog="true"/>
```

What to do next

After you configure eXtreme Scale servers, you can start yours servers in the Liberty profile. For more information, see Starting and stopping servers in the Liberty profile.

Scenario: Configuring HTTP session failover in the Liberty profile

8.5+ You can configure a web application server so that, when the web server receives an HTTP request for session replication, the request is forwarded to one or more servers that run in the Liberty profile.

Before you begin

To complete this task, you must install the Liberty profile. For more information, see Installing the Liberty profile.

About this task

The Liberty profile does not include session replication. However, if you use WebSphere® eXtreme Scale with the Liberty profile, then you can replicate sessions. Therefore, if a server fails, then application users do not lose session data.
When you add the web feature to the server definition and configure the session manager, you can use session replication in your eXtreme Scale applications that run in the Liberty profile.

- 8.5 Enabling the eXtreme Scale web feature in the Liberty profile
  You can enable the web feature to use HTTP session failover in the Liberty profile.
- Configuring a web server plug-in to forward requests to multiple servers in the Liberty profile
  Use this task to configure the web server plug-in to distribute HTTP server requests between multiple servers in the Liberty profile.
- Merging plug-in configuration files for deployment to the application server plug-in
  Generate plug-in configuration files after you configure a unique clone ID in the Liberty server.xml configuration file.
- 8.5+ Enabling the eXtreme Scale web feature in the Liberty profile
  You can enable the web feature to use HTTP session failover in the Liberty profile.
- 8.5+ Configuring a web server plug-in to forward requests to multiple servers in the Liberty profile
  Use this task to configure the web server plug-in to distribute HTTP server requests between multiple servers in the Liberty profile.
- 8.5+ Merging plug-in configuration files for deployment to the application server plug-in
  Generate plug-in configuration files after you configure a unique clone ID in the Liberty server.xml configuration file.

Related tasks:
Scenario: Using an OSGi environment to develop and run eXtreme Scale plug-ins
8.5+ Scenario: Using JCA to connect transactional applications to eXtreme Scale clients
8.5+ Scenario: Running grid servers in the Liberty profile using Eclipse tools
Migrating a WebSphere Application Server memory-to-memory replication or database session to use WebSphere eXtreme Scale session management
8.5+

Enabling the eXtreme Scale web feature in the Liberty profile

8.5+ You can enable the web feature to use HTTP session failover in the Liberty profile.

About this task

The web feature is deprecated. Use the webApp feature instead. When you add the webApp feature to the server definition and configure the session manager, you can use session replication in your WebSphere® eXtreme Scale applications that run in the Liberty profile.

When you install the WebSphere Application Server Liberty profile, it does not include session replication. However, if you use WebSphere eXtreme Scale with the Liberty profile, then you can replicate sessions so that if a server goes down, the application users do not lose session data.

When you add the web feature to the server definition and configure the session manager, you can use session replication in your eXtreme Scale applications that run in the Liberty profile.

Procedure

8.5 Define a web application to run in the Liberty profile.

What to do next

Next, configure a web server plug-in to forward HTTP requests to multiple servers in the Liberty profile.
Related reference:
Liberty profile web feature properties
Liberty profile xsWebGrid feature properties
Liberty profile webApp feature properties

Configuring a web server plug-in to forward requests to multiple servers in the Liberty profile

8.5+ Use this task to configure the web server plug-in to distribute HTTP server requests between multiple servers in the Liberty profile.

Before you begin

Before you configure the web server plug-in to route HTTP requests to multiple server, complete the following task:

- 8.5 Enabling the eXtreme Scale web feature in the Liberty profile

About this task

Configure the web server plug-in so that the web server receives an HTTP request for dynamic resources, the request is forwarded to multiple servers that run in the Liberty profile.

Procedure

See Configuring the Liberty profile with a web server plug-in in the WebSphere® Application Server Information Center to complete this task.

What to do next

Next, merge the plugin-cfg.xml files from multiple application server cells. You must also ensure that unique clone IDs exist for each application server that runs in the Liberty profile.

Merging plug-in configuration files for deployment to the application server plug-in

8.5+ Generate plug-in configuration files after you configure a unique clone ID in the Liberty server.xml configuration file.

Before you begin

If you are generating and merging plug-in configuration files to configure HTTP session failover in a Liberty profile, then you must complete the following tasks:

- Enabling the eXtreme Scale web feature in the Liberty profile
- Configuring a web server plug-in to forward requests to multiple servers in the Liberty profile

About this task

Use the WebSphere® Application Server administrative console to complete this task.

Procedure

1. Merge the plugin-cfg.xml files from multiple application server cells. You can either manually merge the plugin-cfg.xml files or use the pluginCfgMerge tool to automatically merge the plugin-cfg.xml file from multiple application server profiles into a single output file. The pluginCfgMerge.bat and pluginCfgMerge.sh files are in the *install_root*/bin directory.
   For more information about manually merging the plugin-cfg.xml files, see the technote about merging plugin-cfg.xml files from multiple application server profiles.
2. Ensure that the cloneID value for each application server is unique. Examine the cloneID value for each application server in the merged file to ensure that this value is unique for each application server. If the cloneID values in the merged file are not all unique, or if you are running with memory to memory session replication in peer to peer mode, use the administrative console to configure unique HTTP session cloneIDs.
   To configure a unique HTTP session clone ID with the WebSphere Application Server administrative console, complete the following steps:
   a. Click Servers > Server Types > WebSphere application servers > *server_name*.
   b. Under Container Settings, click Web Container Settings > Web container.
   c. Under Additional Properties, click Custom properties > New.
   d. Enter `HttpSessionCloneId` in the Name field, and enter a unique value for the server in the Value field. The unique value must be eight to nine alphanumeric characters in length. For example, test1234 is a valid cloneID value.
   e. Click Apply or OK.
   f. Click Save to save the configuration changes to the master configuration.
3. Copy the merged plugin-cfg.xml file to the *plugin_installation_root*/config/web_server_name directory on the web server host.
4. Ensure that you defined the correct operating system, file access permissions for the merged plugin-cfg.xml file. These file access permissions allow the HTTP server plug-in process to read the file.

Results

When you complete this task, you have one plug-in configuration file for multiple application server cells, and your eXtreme Scale applications that run in the Liberty profile are enabled for session replication.

Administering

Administering and operating the product environment includes starting and stopping servers, managing the availability of the data grid, and recovering from data center failure scenarios. After you configure your catalog servers and container servers, you can start and stop the servers using various methods. The method that you use to start and stop servers depends on if you are using an embedded topology, a stand-alone topology, or a topology that is running within WebSphere® Application Server.

- Starting and stopping stand-alone servers
  You can start and stop stand-alone catalog and container servers with scripts or the embedded server API.
- Stopping servers gracefully with the xscmd utility
  You can use the **xscmd** utility with the -c teardown command to stop a list or group of catalog and container servers. This command simplifies shutting down all or portions of a data grid. It also prevents unnecessary placement and recovery catalog service actions that normally occur when processes are stopped ungracefully.
- Starting and stopping servers in a WebSphere Application Server environment
  Catalog and container servers can automatically start in a WebSphere Application Server or WebSphere Application Server Network Deployment environment.
- Starting and stopping servers in the Liberty profile
  Use the Liberty profile **server** command to start and stop WebSphere eXtreme Scale servers in the Liberty profile.
- Using the embedded server API to start and stop servers
  With WebSphere eXtreme Scale, you can use a programmatic API for managing the life cycle of embedded servers and containers. You can programmatically configure the server with any of the options that you can also configure with the command line options or file-based server properties. You can configure the embedded server to be a container server, a catalog service, or both.
- Administering with the xscmd utility
  With the **xscmd** utility, you can complete administrative tasks in the environment such as: establishing multi-master replication links, overriding quorum, and stopping groups of servers with the teardown command.
- Controlling placement
  You can use several different options to control when shards are placed on various container servers in the configuration. During startup, you might choose to delay the placement of shards. When you are running all of your container servers, you might need to suspend, resume, or change placement while you maintain servers.
- Managing ObjectGrid availability
  The availability state of an ObjectGrid instance determines which requests can be processed at any particular time. You can use the StateManager interface to set and retrieve the state of an ObjectGrid instance.
- Managing data center failures
  How you manage failures in your data centers depends on if you have enabled quorum in the catalog servers. If quorum is enabled, all placement activities are stopped when a failure is detected. You must override quorum and take further administrative actions.
- 8.5+ Querying and invalidating data
  You can use the query interfaces in the monitoring console and in the **xscmd** utility to retrieve small sets of keys from a map and invalidate sets of data.
- 8.5+ Retrieving eXtreme Scale environment information with the xscmd utility
  You can use the **xscmd** utility with the -c showinfo command to view important details about the servers running in your WebSphere eXtreme Scale environment, including: WebSphere eXtreme Scale servers, Java™ virtual machines, and (if applicable) servers running with WebSphere Application Server. Issue this command to retrieve name and version information, hostname and IP address, and the installation directories of these servers. Using -c showinfo command lets you retrieve these details without having to check log files, directories, or use third party applications.
- Starting eXtreme Scale servers using the Eclipse Equinox OSGi framework
  WebSphere eXtreme Scale container servers can be started in an Eclipse Equinox OSGi framework using several methods.
- Installing and starting OSGi-enabled plug-ins
  In this task, you install the dynamic plug-in bundle into the OSGi framework. Then, you start the plug-in.
- Administering OSGi-enabled services using the xscmd utility
  You can use the **xscmd** utility to complete administrator tasks, such as viewing services and their rankings that are being used by each container, and updating the runtime environment to use new versions of the bundles.
- Administering with Managed Beans (MBeans)
  You can use several different types of Java Management Extensions (JMX) MBeans to administer and monitor deployments. Each MBean refers to a specific entity, such as a map, data grid, server, or service.
- 8.5+ Administering J2C client connections
  The WebSphere eXtreme Scale connection factory includes an eXtreme Scale client connection that can be shared between applications and persisted through application restarts.

Related tasks:
Troubleshooting administration
Administering with the xscmd utility

Starting a stand-alone catalog service
Configuring WebSphere eXtreme Scale with WebSphere Application Server

Starting and stopping stand-alone servers

You can start and stop stand-alone catalog and container servers with scripts or the embedded server API.

Before you begin

If you are starting or stopping servers in a stand-alone environment that is using an external client security provider, you must set the *CLIENT_AUTH_LIB* environment variable before you run the start and stop scripts. For more information about setting this environment variable, see Starting secure servers in a stand-alone environment.

- Starting stand-alone servers
  When you are running a stand-alone configuration, the environment is comprised of catalog servers, container servers, and client processes. WebSphere® eXtreme Scale servers can also be embedded within existing Java™ applications by using the embedded server API. You must manually configure and start these processes.
- Stopping stand-alone servers
  You can use the stopOgServer script to stop eXtreme Scale server processes.

Starting stand-alone servers

When you are running a stand-alone configuration, the environment is comprised of catalog servers, container servers, and client processes. WebSphere® eXtreme Scale servers can also be embedded within existing Java™ applications by using the embedded server API. You must manually configure and start these processes.

Before you begin

You can start WebSphere eXtreme Scale servers in an environment that does not have WebSphere Application Server installed. If you are using WebSphere Application Server, see Configuring WebSphere eXtreme Scale with WebSphere Application Server.

- Starting a stand-alone catalog service
  You must start the catalog service manually when you are using a distributed WebSphere eXtreme Scale environment that is not running in WebSphere Application Server.
- Starting container servers
  You can start container servers from the command line using a deployment topology or using a server.properties file.
- startOgServer script
  The **startOgServer** script starts container and catalog servers . You can use a variety of parameters when you start your servers to enable trace, specify port numbers, and so on.

Starting a stand-alone catalog service

You must start the catalog service manually when you are using a distributed WebSphere® eXtreme Scale environment that is not running in WebSphere Application Server.

Before you begin

- If you are using WebSphere Application Server, the catalog service automatically starts within the existing processes. For more information, see Starting and stopping servers in a WebSphere Application Server environment.

About this task

Start the catalog service with the **startOgServer** script. When you call the start command, use the **startOgServer.sh** script on UNIX platforms or **startOgServer.bat** on Windows.
The catalog service can run in a single process or can include multiple catalog servers to form a catalog service domain. A catalog service domain is required in a production environment for high availability. For more information, see High availability catalog service. You can also specify additional parameters to the script to bind the Object Request Broker (ORB) to a specific host and port, specify the domain, or enable security.

Procedure

- **Start a single catalog server process.**
  To start a single catalog server, type the following commands from the command line:

  1. Navigate to the bin directory.

     ```
     cd objectgridRoot/bin
     ```

  2. Run the **startOgServer** command.

     ```
     startOgServer.bat|sh catalogServer
     ```

  For a list of all of the available command-line parameters, see startOgServer script. Do not use a single Java™ virtual machine (JVM) to run the catalog service in a production environment. If the catalog service fails, no new clients are able to route to the deployed eXtreme Scale, and no new ObjectGrid instances can be added to the domain. For these reasons, you should start a set of Java virtual machines to run a catalog service domain.
- **Start a catalog service domain that consists of multiple endpoints.**
  To start a set of servers to run a catalog service, you must use the -catalogServiceEndPoints option on the startOgServer script. This argument accepts a list of catalog service endpoints in the format of *serverName*:*hostName*:*clientPort*:*peerPort*.

  The following example shows how to start the first of three Java virtual machines to host a catalog service:
  1. Navigate to the bin directory.

     ```
     cd wxs_install_root/bin
     ```

  2. Run the **startOgServer** command.

     ```
     startOgServer.bat|sh cs1 -catalogServiceEndPoints
     cs1:MyServer1.company.com:6601:6602,cs2:MyServer2.company.com:6601:6602,cs3:MyServer3.company.com:6601:6602
     ```

     In this example, the `cs1` server on the `MyServer1.company.com` host is started. This server name is the first argument that is passed to the script. During initialization of the `cs1` server, the -catalogServiceEndpoints parameters are examined to determine which ports are allocated for this process. The list is also used to allow the `cs1` server to accept connections from other servers: `cs2` and `cs3`.
  3. To start the remaining catalog servers in the list, pass the following arguments to the **startOgServer** script. Starting the `cs2` server on the `MyServer2.company.com` host.

     ```
     startOgServer.bat|sh cs2 -catalogServiceEndPoints
     cs1:MyServer1.company.com:6601:6602,cs2:MyServer2.company.com:6601:6602,cs3:MyServer3.company.com:6601:6602
     ```

     Starting `cs3` on `MyServer3.company.com`:

     ```
     startOgServer.bat|sh cs3 -catalogServiceEndPoints
     cs3:MyServer3.company.com:6601:6602,cs1:MyServer1.company.com:6601:6602,cs2:MyServer2.company.com:6601:6602
     ```

     The order of the list for the -catalogServiceEndpoints parameter can be different for the various catalog servers, but the servers contained in the list must be the same. Do not put any spaces in the list.
     Important: **Start at least two catalog servers in parallel.**
     You must start catalog servers that are in a data grid in parallel, because each server pauses to wait for the other catalog servers to join the core group. A catalog server that is configured for a data grid does not start until it identifies other members in the group. The catalog server eventually times out if no other servers become available.

- **Bind the ORB to a specific host and port.**
  Aside from ports defined in the catalogServiceEndpoints argument, each catalog service also uses an Object Request Broker (ORB) to accept connections from clients and containers. By default, the ORB listens on port `2809` of the localhost. If you want to bind the ORB to a specific host and port on a catalog service JVM, use the -listenerHost and -listenerPort arguments. The following example shows how to start a single JVM catalog server with its ORB bound to port `7000` on `MyServer1.company.com`:

  ```
  startOgServer.sh catalogServer -listenerHost MyServer1.company.com
  -listenerPort 7000
  ```

  Each eXtreme Scale container and client must be provided with catalog service ORB endpoint data. Clients only need a subset of this data, but you should use at least two endpoints for high availability.
- Optional: **Name the catalog service domain**

A catalog service domain name is not required when starting a catalog service. However, if you are using multi-master replication or are using multiple catalog service domains within the same set of processes, then you need to define a unique catalog service domain name. The default domain name is `DefaultDomain`. To give your domain a name, use the -domain option. The following example demonstrates how to start a single catalog service JVM with the domain name `myDomain`.

```
startOgServer.sh catalogServer -domain myDomain
```

For more information about configuring multi-master replication, see Configuring multiple data center topologies.

- **Start a secure catalog service.** For more information, see Starting secure servers in a stand-alone environment.
- **Start the catalog service programmatically.**
  Any JVM setting that is flagged by the CatalogServerProperties.setCatalogServer method can host the catalog service for eXtreme Scale. This method indicates to the eXtreme Scale server run time to instantiate the catalog service when the server is started. The following code shows how to instantiate the eXtreme Scale catalog server:

```
CatalogServerProperties catalogServerProperties =
        ServerFactory.getCatalogProperties();
catalogServerProperties.setCatalogServer(true);

//The getInstance() method will start the catalog service.
Server server = ServerFactory.getInstance();
```

For more information about starting servers programmatically, see Using the embedded server API to start and stop servers.

Example: Configuring catalog service domains
Administering
Related tasks:
Starting container servers
Related reference:
startOgServer script

Starting container servers

You can start container servers from the command line using a deployment topology or using a server.properties file.

About this task

To start a container process, you need an ObjectGrid XML file. The ObjectGrid XML file specifies which eXtreme Scale servers the container hosts. Ensure that your container is equipped to host each ObjectGrid in the XML that you pass to it. All of the classes that these ObjectGrids require must be in the classpath for the container. For more information about the ObjectGrid XML file, see objectGrid.xsd file.

Procedure

- **Start the container server from the command line.**
  1. From the command line, navigate to the bin directory:

     ```
     cd wxs_install_root/bin
     ```

  2. Run the following command:

     ```
     startOgServer.sh c0 -objectGridFile ../xml/companyGrid.xml
     -catalogServiceEndPoints MyServer1.company.com:2809
     ```

  Important: On the container server, the -catalogServiceEndPoints option is used to reference the Object Request Broker (ORB) host and port on the catalog service. The catalog service uses the -listenerHost and -listenerPort options to specify the host and port for ORB binding or accepts the default binding. When you are starting a container, use the -catalogServiceEndPoints option to reference the values that are passed to the -listenerHost and -listenerPort options on the catalog service. If -listenerHost and -listenerPort options are not used when the catalog service is started, the ORB binds to port 2809 on the localhost for the catalog service. Do not use the -catalogServiceEndPoints option to reference the hosts and ports that were passed to the -catalogServiceEndPoints option on the catalog service. On the catalog service, the -catalogServiceEndPoints option is used to specify ports necessary for static server configuration.
  This process is identified by c0, the first argument passed to the script. Use the companyGrid.xml to start the container. If your catalog server ORB is running on a different host than your container or it is using a non-default port, you must use the -catalogServiceEndPoints argument to connect to the ORB. For this example, assume that a single catalog service is running on port `2809` on `MyServer1.company.com`
- **Start the container using a deployment policy.**
  Although not required, a deployment policy is recommended during container start up. The deployment policy is used to set up partitioning and replication for eXtreme Scale. The deployment policy can also be used to influence placement behavior. Because the previous example did not provide a deployment policy file, the example receives all default values with regard to replication, partitioning, and placement. So, the maps in the CompanyGrid are in one mapSet. The mapSet is not partitioned or replicated. For more information about deployment policy files, see Deployment policy descriptor XML file. The following example uses the companyGridDpReplication.xml file to start a container JVM, the c0 JVM:

  1. From the command line, navigate to the bin directory:

     ```
     cd wxs_install_root/bin
     ```

  2. Run the following command:

```
startOgServer.sh c0 -objectGridFile ../xml/companyGrid.xml
-deploymentPolicyFile ../xml/companyGridDpReplication.xml
-catalogServiceEndPoints MyServer1.company.com:2809
```

Note: If you have Java™ classes stored in a specific directory, or you are using a loader or agent, instead of altering the StartOgServer script, you can launch the server with arguments as follows: `-jvmArgs -cp C:\ . . . \DirectoryPOJOs\POJOs.jar` . In the companyGridDpReplication.xml file, a single map set contains all of the maps. This mapSet is divided into 10 partitions. Each partition has one synchronous replica and no asynchronous replicas. Any container that uses the companyGridDpReplication.xml deployment policy paired with the companyGrid.xml ObjectGrid XML file is also able to host CompanyGrid shards. Start another container JVM, the c1 JVM:

1. From the command line, navigate to the bin directory:

   ```
   cd wxs_install_root/bin
   ```

2. Run the following command:

   ```
   startOgServer.sh c1 -objectGridFile ../xml/companyGrid.xml
   -deploymentPolicyFile ../xml/companyGridDpReplication.xml
   -catalogServiceEndPoints MyServer1.company.com:2809
   ```

Each deployment policy contains one or more objectgridDeployment elements. When a container is started, it publishes its deployment policy to the catalog service. The catalog service examines each objectgridDeployment element. If the objectgridName attribute matches the objectgridName attribute of a previously received objectgridDeployment element, the latest objectgridDeployment element is ignored. The first objectgridDeployment element received for a specific objectgridName attribute is used as the master. For example, assume that the c2 JVM uses a deployment policy that divides the mapSet into a different number of partitions:

companyGridDpReplicationModified.xml

```
<?xml version="1.0" encoding="UTF-8"?>
<deploymentPolicy xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://ibm.com/ws/objectgrid/deploymentPolicy
                ../deploymentPolicy.xsd"
    xmlns="http://ibm.com/ws/objectgrid/deploymentPolicy">

    <objectgridDeployment objectgridName="CompanyGrid">
        <mapSet name="mapSet1" numberOfPartitions="5"
            minSyncReplicas="1" maxSyncReplicas="1"
            maxAsyncReplicas="0">
            <map ref="Customer" />
            <map ref="Item" />
            <map ref="OrderLine" />
            <map ref="Order" />
        </mapSet>
    </objectgridDeployment>

</deploymentPolicy>
```

Now, you can start a third JVM, the c2 JVM:

1. From the command line, navigate to the bin directory:

   ```
   cd wxs_install_root/bin
   ```

2. Run the following command:

   ```
   startOgServer.sh c2 -objectGridFile ../xml/companyGrid.xml
   -deploymentPolicyFile ../xml/companyGridDpReplicationModified.xml
   -catalogServiceEndPoints MyServer1.company.com:2809
   ```

The container on the c2 JVM is started with a deployment policy that specifies 5 partitions for mapSet1. However, the catalog service already holds the master copy of the objectgridDeployment for the CompanyGrid. When the c0 JVM was started it specified that 10 partitions exist for this mapSet. Because it was the first container to start and publish its deployment policy, its deployment policy became the master. Therefore, any objectgridDeployment attribute value that is equal to `CompanyGrid` in a subsequent deployment policy is ignored.

- **Start a container using a server properties file.**
  You can use a server properties file to set up trace and configure security on a container. Run the following commands to start container c3 with a server properties file:

  1. From the command line, navigate to the bin directory:

     ```
     cd wxs_install_root/bin
     ```

  2. Run the following command:

     ```
     startOgServer.sh c3 -objectGridFile ../xml/companyGrid.xml
     -deploymentPolicyFile ../xml/companyGridDpReplicationModified.xml
     -catalogServiceEndPoints MyServer1.company.com:2809
     -serverProps ../serverProps/server.properties
     ```

  An example server.properties file follows:

  ```
  server.properties
  workingDirectory=
  traceSpec=*=all=disabled
  systemStreamToFileEnabled=true
  enableMBeans=true
  memoryThresholdPercentage=50
  ```

  This is a basic server properties file that does not have security enabled. For more information about the server.properties file, see Server properties file.

- **Start a container server programmatically.**
  For more information about starting container servers programmatically, see Using the embedded server API to start and stop servers.

Configuring distributed deployments

startOgServer script

The **startOgServer** script starts container and catalog servers . You can use a variety of parameters when you start your servers to enable trace, specify port numbers, and so on.

Purpose

You can use the **startOgServer** script to start servers.

Location

The **startOgServer** script is in the bin directory of the root directory, for example:

```
cd wxs_install_root/bin
```

Note: If you have Java™ classes stored in a specific directory, or you are using a loader or agent, instead of altering the **startOgServer** script, you can launch the server with arguments as follows: `-jvmArgs -cp C:\ . . . \DirectoryPOJOs\POJOs.jar`
.

Usage for catalog servers

To start a catalog server:

Windows

```
startOgServer.bat <server> [options]
```

UNIX

```
startOgServer.sh <server>[options]
```

To start a default configured catalog server, use the following commands:
Windows

```
startOgServer.bat catalogServer
```

UNIX

```
startOgServer.sh catalogServer
```

Options for starting catalog servers

The following parameters are all optional.

Parameters for starting a catalog server:

-catalogServiceEndPoints <serverName:hostName:clientPort:peerPort>
Specifies a list of catalog servers to link together into a catalog service domain. Each attribute is defined as follows:

serverName
Specifies the name of the catalog server.
hostName
Specifies the host name for the computer where the server is launched.
clientPort
Specifies the port that is used for peer catalog service communication.
peerPort
This value is the same as the haManagerPort. Specifies the port that is used for peer catalog service communication.

The following example starts the cs1 catalog server, which is in the same catalog service domain as the cs2 and cs3 servers:

```
startOgServer.bat|sh cs1 -catalogServiceEndPoints
cs1:MyServer1.company.com:6601:6602,cs2:MyServer2.company.com:6601:6602,cs3:MyServer3.company.com:6601:6602
```

If you start additional catalog servers, they must include the same servers in the -catalogServiceEndPoints argument. The order of the list can be different, but the servers contained in the list must be the same for each catalog server. Do not put any spaces in the list.
-clusterSecurityFile <cluster security xml file>

Specifies the objectGridSecurity.xml file on the hard disk, which describes the security properties that are common to all servers (including catalog servers and container servers). One of the property example is the authenticator configuration which represents the user registry and authentication mechanism.
Example: `/opt/xs/ogsecurity.xml`

Windows Important: If you are using Windows, the directory path does not support backslashes. If you have used backslashes, you must escape any backslash (\ ) characters in the path. For example, if you want to use the path C:\opt\ibm, enter C:\\opt\\ibm in the properties file. Windows directories with spaces are not supported.

-clusterSecurityUrl <cluster security xml URL>
Specifies the objectGridSecurity.xml file as a URL to the file on the hard disk or on the network, which describes the security properties that are common to all servers (including catalog servers and container servers). One of the property example is the authenticator configuration which represents the user registry and authentication mechanism.
Example: `file:///opt/xs/ogsecurity.xml`

-domain <domain name>
Specifies the name of the catalog service domain for this catalog server. The catalog service domain creates a group of highly available catalog servers. Each catalog server for a single domain should specify the same value for the -domain parameter.

-haManagerPort <port>
Specifies the port that is used by the high availability (HA) manager for heartbeat communication between peer container servers. The haManagerPort port is only used for peer-to-peer communication between container servers that are in same domain. If the haManagerPort property is not defined, then an ephemeral port is used. In WebSphere® Application Server, this setting is inherited by the high availability manager port configuration.

-heartbeat 0|1|-1
Specifies how often a server failover is detected. An aggressive heartbeat interval can be useful when the processes and network are stable. If the network or processes are not optimally configured, heartbeats might be missed, which can result in a false failure detection. The heartbeat frequency level is a trade-off between use of resources and failure discovery time. The more frequent a heartbeat occurs, then more resources are used. However, failures are discovered more quickly. This property applies to the catalog service only.

Table 1. Valid heartbeat values

Value	Action	Description
-1	Aggressive	Specifies an aggressive heartbeat level. With this value, failures are detected more quickly, but more processor and network resources are used. This level is more sensitive to missing heartbeats when the server is busy. Failovers are typically detected within 5 seconds.
0	Typical (default)	Specifies a heartbeat level at a typical rate. With this value, failover detection occurs at a reasonable rate without overusing resources. Failovers are typically detected within 30 seconds.
1	Relaxed	Specifies a relaxed heartbeat level. With this value, a decreased heartbeat frequency increases the time to detect failures, but also decreases processor and network use. Failovers are typically detected within 180 seconds.

-JMXConnectorPort <port>
Defines the Secure Sockets Layer (SSL) port to which the Java Management Extensions (JMX) service binds. Only required if an SSL transport protocol is needed for JMX data.

-JMXServicePort <port>
Required only for WebSphere eXtreme Scale in a stand-alone environment. Specifies the port number on which the MBean server listens for communication with Java Management Extensions (JMX).
Default: `1099` for catalog servers

-jvmArgs <JVM arguments>
Specifies a set of JVM arguments. Every option after the -jvmArgs option is used to start the server Java virtual machine (JVM). When the -jvmArgs parameter is used, ensure that it is the last optional script argument specified.
Example: `-jvmArgs -Xms256M -Xmx1G`

-listenerHost <host name>
Specifies the host name to which the Object Request Broker (ORB) transport protocol binds for communication. The value must be a fully qualified domain name or IP address. If your configuration involves multiple network cards, set the listener host and port to the IP address for which to bind. By setting the listener and host port, it allows the transport mechanism in the JVM know which IP address to use. If you do not specify which IP address to use, symptoms such as connection timeouts, unusual API failures, and clients that seem to hang can occur.

Default: `localhost`

-listenerPort <port>
Specifies the port number to which the ORB transport protocol binds for communication. **Default:** `2809`

-quorum true|false
Enables quorum for the catalog service. Quorum is used to ensure that most of the catalog service domain is available before partitions are moved to the available container servers. To enable quorum, set the value to `true` or `enabled`. The default value is `disabled`. This property applies to the catalog service only. For more information, see Catalog server quorums.

-script <script file>
Specifies the location of a custom script for commands you specify to start catalog servers or containers and then parameterize or edit as you require.

-serverProps <server properties file>
Specifies the server property file that contains the server-specific security properties. The file name specified for this property is just in plain file path format, such as c:/tmp/og/catalogserver.props.

-traceSpec <trace specification>
Enables trace and the trace specification string for the container server. Trace is disabled by default. This property applies to both the container server and the catalog service. Examples:

- `ObjectGrid=all=enabled`
- `ObjectGrid*=all=enabled`

-traceFile <trace file>
Specifies a file name to write trace information. This property applies to both the container server and the catalog service.

-timeout <seconds>
Specifies a number of seconds before the server start times out.

Usage for container servers

Windows

```
startOgServer.bat <server> -objectgridFile <xml file>
-deploymentPolicyFile <xml file> [options]
```

Windows

```
startOgServer.bat <server> -objectgridUrl <xml URL>
-deploymentPolicyUrl <xml URL> [options]
```

UNIX

```
startOgServer.sh <server> -objectgridFile <xml file>
-deploymentPolicyFile <xml file> [options]
```

UNIX

```
 startOgServer.sh <server> -objectgridUrl <xml URL>
-deploymentPolicyUrl <xml URL> [options]
```

Options for container servers

-catalogServiceEndPoints <hostName:port,hostName:port>
Specifies the Object Request Broker (ORB) host and port on the catalog service.
Default: localhost:2809

-deploymentPolicyFile <deployment policy xml file>
Specifies the path to the deployment policy file on the hard disk. The deployment policy is used to set up partitioning and replication. The deployment policy can also be used to influence placement behavior.
Example: ../xml/SimpleDP.xml

-deploymentPolicyUrl <deployment policy url>
Specifies the URL for the deployment policy file on the hard disk or on the network. The deployment policy is used to set up partitioning and replication. The deployment policy can also be used to influence placement behavior.
Example: file://xml/SimpleDP.xml

-JMXConnectorPort <port>
Defines the Secure Sockets Layer (SSL) port to which the Java Management Extensions (JMX) service binds. Only required if an SSL transport protocol is needed for JMX data.
-JMXServicePort <port>
Required only for WebSphere eXtreme Scale in a stand-alone environment. Specifies the port number on which the MBean server listens for communication with Java Management Extensions (JMX).

Default: `1099`
-jvmArgs <JVM arguments>
Specifies a set of JVM arguments. Every option after the -jvmArgs option is used to start the server Java virtual machine (JVM). When the -jvmArgs parameter is used, ensure that it is the last optional script argument specified.
Example:`-jvmArgs -Xms256M -Xmx1G`

-listenerHost <host name>
Specifies the host name to which the Object Request Broker (ORB) transport protocol binds for communication. The value must be a fully qualified domain name or IP address. If your configuration involves multiple network cards, set the listener host and port to the IP address for which to bind. By setting the listener and host port, it allows the transport mechanism in the JVM know which IP address to use. If you do not specify which IP address to use, symptoms such as connection timeouts, unusual API failures, and clients that seem to hang can occur.

Default: `localhost`
-listenerPort <port>
Specifies the port number to which the ORB transport protocol binds for communication. **Default:** `2809`
-objectgridFile <ObjectGrid descriptor xml file>
Specifies the path to the ObjectGrid descriptor file. The ObjectGrid XML file specifies which eXtreme Scale servers the container hosts.
-objectgridUrl <ObjectGrid descriptor url>
Specifies a URL for the ObjectGrid descriptor file. The ObjectGrid XML file specifies which eXtreme Scale servers the container hosts.
-script <script file>
Specifies the location of a custom script for commands you specify to start catalog servers or containers and then parameterize or edit as you require.
-serverProps <server properties file>
Specifies the path to the server property file.
Example:../security/server.props

-timeout <seconds>
Specifies a number of seconds before the server start times out.
-traceFile <trace file>
Specifies a file name to write trace information. This property applies to both the container server and the catalog service.

-traceSpec <trace specification>
Enables trace and the trace specification string for the container server. Trace is disabled by default. This property applies to both the container server and the catalog service. Examples:

- `ObjectGrid=all=enabled`
- `ObjectGrid*=all=enabled`

-zone <zone name>
Specifies the zone to use for all of the containers within the server. See Zone-preferred routing for more information about configuring zones.

Stopping stand-alone servers

You can use the stopOgServer script to stop eXtreme Scale server processes.

About this task

Run the **stopOgServer** script by navigating to the bin directory:

```
cd wxs_install_root/bin
```

Procedure

- **Stop a single container server.**
  Run the **stopOgServer** script to stop the container server. Use this command only when you are stopping a single container server. If you run the single catalog server stop command on several container servers in succession, you might see performance and churn issues for shard placement.

  ```
  stopOgServer containerServer -catalogServiceEndPoints MyServer1.company.com:2809
  ```

  Attention: The -catalogServiceEndPoints option should match the value of the -catalogServiceEndPoints option that was used to start the container. If a -catalogServiceEndPoints was not used to start the container, the default values are likely localhost or the hostname and 2809 for the ORB port to connect to the catalog service. Otherwise, use the values that are passed to -listenerHost and -listenerPort on the catalog service. If the -listenerHost and -listenerPort options are not used when starting the catalog service, the ORB binds to port 2809 on the localhost for the catalog service.
- **Stop multiple container servers.**
  To prevent churn and performance issues for shard placement when you want to stop multiple container servers at the same time, use the following command format. Separate a list of container servers with commas:

  ```
  stopOgServer containerServer0,containerServer1,containerServer2
  -catalogServiceEndPoints MyServer1.company.com:2809
  ```

  If you want to stop all of the containers on a specific zone or host, you can use the -teardown parameter. See Stopping servers gracefully with the xscmd utility for more information.
- **Stop catalog servers.**
  Run the **stopOgServer** script to stop the catalog server.

  ```
  stopOgServer.sh catalogServer -catalogServiceEndPoints MyServer1.company.com:2809
  ```

  Attention: When you are stopping a catalog service, use the -catalogServiceEndPoints option to reference the Object Request Broker (ORB) host and port on the catalog service. The catalog service uses -listenerHost and -listenerPort options to specify the host and port for ORB binding or accepts the default binding. If the -listenerHost and -listenerPort options are not used when starting the catalog service, the ORB binds to port 2809 on the localhost for the catalog service. The -catalogServiceEndPoints option is different when stopping a catalog service than when you started the catalog service.
  Starting a catalog service requires peer access ports and client access ports, if the default ports were not used. Stopping a catalog service requires only the ORB port.

- **Stop the web console server.** To stop the web console server, run the **stopConsoleServer.bat|sh** script. This script is in the *wxs_install_root*/ObjectGrid/bin directory of your installation. For more information, see Starting and logging on to the web console.
- **Enable trace for the server stop process.**

If a container fails to stop, you can enable trace to help with debugging the problem. To enable trace during the stop of a server, add the -traceSpec and -traceFile parameters to the stop commands. The -traceSpec parameter specifies the type of trace to enable and the -traceFile parameter specifies path and name of the file to create and use for the trace data.

1. From the command line, navigate to the bin directory.

   ```
   cd wxs_install_root/bin
   ```

2. Run the **stopOgServer** script with trace enabled.

   ```
   stopOgServer.sh c4 -catalogServiceEndPoints MyServer1.company.com:2809
    -traceFile ../logs/c4Trace.log -traceSpec ObjectGrid=all=enabled
   ```

   After the trace is obtained, look for errors related to port conflicts, missing classes, missing or incorrect XML files or any stack traces. Suggested startup trace specifications are:
   - `ObjectGrid=all=enabled`
   - `ObjectGrid*=all=enabled`

   For all of the trace specification options, see Server trace options.

- **Stop embedded servers programmatically.**
  For more information about stopping embedded servers programmatically, see Using the embedded server API to start and stop servers.

Related tasks:
Starting stand-alone servers

stopOgServer script

The **stopOgServer** script stops catalog and container servers.

Purpose

Use the **stopOgServer** script to stop a server. You must provide the name of the server and its catalog service endpoints.
Deprecated: The **startOgServer** and **stopOgServer** commands start servers that use the Object Request Broker (ORB) transport mechanism. The ORB is deprecated, but you can continue using these scripts if you were using the ORB in a previous release. The IBM eXtremeIO (XIO) transport mechanism replaces the ORB. Use the **startXsServer** and **stopXsServer** scripts to start and stop servers that use the XIO transport.

Location

The **stopOgServer** script is in the bin directory of the root directory, for example:

```
cd wxs_install_root/bin
```

Usage

To stop a catalog or container server: Windows

```
stopOgServer.bat <server_name> -catalogServiceEndPoints
<csHost:csListenerPort,csHost:csListenerPort> [options]
```

UNIX

```
stopOgServer.sh <server_name> -catalogServiceEndPoints
<csHost:csListenerPort,csHost:csListenerPort> [options]
```

Options

-catalogServiceEndPoints <csHost:csListenerPort, csHost:csListenerPort...>
Specifies the Object Request Broker (ORB) host and port number.
For container severs: The list of catalog service endpoints should be the same as the list that was used to start the container server. If you did not specify this option when you started the container server, use the default value of `localhost:2809`.

For catalog servers: If you are stopping the catalog service, use the values that you indicated for the -listenerHost and -listenerPort options when you started the catalog service. If you did not specify these options when you started the catalog server, use the default value of `localhost:2809`. The -catalogServiceEndPoints value you use when you stop the catalog service is different from when you start the catalog service.

-clientSecurityFile <security properties file>
Specifies the path to the client properties file that defines security properties for the client. See Client properties file for more information about the security settings in this file.

-traceSpec <trace specification>
Enables trace and the trace specification string for the container server. Trace is disabled by default. This property applies to both the container server and the catalog service. Examples:

- `ObjectGrid=all=enabled`
- `ObjectGrid*=all=enabled`

-traceFile <trace file>

Specifies a file name to write trace information. This property applies to both the container server and the catalog service.

-jvmArgs <JVM arguments>
Specifies a set of JVM arguments. Every option after the -jvmArgs option is used to start the server Java™ virtual machine (JVM). When the -jvmArgs parameter is used, ensure that it is the last optional script argument specified.
Example:`-jvmArgs -Xms256M -Xmx1G`

Getting started tutorial lesson 4: Monitor your environment

Stopping servers gracefully with the xscmd utility

You can use the **xscmd** utility with the -c teardown command to stop a list or group of catalog and container servers. This command simplifies shutting down all or portions of a data grid. It also prevents unnecessary placement and recovery catalog service actions that normally occur when processes are stopped ungracefully.

Procedure

- Stop a specific list of servers.
  Provide a list of servers after the -teardown parameter:

  ```
  xscmd -c teardown -sl catalogServer1,catalogServer2,containerServer1
  ```

- Stop all the servers in a specific zone.
  Use the -z parameter and provide the name of the zone. The catalog server determines the servers that are running in the zone. The **xscmd** utility also prompts you with a list of the servers in the selected zone before the servers are shut down.

  ```
  xscmd -c teardown -z zone_name
  ```

- Stop all the servers on a specific host. For example, to shut down all the servers on `myhost.mycompany.com`, enter `-hf myhost.mycompany.com`.
  Use the -hf parameter and provide the name of the host. The catalog server determines the servers that are running on the host. The **xscmd** utility prompts you with a list of the servers in the selected host before the servers are shut down.

  ```
  xscmd -teardown -hf <host_name>
  ```

  Attention: By default, the JVM continues to run when each eXtreme Scale server in an OSGi framework is stopped in the **xscmd** utility with the **-c teardown** command. If you want eXtreme Scale to exit the JVM, then this type of implementation must be planned for. You must set the server property exitJVMOnTeardown to `true` before the server is started. For more information, see Server properties file.

Starting and stopping servers in a WebSphere Application Server environment

Catalog and container servers can automatically start in a WebSphere® Application Server or WebSphere Application Server Network Deployment environment.

Before you begin

Configure catalog servers and container servers to run on WebSphere Application Server:

- Configuring the catalog service in WebSphere Application Server
- Configuring container servers in WebSphere Application Server

About this task

The life cycle of catalog and container servers in WebSphere Application Server is linked to the processes on which these servers run.

Procedure

- **Start catalog services in WebSphere Application Server**:

The life cycle a catalog server is tied to the WebSphere Application Server process. After you configure the catalog service domain in WebSphere Application Server, restart each server that you defined as a part of the catalog service domain. The catalog service starts automatically on the servers that you associated with the catalog service domain. The catalog service can also start automatically in the following scenarios, depending on the edition of WebSphere Application Server:

  - **Base WebSphere Application Server**: You can configure your application to automatically start a container server and catalog service. This feature simplifies unit testing in development environments such as Rational® Application Developer because you do not need to explicitly start a catalog service. See Configuring WebSphere Application Server applications to automatically start container servers for more information.
  - **WebSphere Application Server Network Deployment**: The catalog service automatically starts in the deployment manager process if the deployment manager node has WebSphere eXtreme Scale installed and the deployment manager profile is augmented. See Configuring the catalog service in WebSphere Application Server for more information.

- **Start container servers in WebSphere Application Server**:
  The life cycle of a container server is tied to the WebSphere Application Server application. When you start the configured application, the container servers also start.

- **Stop an entire data grid of servers**:
  You can stop catalog and container servers by stopping the applications and associated application servers. However, you can also stop an entire data grid with the **xscmd** utility or MBeans:
  - **In the xscmd utility:**
    See Stopping servers gracefully with the xscmd utility for more information about stopping an entire data grid.

  - **With Mbeans:**
    Use the tearDownServers operation on the PlacementServiceMBean Mbean.

- **Stop Liberty profile processes**:
  You can stop Liberty servers using the Liberty profile server command.

Starting and stopping servers in the Liberty profile

8.5+ Use the Liberty profile **server** command to start and stop WebSphere® eXtreme Scale servers in the Liberty profile.

Before you begin

The Liberty profile is the Java virtual machine (JVM) process that starts in OSGi and provides a flexible framework for serving applications. The eXtreme Scale server is the mechanism that provides grid services. The main two services are the catalog service and the container service. A Liberty profile is started from the command line with the `server start server_name` or `server run server_name` commands. When the Liberty profile starts, it reads the `server.xml` file to determine what Liberty profile features to start. WebSphere eXtreme Scale has three features: server, client, and web. If you add the server feature to the feature manager, then the Liberty profile starts the eXtreme Scale server bundles. However, adding the server feature does not necessarily start any eXtreme Scale servers.

The eXtreme Scale servers start only when a valid service is configured. For example, if you want to configure a catalog service, then the `isCatalog="true"` attribute must be set on the `xsServer ...` element in the server.xml file.

The following options are available to configure a container service:

- Copy a valid objectgrid.xml file (with or without an accompanying objectGridDeployment.xml file) into the wlp_home/usr/servers/*server_name*/grids directory. This grids directory is a monitored directory, and changes to files in this directory initiate events in the Liberty profile runtime environment. For example, when new objectgrid.xml, objectGridDeployment.xml, or both files are found, eXtreme Scale creates and starts a new container. When one of these files are deleted, eXtreme Scale stops that container. When files are modified, eXtreme Scale stops and restarts the container. Multiple containers can exist in the same eXtreme Scale server, which requires that subdirectories exist inside the grids directory.
- Install an OSGi bundle. This bundle must reference a blueprint.xml file that contains server metadata. This method of starting a server is similar to how you can start servers OSGi environments without the Liberty profile in WebSphere eXtreme Scale Version 7.1.1. In Version 8.5, the server element is no longer required in the blueprint.xml file. Therefore, you must define the server metadata in the server.xml file. Additionally, bundles are simple to install and start by dropping them into the grids directory in a similar way that you drop XML files in the grids directory.
- Use the embedded server API. This option is similar to the process for starting the server in a stand-alone environment. With the Liberty profile, however, you must ensure that you run your code to start the eXtreme Scale server.

About this task

Use this task to start eXtreme Scale servers with the Liberty profile **server** command. The wlp/bin directory contains a script called **server** to help control the server process. The following syntax for this command is supported:

```
server <task> [server] [options]
```

Procedure

- Start eXtreme Scale servers. When you run the **start** command, the server is launched as a background process. Use the following example to start the server:

  ```
  bin/server start server_name
  bin/server.bat start server_name
  ```

- Stop eXtreme Scale servers; for example: When you run the **stop** command, the running server is stopped. Use the following example to stop the server:

  ```
  bin/server stop server_name
  bin/server.bat stop server_name
  ```

Using the embedded server API to start and stop servers

With WebSphere® eXtreme Scale, you can use a programmatic API for managing the life cycle of embedded servers and containers. You can programmatically configure the server with any of the options that you can also configure with the command line options or file-based server properties. You can configure the embedded server to be a container server, a catalog service, or both.

Before you begin

- You must have a method for running code from within an already existing Java™ virtual machine. The eXtreme Scale classes must be available through the class loader tree.
- If your container servers are using IBM® eXtremeMemory, you must first configure the native libraries. For more information, see Configuring IBM eXtremeMemory.

About this task

You can run many administration tasks with the Administration API. One common use of the API is as an internal server for storing Web application state. The Web server can start an embedded WebSphere eXtreme Scale server, report the container server to the catalog service, and the server is then added as a member of a larger distributed grid. This usage can provide scalability and high availability to an otherwise volatile data store.

You can programmatically control the complete life cycle of an embedded eXtreme Scale server. The examples are as generic as possible and only show direct code examples for the outlined steps.

Procedure

1. Obtain the ServerProperties object from the ServerFactory class and configure any necessary options. For more information about the ServerProperties interface, see ServerProperties interface.
   Every eXtreme Scale server has a set of configurable properties. When a server starts from the command line, those properties are set to defaults, but you can override several properties by providing an external source or file. In the embedded scope, you can directly set the properties with a ServerProperties object. You must set these properties before you obtain a server instance from the ServerFactory class. The following example snippet obtains a ServerProperties object, sets the CatalogServiceBootStrap field, and initializes several optional server settings. See the API documentation for a list of the configurable settings.

   ```
   ServerProperties props = ServerFactory.getServerProperties();
   props.setCatalogServiceBootstrap("host:port"); // required to connect to specific catalog service
   props.setServerName("ServerOne"); // name server
   props.setTraceSpecification("com.ibm.ws.objectgrid=all=enabled"); // Sets trace spec
   ```

2. If you want the server to be a catalog service, obtain the CatalogServerProperties object.
   For more information about the CatalogServerProperties interface, see CatalogServerProperties interface.

   Every embedded server can be a catalog service, a container server, or both a container server and a catalog service. The following example obtains the CatalogServerProperties object, enables the catalog service option, and configures various catalog service settings.

   ```
   CatalogServerProperties catalogProps = ServerFactory.getCatalogProperties();
   catalogProps.setCatalogServer(true); // false by default, it is required to set as a catalog service
   catalogProps.setQuorum(true); // enables / disables quorum
   ```

3. Obtain a Server instance from the ServerFactory class. The Server instance is a process-scoped singleton that is responsible for managing the membership in the grid. After this instance has been instantiated, this process is connected and is highly available with the other servers in the grid.
   For more information about the Server interface, see Server interface. For more information abut the ServerFactory class, see ServerFactory class.

   The following example shows how to create the Server instance:

   ```
   Server server = ServerFactory.getInstance();
   ```

   Reviewing the previous example, the ServerFactory class provides a static method that returns a Server instance. The ServerFactory class is intended to be the only interface for obtaining a Server instance. Therefore, the class ensures that the instance is a singleton, or one instance for each JVM or isolated classloader. The getInstance method initializes the Server instance. You must configure all the server properties before you initialize the instance. The Server class is responsible for creating new Container instances. You can use both the ServerFactory and Server classes for managing the life cycle of the embedded Server instance.

For more information about the Container interface, see Container interface.

4. Start a Container instance using the Server instance.
   Before shards can be placed on an embedded server, you must create a container on the server. The Server interface has a createContainer method that takes a DeploymentPolicy argument. The following example uses the server instance that you obtained to create a container using a created DeploymentPolicy file. Note that Containers require a classloader that has the application binaries available to it for serialization. You can make these binaries available by calling the createContainer method with the Thread context classloader set to the classloader that you want to use.

```
DeploymentPolicy policy = DeploymentPolicyFactory.createDeploymentPolicy(new
          URL("file://urltodeployment.xml"),
        new URL("file://urltoobjectgrid.xml"));
Container container = server.createContainer(policy);
```

5. Remove and clean up a container server.
   You can remove and clean up a container server by using the running the teardown method on the obtained Container instance. Running the teardown method on a container properly cleans up the container and removes the container from the embedded server.

   The process of cleaning up the container includes the movement and tearing down of all the shards that are placed within that container. Each server can contain many containers and shards. Cleaning up a container does not affect the life cycle of the parent Server instance. The following example demonstrates how to run the teardown method on a server. The teardown method is made available through the ContainerMBean interface. By using the ContainerMBean interface, if you no longer have programmatic access to this container, you can still remove and clean up the container with its MBean. A terminate method also exists on the Container interface, do not use this method unless it is absolutely needed. This method is more forceful and does not coordinate appropriate shard movement and clean up.

```
container.teardown();
```

6. Stop the embedded server.
   When you stop an embedded server, you also stop any containers and shards that are running on the server. When you stop an embedded server, you must clean up all open connections and move or tear down all the shards. The following example demonstrates how to stop a server and using the waitFor method on the Server interface to ensure that the Server instance shuts down completely. Similarly to the container example, the stopServer method is made available through the ServerMBean interface. With this interface, you can stop a server with the corresponding Managed Bean (MBean).

```
ServerFactory.stopServer();  // Uses the factory to kill the Server singleton
 // or
server.stopServer(); // Uses the Server instance directly
server.waitFor(); // Returns when the server has properly completed its shutdown procedures
```

   Full code example:

```
 import java.net.MalformedURLException;
import java.net.URL;

import com.ibm.websphere.objectgrid.ObjectGridException;
import com.ibm.websphere.objectgrid.deployment.DeploymentPolicy;
import com.ibm.websphere.objectgrid.deployment.DeploymentPolicyFactory;
import com.ibm.websphere.objectgrid.server.Container;
import com.ibm.websphere.objectgrid.server.Server;
import com.ibm.websphere.objectgrid.server.ServerFactory;
import com.ibm.websphere.objectgrid.server.ServerProperties;

public class ServerFactoryTest {

    public static void main(String[] args) {

        try {

            ServerProperties props = ServerFactory.getServerProperties();
            props.setCatalogServiceBootstrap("catalogservice-hostname:catalogservice-port");
            props.setServerName("ServerOne"); // name server
            props.setTraceSpecification("com.ibm.ws.objectgrid=all=enabled"); // TraceSpec

            /*
             * In most cases, the server will serve as a container server only
             * and will connect to an external catalog service. This is a more
             * highly available way of doing things. The commented code excerpt
             * below will enable this Server to be a catalog service.
             *
             *
             * CatalogServerProperties catalogProps =
             * ServerFactory.getCatalogProperties();
             * catalogProps.setCatalogServer(true); // enable catalog service
             * catalogProps.setQuorum(true); // enable quorum
             */

            Server server = ServerFactory.getInstance();

            DeploymentPolicy policy = DeploymentPolicyFactory.createDeploymentPolicy
                                      (new URL("url to deployment xml"),  new URL("url to objectgrid xml file"));
            Container container = server.createContainer(policy);

            /*
             * Shard will now be placed on this container if the deployment requirements are met.
             * This encompasses embedded server and container creation.
             *
             * The lines below will simply demonstrate calling the cleanup methods
             */
```

```
            container.teardown();
            server.stopServer();
            int success = server.waitFor();

        } catch (ObjectGridException e) {
            // Container failed to initialize
        } catch (MalformedURLException e2) {
            // invalid url to xml file(s)
        }

    }

}
```

Embedded server API

WebSphere® eXtreme Scale includes application programming interfaces (APIs) and system programming interfaces for embedding eXtreme Scale servers and clients within your existing Java™ applications.

Instantiate the eXtreme Scale server

You can use several properties to configure the eXtreme Scale server instance, which you can retrieve from the ServerFactory.getServerProperties method. The ServerProperties object is a singleton, so each call to the getServerProperties method retrieves the same instance.

You can create a server with the following code.

```
Server server = ServerFactory.getInstance();
```

All properties set before the first invocation of the getInstance method are used to initialize the server.

Set server properties

You can set the server properties until the ServerFactory.getInstance method is called for the first time. The first call of the getInstance method instantiates the eXtreme Scale server, and reads all the configured properties. Setting the properties after creation has no effect. The following example shows how to set properties before instantiating a Server instance.

```
// Get the server properties associated with this process.
ServerProperties serverProperties = ServerFactory.getServerProperties();

// Set the server name for this process.
serverProperties.setServerName("EmbeddedServerA");

// Set the name of the zone this process is contained in.
serverProperties.setZoneName("EmbeddedZone1");

// Set the end point information required to bootstrap to the catalog service.
serverProperties.setCatalogServiceBootstrap("localhost:2809");

// Set the listener host name to use to bind to.
serverProperties.setListenerHost("host.local.domain");

// Set the listener port to use to bind to.
serverProperties.setListenerPort(9010);

// Turn off all MBeans for this process.
serverProperties.setMBeansEnabled(false);

Server server = ServerFactory.getInstance();
```

Embed the catalog service

Any JVM setting that is flagged by the CatalogServerProperties.setCatalogServer method can host the catalog service for eXtreme Scale. This method indicates to the eXtreme Scale server run time to instantiate the catalog service when the server is started. The following code shows how to instantiate the eXtreme Scale

catalog server:

```
CatalogServerProperties catalogServerProperties =
        ServerFactory.getCatalogProperties();
catalogServerProperties.setCatalogServer(true);

Server server = ServerFactory.getInstance();
```

Embed a container server

Run the Server.createContainer method for any JVM to host multiple eXtreme Scale container servers. The following code shows how to instantiate a container server:

```
Server server = ServerFactory.getInstance();
DeploymentPolicy policy = DeploymentPolicyFactory.createDeploymentPolicy(
    new File("META-INF/embeddedDeploymentPolicy.xml").toURI().toURL(),
    new File("META-INF/embeddedObjectGrid.xml").toURI().toURL());
Container container = server.createContainer(policy);
```

Self-contained server process

You can start all the services together, which is useful for development and also practical in production. By starting the services together, a single process does all of the following actions: starts the catalog service, starts a set of containers, and runs the client connection logic. Starting the services in this way sorts out programming issues before deploying in a distributed environment. The following code shows how to instantiate a self-contained eXtreme Scale server:

```
CatalogServerProperties catalogServerProperties =
        ServerFactory.getCatalogProperties();
catalogServerProperties.setCatalogServer(true);

Server server = ServerFactory.getInstance();
DeploymentPolicy policy = DeploymentPolicyFactory.createDeploymentPolicy(
    new File("META-INF/embeddedDeploymentPolicy.xml").toURI().toURL(),
    new File("META-INF/embeddedObjectGrid.xml").toURI().toURL());
Container container = server.createContainer(policy);
```

Embed eXtreme Scale in WebSphere Application Server

The configuration for eXtreme Scale is set up automatically when you install eXtreme Scale in a WebSphere Application Server environment. You are not required to set any properties before you access the server to create a container. The following code shows how to instantiate an eXtreme Scale server inWebSphere Application Server:

```
Server server = ServerFactory.getInstance();
DeploymentPolicy policy = DeploymentPolicyFactory.createDeploymentPolicy(
    new File("META-INF/embeddedDeploymentPolicy.xml").toURI().toURL(),
    new File("META-INF/embeddedObjectGrid.xml").toURI().toURL);
Container container = server.createContainer(policy);
```

For a step by step example on how to start an embedded catalog service and container programmatically, see Using the embedded server API to start and stop servers.

Administering with the xscmd utility

With the **xscmd** utility, you can complete administrative tasks in the environment such as: establishing multi-master replication links, overriding quorum, and stopping groups of servers with the teardown command.

Before you begin

- Your catalog servers and container servers must be started. If your catalog servers are in a catalog service domain, at least two catalog servers must be started.

- Verify that the *JAVA_HOME* environment variable is set to use the runtime environment that installed with the product. If you are using the trial version of the product, you must set the *JAVA_HOME* environment variable.

About this task

The **xscmd** utility replaces the **xsadmin** sample utility as a fully supported monitoring and administration tool. You could complete similar operations with the **xsadmin** tool, but this tool is not supported. The **xsadmin** sample provides a method for parsing and discovering current deployment data, and can be used as a foundation for writing custom utilities. If you were previously using the **xsadmin** tool for monitoring and administration, consider updating your scripts to use the **xscmd** utility. For information about mapping **xsadmin** commands to the new **xscmd** commands, see xsadmin tool to xscmd tool migration.

Procedure

1. Optional: If client authentication is enabled: Open a command-line window. On the command line, set appropriate environment variables.
2. Go to the *wxs_home*/bin directory.
   `cd wxs_home/bin`
3. Display help for the various **xscmd** options.
   - To display the general help, run the following command:
     - UNIX `./xscmd.sh -h`
     - Windows `xscmd.bat -h`
   - To display a list of all of the commands, run the following command:
     - UNIX `./xscmd.sh -lc`
     - Windows `xscmd.bat -lc`
   - To display the help for a specific command, run the following command:
     - UNIX `./xscmd.sh -h command_name`
     - Windows `xscmd.bat -h command_name`
   - To display a list of the command groups, run the following command:
     - UNIX `./xscmd.sh -lcg`
     - Windows `xscmd.bat -lcg`
   - To display a list of the commands within a command group, run the following command:
     - UNIX `./xscmd.sh -lc command_group_name`
     - Windows `xscmd.bat -lc command_group_name`
4. Run commands that connect to specific catalog servers. By default, **xscmd** connects to the catalog server on the local host, using the host name and port of `localhost:2809`. You can also provide a list of host names and ports to the command so that you can connect to catalog servers on other hosts. From the list, the **xscmd** utility connects to a random host. The list of hosts that you provide must be within the same catalog service domain.
   - Provide a list of stand-alone catalog servers to connect:
     - UNIX `./xscmd.sh -c <command_name> -cep hostname:port(,hostname:port)`
     - Windows `xscmd.bat -c <command_name> -cep hostname:port(,hostname:port)`

     In the previous commands, *command_name* is the name of the command that you are running. The *hostname:port* value is the catalog server host name and listener port. The listener port value on a stand-alone catalog server is specified when you run the **startOgServer** command.
   - Provide a list of WebSphere® Application Server catalog servers to connect. You cannot connect to catalog servers that are running on WebSphere Application Server with the default localhost value:
     - UNIX `./xscmd.sh -c <command_name> -cep was_hostname:port(,hostname:port)`
     - Windows `xscmd.bat -c <command_name> -cep was_hostname:port(,hostname:port)`

     In the previous commands, *command_name* is the name of the command that you are running. The *was_hostname* value is the host name of the catalog server in the WebSphere Application Server cell. The *port* value is the listener port. The listener port value in WebSphere Application Server is inherited by the BOOTSTRAP_ADDRESS port configuration. The default value is `9809` if the catalog server is running on the deployment manager. If you are running the catalog server on an application server, check the BOOTSTRAP_ADDRESS port configuration of the application server to determine the port number.
     Important: If your container servers are running in a secured WebSphere Application Server environment, run the **xscmd** utility from the WebSphere eXtreme Scale Client installation in the WebSphere Application Server environment. For example, from the /opt/IBM/WebSphere/AppServer/bin directory.

Controlling placement

You can use several different options to control when shards are placed on various container servers in the configuration. During startup, you might choose to delay the placement of shards. When you are running all of your container servers, you might need to suspend, resume, or change placement while you maintain servers.

Procedure

Controlling placement during startup

You can control when shards begin to be placed while your environment is starting. Some control is in place by default. If you do not take any actions to control placement, shards begin to be placed immediately. When shards are placed immediately, the shards might not be placed evenly as subsequent container servers start, and further placement operations run to balance the distribution.

- Temporarily suspend the balancing of shards to prevent immediate shard placement when your container servers are starting.
  Suspending the balancing of shards prevents uneven shard placement. Before you start your container servers, use the **xscmd -c suspendBalancing** command to stop the balancing of shards for a specific data grid and map set. After the container servers are started, you can use the **xscmd -c resumeBalancing** command to begin the placement of shards on the container servers.

- Suspend or resume placement and heartbeating. A placement bottleneck occurs when the catalog service runs through the balance algorithm on each container start. In this case, you can suspend placement, start all the containers, and then resume placement so that the balance algorithm is only run once after all the containers are started. You can also suspend heartbeating to prevent consistency issues when the high availability manager core group is formed. When many container servers are started at the same time, the catalog server sends out a new defined list of container servers to a high availability core group. At the same time, the container servers are also trying to create the current view of the high availability core group. Since there is a chance for inconsistencies in the catalog server's list of core group members versus the container's list of core group members, it is optimal to have the catalog process reports from the containers on core group health only after all the containers are started. The result is that there is a final defined set for each corresponding core group, and the containers can form a high availability manager view around those core groups. As such, there is benefit to ignoring high availability manager core group events when servers are started concurrently. WebSphere® eXtreme Scale provides an administrative option that is called suspend heartbeating, which ignores high availability manager core group events. When you suspend heartbeating, the catalog server ignores any failure detection reports from the high availability catalog service. You can also resume heartbeating, in which the default behavior returns and container failures are detected and reported by the high availability catalog service. When heartbeat is resumed, it also includes any containers that failed to start while heartbeating was suspended. Those failures are still detected and acted upon after heartbeating is resumed. For more information, see Tuning the heartbeat interval setting for failover detection.
  1. Use the **xscmd -c suspend** command to stop heartbeating and placement for a shard container or a domain.
     The following example illustrates how heartbeating and placement for a domain named `E13896FA-6141-4435-E000-000C2962AA71` is suspended using this command. The domain contains three data grids **myOG3**, **myOG2**, and **myOG1** and a mapset named **myMapSet**.

```
Console> xscmd -c suspend

[Tue Oct 22 2013 17:38:36] xscmd starting...
Starting at: 2013-10-22 17:38:38.012

CWXSI0068I: Executing command: suspend

Type      Suspendable Object Name Status Details
--------- ------------------ ---- ------ -------
heartbeat Domain name E13896FA-6141-4435-E000-000C2962AA71 Heartbeating was suspended.
placement Grid Name/Map Set Name myOG3/myMapSet Balancing was suspended.
placement Grid Name/Map Set Name myOG1/myMapSet Balancing was suspended.
placement Grid Name/Map Set Name myOG2/myMapSet Balancing was suspended.
```

```
CWXSI0040I: The suspend command completed successfully.
```

When heartbeating and placement is suspended, the following placement actions can still run:
- Shard promotion can occur when container servers fail.
- Shard role swapping with the **xscmd -c swapShardWithPrimary** command.
- Shard placement triggered balancing with the **xscmd -c triggerPlacement -g myOG -ms myMapSet** command, where *myOG* and *myMapSet* are set to values for your data grid and map set.

2. Start the container servers.
3. Use the **xscmd -c resume -t placement** command to resume placement. The following example illustrates how placement is resumed for the data grids **myOG3**, **myOG1**, and **myOG2** and the map set **myMapSet**.

```
Console> xscmd -c resume -t placement

[Tue Oct 22 2013 17:40:28] xscmd starting...
Starting at: 2013-10-22 17:40:29.509

CWXSI0068I: Executing command: resume

Type Suspendable Object Name Status Details
---- ------------------ ---- ------ -------
placement Grid Name/Map Set Name myOG3/myMapSet Balancing has resumed.
placement Grid Name/Map Set Name myOG1/myMapSet Balancing has resumed.
placement Grid Name/Map Set Name myOG2/myMapSet Balancing has resumed.

CWXSI0040I: The resume command completed successfully.
Ending at: 2013-10-22 17:40:34.371
```

Important: After placement is resumed, use the **xscmd -c showPlacement** command until all partitions show up as placed.

4. Optional: Use the **xscmd -c balanceShardTypes** command to adjust the ratio of primary and replica shards to be equitable among the running container servers in the configuration. The ratio is consistent within one shard on each container server.
5. Use the **xscmd -c resume -t heartbeat** command to resume heartbeating after placement has finished. The following example illustrates how heartbeating is resumed for the domain `E13896FA-6141-4435-E000-000C2962AA71`.

```
Console> xscmd -c resume -t heartbeat

[Tue Oct 22 2013 17:42:59] xscmd starting...
Starting at: 2013-10-22 17:42:59.872

CWXSI0068I: Executing command: resume

Type Suspendable Object Name Status Details
---- ------------------ ---- ------ -------
heartbeat Domain name E13896FA-6141-4435-E000-000C2962AA71 Balancing has resumed.

CWXSI0040I: The resume command completed successfully.
Ending at: 2013-10-22 17:43:04.549
```

- Configure the placementDeferralInterval property to minimize the number of shard placement cycles on the container servers. Shard placement is triggered at the defined time interval.

  placementDeferralInterval
  : Specifies the interval in milliseconds for deferring the balancing and placement of shards on the container servers. Placement does not start until after the time specified in the property has passed. Increasing the deferral interval lowers processor utilization, but the placement of work items is completed over time. A decrease in the deferral interval increases short-term processor usage, but the placement of work items is more immediate and expedited.
    If multiple container servers are starting in succession, the deferral interval timer is reset if a new container server starts within the given interval. For example, if a second container server starts 10 seconds after the first container server, placement does not start until 15 seconds after the second container server started. However, if a third container server starts 20 seconds after the second container server, placement has already begun on the first two container servers.

    When container servers become unavailable, placement is triggered as soon as the catalog server learns of the event so that recovery can occur as quickly as possible.

    Default: 15000 ms (15 seconds)

  You can use the following tips to help determine if your placement deferral value is set to the right amount of time:
  - As you concurrently start the container servers, look at the CWOBJ1001 messages in the SystemOut.log file for each container server. The timestamp of these messages in each container server log file indicates the actual container server start time. You might consider adjusting the placementDeferralInterval property to include more container server starts. For example, if the first container server starts 90 seconds before the last container server, you might set the property to 90 seconds.
  - Note how long the CWOBJ1511 messages occur after the CWOBJ1001 messages. This amount of time can indicate if the deferral has occurred successfully.
  - If you are using a development environment, consider the length of the interval when you are testing your application.
- Configure the numInitialContainers attribute.
  If you previously used the numInitialContainers attribute, you can continue using the attribute. However, the use of the **xscmd -c suspendBalancing** and **xscmd -c resumeBalancing** commands followed by the placementDeferralInterval are suggested over the numInitialContainers attribute to control placement. The numInitialContainers attribute specifies the number of container servers that are required before initial placement occurs for the shards in this mapSet element. The numInitialContainers attribute is in the deployment policy descriptor XML file. If you have both numInitialContainers and placementDeferralInterval set, note that until the numInitialContainers value has been met, no placement occurs, regardless of the value of the placementDeferralInterval property.

Controlling placement after initial startup

- Force placement to occur.
  You can use the **xscmd -c triggerPlacement -g myOG -ms myMapSet** command, where *myOG* and *myMapSet* are set to values for your data grid and map set, to force placement to occur during a point in time at which placement might not occur otherwise. For example, you might run this command when the amount of time specified by the placementDeferralInterval property has not yet passed or when balancing is suspended.
- Reassign a primary shard.
  Use the **xscmd -c swapShardWithPrimary** command to assign a replica shard to be the new primary shard. The previous primary shard becomes a replica.
- Rebalance the primary and replica shards.
  Use the **xscmd -c balanceShardTypes** command to adjust the ratio of primary and replica shards to be equitable among the running container servers in the configuration. The ratio is consistent within one shard on each container server.
- Suspend or resume placement.
  Use the **xscmd -c suspendBalancing** command or the **xscmd -c resumeBalancing** command to stop and start the balancing of shards for a specific data grid and map set. When balancing has been suspended, the following placement actions can still run:
  - Shard promotion can occur when container servers fail.
  - Shard role swapping with the **xscmd -c swapShardWithPrimary** command.
  - Shard placement triggered balancing with the **xscmd -c triggerPlacement -g myOG -ms myMapSet** command, where *myOG* and *myMapSet* are set to values for your data grid and map set.

What to do next

You can monitor the placement in the environment with the **xscmd -c placementServiceStatus** command.

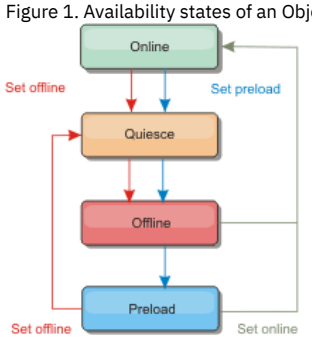
Managing ObjectGrid availability

The availability state of an ObjectGrid instance determines which requests can be processed at any particular time. You can use the StateManager interface to set and retrieve the state of an ObjectGrid instance.

About this task

Four availability states exist for a given ObjectGrid instance.

Figure 1. Availability states of an ObjectGrid instance



ONLINE
: The ONLINE state is the default availability state for an ObjectGrid. An ONLINE ObjectGrid is able to process any requests from a typical eXtreme Scale client. However, requests from a preload client are rejected while the ObjectGrid is ONLINE.

QUIESCE
: The QUIESCE state is transitional. An ObjectGrid that is in QUIESCE is soon moved to the OFFLINE state. While in the QUIESCE state, an ObjectGrid is allowed to process outstanding transactions. However, any new transactions are rejected. An ObjectGrid can remain in QUIESCE for up to 30 seconds. After this time, the availability state is moved to OFFLINE.

OFFLINE
: The OFFLINE state results in the rejection of all transactions that are sent to the ObjectGrid.

PRELOAD
: The PRELOAD state can be used to load data into an ObjectGrid from a preload client. While the ObjectGrid is in the PRELOAD state, only a preload client can commit transactions against the ObjectGrid. All other transactions are rejected.

A request is rejected if an ObjectGrid is not in the appropriate availability state to support that request. An AvailabilityException exception results whenever a request is rejected.

Procedure

1. Set the initial state of an ObjectGrid with the ObjectGrid configuration XML file.
   You can use the initialState attribute on an ObjectGrid to indicate its startup state. Normally, when an ObjectGrid completes initialization, it is available for routing. The state can later be changed to prevent traffic from routing to an ObjectGrid. If the ObjectGrid needs to be initialized, but not immediately available, you can use the initialState attribute.

   The initialState attribute is set on the ObjectGrid configuration XML file. The default state is ONLINE. Valid values include:
   - ONLINE (default)
   - PRELOAD
   - OFFLINE

   See ObjectGrid descriptor XML file for more information about the initialState attribute.
   If the initialState attribute is set on an ObjectGrid, the state must be explicitly set back to online or the ObjectGrid will remain unavailable. An AvailabilityException exception results if the ObjectGrid is not in the ONLINE state.

   See AvailabilityState API documentation for more information.

   Using the initialState attribute for preloading

   If the ObjectGrid is preloaded with data, there can be a period of time between when the ObjectGrid is available and switching to a preload state to block client traffic. To avoid this time period, the initial state on an ObjectGrid can be set to PRELOAD. The ObjectGrid still completes all the necessary initialization, but it blocks traffic until the state has changed and allows the preload to occur.

   The PRELOAD and OFFLINE states both block traffic, but you must use the PRELOAD state if you want to initiate a preload.

   Failover and balancing behavior

   If a replica data grid is promoted to be a primary data grid, the replica does not use the initialState setting. If the primary data grid is moved for a rebalance, the initialState setting is not used because the data is copied to the new primary location before the move is completed. If replication is not configured, then the primary goes into the initialState setting if failover occurs, and a new primary must be placed.

2. Change the availability state with the StateManager interface.
   Use the StateManager interface to set the availability state of an ObjectGrid. To set the availability state of an ObjectGrid running on the servers, pass a corresponding ObjectGrid client to the StateManager interface. The following code demonstrates how to change the availability state of an ObjectGrid.

   ```
   ClientClusterContext client = ogManager.connect("localhost:2809", null, null);
   ObjectGrid myObjectGrid = ogManager.getObjectGrid(client, "myObjectGrid");
   StateManager stateManager = StateManagerFactory.getStateManager();
   stateManager.setObjectGridState(AvailabilityState.OFFLINE, myObjectGrid);
   ```

   Each shard of the ObjectGrid transitions to the desired state when the setObjectGridState method is called on the StateManager interface. When the method returns, all shards within the ObjectGrid should be in the proper state.
   Use an ObjectGridEventListener plug-in to change the availability state of a server side ObjectGrid. Only change the availability state of a server-side ObjectGrid when the ObjectGrid has a single partition. If the ObjectGrid has multiple partitions, the shardActivated method is called on each primary, which results in superfluous calls to change the state of the ObjectGrid

   ```
   public class OGListener implements ObjectGridEventListener,
                           ObjectGridEventGroup.ShardEvents {
       public void shardActivated(ObjectGrid grid) {
               StateManager stateManager = StateManagerFactory.getStateManager();
               stateManager.setObjectGridState(AvailabilityState.PRELOAD, grid);
       }
   }
   ```

   Because QUIESCE is a transitional state, you cannot use the StateManager interface to put an ObjectGrid into the QUIESCE state. An ObjectGrid passes through this state on its way to the OFFLINE state.

3. Retrieve the availability state.
   Use the getObjectGridState method of the StateManager interface to retrieve the availability state of a particular ObjectGrid.

   ```
   StateManager stateManager = StateManagerFactory.getStateManager();
   AvailabilityState state = stateManager.getObjectGridState(inventoryGrid);
   ```

   The getObjectGridState method chooses a random primary within the ObjectGrid and returns its AvailabilityState. Because all shards of an ObjectGrid should be in the same availability state or transitioning to the same availability state, this method provides an acceptable result for the current availability state of the ObjectGrid.

Managing data center failures when quorum is enabled

When the data center enters a failure scenario, consider overriding quorum so that the container server life cycle events are not ignored based on your analysis of the failure scenario. You can use the **xscmd** utility to query about and run quorum tasks, such as the quorum status and overriding quorum.

Before you begin

- Configure the quorum mechanism to be the same setting in all of your catalog servers. See Configuring the quorum mechanism for more information.
- Quorum is the minimum number of catalog servers that are necessary to conduct placement operations for the data grid and is the full set of catalog servers, unless you configure a lower number. WebSphere® eXtreme Scale expects to lose quorum for the following reasons:
  - Catalog service JVM member fails
  - Network brown out
  - Data center loss
  - Garbage collection
  - Disk I/O
  - Severe swapping

  The following message indicates that quorum has been lost. Look for this message in your catalog service logs.

  ```
  CWOBJ1254W: The catalog service is waiting for quorum.
  ```

About this task

Override quorum in a data center failure scenario only. When you override quorum, any surviving catalog server instance can be used. All survivors are notified when one is told to override quorum.
To resolve these communication issues, you search the logs for your catalog servers for certain messages to determine and fix the problem. You also must look at your environment to determine if any existing issues need to be resolved. To find the message in the logs, you can either search the SystemOut*.log files for each catalog server, or you can use the message center to filter the logs for all the connected catalog servers.

Procedure

1. Query quorum status with the **xscmd** utility.

   ```
   xscmd -c showQuorumStatus -cep cathost:2809
   ```

   Use this option to display the quorum status of a catalog service instance. The command displays the current quorum status of each catalog server. The quorum column displays one of the following outcomes:
   - `TRUE`: The server has quorum enabled and the system is working normally. Quorum is met.
   - `FALSE`: The server has quorum enabled, but quorum is lost. The catalog servers do not allow changes to the catalog service domain.
   - `UNAVAILABLE`: The server cannot be contacted. It is either not running or there is a network problem and the server cannot be reached.
   - `DISABLED`: The server does not have quorum enabled.
2. Remove catalog servers that are having heartbeating failures.
   a. Examine the log files for each catalog server. If you see the following message in multiple catalog server logs, multiple catalog servers have declared themselves as the primary catalog server.

      ```
      CWOBJ8106I: The master catalog service cluster activated with cluster {0}
      ```

   b. Declare one primary catalog server by manually ending the processes for the other catalog servers.
      Manually stop the processes that are associated with the primary catalog servers that you have chosen not to use. End the processes with the command that is appropriate for your operating system, with a command such as the `kill` command.

   c. On the servers where you stopped catalog server processes, resolve any garbage collection, operating system, hardware, or networking issues. Garbage collection information is in the file where the JVM stores the garbage collection information.
3. Override quorum with the **xscmd** utility.

   ```
   xscmd -c overrideQuorum -cep hostname:port
   ```

   Running this command forces the surviving catalog servers to re-establish a quorum.
4. Run the **xscmd -c triggerPlacement** command. Running this command initiates failure recovery so that the remaining system can service requests.
5. Validate that recovery was successful.
   a. Run the **xscmd -c showPlacement** command every 15 seconds for a minute. Confirm placement is stable and that no changes are occurring.
   b. Run the **xscmd -c routetable** command. This command displays the current route table by simulating a new client connection to the data grid. It also validates the route table by confirming that all container servers are recognizing their role in the route table, such as which type of shard for which partition.

      ```
      xscmd -c routetable -cep hostname:port -g myGrid
      ```

   c. Run the **xscmd -c showMapSizes** command to track that data is flowing to the data grid as expected. Verify that key distribution is uniform over the shards in the key. If some container servers have more keys than others, then it is likely the hash function on the key objects has a poor distribution.

      ```
      xscmd -c showMapSizes -cep hostname:port -g myGrid -ms myMapSet
      ```

   d. Run the **xscmd -c revisions** command. If any revisions come back in the list, the primary and replica pairs are not completely replicated. Depending on your load, incomplete replication is okay. However, if you see a difference between the revision numbers of a primary and replica growing over time, then replication might not be working or is struggling to keep up with your load. Run this command multiple times to watch for trends.
   e. Run the **xscmd -c listCoreGroups** command to display a list of all the core groups for the catalog server.

```
xscmd -c listCoreGroups -cep hostname:port
```

Querying and invalidating data

8.5+ You can use the query interfaces in the monitoring console and in the **xscmd** utility to retrieve small sets of keys from a map and invalidate sets of data.

Before you begin

- If you are using the web console to query and invalidate data, configure the monitoring console first. For more information, see Monitoring with the web console.
- If you are using **xscmd** to query and invalidate data, set up the **xscmd** utility. For more information, see Administering with the xscmd utility.

About this task

You can use the console or the **xscmd** utility to query data grid contents. You can query the data by running a regular expression on the data key. You can then use the same query to invalidate data. For examples of regular expressions, see Regular expression syntax.

Procedure

- Query or invalidate data with the console.
  1. Go to the query page in the console. In the web console, click Management > Query Data Grid Contents. Choose the map on which you want to filter.
  2. Search or filter the data in the map. You can use one of the following options to search or filter the data:
     - Type a regular expression in the field and click the Search button (). A list of keys that match the regular expression displays. The list of data could be a subset of all of the matching data.
     - To filter the results on a set of partitions, click the Filter button (). You can then type a regular expression and choose a range of partitions on which you want to filter the results.
  3. Invalidate data. When you invalidate the data, the data is permanently removed from the data grid.

     Selected keys
     : You can select keys from the table to invalidate. You can either click entries individually or click the select all check box, which selects a maximum of 500 entries that are in the table. When you have the entries selected that you want to remove, click Invalidate > Selected keys.

     All keys matching query
     : You can also invalidate all the data that matches your regular expression. Using this option deletes all data in the data grid that matches the regular expression, not just the maximum of 500 entries that is displayed in the console. To invalidate entries with the selected regular expression, click Invalidate > All keys matching query.

- Query or invalidate data with the **xscmd** utility.

  Query data:

  ```
  xscmd.sh -c findbykey -g <data_grid> -m <map>
  -fs <find_string> [-fp <partitionid>]
  ```

  You must include the data grid, map, and regular expression for the find string value. You can also filter on the partition ID. The result returns a subset of the entire query.

  Invalidate data:
  : Include the -inv argument in the command to invalidate the data that is selected by the query.

  ```
  xscmd -c findbykey -g <data_grid> -m <map>
  -fs <find_string> [-fp <partitionid>] -inv
  ```

  You must include the data grid, map, and regular expression for the find string value. You can also filter on the partition ID. When you run the invalidation, all matching values are invalidated, not just the small set that is returned by the query.

UNIX Linux Important: If your regular expression starts with the characters `.*`, the characters might not process correctly when you run the command. To resolve this issue, format your regular expression in one of the following ways:
- Enclose your regular expression with apostrophe characters: `-fs '.*'`
- Use a backslash to escape the asterisk character: `-fs .\*`

Example:
The following example looks for all entries in the `Grid` data grid and `Map1` map.

```
xscmd -c findbykey -g Grid -m Map1 -fs ".*"
```

The command returns the following results:

```
3 matching keys were found.

Partition Key
--------- ---
2         keyghi
4         keydef
6         keyabc
```

Retrieving eXtreme Scale environment information with the xscmd utility

8.5+ You can use the **xscmd** utility with the -c showinfo command to view important details about the servers running in your WebSphere® eXtreme Scale environment, including: WebSphere eXtreme Scale servers, Java™ virtual machines, and (if applicable) servers running with WebSphere Application Server. Issue this command to retrieve name and version information, hostname and IP address, and the installation directories of these servers. Using -c showinfo command lets you retrieve these details without having to check log files, directories, or use third party applications.

Procedure

- Ensure that at least one of your catalog servers is running. If you want to retrieve environment details for your entire eXtreme Scale domain, then ensure that all of your servers are running.
  To retrieve environment information for your entire eXtreme Scale domain, issue: Windows

  ```
  xscmd.bat -c showinfo
  ```

  UNIX

  ```
  ./xscmd.sh -c showinfo
  ```

  The command returns all information about the servers running in your environment.
- To retrieve information about a specific server, use the -s parameter and specify the name of the server.
  Windows

  ```
  xscmd.bat -c showinfo -s <server_name>
  ```

  UNIX

  ```
  ./xscmd.sh -c showinfo -s <server_name>
  ```

- To view a list of servers, use the -sl parameter.
  Windows

  ```
  xscmd.bat -c showinfo -sl  <server_name>[,<server_name>]
  ```

  UNIX

  ```
  ./xscmd.sh -c showinfo -sl  <server_name>[,<server_name>]
  ```

- To retrieve environment information for a specific set of servers running on a particular host, use the -hf parameter and provide the name of the host.
  Windows

  ```
  xscmd.bat -c showinfo -hf <host_name>
  ```

  UNIX

  ```
  ./xscmd.sh -c showinfo -hf <host_name>
  ```

Starting eXtreme Scale servers using the Eclipse Equinox OSGi framework

WebSphere® eXtreme Scale container servers can be started in an Eclipse Equinox OSGi framework using several methods.

Before you begin

Before you can start an eXtreme Scale container, you must have completed the following tasks:

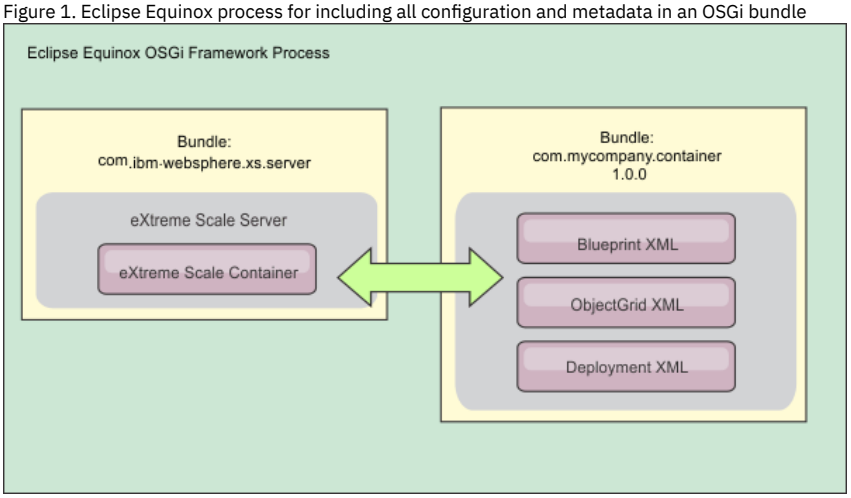
1. The WebSphere eXtreme Scale server bundle must be installed into Eclipse Equinox.
2. Your application must be packaged as an OSGi bundle.
3. Your WebSphere eXtreme Scale plug-ins (if any) must be packaged as an OSGi bundle. They can be bundled in the same bundle as your application or as separate bundles.
4. If your container servers are using IBM® eXtremeMemory, you must first configure the native libraries. For more information, see Configuring IBM eXtremeMemory.

About this task

This task describes how to start an eXtreme Scale container server in an Eclipse Equinox OSGi framework. You can use any of the following methods to start container servers using the Eclipse Equinox implementation:

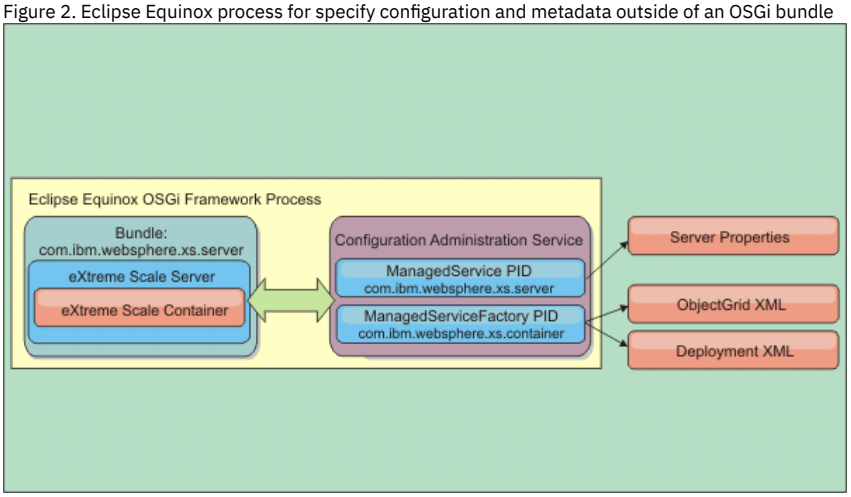
- OSGi Blueprint service
  You can include all configuration and metadata in an OSGi bundle. See the following image to understand the Eclipse Equinox process for this method:

  Figure 1. Eclipse Equinox process for including all configuration and metadata in an OSGi bundle

- OSGi Configuration Admin service
  You can specify configuration and metadata outside of an OSGi bundle. See the following image to understand the Eclipse Equinox process for this method:

  Figure 2. Eclipse Equinox process for specify configuration and metadata outside of an OSGi bundle

- Programmatically
  Supports customized configuration solutions.

In each case, an eXtreme Scale server singleton is configured and one or more containers are configured.

The eXtreme Scale server bundle, objectgrid.jar, includes all of the required libraries to start and run an eXtreme Scale grid container in an OSGi framework. The server runtime environment communicates with user-supplied plug-ins and data objects using the OSGi service manager.

Important: After an eXtreme Scale server bundle is started and the eXtreme Scale server is initialized, it cannot be restarted . The Eclipse Equinox process must be restarted to restart an eXtreme Scale server.
You can use eXtreme Scale support for Spring namespace to configure eXtreme Scale container servers in a Blueprint XML file. When the server and container XML elements are added to the Blueprint XML file, the eXtreme Scale namespace handler automatically starts a container server using the parameters that are defined in the Blueprint XML file when the bundle is started. The handle stops the container when the bundle is stopped.

To configure eXtreme Scale container servers with Blueprint XML, complete the following steps:

Procedure

- Start an eXtreme Scale container server using OSGi blueprint.
  1. Create a container bundle.
  2. Install the container bundle into the Eclipse Equinox OSGi framework. See Installing and starting OSGi-enabled plug-ins.
  3. Start the container bundle.
- Start an eXtreme Scale container server using OSGi configuration admin.
  1. Configure the server and container using config admin.
  2. When the eXtreme Scale server bundle is started, or the persistent identifiers are created with config admin, the server and container automatically start.
- Start an eXtreme Scale container server using the ServerFactory API. See the server API documentation.
  1. Create an OSGi bundle activator class, and use the eXtreme Scale ServerFactory API to start a server.

Related tasks:
Running eXtreme Scale containers with non-dynamic plug-ins in an OSGi environment

Installing and starting OSGi-enabled plug-ins

In this task, you install the dynamic plug-in bundle into the OSGi framework. Then, you start the plug-in.

Before you begin

Complete the following tasks before the OSGi-enabled plug-ins are installed and started.

- The eXtreme Scale server or client bundle is installed into the Eclipse Equinox OSGi framework. See Installing eXtreme Scale bundles.
- One or more dynamic BackingMap or ObjectGrid plug-ins are implemented. See Building eXtreme Scale dynamic plug-ins.
- The dynamic plug-ins are packaged as OSGi services in OSGi bundles.
- By default, the JVM continues to run when each eXtreme Scale server in an OSGi framework is stopped in the **xscmd** utility with the **-c teardown** command. If you want eXtreme Scale to exit the JVM after each server is stopped, then set the server property exitJVMOnTeardown to `true`. For more information, see Server properties file.

About this task

Install the bundle with the Eclipse Equinox console. There are several different methods to install the bundle, including a modification of the config.ini configuration file. Products that embed Eclipse Equinox include alternative methods for adding bundles in the config.ini file. For more information, seeEclipse runtime options.

OSGi allows bundles to be started that have duplicate services. WebSphere eXtreme Scale uses the latest service ranking. When multiple OSGi frameworks are started in an eXtreme Scale data grid, you must make sure that the correct service rankings are started on each server. Failure to do so causes the grid to be started with a mixture of different versions.

To see which versions are in-use by the data grid, use the **xscmd** utility to check the current and available rankings. For more information, see Updating OSGi services for eXtreme Scale plug-ins with xscmd.

Procedure

Install the plug-in bundle into the Eclipse Equinox OSGi framework with the OSGi console.

1. Start the Eclipse Equinox framework with the console enabled.

   ```
   <java_home>/bin/java -jar <equinox_root>/plugins/org.eclipse.osgi_3.6.1.R36x_v20100806.jar -console
   ```

2. Install the plug-in bundle in the Equinox console.

   ```
   osgi> install file:///<path to bundle>
   ```

   Equinox lists the bundle ID for the newly installed bundle:

   ```
   Bundle id is 17
   ```

3. Enter the following line to start the bundle in the Equinox console, where `<id>` is the bundle ID assigned when the bundle was installed:

   ```
   osgi>  start <id>
   ```

4. Retrieve the service status in the Equinox console to verify that the bundle started:

   ```
   osgi> ss
   ```

When the bundle starts, the bundle lists the ACTIVE state, for example:

```
17      ACTIVE      com.mycompany.plugin.bundle_VRM
```

Install the plug-in bundle into the Eclipse Equinox OSGi framework with the config.ini file.

5. Copy the plug-in bundle into the Eclipse Equinox plug-ins directory: For example:

   ```
   <equinox_root>/plugins
   ```

6. Edit the Eclipse Equinox config.ini configuration file, and add the bundle to the osgi.bundles property. For example:

   ```
   osgi.bundles=\
   org.eclipse.osgi.services_3.2.100.v20100503.jar@1:start, \
   org.eclipse.osgi.util_3.2.100.v20100503.jar@1:start, \
   org.eclipse.equinox.cm_1.0.200.v20100520.jar@1:start, \
   com.mycompany.plugin.bundle_VRM.jar@1:start
   ```

   Important: Verify that there is a blank line after the last bundle name. Each bundle is separated by a comma.
7. Start the Eclipse Equinox framework with the console enabled. For example:

   ```
   <java_home>/bin/java -jar <equinox_root>/plugins/org.eclipse.osgi_3.6.1.R36x_v20100806.jar -console
   ```

8. Retrieve the service status in the Equinox console to verify that the bundle started. For example:

   ```
   osgi> ss
   ```

   When the bundle starts, the bundle lists the ACTIVE state; for example:

   ```
   17      ACTIVE      com.mycompany.plugin.bundle_VRM
   ```

Results

The plug-in bundle is now installed and started. The eXtreme Scale container or client can now be started. For more information on developing eXtreme Scale plug-ins, see the System APIs and Plug-ins topic.

Administering OSGi-enabled services using the xscmd utility

You can use the **xscmd** utility to complete administrator tasks, such as viewing services and their rankings that are being used by each container, and updating the runtime environment to use new versions of the bundles.

About this task

With the Eclipse Equinox OSGi framework, you can install multiple versions of the same bundle, and you can update those bundles during run time. WebSphere® eXtreme Scale is a distributed environment that runs the container servers in many OSGi framework instances.
Administrators are responsible for manually copying, installing, and starting bundles into the OSGi framework. eXtreme Scale includes an OSGi ServiceTrackerCustomizer to track any services that have been identified as eXtreme Scale plug-ins in the ObjectGrid descriptor XML file. Use the **xscmd** utility to validate which version of the plug-in is used, which versions are available to be used, and to perform bundle upgrades.

eXtreme Scale uses the service ranking number to identify the version of each service. When two or more services are loaded with the same reference, eXtreme Scale automatically uses the service with the highest ranking.

Procedure

- Run the **osgiCurrent** command, and verify that each eXtreme Scale server is using the correct plug-in service ranking.
  Since eXtreme Scale automatically chooses the service reference with the highest ranking, it is possible that the data grid may start with multiple rankings of a plug-in service.

  If the command detects a mismatch of rankings or if it is unable to find a service, a non-zero error level is set. If the command completed successfully then the error level is set to 0.

  The following example shows the output of the **osgiCurrent** command when two plug-ins are installed in the same grid on four servers. The loaderPlugin plug-in is using ranking 1, and the txCallbackPlugin is using ranking 2.

  ```
  OSGi Service Name Current Ranking ObjectGrid Name MapSet Name Server Name
  ----------------- --------------- --------------- ----------- -----------
  loaderPlugin      1               MyGrid          MapSetA     server1
  loaderPlugin      1               MyGrid          MapSetA     server2
  loaderPlugin      1               MyGrid          MapSetA     server3
  loaderPlugin      1               MyGrid          MapSetA     server4
  txCallbackPlugin  2               MyGrid          MapSetA     server1
  txCallbackPlugin  2               MyGrid          MapSetA     server2
  txCallbackPlugin  2               MyGrid          MapSetA     server3
  txCallbackPlugin  2               MyGrid          MapSetA     server4
  ```

  The following example shows the output of the **osgiCurrent** command when server2 was started with a newer ranking of the loaderPlugin:

  ```
  OSGi Service Name Current Ranking ObjectGrid Name MapSet Name Server Name
  ----------------- --------------- --------------- ----------- -----------
  ```

```
loaderPlugin      1              MyGrid          MapSetA     server1
loaderPlugin      2              MyGrid          MapSetA     server2
loaderPlugin      1              MyGrid          MapSetA     server3
loaderPlugin      1              MyGrid          MapSetA     server4
txCallbackPlugin  2              MyGrid          MapSetA     server1
txCallbackPlugin  2              MyGrid          MapSetA     server2
txCallbackPlugin  2              MyGrid          MapSetA     server3
txCallbackPlugin  2              MyGrid          MapSetA     server4
```

- Run the **osgiAll** command to verify that the plug-in services have been correctly started on each eXtreme Scale container server.
When bundles start that contain services that an ObjectGrid configuration is referencing, the eXtreme Scale runtime environment automatically tracks the plug-in, but does not immediately use it. The **osgiAll** command shows which plug-ins are available for each server.

  When run without any parameters, all services are shown for all grids and servers. Additional filters, including the **-serviceName** `<service_name>` filter can be specified to limit the output to a single service or a subset of the data grid.

  The following example shows the output of the **osgiAll** command when two plug-ins are started on two servers. The loaderPlugin has both rankings 1 and 2 started and the txCallbackPlugin has ranking 1 started. The summary message at the end of the output confirms that both servers see the same service rankings:

```
Server: server1
   OSGi Service Name   Available Rankings
   -----------------   ------------------
   loaderPlugin        1, 2
   txCallbackPlugin    1

Server: server2
   OSGi Service Name   Available Rankings
   -----------------   ------------------
   loaderPlugin        1, 2
   txCallbackPlugin    1

Summary - All servers have the same service rankings.
```

  The following example shows the output of the **osgiAll** command when the bundle that includes the loaderPlugin with ranking 1 is stopped on server1. The summary message at the bottom of the output confirms that server1 is now missing the loaderPlugin with ranking 1:

```
Server: server1
   OSGi Service Name   Available Rankings
   -----------------   ------------------
   loaderPlugin        2
   txCallbackPlugin    1

Server: server2
   OSGi Service Name   Available Rankings
   -----------------   ------------------
   loaderPlugin        1, 2
   txCallbackPlugin    1

Summary - The following servers are missing service rankings:
   Server  OSGi Service Name Missing Rankings
   ------  ----------------- -----------------
   server1 loaderPlugin      1
```

  The following example shows the output if the service name is specified with the **-sn** argument, but the service does not exist:

```
Server: server2
   OSGi Service Name Available Rankings
   ----------------- ------------------
   invalidPlugin     No service found

Server: server1
   OSGi Service Name Available Rankings
   ----------------- ------------------
   invalidPlugin     No service found

Summary - All servers have the same service rankings.
```

- Run the **osgiCheck** command to check sets of plug-in services and rankings to see if they are available.
The **osgiCheck** command accepts one or more sets of service rankings in the form: `-serviceRankings <service name>;<ranking>[, <serviceName>;<ranking>]`

  When the rankings are all available, the method returns with an error level of 0. If one or more rankings are not available, a non-zero error level is set. A table of all of the servers that do not include the specified service rankings is displayed. Additional filters can be used to limit the service check to a subset of the available servers in the eXtreme Scale domain.

  For example, if the specified ranking or service is absent, the following message is displayed:

```
Server  OSGi Service Unavailable Rankings
------  ------------ --------------------
server1 loaderPlugin 3
server2 loaderPlugin 3
```

- Run the **osgiUpdate** command to update the ranking of one or more plug-ins for all servers in a single ObjectGrid and MapSet in a single operation.
The command accepts one or more sets of service rankings in the form: `-serviceRankings <service name>;<ranking>[,<serviceName>; <ranking>] -g <grid name> -ms <mapset name>`

  With this command, you can complete the following operations:

- Verify that the specified services are available for updating on each of the servers.
- Change the state of the grid to offline using the StateManager interface. See Managing ObjectGrid availability for more information. This process quiesces the grid and waits until any running transactions have completed and prevents any new transactions from starting. This process also signals any ObjectGridLifecycleListener and BackingMapLifecycleListener plug-ins to discontinue any transactional activity. See Plug-ins for providing event listeners for information about event listener plug-ins.
- Update each eXtreme Scale container running in an OSGi framework to use the new service versions.
- Changes the state of the grid to online, allowing transactions to continue.

The update process is idempotent so that if a client fails to complete any one task, it results in the operation being rolled back. If a client is unable to perform the rollback or is interrupted during the update process, the same command can be issued again, and it continues at the appropriate step.

If the client is unable to continue, and the process is restarted from another client, use the -force option to allow the client to perform the update. The **osgiUpdate** command prevents multiple clients from updating the same map set concurrently. For more details about the **osgiUpdate** command, see Updating OSGi services for eXtreme Scale plug-ins with xscmd.

- Updating OSGi services for eXtreme Scale plug-ins with xscmd
  WebSphere eXtreme Scale supports upgrading container server plug-in bundles while the grid is active. This support allows administrators to complete application updates and additions without needing to restart grid processes.

Updating OSGi services for eXtreme Scale plug-ins with xscmd

WebSphere® eXtreme Scale supports upgrading container server plug-in bundles while the grid is active. This support allows administrators to complete application updates and additions without needing to restart grid processes.

Before you begin

Complete the following steps before you update eXtreme Scale OSGi bundles to a new version:

1. Start eXtreme Scale servers in a supported OSGi framework.
2. Separate all eXtreme Scale plug-ins into bundles, and they must use service rankings to identify each version of the plug-ins.
3. Specify cache objects as either Java™ primitive types such as `byte[]`, Integer or String, or they must be stored using a MapSerializerPlugin plug-in The data objects are stored in the eXtreme Scale bundle and are not upgraded. Only the plug-ins that interact with the data are updated.
4. Design cache object data to be version compatible. New plug-ins must be able to interact with data created by older plug-ins.
5. Design plug-ins to listen for ObjectGridLifecycle and BackingMapLifecycle events to refresh any references to other plug-ins or the metadata that the plug-ins might have so that they can be refreshed when it is updated.
6. The eXtreme Scale OSGi update process only affects servers. You must independently update any clients that are using plug-ins.

About this task

Without OSGi enablement, if an administrator needs to update the application plug-ins or cache objects, each grid node must be upgraded one-by-one, causing stress on the network, memory and cpu utilization. This is required since plug-ins and cache Java objects are directly stored in the grid. When classes are updated without restarting the processes, the grid plug-ins have conflicts because each class has a different ClassLoader.

The eXtreme Scale product includes the xscmd utility and MBeans that allows administrators to view all the plug-in bundles installed in each grid container's hosting OSGi framework and choose which revision to use. When the xscmd is used to update the plug-ins to a new ranking, the grid is quiesced and all transactions are drained, the plug-ins are updated, and the grid is activated again. If an error occurs during the update process, the process is rolled-back and the old ranking is restored.

Procedure

1. Create a version of the bundle, increasing the version number in the bundle manifest, and increasing the ranking for each eXtreme Scale plug-in service. If the original bundle version is `Bundle-Version: 1.0.0`, then the next version can be defined as `Bundle-Version: 1.1.0`.
   If the original service ranking is `ranking="1"`, then the next ranking can be defined as `ranking="2"`.

   Important: OSGi service rankings must be integers.
2. Copy the new bundle to each OSGi framework node that is hosting an eXtreme Scale container server.
3. Install the new bundle into the OSGi framework. The bundle is assigned a bundle identifier; for example:

   ```
   osgi> install <URL to bundle>
   ```

4. Start the new bundle using the assigned bundle identifier; for example:

   ```
   osgi> start <id>
   ```

   After the new bundle is started, the eXtreme Scale OSGi service tracker detects the bundle and makes it available for updating.

5. Use the **xscmd -c osgiAll** command to verify that each container server sees the new bundle. The **osgiAll** command queries all containers in the grid for all services that are referenced in the ObjectGrid descriptor XML file and displays all rankings that are available; for example:

```
xscmd -c osgiAll

Server: server1
   OSGi Service Name          Available Rankings
   -----------------          ------------------
   myLoaderServiceFactory     1, 2
   mySerializerServiceFactory 1, 2

Server: server2
   OSGi Service Name          Available Rankings
   -----------------          ------------------
   myLoaderServiceFactory     1, 2
   mySerializerServiceFactory 1, 2

Summary - All servers have the same service rankings.
```

6. Use the **xscmd -c osgiCheck** command to verify that one or more service rankings are valid update targets; for example:

```
xscmd -c osgiCheck -sr
mySerializerServiceFactory;2,myLoaderServiceFactory;2

CWXSI0040I: The command osgiCheck has completed successfully.
```

7. If the **osgiCheck** command did not find any resulting errors, suspend the balancer of the placement service to avoid shard movements, in case of a failure during the update process. To suspend placement, use the **xscmd -c suspendBalancing** command for each object grid and map set that are affected by the update; for example:

```
xscmd -c suspendBalancing -g MyGrid -ms MyMapSet
```

8. After balancing has been suspended for each object grid and map set, use the **xscmd -c osgiCheck** command again to verify that one or more service rankings are valid update targets; for example:

```
xscmd -c osgiCheck -sr
mySerializerServiceFactory;2,myLoaderServiceFactory;2

CWXSI0040I: The command osgiCheck has completed successfully.
```

9. After balancing has been suspended for the object grid and map set, use the **osgiUpdate** command to update the service on all of the servers for an object grid and map set; for example:

```
xscmd -c osgiUpdate  -sr
mySerializerServiceFactory;2,myLoaderServiceFactory;2 -g MyGrid -ms MyMapSet
```

10. Verify that the upgrade succeeded; for example:

```
Update succeeded for the following service rankings:
Service                    Ranking
-------                    -------
mySerializerServiceFactory  2
myLoaderServiceFactory      2
```

11. After you verify that the ranking has been updated successfully, enable balancing again, using the **xscmd -c resumeBalancing** command; for example:

```
xscmd -c resumeBalancing -g MyGrid -ms MyMapSet
```

12. Stop and uninstall the old bundle in each OSGi framework that is hosting the eXtreme Scale container. For example, enter the following code in the Eclipse Equinox console:

```
osgi> stop <id>
osgi> uninstall <id>
```

Results

The eXtreme Scale bundle has been updated to a new version.

Administering with Managed Beans (MBeans)

You can use several different types of Java™ Management Extensions (JMX) MBeans to administer and monitor deployments. Each MBean refers to a specific entity, such as a map, data grid, server, or service.

JMX MBean interfaces and WebSphere eXtreme Scale

Each MBean has get methods that represent attribute values. These get methods cannot be called directly from your program. The JMX specification treats attributes differently from operations. You can view attributes with a vendor JMX console, and you can perform operations in your program or with a vendor JMX console.

Package com.ibm.websphere.objectgrid.management

See the API documentation for an overview and detailed programming specifications for all of the available MBeans:Package com.ibm.websphere.objectgrid.management .

- Accessing Managed Beans (MBeans) using the wsadmin tool
  You can use the wsadmin utility provided in WebSphere® Application Server to access managed bean (MBean) information.
- Accessing Managed Beans (MBeans) programmatically
  You can connect to MBeans with Java applications. These applications use the interfaces in the com.ibm.websphere.objectgrid.management package.

Accessing Managed Beans (MBeans) using the wsadmin tool

You can use the wsadmin utility provided in WebSphere® Application Server to access managed bean (MBean) information.

Procedure

Run the wsadmin tool from the bin directory in your WebSphere Application Server installation. The following example retrieves a view of the current shard placement in a dynamic eXtreme Scale. You can run the wsadmin tool from any installation where eXtreme Scale is running. You do not have to run the wsadmin tool on the catalog service.

```
$ wsadmin.sh -lang jython
wsadmin>placementService = AdminControl.queryNames
        ("com.ibm.websphere.objectgrid:*,type=PlacementService")
wsadmin>print AdminControl.invoke(placementService,
        "listObjectGridPlacement","library ms1")

<objectGrid name="library" mapSetName="ms1">
  <container name="container-0" zoneName="DefaultDomain"
               hostName="host1.company.org" serverName="server1">
     <shard type="Primary" partitionName="0"/>
     <shard type="SynchronousReplica" partitionName="1"/>
  </container>
  <container name="container-1" zoneName="DefaultDomain"
               hostName="host2.company.org" serverName="server2">
     <shard type="SynchronousReplica" partitionName="0"/>
     <shard type="Primary" partitionName="1"/>
  </container>
  <container name="UNASSIGNED" zoneName="_ibm_SYSTEM"
               hostName="UNASSIGNED" serverName="UNNAMED">
    <shard type="SynchronousReplica" partitionName="0"/>
    <shard type="AsynchronousReplica" partitionName="0"/>
  </container>
</objectGrid>
```

Interface PlacementServiceMBean

Accessing Managed Beans (MBeans) programmatically

You can connect to MBeans with Java applications. These applications use the interfaces in the com.ibm.websphere.objectgrid.management package.

About this task

Programmatic methods for accessing MBeans vary depending on the type of server to which you are connecting.

- Connect to a stand-alone catalog service MBean server
- Connect to a container MBean server
- Connect to a catalog service MBean server that is hosted in WebSphere® Application Server
- Connect to a catalog service MBean server with security enabled

Procedure

- **Connect to a stand-alone catalog service MBean server:**
  The following example program connects to a stand-alone catalog service MBean server and returns an XML formatted string that lists each container server along with its allocated shards for a given ObjectGrid and MapSet.

  Figure 1. CollectPlacementPlan.java

```
package com.ibm.websphere.sample.xs.admin;

import java.util.Set;

import javax.management.MBeanServerConnection;
import javax.management.ObjectName;
import javax.management.remote.JMXConnector;
import javax.management.remote.JMXConnectorFactory;
import javax.management.remote.JMXServiceURL;

/**
 * Collects the placement information from the Catalog Server for a given ObjectGrid.
 */
public final class CollectPlacementPlan {
    private static String hostName = "localhost";

    private static int port = 1099;

    private static String objectGridName = "library";

    private static String mapSetName = "ms1";

    /**
     * Connects to the ObjectGrid Catalog Service to retrieve placement information and
           * prints it out.
     *
     * @param args
     * @throws Exception
     *             If there is a problem connecting to the catalog service MBean server.
     */
    public static void main(String[] args) throws Exception {
        String serviceURL = "service:jmx:rmi:///jndi/rmi://" + hostName + ":" + port +
                    "/objectgrid/MBeanServer";
        JMXServiceURL jmxUrl = new JMXServiceURL(serviceURL);
        JMXConnector jmxCon = JMXConnectorFactory.connect(jmxUrl);

        try {
            MBeanServerConnection catalogServerConnection = jmxCon.getMBeanServerConnection();

            Set placementSet = catalogServerConnection.queryNames(new
                                                ObjectName("com.ibm.websphere.objectgrid"
             + ":*,type=PlacementService"), null);
            ObjectName placementService = (ObjectName) placementSet.iterator().next();
            Object placementXML = catalogServerConnection.invoke(placementService,
                "listObjectGridPlacement", new Object[] {
                objectGridName, mapSetName }, new String[] { String.class.getName(),
                                                        String.class.getName() });
            System.out.println(placementXML);
        } catch (Exception e) {
            if(jmxCon != null) {
                jmxCon.close();
            }
        }
    }

}
```

  A few notes regarding the sample program:
  - The JMXServiceURL value for the catalog service is always of the following form: `service:jmx:rmi:///jndi/rmi://<host>:<port>/objectgrid/MBeanServer`, where `<host>` is the host on which the catalog service is running and `<port>` is the JMX service port that is provided with the -JMXServicePort option when starting the catalog service. If no port is specified, the default is `1099`.

- For the ObjectGrid or map statistics to be enabled, you must specify the following property in the server properties file when you are starting an ObjectGrid container: `statsSpec=all=enabled`
- To disable the MBeans that are running in the container servers, specify the following property in the server properties file: `enableMBeans=false`.

An example of the output follows. This output indicates that two container servers are active. The `Container-0` container server hosts four primary shards. The `Container-1` container server hosts a synchronous replica for each of the primary shards on the `Container-0` container server. In this configuration, two synchronous replicas and one asynchronous replica are configured. As a result, the `Unassigned` container server is left with the remaining shards. If two more container servers are started, the `Unassigned` container server is not displayed.

```
<objectGrid name="library" mapSetName="ms1">
  <container name="Container-1" zoneName="DefaultZone"
    hostName="myhost.mycompany.com" serverName="ogserver">
    <shard type="SynchronousReplica" partitionName="0"/>
    <shard type="SynchronousReplica" partitionName="1"/>
    <shard type="SynchronousReplica" partitionName="2"/>
    <shard type="SynchronousReplica" partitionName="3"/>
  </container>
  <container name="Container-0" zoneName="DefaultZone"
    hostName="myhost.mycompany.com" serverName="ogserver">
    <shard type="Primary" partitionName="0"/>
    <shard type="Primary" partitionName="1"/>
    <shard type="Primary" partitionName="2"/>
    <shard type="Primary" partitionName="3"/>
  </container>
  <container name="library:ms1:_UnassignedContainer_" zoneName="_ibm_SYSTEM"
    hostName="UNASSIGNED" serverName="UNNAMED">
    <shard type="SynchronousReplica" partitionName="0"/>
    <shard type="SynchronousReplica" partitionName="1"/>
    <shard type="SynchronousReplica" partitionName="2"/>
    <shard type="SynchronousReplica" partitionName="3"/>
    <shard type="AsynchronousReplica" partitionName="0"/>
    <shard type="AsynchronousReplica" partitionName="1"/>
    <shard type="AsynchronousReplica" partitionName="2"/>
    <shard type="AsynchronousReplica" partitionName="3"/>
  </container>
</objectGrid>
```

- **Connect to a container MBean server:**
  Container servers host MBeans to query information about the individual maps and ObjectGrid instances that are running within the container server. The following example program prints the status of each container server that is hosted by the catalog server with the JMX address of `localhost:1099`:

  Figure 2. CollectContainerStatus.java

```
package com.ibm.websphere.sample.xs.admin;

import java.util.List;
import java.util.Set;

import javax.management.MBeanServerConnection;
import javax.management.ObjectInstance;
import javax.management.ObjectName;
import javax.management.remote.JMXConnector;
import javax.management.remote.JMXConnectorFactory;
import javax.management.remote.JMXServiceURL;

/**
 * Collects placement status from each of the available containers directly.
 */
public final class CollectContainerStatus {
    private static String hostName = "localhost";

    private static int port = 1099;

    /**
     * @param args
     */
    public static void main(String[] args) throws Exception {
        String serviceURL = "service:jmx:rmi:///jndi/rmi://" + hostName + ":" + port + "/objectgrid/MBeanServer";
        JMXServiceURL jmxUrl = new JMXServiceURL(serviceURL);
        JMXConnector jmxCon = JMXConnectorFactory.connect(jmxUrl);

        try {
            MBeanServerConnection catalogServerConnection = jmxCon.getMBeanServerConnection();

            Set placementSet = catalogServerConnection.queryNames(new ObjectName("com.ibm.websphere.objectgrid"
                    + ":*,type=PlacementService"), null);

            ObjectName placementService = (ObjectName) placementSet.iterator().next();
            List<String> containerJMXAddresses = (List<String>) catalogServerConnection.invoke(placementService,
                    "retrieveAllServersJMXAddresses", new Object[0], new String[0]);
            for (String address : containerJMXAddresses) {
                JMXServiceURL containerJMXURL = new JMXServiceURL(address);
                JMXConnector containerConnector = JMXConnectorFactory.connect(containerJMXURL);
                MBeanServerConnection containerConnection = containerConnector.getMBeanServerConnection();
                Set<ObjectInstance> containers = containerConnection.queryMBeans(
                        new ObjectName("*:*,type=ObjectGridContainer"), null);
                for (ObjectInstance container : containers) {
                    System.out.println(containerConnection.getAttribute(container.getObjectName(), "Status"));
                }
            }
```

```
        } finally {
            if(jmxCon != null) {
                jmxCon.close();
            }
        }
    }
}
```

The example program prints out the container server status for each container. An example of the output follows:

```
<container name="Container-0" zoneName="DefaultZone" hostName="descartes.rchland.ibm.com"
               serverName="ogserver">
  <shard type="Primary" partitionName="1"/>
  <shard type="Primary" partitionName="0"/>
  <shard type="Primary" partitionName="3"/>
  <shard type="Primary" partitionName="2"/>
</container>
```

- **Connect to a catalog service MBean server that is hosted in WebSphere Application Server:**
  The method for programmatically accessing MBeans in WebSphere Application Server is slightly different from accessing MBeans in a stand-alone configuration.

  1. Create and compile a Java program to connect to the MBean server. An example program follows:
     Figure 3. CollectPlacementPlan.java

     ```
     package com.ibm.websphere.sample.xs.admin;

     import java.util.Set;

     import javax.management.MBeanServerConnection;
     import javax.management.ObjectName;
     import javax.management.remote.JMXConnector;
     import javax.management.remote.JMXConnectorFactory;
     import javax.management.remote.JMXServiceURL;

     /**
      * Collects the placement information from the catalog server running in a deployment manager for a given
     ObjectGrid.
      */
     public final class CollectPlacementPlanWAS {
         private static String hostName = "localhost";

         private static int port = 9809;

         private static String objectGridName = "library";

         private static String mapSetName = "ms1";

         /**
          * Connects to the catalog service to retrieve placement information and prints it out.
          *
          * @param args
          * @throws Exception
          *             If there is a problem connecting to the catalog service MBean server.
          */
         public static void main(String[] args) throws Exception {

             // connect to bootstrap port of the deployment manager
             String serviceURL = "service:jmx:iiop://" + hostName + ":" + port + "/jndi/JMXConnector";
             JMXServiceURL jmxUrl = new JMXServiceURL(serviceURL);
             JMXConnector jmxCon = JMXConnectorFactory.connect(jmxUrl);

             try {
                 MBeanServerConnection catalogServerConnection = jmxCon.getMBeanServerConnection();

                 Set placementSet =
                                                     catalogServerConnection.queryNames(new
     ObjectName("com.ibm.websphere.objectgrid"
                      + ":*,type=PlacementService"), null);

                 ObjectName placementService = (ObjectName) placementSet.iterator().next();
                 Object placementXML = catalogServerConnection.invoke(placementService,
                             "listObjectGridPlacement", new Object[] {
                         objectGridName, mapSetName }, new String[] { String.class.getName(),
                                                                      String.class.getName() });
                 System.out.println(placementXML);
             } finally {
                 if(jmxCon != null) {
                     jmxCon.close();
                 }
             }
         }

     }
     ```

  2. Run the following command.

     ```
     "$JAVA_HOME/bin/java" "$WAS_LOGGING" -
     Djava.security.auth.login.config="$app_server_root/properties/wsjaas_client.conf" \
      -Djava.ext.dirs="$JAVA_HOME/jre/lib/ext:$WAS_EXT_DIRS:$WAS_HOME/plugins:$WAS_HOME/lib/WMQ/java/lib" \
     ```

```
-Djava.naming.provider.url=<an_IIOP_URL_or_a_corbaloc_URL_to_your_application_server_machine_name> \
-Djava.naming.factory.initial=com.ibm.websphere.naming.WsnInitialContextFactory \
-Dserver.root="$WAS_HOME" "$CLIENTSAS" "$CLIENTSSL" $USER_INSTALL_PROP \
-classpath "$WAS_CLASSPATH":<list_of_your_application_jars_and_classes> \
<fully_qualified_class_name_to_run> <your_application_parameters>
```

This command assumes that the *was_root*/bin/setupCmdLine.sh script has been run to set the variables properly. An example of the format of the java.naming.provider.url property value is `corbaloc:iiop:1.0@<host>:<port>/NameService`.

- **Connect to a catalog service MBean server with security enabled:**
  For more information about connecting to the catalog service MBean with security enabled, see Java Management Extensions (JMX) security.

What to do next

For more examples on how to display statistics and perform administrative operations with MBeans, see the **xsadmin** sample application. You can look at the source code of the xsadmin sample application in the *wxs_home*/samples/xsadmin.jar file in a stand-alone installation, or in the *wxs_home*/xsadmin.jar file in a WebSphere Application Server installation. See Sample: xsadmin utility for more information about the operations you can complete with the **xsAdmin** sample application.
You can also find more information about MBeans in the com.ibm.websphere.objectgrid.management package.

Administering J2C client connections

8.5+ The WebSphere® eXtreme Scale connection factory includes an eXtreme Scale client connection that can be shared between applications and persisted through application restarts.

About this task

The client connection includes a management bean that provides connection status information and lifecycle management operations.

Procedure

Maintain client connections. When the first connection is obtained from the XSConnectionFactory connection factory object, an eXtreme Scale client connection is established to the remote data grid and the ObjectGridJ2CConnection MBean is created. The client connection is maintained for the life of the process. To end a client connection, invoke one of the following events::

- Stop the resource adapter. A resource adapter can be stopped, for example, when it is embedded in an application and the application is stopped.
- Invoke the resetConnection MBean operation on the ObjectGridJ2CConnection MBean. When the connection is reset, all connections are invalidated, transactions completed, and the ObjectGrid client connection is destroyed. Subsequent calls to the getConnection methods on the connection factory result in a new client connection.

WebSphere Application Server also provides additional management beans for managing J2C connections, monitoring connection pools, and performance.

Developing applications

	8.5 Develop applications that use the data grid. The tasks for developing applications include: • Accessing data • System APIs and plug-ins • JPA integration • Spring integration

- Setting up the development environment
  Before you begin developing applications, you must set up your development environment.
- Accessing data with client applications
  After you configure your development environment, you can begin to develop applications that create, access, and manage the data in your data grid.
- System APIs and plug-ins
  A plug-in is a component that provides a function to the pluggable components, which include ObjectGrid and BackingMap. To most effectively use eXtreme Scale as an in-memory data grid or database processing space, you should carefully determine how best you can maximize performance with available plug-ins.
- Programming to use the OSGi framework
  You can start eXtreme Scale servers and clients in an OSGi container, which allows you to dynamically add and update eXtreme Scale plug-ins to the runtime environment.
- Programming for JPA integration
  The Java™ Persistence API (JPA) is a specification that allows mapping Java objects to relational databases. JPA contains a full object-relational mapping (ORM) specification using Java language metadata annotations, XML descriptors, or both to define the mapping between Java objects and a relational database. A number of open-source and commercial implementations are available.
- Developing applications with the Spring framework
  Learn how to integrate your eXtreme Scale applications with the popular Spring framework.

Setting up the development environment

Before you begin developing applications, you must set up your development environment.

Before you begin

See Planning to develop WebSphere eXtreme Scale applications for more information about the available programming interfaces and considerations.

- Accessing API documentation
  You can access the API documentation for WebSphere® eXtreme Scale by downloading a zip file archive, incorporating the API documentation into your development environment, or viewing the API documentation in the information center.
- Setting up a stand-alone development environment in Eclipse
  Use Eclipse-based integrated development environment to build and run a Java™ SE application with the stand-alone version of WebSphere eXtreme Scale.
- Running a WebSphere eXtreme Scale application that uses an application server other than WebSphere Application Server in Eclipse
  You can configure a Java EE application that uses WebSphere eXtreme Scale to run in an application server other than WebSphere Application Server in Eclipse.
- Running an integrated client or server application with WebSphere Application Server in Rational Application Developer
  Configure and run a Java EE application with a WebSphere eXtreme Scale client or server with the WebSphere Application Server runtime embedded in Rational® Application Developer.

Accessing API documentation

You can access the API documentation for WebSphere® eXtreme Scale by downloading a zip file archive, incorporating the API documentation into your development environment, or viewing the API documentation in the information center.

About this task

You can access API documentation in one of the following locations:

Information center
: Using the information center API documentation is useful for searching along with the rest of the WebSphere eXtreme Scale product information.

Zip file archive
: You can download this file for each release. You can then use compare tools to see what APIs changed from release to release. You can also directly link the compressed file in your Eclipse projects when you are compiling against the objectgrid.jar file. Using this linking integrates the API documentation in the IDE.

Procedure

- View API documentation in the information center. For more information, see API documentation.
- Download a zip archive of the API documentation.
  If you want to download the API documentation to browse offline, you can download a zip file for the appropriate release from the following page: IBM Elastic Caching Community wiki: API documentation downloads.

What to do next

For more information about accessing the API documentation within the development environment, see Setting up a stand-alone development environment in Eclipse.

API documentation

Setting up a stand-alone development environment in Eclipse

Use Eclipse-based integrated development environment to build and run a Java™ SE application with the stand-alone version of WebSphere® eXtreme Scale.

Before you begin

- Install the WebSphere eXtreme Scale product into a new or empty directory and apply the latest WebSphere eXtreme Scale fix pack. For more information, see Installing.
- Download the API documentation. For more information, see IBM Elastic Caching Community wiki: API documentation downloads.

Procedure

- Configure Eclipse to build and run a Java SE application with WebSphere eXtreme Scale.
  1. Define a user library to allow your application to reference WebSphere eXtreme Scale application programming interfaces.
     a. In your Eclipse or IBM® Rational® Application Developer environment, click Window > Preferences.
     b. Expand the Java > Build Path branch and select User Libraries. Click New.
     c. Select the eXtreme Scale user library. Click Add JARs.
        i. Browse and select the objectgrid.jar or ogclient.jar files from the *wxs_root*/lib directory. Click OK. Select the ogclient.jar file if you are developing client applications or local, in-memory caches. If you are developing and testing eXtreme Scale servers, use the objectgrid.jar file.
        ii. To include Javadoc for the ObjectGrid APIs, select the Javadoc location for the objectgrid.jar or ogclient.jar file that you added in the previous step. Click Edit.
     d. Click OK to apply the settings and close the Preferences window.

     The eXtreme Scale libraries are now in the build path for the project.
  2. Add the user library to your Java project.
     a. From the package explorer, right-click the project and select Properties.
     b. Select the Libraries tab.
     c. Click Add Library.
     d. Select User Library. Click Next.
     e. Select the eXtreme Scale user library that you configured earlier.
     f. Click OK to apply the changes and close the Properties window.
- Run a Java SE application in Eclipse. Create a run configuration to run your application.
  1. Configure Eclipse to build and run a Java SE application with WebSphere eXtreme Scale. From the Run menu select Run Configurations.
  2. Right-click the Java Application category and select New.
  3. Select the new run configuration, named *New_Configuration*.
  4. Configure the profile.
     - Project (on main tabbed page): *your_project_name*
     - Main Class (on main tabbed page): *your_main_class*
     - VM arguments (on arguments tabbed page): `-Djava.endorsed.dirs=wxs_root/lib/endorsed`

     Problems with the VM Arguments often occur because the path to java.endorsed.dirs must be an absolute path with no variables or shortcuts.

     Other common setup problems involve the Object Request Broker (ORB). You might see the following error. Refer to Configuring a custom Object Request Broker for more information:

     ```
     Caused by: java.lang.RuntimeException: The ORB that comes
     with the Sun Java implementation does not work with
     ObjectGrid at this time.
     ```

     If you do not have the objectGrid.xml or deployment.xml accessible to the application, you might see the following error:

     ```
     Exception in thread "P=211046:O=0:CT" com.ibm.websphere.objectgrid.
                                    ObjectGridRuntimeException: Cannot start OG container at
                                    Client.startTestServer(Client.java:161) at Client.
                                    main(Client.java:82) Caused by: java.lang.IllegalArgumentException:
                                    The objectGridXML must not be null      at com.ibm.websphere.objectgrid.
                                    deployment.DeploymentPolicyFactory.createDeploymentPolicy
                               (DeploymentPolicyFactory.java:55) at Client.startTestServer(Client.
                                    java:154) .. 1 more
     ```

  5. Click Apply and close the window, or click Run.

Running a WebSphere eXtreme Scale application that uses an application server other than WebSphere Application Server in Eclipse

You can configure a Java™ EE application that uses WebSphere® eXtreme Scale to run in an application server other than WebSphere Application Server in Eclipse.

Before you begin

- Install the stand-alone version of the WebSphere eXtreme Scale product, or download and extract the WebSphere eXtreme Scale trial version. For more information, see Installing.
- Install an application server, such as Apache Tomcat Version 6.0 or later.
- Install Eclipse and create a Java EE web application. The Java EE perspective is required and must be installed in your Eclipse environment.
- Download the API documentation. For more information, see IBM Elastic Caching Community wiki: API documentation downloads.

About this task

The following procedure was tested with Apache Tomcat and JBoss Application Server. The instructions also apply to other application servers.

Procedure

1. Add WebSphere eXtreme Scale runtime library to your Java EE build path. The steps vary slightly if you are using a full installation of WebSphere eXtreme Scale or an installation of .
   WebSphere eXtreme Scale Client

   Use the following steps if you have only WebSphere eXtreme Scale Client installed:

   a. Window > Preferences > Java > Build Path > User Libraries. Click New.
   b. Enter a User library name of `eXtremeScaleClient`, and click OK.
   c. Click Add Jars..., and select the *wxs_home*/lib/ogclient.jar file. Click Open.
   d. Optional: To add Javadoc, select Javadoc location and click Edit.... Enter your local download location.
   e. Click OK.
   f. Click OK to close out the User Libraries dialog.
   g. Click Project > Properties.
   h. Click Java Build Path.
   i. Click Add Library.
   j. Select User Library. Click Next.
   k. Check the eXtremeScaleClient library and click Finish.
   l. Click OK to close the Project Properties dialog.

   Full WebSphere eXtreme Scale installation

   Use the following steps if you used the full installation to install a client and server:

   a. Click Window > Preferences > Java > Build Path > User Libraries. Click New.
   b. Enter a User library name of `eXtremeScale`, and click OK.
   c. Click Add Jars..., and select *wxs_home*/lib/objectgrid.jar. Click Open.
   d. (Optional) To add Javadoc, select Javadoc location and click Edit.... Enter your local download location.
   e. Click OK.
   f. Click OK to close out the User Libraries dialog.
   g. Click Project > Properties.
   h. Click Java Build Path.
   i. Click Add Library.
   j. Select User Library. Click Next.
   k. Check the eXtremeScaleClient library and click Finish.
   l. Click OK to close the Project Properties dialog.
2. Add Java EE application projects to the server.
   a. Ensure that you are in the Java EE perspective and click the Servers tab in the bottom pane. You can also click Window > Show View > Servers.
   b. Right-click in the Servers pane, and choose New > Server.
   c. Choose your application server. Click Next.
   d. Click Browse... Select the root directory of your application server. Click OK.
   e. Click Next.
   f. Select your Java EE application project in the left Available pane and click Add > to move it to the right Configured pane on the server, and click Finish.
3. Resolve any remaining errors for the Project. Use the following steps to eliminate errors in the Problems pane:
   a. Click Project > Clean > *project_name*. Click OK. Build the project.
   b. Right-click on the Java EE project, and choose Build Path > Configure Build Path.
   c. Click the Libraries tab. Ensure that Apache Tomcat or your other application server, eXtremeScaleClient, and JRE are on the path.

4. Create a run configuration to run your application.
    a. From the Run menu, select Run Configurations.
    b. Right-click the Java Application category and select New.
    c. Select the new run configuration, named *New_Configuration*.
    d. Configure the profile.
        - Project (on main tabbed page): *your_project_name*
        - Main Class (on main tabbed page): *your_main_class*
        - VM arguments (on arguments tabbed page): `-Djava.endorsed.dirs=wxs_home/lib/endorsed`

    Problems with the VM arguments often occur because the path to the java.endorsed.dirs directory must be an absolute path with no variables or shortcuts.

    Other common setup problems involve the Object Request Broker (ORB). You might see the following error:

    ```
    Caused by: java.lang.RuntimeException: The ORB that comes with the

Running an integrated client or server application with WebSphere Application Server in Rational Application Developer

Configure and run a Java™ EE application with a WebSphere® eXtreme Scale client or server with the WebSphere Application Server runtime embedded in Rational® Application Developer.

Before you begin

The following steps are for WebSphere Application Server Version 7.0 with Rational Application Developer Version 7.5. The following steps might vary if you are using different versions of these products.

- Install Rational Application Developer with WebSphere Application Server Test Environment extensions.
- Install WebSphere eXtreme Scale into the WebSphere Application Server, Version 7.0 Test Environment in the *rad_home*\runtimes\base_v7 directory. For more information, see Installing WebSphere eXtreme Scale or WebSphere eXtreme Scale Client with WebSphere Application Server.

Procedure

1. Define a eXtreme Scale server that is integrated with WebSphere Application Server for your project.
    a. In the Java EE perspective, click Window > Show View > Servers.
    b. Right-click in the Servers pane. Choose New > Server.
    c. Choose **IBM® WebSphere Application Server v7.0**. Click Next.
    d. Select a profile to use. The default is `was70profile1`.
    e. Enter the server name. The default is `server1`.
    f. Click Next.
    g. Select your Java EE application in the Available pane. Click Add > to move it to the Configured pane on the server. Click Finish.
2. To run the Java EE application, start the application server. Right-click **WebSphere Application Server v7.0** and select Start.

Accessing data with client applications

After you configure your development environment, you can begin to develop applications that create, access, and manage the data in your data grid.

About this task

From the perspective of a client application, using WebSphere® eXtreme Scale involves the following main steps:

- Connecting to the catalog service by obtaining a ClientClusterContext instance.
- Obtaining a client ObjectGrid instance.
- Getting a Session instance.
- Getting an ObjectMap instance.
- Using the ObjectMap methods.

- Connecting to distributed ObjectGrid instances programmatically
  You can connect to a distributed ObjectGrid with the connection end points for the catalog service domain. You must have the host name and listener port of each catalog server in the catalog service domain to which you want to connect.
- Tracking map updates by an application
  When an application is making changes to a Map during a transaction, a LogSequence object tracks those changes. If the application changes an entry in the map, a corresponding LogElement object provides the details of the change.
- Interacting with an ObjectGrid using the ObjectGridManager interface
  The ObjectGridManagerFactory class and the ObjectGridManager interface provide a mechanism to create, access, and add data to ObjectGrid instances. The ObjectGridManagerFactory class is a static helper class to access the ObjectGridManager interface, a singleton. The ObjectGridManager interface includes several convenience methods to create instances of an ObjectGrid object. The ObjectGridManager interface also facilitates creation and caching of ObjectGrid instances that can be accessed by several users.
- Accessing data with indexes (Index API)
  Use indexing for more efficient data access.
- Using Sessions to access data in the grid
  Your applications can begin and end transactions through the Session interface. The Session interface also provides access to the application-based ObjectMap and JavaMap interfaces.
- Caching objects with no relationships involved (ObjectMap API)
  ObjectMaps are like Java™ Maps that allow data to be stored as key-value pairs. ObjectMaps provide a simple and intuitive approach for the application to store data. An ObjectMap is ideal for caching objects that have no relationships involved. If object relationships are involved, then you should use the EntityManager API.
- Caching objects and their relationships (EntityManager API)
  Most cache products use map-based APIs to store data as key-value pairs. The ObjectMap API and the dynamic cache in WebSphere Application Server, among others, use this approach. However, map-based APIs have limitations. The EntityManager API simplifies the interaction with the data grid by providing an easy way to declare and interact with a complex graph of related objects.
- Retrieving entities and objects (Query API)
  WebSphere eXtreme Scale provides a flexible query engine for retrieving entities using the EntityManager API and Java objects using the ObjectQuery API.
- Programming for transactions in Java applications
  When you write a Java application that requires transactions, you must consider issues such as lock handling, collision handling, and transaction isolation.
- Configuring Java clients programmatically
  You can override client-side settings programmatically. Create an ObjectGridConfiguration object that is similar in structure to the server-side ObjectGrid instance.

Connecting to distributed ObjectGrid instances programmatically

You can connect to a distributed ObjectGrid with the connection end points for the catalog service domain. You must have the host name and listener port of each catalog server in the catalog service domain to which you want to connect.

Before you begin

- To connect to a distributed data grid, you must configure your server-side environment with a catalog service and container servers.
- You must have the listener port for each catalog service. For more information, see Planning for network ports.
- If the client application is running in WebSphere Application Server augmented with eXtreme Scale, configure the catalog service domain using the WebSphere Application Server administrative console or wsadmin.

About this task

8.5+ When running in a Java™ EE application, consider using the eXtreme Scale resource adapter. The resource adapter allows the application to look up a ObjectGrid connection in Java Naming Directory Interface (JNDI) using a Java Connector Architecture (JCA) connection factory, which significantly simplifies access to the data grid and allows integration with Java Transaction API (JTA) transactions. For more information, see Scenario: Using JCA to connect transactional applications to eXtreme Scale clients.

The ObjectGridManager.connect() methods connect to a catalog service domain using the supplied connection end points and returns a ClientClusterContext object that is used to retrieve ObjectGrid instances for the domain. The connection end points are a comma-delimited list of host and port combinations for each catalog server in the catalog service domain. See the following format of the catalog service endpoints:

```
catalogServiceEndpoints ::= <catalogServiceEndpoint> [,<catalogServiceEndpoint>]
catalogServiceEndpoint  ::= <hostName> : <listenerPort>
hostName                ::= The IP address or host name of a catalog service.
listenerPort            ::= The listener port that the catalog service is configured to use.
```

After you connect to the catalog service domain, use the ObjectGridManagerFactory.getObjectGrid(ClientClusterContext ccc, String objectGridName) method to retrieve a named ObjectGrid client instance. This ObjectGrid instance is a proxy for the named data grid and is cached in the client application. The ObjectGrid instance represents a logical connection to the remote data grid and is thread safe. All underlying physical connections to the data grid are managed automatically and can tolerate failure events.

The connection steps vary depending on whether you are using a stand-alone configuration or WebSphere Application Server.

Procedure

- Connect to a stand-alone distributed data grid using explicit catalog service end points.

```
// Retrieve an ObjectGridManager instance.
ObjectGridManager ogm = ObjectGridManagerFactory.getObjectGridManager();

// Obtain a ClientClusterContext by connecting to a catalog
// service domain, manually suppling the catalog service endpoints,
// and optionally specifying the ClientSecurityConfiguration and
// client ObjectGrid override XML file URL.
String catalogServiceEndpoints = "host1:2809,host2:2809";
ClientClusterContext ccc = ogm.connect(catalogServiceEndpoints,
                (ClientSecurityConfiguration) null, (URL) null);

// Obtain a distributed ObjectGrid using ObjectGridManager and providing
// the ClientClusterContext.
ObjectGrid og = ogm.getObjectGrid(ccc, "Mygrid");
```

- Connect to a catalog service domain from a client application that is hosted in WebSphere Application Server, where the catalog service domain was configured using the administrative console or admin task. The catalog service endpoints can be retrieved from a named domain identifier or for the default domain using the ObjectGridManager.

```
// Retrieve an ObjectGridManager instance.
ObjectGridManager ogm = ObjectGridManagerFactory.getObjectGridManager();

// Retrieve the domain by its ID (the name given to it in the admin console or wsadmin)
// The CatalogDomainManager also includes methods to retrieve all domains and the default domain.
CatalogDomainInfo di = ogm.getCatalogDomainManager().getDomainInfo("ProductionDomain");
if(di == null) throw new IllegalStateException("Domain not configured");

// Connect to the domain using the catalog service endpoints and the security configuration
// in the CatalogDomainInfo object.  The client override ObjectGrid XML is optional
// and is manually supplied.
ClientClusterContext ccc = ogm.connect(di.getClientCatalogServiceEndpoints(),
                di.getClientSecurityConfiguration(), (URL) null);

// Obtain a distributed ObjectGrid using ObjectGridManager and by providing
// the ClientClusterContext.
ObjectGrid og = ogm.getObjectGrid(ccc, "MyGrid");
```

What to do next

If the catalog service domain is hosted in a WebSphere Application Server deployment manager, clients outside of the cell, including Java Platform, Enterprise Edition clients, must connect to the catalog service using the deployment manager host name and the IIOP bootstrap port. When the catalog service runs in WebSphere Application Server cells, and the clients run outside of the cells, look to the eXtreme Scale domain configuration pages in the WebSphere Application Server administrative console for the information that you need to point a client to the catalog service.

Tracking map updates by an application

When an application is making changes to a Map during a transaction, a LogSequence object tracks those changes. If the application changes an entry in the map, a corresponding LogElement object provides the details of the change.

Loaders are given a LogSequence object for a particular map whenever an application calls for a flush or commit to the transaction. The Loader iterates over the LogElement objects within the LogSequence object and applies each LogElement object to the backend.

ObjectGridEventListener listeners that are registered with an ObjectGrid also use LogSequence objects. These listeners are given a LogSequence object for each map in a committed transaction. Applications can use these listeners to wait for certain entries to change, like a trigger in a conventional database.

The following log-related interfaces or classes are provided by the eXtreme Scale framework:

- com.ibm.websphere.objectgrid.plugins.LogElement
- com.ibm.websphere.objectgrid.plugins.LogSequence
- com.ibm.websphere.objectgrid.plugins.LogSequenceFilter
- com.ibm.websphere.objectgrid.plugins.LogSequenceTransformer

LogElement interface

A LogElement represents an operation on an entry during a transaction. A LogElement object has several methods to get its various attributes. The most commonly used attributes are the type and the current value attributes fetched by getType() and getCurrentValue().

8.5 The type is represented by one of the constants defined in the LogElement interface: INSERT, UPDATE, DELETE, EVICT, FETCH, or TOUCH.

The current value represents the new value for the operation if it is INSERT, UPDATE, or FETCH. If the operation is TOUCH, DELETE, or EVICT, then the current value is null. This value can be cast to ValueProxyInfo when a ValueInterface is in use.

See the API documentation for more details on the LogElement interface.

LogSequence interface

In most transactions, operations to more than one entry in a map occur, so multiple LogElement objects are created. You should create an object that behaves as a composite of multiple LogElement objects. The LogSequence interface serves this purpose by containing a list of LogElement objects.

See the API documentation for more details on the LogSequence interface.

Using LogElement and LogSequence

LogElement and LogSequence are widely used in eXtreme Scale and by ObjectGrid plug-ins that are written by users when operations are propagated from one component or server to another component or server. For example, a LogSequence object can be used by the distributed ObjectGrid transaction propagation function to propagate the changes to other servers, or it can be applied to the persistence store by the loader. LogSequence is mainly used by the following interfaces.

- com.ibm.websphere.objectgrid.plugins.ObjectGridEventListener
- com.ibm.websphere.objectgrid.plugins.Loader
- com.ibm.websphere.objectgrid.plugins.Evictor
- com.ibm.websphere.objectgrid.Session

Loader example

This section demonstrates how the LogSequence and LogElement objects are used in a Loader. A Loader is used to load data from and persist data into a persistent store. The batchUpdate method of the Loader interface uses LogSequence object:

```
void batchUpdate(TxID txid, LogSequence sequence) throws
                        LoaderException, OptimisticCollisionException;
```

The batchUpdate method is called when an ObjectGrid needs to apply all current changes to the Loader. The Loader is given a list of LogElement objects for the map, encapsulated in a LogSequence object. The implementation of the batchUpdate method must iterate over the changes and apply them to the backend. The following code snippet demonstrates how a Loader uses a LogSequence object. The snippet iterates over the set of changes and builds up three batch Java™ database connectivity (JDBC) statements: inserts, updates, and deletes:

```
public void batchUpdate(TxID tx, LogSequence sequence) throws LoaderException
{
    // Get a SQL connection to use.
    Connection conn = getConnection(tx);
    try
    {
    // Process the list of changes and build a set of prepared
    // statements for executing a batch update, insert, or delete
    // SQL operations. The statements are cached in stmtCache.
    Iterator iter = sequence.getPendingChanges();
    while ( iter.hasNext() )
    {
        LogElement logElement = (LogElement)iter.next();
        Object key = logElement.getCacheEntry().getKey();
        Object value = logElement.getCurrentValue();
        switch ( logElement.getType().getCode() )
        {
            case LogElement.CODE_INSERT:
                buildBatchSQLInsert( key, value, conn );
                break;
```

```
            case LogElement.CODE_UPDATE:
                buildBatchSQLUpdate( key, value, conn );
                break;
            case LogElement.CODE_DELETE:
                buildBatchSQLDelete( key, conn );
                break;
        }
    }
    // Run the batch statements that were built by above loop.
    Collection statements = getPreparedStatementCollection( tx, conn );
    iter = statements.iterator();
    while ( iter.hasNext() )
    {
        PreparedStatement pstmt = (PreparedStatement) iter.next();
        pstmt.executeBatch();
    }
} catch (SQLException e)
{
    LoaderException ex = new LoaderException(e);
    throw ex;
}
}
```

The previous sample illustrates the high-level logic of processing the LogSequence argument. However, the sample does not illustrate the details of how an SQL insert, update, or delete statement is built. The getPendingChanges method is called on the LogSequence argument to obtain an iterator of LogElement objects that a Loader needs to process, and the LogElement.getType().getCode() method is used to determine whether a LogElement is for an SQL insert, update, or delete operation.

Evictor sample

You can also use LogSequence and LogElement objects with an Evictor. An Evictor is used to evict the map entries from the backing map based on certain criteria. The apply method of the Evictor interface uses LogSequence.

```
/**
* This is called during cache commit to allow the evictor to track object usage
* in a backing map. This will also report any entries that have been successfully
* evicted.
*
* @param sequence LogSequence of changes to the map
*/
void apply(LogSequence sequence);
```

For information on how the apply method uses LogSequence, refer to the code sample in the Custom evictors topic.

LogSequenceFilter and LogSequenceTransformer interfaces

Sometimes, it is necessary to filter the LogElement objects so that only LogElement objects with certain criteria are accepted, and reject other objects. For example, you might want to serialize a certain LogElement based on some criterion.

LogSequenceFilter solves this problem with the following method.

```
public boolean accept (LogElement logElement);
```

This method returns true if the given LogElement should be used in the operation, and returns false if the given LogElement should not be used.

LogSequenceTransformer is a class that uses the LogSequenceFilter function. It uses the LogSequenceFilter to filter out some LogElement objects and then serialize the accepted LogElement objects. This class has two methods. The first method follows.

```
public static void serialize(Collection logSequences, ObjectOutputStream stream,
                        LogSequenceFilter filter, DistributionMode mode) throws IOException
```

This method allows the caller to provide a filter for determining which LogElements to include in the serialization process. The DistributionMode parameter allows the caller to control the serialization process. For example, if the distribution mode is invalidation only, then there is no need to serialize the value. The second method of this class is the inflate method, as follows.

```
public static Collection inflate(ObjectInputStream stream, ObjectGrid
                        objectGrid) throws IOException, ClassNotFoundException
```

The inflate method reads the log sequence serialized form, which was created by the serialize method, from the provided object input stream.

Interacting with an ObjectGrid using the ObjectGridManager interface

The ObjectGridManagerFactory class and the ObjectGridManager interface provide a mechanism to create, access, and add data to ObjectGrid instances. The ObjectGridManagerFactory class is a static helper class to access the ObjectGridManager interface, a singleton. The ObjectGridManager interface includes several convenience methods to create instances of an ObjectGrid object. The ObjectGridManager interface also facilitates creation and caching of ObjectGrid instances that can be accessed by several users.

- Creating ObjectGrid instances with the ObjectGridManager interface
  Each of these methods creates a local instance of an ObjectGrid.

- Retrieving a ObjectGrid instance with the ObjectGridManager interface
  Use the ObjectGridManager.getObjectGrid methods to retrieve cached instances.
- Removing ObjectGrid instances with the ObjectGridManager interface
  You can use two different removeObjectGrid methods to remove ObjectGrid instances from the cache.
- Controlling the lifecycle of an ObjectGrid with the ObjectGridManager interface
  You can use the ObjectGridManager interface to control the lifecycle of an ObjectGrid instance using either a startup bean or a servlet.
- Accessing the ObjectGrid shard
  WebSphere® eXtreme Scale achieves high processing rates by moving the logic to where the data is and returning only results back to the client.

Creating ObjectGrid instances with the ObjectGridManager interface

Each of these methods creates a local instance of an ObjectGrid.

Local in-memory instance

The following code snippet illustrates how to obtain and configure a local ObjectGrid instance with eXtreme Scale.

```
// Obtain a local ObjectGrid reference
        // you can create a new ObjectGrid, or get configured ObjectGrid
        // defined in ObjectGrid xml file
        ObjectGridManager objectGridManager =
                                        ObjectGridManagerFactory.getObjectGridManager();
        ObjectGrid ivObjectGrid =
                                        objectGridManager.createObjectGrid("objectgridName");

        // Add a TransactionCallback into ObjectGrid
        HeapTransactionCallback tcb = new HeapTransactionCallback();
        ivObjectGrid.setTransactionCallback(tcb);

        // Define a BackingMap
        // if the BackingMap is configured in ObjectGrid xml
        // file, you can just get it.
        BackingMap ivBackingMap = ivObjectGrid.defineMap("myMap");

        // Add a Loader into BackingMap
        Loader ivLoader = new HeapCacheLoader();
        ivBackingMap.setLoader(ivLoader);

        // initialize ObjectGrid
        ivObjectGrid.initialize();

        // Obtain a session to be used by the current thread.
        // Session can not be shared by multiple threads
        Session ivSession = ivObjectGrid.getSession();

        // Obtaining ObjectMap from ObjectGrid Session
        ObjectMap objectMap = ivSession.getMap("myMap");
```

Default shared configuration

The following code is a simple case of creating an ObjectGrid to share among many users.

```
import com.ibm.websphere.objectgrid.ObjectGrid;
import com.ibm.websphere.objectgrid.ObjectGridException;
import com.ibm.websphere.objectgrid.ObjectGridManagerFactory;
import com.ibm.websphere.objectgrid.ObjectGridManager;
final ObjectGridManager oGridManager=
                ObjectGridManagerFactory.getObjectGridManager();
ObjectGrid employees =
        oGridManager.createObjectGrid("Employees",true);
employees.initialize();
employees.
/*sample continues..*/
```

The preceding Java™ code snippet creates and caches the Employees ObjectGrid. The Employees ObjectGrid is initialized with the default configuration and is ready for use. The second parameter in the createObjectGrid method is set to true, which instructs the ObjectGridManager to cache the ObjectGrid instance it creates. If this parameter is set to false, the instance is not cached. Every ObjectGrid instance has a name, and the instance can be shared among many clients or users based on that name.

If the objectGrid instance is used in peer-to-peer sharing, the caching must be set to true. For more information on peer-to-peer sharing, see Distributing changes between peer Java Virtual Machines.

XML configuration

WebSphere® eXtreme Scale is highly configurable. The previous example demonstrates how to create a simple ObjectGrid without any configuration. This example shows you how to create a pre-configured ObjectdGrid instance that is based on an XML configuration file. You can configure an ObjectGrid instance programmatically or using an XML-based configuration file. You can also configure ObjectGrid using a combination of both approaches. The ObjectGridManager interface allows creation of an ObjectGrid instance based on the XML configuration. The ObjectGridManager interface has several methods that take a URL as an argument. Every XML file that is passed into the ObjectGridManager must be validated against the schema. XML validation can be disabled only when the file is previously validated and no changes have been made to the file since its last validation. Disabling validation saves a small amount of overhead but introduces the possibility of using an invalid XML file. The IBM® Java Developer Kit (JDK)Version 5 or later has support for XML validation. When using a JDK that does not have this support, Apache Xerces might be required to validate the XML.

The following Java code snippet demonstrates how to pass in an XML configuration file to create an ObjectGrid.

```
import java.net.MalformedURLException;
import java.net.URL;
import com.ibm.websphere.objectgrid.ObjectGrid;
import com.ibm.websphere.objectgrid.ObjectGridException;
import com.ibm.websphere.objectgrid.ObjectGridManager;
import com.ibm.websphere.objectgrid.ObjectGridManagerFactory;
boolean validateXML = true; // turn XML validation on
boolean cacheInstance = true; // Cache the instance
String objectGridName="Employees"; // Name of Object Grid URL
allObjectGrids = new URL("file:test/myObjectGrid.xml");
final ObjectGridManager oGridManager=
        ObjectGridManagerFactory.getObjectGridManager();
 ObjectGrid employees =
        oGridManager.createObjectGrid(objectGridName, allObjectGrids,
                bvalidateXML, cacheInstance);
```

The XML file can contain configuration information for several ObjectGrids. The previous code snippet specifically returns ObjectGrid Employees, assuming that the Employees configuration is defined in the file.

createObjectGrid methods

.

```
/**
 * A simple factory method to return an instance of an
 * Object Grid. A unique name is assigned.
 * The instance of ObjectGrid is not cached.
 * Users can then use {@link ObjectGrid#setName(String)} to change the
 * ObjectGrid name.
 *
 * @return ObjectGrid an instance of ObjectGrid with a unique name assigned
 * @throws ObjectGridException any error encountered during the
 * ObjectGrid creation
 */
public ObjectGrid createObjectGrid() throws ObjectGridException;

/**
 * A simple factory method to return an instance of an ObjectGrid with the
 * specified name. The instances of ObjectGrid can be cached. If an ObjectGrid
 * with the this name has already been cached, an ObjectGridException
 * will be thrown.
 *
 * @param objectGridName the name of the ObjectGrid to be created.
 * @param cacheInstance true, if the ObjectGrid instance should be cached
 * @return an ObjectGrid instance
 * @this name has already been cached or
 * any error during the ObjectGrid creation.
 */
public ObjectGrid createObjectGrid(String objectGridName, boolean cacheInstance)
                throws ObjectGridException;

/**
 * Create an ObjectGrid instance with the specified ObjectGrid name. The
 * ObjectGrid instance created will be cached.
 * @param objectGridName the Name of the ObjectGrid instance to be created.
 * @return an ObjectGrid instance
 * @throws ObjectGridException if an ObjectGrid with this name has already
 * been cached, or any error encountered during the ObjectGrid creation
 */
public ObjectGrid createObjectGrid(String objectGridName)
                throws ObjectGridException;

/**
 * Create an ObjectGrid instance based on the specified ObjectGrid name and the
```

```

Retrieving a ObjectGrid instance with the ObjectGridManager interface

Use the ObjectGridManager.getObjectGrid methods to retrieve cached instances.

Retrieving a cached instance

Since the Employees ObjectGrid instance was cached by the ObjectGridManager interface, another user can access it with the following code snippet:

```
ObjectGrid myEmployees = oGridManager.getObjectGrid("Employees");
```

The following two getObjectGrid methods return cached ObjectGrid instances:

- **Retrieving all cached instances**
  To obtain all of the ObjectGrid instances that have been previously cached, use the getObjectGrids method, which returns a list of each instance. If no cached instances exist, the method will return null.
- **Retrieving a cached instance by name**
  To obtain a single cached instance of an ObjectGrid, use getObjectGrid(String objectGridName), passing the name of the cached instance into the method. The method either returns the ObjectGrid instance with the specified name or returns null if there is no ObjectGrid instance with that name.

Note: You can also use the getObjectGrid method to connect to a distributed grid. See Connecting to distributed ObjectGrid instances programmatically for more information.

Removing ObjectGrid instances with the ObjectGridManager interface

You can use two different removeObjectGrid methods to remove ObjectGrid instances from the cache.

Remove an ObjectGrid instance

To remove ObjectGrid instances from the cache, use one of the removeObjectGrid methods. The ObjectGridManager interface does not keep a reference of the instances that are removed. Two remove methods exist. One method takes a boolean parameter. If the boolean parameter is set to `true`, the destroy method is called on the ObjectGrid. The call to the destroy method on the ObjectGrid shuts down the ObjectGrid and frees up any resources the ObjectGrid is using. A description of how to use the two removeObjectGrid methods follows:

```
/**
 * Remove an ObjectGrid from the cache of ObjectGrid instances
 *
 * @param objectGridName the name of the ObjectGrid instance to remove
 * from the cache
 *
 * @throws ObjectGridException if an ObjectGrid with the objectGridName
 * was not found in the cache
 */
public void removeObjectGrid(String objectGridName) throws ObjectGridException;

/**
 * Remove an ObjectGrid from the cache of ObjectGrid instances and
 * destroy its associated resources
 *
 * @param objectGridName the name of the ObjectGrid instance to remove
 * from the cache
 *
 * @param destroy destroy the objectgrid instance and its associated
 * resources
 *
 * @throws ObjectGridException if an ObjectGrid with the objectGridName
 * was not found in the cache
 */
public void removeObjectGrid(String objectGridName, boolean destroy)
        throws ObjectGridException;
```

Controlling the lifecycle of an ObjectGrid with the ObjectGridManager interface

You can use the ObjectGridManager interface to control the lifecycle of an ObjectGrid instance using either a startup bean or a servlet.

Managing lifecycle with a startup bean

A startup bean is used to control the lifecycle of an ObjectGrid instance. A startup bean loads when an application starts. With a startup bean, code can run whenever an application starts or stops as expected. To create a startup bean, use the home com.ibm.websphere.startupservice.AppStartUpHome interface and use the remote com.ibm.websphere.startupservice.AppStartUp interface. Implement the start and stop methods on the bean. The start method is invoked whenever the application starts up. The stop method is invoked when the application shuts down. The start method is used to create ObjectGrid instances. The stop method is used to remove ObjectGrid instances. A code snippet that demonstrates this ObjectGrid lifecycle management in a startup bean follows:

```
public class MyStartupBean implements javax.ejb.SessionBean {
    private ObjectGridManager objectGridManager;

    /* The methods on the SessionBean interface have been
```

```
     * left out of this example for the sake of brevity */

    public boolean start(){
        // Starting the startup bean
        // This method is called when the application starts
        objectGridManager = ObjectGridManagerFactory.getObjectGridManager();
        try {
            // create 2 ObjectGrids and cache these instances
            ObjectGrid bookstoreGrid = objectGridManager.createObjectGrid("bookstore", true);
            bookstoreGrid.defineMap("book");
            ObjectGrid videostoreGrid = objectGridManager.createObjectGrid("videostore", true);
            // within the JVM,
            // these ObjectGrids can now be retrieved from the
            //ObjectGridManager using the getObjectGrid(String) method
        } catch (ObjectGridException e) {
            e.printStackTrace();
            return false;
        }

        return true;
    }

    public void stop(){
        // Stopping the startup bean
        // This method is called when the application is stopped
        try {
            // remove the cached ObjectGrids and destroy them
            objectGridManager.removeObjectGrid("bookstore", true);
            objectGridManager.removeObjectGrid("videostore", true);
        } catch (ObjectGridException e) {
            e.printStackTrace();
        }
    }
}
```

After the start method is called, the newly created ObjectGrid instances are retrieved from the ObjectGridManager interface. For example, if a servlet is included in the application, the servlet accesses the eXtreme Scale using the following code snippet:

```
ObjectGridManager objectGridManager =
        ObjectGridManagerFactory.getObjectGridManager();
ObjectGrid bookstoreGrid = objectGridManager.getObjectGrid("bookstore");
ObjectGrid videostoreGrid = objectGridManager.getObjectGrid("videostore");
```

Managing lifecycle with a servlet

To manage the lifecycle of an ObjectGrid in a servlet, you can use the init method to create an ObjectGrid instance and the destroy method to remove the ObjectGrid instance. If the ObjectGrid instance is cached, it is retrieved and manipulated in the servlet code. Sample code that demonstrates ObjectGrid creation, manipulation, and destruction within a servlet follows:

```
public class MyObjectGridServlet extends HttpServlet implements Servlet {
    private ObjectGridManager objectGridManager;

    public MyObjectGridServlet() {
        super();
    }

    public void init(ServletConfig arg0) throws ServletException {
        super.init();
        objectGridManager = ObjectGridManagerFactory.getObjectGridManager();
        try {
            // create and cache an ObjectGrid named bookstore
            ObjectGrid bookstoreGrid =
                                        objectGridManager.createObjectGrid("bookstore", true);
            bookstoreGrid.defineMap("book");
        } catch (ObjectGridException e) {
            e.printStackTrace();
        }
    }

    protected void doGet(HttpServletRequest req, HttpServletResponse res)
        throws ServletException, IOException {
        ObjectGrid bookstoreGrid = objectGridManager.getObjectGrid("bookstore");
        Session session = bookstoreGrid.getSession();
        ObjectMap bookMap = session.getMap("book");
        // perform operations on the cached ObjectGrid
        // ...
        // Close the session (optional in Version 7.1.1 and later) for improved performance
        session.close();
         }
    public void destroy() {
        super.destroy();
        try {
            // remove and destroy the cached bookstore ObjectGrid
            objectGridManager.removeObjectGrid("bookstore", true);
        } catch (ObjectGridException e) {
            e.printStackTrace();
        }
    }
}
```

Accessing the ObjectGrid shard

WebSphere® eXtreme Scale achieves high processing rates by moving the logic to where the data is and returning only results back to the client.

Application logic in a client Java™ virtual machine (JVM) needs to pull data from the server JVM that is holding the data and push it back when the transaction commits. This process slows down the rate the data can be processed. If the application logic was on the same JVM as the shard that is holding the data, then the network latency and marshalling cost is eliminated and can provide a significant performance boost.

Local reference to shard data

The ObjectGrid APIs provide a Session to the server-side method. This session is a direct reference to the data for that shard. No routing logic is on that path. The application logic can work with the data for that shard directly. The session cannot be used to access data in another partition because no routing logic exists.

A Loader plug-in also provides a way to receive an event when a shard becomes a primary partition. An application can implement a Loader and implement the ReplicaPreloadController interface. The check preload status method is only called when a shard becomes a primary. The session provided to that method is a local reference to the shards data. This approach is typically used if a partition primary needs to start some threads or subscribe to a message fabric for partition-related traffic. It might start a thread to listen for messages in a local Map using the getNextKey API.

Collocated client-server optimization

If an application uses the client APIs to access a partition that happens to be collocated with the JVM that contains the client, then the network is avoided but some marshalling still occurs because of current implementation issues. If a partitioned grid is used, then no impact on the performance of the application is made because (N-1)/N number of calls route to a different JVM. If you need local access always with a shard, then use the Loader or ObjectGrid APIs to invoke that logic.

Accessing data with indexes (Index API)

Use indexing for more efficient data access.

About this task

The HashIndex class is the built-in index plug-in implementation that can support both of the built-in application index interfaces: MapIndex and MapRangeIndex. You also can create your own indexes. You can add HashIndex as either a static or dynamic index into the backing map, obtain either MapIndex or MapRangeIndex index proxy object, and use the index proxy object to find cached objects.

If you want to iterate through the keys in a local map, you can use the default index. This index does not require any configuration, but it must be used against the shard, using an agent or an ObjectGrid instance retrieved from the ShardEvents.shardActivated(ObjectGrid shard) method.

Note: In a distributed environment, if the index object is obtained from a client ObjectGrid, the index has a type client index object and all index operations run in a remote server ObjectGrid. If the map is partitioned, the index operations run on each partition remotely. The results from each partition are merged before returning the results to the application. The performance is determined by the number of partitions and the size of the result returned by each partition. Poor performance might occur if both factors are high.

Procedure

1. If you want to use indexes other than the default local index, add index plug-ins to the backing map.
   - **XML configuration:**

```
<backingMapPluginCollection
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsidxnonkey_person">
     <bean
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.websphere.extremescale.doc_txsidxnonkey_MapIndexplugin
"
                        className="com.ibm.websphere.objectgrid.plugins.index.HashIndex">
        <property name="Name" type="java.lang.String" value="CODE"
                                              description="index name" />
        <property name="RangeIndex" type="boolean" value="true"
                                              description="true for MapRangeIndex" />
        <property name="AttributeName" type="java.lang.String" value="employeeCode"
                                              description="attribute name" />
     </bean>
</backingMapPluginCollection>
```

     In this XML configuration example, the built-in HashIndex class is used as the index plug-in. The HashIndex class supports properties that users can configure, such as Name, RangeIndex, and AttributeName in the previous example.

     - The Name property is configured as `CODE`, a string identifying this index plug-in. The Name property value must be unique within the scope of the BackingMap, and can be used to retrieve the index object by name from the ObjectMap instance for the BackingMap.
     - The RangeIndex property is configured as `true`, which means the application can cast the retrieved index object to the MapRangeIndex interface. If the RangeIndex property is configured as `false`, the application can only cast the retrieved index object to the MapIndex interface. A MapRangeIndex supports functions to find data using range functions such as greater than, less than, or both, while a MapIndex

only supports equals functions. If the index is used by query, the RangeIndex property must be configured to `true` on single-attribute indexes. For a relationship index and composite index, the RangeIndex property must be configured to `false`.
    - The AttributeName property is configured as `employeeCode`, which means the employeeCode attribute of the cached object is used to build a single-attribute index. If an application needs to search for cached objects with multiple attributes, the AttributeName property can be set to a comma-delimited list of attributes, yielding a composite index.
- **Programmatic configuration:**
  The BackingMap interface has two methods that you can use to add static index plug-ins: addMapIndexplugin and setMapIndexplugins. For more information, see BackingMap API. The following example creates the same configuration as the XML configuration example:

```
import com.ibm.websphere.objectgrid.ObjectGridManagerFactory;
import com.ibm.websphere.objectgrid.ObjectGridManager;
import com.ibm.websphere.objectgrid.ObjectGrid;
import com.ibm.websphere.objectgrid.BackingMap;

    ObjectGridManager ogManager = ObjectGridManagerFactory.getObjectGridManager();
    ObjectGrid ivObjectGrid = ogManager.createObjectGrid( "grid" );
    BackingMap personBackingMap = ivObjectGrid.getMap("person");

    // use the builtin HashIndex class as the index plugin class.
    HashIndex mapIndexplugin = new HashIndex();
    mapIndexplugin.setName("CODE");
    mapIndexplugin.setAttributeName("EmployeeCode");
    mapIndexplugin.setRangeIndex(true);
    personBackingMap.addMapIndexplugin(mapIndexplugin);
```

2. Access map keys and values with indexes.
    - **Local index:**
      To iterate through the keys and values in a local map, you can use the default index. The default index only works against the shard, using an agent or using the ObjectGrid instance retrieved from the ShardEvents.shardActivated(ObjectGrid shard) method. See the following example:

```
MapIndex keyIndex = (MapIndex)
objMap.getIndex(MapIndexPlugin.SYSTEM_KEY_INDEX_NAME);
Iterator keyIterator = keyIndex.findAll();
```

    - **Static indexes:**
      After a static index plug-in is added to a BackingMap configuration and the containing ObjectGrid instance is initialized, applications can retrieve the index object by name from the ObjectMap instance for the BackingMap. Cast the index object to the application index interface. Operations that the application index interface supports can now run.

```
Session session = ivObjectGrid.getSession();
ObjectMap map = session.getMap("person ");
MapRangeIndex codeIndex = (MapRangeIndex) m.getIndex("CODE");
Iterator iter = codeIndex.findLessEqual(new Integer(15));
while (iter.hasNext()) {
                Object key = iter.next();
                Object value = map.get(key);
}
// Close the session (optional in Version 7.1.1 and later) for improved performance
session.close();
```

    - **Dynamic indexes:**
      You can create and remove dynamic indexes from a BackingMap instance programmatically at any time. A dynamic index differs from a static index in that the dynamic index can be created even after the containing ObjectGrid instance is initialized. Unlike static indexing, the dynamic indexing is an asynchronous process, which requires the dynamic index to be in ready state before you use it. This method uses the same approach for retrieving and using the dynamic indexes as static indexes. You can remove a dynamic index if it is no longer needed. The BackingMap interface has methods to create and remove dynamic indexes.

      See the BackingMap API for more information about the createDynamicIndex and removeDynamicIndex methods.

```
import com.ibm.websphere.objectgrid.ObjectGridManagerFactory;
import com.ibm.websphere.objectgrid.ObjectGridManager;
import com.ibm.websphere.objectgrid.ObjectGrid;
import com.ibm.websphere.objectgrid.BackingMap;

        ObjectGridManager ogManager = ObjectGridManagerFactory.getObjectGridManager();
        ObjectGrid og = ogManager.createObjectGrid("grid");        BackingMap bm = og.getMap("person");
        og.initialize();
        // create index after ObjectGrid initialization without DynamicIndexCallback.
        bm.createDynamicIndex("CODE", true, "employeeCode", null);

        try {
            // If not using DynamicIndexCallback, need to wait for the Index to be ready.
            // The waiting time depends on the current size of the map
            Thread.sleep(3000);
        } catch (Throwable t) {
            // ...
        }

        // When the index is ready, applications can try to get application index
        // interface instance.
        // Applications have to find a way to ensure that the index is ready to use,
        // if not using DynamicIndexCallback interface.
        // The following example demonstrates the way to wait for the index to be ready
        // Consider the size of the map in the total waiting time.

        Session session = og.getSession();
        ObjectMap m = session.getMap("person");
```

```
        MapRangeIndex codeIndex = null;

        int counter = 0;
        int maxCounter = 10;
        boolean ready = false;
        while (!ready && counter < maxCounter) {
            try {
                counter++;
                codeIndex = (MapRangeIndex) m.getIndex("CODE");
                ready = true;
            } catch (IndexNotReadyException e) {
                // implies index is not ready, ...
                System.out.println("Index is not ready. continue to wait.");
                try {
                    Thread.sleep(3000);
                } catch (Throwable tt) {
                    // ...
                }
            } catch (Throwable t) {
                // unexpected exception
                t.printStackTrace();
            }
        }

        if (!ready) {
            System.out.println("Index is not ready.  Need to handle this situation.");
        }

        // Use the index to peform queries
        // Refer to the MapIndex or MapRangeIndex interface for supported operations.
        // The object attribute on which the index is created is the EmployeeCode.
        // Assume that the EmployeeCode attribute is Integer type: the
        // parameter that is passed into index operations has this data type.

        Iterator iter = codeIndex.findLessEqual(new Integer(15));

        // remove the dynamic index when no longer needed

        bm.removeDynamicIndex("CODE");
        // Close the session (optional in Version 7.1.1 and later) for improved performance
        session.close();
```

What to do next

You can use the DynamicIndexCallback interface to get notifications at the indexing events. See DynamicIndexCallback interface for more information.

- DynamicIndexCallback interface
  The DynamicIndexCallback interface is designed for applications that want to get notifications at the indexing events of ready, error, or destroy. The DynamicIndexCallback is an optional parameter for the createDynamicIndex method of the BackingMap. With a registered DynamicIndexCallback instance, applications can run business logic upon receiving notification of an indexing event.

DynamicIndexCallback interface

The DynamicIndexCallback interface is designed for applications that want to get notifications at the indexing events of ready, error, or destroy. The DynamicIndexCallback is an optional parameter for the createDynamicIndex method of the BackingMap. With a registered DynamicIndexCallback instance, applications can run business logic upon receiving notification of an indexing event.

Indexing events

For example, the ready event means that the index is ready for use. When a notification for this event is received, an application can try to retrieve and use the application index interface instance.

Example: Using the DynamicIndexCallback interface

```
BackingMap personBackingMap = ivObjectGrid.getMap("person");
    DynamicIndexCallback callback = new DynamicIndexCallbackImpl();
    personBackingMap.createDynamicIndex("CODE", true, "employeeCode", callback);

    class DynamicIndexCallbackImpl implements DynamicIndexCallback {
        public DynamicIndexCallbackImpl() {
        }

        public void ready(String indexName) {
            System.out.println("DynamicIndexCallbackImpl.ready() -> indexName = " + indexName);

            // Simulate what an application would do when notified that the index is ready.
            // Normally, the application would wait until the ready state is reached and then proceed
            // with any index usage logic.
            if("CODE".equals(indexName)) {
                ObjectGridManager ogManager = ObjectGridManagerFactory.getObjectGridManager();
                ObjectGrid og = ogManager.createObjectGrid( "grid" );
                Session session = og.getSession();
                ObjectMap map = session.getMap("person");
                MapIndex codeIndex = (MapIndex) map.getIndex("CODE");
                Iterator iter = codeIndex.findAll(codeValue);
                // Close the session (optional in Version 7.1.1 and later) for improved performance
                session.close();
                                        }
        }

        public void error(String indexName, Throwable t) {
            System.out.println("DynamicIndexCallbackImpl.error() -> indexName = " + indexName);
            t.printStackTrace();
        }

        public void destroy(String indexName) {
            System.out.println("DynamicIndexCallbackImpl.destroy() -> indexName = " + indexName);
        }
    }
```

Using Sessions to access data in the grid

Your applications can begin and end transactions through the Session interface. The Session interface also provides access to the application-based ObjectMap and JavaMap interfaces.

Each ObjectMap or JavaMap instance is directly tied to a specific Session object. Each thread that wants access to an eXtreme Scale must first obtain a Session instance from the ObjectGrid object. A Session instance cannot be shared concurrently between threads. WebSphere® eXtreme Scale does not use any thread local storage, but platform restrictions might limit the opportunity to pass a Session instance from one thread to another.

Methods

Get method

An application obtains a Session instance from an ObjectGrid object using the ObjectGrid.getSession method. The following example demonstrates how to obtain a Session instance:

```
ObjectGrid objectGrid = ...;
Session sess = objectGrid.getSession();
```

After a Session instance is obtained, the thread keeps a reference to the session for its own use. Calling the getSession method multiple times returns a new Session object each time.

Transactions and Session methods

A Session can be used to begin, commit, or rollback transactions. Operations against BackingMaps using ObjectMaps and JavaMaps are most efficiently performed within a Session transaction. After a transaction has started, any changes to one or more BackingMaps in that transaction scope are stored in a special transaction cache until the transaction is committed. When a transaction is committed, the pending changes are applied to the BackingMaps and Loaders and become visible to any other clients of that ObjectGrid.

WebSphere eXtreme Scale also supports the ability to automatically commit transactions, also known as auto-commit. If any ObjectMap operations are performed outside of the context of an active transaction, an implicit transaction is started before the operation and the transaction is automatically committed before returning control to the application.

```
Session session = objectGrid.getSession();
ObjectMap objectMap = session.getMap("someMap");
session.begin();
objectMap.insert("key1", "value1");
objectMap.insert("key2", "value2");
session.commit();
objectMap.insert("key3", "value3"); // auto-commit
```

Session.flush method

The Session.flush method only makes sense when a Loader is associated with a BackingMap. The flush method invokes the Loader with the current set of changes in the transaction cache. The Loader applies the changes to the backend. These changes are not committed when the flush is invoked. If a Session transaction is committed after a flush invocation, only updates that happen after the flush invocation are applied to the Loader. If a Session transaction is rolled back after a flush invocation, the flushed changes are discarded with all other pending changes in the transaction. Use the Flush method sparingly because it limits the opportunity for batch operations against a Loader. Following is an example of the usage of the Session.flush method:

```
Session session = objectGrid.getSession();
session.begin();
// make some changes
...
session.flush(); // push these changes to the Loader, but don't commit yet
// make some more changes
...
session.commit();
```

NoWriteThrough method

Some maps are backed by a Loader, which provides persistent storage for the data in the map. Sometimes it is useful to commit data just to the backing map and not push data out to the Loader. The Session interface provides the beginNoWriteThough method for this purpose. The beginNoWriteThrough method starts a transaction like the begin method. With the beginNoWriteThrough method, when the transaction is committed, the data is only committed to the in-memory map and is not committed to the persistent storage that is provided by the Loader. This method is very useful when performing data preload on the map.

When using a distributed ObjectGrid instance, the beginNoWriteThrough method is useful for making changes to the near cache only, without modifying the far cache on the server. If the data is known to be stale in the near cache, using the beginNoWriteThrough method can allow entries to be invalidated on the near cache without invalidating them on the server as well.

The Session interface also provides the isWriteThroughEnabled method to determine what type of transaction is currently active.

```
Session session = objectGrid.getSession();
session.beginNoWriteThrough();
// make some changes ...
session.commit(); // these changes will not get pushed to the Loader
```

Obtain the TxID object method

The TxID object is an opaque object that identifies the active transaction. Use the TxID object for the following purposes:

- For comparison when you are looking for a particular transaction.
- To store shared data between the TransactionCallback and Loader objects.

For more information, see Introduction to plug-in slots.

Performance monitoring method

If you are using eXtreme Scale within WebSphere Application Server, it might be necessary to reset the transaction type for performance monitoring. You can set the transaction type with the setTransactionType method. See Monitoring ObjectGrid performance with WebSphere Application Server performance monitoring infrastructure (PMI) for more information about the setTransactionType method.

Process a complete LogSequence method

WebSphere eXtreme Scale can propagate sets of map changes to ObjectGrid listeners as a means of distributing maps from one Java™ virtual machine to another. To make it easier for the listener to process the received LogSequences, the Session interface provides the processLogSequence method. This method examines each LogElement within the LogSequence and performs the appropriate operation, for example, insert, update, invalidate, and so on, against the BackingMap that is identified by the LogSequence MapName. An ObjectGrid Session must be available before the processLogSequence method is invoked. The application is also responsible for issuing the appropriate commit or rollback calls to complete the Session. Autocommit processing is not available for this method invocation. Normal processing by the receiving ObjectGridEventListener at the remote JVM would be to start a Session using the beginNoWriteThrough method, which prevents endless propagation of changes, followed by a call to this processLogSequence method, and then committing or rolling back the transaction.

```
// Use the Session object that was passed in during
//ObjectGridEventListener.initialization...
session.beginNoWriteThrough();
// process the received LogSequence
try {
        session.processLogSequence(receivedLogSequence);
} catch (Exception e) {
        session.rollback(); throw e;
}
// commit the changes
session.commit();
```

markRollbackOnly method

This method is used to mark the current transaction as "rollback only". Marking a transaction "rollback only" ensures that even if the commit method is called by application, the transaction is rolled back. This method is typically used by ObjectGrid itself or by the application when it knows that data corruption could occur if the transaction was allowed to be committed. After this method is called, the Throwable object that is passed to this method is chained to the com.ibm.websphere.objectgrid.TransactionException exception that results by the commit method if it is called on a Session that was previously marked a "rollback only". Any subsequent calls to this method for a transaction that is already marked as "rollback only" is ignored. That is, only the first call that passes a non-null Throwable reference is used. Once the marked transaction is completed, the "rollback only" mark is removed so that the next transaction that is started by the Session can be committed.

isMarkedRollbackOnly method

Returns if Session is currently marked as "rollback only". Boolean true is returned by this method if and only if markRollbackOnly method was previously called on this Session and the transaction started by the Session is still active.

setTransactionTimeout method

Set transaction timeout for next transaction started by this Session to a specified number of seconds. This method does not affect the transaction timeout of any transactions previously started by this Session. It only affects transactions that are started after this method is called. If this method is never called, then the timeout value that was passed to the setTxTimeout method of the com.ibm.websphere.objectgrid.ObjectGrid method is used.

getTransactionTimeout method

This method returns the transaction timeout value in seconds. The last value that was passed as the timeout value to the setTransactionTimeout method is returned by this method. If the setTransactionTimeout method is never called, then the timeout value that was passed to the setTxTimeout method of the com.ibm.websphere.objectgrid.ObjectGrid method is used.

transactionTimedOut method

This method returns boolean true if the current transaction that was started by this Session has timed out.

isFlushing method

This method returns boolean true if and only if all transaction changes are being flushed out to the Loader plug-in as a result of the flush method of Session interface being invoked. A Loader plug-in may find this method useful when it needs to know why its batchUpdate method was invoked.

isCommitting method

This method returns boolean true if and only if all transaction changes are being committed as a result of the commit method of Session interface being invoked. A Loader plug-in might find this method useful when it needs to know why its batchUpdate method was invoked.

setRequestRetryTimeout method

This method sets the request retry timeout value for the Session in milliseconds. If the client set a request retry timeout, the Session setting overrides the client value.

getRequestRetryTimeout method

This method gets the current request retry timeout setting on the Session. A value of `-1` indicates that the timeout is not set. A value of `0` indicates it is in fail-fast mode. A value greater than `0` indicates the timeout setting in milliseconds.

- SessionHandle for routing
  When you are using a per-container partition placement policy, you can use a SessionHandle object. A SessionHandle object contains partition information for the current Session and can be reused for a new Session.
- SessionHandle integration
  A SessionHandle object includes the partition information for the Session to which it is bound and facilitates request routing. SessionHandle objects apply to the per-container partition placement scenario only.

Related tasks:
Configuring request and retry timeout values

SessionHandle for routing

When you are using a per-container partition placement policy, you can use a SessionHandle object. A SessionHandle object contains partition information for the current Session and can be reused for a new Session.

A SessionHandle object includes information for the partition to which the current Session is bound. SessionHandle is extremely useful for the per-container partition placement policy and can be serialized with standard Java™ serialization.

If you have a SessionHandle object, you can apply that handle to a Session with the setSessionHandle(SessionHandle target) method, passing the handle in as the target. You can retrieve the SessionHandle object with the Session.getSessionHandle method.

Because it is only applicable in a per-container placement scenario, getting the SessionHandle object throws an IllegalStateException if a given data grid has multiple per-container map sets or has no per-container map sets. If you do not invoke the setSessionHandle method before calling the getSessionHandle method, the appropriate SessionHandle object is selected based on your client properties configuration.

You can also use the SessionHandleTransformer helper class to convert the handle into different formats. The methods of this class can change a handle's representation from byte array to instance, string to instance, and vice versa for both cases, and can also write the handle's contents into the output stream.

For an example on how you can use a SessionHandle object, see Zone-preferred routing.

SessionHandle integration

A SessionHandle object includes the partition information for the Session to which it is bound and facilitates request routing. SessionHandle objects apply to the per-container partition placement scenario only.

SessionHandle object for request routing

You can bind a SessionHandle object to a Session in the following ways:

Tip: In each of the following method calls, after a SessionHandle object is bound to a Session, the SessionHandle object can be obtained from the Session.getSessionHandle method.

- **Call the Session.getSessionHandle method:** When this method is called, if no SessionHandle object is bound to the Session, a SessionHandle object is selected randomly and bound to the Session.
- **Call transactional create, read, update, delete operations:** When these methods are called or at commit time, if no SessionHandle object is bound to the Session, a SessionHandle object is selected randomly and bound to the Session.
- **Call ObjectMap.getNextKey method:** When this method is called, if no SessionHandle object is bound to the Session, the operation request is randomly routed to individual partitions until a key is obtained. If a key is returned from a partition, a SessionHandle object that corresponds to that partition is bound to the Session. If no key is found, no SessionHandle is bound to the Session.
- **Call the QueryQueue.getNextEntity or QueryQueue.getNextEntities methods:** At the time this method is called, if no SessionHandle object is bound to the Session, the operation request is randomly routed to individual partitions until an object is obtained. If an object is returned from a partition, a SessionHandle object that corresponds to that partition is bound to the Session. If no object is found, no SessionHandle is bound to the Session.
- **Set a SessionHandle with the Session.setSessionHandle(SessionHandle sh) method:** If a SessionHandle is obtained from the Session.getSessionHandle method, the SessionHandle can be bound to a Session. Setting a SessionHandle influences request routing within the scope of the Session to which it is bound.

The Session.getSessionHandle method always returns a SessionHandle object. The method also automatically binds a SessionHandle on the Session if no SessionHandle object is bound to the Session. If you want to verify whether a Session has a SessionHandle object only , call the Session.isSessionHandleSet method. If this method returns a value of `false`, no SessionHandle object is currently bound to the Session.

Major operation types in the per-container placement scenario

A summary of the routing behavior of major operation types in the per-container partition placement scenario with respect to SessionHandle objects follows.

- **Session object with bound SessionHandle object**
  - Index - MapIndex and MapRangeIndex API: SessionHandle
  - Query and ObjectQuery: SessionHandle
  - Agent - MapGridAgent and ReduceGridAgent API: SessionHandle
  - ObjectMap.Clear: SessionHandle
  - ObjectMap.getNextKey: SessionHandle
  - QueryQueue.getNextEntity, QueryQueue.getNextEntities: SessionHandle
  - Transactional create, retrieve, update, and delete operations (ObjectMap API and EntityManager API): SessionHandle
- **Session object without bound SessionHandle object**
  - Index - MapIndex and MapRangeIndex API: All current active partitions
  - Query and ObjectQuery: Specified partition with setPartition method of Query and ObjectQuery
  - Agent - MapGridAgent and ReduceGridAgent
    - Not supported: ReduceGridAgent.reduce(Session s, ObjectMap map, Collection keys) and MapGridAgent.process(Session s, ObjectMap map, Object key) method.
    - All current active partitions: ReduceGridAgent.reduce(Session s, ObjectMap map) and MapGridAgent.processAllEntries(Session s, ObjectMap map) method.
  - ObjectMap.clear: All current active partitions.
  - ObjectMap.getNextKey: Binds a SessionHandle to the Session if a key is returned from one of the randomly selected partitions. If no key is returned, the Session is not bound to a SessionHandle.
  - QueryQueue: Specifies a partition with the QueryQueue.setPartition method. If no partition is set, the method randomly selects a partition to return. If an object is returned, the current Session is bound with the SessionHandle that is bound to the partition that returns the object. If no object is returned, the Session is not bound to a SessionHandle.
  - Transactional create, retrieve, update, and delete operations (ObjectMap API and EntityManager API): Randomly select a partition.

  In most cases, use SessionHandle to control routing to a particular partition. You can retrieve and cache the SessionHandle from the Session that inserts data. After caching the SessionHandle, you can set it on another Session so that you can route requests to the partition specified by the cached SessionHandle. To perform operations such as ObjectMap.clear without SessionHandle, you can temporarily set the SessionHandle to null by calling Session.setSessionHandle(null). Without a specified SessionHandle, operations run on all current active partitions.

- **QueryQueue routing behavior**
  In the per-container partition placement scenario, you can use SessionHandle to control routing of getNextEntity and getNextEntities methods of the QueryQueue API. If the Session is bound to a SessionHandle, requests route to the partition to which the SessionHandle is bound. If the Session is not bound to a SessionHandle, requests are routed to the partition set with the QueryQueue.setPartition method if a partition has been set in this way. If the Session has no bound SessionHandle or partition, a randomly selected partition are returned. If no such partition is found, the process stops and no SessionHandle is bound to the current Session.

The following snippet of code shows how to use SessionHandle objects.

```
Session ogSession = objectGrid.getSession();

// binding the SessionHandle
SessionHandle sessionHandle = ogSession.getSessionHandle();

ogSession.begin();
ObjectMap map = ogSession.getMap("planet");
map.insert("planet1", "mercury");

// transaction is routed to partition specified by SessionHandle
ogSession.commit();

// cache the SessionHandle that inserts data
SessionHandle cachedSessionHandle = ogSession.getSessionHandle();
```

```
// verify if SessionHandle is set on the Session
boolean isSessionHandleSet = ogSession.isSessionHandleSet();

// temporarily unbind the SessionHandle from the Session
if(isSessionHandleSet) {
    ogSession.setSessionHandle(null);
}

// if the Session has no SessionHandle bound,
// the clear operation will run on all current active partitions
// and thus remove all data from the map in the entire grid
map.clear();

// after clear is done, reset the SessionHandle back,
// if the Session needs to use previous SessionHandle.
// Optionally, calling getSessionHandle can get a new SessionHandle
ogSession.setSessionHandle(cachedSessionHandle);
```

Application design considerations

In the per-container placement strategy scenario, use the SessionHandle object for most operations. The SessionHandle object controls routing to partitions. To retrieve data, the SessionHandle object that you bind to the Session must be same SessionHandle object from any insert data transaction.

When you want to perform an operation without a SessionHandle set on the Session, you can unbind a SessionHandle from a Session by making a Session.setSessionHandle(null) method call.

When a Session is bound to a SessionHandle, all operation requests route to the partition that is specified by the SessionHandle object. Without the SessionHandle object set, operations route to either all partitions or a randomly selected partition.

Caching objects with no relationships involved (ObjectMap API)

ObjectMaps are like Java™ Maps that allow data to be stored as key-value pairs. ObjectMaps provide a simple and intuitive approach for the application to store data. An ObjectMap is ideal for caching objects that have no relationships involved. If object relationships are involved, then you should use the EntityManager API.

For more information about the EntityManager API, see Caching objects and their relationships (EntityManager API).

Applications typically obtain a WebSphere eXtreme Scale reference and then obtain a Session object from the reference for each thread. Sessions cannot be shared between threads. The getMap method of Session returns a reference to an ObjectMap to use for this thread.

- Introduction to ObjectMap
  The ObjectMap interface is used for transactional interaction between applications and BackingMaps.
- Creating dynamic maps with Java APIs
  You can create dynamic maps with Java APIs after the data grid has been instantiated. You can dynamically instantiate maps that are based on a set of map templates. You can create your own map templates.
- ObjectMap and JavaMap
  A JavaMap instance is obtained from an ObjectMap object. The JavaMap interface has the same method signatures as ObjectMap, but with different exception handling. JavaMap extends the java.util.Map interface, so all exceptions are instances of the java.lang.RuntimeException class. Because JavaMap extends the java.util.Map interface, it is easy to quickly use WebSphere eXtreme Scale with an existing application that uses a java.util.Map interface for object caching.
- Maps as FIFO queues
  With WebSphere eXtreme Scale, you can provide a first-in first-out (FIFO) queue-like capability for all maps. WebSphere eXtreme Scale tracks the insertion order for all maps. A client can ask a map for the next unlocked entry in a map in the order of insertion and lock the entry. This process allows multiple clients to consume entries from the map efficiently.

Routing cache objects to the same partition

When an eXtreme Scale configuration uses the fixed partition placement strategy, it depends on hashing the key to a partition to insert, get, update, or remove the value. The hashCode method is called on the key and it must be well defined if a custom key is created. However, another option is to use the

PartitionableKey interface. With the PartitionableKey interface, you can use an object other than the key to hash to a partition.

You can use the PartitionableKey interface in situations where there are multiple maps and the data you commit is related and thus should be put on the same partition. WebSphere® eXtreme Scale does not support two-phase commit so multiple map transactions should not be committed if they span multiple partitions. If the PartitionableKey hashes to the same partition for keys in different maps in the same map set, they can be committed together.

You can also use the PartitionableKey interface when groups of keys should be put on the same partition, but not necessarily during a single transaction. If keys should be hashed based on location, department, domain type, or some other type of identifier, children keys can be given a parent PartitionableKey.

For example, employees should hash to the same partition as their department. Each employee key would have a PartitionableKey object that belongs to the department map. Then, both the employee and department would hash to the same partition.

The PartitionableKey interface supplies one method, called ibmGetPartition. The object returned from this method must implement the hashCode method. The result returned from using the alternate hashCode will be used to route the key to a partition.

Example

See the following example key that demonstrates how to use the PartitionableKey interface and the hashCode method to clone an existing key, and route the resulting keys to the same partition.

```
package com.ibm.websphere.cjtester;

import java.io.Serializable;

import com.ibm.websphere.objectgrid.plugins.PartitionableKey;

public class RoutableKey implements Serializable, Cloneable, PartitionableKey {
    private static final long serialVersionUID = 1L;

    // The data that makes up the actual data object key.
    public final String realKey;

    // The key of the data object you want to use for routing.
    // This is typically the key of a parent object.
    public final Object keyToRouteWith;

    public RoutableKey(String realKey, Object keyToRouteWith) {
        super();
        this.realKey = realKey;
        this.keyToRouteWith = keyToRouteWith;
    }

    /**
     * Return the hashcode of the key we are using for routing.
     * If not supplied, eXtreme Scale will use the hashCode of THIS key.
     */
    public Object ibmGetPartition() {
        return new Integer(keyToRouteWith.hashCode());
    }

    @Override
    public RoutableKey clone() throws CloneNotSupportedException {
        return (RoutableKey) super.clone();
    }

    @Override
    public int hashCode() {
        final int prime = 31;
        int result = 1;
        result = prime * result + ((keyToRouteWith == null) ? 0 : keyToRouteWith.hashCode());
        result = prime * result + ((realKey == null) ? 0 : realKey.hashCode());
        return result;
    }

    @Override
    public boolean equals(Object obj) {
        if (this == obj) return true;
        if (obj == null) return false;
        if (getClass() != obj.getClass()) return false;
        RoutableKey other = (RoutableKey) obj;
        if (keyToRouteWith == null) {
            if (other.keyToRouteWith != null) return false;
        } else if (!keyToRouteWith.equals(other.keyToRouteWith)) return false;
        if (realKey == null) {
            if (other.realKey != null) return false;
        } else if (!realKey.equals(other.realKey)) return false;
        return true;
    }
}
```

Introduction to ObjectMap

The ObjectMap interface is used for transactional interaction between applications and BackingMaps.

Purpose

An ObjectMap instance is obtained from a Session object that corresponds to the current thread. The ObjectMap interface is the main vehicle that applications use to make changes to entries in a BackingMap.

Obtain an ObjectMap instance

An application gets an ObjectMap instance from a Session object using the Session.getMap(String) method. The following code snippet demonstrates how to obtain an ObjectMap instance:

```
ObjectGrid objectGrid = ...;
BackingMap backingMap = objectGrid.defineMap("mapA");
Session sess = objectGrid.getSession();
ObjectMap objectMap = sess.getMap("mapA");
```

Each ObjectMap instance corresponds to a particular Session object. Calling the getMap method multiple times on a particular Session object with the same BackingMap name always returns the same ObjectMap instance.

Automatically commit transactions

Operations against BackingMaps that use ObjectMaps and JavaMaps are performed most efficiently within a Session transaction. WebSphere® eXtreme Scale provides autocommit support when methods on the ObjectMap and JavaMap interfaces are called outside of a Session transaction. The methods start an implicit transaction, perform the requested operation, and commit the implicit transaction.

Method semantics

An explanation of the semantics behind each method on the ObjectMap and JavaMap interfaces follows.

containsKey method
: The containsKey method determines if a key has a value in the BackingMap or Loader. If null values are supported by an application, this method can be used to determine if a null reference that is returned from a get operation refers to a null value or indicates that the BackingMap and Loader do not contain the key.

flush method
: The flush method semantics are similar to the flush method on the Session interface. The notable difference is that the Session flush applies the current pending changes for all of the maps that are modified in the current session. With this method, only the changes in this ObjectMap instance are flushed to the loader.

get method
: The get method fetches the entry from the BackingMap instance. If the entry is not found in the BackingMap instance but a Loader is associated with the BackingMap instance, the BackingMap instance attempts to fetch the entry from the Loader. The getAll method is provided to allow batch fetch processing.

getForUpdate method
: The getForUpdate method is the same as the get method, but using the getForUpdate method tells the BackingMap and Loader that the intention is to update the entry. A Loader can use this hint to issue a SELECT for UPDATE query to a database backend. If a pessimistic locking strategy is defined for the BackingMap, the lock manager locks the entry. The getAllForUpdate method is provided to allow batch fetch processing.

insert method
: The insert method inserts an entry into the BackingMap and the Loader. Using this method tells the BackingMap and Loader that you want to insert an entry that did not previously exist. When you invoke this method on an existing entry, an exception occurs when the method is invoked or when the current transaction is committed.

invalidate method
: The semantics of the invalidate method depend on the value of the isGlobal parameter that is passed to the method. The invalidateAll method is provided to allow batch invalidate processing.
  Local invalidation is specified when the value false is passed as the isGlobal parameter of the invalidate method. Local invalidation discards any changes to the entry in the transaction cache. If the application issues a get method, the entry is fetched from the last committed value in the BackingMap. If no entry is present in the BackingMap, the entry is fetched from the last flushed or committed value in the Loader. When a transaction is committed, any entries that are marked as locally invalidated have no impact on the BackingMap. Any changes that were flushed to the Loader are still committed even if the entry was invalidated.

Global invalidation is specified when true is passed as the isGlobal parameter of the invalidate method. Global invalidation discards any pending changes to the entry in the transaction cache and bypasses the BackingMap value on subsequent operations that are performed on the entry. When a transaction is committed, any entries that are marked as globally invalidated are evicted from the BackingMap.

Consider the following use case for invalidation as an example: The BackingMap is backed by a database table that has an auto increment column. Increment columns are useful for assigning unique numbers to records. The application inserts an entry. After the insert, the application needs to know the sequence number for the inserted row. It knows that its copy of the object is old, so it uses global invalidation to get the value from the Loader. The following code demonstrates this use case:

```
Session sess = objectGrid.getSession();
ObjectMap map = sess.getMap("mymap");
sess.begin();
map.insert("Billy", new Person("Joe", "Bloggs", "Manhattan"));
sess.flush();
map.invalidate("Billy", true);
Person p = map.get("Billy");
System.out.println("Version column is: " + p.getVersion());
map.commit();
// Close the session (optional in Version 7.1.1 and later) for improved performance
session.close();
```

This code sample adds an entry for `Billy`. The version attribute of Person is set using an auto-increment column in the database. The application first performs an insert command. It then issues a flush, which causes the insert to be sent to the Loader and database. The database sets the version column to the next number in the sequence, which makes the Person object in the transaction outdated. To update the object, the application is globally invalidated. The next get method that is issued gets the entry from the Loader, ignoring the transaction value. The entry is fetched from the database with the updated version value.

put method
: The semantics of the put method are dependent on whether a previous get method was invoked in the transaction for the key. If the application issues a get operation that returns an entry that exists in the BackingMap or loader, the put method invocation is interpreted as an update and returns the previous value in the transaction. If a put method invocation ran without a previous get method invocation, or a previous get method invocation did not find an entry, the operation is interpreted as an insert. The semantics of the insert and update methods apply when the put operation is committed. The putAll method is provided to enable batch insert and update processing.

remove method
: The remove method removes the entry from the BackingMap and the Loader, if a Loader is plugged in. The value of the object that was removed is returned by this method. If the object does not exist, this method returns a null value. The removeAll method is provided to enable batch deletion processing without the return values.

setCopyMode method
: The setCopyMode method specifies a CopyMode value for this ObjectMap. With this method, an application can override the CopyMode value that is specified on the BackingMap. The specified CopyMode value is in effect until clearCopyMode method is invoked. Both methods are invoked outside of transactional bounds. A CopyMode value cannot be changed in the middle of a transaction.

touch method
: The touch method updates the last access time for an entry. This method does not retrieve the value from the BackingMap. Use this method in its own transaction. If the provided key does not exist in the BackingMap because of invalidation or removal, an exception occurs during commit processing.

update method
: The update method explicitly updates an entry in the BackingMap and the Loader. Using this method indicates to the BackingMap and Loader that you want to update an existing entry. An exception occurs if you invoke this method on an entry that does not exist when the method is invoked or during commit processing.

getIndex method
: The getIndex method attempts to obtain a named index that is built on the BackingMap. The index cannot be shared between threads and works on the same rules as a Session. The returned index object should be cast to the right application index interface such as the MapIndex interface, the MapRangeIndex interface, or a custom index interface.

clear method
: The clear method removes all cache entries from a map from all partitions. This operation is an auto-commit function, so no active transaction should be present when calling clear.
Note: The clear method only clears out the map on which it is called, leaving any related entity maps unaffected. This method does not invoke the Loader plug-in.
