`tos:typeahead&term=`*`term`*

where `term` represents the beginning of a term that a user is typing for which you want the portal to provide typeahead suggestions.

The returned feed is by default sorted by relevance. This means that tags that have been applied more often are displayed before tags that have been applied less often.

This query allows you to modify all of the following:

- The parameters `order`, `orderMetric`, `locales` . The parameters control how the type-ahead result looks. For more details see the topic about *Adding query parameters* under the sections about *Sorting the results* and *Locale sensitive queries*.
- The pagination of the type-ahead results, that is with which item the result list starts and how many results are displayed. For more details see the topic about *Adding query parameters* under the section about *Limiting the results*.

You can configure how the tag names are displayed in terms of normalization. To do this, use the setting `com.ibm.wps.cp.tagging.normalization.typeAhead` in the CP Configuration Service. The response of the suggestions is in the JSON (JavaScript Object Notation) format and consists of an array that contains the searched partial term and suggestions.

Example: If the search term is `web`, then the response to `tos:typeahead&term=web` contains the suggestions `WebSphere`, `Website`, and `WebBrowser`. The notation in JSON is as follows in the mime type application/json: `["Web",["WebSphere", "Website", "WebBrowser"]]` . This is the format proposed by OpenSearch Suggestions extension Version 1.1 draft 1.

"Adding query parameters" on page 3181
You can add query parameters as required by using the following instructions.

"Type-ahead feature for the deprecated tag widget" on page 1306
The tag widget from earlier IBM WebSphere Portal Express versions provided a type-ahead feature. With portal V 8.5, that tag widget is deprecated. The type-ahead feature makes it easier for users to find suitable tags. Type-ahead supports users when they work with tags. For example, when users apply tags using the tag widget, or when they search for tags, for example by using the open search functionality, type-ahead provides users suggestions for tags that other users have applied already before. Type-ahead can also help reduce the number of variants of tags.

"Normalizing tags" on page 1305
The portal provides several options for normalizing tags. Normalization is a process of transforming a text fragment, such as a tag, into another, more generic representation. This bundles different spellings or grammatical versions of the same lexical word that users might use as tags, for example `color`, `Color`, `COLOR`, `colour`, `colors`, `colored`.

OpenSearch Suggestions extension Version 1.1 draft 1: http://www.opensearch.org/Specifications/OpenSearch/Extensions/Suggestions/1.1

Search suggestions for tag names:

To make search for tag names by users easier, search suggestions provide suggestions for tag names as they appear in the tag cloud and in the tag result portlet.

This is important with respect to normalization as you can configure the display mode of the tags in a tag cloud independently from the type-ahead suggestions. Compared to the query for the type-ahead feature, the search suggestions behave in terms of normalization like the display mechanism of the Tag Cloud.

To query for search suggestions, use the following query:

`tos:searchsuggestions&term=`*`term`*

where `term` represents the beginning of a term that a user is typing for which you want the portal to provide search suggestions.

The returned feed is by default sorted by relevance. This means that tags that have been applied more often are displayed before tags that have been applied less often.

This query allows you to modify all of the following:

- The parameters `order`, `orderMetric`, `locales` . The parameters control how the type-ahead result looks. For more details see the topic about *Adding query parameters* under the sections about *Sorting the results* and *Locale sensitive queries*.
- The pagination of the type-ahead results, that is with which item the result list starts and how many results are displayed. For more details see the topic about *Adding query parameters* under the section about *Limiting the results*.

Note: The type-ahead feature works only with the dialog tag widget of the default tagging user interface of portal versions earlier than V 8.5. With WebSphere Portal Express V 8.5, the tag and rating widgets of earlier portal versions are deprecated.

You can configure how the tag names are displayed in terms of normalization. To do this, use the setting `com.ibm.wps.cp.tagging.normalization.displayNormalizedName` in the CP Configuration Service. The response of the suggestions is in the JSON (JavaScript Object Notation) format and consists of an array that contains the searched partial term and suggestions.

Example: If the search term is `web`, then the response to `tos:searchsuggestion &term=web` contains the search suggestions `WebSphere`, `Website`, and `WebBrowser`. The notation in JSON is as follows in the mime type application/json: `["Web",["WebSphere", "Website", "WebBrowser"]]` . This is the format proposed by OpenSearch Suggestions extension Version 1.1 draft 1.

Querying for the OpenSearch description document:

You can query for the OpenSearch description document.

To query for the OpenSearch description document, use the following query:
`tos:search&osbu=`*`bundle-name`*`&osde=`*`key-description`*`&ossn=`*`key-short-name`*`&osic16=`*`url-icon-16`*

The following query parameters are mandatory with this query:

osbu Use this query parameter to specify the base name of a resource bundle. Specify a fully qualified Java class name.

osde Use this query parameter to specify the key within the previous given resource bundle the value of which you want to be used as the description of the OpenSearch description document.

ossn Use this query parameter to specify the key within the previous given resource bundle the value of which you want to be used as the short name of the OpenSearch description document.

Optionally, you can specify the following query parameter:

osic16
Use this query parameter to pass a URL for an icon that browsers can render to visualize the OpenSearch description document. For details about the characteristics of the icon refer to the JavaDoc of the interface `com.ibm.portal.resolver.opensearch.DefaultOpenSearchContentHandler.startImage(int, int, String)` . Note that the icon must be 16 pixels by 16 pixels.

Using the Rest API to add, update, and delete tags and ratings

You can create, update, and delete tags and ratings by using the REST API.

Creating and deleting tags by using the REST API

To create a tag, send an HTTP POST against the URI `tm:ts:all` with the following payload:

```
<?xml version="1.0" encoding="UTF-8"?>',
<atom:feed xmlns:atom="http://www.w3.org/2005/Atom"
   xmlns:xhtml="http://www.w3.org/1999/xhtml"
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xmlns:creation-context=
      "http://www.ibm.com/xmlns/prod/websphere/portal/v6.1.0/portal-creation-context"
   xmlns:trc="http://www.ibm.com/xmlns/prod/websphere/portal/v7.0/portal-tag-rate-comment"
   xmlns:cp="http://www.ibm.com/xmlns/prod/websphere/portal/v7.0/portal-contextual-portal"
   xmlns:portal="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0.1/portal-model"
   xmlns:thr="http://purl.org/syndication/thread/1.0"
   xmlns:model="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0.1/portal-model-elements"
   xmlns:base="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0/ibm-portal-composite-base"
   xmlns:opensearch="http://a9.com/-/spec/opensearch/1.1/"
   xml:base="http://localhost/wps/poc">
```

```
      <atom:author>
         <atom:name>IBM WebSphere Portal/8.5</atom:name>
      </atom:author>
      <atom:title>IBM WebSphere Portal Model Feed</atom:title>
      <atom:link href="." rel="self" type="application/atom+xml"/>
      <atom:entry creation-context:private="${isPrivate}">
         <atom:title xml:lang="${locale}">${tagname}</atom:title>
         <atom:id>${id}</atom:id>
         <atom:link portal:uri="${resourceURI}" rel="replies" href="example.org" />
         <atom:category term="${category}" />
      </atom:entry>
</atom:feed>
```

Replace the variables `isPrivate`, `tagname`, `resourceURI`, and `category` (optional) by the appropriate values.

To delete a tag, send an HTTP DELETE against the URI `uri tm:oid:`*`oid_of_a_tag`*.

Creating and deleting ratings by using the REST API

To create a rating, send an HTTP POST against the URI `rtm:rs:all` with the following payload:

```
<?xml version="1.0" encoding="UTF-8"?>',
<atom:feed xmlns:atom="http://www.w3.org/2005/Atom"
   xmlns:xhtml="http://www.w3.org/1999/xhtml"
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xmlns:creation-context=
      "http://www.ibm.com/xmlns/prod/websphere/portal/v6.1.0/portal-creation-context"
   xmlns:trc="http://www.ibm.com/xmlns/prod/websphere/portal/v7.0/portal-tag-rate-comment"
   xmlns:cp="http://www.ibm.com/xmlns/prod/websphere/portal/v7.0/portal-contextual-portal"
   xmlns:portal="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0.1/portal-model"
   xmlns:thr="http://purl.org/syndication/thread/1.0"
   xmlns:model="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0.1/portal-model-elements"
   xmlns:base="http://www.ibm.com/xmlns/prod/websphere/portal/v6.0/ibm-portal-composite-base"
   xmlns:opensearch="http://a9.com/-/spec/opensearch/1.1/"
   xml:base="http://localhost/wps/poc">
      <atom:author>
         <atom:name>IBM WebSphere Portal/8.5</atom:name>
      </atom:author>
      <atom:title>IBM WebSphere Portal Model Feed</atom:title>
      <atom:link href="." rel="self" type="application/atom+xml"/>
         <atom:entry creation-context:private="${isPrivate}">
            <atom:title>${rating}</atom:title>
            <atom:id>${id}</atom:id>
            <atom:link portal:uri="${resourceURI}" rel="replies" href="example.org" />
            <atom:category term="${category}" />
         </atom:entry>
</atom:feed>
```

Replace the variables `isPrivate`, `rating`, `resourceURI`, and `category` (optional) by the appropriate values.

To update a rating, send an HTTP PUT that contains the same payload against the same URI.

To delete a rating, send an HTTP DELETE against the URI `uri rtm:oid:`*`oid_of_a_rating`*.

How to create a custom launch page

You can configure an authoring portlet to use a launch page of your own design instead of the default user interface.

A custom launch page can either be a JSP or HTML file. You use remote actions to call different views and functions from with the authoring portlet's user interface. You can also use the web content API to add other functions to your launch page. When you create a custom launch page, you configure your authoring portlet to use the custom launch page instead of the default authoring portlet user interface.

Storing JSP files: JSP files are stored within a web application that runs on the portal. To reference a JSP file in another web application, use the following path: `contextPath;jspPath`. For example: `/wps/customapplication;/jsp/jspFilename.jsp`.

A dynamic context path value can be defined by adding a token to the context path that corresponds to a key and value pair to the Web Content Manager configuration service environment provider. When this key is used as the token in the jsp value field, it is replaced dynamically at render time. For example: `[my.custom.key];myfile` where *my.custom.key* is a constant within the Web Content Manager configuration service.

A custom launch page example

This is a simple example of some code you can add to a JSP or HTML file, to allow users to create and view content items by using remote actions.

```
<%--
/* Sample Launch Page */
--%>

<%@ taglib uri="/WEB-INF/tld/wcm.tld" prefix="wcm" %>

<%--
/* Add your username and password here */
--%>
<wcm:initworkspace username="wpsadmin" password="wpsadmin" >
An error occurred initializing the WCM workspace:
<%=error%>
</wcm:initworkspace>

<%--
/* Setup your context here */
--%>
<wcm:setExplicitContext wcmWebAppPath="http://localhost:10039/wps/wcm"
wcmServletPath="/myconnect" path="Web Content/Articles/Sample Article" >
An error occurred setting the WCM context:
<%=error%>
</wcm:setExplicitContext>

<div>
   <div>
      <a href='<wcm:plugin name="RemoteAction" action="new"
type="com.ibm.workplace.wcm.api.WCM_Content"/>'>New Content</a>
   </div>
   <div>
      <a href='<wcm:plugin name="RemoteAction" view="contentbytitle"
action="openmainview"/>'>View Content by Title</a>
   </div>
   <div>
```

```
 <a href='<wcm:plugin name="RemoteAction" view="explorer"
action="openmainview"/>'>Open the Library Explorer view</a>
        </div>
</div>
```

Reloading JSP files:

JSP files that are stored in the PA_WCM_Authoring_UI application are not reloaded, even if they are updated. You must restart the server, or put the JSP in a separate web application that is configured to reload JSP files, in order for changes you make to the JSP to be displayed.

How to create a custom HTML editor integration

You can use custom HTML editors in all HTML fields of the authoring interface or specific HTML elements that are defined in an authoring template. Custom HTML fields are used to integrate third-party editors into the authoring interface.

A custom HTML field is JSP that is rendered in place of the standard HTML field of the authoring interface. The custom field is composed of a number of pieces that together work to identify the field that is being modified, register the customization with the authoring interface, access standard HTML field dialogs, and update values when the time comes to commit changes. The `com.ibm.workplace.wcm.api.authoring.HTMLEditorBean`, that is available in the JSP, provides basic field metadata such as the name and whether the field is editable. The `ibm.wcm.ui.html.HTMLEditor` JavaScript library defines the client-side framework that integrates the custom field on the authoring interface. Each integration must implement its own HTMLEditor.

Storing JSP files: JSP files are stored within a web application that runs on the portal. To reference a JSP file in another web application, use the following path: `contextPath;jspPath`. For example: `/wps/customapplication;/jsp/jspFilename.jsp`.

A dynamic context path value can be defined by adding a token to the context path that corresponds to a key and value pair to the Web Content Manager configuration service environment provider. When this key is used as the token in the jsp value field, it is replaced dynamically at render time. For example: `[my.custom.key];myfile` where *my.custom.key* is a constant within the Web Content Manager configuration service.

Reloading JSP files:

JSP files that are stored in the PA_WCM_Authoring_UI application are not reloaded, even if they are updated. You must restart the server, or put the JSP in a separate web application that is configured to reload JSP files, in order for changes you make to the JSP to be displayed.

An example integration

This is a simple example of a basic integration that shows all necessary steps to render and register a custom field with the authoring interface. In this example, the text area that is used to edit HTML is extended by using the Dojo Text Area dijit.

The JSP is broken up into three distinct parts. The first is a simple code snippet to extract the name of the editor field. The next part of the JSP defines the implementation of the custom `ibm.wcm.ui.html.HTMLEditor` object. The `ibm.sample.Editor` defines a constructor to capture the dijit to manage and implement the necessary methods to integrate with the Authoring interface.

Note: It also chooses to show the HTML field toolbar by calling `this.showToolbar(true)` that starts the method on `ibm.wcm.ui.html.HTMLEditor` that controls the visibility of the toolbar.
Finally the dijit is defined, and an instance of the `ibm.sample.Editor` created.

Note: While this sample defines `ibm.sample.Editor` within the JSP, it would be more efficient to load this by using the static JavaScript library. This is important because if you have more than one editor on the page, the JavaScript definition of `ibm.sample.Editor` is loaded each time, but only the last one is loaded and used.

```
<%--
/* Sample HTML Editor */
--%>

<%@ taglib uri="/WEB-INF/tld/portlet.tld" prefix="portletAPI" %>
<%@ page import="com.ibm.workplace.wcm.app.ui.portlet.widget.HTMLEditorBean" %><portletAPI:init /><%
    HTMLEditorBean editor = (HTMLEditorBean) request.getAttribute("EditorBean");

    // The name of the editor corresponds to the ID of the text area field that will be rendered wit
    String docId = editor.getName();
%>

<script>
   dojo.declare("ibm.sample.Editor", [ibm.wcm.ui.html.HTMLEditor], {

      /** Hold a reference to the text area we enriched. */
      theTextArea: null,

      /** Simple overloaded constructor that will dynamically enrich the target text area with a dojo
      constructor: function(editorId, textArea) {
         this.inherited(arguments);
         this.theTextArea = textArea;

         textArea.startup();

         this.showToolbar(true);
      },

      /** This method is called by the HTML/RTF field dialogs. For example when the user has selecte
      insertMarkupAtCursor: function(markup){
         // Do cross browser text insertion
         if (document.selection && (!this.theTextArea.textbox.selectionStart || this.theTextArea.text
         {
            // Handle IE, which defines document.selection
            this.theTextArea.focus();
            var textRange = document.selection.createRange();
            textRange.text = markup;
         }
         else if (this.theTextArea.textbox.selectionStart || this.theTextArea.textbox.selectionStart
         {
            // Handle Mozilla, Opera, which define document.selectionStart
            // Create the new text for the text field. createRange() isn't supported by these browse
            var startPos = this.theTextArea.textbox.selectionStart;
            var endPos = this.theTextArea.textbox.selectionEnd;
            var scrollTop = this.theTextArea.textbox.scrollTop;
            this.setMarkup(this.theTextArea.value.substring(0, startPos) + markup + this.theTextArea

            // Restore the cursor and scroll position which were lost by replacing the text field's
            this.theTextArea.focus();
```

```
            }
        },

        /** This method is called when a user triggers the import markup action of the field. */
        setMarkup: function(markup){
            this.theTextArea.set("value", markup);
        },

        /** This method is called whenever the authoring interface requires the current value of the
        getMarkup: function(){
            return this.theTextArea.value;
        },

        /** This method will be called when the user submits the form to the server. This gives the
        notifySubmit: function() {
            // As we are enriching the text area being submitted, the value
            // is already up to date and we do not need to do anything
        }
    });

    require(["dijit/form/Textarea", "dojo/domReady!"], function(Textarea){
        var textArea = new Textarea({name: '<%= docId %>', style: "width:100%;max-width:910px;min-he
        new ibm.sample.Editor('<%= docId %>', textArea);
    });

</script>
```

Helper methods

The `ibm.wcm.ui.html.HTMLEditor` includes a number of helper methods to make it possible to start the standard set of HTML field dialogs programmatically. Meaning it would be possible to keep the HTML editor toolbar hidden and still provide all the functionality that it exposes.

The available methods are:

- `launchInsertImageDialog()`
- `launchInsertLinkDialog(/* String */ linkText, /* String */ linkHref, /* String */ linkTarget, /* String */ linkDescription, /* String */ linkAttributes)`
- `launchInsertTagDialog(/* boolean */ includeConsumableTags){`

How to use remote actions

Remote actions are used to trigger actions from the IBM Web Content Manager application.

You can reference remote actions by using plug-in tags by using the following format:

```
[plugin:RemoteAction action=" " docid=" "
dialog=" " dialogSize=" " dialogTitle=" " useCurrentContext=" " showInfoMsg=" " ]
```

action This is the remote action to perform.

docid This is the document ID of the item to run the remote action against.

useCurrentContext
If set to true, then the document ID is obtained form the rendering context instead of the docid attribute.

dialog If set to true, when rendered within a Web Content Viewer portlet, the

remote action is rendered as a URL that redirects the user to a hidden portal page that is used by the Web Content Viewer portlet for inline editing.

dialogSize
This optional setting defines the size of the dialog executing the remote action. The value must be in the format "width,height". For example, `dialogSize="200,300"` for a dialog of width 200 pixel and a height of 300 pixel. If omitted, the dialog size is calculated from the content that is displayed in the dialog. This setting is only used if dialog="true".

dialogTitle
This optional setting sets the title of the dialog executing the remote action. If omitted, the action name is used instead. This setting is only used if dialog="true".

showInfoMsg
Set this to true to display success status and other information messages after the remote action has finished. If omitted, this parameter is set to false and only warning and error status messages are displayed. This setting can only be used if dialog="true".

Remote actions can also be appended to the URL of an authoring portlet. For example:

```
http://[host]/wps/myportal/wcmAuthoring?wcmAuthoringAction=action
```

You can also append remote actions to the URL of a local web Content Viewer portlet. This can be useful in sites that feature inline editing of content items.

Custom authoring interfaces: Remote actions are not intended to be used to create a custom authoring interface. There are limitations to the functions delivered using remote actions. For example, remote actions only support plain text. You cannot use remote actions to add markup into elements such as HTML elements. You instead use the Web Content Manager API to create custom authoring interfaces.

Note: Each web content item can be identified by a DocumentId. The "docid" can be retrieved by using the web content API. In the following examples, the value of the "docid" parameter should be the DocumentId as retrieved by using the `DocumentID.getID()` API method. A document ID consists of a document type and a unique ID. The "docid" values that are provided in the examples are placeholders for real document IDs. For example, `com.ibm.workplace.wcm.api.WCM_Content/ID1`

Remote action types

new This is used to open a new item form. You must also specify a "type" parameter.

For example:

- `[plugin:RemoteAction action="new" type="com.ibm.workplace.wcm.api.WCM_Content" ]`

The following type parameters can be used:

- `com.ibm.workplace.wcm.api.WCM_AuthoringTemplate`
- `com.ibm.workplace.wcm.api.WCM_Category`
- `com.ibm.workplace.wcm.api.WCM_Content`
- `com.ibm.workplace.wcm.api.WCM_DateComponent`
- `com.ibm.workplace.wcm.api.WCM_FileComponent`

- com.ibm.workplace.wcm.api.WCM_HTMLComponent
- com.ibm.workplace.wcm.api.WCM_ImageComponent
- com.ibm.workplace.wcm.api.WCM_NumericComponent
- com.ibm.workplace.wcm.api.WCM_PresentationTemplate
- com.ibm.workplace.wcm.api.WCM_RichTextComponent
- com.ibm.workplace.wcm.api.WCM_ShortTextComponent
- com.ibm.workplace.wcm.api.WCM_SiteArea
- com.ibm.workplace.wcm.api.WCM_Taxonomy
- com.ibm.workplace.wcm.api.WCM_TextComponent
- com.ibm.workplace.wcm.api.WCM_Workflow
- com.ibm.workplace.wcm.api.WCM_WorkflowStage

When creating a new content item, you can specify a default authoring template by providing the document ID of the authoring template in the **atid** parameter:

- [plugin:RemoteAction action="new" type="com.ibm.workplace.wcm.api.WCM_Content" atid="com.ibm.workplace.wcm.api.WCM_AuthoringTemplate/ID1"]

When creating site areas, content items and categories, you can specify the document ID of the parent item to save the new item under. Specify this ID in the **pid** parameter:

- [plugin:RemoteAction action="new" type="com.ibm.workplace.wcm.api.WCM_Content" pid="com.ibm.workplace.wcm.api.WCM_SiteArea/ID"]
- [plugin:RemoteAction action="new" type="com.ibm.workplace.wcm.api.WCM_SiteArea" pid="com.ibm.workplace.wcm.api.WCM_SiteArea/ID"]
- [plugin:RemoteAction action="new" type="com.ibm.workplace.wcm.api.WCM_Category" pid="com.ibm.workplace.wcm.api.WCM_Taxonomy/ID"]

When creating site areas, you can specify the position of the new site area by using a **position** parameter. You can specify to save the new site area at the start or end relative to any existing site areas. If not specified, the new site area is saved at the start relative to any existing site areas:

- [plugin:RemoteAction action="new" type="com.ibm.workplace.wcm.api.WCM_Content" position="start"]
- [plugin:RemoteAction action="new" type="com.ibm.workplace.wcm.api.WCM_SiteArea" position="end"]

delete This is used to delete an item. You must also specify the **docid** of the item.

For example:

- [plugin:RemoteAction action="delete" docid="com.ibm.workplace.wcm.api.WCM_Content/ID1"]

edit This is used to open an item form in edit mode. You must also specify the **docid** of the item.

For example:

- [plugin:RemoteAction action="edit" docid="com.ibm.workplace.wcm.api.WCM_Content/ID1"]

read This is used to open an item form in read-only mode. You must also specify the **docid** of the item.

For example:

- `[plugin:RemoteAction action="read" docid="com.ibm.workplace.wcm.api.WCM_Content/ID1"]`

openmainview
This is used to open a view within an authoring portlet. You must also specify a **view** parameter.

For example:

- `[plugin:RemoteAction action="openmainview" view="contentbysitearea"]`

The following view parameters can be used:

- `contentbysitearea`
- `contentbytitle`
- `myrecent`
- `mydraft`
- `mypendingapproval`
- `mypublished`
- `myexpired`
- `mydeleted`
- `alldraftitems`
- `allexpireditems`
- `allpublisheditems`
- `alldeleteditems`
- `componentsbytype`

move This is used to move a site area or content item.

For example, to open the move dialog for a content item or site area:

- `[plugin:RemoteAction action="move" docid="com.ibm.workplace.wcm.api.WCM_Content/ID1"]`

A move direction is specified as "1" for up and "-1" for down. For example, to move a content item up one position:

- `[plugin:RemoteAction action="move" docid="com.ibm.workplace.wcm.api.WCM_Content/ID1" pid="com.ibm.workplace.wcm.api.WCM_SiteArea/ID1" moveDirection="1"]`

link This will link a content item to a site area.

For example:

- `[plugin:RemoteAction action="link" docid="com.ibm.workplace.wcm.api.WCM_Content/ID1" pid="com.ibm.workplace.wcm.api.WCM_SiteArea/ID2"]`

When linking items, you can specify the path to the parent item by using the **ppath** parameter instead of the **pid** parameter:

- `[plugin:RemoteAction action="link" docid="com.ibm.workplace.wcm.api.WCM_Content/ID1" ppath="library1/sitearea1/sitearea2"]`

When linking items, you can create a new parent item by using the **autoCreateParent** parameter. You must also specify the library where the item being linked is located by using the **slibrary** parameter. The **ppath** parameter is used to specify the existing parent that the new parent item is created under:

- `[plugin:RemoteAction action="link" docid="com.ibm.workplace.wcm.api.WCM_Content/ID1" autoCreateParent="true" slibrary="libraryname" ppath="library1/sitearea1/sitearea2"]`

copy This is used to make a copy of an item.

For example, to copy a content item to a new site area:

- `[plugin:RemoteAction action="copy" docid="com.ibm.workplace.wcm.api.WCM_Content/ID1" pid="com.ibm.workplace.wcm.api.WCM_SiteArea/ID2"]`

You can use the following extra parameters when copying:

- `copyAsDraft="true"`

  This will restart the workflow of the copy being creating. In most cases this would result in the copy being created with a status of draft.
- `wid="com.ibm.workplace.wcm.api.WCM_Workflow/ID1"`

  Use this to specify a different workflow to use when creating the copy. This will also restart the workflow of the copy being creating. In most cases this would result in the copy being created with a status of draft.
- `position="start"`

  This will create the copy as the first item under the specified parent item. If not specified the item is copied as the last child of the specified parent item.

When copying items you can specify the path to the parent item by using the **ppath** parameter instead of the **pid** parameter:

- `[plugin:RemoteAction action="copy" docid="com.ibm.workplace.wcm.api.WCM_Content/ID1" ppath="library1/sitearea1/sitearea2"]`

When copying items you can create a new parent item by using the **autoCreateParent** parameter. You must also specify the library where the item being copied is located by using the **slibrary** parameter. The **ppath** parameter is used to specify the existing parent that the new parent item is created under:

- `[plugin:RemoteAction action="copy" docid="com.ibm.workplace.wcm.api.WCM_Content/ID1" autoCreateParent="true" slibrary="libraryname" ppath="library1/sitearea1/sitearea2"]`

approve
This is used to approve an item in a workflow. You must also specify the **docid** of the item.

For example:

- `[plugin:RemoteAction action="approve" docid="com.ibm.workplace.wcm.api.WCM_Content/ID1"]`

decline
This is used to decline an item in a workflow. You must also specify the **docid** of the item.

For example:

- `[plugin:RemoteAction action="decline" docid="com.ibm.workplace.wcm.api.WCM_Content/ID1"]`

saveandapprove
This is used to approve an item in a workflow where that item is open in edit mode within the same session. You must also specify the **docid** of the item.

For example:

- `[plugin:RemoteAction action="saveandapprove" docid="com.ibm.workplace.wcm.api.WCM_Content/ID1"]`
- `[plugin:RemoteAction action="saveandapprove" docid="com.ibm.workplace.wcm.api.WCM_Content/ID1" isdraft="true"]`

previousstage
This is used to move an item to the previous stage in a workflow. You must also specify the **docid** of the item.

For example:

- `[plugin:RemoteAction action="previousstage" docid="com.ibm.workplace.wcm.api.WCM_Content/ID1"]`

viewversions
This is used to open the versions dialog for an item. You must also specify the **docid** of the item.

For example:

- `[plugin:RemoteAction action="viewversions" docid="com.ibm.workplace.wcm.api.WCM_Content/ID1"]`

viewhistory
This is used to open the history dialog for an item. You must also specify the **docid** of the item.

For example:

- `[plugin:RemoteAction action="viewhistory" docid="com.ibm.workplace.wcm.api.WCM_Content/ID1"]`

Populating fields when creating or editing content

When using the "new" or "edit" parameters with content items, you can also add data to different fields in the content item using a URL.

For example, to add "newcontent" as the name of the content item, you would use this URL:

- `[plugin:RemoteAction action="new" type="com.ibm.workplace.wcm.api.WCM_Content" wcmfield.content.name="newcontent"]`

The following parameters can be used to populate fields when creating or editing content:

- `wcmfield.content.name=`
- `wcmfield.content.title=`
- `wcmfield.content.description=`
- `wcmfield.content.authors=`
- `wcmfield.content.owners=`

- wcmfield.content.publishDate=
- wcmfield.content.expiryDate=
- wcmfield.content.generalDateOne=
- wcmfield.content.generalDateTwo=
- wcmfield.content.workflow= (This can only be used when creating content.)
- wcmfield.content.categories=
- wcmfield.content.keywords=
- wcmfield.element.*elementname*=

  Note: You replace *elementname* with the name of the element you are populating. The element parameter can only be used with the following element types:
  - Text
  - Html
  - Rich text
  - Option Selection
  - User Selection
  - Date and time
  - Number
  - JSP
  - Link
  - Component Reference

When populating fields with user IDs, you must use this format:

- [plugin:RemoteAction action="new"
  type="com.ibm.workplace.wcm.api.WCM_Content"
  wcmfield.content.authors="uid=*usera*,cn=*cn-name*,dc=*dc-name*"]

When populating workflow and category fields, you must use the document IDs as their values:

- [plugin:RemoteAction action="new"
  type="com.ibm.workplace.wcm.api.WCM_Content"
  wcmfield.content.workflow="ID1"]
- [plugin:RemoteAction action="new"
  type="com.ibm.workplace.wcm.api.WCM_Content"
  wcmfield.content.categories="ID1"]

When populating date fields, the date format must be US English. Either a date and time, or just a date can be specified. If only a date is specified, the time used will be 12:00:00 AM. For example:

- [plugin:RemoteAction action="new"
  type="com.ibm.workplace.wcm.api.WCM_Content"
  wcmfield.content.generalDateOne="Feb 14, 2008 12:53:03 PM"]
- [plugin:RemoteAction action="new"
  type="com.ibm.workplace.wcm.api.WCM_Content"
  wcmfield.content.generalDateOne="Feb 14, 2008"]

The date and time set here are based on the server's timezone, not the timezone of the user's computer.

When populating a JSP element, you need to specify the path to the JSP file:

- [plugin:RemoteAction action="new"
  type="com.ibm.workplace.wcm.api.WCM_Content"
  wcmfield.element.jspelementname="/wps/wcm/jsp/html/example.jsp"]

When populating a component reference element, you specify the component to reference. For example:

- [plugin:RemoteAction action="new"
  type="com.ibm.workplace.wcm.api.WCM_Content"
  wcmfield.element.mycompref.type="com.aptrix.pluto.cmpnt.NavigatorCmpnt"
  wcmfield.element.mycompref.id="e4bdf10042d0769698ccbeb0e25cc973"]

When populating an option selection element, you specify each selection option. For example:

- [plugin:RemoteAction action="new"
  type="com.ibm.workplace.wcm.api.WCM_Content"
  wcmfield.element.elementname="AA" wcmfield.element.elementname="BB"]

When populating a user selection element, you specify each user. For example:

- [plugin:RemoteAction action="new"
  type="com.ibm.workplace.wcm.api.WCM_Content"
  wcmfield.element.elementname="uid=wpsadmin,o=defaultWimFileBasedRealm"
  wcmfield.element.elementname="uid=wpsadmin2,o=defaultWimFileBasedRealm"]

When populating a Link element, you can specify the following parameters:

Adding a link to a content item:

```
[plugin:RemoteAction action="new"
type="com.ibm.workplace.wcm.api.WCM_Content"
wcmfield.element.elementname.type="content"
wcmfield.element.elementname.id="contentID"]
```

Adding a link to a link component:

```
[plugin:RemoteAction action="new"
type="com.ibm.workplace.wcm.api.WCM_Content"
wcmfield.element.elementname.type="link"
wcmfield.element.elementname.id="linkcomponentID"]
```

Adding a link to an image or file resource component:

```
[plugin:RemoteAction action="new"
type="com.ibm.workplace.wcm.api.WCM_Content"
wcmfield.element.elementname.type="resource"
wcmfield.element.elementname.id="componentID"]
```

Adding a link to a URL:

```
[plugin:RemoteAction action="new"
type="com.ibm.workplace.wcm.api.WCM_Content"
wcmfield.element.elementname.type="external"
wcmfield.element.elementname.externalReference="myurl"]
```

To specify whether to use the name of the item you are linking to as the link text, add this to the tag:

```
wcmfield.element.elementname.useReferenceLinkText="true"
```

When specifying an image to display as the link, add this to the tag:

```
wcmfield.element.elementname.linkImage="imagecomponentID"
```

When specifying the text of the link, add this to the URL:

```
wcmfield.element.elementname.linkText="text"
```

When specifying the description of the link, add this to the URL:

`wcmfield.element.elementname.linkDescription="text"`

When specifying a link target, add this to the URL:

`wcmfield.element.elementname.linkTarget=`

- `_blank`
- `_parent`
- `_self`
- `_top`
- `targetname`

Save parameters

You can add the following "save" parameters to a remote action tag.

`autoSave`

This is used to save a controllable. This happens in the background and is not displayed to users.

For example:

- `wcmfield.autosave="true"`

`saveValidate`

This parameter determines if warning and error messages resulting from the autosave is displayed to the user. If set to "true", warning and error messages are displayed to the user. If set to false, messages are suppressed. The default is true.

For example:

- `&wcmfield.saveValidate="false"`

Adding comments to the item history

When creating items that use a workflow with "Enter comment on approval" set to true, you can add a comment to the item history by adding `comment="comment text"` to the URL.

For example:

```
[plugin:RemoteAction action="edit" docid="com.ibm.workplace.wcm.api.WCM_Content/ID1"
createDraft="true" comment="comment text"]
```

Examples

Open the versions view for an item:

- Tag: `[plugin:RemoteAction action="viewversions" docid="com.ibm.workplace.wcm.api.WCM_Content/ID1"]`
- Url: `http://<host>/wps/myportal/wcmAuthoring?wcmAuthoringAction=viewversions &docid=com.ibm.workplace.wcm.api.WCM_Content/ID1`

Open the history view for an item:

- Tag: `[plugin:RemoteAction action="viewhistory" docid="com.ibm.workplace.wcm.api.WCM_Content/ID1"]`
- Url: `http://<host>/wps/myportal/wcmAuthoring?wcmAuthoringAction=viewhistory &docid=com.ibm.workplace.wcm.api.WCM_Content/ID1`

Open a content item in read mode:

- Tag: `[plugin:RemoteAction action="read" docid="com.ibm.workplace.wcm.api.WCM_Content/ID1"]`
- Url: `http://<host>/wps/myportal/wcmAuthoring?wcmAuthoringAction=read &docid=com.ibm.workplace.wcm.api.WCM_Content/ID1`

Open a content item in edit mode:

- Tag: `[plugin:RemoteAction action="edit" &docid=com.ibm.workplace.wcm.api.WCM_Content/ID1]`
- Url: `http://<host>/wps/myportal/wcmAuthoring?wcmAuthoringAction=edit &docid=com.ibm.workplace.wcm.api.WCM_Content/ID1`

Move a content item up:

- Tag: `[plugin:RemoteAction action="move" docid="com.ibm.workplace.wcm.api.WCM_Content/ID1" moveDirection="1" pid="com.ibm.workplace.wcm.api.WCM_SiteArea/ID1"]`
- Url: `http://<host>/wps/myportal/wcmAuthoring?wcmAuthoringAction=move &docid=com.ibm.workplace.wcm.api.WCM_Content/ID1&moveDirection=1 &pid=com.ibm.workplace.wcm.api.WCM_SiteArea/ID1`

Move a site area down:

- Tag: `[plugin:RemoteAction action="move" docid="com.ibm.workplace.wcm.api.WCM_SiteArea/ID1" "moveDirection="-1" pid="com.ibm.workplace.wcm.api.WCM_SiteArea/ID1"]`
- Url: `http://<host>/wps/myportal/wcmAuthoring?wcmAuthoringAction=move &docid=com.ibm.workplace.wcm.api.WCM_SiteArea/ID1&moveDirection=-1 &pid=com.ibm.workplace.wcm.api.WCM_SiteArea/ID1`

Create a new content item with title of 'newcontent':

- Tag: `[plugin:RemoteAction action="new" type="com.ibm.workplace.wcm.api.WCM_Content" wcmfield.content.title="newcontent"]`
- Url: `http://<host>/wps/myportal/wcmAuthoring?wcmAuthoringAction=new &type=com.ibm.workplace.wcm.api.WCM_Content &wcmfield.content.title=newcontent`

To open a content item in edit mode and automatically change keywords:

- Tag: `[plugin:RemoteAction action="edit" docid="com.ibm.workplace.wcm.api.WCM_Content/ID1" wcmfield.content.keywords="keyword1" wcmfield.content.keywords="keyword2"]`
- Url: `http://<host>/wps/myportal/wcmAuthoring?wcmAuthoringAction=edit &docid=com.ibm.workplace.wcm.api.WCM_Content/ID1 &wcmfield.content.keywords=keyword1&wcmfield.content.keywords=keyword2`

To edit a content item, automatically change the keywords and use autosave to automatically save the content (no dialog opens):

- Tag: `[plugin:RemoteAction action="edit" docid="com.ibm.workplace.wcm.api.WCM_Content/ID1" wcmfield.content.keywords="keyword1" wcmfield.content.keywords="keyword2" wcmfield.autosave="true"]`

- Url: `http://<host>/wps/myportal/wcmAuthoring?wcmAuthoringAction=edit &docid=com.ibm.workplace.wcm.api.WCM_Content/ID1 &wcmfield.content.keywords=keyword1&wcmfield.content.keywords=keyword2 &wcmfield.autosave=true`

To edit a content item, automatically save the item and prevent any validation exception from being displayed, use autosave with saveValidate=false:

- Tag: `[plugin:RemoteAction action="edit" docid="com.ibm.workplace.wcm.api.WCM_Content/ID1" wcmfield.content.keywords="keyword1" wcmfield.autosave="true" wcmfield.saveValidate="false"]`
- Url: `http://<host>/wps/myportal/wcmAuthoring?wcmAuthoringAction=edit &docid=com.ibm.workplace.wcm.api.WCM_Content/ID1 &wcmfield.content.keywords=keyword1&wcmfield.autosave=true &wcmfield.saveValidate=false`

To create a content item, set the name and use autosave to automatically save the content (no dialog opens). The authoring template that is used by the content item must have a workflow pre-selected:

- Tag: `[plugin:RemoteAction action="new" type="com.ibm.workplace.wcm.api.WCM_Content" atid="com.ibm.workplace.wcm.api.WCM_AuthoringTemplate/ID1" pid="com.ibm.workplace.wcm.api.WCM_SiteArea/ID2" wcmfield.content.name="newcontent" wcmfield.autosave="true" wcmfield.saveValidate="true"]`
- Url: `http://<host>/wps/myportal/wcmAuthoring?wcmAuthoringAction=new &type=com.ibm.workplace.wcm.api.WCM_Content &atid=com.ibm.workplace.wcm.api.WCM_AuthoringTemplate/ID1 &pid=com.ibm.workplace.wcm.api.WCM_SiteArea/ID2 &wcmfield.content.name=newcontent&wcmfield.autosave=true &wcmfield.saveValidate=true`

To edit a content item and create a draft on the edit and set the history log comment:

- Tag: `[plugin:RemoteAction action="edit" docid="com.ibm.workplace.wcm.api.WCM_Content/ID1" createDraft="true" comment="comment"]`
- Url: `http://<host>/wps/myportal/wcmAuthoring?wcmAuthoringAction=edit &docid=com.ibm.workplace.wcm.api.WCM_Content/ID1&createDraft=true &comment=comment`

How to create custom plug-ins

A custom plug-in is a reusable Java class that you create to run a task. You can create custom plug-ins such as custom workflow actions, plug-ins to run when a page is rendered, plug-ins to store multi-locale text strings and plug-ins to run when a file is uploaded.

"Creating a custom button class" on page 3207
You can create custom button classes that dynamically add custom actions to the authoring interface. Custom buttons are used to integrate third-party tools into the authoring interface without using a custom element. For example, you can use a custom button that adds automatic profiling of a content item or that adds or changes elements on the item forms.

"Deploying custom plug-in applications" on page 3254
You must deploy your custom plug-in applications on your server before they can be used in your web content system.

Creating a custom button class

You can create custom button classes that dynamically add custom actions to the authoring interface. Custom buttons are used to integrate third-party tools into the authoring interface without using a custom element. For example, you can use a custom button that adds automatic profiling of a content item or that adds or changes elements on the item forms.

About this task

Each extension adds an optional single button to the Read or Edit mode of an item form. When started, the extension can run any data modification on the item. Even in read mode, the extension can change the item state and run save operations. To create a custom button plug-in, you must create a custom button class and then register the class by deploying it on the server.

Procedure

1. Create a java class that implements the interface `com.ibm.workplace.wcm.api.extensions.authoring.AuthoringAction`. This class must implement the following methods:

   `public boolean isValidForForm(final FormContext formContext) {}`
   This method flags whether the button should be included on the button bar or ignored for the open item. Any uncommitted changes that are made to the document contained within the form context is discarded when this method runs. The method is started each time that the page is rendered to limit performance impacts. Use the target authoring form for *formContext*.

   `public int ordinal() {}`
   This method returns a number that determines where the button is placed relative to any other buttons created by other AuthoringAction classes. The button with the lowest number is listed first.

   See the Javadoc documentation for further information. The Javadoc files for Web Content Manager are in the *`PortalServer_root`*`/doc/Javadoc/spi_docs/com/ibm/workplace/wcm` directory.

2. Implement the `ActionResult execute(final FormContext formContext)` method, which is started when the user clicks the button.

   Any uncommitted changes that are made to the document contained within the form context is discarded when this method runs. Use the target authoring form for *formContext*.

3. A plugin.xml file is needed whether the deployment is done by using a WAR or EAR, or by using a loose jar. If deploying by using an application in a WAR or EAR, include the plugin.xml file in the application's "WEB-INF" folder. When using a jar, include the plugin.xml in the root of the jar.

```
<?xml version="1.0" encoding="UTF-8"?>
<plugin id="com.ibm.workplace.wcm.sample.authoringaction"
        name="Sample Authoring Action Extension"
        version="1.0.0"
        provider-name="IBM">
  <extension
     point="com.ibm.workplace.wcm.api.AuthoringAction
```

```
      id="SampleAuthoringAction" >
      <provider class="com.ibm.workplace.wcm.sample.MyAuthoringAction"/>
  </extension>
</plugin>
```

What to do next

- The ID of each plug-in must be unique.
- You must replace the plug-in ID specified in this example, `com.ibm.workplace.wcm.sample.authoringaction`, with a different ID for each extension you create.
- Each AuthoringAction extension is represented by a single `<extension></extension>` tag.
- The value of the point attribute must be `com.ibm.workplace.wcm.api.AuthoringAction`.
- Provide an id value of your choice.
- Specify the provider class for your AuthoringAction extension.

Naming conventions:

If you create a new plug-in application with the same names and IDs as an existing plug-in, the new plug-in can override the first. When creating plug-in applications ensure that the following are unique across your system:

- The plug-in ID, plug-in name and extension ID of the plugin.xml file.
- The fully qualified class name plus path of all classes within the application.
- The file path of any files within the application.

How to create a rendering plug-in class

A rendering plug-in is a reusable class that you create to run a task at render time. It can be referenced within web content by using a plug-in tag. For example, you might write a plug-in that uses attributes from the current user's profile to determine whether the body of the plug-in tag is rendered or not. A rendering plug-in class requires you to reference a set of web content API methods.

Creating a plug-in class

1. Create a Java class that implements the interface `com.ibm.workplace.wcm.api.plugin.rendering.RenderingPlugin` or `RenderingPluginDefinition`. This class must implement the following methods:
   - `public String getName()` .

     Note: This name is used as the "name" parameter of the plug-in tag. See Creating a plug-in tag for further information.
   - `public Boolean render(RenderingPluginModel p_model)` throws `RenderingPluginException`.
2. Implement `render()method`. This method contains the code that is run when the plug-in is started during rendering of a layout that contains a "plug-in" tag that references the custom plug-in. Returning true renders the body markup that is defined in the plug-in tag. If false is returned, the body of the plug-in tag is skipped. If the plug-in tag has no body markup, then the return value is ignored.
3. Methods that are inherited from *com.ibm.portal.Localized* must also be implemented.

public String getTitle(Locale displayLocale) {}
This method returns the title for the rendering plug-in that is used to allow selection of the rendering plug-in.

public ListModel<Locale> getLocales()
This method returns a list of locales that are supported by this rendering plug-in.

public String getDescription(Locale p_arg0)
This method returns a description of the rendering plug-in.

See the Javadoc documentation for further information. The Javadoc files for Web Content Manager are in the *PortalServer_root*/doc/Javadoc/spi_docs/com/ibm/workplace/wcm directory.

4. The rendering plug-in can optionally implement `RenderingPluginDefinition` instead of `RenderingPlugin` to define its type and parameters. This is recommended, because it allows the rendering plug-ins to be used more easily.

   To do this, implement the methods:

   - `public RenderingPluginType getType()`.
   - `public List<RenderingPluginParameter>getParameters()`.

   Note: When creating a custom rendering plug-in:

   - Do not use "name" as a parameter in the rendering plug-in, because the name of the plug-in is stored as the "name" parameter.
   - If you use "id" as a rendering parameter, it will not be displayed in read mode.

For example:

```
package test;

import java.io.IOException;
import java.io.Writer;
import java.util.ArrayList;
import java.util.Iterator;
import java.util.List;
import java.util.Locale;
import java.util.Map;
import java.util.Set;

import com.ibm.portal.ListModel;
import com.ibm.portal.ModelException;
import com.ibm.workplace.wcm.api.plugin.rendering.RenderingPluginDefinition;
import com.ibm.workplace.wcm.api.plugin.rendering.RenderingPluginException;
import com.ibm.workplace.wcm.api.plugin.rendering.RenderingPluginModel;
import com.ibm.workplace.wcm.api.plugin.rendering.RenderingPluginParameter;
import com.ibm.workplace.wcm.api.plugin.rendering.RenderingPluginParameterAdapter;
import com.ibm.workplace.wcm.api.plugin.rendering.RenderingPluginParameterImpl;
import com.ibm.workplace.wcm.api.plugin.rendering.RenderingPluginType;
import com.ibm.workplace.wcm.api.plugin.rendering.RenderingPluginTypes;
import com.ibm.workplace.wcm.api.plugin.rendering.RenderingPluginParameter.Required;
import com.ibm.workplace.wcm.api.plugin.rendering.ValueOptionImpl;

/**
 * A simple rendering plugin to demonstrate the use of the <code>RenderingPlugin</code> API.
 */
public class SimpleRenderingPlugin implements RenderingPluginDefinition
{
   /** The 'render body' parameter */
   private static final String RENDER_BODY_PARAM = "renderbody";

   /**
    * A simple list model holding locales.
```

```
 */
protected static class SimpleLocaleListModel<K> implements ListModel<Locale>
{
   /** the list of locales of this list model */
   final List<Locale> m_localeList = new ArrayList<Locale>();

   /**
    * Constructs this simple list model holding the given locales.
    *
    * @param p_locales
    *           the locales of this list model. May be <code>null</code>.
    */
   public SimpleLocaleListModel(final Locale[] p_locales)
   {
      if (p_locales != null)
      {
         for (int i = 0; i < p_locales.length; ++i)
         {
            m_localeList.add(p_locales[i]);
         }
      }
   }

   @Override
   public Iterator<Locale> iterator() throws ModelException
   {
      return m_localeList.iterator();
   }
}

/** a list model that only contains the English language locale */
private static final ListModel<Locale> ENGLISH_ONLY = new SimpleLocaleListModel<Locale>(new Locale

@Override
public String getDescription(final Locale p_locale)
{
   return "This is a simple rendering plugin.";
}

@Override
public ListModel<Locale> getLocales()
{
   return ENGLISH_ONLY;
}

@Override
public String getName()
{
   return "SimpleRenderingPlugin";
}

@Override
public String getTitle(final Locale p_locale)
{
   return "SimpleRenderingPlugin";
}

@Override
public boolean isShownInAuthoringUI()
{
   return false;
}

@Override
public boolean render(final RenderingPluginModel p_model) throws RenderingPluginException
{
   final Map<String, List<String>> params = p_model.getPluginParameters();
```

```
      // determine whether the inner contents of the plugin should actually be rendered
      final boolean renderBody;
      final List<String> renderBodyList = params.get(RENDER_BODY_PARAM);
      if (renderBodyList != null && renderBodyList.get(0).equals("false"))
      {
         renderBody = false;
      }
      else
      {
         renderBody = true;
      }

      // render the output of the plugin to the writer provided by the RenderingPluginModel
      final Writer writer = p_model.getWriter();
      try
      {
         writer.write("<b>Simple RenderingPlugin</b>");

         final Set<String> keys = params.keySet();

         final Iterator<String> iter = keys.iterator();
         while (iter.hasNext())
         {
            String key = iter.next();
            writer.write("<br>" + key + " = " + params.get(key));
         }

         writer.write("<br><br>");
      }
      catch (IOException e)
      {
         e.printStackTrace();
      }

      return renderBody;
   }

   @Override
   public RenderingPluginType getType()
   {
      return RenderingPluginTypes.CONTENT;
   }

   @Override
   public List<RenderingPluginParameter> getParameters()
   {
      List<RenderingPluginParameter> parameters = new ArrayList<RenderingPluginParameter>();
      RenderingPluginParameterAdapter renderBodyParam = new RenderingPluginParameterImpl(RENDER_BO
      parameters.add(renderBodyParam);
      return parameters;
   }
}
```

Create a `plugin.xml` file

A `plugin.xml` file is needed whether the deployment is done by using a WAR or EAR, or by using a loose jar. If deploying an application in a WAR or EAR, include the `plugin.xml` file in the application's `WEB-INF`folder. When using a jar, include the `plugin.xml` in the root of the jar.

```
<?xml version="1.0" encoding="UTF-8"?>
<?eclipse version="3.0"?>
<plugin
   id="Test"
   name="Simple Rendering Plug-in Test"
```

```
    version="1.0.0"
    provider-name="IBM">

    <extension
      point="com.ibm.workplace.wcm.api.RenderingPlugin"
      id="SimpleRenderingPlugin">
      <provider class="test.SimpleRenderingPlugin"/>
    </extension>
</plugin>
```

- Each plug-in is represented by a single `<extension></extension>` tag.
- The value of the point attribute must be `com.ibm.workplace.wcm.api.RenderingPlugin`.
- Provide an ID value of your choice.
- Specify the provider class for your plug-in.

Naming conventions:

If you create a plug-in application with the same names and IDs as an existing plug-in, the new plug-in will not be registered. When creating plug-in applications ensure that the following are unique across your system:

- The plug-in ID, plug-in name, and extension ID of the `plugin.xml` file.
- The fully qualified class name plus path of all classes within the application.
- The file path of any files within the application.

How to create a custom workflow action class

You can create custom workflow action classes to add custom workflow actions to a workflow.

Creating the custom workflow action class

1. Create a java class that implements the interface `com.ibm.workplace.wcm.api.custom.CustomWorkflowAction`. This class must implement the following methods:
   - `public Date getExecuteDate(Document p_document) {}` (This method specifies when the custom action is run.)
   - `public CustomWorkflowActionResult execute(Document p_document) {}` (This method contains the code that runs when the custom action is run.)
2. Implement `execute()method`. This method contains the code that is run against the supplied Document. This method must return a `com.ibm.workplace.wcm.api.custom.CustomWorkflowActionResult` object to indicate the result of the custom code by using `com.ibm.workplace.wcm.api.custom.Directives`.
   - A custom workflow action result object is created by first retrieving a reference to the `WebContentCustomWorkflowService` object, and then calling the method `webContentCustomWorkflowService.getCustomWorkflowService().createResult`. If the `CustomWorkflowActionResult` does not indicate a failure, changes to the document is saved.

     See the Javadoc documentation for further information. The Javadoc files for Web Content Manager are in the *`PortalServer_root`*`/doc/Javadoc/spi_docs/com/ibm/workplace/wcm` directory.
   - Also, see the Web Content Manager Javadoc for further information on valid directives.

3. Create a custom workflow action factory class that implements the interface `com.ibm.workplace.wcm.api.custom.CustomWorkflowActionFactory`.

Create a `plugin.xml` file

A `plugin.xml` file is needed whether the deployment is done by using a WAR or EAR, or by using a loose jar. If you deploy using an application in a WAR or EAR, include the `plugin.xml` file in the application's `WEB-INF` folder. When you use a jar, include the `plugin.xml` in the root of the jar.

```
<?xml version="1.0" encoding="UTF-8"?>
<plugin id="com.ibm.workplace.wcm.sample.customworkflowaction"
name="Sample Custom Workflow Action Factory"
version="1.0.0"
provider-name="IBM">

<extension
point="com.ibm.workplace.wcm.api.CustomWorkflowActionFactory"
id="SimpleCustomWorkflowActionFactory">
<provider class="com.ibm.workplace.wcm.sample.customworkflowaction.SimpleCustomWorkflowActionFacto
</extension>

</plugin>
```

- The ID of each plug-in must be unique. You must replace the plug-in ID specified in this example, *com.ibm.workplace.wcm.sample.customworkflowaction*, with a different ID for each custom workflow you create.
- Each custom workflow action factory is represented by a single `<extension></extension>` tag.
- The value of the point attribute must be `com.ibm.workplace.wcm.api.CustomWorkflowActionFactory`.
- Provide an ID value of your choice.
- Specify the provider class for your custom workflow action factory.

Naming conventions:

If you create a new plug-in application with the same names and IDs as an existing plug-in, the new plug-in can override the first. When you create plug-in applications ensure that the following are unique across your system:

- The plug-in ID, plug-in name, and extension ID of the `plugin.xml` file.
- The fully qualified class name plus path of all classes within the application.
- The file path of any files within the application.

Creating a Text Provider class

A text provider is used to provide localized text that can be used within web content item forms. For example, a text provider can be used to localize the field labels or help text within an authoring template so that each user sees the labels or help text in their own language.

About this task

To use a text provider, you must create a text provider class and then register the text provider by deploying it on the server.

Procedure

1. Create a java class that implements the interface *com.ibm.workplace.wcm.api.plugin.textprovider.TextProvider*. This class must implement the following methods:

   public String getProviderName()
   This method returns the unique name of the text provider.

   public String getString(String key, Locale displayLocale)
   This method returns some translated text, given a key identifying the message, and a locale.

   public Collection<String> getProviderKeys()
   This method returns a list of keys that are used when accessing the text provider. These keys are displayed in the authoring UI when a user is configuring the text provider.

   public boolean isShownInAuthoringUI()
   This method is used to prevent your text provider from appearing in the authoring UI.

   See the Javadoc documentation for further information. The Javadoc files for Web Content Manager are in the *PortalServer_root*/doc/Javadoc/spi_docs/com/ibm/workplace/wcm directory.

2. Methods that are inherited from *com.ibm.portal.Localized* must also be implemented.

   public String getTitle(Locale displayLocale)
   This method returns the title for the text provider that is used to allow selection of the text provider.

   public ListModel<Locale> getLocales()
   This method returns a list of locales that are supported by this text provider.

   public String getDescription(Locale p_arg0)
   This method returns a description of the text provider.

   For example:

```
package test;

import java.io.IOException;
import java.util.ArrayList;
import java.util.Collection;
import java.util.Iterator;
import java.util.LinkedHashSet;
import java.util.List;
import java.util.Locale;
import java.util.MissingResourceException;
import java.util.Properties;
import java.util.ResourceBundle;
import java.util.Set;

import com.ibm.portal.ListModel;
import com.ibm.portal.ModelException;
import com.ibm.workplace.wcm.api.plugin.textprovider.TextProvider;

/**
 * A simple text provider implementation
 */
public class SimpleTextProvider implements TextProvider
{
   /** Path to Bundle properties file (English used for loading keyset) */
   private static final String BUNDLE_PROPERTIES = "/test/SimpleBundle_en.properties";
```

```
/** The text provider title */
public static final String PROVIDER_TITLE = "Simple Text Provider";

/** The unique text provider name */
public static final String PROVIDER_NAME = "test.SimpleTextProvider";

/** A brief description of this text provider */
private static final String PROVIDER_DESCRIPTION = "Simple Text provider";

/** The resource bundle used to lookup strings */
private static final String RESOURCE_BUNDLE_NAME = "test.SimpleBundle";

/**
 * A simple list model holding locales.
 */
protected static class SimpleLocaleListModel<K> implements ListModel<Locale>
{
   /** the list of locales of this list model */
   final List<Locale> m_localeList = new ArrayList<Locale>();

   /**
    * Constructs this simple list model holding the given locales.
    *
    * @param p_locales
    *           the locales of this list model. May be <code>null</code>.
    */
   public SimpleLocaleListModel(final Locale[] p_locales)
   {
      if (p_locales != null)
      {
         for (int i = 0; i < p_locales.length; ++i)
         {
            m_localeList.add(p_locales[i]);
         }
      }
   }

   @Override
   public Iterator<Locale> iterator() throws ModelException
   {
      return m_localeList.iterator();
   }
}

/** a list model that only contains the English language locale */
private static final ListModel<Locale> ENGLISH_ONLY = new SimpleLocaleListModel<Locale>(new

@Override
public String getProviderName()
{
   return PROVIDER_NAME;
}

@Override
public String getTitle(Locale p_displayLocale)
{
   // Perform any localization for the plug-in title here
   return PROVIDER_TITLE;
}

@Override
public String getDescription(Locale p_displayLocale)
{
   return PROVIDER_DESCRIPTION;
}
```

```
@Override
public String getString(String p_key, Locale p_displayLocale)
{
   String value;

   try
   {
      ResourceBundle bundle = ResourceBundle.getBundle(RESOURCE_BUNDLE_NAME, p_displayLocale);
      value = bundle.getString(p_key);
   }
   catch (MissingResourceException e)
   {
      // The bundle or key was not found. Return null.
      value = null;
   }
   return value;
}

@Override
public Collection<String> getProviderKeys()
{
   Collection<String> keys = null;
   try
   {
      LinkedProperties props = new LinkedProperties();
      props.load(getClass().getClassLoader().getResourceAsStream(BUNDLE_PROPERTIES));

      keys = props.getKeySet();
   }
   catch (IOException e)
   {
      // The bundle was not found. Return null.
      e.printStackTrace();
   }

   return keys;
}

@Override
public ListModel<Locale> getLocales()
{
   return ENGLISH_ONLY;
}

@Override
public boolean isShownInAuthoringUI()
{
   return true;
}

/** Used to provide the properties in order */
private class LinkedProperties extends Properties {

   /** Keys */
   private final LinkedHashSet<String> keys = new LinkedHashSet<String>();

   /**
    * @return An ordered set of keys
    */
   public Set<String> getKeySet()
   {
      return keys;
   }

   @Override
   public Object put(Object key, Object value) {
```

```
            keys.add((String) key);
            return super.put(key, value);
        }
    }
}
```

See the Javadoc documentation for further information.

3. A `plugin.xml` file is needed whether the deployment is done using a WAR or EAR, or using a loose jar. If deploying via an application in a WAR or EAR, include the `plugin.xml` file in the application's `WEB-INF` folder. When using a jar, include the `plugin.xml` in the root of the jar.

```
<?xml version="1.0" encoding="UTF-8"?>
<plugin id="com.acme"
       name="Sample Text Provider"
       version="1.0.0"
       provider-name="IBM">

 <extension
    point="com.ibm.workplace.wcm.api.TextProvider"
    id="SampleTextProvider">
    <provider class="com.acme.SampleTextprovider"/>
 </extension>

</plugin>
```

Extend the Text ProviderAdapter: If you are creating a text provider that uses a resource bundle to provide the translated strings, your text provider class can extend `com.ibm.workplace.wcm.api.plugin.textprovider.TextProviderAdapter` instead of implementing `TextProvider`. If you choose to do this, the `getString()` and `getProviderKeys()` method are implemented for you, so you do not have to override them.

```
package com.ibm.workplace.wcm.ctc;

import java.util.Locale;

import java.io.IOException;
import java.util.ArrayList;
import java.util.Collection;
import java.util.Iterator;
import java.util.LinkedHashSet;
import java.util.List;
import java.util.MissingResourceException;
import java.util.Properties;
import java.util.ResourceBundle;
import java.util.Set;

import com.ibm.portal.ListModel;
import com.ibm.portal.ModelException;
import com.ibm.workplace.wcm.api.plugin.textprovider.TextProviderAdapter;

/**
 * A simple text provider implementation that extends TextProviderAdapter.
 */
public class SimpleTextProvider extends TextProviderAdapter
{
   /** The resource bundle used to lookup strings */
   private static final String RESOURCE_BUNDLE_NAME = "test.SimpleBundle";

   /** The text provider title */
   public static final String PROVIDER_TITLE = "Simple Text Provider";

   /** A brief description of this text provider */
   private static final String PROVIDER_DESCRIPTION = "Simple Text provider";
```

```
/** The unique text provider name */
public static final String PROVIDER_NAME = "test.SimpleTextProvider";

/**
 * A simple list model holding locales.
 */
protected static class SimpleLocaleListModel<K> implements ListModel<Locale>
{
   /** the list of locales of this list model */
   final List<Locale> m_localeList = new ArrayList<Locale>();

   /**
    * Constructs this simple list model holding the given locales.
    *
    * @param p_locales
    *           the locales of this list model. May be <code>null</code>.
    */
   public SimpleLocaleListModel(final Locale[] p_locales)
   {
      if (p_locales != null)
      {
         for (int i = 0; i < p_locales.length; ++i)
         {
            m_localeList.add(p_locales[i]);
         }
      }
   }

   @Override
   public Iterator<Locale> iterator() throws ModelException
   {
      return m_localeList.iterator();
   }
}

/** a list model that only contains the English language locale */
private static final ListModel<Locale> ENGLISH_ONLY = new SimpleLocaleListModel<Locale>(new Lo

@Override
public String getProviderName()
{
   return PROVIDER_NAME;
}

@Override
public String getTitle(Locale p_displayLocale)
{
   // Perform any localization for the plug-in title here
   return PROVIDER_TITLE;
}

@Override
public String getDescription(Locale p_displayLocale)
{
   return PROVIDER_DESCRIPTION;
}

@Override
public boolean isShownInAuthoringUI()
{
   return true;
}

@Override
protected String getResourceBundleName()
{
   return RESOURCE_BUNDLE_NAME;
```

```
    }

    @Override
    public ListModel<Locale> getLocales()
    {
       return ENGLISH_ONLY;
    }
}
```

What to do next

- Each plug-in is represented by a single `<extension></extension>` tag.
- The value of the point attribute must be `com.ibm.workplace.wcm.api.TextProvider`.
- Provide an id value of your choice.
- Specify the provider class for your plug-in.

Naming conventions:

If you create a new plug-in application with the same names and IDs as an existing plugin, the new plug-in may override the first. When creating plug-in applications ensure that the following are unique across your system:

- The plug-in ID, plug-in name and extension ID of the `plugin.xml` file.
- The fully qualified class name plus path of all classes within the application.
- The file path of any files within the application.

Sorting conventions:

When sorting is applied to a set of items, the item title is used to sort the items, not the title specified in the text provider.

Content plug-ins

Creating a Text Provider Factory class

A text provider factory is used to provide multiple text providers that can be used within web content item forms. Text provider can be used to localize the field labels or help text within an authoring template so that each user sees the labels or help text in their own language. A text provider factory can make multiple such text providers available.

About this task

To use a text provider factory, you must create a text provider factory class and then register the text provider factory by deploying it on the server.

Procedure

1. Create a java class that implements the interface *com.ibm.workplace.wcm.api.plugin.textprovider.TextProviderFactory*. This class must implement the following methods:

   `public String getProviderName()`
   This method returns the unique name of the text provider factory.

   `public List<TextProvider> getTextProviders()`
   This method returns a list of text providers supplied by this factory.

public Collection<String> getTextProvider(String p_providerName)
This method returns the text providers in the factory with the given name.

public boolean isShownInAuthoringUI()
This method is used to prevent the text providers in your text provider factory from appearing in the authoring UI.

See the Javadoc documentation for further information. The Javadoc files for Web Content Manager are in the *PortalServer_root*/doc/Javadoc/spi_docs/com/ibm/workplace/wcm directory.

2. A plugin.xml file is needed whether the deployment is done using a WAR or EAR, or using a loose jar. If deploying via an application in a WAR or EAR, include the plugin.xml file in the application's WEB-INF folder. When using a jar, include the plugin.xml in the root of the jar.

```
<?xml version="1.0" encoding="UTF-8"?>
<plugin id="com.acme"
       name="Sample text provider factory"
       version="1.0.0"
       provider-name="IBM">

 <extension
    point="com.ibm.workplace.wcm.api.TextProviderFactory"
    id="SampleTextProviderFactory">
    <provider class="com.acme.SampleTextproviderFactory"/>
 </extension>

</plugin>
```

What to do next

- Each plug-in is represented by a single <extension></extension> tag.
- The value of the point attribute must be com.ibm.workplace.wcm.api.TextProvider.
- Provide an id value of your choice.
- Specify the provider class for your plug-in.

Naming conventions:

If you create a new plug-in application with the same names and IDs as an existing plugin, the new plug-in may override the first. When creating plug-in applications ensure that the following are unique across your system:

- The plug-in ID, plug-in name and extension ID of the plugin.xml file.
- The fully qualified class name plus path of all classes within the application.
- The file path of any files within the application.

Sorting conventions:

When sorting is applied to a set of items, the item title is used to sort the items, not the title specified in the text provider factory.

Creating a file upload validation class

A file upload validation plug-in is started anytime a file is uploaded into Web Content Manager. This includes uploading files into file resource, image and stylesheet elements, and images that are uploaded into rich text or HTML elements. The plug-in is called within the "validation" processing that is used by Web Content Manager when uploading files.

About this task

To create a file upload validation plug-in, you must create a file upload validation class and then register the file upload validation class by deploying it on the server.

Procedure

1. Create a java class that implements the interface `com.ibm.workplace.wcm.api.extensions.validation.FileUploadValidationPlugin`. This class must implement the following methods:

   `public String getName()`
   This method returns the unique name of the file upload validation plug-in.

   `public boolean validate(InputStream p_inptStream, FileUploadValidationContext p_context)`
   This method throws the FileUploadValidationException.

   See the Javadoc documentation for further information. The Javadoc files for Web Content Manager are in the *`PortalServer_root`*`/doc/Javadoc/spi_docs/com/ibm/workplace/wcm` directory.

2. Implement `validate()method`. This method contains the code that will be run when the plug-in is invoked when uploading a file. If validated, the file continues to upload. If not validated then the file upload is stopped. You can display a message in the user interface by including the following code in validate method:

   ```
   throw new FileUploadValidationException( your own message );
   ```

   For example:

   ```
   package pers.smp.extension.test.validation;

   import java.io.InputStream;
   import java.util.logging.Logger;

   import com.ibm.workplace.wcm.api.extensions.validation.FileUploadValidationContext;
   import com.ibm.workplace.wcm.api.extensions.validation.FileUploadValidationException;
   import com.ibm.workplace.wcm.api.extensions.validation.FileUploadValidationPlugin;
   import com.ibm.workplace.wcm.services.validation.FileUploadValidationContextImpl;

   public class SMPValidation1 implements FileUploadValidationPlugin
   {
      private final long MAX_SIZE_IMAGES = 512 * 1024;
      private final long MAX_SIZE_FILES = 1024 * 1024;

      private static Logger s_log = Logger.getLogger(SMPValidation1.class.getName());

      public String getName()
      {
         return "SMPValidation1";
      }

      public boolean validate(InputStream p_inptStream, FileUploadValidationContext p_context)
   throws FileUploadValidationException
      {
         s_log.info("File Name : " + p_context.getFileName() );
         s_log.info("File Type : " + p_context.getMimeType() );
         s_log.info("File Size : " + p_context.getFileSize() );
         s_log.info("Document Type : " + p_context.getDocumentType() );

         boolean valid = true;
         String message = null;
   ```

```
      String mimeType = p_context.getMimeType();

      if ( mimeType != null && mimeType.startsWith( "image/" ) )
      {
         if ( ! (mimeType.equalsIgnoreCase( "image/gif") ||
mimeType.equalsIgnoreCase( "image/jpeg") ) )
         {
            throw new FileUploadValidationException( "Invalid image type : " + mimeType +
" will only accept GIF and JPG images" );
         }
         if ( p_context.getFileSize() > MAX_SIZE_IMAGES )
         {
            throw new FileUploadValidationException( "Image is too big 500K is maximum
size allowed for images.  Size is
" +  p_context.getFileSize());
         }
      }
      else
      {
         if ( p_context.getFileSize() > MAX_SIZE_FILES )
         {
            throw new FileUploadValidationException( "File is too big 1M is maximum
size allowed for
" + mimeType + ".  Size is " +  p_context.getFileSize());
         }

      }

      return valid;
   }
}
```

3. A plugin.xml file is needed whether the deployment is done using a WAR or EAR, or using a loose jar. If deploying via an application in a WAR or EAR, include the plugin.xml file in the application's "WEB-INF" folder. When using a jar, include the plugin.xml in the root of the jar.

```
<?xml version="1.0" encoding="UTF-8"?>
<plugin id="pers_smp_extension_test"
        name="SMP Test Extensions"
        version="1.0.0"
        provider-name="IBM">

  <extension
     point="com.ibm.workplace.wcm.api.FileUploadValidationPlugin" id="SMPValidation1">
     <provider class="pers.smp.extension.test.validation.SMPValidation1"/>
  </extension>

</plugin>
```

What to do next

- Each plug-in is represented by a single `<extension></extension>` tag.
- The value of the point attribute must be `com.ibm.workplace.wcm.api.FileUploadValidationPlugin`.
- Provide an ID value of your choice.
- Specify the provider class for your plug-in.

Naming conventions:

If you create a new plug-in application with the same names and IDs as an existing plug-in, the new plug-in can override the first. When creating plug-in applications ensure that the following are unique across your system:

- The plug-in ID, plug-in name and extension ID of the `plugin.xml` file.

- The fully qualified class name plus path of all classes within the application.
- The file path of any files within the application.

Creating an item validation plug-in class

An item validation plug-in is used to validate a TemplatedDocument prior to it being committed to the repository. It is invoked as part of the standard item validation step. For example, saves occurring in the authoring interface, public API or REST API.

Possibly usages of this extension point include:

- Validating cross field relationships
- Complex custom field validation
- Workflow validation for an item based on type and location in the repository

Creating the item validation plug-in class

1. Create a Java class that implements the interface `com.ibm.workplace.wcm.api.ItemValidationPlugin` . This class must implement the following methods:
   - `DocumentId<? extends AbstractAuthoringTemplate>[]validationScope()`
   - `ItemValidationResult validate(ItemContext context)`

   Note: The validate method returns a *ItemValidationResult* that reports back any errors to be shown to the current user.
2. Within the validate method any field of the item can be modified. After all validation plug-ins are started the standard item and template validation is performed. See the Web Content Manager Javadoc for further information.

   For example:

```
package com.sample;

import java.util.ArrayList;
import java.util.Iterator;
import java.util.List;
import java.util.Locale;

import com.ibm.portal.ListModel;
import com.ibm.portal.Localized;
import com.ibm.portal.ModelException;
import com.ibm.workplace.wcm.api.AbstractAuthoringTemplate;
import com.ibm.workplace.wcm.api.AuthoringTemplate;
import com.ibm.workplace.wcm.api.Content;
import com.ibm.workplace.wcm.api.Document;
import com.ibm.workplace.wcm.api.DocumentId;
import com.ibm.workplace.wcm.api.DocumentLibrary;
import com.ibm.workplace.wcm.api.DocumentTypes;
import com.ibm.workplace.wcm.api.RichTextComponent;
import com.ibm.workplace.wcm.api.WCM_API;
import com.ibm.workplace.wcm.api.Workspace;
import com.ibm.workplace.wcm.api.exceptions.ComponentNotFoundException;
import com.ibm.workplace.wcm.api.exceptions.OperationFailedException;
import com.ibm.workplace.wcm.api.exceptions.ServiceNotAvailableException;
import com.ibm.workplace.wcm.api.extensions.validation.ItemContext;
import com.ibm.workplace.wcm.api.ItemValidationPlugin;

Create a `plugin.xml` file

A `plugin.xml` file is needed whether the deployment is done by using a WAR or EAR, or by using a loose jar. If you deploy using an application in a WAR or EAR, include the `plugin.xml` file in the application's `WEB-INF` folder. When you use a jar, include the `plugin.xml` in the root of the jar.

```
<?xml version="1.0" encoding="UTF-8"?>

<plug-in
   id="Test"
   name="Simple Item Validation Plug-in"
   version="1.0.0"
   provider-name="IBM">

   <extension
     point="com.ibm.workplace.wcm.api.ItemValidationPlugin"
     id="SimpleItemValidationPlugin">
     <provider class="com.sample.SampleItemValidator"/>
   </extension>
</plug-in>
```

- Each plug-in is represented by a single `<extension></extension>` tag.
- The value of the point attribute must be `com.ibm.workplace.wcm.api.ItemValidationPlugin`.
- Provide an ID value of your choice.
- Specify the provider class for your plug-in.

Naming conventions:

If you create a new plug-in application with the same names and IDs as an existing plug-in, the new plug-in can override the first. When you create plug-in applications, ensure that the following are unique across your system:

- The plug-in ID, plug-in name, and extension ID of the `plugin.xml` file.
- The fully qualified class name plus path of all classes within the application.
- The file path of any files within the application.

Creating a subscriber class

A subscriber plug-in is used to run extra functions on the subscriber that can be used to determine if the subscriber is ready for syndication when a syndication event is started.

About this task

To create a subscriber plug-in, you must create a subscriber class and then register the subscriber class by deploying it on the server.

Procedure

1. Create a java class that implements the interface com.ibm.workplace.wcm.api.extensions.syndication.SubscriberReady. This class must implement the following methods:

   public ResultDirective onSubscriberReady(SubscriberEvent eventInfo)

   - This method contains the code that is run when the syndication run starts.
   - This method is run on the subscriber.
   - The extensions are run only when there are changes in the syndicator.
   - The extension is not run every time automatic syndication queues the syndicator.

   See the Javadoc documentation for further information. The Javadoc files for Web Content Manager are in the *PortalServer_root*/doc/Javadoc/spi_docs/com/ibm/workplace/wcm directory.
2. Implement the onSubscriberReady method. This method must return a com.ibm.workplace.wcm.api.extensions.syndication.ResultDirective object to indicate whether the syndication engine can continue or stop the syndication process.
3. A plugin.xml file is needed whether the deployment is done by using a WAR or EAR, or by using a loose jar. If deploying using an application in a WAR or EAR, include the plugin.xml file in the application's WEB-INF folder. When using a jar, include the plugin.xml in the root of the jar.

```
<?xml version="1.0" encoding="UTF-8"?>
<plugin id="com.ibm.workplace.wcm.sample.subscriberready"
        name="Sample Subscriber Ready Extension"
        version="1.0.0"
        provider-name="IBM">
  <extension
     point="com.ibm.workplace.wcm.api.SubscriberReady"
     id="SubscriberReadyExtension" >
     <provider class="com.ibm.workplace.wcm.sample.subscriberready.SubscriberReadyExtension"/>
  </extension>
</plugin>
```

What to do next

- The ID of each plug-in must be unique.
- You must replace the plug-in ID specified in this example, com.ibm.workplace.wcm.sample.subscriberready, with a different ID for each SubscriberReady extension you create.
- Each SubscriberReady extension is represented by a single <extension></extension> tag.
- The value of the point attribute must be com.ibm.workplace.wcm.api.SubscriberReady.
- Provide an ID value of your choice.
- Specify the provider class for your SubscriberReady extension.

Naming conventions:

If you create a new plug-in application with the same names and IDs as an existing plug-in, the new plug-in might override the first. When you create plug-in applications ensure that the following are unique across your system:

- The plug-in ID, plug-in name and extension ID of the plugin.xml file.

- The fully qualified class name plus path of all classes within the application.
- The file path of any files within the application.

Creating a syndicator class

A syndicator plug-in is used to run extra functions on the syndicator when a syndication event is started.

About this task

To create a syndicator plug-in, you must create a syndicator class and then register the syndicator class by deploying it on the server.

Procedure

1. Create a java class that implements the interface `com.ibm.workplace.wcm.api.extensions.syndication.SyndicatorStarted`. This class must implement the following methods:

   `public ResultDirective onSyndicatorStarted(SyndicatorEvent eventInfo)`

   - This method contains the code that is run when the syndication run starts.
   - This method is run after the plug-ins for the `SubscriberReady` extension point are run.
   - The extensions are run only when there are changes on the syndicator.
   - The extension is not run every time automatic syndication queues the syndicator.

   See the Javadoc documentation for further information. The Javadoc files for Web Content Manager are in the *PortalServer_root*`/doc/Javadoc/spi_docs/com/ibm/workplace/wcm` directory.
2. Implement the `onSyndicatorStarted` method.
   - This method contains the code that is run on the syndicator when there are changes available for syndication to the subscriber.
   - This method must return a `com.ibm.workplace.wcm.api.extensions.syndication.ResultDirective` object to indicate whether the syndication engine can continue or stop the syndication process.
3. A `plugin.xml` file is needed whether the deployment is done by using a WAR or EAR, or by using a loose jar. If deployed by using an application in a WAR or EAR, include the `plugin.xml` file in the application's `WEB-INF` folder. When you use a jar, include the `plugin.xml` in the root of the jar.

```
<?xml version="1.0" encoding="UTF-8"?>
<plugin id="com.ibm.workplace.wcm.sample.syndicatorstarted"
        name="Sample Syndicator Started Extension"
        version="1.0.0"
        provider-name="IBM">
  <extension
     point="com.ibm.workplace.wcm.api.SyndicatorStarted"
     id="SyndicatorStartedExtension" >
     <provider class="com.ibm.workplace.wcm.sample.syndicatorstarted.SyndicatorStartedExtensio
  </extension>
</plugin>
```

What to do next

- The ID of each plug-in must be unique.

- You must replace the plug-in ID specified in this example, com.ibm.workplace.wcm.sample.syndicatorstarted, with a different ID for each SyndicatorStarted extension you create.
- Each SyndicatorStarted extension is represented by a single <extension></extension> tag.
- The value of the point attribute must be com.ibm.workplace.wcm.api.SyndicatorStarted.
- Provide an ID value of your choice.
- Specify the provider class for your SyndicatorStarted extension.

Naming conventions:

If you create a new plug-in application with the same names and IDs as an existing plug-in, the new plug-in might override the first. When you create plug-in applications, ensure that the following are unique across your system:

- The plug-in ID, plug-in name, and extension ID of the plugin.xml file.
- The fully qualified class name plus path of all classes within the application.
- The file path of any files within the application.

Creating a context processor class

When configured, a context processor plug-in is started by the web content viewer portlet before rendering and allows the current context, such as the item to display, to be modified.

About this task

To create a context processor plug-in, you must create a context processor class and then register the context processor class by deploying it on the server and selecting it from within a web content viewer portlet.

Procedure

1. Create a Java class that implements the interface com.ibm.workplace.wcm.api.ContextProcessor. This class must implement the following method:

```
/**
    * Processes the supplied <i>ContextProcessorParams</i> and updates parameters within
    * as necessary
    *
    * @param p_currentSession The current Http Session
    * @param p_contextProcessorParams The editable <i>ContextProcessorParams</i> object
    */
   public void process(HttpSession p_currentSession, ContextProcessorParams p_contextProcessorPar
```

   See the Javadoc documentation for further information. The Javadoc files for Web Content Manager are in the *PortalServer_root*/doc/Javadoc/spi_docs/com/ibm/workplace/wcm directory.
2. Implement the process method. This method contains the code that is run when the plug-in is started and modifies the current context by using the ContextProcessorParams object before the current context is rendered.
3. A plugin.xml file is needed whether the deployment is done by using a WAR or EAR, or by using a loose JAR file. If deployed by using an application in a WAR or EAR, include the plugin.xml file in the application "WEB-INF" folder. When a JAR file is used, include the plugin.xml in the root of the JAR file.

```
<?xml version="1.0" encoding="UTF-8"?>
<plugin id="SampleContextProcessorPluginId"
name="SampleContextProcessor" provider-name="IBM" version="1.0.0">
    <extension point="com.ibm.workplace.wcm.api.ContextProcessor"
    id="SampleContextProcessorPlugin" >
        <processor class="com.acme.SampleContextProcessor"/>
    </extension>
</plugin>
```

4. Edit the settings of the web content viewer portlet you want to associate with your context processor:
   a. Go to the "configuration" or "edit shared settings" view of a web content viewer portlet.
   b. Go to **Advanced Options** > **Plugins**
   c. Select a context processor plug-in.

What to do next

- Each plug-in is represented by a single `<extension></extension>` tag.
- The value of the point attribute must be "`com.ibm.workplace.wcm.api.ContextProcessor`".
- Provide an ID value of your choice.
- Specify the provider class for your plug-in.

Naming conventions:

If you create a plug-in application with the same names and IDs as an existing plug-in, the new plug-in might override the first. When you create plug-in applications, ensure that the following are unique across your system:

- The plug-in ID, plug in name, and extension ID of the `plugin.xml` file.
- The fully qualified class name plus path of all classes within the application.
- The file path of any files within the application.

Creating a content page resolution filter class

A content page resolution filter is used to customize the behavior of the content page resolution filter chain. This method is used to tailor the response to a web content request in several ways, including overriding the content item that is displayed or the portal page that is used to display a content item in the web content viewer.

About this task

The content page resolution filter chain is composed of filters that are based on the Intercepting Filter design pattern, which provides a mechanism for intercepting a request and manipulating the request and its response. When used with requests for web content, the content page resolution filter chain has default filters that process any URL parameters that are contained in the web content request and then determine which portal page has a matching web content association. The default filters occur at the end of the filter chain.

You can customize the content page resolution filter chain by creating custom filters that are registered with the portal through the Eclipse plug-in framework with the extension ID `com.ibm.workplace.wcm.api.ContentPageResolutionFilter`. The sequence of filters in the filter chain is specified by a weight value associated with each filter. To insert custom filters into the filter chain before the default

filters, you can use the `weight` attribute in the `plugin.xml` file. If the `weight` attribute is not present, filter sequence is determined by the `getFilterChainWeight` method of each custom filter.

Custom filters can perform various actions:

- Modify parameters before calling the default filters.
- Modify the result of the default filters.
- Handle exceptions that are generated by the default filters.
- Determine whether the default filters are started.
- Modify the content path that is used as input for the default filters.
- Explicitly set a target page for displaying content.
- Determine which web content page are used, if the default filters find more than one matching web content page for the request.
- Modify the presentation template selection.
- Set HTTP response status codes.
- Send redirects to external web resources.

To use a content page resolution filter, you must create a content page resolution filter class and then register the filter by deploying it on the server.

Procedure

1. Create a java class that implements the interface *com.ibm.workplace.wcm.api.extensions.resolution.ContentPageResolutionFilter*. This class must implement the following methods:

   `public int getFilterChainWeight() {}`
   This method returns the weight that is applied to the content page resolution filter elements in the filter chain. The less it is weighted, the earlier the filter is inserted into the chain.If the `weight` parameter is defined in the `plugin.xml` file, that value overrides the value that is returned by this method.

   `public void resolve(ContentPageResolutionRequest request, ContentPageResolutionResponse response, ContentPageResolutionFilterChain chain) {}`
   This method is started during `ContentPageResolution` processing. The `response` parameter is used to modify the content item that is displayed, the portal page where the content is displayed, and the presentation template that is used to render the content item. The request extends the resolver interface with an extra method that gets the content item that is addressed. The filter chain contains the subsequent filters that can be started if needed.

   See the Javadoc documentation for further information. The Javadoc files for Web Content Manager are in the *`PortalServer_root`*`/doc/Javadoc/spi_docs/com/ibm/workplace/wcm` directory.

2. A `plugin.xml` file is needed whether the deployment is done by using a WAR or EAR, or by using a loose jar. If deploying with an application in a WAR or EAR, include the `plugin.xml` file in the application's "WEB-INF" folder. When using a jar, include the `plugin.xml` in the root of the jar.

   ```
   <?xml version="1.0" encoding="UTF-8"?>
   <plugin id="com.example"
          name="Sample Content Page Resolution Filter"
          version="1.0.0"
          provider-name="IBM">
   ```

```
 <extension
    point="com.ibm.workplace.wcm.api.ContentPageResolutionFilter"
    id="SampleContentPageResolutionFilter">
    <provider class="com.example.SampleContentPageResolutionFilter"
              weight="1"/>
 </extension>

</plugin>
```

When creating plug-ins, note the following:

- Each plug-in is represented by a single `<extension>` tag.
- The value of the extension point attribute must be `com.ibm.workplace.wcm.api.ContentPageResolutionFilter`.
- Provide an ID value of your choice.
- Specify the filter class for your plug-in.
- The `weight` parameter overrides the value of the `getFilterChainWeight` method.

Naming conventions:

If you create a new plug-in application with the same names and IDs as an existing plug-in, the new plug-in can override the first. When creating plug-in applications ensure that the following are unique across your system:

- The plug-in ID, plug-in name, and extension ID of the `plugin.xml` file.
- The fully qualified class name and path of all classes within the application.
- The file path of any files within the application.

Examples

- The `LocaleDependantSelectionFilter` example performs the default page resolution and selects a target page from the candidate pages, according to the user's locale.

```
package com.ibm.workplace.wcm.extension.resolution;

import java.util.List;
import java.util.Locale;

import javax.naming.InitialContext;
import javax.naming.NamingException;

import com.ibm.portal.ObjectID;
import com.ibm.portal.model.CorLocalizedContextHome;
import com.ibm.portal.model.LocalizedContext;
import com.ibm.workplace.wcm.api.extensions.resolution.ContentPageResolutionFilter;
import com.ibm.workplace.wcm.api.extensions.resolution.ContentPageResolutionFilterChain;
import com.ibm.workplace.wcm.api.extensions.resolution.ContentPageResolutionRequest;
import com.ibm.workplace.wcm.api.extensions.resolution.ContentPageResolutionResponse;
import com.ibm.workplace.wcm.api.extensions.resolution.exceptions.ContentPageResolutionException;

public class LocaleDependantSelectionFilter implements ContentPageResolutionFilter
{
   CorLocalizedContextHome localizedContextHome;

   public LocaleDependantSelectionFilter()
   {
      try
      {
         InitialContext ctx = new InitialContext();
         localizedContextHome = (CorLocalizedContextHome) ctx.lookup(CorLocalizedContextHome.JNDI_NAME);
      }
      catch(NamingException e)
      {
         e.printStackTrace();
      }
   }

   public int getFilterChainWeight()
   {
      return 2;
   }
```

```
   public void resolve(ContentPageResolutionRequest request, ContentPageResolutionResponse response,
ContentPageResolutionFilterChain chain)
         throws ContentPageResolutionException
   {
      // do standard resolution first
      chain.resolve(request, response);

      // check if more than one candidate pages
      List<ObjectID> candidates = response.getCandidatePageIds();
      if (candidates.size() > 1)
      {
         LocalizedContext context = localizedContextHome.getLocalizedContext(request.getContext());
         Locale locale = context.getPreferredSupportedLocale();
         String lang = locale.getLanguage();
         // find page with matching unique name
         for (ObjectID pageId : candidates)
         {
            if (pageId.getUniqueName().endsWith("." + lang))
            {
               response.setPageID(pageId);
               break;
            }
         }
      }
   }
}
```

- The `ChangeContentPathFilter` example overrides the path of the content that is rendered but the page resolution is performed on the originally requested content.

```
package com.ibm.workplace.wcm.extension.resolution;

import com.ibm.workplace.wcm.api.extensions.resolution.ContentPageResolutionFilter;
import com.ibm.workplace.wcm.api.extensions.resolution.ContentPageResolutionFilterChain;
import com.ibm.workplace.wcm.api.extensions.resolution.ContentPageResolutionRequest;
import com.ibm.workplace.wcm.api.extensions.resolution.ContentPageResolutionResponse;
import com.ibm.workplace.wcm.api.extensions.resolution.exceptions.ContentPageResolutionException;

public class ChangeContentPathFilter implements ContentPageResolutionFilter
{
   public int getFilterChainWeight()
   {
      return 3;
   }

   public void resolve(ContentPageResolutionRequest request, ContentPageResolutionResponse response,
ContentPageResolutionFilterChain chain)
         throws ContentPageResolutionException
   {
      // resolve page using requested content
      chain.resolve(request, response);

      // but instead of england render UK
      if ("countries/world/europe/england".equals(response.getContentPath()))
      {
         response.setContentPath("countries/world/europe/uk");
      }
   }
}
```

- The `ResolveToSpecificPageFilter` example resolves to a specific page. No default resolution is performed in this case.

```
package com.ibm.workplace.wcm.extension.resolution;
import java.util.Arrays;
import javax.naming.InitialContext;
import javax.naming.NamingException;
import com.ibm.portal.ObjectID;
import com.ibm.portal.identification.Identification;
import com.ibm.portal.serialize.SerializationException;
import com.ibm.workplace.wcm.api.extensions.resolution.ContentPageResolutionFilter;
import com.ibm.workplace.wcm.api.extensions.resolution.ContentPageResolutionFilterChain;
import com.ibm.workplace.wcm.api.extensions.resolution.ContentPageResolutionRequest;
import com.ibm.workplace.wcm.api.extensions.resolution.ContentPageResolutionResponse;
import com.ibm.workplace.wcm.api.extensions.resolution.exceptions.ContentPageResolutionException;

public class ResolveToSpecificPageFilter implements ContentPageResolutionFilter
{
   private Identification identification;

   public ResolveToSpecificPageFilter()
   {
      try
      {
          InitialContext ctx = new InitialContext();
          identification = (Identification) ctx.lookup("portal:service/Identification");
      }
      catch (NamingException nx)
      {

 Intercepting Filter design pattern

Creating a content URL generation filter class

A content URL generation filter is used to customize the URLs that are generated by a web content viewer. By creating a plug-in that implements a content URL generation filter, you can tailor the URLs to content items.

About this task

The web content viewer generates a content URL whenever there is a URL to web content within content that the viewer is displaying.

The content URL generation filter chain is a chain of filters that are based on the Intercepting Filter design pattern. This design pattern provides a mechanism for intercepting a request and manipulating the request and its response. When used with requests for content URL generation, the content URL generation filter chain has default filters that run the following actions:

- Process any request to generate a URL that target a web content item.
- Create a URL based on the configuration of the web content viewer and any parameters set on the URL generation tags, such as the `URLCmpnt` tag.

The default filters occur at the end of the filter chain.

You can customize the content URL generation filter chain by creating custom filters. These filters are registered with the portal through the Eclipse plug-in framework with the extension ID `com.ibm.workplace.wcm.api.ContentUrlGenerationFilter`. The sequence of filters in the filter chain is specified by a weight value that is associated with each filter plug-in. To insert custom filters into the filter chain before the default filters, you can use the `weight` attribute in the `plugin.xml` file. If the `weight` attribute is not present, filter sequence is determined by the `getFilterChainWeight` method of each custom filter factory.

Custom content URL generation filters can run various actions:

- Modify parameters before you call the default URL generation filters.
- Modify the URL that is generated by the default filters.
- Handle exceptions that are generated by the default filters.
- Determine whether the default filters are started.
- Modify the content path that is used as input for the default URL generation filters.
- Generate any type of URL without using the default URL generation filters.

Important: You can use custom content URL generation filters to modify only URLs that are generated by web content tags, such as the `Placeholder` or the `URLCmpnt` tag. The Web Content Viewer does not call custom content URL generation filters when it generates, for example, the URLs of a page navigation component.

To use a content URL generation filter, you must create two classes:

- A content URL generation filter that is used to create URLs.
- A content URL generation filter factory that is used to create new instances of the filter.

You must deploy both classes on the server and register the filter factory by using a `plugin.xml` file.

Procedure

1. Create a Java class that implements the interface *com.ibm.workplace.wcm.api.extensions.url.ContentUrlGenerationFilterFactory*. This class must implement the following methods:

   `public ContentUrlGenerationFilter getFilter(RenderRequest portletRequest, RenderResponse portletResponse) throws ContentUrlFilterInstantiationException`
   This method is called by the content URL generation chain once for each content item that is rendered. The method creates an instance of a content URL generation filter, which generates all URLs that appear in the rendered web content.

   `public int getFilterChainWeight() {}`
   This method returns the weight that is applied to the content URL generation filter elements in the filter chain. The less it is weighted, the earlier the filter is inserted into the chain. If the `weight` parameter is defined in the `plugin.xml` file, that value overrides the value that is returned by this method.

   See the Javadoc documentation for further information. The Javadoc files for Web Content Manager are in the *`PortalServer_root`*`/doc/Javadoc/spi_docs/com/ibm/workplace/wcm` directory.

2. Create a Java class that implements the interface *com.ibm.workplace.wcm.api.extensions.url.ContentUrlGenerationFilter*. This class must implement the following methods:

   `public void writeURL(ContentUrlGenerationRequest request, ContentUrlGenerationResponse response, ContentUrlGenerationFilterChain chain) throws ContentUrlGenerationException, IOException`
   This method is started during content URL generation processing and is started once per content URL. The response parameter is used to write to the URL. The request parameter contains the following information:
   - Information about the item for which the URL is generated.
   - Any web content viewer configuration and related information that might affect the generation of the URL.

   The filter chain contains the subsequent filters that can be started when needed.

   `public void dispose()`
   This method is started by the filter chain after all URLs that appear in the rendered content items are written. The method enables filters to run a cleanup of their internal state.

   For more information about this class, see the Javadoc documentation.

3. A `plugin.xml` file is needed whether the deployment is done by using a WAR or EAR file, or by using a JAR file. If you deploy with an application in a WAR or EAR file, include the `plugin.xml` file in the `WEB-INF` folder. When you use a JAR file, include the `plugin.xml` in the root of the JAR file.

   ```
   <?xml version="1.0" encoding="UTF-8"?>
   <plugin id="com.example.content.url"
          name="Sample content URL generation filter"
          version="1.0.0"
          provider-name="IBM">
   ```

```
 <extension
    point="com.ibm.workplace.wcm.api.ContentUrlGenerationFilter"
    id="SampleContentUrlGenerationFilter">
    <factory class="com.example.SampleContentUrlGenerationFilterFactory"
             weight="1"/>
 </extension>

</plugin>
```

When you create plug-ins, note the following characteristics:

- Each plug-in is represented by a single `<extension>` tag.
- The value of the extension point attribute must be `com.ibm.workplace.wcm.api.ContentUrlGenerationFilter`.
- Provide an ID value of your choice.
- Specify the filter factory class for your plug-in.
- The `weight` parameter overrides the value of the `getFilterChainWeight` method.

Naming conventions:

If you create a new plug-in application with the same names and IDs as an existing plug-in, the new plug-in might override the first. When you create plug-in applications ensure that the following elements are unique across your system:

- The plug-in ID, plug-in name, and extension ID of the `plugin.xml` file.
- The fully qualified class name and path of all classes within the application.
- The file path of any files within the application.

"Example 1: Append a prefix to a content URL"
This example demonstrates a content URL generation filter that appends a prefix to each content URL that is written. This type of content URL generation filter is useful when used with an HTTP server that dynamically rewrites incoming URLs.

    <extension point="com.ibm.workplace.wcm.api.ContentUrlGenerationFilter" id="MyRewriteUrlGenerationFilter">
        <factory class="com.ibm.workplace.wcm.api.samples.RewriteUrlGenerationFilterFactory"
                 weight="5"/>
    </extension>
</plugin>
```

Example 2: Generate a friendly URL for web content

This example demonstrates a content URL generation filter that generates a friendly URL for web content.

The filter determines the target portal page that is used to render the web content. If there is a web content page that has a content association that references a parent site area of the content, the filter creates a friendly URL to the content.

Friendly URLs for web content are constructed according to several factors. For example, the friendly URL `/wps/myportal/home/news/news+1` is determined by the following details:

- Content path: `/Library1/News/News 1`

- Content association on the web content page where the content is rendered: `/Library1/News` site area
- Friendly URL of this page: `/home/news`

To use the sample filter that is described here, each page for which a content URL is generated must have these characteristics:

- The page must be a web content page with a friendly name.
- The page must have a default content association that references the parent site area of the content item.

The friendly URLs that are generated by this sample filter do not contain any portlet state information. When a user clicks one of these friendly URLs from within a web content viewer that does maintain state information, the state information in the viewer is cleared.

Important:

- These sample filter classes are not provided by default with IBM Web Content Manager. Example code is provided here that you can take and use to implement the classes yourself.
- Some web content URLs strictly require state information, for example the URLs that are generated by page navigation components. Therefore, web content URLs that are not generated by web content tags, such as the `Placeholder` or the `URLCmpnt` tag, are not processed by custom content URL generation filters.

  "Example 2: Filter factory class"
  This sample demonstrates a filter factory class. This filter class creates an instance of the filter for each request to render web content that contains URLs to other web content items.

  "Example 2: Filter class" on page 3245
  This sample filter generates the friendly URL.

  "Example 2: `plugin.xml` file" on page 3254
  You can use this sample `plugin.xml` file to register the sample filter.

Related concepts:

"Friendly URLs and Web Content Viewers" on page 2040
Friendly URLs provide a way for you to define a custom address for a portal page that is easy to remember and share. The Web Content Viewer expands on friendly URL support so you can specify extra path information in the friendly URL.

Related tasks:

"Using friendly URLs without state information" on page 1281
By default, WebSphere Portal Express URLs include navigational state information. If you configure pages for friendly URLs, the portal appends the state information to the friendly URLs. Some scenarios require short and fully human readable URLs that omit the state information. For such scenarios, you can configure friendly URLs so that the portal does not show that state information.

Example 2: Filter factory class:

This sample demonstrates a filter factory class. This filter class creates an instance of the filter for each request to render web content that contains URLs to other web content items.

The factory also obtains references to portal services and models that are required by the filter. These references are required to look up web content pages according to these criteria:

- The path of the web content for which the URL is generated.
- The configuration of the web content viewer.

By default, this sample filter is enabled after you deploy the sample classes. However, you can disable the sample filter by setting the following portlet preference in the web content viewer configuration:

- Preference: **DISABLE_FriendlyUrlGenerationFilter**
- Value: `true`

Example 2: Filter class:

This sample filter generates the friendly URL.

The filter runs several steps to create the friendly URL:

1. The filter determines the target portal page from one of the following sources:
   - The configuration of the web content viewer.
   - Any web content pages that have a content association to the content for which the URL is generated.
   - A target page that is specified by the `UrlCmpnt` tag.
2. If a target page is identified, the filter verifies that the page is a web content page with a content association. The filter then validates that the content for which the URL is generated is a child of the site area that is mapped to the page. If the content to render is not a child of the site area that is associated with the page, the filter writes a new URL.
3. The filter then writes the friendly URL by combining the following information:
   - The friendly URL name of the target page.
   - The path to the content, relative to the site area that is associated with the target page.

/**
 * Content URL generation filter that tries to generate stateless friendly URLs
 * for web content pages.
 *
 * The filter that writes the friendly URL does the following steps to generate
 * the friendly URL
 *
 * <ol>
 * <li>It determines the target portal page from one of the following sources The
 * Web Content Viewer configuration Web content pages that have a content
 * mapping for the content the URL is generated for A target page specification
 * from the WCM [UrlCmpnt] tag
 * </li>
 * <li>If a page could be determined it checks if the page is a web content page
 * i.e. if the page has a content mapping assign. It then validates that the
 * content the URL is generated for is a children of the site area mapped to the
 * page. In case the content is not a children of the site area mapped to the
 * page new URL is written by this filter.
 * </li>
 * <li>Finally the friendly URL is written that is build from the friendly URL
 * name of the target page appended with the content path relative to the site
 * area mapped to the target page.</li>
 * </ol>
 * <p>
 * <b>Note:</b> In order to use the following sample filter all pages a content URL is
 * generated for need to be web content pages with a friendly name assigned and
 * a default content mapping that points to a parent of the content.</p>

Example 2: `plugin.xml` file:

You can use this sample `plugin.xml` file to register the sample filter.

```
<?xml version="1.0" encoding="UTF-8"?>
<?eclipse version="3.0"?>
<plugin id="com.ibm.workplace.wcm.api.samples.plugin" name="My content URL plug-in"
        version="1.0.0" provider-name="IBM">
     <extension point="com.ibm.workplace.wcm.api.ContentUrlGenerationFilter"
                id="MyFriendlyUrlGenerationFilter">
        <factory class="com.ibm.workplace.wcm.api.samples.FriendlyUrlGenerationFilterFactory"
                 weight="4"/>
     </extension>
</plugin>
```

Deploying custom plug-in applications

You must deploy your custom plug-in applications on your server before they can be used in your web content system.

To ensure that the new web content class is available each time your server is started, register the ear file in the WebSphere Integrated Solutions Console:

1. Select **Applications**.
2. Select **New Application**.
3. Select **New Enterprise Application**.
4. Browse for the ear file.
5. Select **next** until you reach **step 2. Map modules to servers**.
6. Select the check box for the custom action module.
7. In the Clusters and servers section, select **WebSphere_Portal** and select **Apply**.
8. Keep selecting **Next** until the end when you select **Finish**.
9. The screen titled Installing is shown. Select **Manage Applications**.
10. Locate and click the application that you installed. The default name is the display name that is defined in the `application.xml` file in your ear file.
11. Under Detail Properties select **Startup behavior**.
12. Under General Properties modify the Startup order to be the same weight as "wcm" and select **Apply**. By default, the weight is 20.
13. Select **Save directly to master configuration**.
14. To immediately start the application you installed, select the application and click **Start**.

To update an existing ear file:

1. Select **Applications**.
2. Select **Application Types**.
3. Select **WebSphere enterprise applications**.
4. Search for the Application name.
5. Select the check box for the custom action application and click **Update**.
6. Select **Replace the entire application** and browse for the ear file.
7. Keep selecting **Next** until the end when you select **Finish**.

8. The screen that is titled 'updating' is shown. Select **Save to Master Configuration** and then click **save**.

IBM Digital Data Connector (DDC) for WebSphere Portal Express

You can use the IBM Digital Data Connector (DDC) for WebSphere Portal Express framework to integrate data from external data sources on your portal pages by using IBM Web Content Manager presentation components. External data means that the data does not need to be stored directly in IBM Web Content Manager. For example, you can use DDC to render social data that you have on your IBM Connections server or on other social platforms in the context of your portal pages. Other possible data sources include news feeds, task lists, product catalog information, to name just a few.

With Digital Data Connector, your website designers can use Web Content Manager presentation components to generate the web page markup for your external data. They can use all the Web Content Manager data management facilities for managing your external data visualizations. These facilities include content syndication, version handling, workflow, and targeting. They can manage the design components in the same way as your other Web Content Manager content and design components. The major benefits of this approach include the following:

- Your Web Content Manager designers can fully control the visual appearance of the integrated data.
- They can visualize the external data in the same way in which they visualize data that is stored in Web Content Manager.
- As a result, they can visualize the external data in a way that is consistent with the corporate design of your overall website by reusing existing Web Content Manager components.
- To quickly adjust existing visualizations of your data or create new visualizations for new kinds of external data, you no longer need the help of software developers or the IT department. Your website designers can start working on the presentation templates directly from your portal pages that show the data. They use the inline editing capabilities of Web Content Manager.
- Your website designers make updates to the Web Content Manager design components in project scope. This way, they can keep updates in draft stage until all updates to the project are completed, approved, and finally published.

You can use Digital Data Connector in the following ways:

- You can code a Java plug-in, a so-called DDC plug-in, that hooks into the DDC. The plug-in loads the external data and transforms it into a generic DDC data structure, so-called bean lists. You can then have the bean lists rendered on your portal pages by using standard Web Content Manager rendering methods.
- You can use the generic XML DDC plug-in that is built into Digital Data Connector. You can use this plug-in to integrate remote XML data without writing or deploying extra Java code. It supports various parameters that you can use to specify from where the plug-in obtains the XML data and how it transforms the data. The transformation turns a specific XML document format into the generic DDC bean list data structure. With DDC, you can define these transformations in a declarative way so that you can use arbitrary XML formats without having to write transformation code.
- You can also use a combination of the two approaches.

Technical concepts

Before you use the IBM Digital Data Connector (DDC) for WebSphere Portal Express framework, you can familiarize yourself with its main technical concepts and building blocks.

To integrate external data of your choice into your WebSphere Portal Express, you hook into the Digital Data Connector framework. To do so, you have the following alternatives:

- You can write a DDC plug-in for the WebSphere extension registry. This approach provides full flexibility but requires creating and deploying Java code.
- If your external data is available in XML format, you can use the generic XML DDC plug-in to integrate your data. In this case, you do not have to write any code. Instead, you integrate data that comes from a specific XML data source by deploying a list-rendering profile.
- You can also use a combination of both approaches. In such a setup, you typically create a custom DDC plug-in. This custom plug-in delegates the loading and transformation of XML data to the generic XML DDC plug-in. You can use the custom plug-in to determine the correct source URL based on the current rendering context. For example, the plug-in can generate a specific product query URL to an e-commerce server. It bases the query on user preferences, request attributes, user agent, and other context information. Furthermore, the custom plug-in can modify the bean list objects that the generic XML DDC plug-in delegate returns. For example, the plug-in can add extra attributes that are computed from the data that is contained in the original bean list object.

The following list shows and describes the main building blocks of the Digital Data Connector framework:

DDC plug-in
: This term refers to Java plug-ins that are hooked into the Digital Data Connector framework. DDC plug-ins implement the `com.ibm.portal.wcm.plr.BeanListProvider` Java interface as defined by the public Digital Data Connector Java API. DDC plug-ins load external data and transform this data into a generic data structure that can be rendered by using list appearance components. List appearance components are described later in this list. WebSphere Portal Express Version 8.5 comes with two preinstalled DDC plug-ins:
  - A DDC plug-in for integrating social data made available by remote Connections servers. This DDC plug-in is used by the social lists feature.
  - A generic XML DDC plug-in. You can use this provider directly for integrating arbitrary remote XML data. You do not have to write or deploy more Java code.

Bean list
: This term refers to the abstract data structure that a DDC plug-in generates based on external data. DDC always represents external data as a list. You can generate detail views for individual data items by using lists of length 1. Individual bean list objects can be transformed into markup by using list appearance components. List appearance components are described later in this list.

List-rendering profile

A list-rendering profile defines the set of attributes available in the beans that are contained in bean lists that a DDC plug-in generates. Furthermore, the generic XML DDC plug-in supports list-rendering profiles to define the mapping between the XML data structure and the actual attribute values. You define this mapping by associating the attribute definitions in the profile with individual XPath expressions.

Digital Data Connector selection rule

This term refers to specific rules that you can create in the WebSphere Portal Express Personalization component or in Web Content Manager Personalization components. A Digital Data Connector selection rule is a Personalization rule of type **Select Action** defined to work on the Pluggable Resources resource collection. You do not have to add any additional properties or selection criteria to this rule. This rule is used to trigger the Digital Data Connector framework when you render the selection rule in a personalization component.

List appearance

This term refers to a Web Content Manager Personalization component that contains or references a Digital Data Connector selection rule. The list appearance defines the visual design of your list by defining the markup fragments that are generated during rendering of the lists. The individual data fragments that the DDC plug-in loads can be referenced by the list appearance by using the `[AttributeResource]` tag. This reference mechanism works the same way as when you render Personalization components that select data from the Web Content or the Web Components resource collections. The set of supported `attributeName` parameter values for the `[AttributeResource]` tag depends on the specific DDC plug-in and the list-rendering profile that you use.

The list appearance also defines the paging behavior of the list.

The term "list appearance" is also used for components that generate details views of individual items. In this case, the individual items are represented by a list of length 1. List appearance components that generate such details views can also be referred to as "details appearance" components.

List-rendering context

This term refers to the context that the `[Plugin:ListRenderingContext]` rendering plug-in generates to control the contents of your lists. This context includes all of the following information:

- Which DDC plug-in you want to be called for building the bean list object from the actual external data
- The selected list-rendering profile
- A list of custom attributes
- Access to the current portlet request and response objects
- A reference to the currently rendered list definition content item.

The addressed DDC plug-in then evaluates the list-rendering context so that it can query the appropriate set of remote information. You can establish the list-rendering context by adding a `[Plugin:ListRenderingContext]` Web Content Manager tag to your presentation templates. You add this tag before you include the Digital Data Connector design component.

List definition

The list definition is a Web Content Manager content item. It holds the following items:

- Information that is needed to establish the required list-rendering context
- A reference to a list appearance component that is responsible for generating a specific visual design for presenting the data that is contained in the resulting bean list object.

To render an individual list, you render the corresponding list definition content item in the Web Content Viewer portlet. To generate the actual list markup, the presentation template that is used to render the list definition content item proceeds by two steps:

1. First, it writes the `[Plugin:ListRenderingContext]` to establish the list-rendering context.
2. Then, it renders the component reference to the list appearance component.

The rendering flow

Read about the rendering flow of IBM Digital Data Connector (DDC) for WebSphere Portal Express.

The rendering flow is as follows:

1. The Web Content Viewer portlet renders a list definition content item.
2. The Web Content Manager rendering engine retrieves the associated presentation template to render the appropriate content item.
3. The presentation template renders a `[Plugin:ListRenderingContext]` tag. This tag establishes the current list-rendering context.
4. The presentation template renders a component reference that points to a list appearance component.
5. The selection rule that is contained in the list appearance component triggers the bean list creation process in the DDC framework. The framework identifies the target DDC plug-in by inspecting the list-rendering context.
6. The addressed DDC plug-in determines which data to load, and how to filter and sort the data, based on information that is pulled from the provided list-rendering context.
7. The DDC plug-in loads the data and transforms it into a corresponding bean list data structure. The generic XML DDC plug-in implements this step by applying the list-rendering profile that the list-rendering context references to the loaded XML data.
8. The DDC plug-in passes the resulting bean list object back to the list appearance component.
9. The Web Content Manager rendering engine produces the markup for the data that is contained in the bean list. Web Content Manager design components can access the individual attributes of the items in the bean list by using the `[AttributeResource]` tag.

Implementing user interactions

With IBM Digital Data Connector (DDC) for WebSphere Portal Express, you can use IBM Web Content Manager presentation components for visualizing external data. As a further benefit, you can also add user interfaces for creating, modifying,

and deleting external data to your DDC list appearance components. This way, your users can use these features to create, modify, or delete external data items from your lists.

In this scenario, the Web Content Viewer portlet acts as a mediator. It forwards information provided by the user to the specified data sink and sets the result information either as a private render parameter or as a session attribute. You can plug in your own data sinks by implementing the `com.ibm.portal.resolver.data.FormDataDataSink` interface. This interface is defined in the public POC resolution framework API. For more detailed information, refer to the *Package `com.ibm.portal.resolver.data` summary*.

"Sending data to the Web Content Viewer portlet"
You can use IBM Web Content Manager presentation components to create user interfaces for creating, modifying, and deleting external data. With this approach, you use Web Content Manager design components to generate specific HTML form markup.

"Setting dynamic Digital Data Connector filter values" on page 3270
IBM Digital Data Connector (DDC) for WebSphere Portal Express defines a dedicated public render parameter that can be used by DDC plug-ins for filtering lists.

Sending data to the Web Content Viewer portlet

You can use IBM Web Content Manager presentation components to create user interfaces for creating, modifying, and deleting external data. With this approach, you use Web Content Manager design components to generate specific HTML form markup.

The HTML form markup triggers a generic portlet action on the Web Content Viewer portlet. The form can use individual input fields to collect information from your web site users in combination with hidden input fields that provide the interaction context. The interaction context includes a target URI that identifies the actual data sink that receives and processes the information that users post by using your form.

In this scenario, the Web Content Viewer portlet acts as a mediator. It forwards the information that the user typed into the HTML form to the specified target URI and sets the result information either as a private render parameter or as a session attribute. After the user submits the form, the portal renders the page with the updates. The list rendering appearance component can then access the result information by using the session attribute or render parameter plug-in tags.

"Creating the HTML form" on page 3261
You can use IBM Web Content Manager design components to generate the HTML forms for the user interfaces that provide the user interactions.

"Receiving the result of an HTML form submission" on page 3262
The interaction requests that the Web Content Viewer portlet mediates result in response information. To access that result information, use the IBM Web Content Manager rendering plug-ins.

"The generic XML Digital Data Connector data sink" on page 3263
The IBM Digital Data Connector (DDC) for WebSphere Portal Express framework contains a generic data sink. You can use the data sink in combination with HTML forms generated by your IBM Web Content Manager design components.

Related information:

The session attribute plug-in

The render parameter plug-in

Creating the HTML form:

You can use IBM Web Content Manager design components to generate the HTML forms for the user interfaces that provide the user interactions.

About this task

To generate the HTML form markup by using IBM Digital Data Connector (DDC) for WebSphere Portal Express design components, perform the following tasks:

Procedure

1. Set the form `method` attribute to the value `post`.
2. Set the form `enctype` attribute to the value `multipart/form-data`.
3. Set the form `action` attribute to a portlet action URL that addresses the web content viewer and triggers its `post` portlet action.
4. Add a hidden input field with the name `_charset_` as the first input field to the form. This input field defines the character set that the browser uses to encode the form data. Initialize it with the character encoding of the page. To do so, use the following HTML code:

   ```
   <input type="hidden" name="_charset_"
          value="[Plugin:EvaluateEL
          value="${pageContext.response.characterEncoding}"
          compute="once"]"/>
   ```

5. To specify the target URI for the interaction, use a second hidden input field named `action.uri`. The target URI identifies the actual recipient of the data that is posted by this form, which must be a data sink. To do so, use the following HTML code:

   ```
   <input type="hidden" name="action.uri" value="..."/>
   ```

6. Add more hidden or visible form input fields to the form. Use these input fields to assemble all the information that is necessary for the recipient of this form post. You can use the `action.uri` parameter to specify the recipient of this form post operation. Example: To trigger the creation of a forum topic reply, proceed as follows:
   a. Define text input fields for gathering the title and body information from the user.
   b. Add further hidden input fields for identifying the target forum topic. These input fields are typically filled by using a corresponding `[AttributeResource]` tags.

Results

The target URI needs to identify a data sink that accepts multipart data requests. You can use data sinks of the following types:

- You can use a data sink that IBM WebSphere Portal Express provides
- You can use a custom implementation of the `com.ibm.portal.resolver.data.FormDataDataSink` interface. This interface is defined in the public POC resolution framework API. For more detailed information, refer to the *Package `com.ibm.portal.resolver.data` summary*.

Here is an example of an HTML form for sending data to the Web Content Viewer portlet:

```
<form method="post" enctype="multipart/form-data"
      action="[Plugin:ActionURL action="post" copyCurrentParams="true"
      param="resultSessionAttribute=myResult" compute="always"]">
     <input type="hidden" name="_charset_" value="[Plugin:EvaluateEL
            value="${pageContext.response.characterEncoding}" compute="once"]"/>
     <input type="hidden" name="action.uri" value="$DATA_SINK_URI"/>
     <input type="hidden" name="myAction" value="createComment"/>
     <input type="hidden" name="myResourceId"
            value="[AttributeResource attributename="id"]"/>
     My Text: <input type="text" name="myTextField"/><br/>
     <input type="submit" value="Submit"/>
</form>
```

Replace the variable `$DATA_SINK_URI` by the appropriate value for your environment.

Related information:

Package com.ibm.portal.resolver.data summary

Receiving the result of an HTML form submission:

The interaction requests that the Web Content Viewer portlet mediates result in response information. To access that result information, use the IBM Web Content Manager rendering plug-ins.

About this task

When you post data to the Web Content Viewer portlet as described under *Sending data to the Web Content Viewer portlet*, the addressed data sink serves the result back in the form of a data source. The Web Content Viewer portlet performs the following operations on that data source:

1. The portlet transforms that data source into a String value by converting the source into a character source.
2. The portlet sets the resulting String value as a corresponding session attribute or private render parameter.

The URL generated for the action parameter of the HTTP form controls whether the resulting string is stored in a session attribute or set as a private render parameter. You can specify the behavior by setting the corresponding `resultSessionAttribute` and `resultRenderParameter` parameters in the action URL plug-in tag that you use to generate the form action URL.

Results

You can then access the session attribute and the render parameter in your web content by using the session attribute rendering plug-in and the render parameter rendering plug-in, respectively. For example, if the data source of a data sink returns JSON data, you can process the data further by using JavaScript that is contained in your web content.

The generic XML Digital Data Connector data sink:

The IBM Digital Data Connector (DDC) for WebSphere Portal Express framework contains a generic data sink. You can use the data sink in combination with HTML forms generated by your IBM Web Content Manager design components.

The data sink plugs into the POC resolver framework. You can address it through the `action.uri` parameter that you defined in your DDC HTML forms.

The data sink supports simple HTTP PUT, POST, and DELETE operations for XML-based remote APIs. This approach follows the Representation State Transfer (REST) design pattern as used in many existing remote APIs. You can use the data sink to transform form post parameters into XML documents that you can then send to remote service end points. You can control the transformation by using list-rendering profiles. You address the generic XML DDC data sink by using the following URI: `ddc:operation:blp:ibm.portal.ddc.xml`.

The result data that the addressed service returns is transformed into a generic JSON object. You can access this object in the Web Content Manager design components after the page refresh that is triggered by the form post.

"Parameters that the generic XML data sink supports"
The generic XML IBM Digital Data Connector (DDC) for WebSphere Portal Express data sink supports the parameters that are listed here.

"The generic XML data sink result object" on page 3269
The IBM Digital Data Connector (DDC) for WebSphere Portal Express data sink returns a JSON string. The JSON string contains the result information for the outbound interaction call that was performed.

Related tasks:

"Creating the HTML form" on page 3261
You can use IBM Web Content Manager design components to generate the HTML forms for the user interfaces that provide the user interactions.

Parameters that the generic XML data sink supports:

The generic XML IBM Digital Data Connector (DDC) for WebSphere Portal Express data sink supports the parameters that are listed here.

`ddc.method`
Use this parameter to identify the HTTP method that you want to be used for sending the data to the outbound target. Supported values are `put`, `post`, and `delete`.

`ddc.uri.target`
Use this parameter to specify a URI that identifies the target of the outbound request. The target can be an HTTP or HTTPs URL, for example, to a remote REST service.

`ddc.uri.template`
Use this parameter to specify a URI that identifies the template XML document that is required for `set`, `addChild`, `addPredecessor`, and `addSuccessor` actions. This document is the starting point for creating the final XML document that is sent to the target service. You can modify the template for starting a specific operation by using form post parameters. The URI used in this parameter needs to identify a well-formed XML document.

`ddc.profile.in`
Use this parameter to define the name of the list-rendering profile that you

want to apply to the template XML document. You can use the item attribute definitions and corresponding XPath statements of this profile to modify specific fragments of the template XML document. This modification is done before the resulting XML document is sent to the target service.

ddc.profile.out
Use this parameter to define the name of the list-rendering profile that you want to apply to the data returned by the target service. You can use the item attribute definitions and corresponding XPath statements of this profile to extract specific XML fragments of XML documents that are served in response to the update operation. If you do not set this parameter, the data sink uses the same profile as the one that the `ddc.profile.in` parameter references.

ddc.itemattribute.value.*suffix*
Use this parameter to specify the value that you want to use for modifying the template XML document that is required for `set`, `addChild`, `addPredecessor`, and `addSuccessor` actions. The value can come from user input or can be specified through hidden form input field that is filled by IBM Web Content Manager tags. For example, such a tag can be the `[AttributeResource]` tag.

Depending on the value of the `valueType` definition of the related operation, specify one of the following values:

- A URI that identifies the item attribute value for the operation. This URI must be a URI that the POC resolver framework can resolve.
- Plain text that represents the item attribute value for the operation.

The *suffix* value does not imply any semantics. Use it to correlate this attribute value specification with an item attribute operation specification. Both specifications must be represented by a `ddc.itemattribute.value.`*suffix* and `ddc.itemattribute.operation.`*suffix* parameter, respectively. For example, the following attribute value specification is correlated with the following item attribute operation specification by using the common suffix `xyz`:
`addc.itemattribute.value.xyz` and `ddc.itemattribute.operation.xyz`.

ddc.itemattribute.template.suffix
Use this parameter to specify an optional item attribute value template. The generic XML DDC data sink data sink replaces all occurrences of the `${value}` string in the template with the value of the related `ddc.itemattribute.value.`*suffix* parameter. This step creates the final value to use for modifying the template XML document that is used for `set`, `addChild`, `addPredecessor`, and `addSuccessor` actions.

If the related `ddc.itemattribute.value.`*suffix* defines more than one value by using a separator specified by the `valueSeparator` parameter, the generic data sink applies each individual value to the template.

Depending on the value of the `templateType` definition of the related operation, specify one of the following values:

- A URI that identifies the item attribute value template for the operation. This URI must be a URI that the POC resolver framework can resolve.
- Plain text that represents the template for the operation.

The *suffix* value does not imply any semantics. Use it to correlate this attribute value with a corresponding item attribute value specification and item attribute operation specification. Both specifications must be represented by a `ddc.itemattribute.value.`*suffix* and `ddc.itemattribute.operation.`*suffix* parameter, respectively. For example, the following attribute value specification is correlated with the following item attribute operation specification by using

the common suffix xyz:
addc.itemattribute.value.xyz and ddc.itemattribute.operation.xyz.

ddc.itemattribute.operation.*suffix*
Use this parameter to specify a modification of the template document. The value for this parameter is comma-separated list of name-value pairs. You can specify the following keys:

action
Use this key to identify the action that you want to be completed on the template document. The data sink completes the following actions on the template XML document. The node selection is based on the itemAttribtueName value and the list-rendering profile that is attached through the ddc.profile.in parameter. You can specify the following values:

set
Use this value to modify the node selected by the itemAttributeName value.

addChild
Use this value to add a child node selected by the itemAttributeName value.

addPredecessor
Use this value to add a predecessor sibling to the node selected by the itemAttributeName value.

addSuccessor
Use this value to add a successor sibling to the node selected by the itemAttributeName value.

remove
Use this value to remove the selected node.

In contrast to the actions listed previously, the get action is not performed on the template document, but on the resulting XML document that the addressed service returns. If you use this action, the node selection is based on the itemAttribtueName value and the list-rendering profile that is attached through the ddc.profile.out parameter.

get
Use this value to add a corresponding entry to the result JSON object that the data sink generates. The entry holds the string value of the selected node in the result XML document.

itemAttributeName
Use this key to reference an individual item attribute definition in the associated list-rendering profile. The XPath that is associated with this item attribute definition is used to select the target node for this operation. In this context, you can use only ItemAttribute definitions. The following definitions are not supported: AssociatedItemAttribute, ComputeItemAttribute, ConstructedItemAttributes.

templateType
Use this key to specify the type of the value of the ddc.uri.template parameter that was listed earlier. You can specify the following values:

text
If you specify the value text, the value of the

ddc.itemattribute.template.*suffix* parameter is used as a normal string that represents the item attribute template. This is the default template type.

uri
If you specify the value uri, the data sink parses the value of the ddc.itemattribute.template.*suffix* parameter as a URI. The data sink determines the actual value by reading the data that is served from this URI. The URI needs to be a URI that the POC resolver framework can resolve.

valueType
Use this key to specify the type of the value of the ddc.itemattribute.value.*suffix* parameter that is related to the operation. You can specify one of the following values:

text
If you specify the value text, the value of the ddc.itemattribute.value.*suffix* parameter is used as a normal string. This is the default value type.

uri
If you specify the value uri, the data sink parses value of the ddc.itemattribute.value.*suffix* parameter as a URI. The data sink determines the actual value by reading the data that is served from this URI. The URI must be a URI that the POC resolver framework can resolve.

valueSeparator
Use this key to enable the operation to support multiple values. The generic data sink computes the individual values by splitting the correlated parameter value using the separator that this key specifies. If the separator consists of multiple characters, each character is treated as a separate separator. Example: To split an input value on all occurrences of commas (**,**) and semicolons (**;**), you combine both separators in the value for this parameter as follows: **;,**. The data sink completes the operation for each fragment of the separated value. Use this parameter only for the following actions: addChild, addPredecessor, addSuccessor.

ddc.state.operation.suffix
Use this parameter to specify a modification of the portlet render state. The value for this parameter is comma-separated list of name-value pairs. You can specify the following keys:

action
Use this key to identify the action that you want to be completed on the portlet render state. You can use the following values:

set
Use this value to set a private render parameter.

add
Use this value to add a private render parameter.

remove
Use this value to remove a private render parameter.

renderParameterName
Use this key to specify the name of the private render parameter that you want to modify.

condition
Use this key to specify the condition under which you want this operation to be performed. You can use the following values:

success
If you specify this value, the modification to the portlet render state is performed only if the overall data sink operation succeeded.

error
If you specify this value, the modification to the portlet render state is performed only if the overall data sink operation resulted in an error.

always
If you specify this value, the modification to the portlet render state is performed independent of whether the overall data sink result succeeded or resulted in an error.

ddc.state.value.suffix
Use this parameter to specify the value for the state operation as described in the corresponding `ddc.state.operation` parameter.

ddc.passback.*name*
Use this parameter to specify custom pass-back parameters. The generic XML DDC data sink does not analyze these parameters. It only adds them to the interaction result JSON object as a `passbackData` member using `name` as an identifier. This parameter can be useful for retaining specific state information after the operation is completed, for example when you create a new resource.

ddc.resultheaders
Use this parameter to specify the names of HTTP response header fields that you want to be included in the result object. The HTTP response header fields refer to the outbound call of the generic XML DDC data sink. To specify more than one header field, use multiple `ddc.resultheaders` parameters. After processing the response from the remote REST service, the data sink adds the specified header fields from the response to the interaction result JSON object as a `resultHeaderData` member. You can use this parameter to access information from the outbound call that the data sink makes.

Example: Creating a resource

Typical XML REST services support the creation of new resources by sending a corresponding resource XML document to the service. To do so, the client typically uses an HTTP POST request. The following HTML fragment shows an HTML form that you can use to create a comment on a Connections blog post:

```
<form id="[AttributeResource attributeName='id']CreateBlogPostComment"
      method="POST" enctype="multipart/form-data"
      action="[Plugin:ActionURL copyCurrentParams="true"
      param="resultSessionAttribute=myResult" compute="always"]">
  <input type="hidden" name="_charset_" value="[Plugin:EvaluateEL
         value="${pageContext.response.characterEncoding}" compute="once"]"/>
  <input type="hidden" name="action.uri" value="ddc:operation:blp:ibm.portal.ddc.xml"/>
  <input type="hidden" name="ddc.uri.template"
         value="wcmrest:LibraryHTMLComponent/[Component
         name="yourLibrary/interaction
         templates/create comment" format="id"]"/>
  <input type="hidden" name="ddc.profile.in"
         value="ibm.portal.sr.blogs.post.comments"/>
  <input type="hidden" name="ddc.itemattribute.operation.addComment"
         value="action=set,itemAttributeName=body"/>
  <textarea title="Content" name="ddc.itemattribute.value.addComment"
            placeholder=" "></textarea>
  <input type="hidden" name="ddc.uri.target" value="[AttributeResource
```

```
        attributeName="rawCommentsEditLink"]"/>
  <input type="hidden" name="ddc.method" value="post"/>
  <input type="submit" class="lotusBtn" value="Submit" name="submitButton"/>
</form>
```

The form sets the `action`, `method`, and `enctype` parameters. The form also specifies the `_charset_` and `action.uri` input fields. For more information about these fields, read *Creating the HTML form*. Additionally, the form specifies the following behavior:

- The form sets the `action.uri` parameter to the value `ddc:operation:blp:ibm.portal.ddc.xml`. As a result, the generic XML Digital Data Connector data sink processes the form.
- The template document that represents the blog post comment XML entry is referenced by using the `ddc.uri.template` parameter. In this example, the template document is served from a Web Content Manager HTML component that is referenced by a corresponding `wcmrest` URI. For more information about the Web Content Manager REST URI format, read *REST service for Web Content Manager* in the Web Content Manager documentation. In this example, the referenced HTML component contains the following XML fragment:

  ```
  <?xml version='1.0' encoding='UTF-8'?>
  <entry xmlns='http://www.w3.org/2005/Atom'
  xmlns:thr="http://purl.org/syndication/thread/1.0">
     <content type='html'>
     </content>
  </entry>
  ```
- The profile for this template document is identified by using the `ddc.profile.in` parameter. As the example posts a blog post comment document, the profile `ibm.portal.sr.blogs.post.comments` is used.
- The parameters `ddc.itemattribute.operation.addComment` and `ddc.itemattribute.value.addComment` define the update of the `<content>` element in the template document. The operation parameter is set to the value `action=set,itemAttributeName=body`. As a result, the value that the user entered in the `ddc.itemattribute.value.addComment` text area is used to update the XML node that the item attribute named `body` selected. The referenced profile holds the information about where to locate the `<content>` element in the template.
- To create the blog post comment, the modified template document needs to be sent to the blog post edit link. To do so, set the `ddc.method` parameter to the value `post`. To extract the blog post edit link from the current DDC list-rendering context, use the tag `[AttributeResource attributeName="rawCommentsEditLink"]`.

Example: Deleting an existing resource

Typical XML REST services support the deletion of existing resources by sending a corresponding an HTTP DELETE request to the resource URL. The following HTML fragment shows an HTML form that you can use to delete a comment from an IBM Connections blog post:

```
<form id="[AttributeResource attributeName="id"
      separator=","]DeleteBlogComment" method="POST"
      enctype="multipart/form-data" action="[Plugin:ActionURL
      action="post" copyCurrentParams="true"
      param="resultSessionAttribute=myResult" compute="always"]">
    <input type="hidden" name="_charset_" value="[Plugin:EvaluateEL
           value="${pageContext.response.characterEncoding}" compute="once"]"/>
    <input type="hidden" name="action.uri"
           value="ddc:operation:blp:ibm.portal.ddc.xml"/>
    <input type="hidden" name="ddc.method" value="delete"/>
```

```
    <input type="hidden" name="ddc.uri.target"
           value="[AttributeResource attributeName="rawEditLink"
                   separator=","]" />
</form>
```

The form specifies the following behavior:

- The form sets the `uri` parameter to the value `ddc:operation:blp:ibm.portal.ddc.xml`. As a result, the generic XML IBM Digital Data Connector (DDC) for WebSphere Portal Express data sink processes the form.
- To delete the resource, you do not need to send XML data to the data sink. Therefore, the form does not specify the parameters `ddc.uri.template` or `ddc.profile.in` or any of the `ddc.itemattribute` parameters.
- To delete the blog post comment, you need to send an HTTP delete request to the blog post edit link. To do so, set the `ddc.method` parameter to the value `delete`. To extract the blog post edit link from the current DDC list-rendering context, use the tag `[AttributeResource attributeName="rawCommentsEditLink"]`.

"REST service for Web Content Manager" on page 3306
Application developers can use Representational State Transfer (REST) services to work with Web Content Manager. The REST service for Web Content Manager provides authoring access to content items and elements. The service follows the Atom Publication Protocol, and Atom feeds, and entries are accessible in XML (application/atom+xml) and JSON (application/json) format.

"How to use REST with content items" on page 3348
You can use the Web Content Manager REST service to create, read, update, and delete content items.

Related tasks:

"Creating the HTML form" on page 3261
You can use IBM Web Content Manager design components to generate the HTML forms for the user interfaces that provide the user interactions.

The generic XML data sink result object:

The IBM Digital Data Connector (DDC) for WebSphere Portal Express data sink returns a JSON string. The JSON string contains the result information for the outbound interaction call that was performed.

The JSON object makes the following data available:

`status`
: This member provides the return status of the interaction. If the target service responded to the outbound request with an error response, the status is set to the value `error`. Otherwise, the value is set to `success`.

`httpStatusCode`
: This member provides the HTTP status code that is returned for the HTTP outbound call by the remote REST service. Designers can use it to distinguish between the following types of operations:
  - Operations that are not available, for example because the item to operate on was not found
  - Operations that are not permitted, because the user does not have sufficient privileges on the remote service.

message
This member returns the error message in case of an error.

resultAttributeData
This JSON member contains a JSON object with the name-value pairs of attributes that the data sink reads from the XML document that the target service returns. It contains the values for all attributes that the corresponding `ddc.itemattribute.operation` parameter references by using the action value `get`.

passbackData
This member contains a JSON object with the name-value pairs for all parameters of the processed operation that you specified by using the `ddc.passback.`*`name`* parameters.

resultHeaderData
This member contains a JSON object with the name-value pairs that represent the HTTP response header field names and values that you specified by using `ddc.resultheaders` parameters for the processed operation. The HTTP response header values refer to the response of the remote REST service.

Setting dynamic Digital Data Connector filter values

IBM Digital Data Connector (DDC) for WebSphere Portal Express defines a dedicated public render parameter that can be used by DDC plug-ins for filtering lists.

You can set the value of the DDC filter public render parameter by submitting an HTML form that addresses the URI `ddc:filter` by using an HTTP get method. You can create the HTML form by using IBM Web Content Manager design components. The following HTML fragment shows a simple search form:

```
<form action="." method="get">
   <input type="hidden" name="uri" value="ddc:filter" />
   <input type="hidden" name="prefix" value="<your DDC filter prefix>" />
   <input type="hidden" name="action" value="set" />
   <input name="value" type="text" value="Enter keywords" title="Search keywords" />
   <input type="submit" value="Submit" name="submitButton" />
</form>
```

When you define such HTML form, take care of the following aspects:

- Set the form action attribute to a period (`.`) and the form method attribute to `get`.
- Add a form parameter with the name `uri` and set it to the value `ddc:filter`.
- Add a form with the name `filter` and specify the filter value prefix that is recognized by the target DDC plug-in. Using such a prefix enables individual DDC plug-ins to track their filter parameters if multiple plug-ins are active on the same portal page. To determine the appropriate prefix value, read the documentation of the DDC plug-in that you use.
- Add a form parameter with the name `action` and specify the action that you want to be completed. To set the value, specify `set`. To remove the value, specify `remove`.
- Add a form parameter with the name `value` to specify the filter value that you want to be set. With the `remove` action, this parameter is ignored.

After the user submits this form, the DDC filter public render parameter is updated in the user's rendering state, and the portal now renders the page in its new state. The parameter value that is set is concatenated from the values of the `prefix` parameter and of the `value` parameter. You can access the full concatenated value in your Web Content Manager design components by using the `RenderParam`

plug-in. To access the value for a specific prefix, you can use the `ListRenderingContext` plug-in with the action attribute set to `getFilter`.

DDC plug-ins can evaluate the active filter parameter value by using the `com.ibm.portal.wcm.plr.ListRenderState` interface that is defined by the public Digital Data Connector API.

Working with list-rendering profiles

You can create new or derived list-rendering profiles. After you create a list-rendering profile, you deploy it.

"Structure of list-rendering profiles"
A list-rendering profile consists of a set of name-value pairs.

"Creating list-rendering profiles" on page 3272
When you create a list-rendering profile, you can either create a completely new profile or create a derived profile by extending an existing profile. A derived profile includes the item attribute and list property declarations of other list-rendering profiles by referencing these profiles.

"Deploying list-rendering profiles" on page 3272
You can choose between two ways of deploying your custom list-rendering profiles.

Structure of list-rendering profiles

A list-rendering profile consists of a set of name-value pairs.

These name-value pairs define the following aspects:

- The name of the profile in a format so that the profile can be referenced from the `[Plugin:ListRenderingContext]` tag.
- The process of dividing a single XML document into a list of separate items.
- The extraction of individual item attributes from data that is contained in those items. The resulting set of item attribute defines the set of attributes that you can access in your IBM Digital Data Connector (DDC) for WebSphere Portal Express list designs by using the `[AttributeResource attributeName=""]` tag.
- The extraction of list properties from the complete XML document. The resulting set of list properties defines the set of key values that you can use with the `[Plugin:ListRenderingContext action="getListProperty" key=""]` tag.
- The translated item attribute titles that you want to be shown to your site designers when they use the **Insert a tag** dialog in the Web Content Manager authoring portlet. The list of attribute titles helps your site designers choose the correct `attributeName` parameter values for the `[AttributeResource]` tag.

WebSphere Portal Express Version 8.5 supports the following two types of list-rendering profiles:

- An XPath centric type of profile. It uses XPath statements to define the data transformation. This data transformation contains the aspects of dividing the XML document and the extraction of item attributes and list properties as listed before.
- A custom type of profile. It does not define a data transformation, but registers only the set of supported item attributes that are shown in the **Insert a tag** dialog. When you use a custom type profile, the corresponding bean list provider must provide the respective values for the attribute names that you want the custom profile to support.

Creating list-rendering profiles

When you create a list-rendering profile, you can either create a completely new profile or create a derived profile by extending an existing profile. A derived profile includes the item attribute and list property declarations of other list-rendering profiles by referencing these profiles.

About this task

When you create a new or derived list-rendering profile, make sure to define an item attribute that is named `id` and to define a name for your profile.

To define a derived profile, use the `Extends` key.

When you model your derived profile from an existing profile, you reference the other profile by specifying its profile name. When you reference another profile, the plug-in imports all `ItemAttribute`, `AssociatedItemAttribute`, `ConstructedItemAttribute`, `ComputedItemAttribute`, and `ListProperty` and XML namespace declarations into the current profile. To include multiple profiles, specify a comma-separated list of profile names. You can overwrite individual imported properties in the profiles. When you create a derived profile, you modify existing item attributes or list property declarations of the existing profile or add more item attribute or list property declarations. To do so, you can extend your profile from the existing profile and add or overwrite the item attribute and list property declarations of that profile as required. The following conditions apply:

- All changes to profiles from which the extended profile is derived are effective on the extended profile if the extended profile does not explicitly overwrite these declarations.
- Your profile can extend from any other profile, independent of how you deployed the individual profiles. But make sure that you do not create any dependency cycles.
- The profiles override each other in the order in which they occur in the comma-separated list. A profile that occurs earlier in the sequence overrides subsequent ones.

  Example: To include the item attribute and list property declarations of profiles that are named `yourCo.Atom` and `yourCo.Base`, specify `xyz.Extends=yourCo.Atom,yourCo.Base`.

  Note: If your `yourCo.Atom` and `yourCo.Base` define the same attribute, the definition in the `yourCo.Atom` profile overrides the definition that is given in the `yourCo.Base` profile.

Related information:

The action URL plug-in

Deploying list-rendering profiles

You can choose between two ways of deploying your custom list-rendering profiles.

About this task

- You can deploy a list-rendering profile by creating all entries that are contained in the list-rendering profile as custom properties in the WP List Rendering Profile Service resource environment provider in the WebSphere Integrated Solutions Console.
- You can implement a plug-in for the extension point with the ID `com.ibm.portal.wcm.plr.ListRenderingProfileProvider`. These extensions can

make multiple list-rendering profiles available to the IBM Digital Data Connector (DDC) for WebSphere Portal Express run time through the following method:

```
com.ibm.portal.wcm.plr.ListRenderingProfileProvider.getListRenderingProfiles()
```

This method is defined in the public Java API for the IBM Digital Data Connector (DDC) for WebSphere Portal Express framework. With this approach, your plug-in returns the individual list-rendering profile entries as properties contained in `java.util.Properties` objects. By using this approach, you can package the required list-rendering profiles together with the DDC plug-in.

List-rendering profiles are cached by the DDC framework. After deploying a list-rendering profile, you must make the framework aware of changes to the list-rendering profile. To do so, either restart the portal or render the IBM Web Content Manager tag `[Plugin:ListRenderingContext action="reloadProfiles"]`.

Integrating remote XML data

The IBM Digital Data Connector (DDC) for WebSphere Portal Express framework provides a generic XML DDC plug-in that is ready to use for integrating external XML data of your choice. You can use this plug-in to render external XML data on your portal pages without having to write custom Java code.

About this task

The generic XML DDC plug-in supports the concept of list-rendering profiles. It therefore makes it possible to integrate XML data. The XML data can be served in arbitrary XML document formats. A list-rendering profile describes the transformation between a specific XML document format and the generic bean list data structure that the DDC framework supports. In addition, the list-rendering profile enumerates all attribute names of the items in the resulting bean list that you can add to the result markup. This way, the IBM Web Content Manager **Insert Tag** user interface can present a dedicated selection box. That selection box contains all supported attributes for a specific list-rendering profile when you author DDC list appearance components.

"The generic XML Digital Data Connector plug-in" on page 3274
You can use the IBM Digital Data Connector (DDC) for WebSphere Portal Express plug-in directly to integrate remote XML data without coding. It makes it possible to integrate XML data that is served in arbitrary XML document formats by supporting the concept of list-rendering profiles.

"Syntax for XPath based list-rendering profiles" on page 3275
An XPath based list-rendering profile contains a set of name-value pairs called entries. This set of entries defines the set of available list properties and item attributes that are available for transforming external data into bean lists.

"Syntax for custom list-rendering profiles" on page 3283
Custom IBM Digital Data Connector (DDC) for WebSphere Portal Express plug-ins that do not delegate the initial bean list computation to the generic XML DDC plug-in can use a custom list-rendering profile. This case typically occurs when you integrate non-XML data.

"The Atom list-rendering profile" on page 3284
IBM Digital Data Connector (DDC) for WebSphere Portal Express provides a list-rendering profile that is ready to use for access to feeds that comply with the Atom syndication format standard.

The generic XML Digital Data Connector plug-in

You can use the IBM Digital Data Connector (DDC) for WebSphere Portal Express plug-in directly to integrate remote XML data without coding. It makes it possible to integrate XML data that is served in arbitrary XML document formats by supporting the concept of list-rendering profiles.

A list-rendering profile describes the transformation between a specific XML document format and the generic bean list data structure that this DDC plug-in generates. You identify the generic XML DDC plug-in by its name `ibm.portal.ddc.xml`. You can address it by using the `[Plugin:ListRenderingContext extension-id="ibm.portal.ddc.xml"]` tag. The generic XML DDC plug-in supports the attributes that are shown in the following list. You can specify these attributes when you set up the list-rendering context by using the `ListRenderingContext` tag that IBM Web Content Manager provides.

source
: You can set this attribute to identify the source URI that serves the XML data. The URI must be accessible through the portal resource addressability framework. Supported URI schemes include `http`, `https`, and `dav`. If you access external XML data by using `http` or `https` URLs, make sure to adjust your outbound HTTP connection to allow outbound access to these URLs. For more information, read the information about proxy configuration in the IBM WebSphere Portal Express documentation. For more information, read *Outbound HTTP connection*. Example:

```
[Plugin:ListRenderingContext action="set" extension-id="ibm.portal.ddc.xml"
   profile="ibm.portal.atom"
   attribute="source=https://www.ibm.com/connections/communities/service/atom/catalog/public"
   compute="always"
```

sortCriteria
: Set this attribute to sort the content of a bean list that is based on a specific attribute. This sorting attribute must be defined in the list-rendering profile that the current list-rendering context uses. This built-in sorting capability sorts only the data that is contained in the current bean list. Therefore, do not use this attribute if the bean list represents only a fragment of a larger result set. In such a situation, provide the sorting process by the backend service. If you do not specify this attribute, the bean list maintains the sequence of items as served by the external data source. To specify the sort order, use the `sortOrder` attribute.

sortOrder
: Use this attribute in combination with the `sortCriteria` attribute to specify the sort order. Supported values are `asc` and `desc` for sorting in ascending or descending order. Example:

```
[Plugin:ListRenderingContext action="set" extension-id="ibm.portal.ddc.xml"
   profile="ibm.portal.atom"
   attribute="source=https://www.ibm.com/connections/communities/service/atom/catalog/public"
   attribute="sortCriteria=title" attribute="sortOrder=asc"]
```

cacheScope
: Set this attribute to identify the cache scope for bean lists that result from a specific list-rendering context. Supported values are as follows:

  public
  : This value is the default value. If you set this attribute to `public`, the cached bean list values are shared across users.

  private
  : If you set this attribute to `private`, individual bean list objects are cached per user. Specify `private` if the bean lists contain user-specific information.

Example:

```
[Plugin:ListRenderingContext action="set" extension-id="ibm.portal.ddc.xml"
   profile="ibm.portal.atom"
   attribute="source=https://www.ibm.com/connections/communities/service/atom/catalog/my"
   attribute="cacheScope=private" compute="always"]
```

cacheType
Set this attribute to identify the cache type that you want to be used for bean lists that result from a specific list-rendering context. Supported values are as follows:

invalidateOnLogin
If you use this setting, cached bean list objects are invalidated if the user for whom the bean list was computed logs in to portal. Use this value only in combination with the setting `cacheScope=private`.

default
If you use this setting, resulting cached bean lists are not invalidated during user login.

invalidateCache
Use this attribute to invalidate the bean list. If you set this attribute to the value `always`, the bean list is always invalidated before the new list-rendering context is set up. In other words, the bean list is recomputed for each rendering. To achieve a conditional invalidation, you can set the attribute to a different value. In this case, the cache is invalidated only if a portlet session attribute or a request attribute with the specified value is available in the current execution context.

clearCache
Use this attribute to clear the bean list cache. If you set this attribute to the value `always`, the cache is always cleared before the new list-rendering context is set up. To achieve a conditional clearing action, you can set the attribute to a different value. In this case, the cache is cleared only if a portlet session attribute or a request attribute with the specified value is available in the current execution context.

Related concepts:

"Outbound HTTP connection" on page 2984
Applications in your IBM WebSphere Portal Express and the related user activities can require outbound HTTP connections to remote computer systems. The outbound HTTP connection service provides an administration infrastructure with a central point of administration for all outbound HTTP connections that are defined in the portal environment.

Syntax for XPath based list-rendering profiles

An XPath based list-rendering profile contains a set of name-value pairs called entries. This set of entries defines the set of available list properties and item attributes that are available for transforming external data into bean lists.

The following list of list-rendering profile entries show a sample XPath based list-rendering profile that you can use for transforming Atom feed documents. For more information, read *The Atom Syndication Format*.

```
sample_atom.BeanListProviderID=ibm.portal.ddc.xml
sample_atom.NamespaceMapping.atom=http://www.w3.org/2005/Atom

sample_atom.ListItemSelection=//atom:entry

# Item Attribute Declarations:
sample_atom.ItemAttribute.id=./atom:id
sample_atom.ItemAttribute.title=./atom:title
```

```
sample_atom.ItemAttribute.summary=./atom:summary
sample_atom.ItemAttribute.subtitle=./atom:subtitle
sample_atom.ItemAttribute.authorName=./atom:author/atom:name
sample_atom.ItemAttribute.authorEmail=./atom:author/atom:email
sample_atom.ItemAttribute.authorUri=./atom:author/atom:uri
sample_atom.ItemAttribute.contributorName=./atom:contributor/atom:name
sample_atom.ItemAttribute.contributorEmail=./atom:contributor/atom:email
sample_atom.ItemAttribute.contributorUri=./atom:contributor/atom:uri
sample_atom.ItemAttribute.updated=./atom:updated
sample_atom.ItemAttribute.updated.Type=Date
sample_atom.ItemAttribute.published=./atom:published
sample_atom.ItemAttribute.published.Type=Date
sample_atom.ItemAttribute.content=./atom:content
sample_atom.ItemAttribute.categoryTerms=./atom:category/@term
sample_atom.ItemAttribute.categorySchemes=./atom:category/@scheme
sample_atom.ItemAttribute.categoryLabels=./atom:category/@label
sample_atom.ItemAttribute.selfLink=./atom:link[@rel='self']/@href
sample_atom.ItemAttribute.enclosureLink=./atom:link[@rel='enclosure']/@href
sample_atom.ItemAttribute.alternateLink=./atom:link[@rel='alternate']/@href
sample_atom.ItemAttribute.editLink=./atom:link[@rel='edit']/@href

# List Property Declarations:
sample_atom.ListProperty.author=/atom:feed/atom:author
sample_atom.ListProperty.id=/atom:feed/atom:id
sample_atom.ListProperty.selfLink=/atom:feed/atom:link[@rel='self']/@href
sample_atom.ListProperty.title=/atom:feed/atom:title
sample_atom.ListProperty.updated=/atom:feed/atom:updated
sample_atom.ListProperty.updated.Type=Date
```

The names that you use in the list-rendering profile entries must adhere to a specific syntax to be parsed correctly by the IBM Digital Data Connector (DDC) for WebSphere Portal Express framework.

The format for the entry names is *profile-id*.*key*[.*name*[.*meta-data-key*]]. The meanings of the portions are described in the following list:

profile.id
This key specifies an internal ID. It is used only to correlate the entries that belong to the same profile.

key
This key identifies the list-rendering profile aspect that is affected by this entry. Valid values are `Name`, `BeanListProviderID`, `ResourceBundleBaseName`, `NamespaceMapping`, `ListItemSelection`, `ItemAttribute`, `AssociatedItemAttribute`, `ComputedItemAttribute`, `ConstructedItemAttribute`, `ListProperty`, `ComputedListProperty`, `Extends`, `ShowInAuthoringUI`, `Shared`, `Escape`.

name
This key specifies the name of the artifact that is to be defined, for example the attribute name. Names must not contain a period (`.`).

meta-data-key
Some list-rendering profiles entries support metadata that can be associated by using corresponding metadata keys. Valid values are `Type`, `Default`, `Format`, `Depends`, `ShowInAuthoringUI`.

The set of valid values for a list-rendering profile entry depend on the key that is used in the entry name. For more information, read the following topics.

"XPath list-rendering profile keys"
The following list shows the set of list-rendering profile entry keys that are available in the IBM Digital Data Connector (DDC) for WebSphere Portal Express framework.

"XPath list-rendering profile metadata keys" on page 3281
Some item attribute and list property declarations support metadata that can be associated by using corresponding metadata keys.

Related information:

The Atom Syndication Format

XPath list-rendering profile keys:

The following list shows the set of list-rendering profile entry keys that are available in the IBM Digital Data Connector (DDC) for WebSphere Portal Express framework.

`Name`
This value specifies the name of this list-rendering profile. Specifying the name is mandatory for each rendering profile. You can reference this value through the profile attribute of the `[Plugin:ListRenderingContext]` tag and through the `Extends` list-rendering profile entry of other list-rendering profiles. The `Extends` list-rendering profile entry is described later in this list. If this profile does not reference a resource bundle through the `ResourceBundleBaseName` key, this name also shows up in the **Insert a tag** dialog of the IBM Web Content Manager authoring user interface. The name must be unique among all list-rendering profiles in the system.

Example: To set the name of the profile that is identified by profile ID `xyz` to `yourCo.ProductList`, specify `xyz.name=yourCo.ProductList`.

`BeanListProviderID`
Specifying the ID for the DDC plug-in is mandatory for each list-rendering profile. It specifies the extension ID of the DDC plug-in that is used with this profile. The DDC plug-in also gets the calls for computing all computed item attributes. Computed item attributes are described later in this list.

Example: To use the generic XML DDC plug-in, specify `xyz.BeanListProviderID=ibm.portal.ddc.xml`.

`ResourceBundleBaseName`
The resource bundle base name is optional. It specifies the base name of the Java resource bundle that serves the translated strings for the name of this profile and all item attributes that are defined in this profile. The translated strings include associated, computed, and constructed item attributes. The resource bundle base name must identify a Java resource bundle that is available in the portal class path.

Example: To use the resource bundle `yourCo.Bundle` for the profile that is identified by profile ID `xyz`, you specify `xyz.ResourceBundleBaseName=yourCo.Bundle`

`ShowInAuthoringUI`
Valid values are `true` and `false`. If you set this attribute to `false`, the list-rendering profile does not show up in the **Select the target component for this tag** selection list of the **Insert a Tag** dialog of the Web Content Manager authoring user interface.

`NamespaceMapping`
The namespace mapping is optional. It specifies an individual XML namespace

mapping that you want to be used when you evaluate XPath expressions on XML documents that are transformed with this profile. For the name, specify the local name of the namespace mapping. For the value, specify the associated XML namespace URI. The namespace mapping is ignored by profiles of type Custom.

Example: To map the XML namespace URI `http://www.w3.org/2005/Atom` to the local name `atom` in the profile that is identified by the profile ID `xyz`, specify `xyz.NamespaceMapping.atom=http://www.w3.org/2005/Atom`.

`ListItemSelection`

Specifying the list item selection is mandatory for profiles of type XPath. It defines the XPath statement that is used to break down the source XML document into a list of individual XML fragments. Each fragment serves the data for a corresponding item in the resulting bean list. The DDC plug-in evaluates the XPath statement against the root element of the source XML document. For the value, specify a valid XPath statement. Profiles of type Custom ignore the list item selection.

Example: To turn all entries in an Atom feed into list items in the profile that is identified by the profile ID `xyz`, specify `xyz.ListItemSelection=//atom:entry`.

`ItemAttribute`

This key declares an attribute available in all items in the list. The attribute values can then be accessed in your Web Content Manager design components by using the `[AttributeResource attributeName=""]` tag by setting `attributeName` to the name value of the corresponding `ItemAttribute` declaration. For example, to access the value of an item attribute declared with the key `xyz.ItemAttribute.myTitle`, you can use the following Web Content Manager tag `[AttributeResource attributeName="myTitle"]`. Furthermore, declared attributes are listed in the **Select attribute resource tag type** selection box of the **Insert a Tag** dialog of the Web Content Manager authoring user interface when you select the containing profile in the **Select the target component for this tag** selection box.

Important: Each profile must define at least one `ItemAttribute` named `id`. This ID is used to uniquely identify an individual item in the list.

In profiles of type XPath, the value for an item attribute declaration is an XPath statement that is used for extracting the declared attribute value from the XML source document. The DDC plug-in evaluates the XPath statement for each item in the lists relative to the corresponding XML fragments that are identified by using the `ListItemSelection` specification.

Example: To extract the title of the entries in an Atom feed XML document, specify `xyz.ItemAttribute.title=./atom:title`.

`AssociatedItemAttribute`

This key declares an attribute that is available in all items in the list. You can access the attribute values accessed in your Web Content Manager design components in the same way as item attributes. They also appear in the same places in the Web Content Manager authoring user interface. The difference is that in XPath based profiles, you can use associated item attribute declarations to extract data not directly from the source XML document. Instead, you can extract data from a linked XML source document that is referenced by the source XML document. To define an associated item attribute, you must build the value for such an entry by combining a source URL with an XPath statement to select the attribute value from the linked document. You specify the source URL by using the name of the attribute that selects the source URL

from the current bean list. You specify the ItemAttribute reference that provides the document URL by using the pattern {$item-attribute-name}

Example: To obtain the full product description from a list of products, specify as follows:

```
xyz.ItemAttribute.detailsLink=./atom:link[@rel="details"]/@href
xyz.AssociatedItemAttribute.productFullDescription={$detailsLink}//Attribute[@id="desc"]
```

The DDC plug-in computes the values for this attribute in the following sequence:

1. The DDC plug-in evaluates the value of the detailsLink item attribute.
2. The DDC plug-in loads the XML document from that URL.
3. The DDC plug-in evaluates the XPath statement detailsLink on that document.

ConstructedItemAttribute

This key declares an attribute that is available in all items in the list. If you define such an attribute, you can access the attribute values in your Web Content Manager design components in the same way as item attributes. The attribute values also appear in the same places as item attributes in the Web Content Manager authoring user interface. The difference between the two attribute types is as follows: You can build the values for constructed item attributes by combining the values from one or more other item attributes that have a static string. To define a constructed item attribute, you must provide a template string that is used to build the actual attribute values. The template string can contain arbitrary text that is mixed with item attribute references. To specify the ItemAttribute references, you provide the document URL by using the pattern {$item-attribute-name}. Example: To construct an image URL from an image location and image file name item attribute, specify as follows:

```
xyz.ItemAttribute.imageLocation=./imageLocation
xyz.ItemAttribute.imageFileName=./imageName
xyz.ConstructedItemAttribute.imageURL={$imageLocation}/{$imageName}
```

ComputedItemAttribute

This key declares an attribute that is available in all items in the list. You can then access the attribute values in your Web Content Manager design components in the same way as item attributes. They attribute values also appear in the same places as item attributes in the Web Content Manager authoring user interface. The difference between the two types of attribute types is as follows: The values for computed item attributes are not extracted from XML documents but computed based on the item attribute values and other context information. The DDC plug-in that is associated to the list-rendering profile through the BeanListProviderID key computes the attribute values. To serve such data, the DDC plug-in must implement the optional com.ibm.portal.wcm.plr.ComputedAttributeValueProvider Java interface. This interface is defined by the public IBM Digital Data Connector (DDC) for WebSphere Portal Express APIs. The computation is typically done based on the non-computed attribute values in combination with configuration data or other extra context information.

Note: The generic XML DDC plug-in supports no computed item attributes.

To define a computed item attribute, you must declare on which data the attribute value computation depends:

- The computed item attribute value depends only on the other item attribute values. In this case, you must set it to value {$lazy}.

- The computed item attribute value depends on other item attribute values and on the current rendering context that is the current portlet request and response objects. These objects are not cached in the bean list cache, but they are recomputed for each rendering request. If the computed item attribute value depends on the current request context, you must set the value of such a computed item attribute value to the string {$default}.

Example: To define an attribute that represents a stateful portal resource URL that points to the current item, you can declare a computed item attribute such as this one: xyz.ComputedItemAttribute.portalLink={default}.

During run time, the DDC framework then requests the actual values for this attribute. It does so by starting the following method on the specific DDC plug-in plug-in that associated with this list-rendering profile:
com.ibm.portal.wcm.plr.ComputedAttributeValueProvider.getComputedItemAttributeValue()

ListProperty

This key declares a property of the list. You can then access the attribute values in your Web Content Manager design components. You do so by using the [Plugin:ListRenderingContext action="getListProperty" key=""] tag and by setting the key to the name value of the corresponding ListProperty declaration. For example, to access the value of a list property that is declared with the key xyz.ListProperty.myProperty, you use the following Web Content Manager tag: [Plugin:ListRenderingContext action="getListProperty" key="myProperty"] The value for a list property declaration is an XPath statement that is used for extracting the declared attribute value from the XML source document. The plug-in evaluates the XPath statement relative to the root of the source XML document.

Example: To get the link to the next feed page of an Atom feed, specify
xyz.ListProperty.nextLink=./atom:feed/atom:link[@rel=\"next\"]/@href

ComputedListProperty

This key declares a list property of the list. You can then access the attribute values in your Web Content Manager design components in the same way as list properties. The difference between list properties and computed list properties as follows: The values for computed list properties are not extracted from XML documents, but computed based on the item attribute values and other context information. The DDC plug-in that is associated to the list-rendering profile through theBeanListProviderID key computes the property values. To serve such data, the DDC plug-in must implement the optional com.ibm.portal.wcm.plr.ComputedAttributeValueProvider Java interface. This interface is defined by the public APIs of Digital Data Connector APIs. The computation is usually done based on the non-computed list property values in combination with configuration data or other extra context information.

Note: The generic XML DDC plug-in does not support computed list properties. To define a computed list property, you must declare on which of the following two types of data the property value computation depends:

- The computed item attribute value depends only on the other list property values. In this case, you must set it to value {$lazy}.
- The computed list property value depends on other list property values and on the current rendering context, that is the current portlet request and response objects. These objects are not cached in the bean list cache, but they are recomputed for each rendering request. If the computed list property value depends on the current request context, you must set the value of such a computed list property value to the value {$default}.

Extends
Use this key to define a derived profile. A derived profile includes the item attribute, list property declarations, and XML namespace mappings of other list-rendering profiles by referencing these profiles. For more information, read *Creating list-rendering profiles*.

Related tasks:

"Creating list-rendering profiles" on page 3272
When you create a list-rendering profile, you can either create a completely new profile or create a derived profile by extending an existing profile. A derived profile includes the item attribute and list property declarations of other list-rendering profiles by referencing these profiles.

XPath list-rendering profile metadata keys:

Some item attribute and list property declarations support metadata that can be associated by using corresponding metadata keys.

You can use them in combination with `ItemAttribute`, `AssociatedItemAttribute`, `ConstructedItemAttribute`, `ComputedItemAttribute`, and `Listproperty` declarations that are listed under *List-rendering profile keys*. The following list describes the supported metadata key values:

Type
Use this metadata key to specify whether the attribute value is of type `String`, `Date`, `XML`, or `NodeList`. You can format values of type `Date` in flexible ways. You do so by using the format parameter of the `[AttributeResource attributeName="" format=""]` tag. Values of type `XML` are written as serialized XML. Values of type `NodeList` are typically meant to be processed further during the computation of computed item attributes. The IBM Digital Data Connector (DDC) for WebSphere Portal Express plug-in can access the attribute value as an object of type `org.w3c.dom.NodeList`.

Example:
```
xyz.ItemAttribute.updated=./atom:updated
xyz.ItemAttribute.updated.Type=Date
```

Use this metadata key to specify of which type the attribute value is. Four types are available:

String
Values of type `String` are written as plain text.

Boolean
If values of type Boolean are available, they are returned as `true` or `false`.

Date
You can format values of type `Date` in flexible ways. You do so by using the format parameter of the `[AttributeResource attributeName="" format=""]` tag.

XML
Values of type `XML` are written as serialized XML.

NodeList
Values of type `NodeList` are typically meant to be processed further during the computation of computed item attributes. The DDC plug-in can access the attribute value as an object of type `org.w3c.dom.NodeList`.

Example:
```
xyz.ItemAttribute.updated=./atom:updated
xyz.ItemAttribute.updated.Type=Date
```

Default

Use this metadata key to specify a static default value that you want to be returned if the appropriate value cannot be retrieved. Example:

```
xyz.ItemAttribute.rating=./avgRating
xyz.ItemAttribute.rating.default=0.5
```

Format

Use this metadata key to specify the format that you want to use to parse an XML fragment into a date object. Example:

```
xyz.ItemAttribute.updated=./atom:updated
xyz.ItemAttribute.updated.Type=Date
xyz.ItemAttribute.updated.Format=yyyy-MM-dd'T'HH:mm:ss.SSS'Z'
```

FormatLocale

This metadata key is available starting with IBM WebSphere Portal Express V 8.5 Cumulative Fix 02. Use this metadata key to specify the locale that you want to use for parsing an XML fragment into a date object. Example:

```
xyz.ItemAttribute.updated=./atom:updated
xyz.ItemAttribute.updated.Type=Date
xyz.ItemAttribute.updated.Format=yyyy-MM-dd'T'HH:mm:ss.SSS'Z'
xyz.ItemAttribute.updated.FormatLocale=de
```

If you do not specify this metadata, the locale `en` is used by default. You can change the system-wide default locale value by specifying a custom property named `ddc.date.format.default.locale` in the portal Configuration Service. To do so, access the WebSphere Integrated Solutions Console, select the WP Config Service resource environment provider, and set the property to the required locale.

Depends

To enforce a specific computation order for the non-lazy computed item attributes and list properties in the current profile, set this metadata on the `ComputedItemAttribute` and `ComputedListProperty`. Such a computation order can be required if specific computed attributes must access the value of other computed attributed values. In this case, the attribute that requires the value of another computed attributed must list the other attribute in the `Depends` metadata key. If the attribute depends on multiple other computed attributes, you can list multiple attribute names as a comma-separated list. Example: You defined computed attributes named `link` and `proxiedLink`. You want to make sure that the value for the `link` attribute is computed before the value for the `proxiedLink` attribute. In this case, specify as follows:

```
xyz.ItemAttribute.link={computed}
xyz.ItemAttribute.proxiedLink={computed}
xyz.ItemAttribute.proxiedLink.depends=link
```

Note: You do not have to flag dependencies on non-computed attributes. Non-computed attributes are always extracted from the XML before the computed attributes are resolved.

Escape

Use this metadata to define the escaping that you want applied when you write the values of this attribute. Specify one of the values `xml`, `json`, `javascript`, or `none`. The default value is `none`.

Shared

Use this metadata in context of `AssociatedItemAttribute` declarations to define the cache scope for the associated XML document. If this document can be shared among multiple users, you can set this metadata to the value `true`. If

the associated document can contain different data for different users, cache it per user. In this case, you can leave this metadata undefined or explicitly set it to `false`.

Note: Associated documents are cached in the `com.ibm.workplace.wcm.pzn.plr.xml.DocumentCache`. Associated documents that are cached in scope `Shared` are not automatically invalidated during user login.

CF03 Processors

Use this metadata on an `ItemAttribute`, `AssociatedItemAttribute`, `ConstructedItemAttribute`, or `ComputedItemAttribute` to specify one or multiple IDs of attribute value processor plug-ins that you want to run when the attribute value is retrieved. The ID specified must reference the unique ID of attribute value processor plug-ins that are deployed to your system. If you specify multiple IDs, separate them using a comma. Example:

```
xyz.ItemAttribute.updated=./atom:title
xyz.ItemAttribute.updated.Processors=com.acme.TransformText
```

For more information, read *Creating and deploying custom attribute value processor plug-ins*.

Related tasks:

CF03 "Creating and deploying custom attribute value processor plug-ins" on page 3296
You can deploy custom attribute value processor plug-ins for DDC into the WebSphere Portal application extension registry. Attribute value processor plug-ins can be used to process the value of an item attribute after the value is determined by the list rendering profile.

Syntax for custom list-rendering profiles

Custom IBM Digital Data Connector (DDC) for WebSphere Portal Express plug-ins that do not delegate the initial bean list computation to the generic XML DDC plug-in can use a custom list-rendering profile. This case typically occurs when you integrate non-XML data.

Custom list-rendering profiles declare the set of available item attributes only. This way, the IBM Web Content Manager authoring user interface can still fill the corresponding **Select attribute resource tag type** selection box of the **Insert a Tag** dialog.

Custom list-rendering profiles are built in the same way as XPath based profiles, but with the following exceptions:

- To identify the profile as a custom list-rendering profile, a custom profile must contain the profile entry `<profile-id>.Type=Custom`.
- Custom list-rendering profile support only the following reduced set of list-rendering profile entry keys: `Name`, `BeanListProviderID`, `ResourceBundleBaseName`, `ItemAttribute`, `IsShownInAuthoringUI`, and `Extends`. The following keys are not supported: `NamespaceMapping`, `ListItemSelection`, `AssociatedItemAttribute`, `ComputedItemAttribute`, `ConstructedItemAttribute`, `ListProperty`, `ComputedListProperty`.
- The values that are used for item attribute declarations by using the `ItemAttribute` key have no significance.

The following list of list-rendering profile entries shows a sample custom list-rendering profile that you can use for transforming local file system information.

```
samples_files.Name=samples.files
samples_files.BeanListProviderID=samples.Files
samples_files.Type=Custom

samples_files.ItemAttribute.id=.
samples_files.ItemAttribute.title=.
samples_files.ItemAttribute.path=.
samples_files.ItemAttribute.encodedPath=.
samples_files.ItemAttribute.absolutePath=.
samples_files.ItemAttribute.uri=.
samples_files.ItemAttribute.parent=.
samples_files.ItemAttribute.encodedParent=.
samples_files.ItemAttribute.length=.
samples_files.ItemAttribute.suffix=.
samples_files.ItemAttribute.lastModified=.
samples_files.ItemAttribute.type=.
```

The Atom list-rendering profile

IBM Digital Data Connector (DDC) for WebSphere Portal Express provides a list-rendering profile that is ready to use for access to feeds that comply with the Atom syndication format standard.

This profile is named `ibm.portal.atom`. The profile is deployed as custom properties of the WP List Rendering Profile Service resource environment provider in the WebSphere Integrated Solutions Console. To display the profile, open the Custom Properties view of that resource environment provider in the WebSphere Integrated Solutions Console and activate a key filter by specifying `atom.*`.

To use this profile in your lists, set the profile attribute of the `ListRenderingContext` rendering plug-in tag to the value `ibm.portal.atom`. Example:

```
[Plugin:ListRenderingContext action="set" extension-id="ibm.portal.ddc.xml"
   profile="ibm.portal.atom"
   attribute="source=https://www.ibm.com/connections/communities/service/atom/catalog/public"
   compute="always"]
```

The Atom list-rendering profile declares the following attributes:

Alternate URL
`alternateLink`
: Link to an alternate representation of the entry or feed, for example a permalink to the HTML version of the entry, or the front page of the weblog.

Author's email address
`authorEmail`
: Email address of the feed entry author.

Author's Name
`authorName`
: Name of the feed entry author.

Author URL
`authorUri`
: URL of the feed entry author.

Category Labels
`categoryLabels`
: Provides a human-readable label for display of the categories.

Category Schemes
categorySchemes
Identifies the categorization schemes via a URI.

Category Terms
categoryTerms
Identifies the categories.

Content
content
The feed entry content.

null
contributorEmail
null

Contributor's email address
authorEmail
Email address of the feed entry contributor.

Contributor's Name
contributorName
Name of the feed entry contributor.

Contributor URL
contributorUri
URL of the feed entry contributor.

Edit URL
editLink
Link to edit the feed entry.

Enclosure URL
enclosureLink
Link to a related resource that might be large and might require special handling, for example an audio or video recording.

ID
id Identifier of the feed entry.

Published Date
published
The date on which the feed entry was published.

Feed URL
selfLink
Link to the feed itself.

Subtitle
subtitle
Subtitle of the feed entry.

Summary
summary
Summary of the feed entry.

Title
title Title of the feed entry.

Updated Date
updated
The date when the feed entry was last updated.

Related information:

Integrating remote JSON data

The IBM Digital Data Connector (DDC) for WebSphere Portal Express framework provides a generic JSON DDC plug-in that is ready to use for integrating external JSON data of your choice. You can use this plug-in to render external JSON data on your portal pages without having to write custom Java code.

About this task

The generic JSON DDC plug-in supports the concept of list-rendering profiles. It therefore makes it possible to integrate JSON data. The JSON data can be served in arbitrary JSON document formats. A list-rendering profile describes the transformation between a specific JSON document format and the generic bean list data structure that the DDC framework supports. In addition, the list-rendering profile enumerates all attribute names of the items in the resulting bean list that you can add to the result markup. This way, the IBM Web Content Manager **Insert Tag** user interface can present a dedicated selection box. That selection box contains all supported attributes for a specific list-rendering profile when you author DDC list appearance components.

CF06 "The generic JSON Digital Data Connector plug-in"
You can use the IBM Digital Data Connector (DDC) for WebSphere Portal Express plug-in directly to integrate remote JSON data without coding. It makes it possible to integrate JSON data that is served in arbitrary JSON document formats by supporting the concept of list-rendering profiles.

CF06 "Syntax of the `BasicJSONSelection`" on page 3288
A `BasicJSONSelection` defines the syntax that you can use to access data in a JSON object.

CF06 "Syntax for `BasicJSONSelection` based list-rendering profiles" on page 3289
A list-rendering profile that is based on `BasicJSONSelection` contains a set of name-value pairs called entries. This set of entries defines the set of available list properties and item attributes that are available for transforming external data into bean lists.

The generic JSON Digital Data Connector plug-in

You can use the IBM Digital Data Connector (DDC) for WebSphere Portal Express plug-in directly to integrate remote JSON data without coding. It makes it possible to integrate JSON data that is served in arbitrary JSON document formats by supporting the concept of list-rendering profiles.

A list-rendering profile describes the transformation between a specific JSON document format and the generic bean list data structure that this DDC plug-in generates. You identify the generic JSON DDC plug-in by its name `ibm.portal.ddc.json`. You can address it by using the `[Plugin:ListRenderingContext extension-id="ibm.portal.ddc.json"]` tag. The generic JSON DDC plug-in supports the attributes that are shown in the following list. You can specify these attributes when you set up the list-rendering context by using the `ListRenderingContext` tag that IBM Web Content Manager provides.

`source`
You can set this attribute to identify the source URI that serves the JSON data. The URI must be accessible through the portal resource addressability framework. Supported URI schemes include `http`, `https`, and `dav`. If you access external JSON data by using `http` or `https` URLs, make sure to adjust your outbound HTTP connection to allow outbound access to these URLs. For more

information, read the information about proxy configuration in the IBM WebSphere Portal Express documentation. For more information, read *Outbound HTTP connection*. Example:

```
[Plugin:ListRenderingContext action="set" extension-id="ibm.portal.ddc.json"
   profile="yourprofile.name"
   attribute="source=https://www.your_company.com/your_json_feed"
   compute="always"
```

sortCriteria
Set this attribute to sort the content of a bean list that is based on a specific attribute. This sorting attribute must be defined in the list-rendering profile that the current list-rendering context uses. This built-in sorting capability sorts only the data that is contained in the current bean list. Therefore, do not use this attribute if the bean list represents only a fragment of a larger result set. In such a situation, provide the sorting process by the backend service. If you do not specify this attribute, the bean list maintains the sequence of items as served by the external data source. To specify the sort order, use the `sortOrder` attribute.

sortOrder
Use this attribute in combination with the `sortCriteria` attribute to specify the sort order. Supported values are `asc` and `desc` for sorting in ascending or descending order. Example:

```
[Plugin:ListRenderingContext action="set" extension-id="ibm.portal.ddc.json"
   profile="yourprofile.name"
   attribute="source=https://www.your_company.com/your_json_feed"
   attribute="sortCriteria=title" attribute="sortOrder=asc"]
```

cacheScope
Set this attribute to identify the cache scope for bean lists that result from a specific list-rendering context. Supported values are as follows:

public
This value is the default value. If you set this attribute to `public`, the cached bean list values are shared across users.

private
If you set this attribute to `private`, individual bean list objects are cached per user. Specify `private` if the bean lists contain user-specific information.

Example:

```
[Plugin:ListRenderingContext action="set" extension-id="ibm.portal.ddc.json"
   profile="yourprofile.name"
   attribute="source=https://www.your_company.com/your_json_feed"
   attribute="cacheScope=private" compute="always"]
```

cacheType
Set this attribute to identify the cache type that you want to be used for bean lists that result from a specific list-rendering context. Supported values are as follows:

invalidateOnLogin
If you use this setting, cached bean list objects are invalidated if the user for whom the bean list was computed logs in to portal. Use this value only in combination with the setting `cacheScope=private`.

default
If you use this setting, resulting cached bean lists are not invalidated during user login.

invalidateCache
Use this attribute to invalidate the bean list. If you set this attribute to the value `always`, the bean list is always invalidated before the new list-rendering

context is set up. In other words, the bean list is recomputed for each rendering. To achieve a conditional invalidation, you can set the attribute to a different value. In this case, the cache is invalidated only if a portlet session attribute or a request attribute with the specified value is available in the current execution context.

clearCache
Use this attribute to clear the bean list cache. If you set this attribute to the value `always`, the cache is always cleared before the new list-rendering context is set up. To achieve a conditional clearing action, you can set the attribute to a different value. In this case, the cache is cleared only if a portlet session attribute or a request attribute with the specified value is available in the current execution context.

listItemSelection
Use this attribute only if you do not specify a profile in your list rendering context. If you set this attribute to a `BasicJSONSelection` expression, it serves as a selector statement that is used to break down the source JSON document into a list of individual JSON objects. Each object serves the data for a corresponding item in the resulting bean list. The DDC plug-in evaluates the `BasicJSONSelection` statement against the root element of the source JSON object. For the value, specify a valid `BasicJSONSelection` statement.

Consequently if you do not specify a profile in your list rendering context, you must specify `BasicJSONSelection` expressions in order to access data in the list designs for you Digital Data Connector. You do so by using the `[AttributeResource attributeName="<basic-json-selection>"]` tag.

Related concepts:

"Outbound HTTP connection" on page 2984
Applications in your IBM WebSphere Portal Express and the related user activities can require outbound HTTP connections to remote computer systems. The outbound HTTP connection service provides an administration infrastructure with a central point of administration for all outbound HTTP connections that are defined in the portal environment.

Syntax of the `BasicJSONSelection`

A `BasicJSONSelection` defines the syntax that you can use to access data in a JSON object.

A `BasicJSONSelection` resembles a basic way for accessing data in JSON feeds. You can use this syntax in `BasicJSONSelection` based list-rendering profiles or directly in an `[AttributeResource]` tag in your IBM Web Content Manager designs.

A `BasicJSONSelection` is made up by a list of selectors that are separated by the period (`.`) character.

You can use the following types of selectors:

Name selector
This selector returns the JSON member with the name from the JSON object. You can apply this selector only to JSON objects but not to JSON arrays.

The format of this selector is `name1.name2`. For the sample JSON object provided later, the `BasicJSONSelection store.address.country` returns `United States of America`.

Index selector
This selector returns a specific item from a JSON array. You can apply this

selector only to JSON arrays. The format of this selector is `[n]` where `n` denotes the nth element in a JSON Array.

For the sample JSON object provided later, the `BasicJSONSelection` `store.book.[0].author` returns `Nigel Rees`.

Attribute selector

This selector returns the first item from a JSON array that has a member the value of which matches the value that is specified in brackets. The format of this selector is `[member=value]` where `member=value` denotes the name of the member that has the value `value`. For the sample JSON object provided later, the `BasicJSONSelection` `store.book.[category=fiction].author` returns `Evelyn Waugh`.

Here is a sample JSON object:

```
{ "store": {
    "address":{
      "street": "Your Co Avanue",
      "city": "Your City",
      "zipcode": "12345",
      "state": "CA",
      "country": "United States of America"
    },
    "book": [
      { "category": "reference",
        "author": "Nigel Rees",
        "title": "Sayings of the Century",
        "isbn": "0-553-22222-3"},
      { "category": "fiction",
        "author": "Evelyn Waugh",
        "title": "Sword of Honour",
        "isbn": "0-553-11111-3"},
      { "category": "fiction",
        "author": "J. R. R. Tolkien",
        "title": "The Lord of the Rings",
        "isbn": "0-395-19395-8"}
    ]
    }
}
```

Syntax for `BasicJSONSelection` based list-rendering profiles

A list-rendering profile that is based on `BasicJSONSelection` contains a set of name-value pairs called entries. This set of entries defines the set of available list properties and item attributes that are available for transforming external data into bean lists.

The following list of list-rendering profile entries shows a sample `BasicJSONSelection` based list-rendering profile that you can use for transforming JSON documents:

```
sample_json.Name=sample.profile.json
sample_json.BeanListProviderID=ibm.portal.ddc.json
sample_json.Type=BasicJSONSelection
sample_json.ListItemSelection=children

# Item Attribute Declarations:
sample_json.ItemAttribute.id=id
sample_json.ItemAttribute.title=title
sample_json.ItemAttribute.authorName=author.name
sample_json.ItemAttribute.authorEmail=author.email

# List Property Declarations:
sample_json.ListProperty.id=id
```

The names that you use in the list-rendering profile entries must adhere to a specific syntax to be parsed correctly by the IBM Digital Data Connector (DDC) for WebSphere Portal Express framework.

The format for the entry names is *profile-id*.*key*[.*name*[.*meta-data-key*]]. The meanings of the portions are described in the following list:

profile.id
This key specifies an internal ID. It is used only to correlate the entries that belong to the same profile.

key
This key identifies the list-rendering profile aspect that is affected by this entry. Valid values are `Name`, `BeanListProviderID`, `ResourceBundleBaseName`, `NamespaceMapping`, `ListItemSelection`, `ItemAttribute`, `AssociatedItemAttribute`, `ComputedItemAttribute`, `ConstructedItemAttribute`, `ListProperty`, `ComputedListProperty`, `Extends`, `ShowInAuthoringUI`, `Shared`, `Escape`.

name
This key specifies the name of the artifact that is to be defined, for example the attribute name. Names must not contain a period (`.`).

meta-data-key
Some list-rendering profiles entries support metadata that can be associated by using corresponding metadata keys. Valid values are `Type`, `Default`, `Format`, `Depends`, `ShowInAuthoringUI`.

The set of valid values for a list-rendering profile entry depend on the key that is used in the entry name. For more information, read the following topics.

CF06 "`BasicJSONSelection` list-rendering profile keys"
The following list shows the set of list-rendering profile entry keys that are available in the IBM Digital Data Connector (DDC) for WebSphere Portal Express framework.

CF06 "`BasicJSONSelection` list-rendering profile metadata keys" on page 3294
Some item attribute and list property declarations support metadata that can be associated by using corresponding metadata keys.

`BasicJSONSelection` list-rendering profile keys:

The following list shows the set of list-rendering profile entry keys that are available in the IBM Digital Data Connector (DDC) for WebSphere Portal Express framework.

Name
This value specifies the name of this list-rendering profile. Specifying the name is mandatory for each rendering profile. You can reference this value through the profile attribute of the `[Plugin:ListRenderingContext]` tag and through the `Extends` list-rendering profile entry of other list-rendering profiles. The `Extends` list-rendering profile entry is described later in this list. If this profile does not reference a resource bundle through the `ResourceBundleBaseName` key, this name also shows up in the **Insert a tag** dialog of the IBM Web Content Manager authoring user interface. The name must be unique among all list-rendering profiles in the system.

Example: To set the name of the profile that is identified by profile ID `xyz` to `yourCo.ProductList`, specify `xyz.name=yourCo.ProductList`.

BeanListProviderID

Specifying the ID for the DDC plug-in is mandatory for each list-rendering profile. It specifies the extension ID of the DDC plug-in that is used with this profile. The DDC plug-in also gets the calls for computing all computed item attributes. Computed item attributes are described later in this list.

Example: To use the generic JSON DDC plug-in, specify `xyz.BeanListProviderID=ibm.portal.ddc.json`.

ResourceBundleBaseName

The resource bundle base name is optional. It specifies the base name of the Java resource bundle that serves the translated strings for the name of this profile and all item attributes that are defined in this profile. The translated strings include associated, computed, and constructed item attributes. The resource bundle base name must identify a Java resource bundle that is available in the portal class path.

Example: To use the resource bundle `yourCo.Bundle` for the profile that is identified by profile ID `xyz`, you specify `xyz.ResourceBundleBaseName=yourCo.Bundle`

ShowInAuthoringUI

Valid values are `true` and `false`. If you set this attribute to `false`, the list-rendering profile does not show up in the **Select the target component for this tag** selection list of the **Insert a Tag** dialog of the Web Content Manager authoring user interface.

ListItemSelection

The list item selection defines the `BasicJSONSelection` statement that is used to break down the source JSON document into a list of individual JSON objects. Each object serves the data for a corresponding item in the resulting bean list. The DDC plug-in evaluates the `BasicJSONSelection` statement against the root element of the source JSON object. For the value, specify a valid `BasicJSONSelection` statement. Specifying the list item selection is mandatory for profiles of type `BasicJSONSelection`.

Example: To turn all entries of a JSON Array with the name `children` that are contained in a JSON member with the name `data` in a JSON feed into list items in the profile that is identified by the profile ID `xyz`, specify `xyz.ListItemSelection=data.children`.

ItemAttribute

This key declares an attribute available in all items in the list. The attribute values can then be accessed in your Web Content Manager design components by using the `[AttributeResource attributeName=""]` tag by setting `attributeName` to the name value of the corresponding `ItemAttribute` declaration. For example, to access the value of an item attribute declared with the key `xyz.ItemAttribute.myTitle`, you can use the following Web Content Manager tag `[AttributeResource attributeName="myTitle"]`. Furthermore, declared attributes are listed in the **Select attribute resource tag type** selection box of the **Insert a Tag** dialog of the Web Content Manager authoring user interface when you select the containing profile in the **Select the target component for this tag** selection box.

Important: Each profile must define at least one `ItemAttribute` named `id`. This ID is used to uniquely identify an individual item in the list.

In profiles of type `BasicJSONSelection`, the value for an item attribute declaration is a `BasicJSONSelection` statement that is used for extracting the

declared attribute value from the JSON source object. The DDC plug-in evaluates the `BasicJSONSelection` statement for each item in the lists relative to the corresponding JSON fragments that are identified by using the `ListItemSelection` specification.

Example: To extract the author email of the entries in a JSON feed, specify `xyz.ItemAttribute.authorEmail=author.email`.

`AssociatedItemAttribute`

This key declares an attribute that is available in all items in the list. You can access the attribute values accessed in your Web Content Manager design components in the same way as item attributes. They also appear in the same places in the Web Content Manager authoring user interface. The difference is that in `BasicJSONSelection` based profiles, you can use associated item attribute declarations to extract data not directly from the source JSON document. Instead, you can extract data from a linked JSON source document that is referenced by the source JSON document. To define an associated item attribute, you must build the value for such an entry by combining a source URL with a `BasicJSONSelection` statement to select the attribute value from the linked document. You specify the source URL by using the name of the attribute that selects the source URL from the current bean list. You specify the `ItemAttribute` reference that provides the document URL by using the pattern `{$item-attribute-name}`

Example: To obtain the full product description from a list of products, specify as follows:

```
xyz.ItemAttribute.detailsLink=entry.link[rel=details]
xyz.AssociatedItemAttribute.productFullDescription={$detailsLink}details.description
```

The DDC plug-in computes the values for this attribute in the following sequence:

1. The DDC plug-in evaluates the value of the `detailsLink` item attribute.
2. The DDC plug-in loads the JSON document from that URL.
3. The DDC plug-in evaluates the `BasicJSONSelection` statement `detailsLink` on that document.

`ConstructedItemAttribute`

This key declares an attribute that is available in all items in the list. If you define such an attribute, you can access the attribute values in your Web Content Manager design components in the same way as item attributes. The attribute values also appear in the same places as item attributes in the Web Content Manager authoring user interface. The difference between the two attribute types is as follows: You can build the values for constructed item attributes by combining the values from one or more other item attributes that have a static string. To define a constructed item attribute, you must provide a template string that is used to build the actual attribute values. The template string can contain arbitrary text that is mixed with item attribute references. To specify the `ItemAttribute` references, you provide the document URL by using the pattern `{$item-attribute-name}`. Example: To construct an image URL from an image location and image file name item attribute, specify as follows:

```
xyz.ItemAttribute.imageLocation=entry.image.location
xyz.ItemAttribute.imageFileName=entry.image.name
xyz.ConstructedItemAttribute.imageURL={$imageLocation}/{$imageName}
```

`ComputedItemAttribute`

This key declares an attribute that is available in all items in the list. You can then access the attribute values in your Web Content Manager design components in the same way as item attributes. They attribute values also

appear in the same places as item attributes in the Web Content Manager authoring user interface. The difference between the two types of attribute types is as follows: The values for computed item attributes are not extracted from JSON objects but computed based on the item attribute values and other context information. The DDC plug-in that is associated to the list-rendering profile through the `BeanListProviderID` key computes the attribute values. To serve such data, the DDC plug-in must implement the optional `com.ibm.portal.wcm.plr.ComputedAttributeValueProvider` Java interface. This interface is defined by the public IBM Digital Data Connector (DDC) for WebSphere Portal Express APIs. The computation is typically done based on the non-computed attribute values in combination with configuration data or other extra context information.

Note: The generic JSON DDC plug-in supports no computed item attributes.

To define a computed item attribute, you must declare on which data the attribute value computation depends:

- The computed item attribute value depends only on the other item attribute values. In this case, you must set it to value `{$lazy}`.
- The computed item attribute value depends on other item attribute values and on the current rendering context that is the current portlet request and response objects. These objects are not cached in the bean list cache, but they are recomputed for each rendering request. If the computed item attribute value depends on the current request context, you must set the value of such a computed item attribute value to the string `{$default}`.

Example: To define an attribute that represents a stateful portal resource URL that points to the current item, you can declare a computed item attribute such as this one: `xyz.ComputedItemAttribute.portalLink={default}`.

During run time, the DDC framework then requests the actual values for this attribute. It does so by starting the following method on the specific DDC plug-in plug-in that associated with this list-rendering profile:

`com.ibm.portal.wcm.plr.ComputedAttributeValueProvider.getComputedItemAttributeValue()`

`ListProperty`

This key declares a property of the list. You can then access the attribute values in your Web Content Manager design components. You do so by using the `[Plugin:ListRenderingContext action="getListProperty" key=""]` tag and by setting the `key` to the name value of the corresponding `ListProperty` declaration. For example, to access the value of a list property that is declared with the key `xyz.ListProperty.myProperty`, you use the following Web Content Manager tag: `[Plugin:ListRenderingContext action="getListProperty" key="myProperty"]` The value for a list property declaration is a `BasicJSONSelection` statement that is used for extracting the declared attribute value from the JSON source document. The plug-in evaluates the `BasicJSONSelection` statement relative to the root of the source JSON document.

Example: To get the link to the next feed page of a JSON feed, specify

`xyz.ListProperty.nextLink=links.[rel=next]`

`ComputedListProperty`

This key declares a list property of the list. You can then access the attribute values in your Web Content Manager design components in the same way as list properties. The difference between list properties and computed list properties as follows: The values for computed list properties are not extracted from JSON documents, but computed based on the item attribute values and

other context information. The DDC plug-in that is associated to the list-rendering profile through `theBeanListProviderID` key computes the property values. To serve such data, the DDC plug-in must implement the optional `com.ibm.portal.wcm.plr.ComputedAttributeValueProvider` Java interface. This interface is defined by the public APIs of Digital Data Connector APIs. The computation is usually done based on the non-computed list property values in combination with configuration data or other extra context information.

Note: The generic JSON DDC plug-in does not support computed list properties. To define a computed list property, you must declare on which of the following two types of data the property value computation depends:

- The computed item attribute value depends only on the other list property values. In this case, you must set it to value `{$lazy}`.
- The computed list property value depends on other list property values and on the current rendering context, that is the current portlet request and response objects. These objects are not cached in the bean list cache, but they are recomputed for each rendering request. If the computed list property value depends on the current request context, you must set the value of such a computed list property value to the value `{$default}`.

`Extends`

Use this key to define a derived profile. A derived profile includes the item attribute and the list property declarations of other list-rendering profiles by referencing these profiles. For more information, read *Creating list-rendering profiles*.

Related tasks:

"Creating list-rendering profiles" on page 3272
When you create a list-rendering profile, you can either create a completely new profile or create a derived profile by extending an existing profile. A derived profile includes the item attribute and list property declarations of other list-rendering profiles by referencing these profiles.

`BasicJSONSelection` list-rendering profile metadata keys:

Some item attribute and list property declarations support metadata that can be associated by using corresponding metadata keys.

You can use them in combination with `ItemAttribute`, `AssociatedItemAttribute`, `ConstructedItemAttribute`, `ComputedItemAttribute`, and `Listproperty` declarations that are listed under *List-rendering profile keys*. The following list describes the supported metadata key values:

`Default`

Use this metadata key to specify a static default value that you want to be returned if the appropriate value cannot be retrieved. Example:

```
xyz.ItemAttribute.rating=./avgRating
xyz.ItemAttribute.rating.default=0.5
```

`Depends`

To enforce a specific computation order for the non-lazy computed item attributes and list properties in the current profile, set this metadata on the `ComputedItemAttribute` and `ComputedListProperty`. Such a computation order can be required if specific computed attributes must access the value of other computed attributed values. In this case, the attribute that requires the value of another computed attributed must list the other attribute in the `Depends`

metadata key. If the attribute depends on multiple other computed attributes, you can list multiple attribute names as a comma-separated list. Example: You defined computed attributes named `link` and `proxiedLink`. You want to make sure that the value for the `link` attribute is computed before the value for the `proxiedLink` attribute. In this case, specify as follows:

```
xyz.ItemAttribute.link={computed}
xyz.ItemAttribute.proxiedLink={computed}
xyz.ItemAttribute.proxiedLink.depends=link
```

Note: You do not have to flag dependencies on non-computed attributes. Non-computed attributes are always extracted from the JSON before the computed attributes are resolved.

Escape

Use this metadata to define the escaping that you want applied when you write the values of this attribute. Specify one of the values `xml`, `json`, `javascript`, or `none`. The default value is `none`.

Shared

Use this metadata in context of `AssociatedItemAttribute` declarations to define the cache scope for the associated JSON document. If this document can be shared among multiple users, you can set this metadata to the value `true`. If the associated document can contain different data for different users, cache it per user. In this case, you can leave this metadata undefined or explicitly set it to `false`.

Note: Associated documents are cached in the `com.ibm.workplace.wcm.pzn.plr.json.DocumentCache`. Associated documents that are cached in scope `Shared` are not automatically invalidated during user login.

Processors

Use this metadata on an `ItemAttribute`, `AssociatedItemAttribute`, `ConstructedItemAttribute`, or `ComputedItemAttribute` to specify one or multiple IDs of attribute value processor plug-ins that you want to run when the attribute value is retrieved. The ID specified must reference the unique ID of attribute value processor plug-ins that are deployed to your system. If you specify multiple IDs, separate them using a comma. Example:

```
xyz.ItemAttribute.updated=entry.title
xyz.ItemAttribute.updated.Processors=com.acme.TransformText
```

For more information, read *Creating and deploying custom attribute value processor plug-ins*.

Related tasks:

CF03 "Creating and deploying custom attribute value processor plug-ins" on page 3296
You can deploy custom attribute value processor plug-ins for DDC into the WebSphere Portal application extension registry. Attribute value processor plug-ins can be used to process the value of an item attribute after the value is determined by the list rendering profile.

Creating and deploying custom Digital Data Connector plug-ins

You can deploy custom IBM Digital Data Connector (DDC) for WebSphere Portal Express plug-ins as plug-ins into the WebSphere Portal application extension registry.

About this task

The extension point ID for custom DDC plug-ins is `com.ibm.portal.wcm.plr.BeanListProvider`. Individual DDC plug-in implementations implement the `com.ibm.portal.wcm.plr.BeanListProvider` Java interface. This interface is defined in the public Digital Data Connector SPI Javadoc documentation.

Individual DDC plug-in implementations can delegate the initial bean list computation to the generic XML DDC plug-in and extend the returned bean list. They do so by modifying the bean list object that the generic XML DDC plug-in returns or by adding more computed attributes. To implement the computation logic for individual computed attributes, DDC plug-ins can use the optional `com.ibm.portal.wcm.plr.ComputedAttributeValueProvider` Java interface. If you implement this interface, the DDC framework calls the corresponding methods whenever a bean list attribute requests computed item attributes.

Related concepts:

"Application extension registry" on page 3148
WebSphere Portal Express provides an application extension registry which is equivalent to the application extension registry provided by IBM WebSphere Application Server. This registry allows any J2EE compliant application to define extension points for other applications to use, or to plug in to other extensible applications.

Creating and deploying custom attribute value processor plug-ins

CF03

You can deploy custom attribute value processor plug-ins for DDC into the WebSphere Portal application extension registry. Attribute value processor plug-ins can be used to process the value of an item attribute after the value is determined by the list rendering profile.

About this task

The extension point ID for custom attribute value processor plug-ins is `com.ibm.portal.wcm.plr.AttributeValueProcessor`.

Individual plug-in implementations implement one of the two following Java interfaces for the object factory responsible for creating the actual attribute value processor instance.

- `com.ibm.portal.wcm.plr.AttributeValueProcessorFactory`
- `com.ibm.portal.wcm.plr.AttributeValueOnRequestProcessorFactory`

The actual attribute value processor implementations must implement the `com.ibm.portal.wcm.plr.AttributeValueProcessor` Java interface.

All three interfaces are defined in the public Digital Data Connector SPI. For more information about these interfaces, see *The developer WebSphere Portal SPI documentation.*

Digital Data Connector cache tuning

To improve performance, you can tune the caches for the IBM Digital Data Connector (DDC) for WebSphere Portal Express framework.

Both social rendering and the DDC framework use the same caches to cache bean list information.

"Digital Data Connector caches"
The IBM Digital Data Connector (DDC) for WebSphere Portal Express framework provides the caches that are listed here.

Related tasks:

Using the list-rendering cache

Digital Data Connector caches

The IBM Digital Data Connector (DDC) for WebSphere Portal Express framework provides the caches that are listed here.

Both social rendering and the DDC framework use the following caches to cache bean list information:

com.ibm.workplace.wcm.pzn.plr.BeanListCache
The bean list cache caches the bean list Java objects that the Digital Data Connector plug-ins return. The DDC plug-ins control the cache key generation for the individual entries and whether the bean lists are automatically removed from the cache during user login. By default, this cache is enabled.

Note: Single entries of this cache can have a size of several MB. Therefore, the default number of cache entries for this cache is much lower than the default of other portal caches. When you use the bean list cache, closely monitor the cache and tune it as required. You might also consider the size of individual cache entries and how to influence it. For more information, read *Configuring the maximum number of items loaded from Connections*.

com.ibm.workplace.wcm.pzn.plr.xml.DocumentCache
The document cache is used by the generic XML DDC plug-in for caching the Document Object Model (DOM) objects for individual source URIs. This cache specifically caches the DOMs for associated item attributes. If an individual associated item attribute is flagged as `shared` in the list-rendering profile, the cache entries are shared between different users. Such shared documents do not get invalidated on user login. Documents that are loaded through non-shared associated item attributes are cached separately per user. These cache entries are automatically invalidated during login. By default, this cache is enabled.

com.ibm.workplace.wcm.pzn.plr.json.DocumentCache
The document cache is used by the generic JSON DDC plug-in for caching the Document Object Model (DOM) objects for individual source URIs. This cache specifically caches the DOMs for associated item attributes. If an individual associated item attribute is flagged as `shared` in the list-rendering profile, the cache entries are shared between different users. Such shared documents do not get invalidated on user login. Documents that are loaded through

non-shared associated item attributes are cached separately per user. These cache entries are automatically invalidated during login. By default, this cache is enabled.

com.ibm.workplace.wcm.pzn.plr.ListRenderingCache
The list-rendering cache caches the markup that a specific appearance component generates for a specific bean list instance. If you enable this cache, the updates in the appearance component might not become visible immediately, as updates to the corresponding IBM Web Content Manager design components do not invalidate this cache. In general, the entries in this cache are invalidated together with the corresponding bean list objects in the bean list cache that is listed earlier. As a result, it is good practice to disable this cache on authoring systems and enable it on delivery systems.

To use this cache, you must use the `ListRenderingCache` rendering plug-in to instrument the Web Content Manager design components that are involved in the markup generation for this cache. For more information, read *Using the list-rendering cache*.

You configure the caches through the WP Cache Manager Service resource environment provider in the WebSphere Integrated Solutions Console. For more information, read the *Portal service configuration* and *Setting service configuration properties*.

IBM WebSphere Portal Express comprises a framework of configuration services to accommodate the different scenarios that portals of today need to address. You can configure some of these services.

Hints and tips for Digital Data Connector

Learn about things that are useful to know when you work with the social rendering integration with IBM Digital Data Connector (DDC) for WebSphere Portal Express.

Configure access on pages that show social rendering content items only for users who also have an account in IBM Connections.
Otherwise, the user gets an error when the user opens the portal page with the social rendering content items. Examples:

- A IBM WebSphere Portal Express administrator might access a page with social rendering content items by using the user ID `wpsadmin`. In this case, an error occurs because that user ID does not exist in Connections.
- Your WebSphere Portal Express might be configured with more than one LDAP, but your Connections might be configured with only one of these LDAPs. If a user who is stored in one of the other LDAPs accesses a page with social rendering content items, an error occurs.

To avoid such errors, give access to such pages only to users who have an account in Connections.

Digital Data Connector does not support WSRP
The Digital Data Connector infrastructure does not support remote rendering through WSRP (Web Services for Remote Portlets). This means that lists rendered through the DDC cannot be provided as remote portlets.

Helper class samples for web content context

You can create the helper classes PortletWCMContextHelper, PortalWCMContextHelper, and WCMContextHelper from the sample code that is provided here to programmatically determine the current web content context. The context indicates a content item or site area that is rendered by a web content viewer.

Important: These helper classes are not provided by default with IBM Web Content Manager. Example code is provided here that you can take and use to implement the classes yourself.

The helper classes can be used by custom themes or custom portlets that need to render information that is related to the current context.

The web content viewer determines the context to be rendered by evaluating several conditions in the following order:

1. Private render parameter
2. **path-info** parameter
3. Public render parameter
4. Portlet configuration setting for the web content viewer
5. Web content association that is defined for the page

The viewer evaluates each condition in turn until it finds a valid context. As soon as the viewer finds a context, remaining conditions are not evaluated.

Private render parameters and portlet configuration settings are visible only to the web content viewer. However, **path-info** parameters, public render parameters, and content associations are visible to all portlets on a page and to portal code (for example, in a theme).

"PortletWCMContextHelper"
Use the PortletWCMContextHelper class to determine the web content context from within a portlet.

"PortalWCMContextHelper" on page 3301
Use the PortalWCMContextHelper class to determine the web content context from within portal code, such as a theme.

"WCMContextHelper" on page 3304
The WCMContextHelper helper class is an abstract class that is used by the PortalWCMContextHelper class and the PortletWCMContextHelper class.

PortletWCMContextHelper

Use the PortletWCMContextHelper class to determine the web content context from within a portlet.

Preparation

To use the PortletWCMContextHelper class, configure the portlet to receive a public render parameter and a **path-info** parameter. Update the`portlet.xml` file for the portlet, and add the following entries inside the `<portlet-app>` tag:

```
<public-render-parameter>
  <description>WCM public context</description>
  <identifier>PUBLIC_CONTEXT</identifier>
  <qname xmlns:wcm="http://www.ibm.com/xmlns/prod/datatype/content">wcm:context</qname>
</public-render-parameter>
<public-render-parameter>
  <description>Shared path-info parameter of WebSphere Portal</description>
  <identifier>PATH_INFO</identifier>
  <qname xmlns:wcm="http://www.ibm.com/xmlns/prod/websphere/portal/publicparams">wcm:path-info</qname>
</public-render-parameter>
```

In addition, update the `<portlet>` tag with the following lines:

```
<supported-public-render-parameter>PUBLIC_CONTEXT</supported-public-render-parameter>
<supported-public-render-parameter>PATH_INFO</supported-public-render-parameter>
```

Implementation

After a new instance of the PortletWCMContextHelper is created, the portlet can start the getCurrentWCMContext method, passing in the parameters **PortletRequest** and **PortletResponse**:

```
public String getCurrentWCMContext(PortletRequest, PortletResponse)
```

This method returns a string that contains the content path that defines the current web content context. To determine the content path, the getCurrentWCMContext method runs the following checks:

1. The method reads the value of the **path-info** public render parameter. The method constructs the content path from the **path-info** parameter and the content association of the current page, when these conditions are true:
   - The **path-info** parameter is present.
   - The `friendly.pathinfo.enabled` property is enabled in the portal configuration service.
2. If the **path-info** parameter is not present or if the `friendly.pathinfo.enabled` property is disabled, the method reads the public render parameter. If the public render parameter is present, the method returns the value of this parameter.
3. If no public render parameter is present, the method evaluates the current page for a default content association. The method then returns the path of the content item that is mapped to the page.

    */

   @SuppressWarnings("unchecked")
   public String getCurrentWCMContext(final RenderRequest request, final RenderResponse response)
         throws ModelException, ContentMappingDataBackendException, ServiceNotAvailableException,
         OperationFailedException, DocumentIdCreationException, DocumentRetrievalException, IllegalDocumentTypeException {

      String contentPath = null;
      final Map<String, String []> publicParameter = request.getPublicParameterMap();
      final ContentNode currentPage =
          getCurrentPageNode(navSelectionModelProvider.getNavigationSelectionModel(request, response));

      // check path info

      if (publicParameter.containsKey("PATH_INFO")) {
         final String [] pathInfo = publicParameter.get("PATH_INFO");
         if (pathInfo != null && pathInfo.length > 0) {
            String contentMapping = getContentMapping(currentPage);
            contentPath = assembleContentPath(contentMapping, pathInfo);
         }
      }
      if (contentPath == null) {
         // check public WCM context
         contentPath = request.getParameter("PUBLIC_CONTEXT");
         if (contentPath == null) {
            // check content mapping
            contentPath = getContentMapping(currentPage);
         }
      }
      return contentPath;
   }
}
```

PortalWCMContextHelper

Use the PortalWCMContextHelper class to determine the web content context from within portal code, such as a theme.

To use the PortalWCMContextHelper class, create an instance of the helper class and start the getCurrentWCMContext method, passing in the parameters **`HttpServletRequest`** and **`HttpServletResponse`**:

```
public String getCurrentWCMContext(HttpServletRequest, HttpServletResponse)
```

This method returns a string that contains the content path that defines the current web content context. To determine the content path, the getCurrentWCMContext method runs the following checks:

1. The method reads the value of the **path-info** public render parameter. The method constructs the content path from the **path-info** parameter and the content association of the current page, when these conditions are true:
   - The **path-info** parameter is present.
   - The `friendly.pathinfo.enabled` property is enabled in the portal configuration service.
2. If the **path-info** parameter is not present or if the `friendly.pathinfo.enabled` property is disabled, the method reads the public render parameter. If the public render parameter is present, the method returns the value of this parameter.
3. If no public render parameter is present, the method evaluates the current page for a default content association. The method then returns the path of the content item that is mapped to the page.

```

WCMContextHelper

The WCMContextHelper helper class is an abstract class that is used by the PortalWCMContextHelper class and the PortletWCMContextHelper class.

The WCMContextHelper class provides three methods:

getCurrentPageID
: This method uses the State API to determine the currently selected page and returns the object ID of the page.

getContentMapping
: This method uses the Content Mapping Service to retrieve the content item that is associated with the current page. The association always contains the ID of the mapped content. After you determine the content ID, the method uses the IBM Web Content Manager API to convert the ID to a content path. The method returns the content path of the mapped item.

assembleContentPath
: This method takes the **path-info** parameter, which has multiple values, and the content association of the current page. The method creates the web content context by appending all elements of the **path-info** parameter to the content mapping. The method then returns the result, which is the content path that defines the web content context.

REST service for Web Content Manager

Application developers can use Representational State Transfer (REST) services to work with Web Content Manager. The REST service for Web Content Manager provides authoring access to content items and elements. The service follows the Atom Publication Protocol, and Atom feeds, and entries are accessible in XML (application/atom+xml) and JSON (application/json) format.

"Getting started with the REST service for Web Content Manager"
Before getting started with the REST service for Web Content Manager you should become familiar with how it works and how to use it.

"How to use REST with Web Content Manager items" on page 3308
Different processes are used when items are created and updated by using REST.

"REST content formats for components and elements" on page 3309
When you use REST with components or elements, use these content formats. These examples can be used as templates for your own REST solutions.

"REST Query service for web content" on page 3316
The REST service for Web Content Manager comes with a defined set of query parameters. You can also define your own query parameters in a white list. You can also predefine a query to run more complex searches, and control the allowable filters on these searches by using a white list.

"How to manage web content items by using REST" on page 3324
You can use the Web Content Manager REST Service to create, read, update, and delete the following item types.

"Reference material for the Web Content Manager REST service" on page 3385
Reference material for REST response codes, links, media types, and attachments.

Getting started with the REST service for Web Content Manager

Before getting started with the REST service for Web Content Manager you should become familiar with how it works and how to use it.

The REST service for Web Content Manager is a collection of web services that are compliant with the Atom Publishing Protocol. They provide access to web content, including versions and workflow states, through HTTP. The service is designed according to the REST (REpresentational State Transfer) architectural style.

REST services make it easy to build interactive content, which can be modified directly by your site users. Responsive, integrated editing tools can be created by embedding HTML and JavaScript in web content components, which bind to the REST service to display or update content asynchronously. (Ajax)

HTTP makes integration with remote clients easier than with a traditional API. Web Content Manager functions can be visible to remote systems without adding more server-side components, such as JSP, to access Java APIs. HTTP allows these services to work seamlessly with your infrastructure including firewall, proxy servers, and caches.

Note: Any examples in this section that contain incomplete XML, or XML without namespace declarations, use the following declarations:

- xmlns:atom="http://www.w3.org/2005/Atom"
- xmlns:app="http://www.w3.org/2007/app"
- xmlns:wcm="http://www.ibm.com/xmlns/wcm"

Service entry points

The URLs, which comprise the REST service can change from release to release, or even with minor updates. Therefore, it is recommended to never bookmark, or generate a URL unless it is for a defined entry point.

Atom publishing protocol service document

`/wps/mycontenthandler/model/service`

This service document includes the entry points for all portal REST services. When you browse for content, you must first retrieve the service document. The AtomPub service document describes the top-level collections in an APP service. These collections represent libraries and other types of content accessible through the service.

Web content queries can be stored in certain collections. This allows administrators to limit the scope and structure of queries, and bind them to specific URLs, which all authenticated users can access to retrieve the results as an Atom feed.

POC Service

If a specific content item is known, it can be accessed directly through the POC service, or the POC service can be used to look up an appropriate URL for the content. The identity of a piece of content in the REST service is represented by its POC URI. The POC URI can be found in the ID element of the Atom Entry documents, which represents the content item.

Queries

While queries can be stored within the REST service, they can also be run directly through a single location:

`/wcmrest/query`

This flexibility is subject to security controls to prevent users from inadvertently overloading production servers with complex queries.

REST Service Access Levels

To use the REST service, for Web Content Manager a client user be assigned the "user" role or higher in the *WCM REST SERVICE* virtual resource. All authenticated users are assigned the "user" role by default.

An administrator can edit the *WCM REST SERVICE* virtual resource. Click the **Administration menu** icon. Then, click **Access** > **Resource Permissions**. Then, click **Virtual Resources**.

Table 484. REST user roles

Header	Header
User	Users assigned the "user" role can: • work with web content items and run defined queries.
Editor	Users assigned the "editor" role can: • work with web content items and run defined queries. • Run custom queries through the following path: `/wcmrest/query`
Manager	Users assigned the "manager" role can: • work with web content items and run defined queries. • Run custom queries through the following path: `/wcmrest/query` • create, read, update, and delete defined queries.

How to use REST with Web Content Manager items

Different processes are used when items are created and updated by using REST.

Item types

A complete list of supported item types are documented here: "REST Item Types" on page 3397.

Content representations

Atom entry documents

Each web content item has an associated Atom entry document. The entry document provides access to the common metadata properties of the item, such as title and description, along with links to related items, and access control information.

The default media type of an entry document is `application/atom+xml`. However, `application/json` representations can also be obtained. Entry documents can be retrieved by running an `HTTP GET` to the entry resource. Entry resource URIs can be obtained from:

- The service document
- Links in other entry documents
- Links in feed documents
- Using POC to resolve an ID

Example links to entry documents:

```
<link rel="edit" href="/wps/mycontenthandler/!ut/p/wcmrest/SiteArea/c6b00ee6-d628-4cbd-9e65-15c90f2093a6"/>
<link rel="parent" href="/wps/mycontenthandler/!ut/p/wcmrest/item/ae6a3632-a1b5-456a-866e-e9baab84fe29"/>
<link rel="library" href="/wps/mycontenthandler/!ut/p/wcmrest/item/54a68ca2-c550-4385-966f-b0b612147547"/>
```

Media resources

In addition to the entry document, most items also have a media resource that is associated with them. The media resource exists to store the content

of the item, for example, HTML or an image. The media resource location is found in the edit-media link of an items entry document. Media resource URLs support HTTP GET and PUT.

```
<link rel="edit-media" type="text/html"
href="/wps/mycontenthandler/!ut/p/wcmrest/PresentationTemplate/02da6e9d-20ca-4c54-ae4a-f1114fa8e948"/>
```

Content Negotiation

When a resource supports multiple representations with different content types, clients can use content negotiation to request a specific representation. For example, entry documents are available in `application/atom+xml; type=entry` and application/json. There are two ways a client can specify the media type that the client can accept:

HTTP Accept header

```
Accept: application/atom+xml
```

Request parameter mime-type

```
GET /wps/mycontenthandler/!ut/p/wcmrest/SiteArea/c6b00ee6-d628-4cbd-
9e65-15c90f2093a6?mime-type=application%2Fjson HTTP/1.0
```

Note: The methods that are used to specify the accept type work for all supported media types as listed in "Supported media types" on page 3392.

Item path

The path of a requested item can be included by specifying the `options=item-path` URL parameter. For example:

```
HTTP 1.1 GET /wps/mycontenthandler/wcmrest/SiteArea/c0b72020-10b7-4197-a436-62a1d94ce03f?options=item-path

<?xml version="1.0" encoding="UTF-8"?>
<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm">
    ...
    <wcm:path>
        <wcm:pathElement>
            <wcm:title xml:lang="en-GB">rest_query_library</wcm:title>
            <wcm:name>rest_query_library</wcm:name>
            <wcm:link label="Read" rel="alternate" xml:lang="en-GB" href="/wps/mycontenthandler/wcmrest/Library/69452890-2f40-4ce6-90af-e65620a552af"/>
        </wcm:pathElement>
        <wcm:pathElement>
            <wcm:title xml:lang="en-GB">site_b</wcm:title>
            <wcm:name>site_b</wcm:name>
            <wcm:link label="Read" rel="alternate" xml:lang="en-GB" href="/wps/mycontenthandler/wcmrest/SiteArea/c44dc8e1-eea5-4262-842c-562788a34461"/>
        </wcm:pathElement>
    </wcm:path>
...
</entry>
```

Example entry

This code is an example in `application/atom+xml` format:

```
<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="wcm/namespace">
    <id>3aabfe14-cc9e-4eb5-ad06-d4fc8fd2f1df</id>
    <title>SampleHTMLComponent</title>
    <link rel="edit" href="/wps/mycontenthandler/!ut/p/wcmrest/LibraryHTMLComponent/3aabfe14-cc9e-4eb5-ad06-d4fc8fd2f1df"/>
    <link rel="edit-media" type="text/html" href="/wps/mycontenthandler/!ut/p/wcmrest/LibraryHTMLComponent/3aabfe14-cc9e-4eb5-ad06-d4fc8fd2f1df"/>
    <link rel="library" href="/wps/mycontenthandler/!ut/p/wcmrest/item/c98d11e1-7f2a-480e-9aac-40eb1949cbda"/>

REST content formats for components and elements

When you use REST with components or elements, use these content formats. These examples can be used as templates for your own REST solutions.

Component reference component or element

XML

```
<content type="application/vnd.ibm.wcm+xml">
   <reference>/wps/mycontenthandler/wcmrest/LibraryShortTextComponent/c63aaf55-7d32-42e3-9bd
</content>
```

JSON

```
"content" :
{
   "type" : "application/vnd.ibm.wcm+xml",
   "reference" : "/wps/mycontenthandler/wcmrest/LibraryShortTextComponent/c63aaf55-7d32-42e3
}
```

Date and Time component or element

XML

```
<content type="application/vnd.ibm.wcm+xml">
   <date type="DateTime">2014-06-18T14:45:00.000Z</date>
</content>
```

JSON

```
"content" :
{
   "type" : "application/vnd.ibm.wcm+xml",
   "date" :
   {
      "type" : "DateTime",
      "value" : "Wed, 18 Jun 2014 14:45:00.000Z"
   }
}
```

File resource component or element for modifying

XML

```
<content type="application/vnd.ibm.wcm+xml">    <wcm:binaryresource type="image/jpg" fileNam
</content>
```

JSON

```
"content" :
{
   "type" : "application/vnd.ibm.wcm+xml",
   "binaryresource" :
   {
      "type" : "text/javascript",
      "fileName" : "testFile.js",
      "value" : "VGhpcyBpcyBub3QgZ3JlYXQgdGVzdCBkYXRhLi4uLg=="
   }
}
```

File resource component or element for reading

XML

```
<content type="application/vnd.ibm.wcm+xml">
   <resourceUri type="image/png">/wps/wcm/myconnect/60e94008-22a6-4e99-bdbf-864a1b12442f/Scr
</data>
```

JSON

```
"content" :
{
   "type" : "application/vnd.ibm.wcm+xml",
   "resourceUri" :
   {
      "type" : "image/png",
      "value" : "/wps/wcm/myconnect/60e94008-22a6-4e99-bdbf-864a1b12442f/Screenshot+from+201
   }
}
```

HTML component or element

XML

```
<content type="text/html">
   <![CDATA[
      <div class="lotusui30">
      <h2 style="display:block;">
         <div>
            <div class="lotusLeft">
               [EditableProperty context="current" type="content" format="div" field="titl
               [Property context="current" type="content" field="title"]
               [/EditableProperty]
           </div>
         </div>
     </h2>
     </div>
   ]]&gt;
</content>
```

JSON

```
"content" :
{
   "type" : "text/html",
   "value" : "this is some html text"
}
```

Image component or element for reading

XML

```
<content type="application/vnd.ibm.wcm+xml">
   <wcm:image xmlns="http://www.ibm.com/xmlns/wcm">
      <dimension height="16" width="16" border="0"/>
      <altText></altText>
      <tagName></tagName>
      <resourceUri type="image/gif">/wps/wcm/myconnect/5e7dd2e9-8a94-4964-a8d4-3a467be462c
   </wcm:image>
</content>
```

JSON

```
"content" :
{
   "type" : "application/vnd.ibm.wcm+xml",
   "image" :
   {
      "dimension" :
      {
         "height" : "50",
         "width" : "50",
         "border" : "1"
      },
      "altText" : "",
      "tagName" : "",
      "fileName" : "Selection_009.png",
      "resourceUri" :
      {
         "type" : "image/png",
         "value" : "/wps/wcm/myconnect/9d2a5e32-d22e-4b1d-a02d-23b54998d024/Selection_009.
      }
   }
}
```

Image component or element for updating

XML

```
<content type="application/vnd.ibm.wcm+xml">
   <wcm:image xmlns="http://www.ibm.com/xmlns/wcm">
      <dimension height="16" width="16" border="0"/>
```

```
      <altText></altText>
      <tagName></tagName>
      <wcm:binaryresource type="image/jpg" fileName="image.jpg">
         VGhpcyBpcyBub3QgZ3JlYXQgdGVzdCBkYXRhLi4uLg==&#xD;
      </wcm:binaryresource>
   </wcm:image>
</content>
```

JSON

```
"content" :
{
   "type" : "application/vnd.ibm.wcm+xml",
   "image" :
   {
      "dimension" :
      {
         "height" : "50",
         "width" : "50",
         "border" : "1"
      },
      "altText" : "",
      "tagName" : "",
      "fileName" : "Selection_009.png",
      "binaryresource" :
      {
         "type" : "text/javascript",
         "fileName" : "testFile.js",
         "value" : "VGhpcyBpcyBub3QgZ3JlYXQgdGVzdCBkYXRhLi4uLg=="
      }
   }
}
```

JSP component or element

XML

```
<content type="application/vnd.ibm.wcm+xml">
   <jsp>
      <path>/test.jsp</path>
      <errorMessage>Failed to locate the JSP file</errorMessage>
   </jsp>
</content>
```

JSON

```
"content" :
{
   "type" : "application/vnd.ibm.wcm+xml",
   "jsp" :
   {
      "path" : "/test.jsp",
      "errorMessage" : "Failed to locate the JSP file"
   }
}
```

Link component or element

XML

```
<content type="application/vnd.ibm.wcm+xml">

    }
}
```

REST Query service for web content

The REST service for Web Content Manager comes with a defined set of query parameters. You can also define your own query parameters in a white list. You can also predefine a query to run more complex searches, and control the allowable filters on these searches by using a white list.

"Defined query Service"
Defined queries are stored queries that can be run and updated as required.

"Query parameters" on page 3319
The following parameters can be used with queries.

Defined query Service

Defined queries are stored queries that can be run and updated as required.

The defined queries feature allows administrators to define a query in XML format through the REST service, and bind that query to a URI. This query is used to obtain the results by sending a GET request to the bound URI.

Create

A defined query is created by sending a POST request to the following URI:

```
/DefinedQueryComponent/
```

For example:

```
HTTP/1.1 POST
http://host:port/wps/mycontenthandler/wcmrest/DefinedQueryComponent
Content-Type: application/atom+xml
<atom:entry xmlns:atom="http://www.w3.org/2005/Atom" xmlns:wcm="wcm/namespace">
    <atom:title>defined query title-1712115665</atom:title>
    <wcm:name>query-name</wcm:name>
    <wcm:description>defined query description</wcm:description>
</atom:entry>

201 Created
```

The URI that is bound to this query has the following format:

```
/definedquery/component-name
```

For example, the URI used to obtain the results of the previous query example is:

```
/definedquery/query-name
```

The response to a create operation contains a link relation "query-results" specifying this URI.

```
<atom:link atom:rel="query-results"
atom:href="/wps/mycontenthandler/!ut/p/wcmrest/definedquery/query-name"/>
```

Note: The only way to update this URI is by modifying the name of the component.

Read

To retrieve a list of defined queries, you send a GET request to the following URI:

`/DefinedQueryComponent/`

For example:

```
HTTP/1.1 GET
http://host:port/wps/mycontenthandler/wcmrest/DefinedQueryComponent
Accept-Type: application/atom+xml

<atom:feed xmlns:atom="http://www.w3.org/2005/Atom" xmlns:wcm="wcm/namespace">

    </atom:entry>
</atom:feed>
```

To retrieve the XML of a specific defined query, you send a GET request to the following URI:

`/DefinedQueryComponent/`*`item-uuid`*

query-name

For example:

```
HTTP/1.1 GET
http://host:port/wps/mycontenthandler/wcmrest/DefinedQueryComponent/6276ff18-f370-45eb-89c3-053d335aba88
Accept-Type: application/atom+xml

200 OK

<atom:entry xmlns:atom="http://www.w3.org/2005/Atom" xmlns:wcm="wcm/namespace">
    <atom:id>wcmrest:6276ff18-f370-45eb-89c3-053d335aba88</atom:id>
    <wcm:type>DefinedQueryComponent</wcm:type>
    <atom:title>defined query title-1460391124</atom:title>
    <wcm:name>query-name</wcm:name>
    <atom:updated>2011-07-04T01:34:01.051Z</atom:updated>
    <wcm:description>defined query description</wcm:description>
    <atom:link atom:rel="edit" atom:href="/wps/mycontenthandler/!ut/p/wcmrest/DefinedQueryComponent/6276ff18-f370-45eb-89c3-053d335aba88"/>
    <atom:link atom:rel="edit-media" atom:type="application/vnd.ibm.wcm+xml" atom:href="/wps/mycontenthandler/!ut/p/wcmrest/DefinedQueryComponent/6276ff18-f370-45eb-89c3-053d335aba88"/>
    <atom:link atom:rel="query-results" atom:href="/wps/mycontenthandler/!ut/p/wcmrest/definedquery/query-name"/>
</atom:entry>
```

To retrieve the raw data of a specific defined query, send a GET request to the edit-media link relation:

`/DefinedQueryComponent/item-id`

For example:

```
HTTP/1.1 GET
http://host:port/wps/mycontenthandler/wcmrest/DefinedQueryComponent/items-id
Accept-Type: application/vnd.ibm.wcm+xml

200 OK

<?xml version="1.0" encoding="UTF-8" standalone="yes"?>
<definedQuery restrictParameters="true" page="1" pageSize="10" depth="DESCENDANTS">
    <select>
        <typeEquals>
            <type>com.ibm.workplace.wcm.api.Content</type>
        </typeEquals>
        <nameLike>
            <name>article%</name>
        </nameLike>
        <titleLike>
            <title>product%</title>
        </titleLike>
    </select>
    <allowParameters>
        <parameter>lastmodifiedbefore</parameter>
        <parameter>workflowid</parameter>
        <parameter>createdbefore</parameter>
        <parameter>authoringtemplateid</parameter>
    </allowParameters>
</definedQuery>
```

Update

To update the metadata of a query, use a PUT request that contains the new specification to the following URI:

`/DefinedQueryComponent/item-uuid`

For example:

```
HTTP/1.1 PUT
http://host:port/wps/mycontenthandler/wcmrest/DefinedQueryComponent/6276ff18-f370-45eb-89c3-053d335aba88
Content-Type: application/atom+xml
(... atom data ... )

200 OK
```

To update the raw data of a query that specifies the parameters that are used to conduct the query, use a PUT request that contains the new specification to the following URI:

`/DefinedQueryComponent/item-uuid`

For example:

```
HTTP/1.1 PUT
http://host:port/wps/mycontenthandler/wcmrest/DefinedQueryComponent/6276ff18-f370-45eb-89c3-053d335aba88
Content-Type: application/vnd.ibm.wcm+xml
(... xml data ... )

200 OK
```

Delete

To delete a defined query, send a DELETE request to the following URI:

`/DefinedQueryComponent/item-id`

For example:

```
HTTP/1.1 DELETE
http://host:port/wps/mycontenthandler/wcmrest/definedquery/6276ff18-f370-45eb-89c3-053d335aba88

200 OK
```

White List

The white list is a list of extra query parameters that can be used to refine the scope of the defined query. These parameters are the only parameters that have an effect when appended to the bound URI.

For example, if the white list includes a parameter of `name`, the following request returns the results of the defined query that have the name "hello world":

```
HTTP/1.1 GET
http://host:port/wps/mycontenthandler/wcmrest/query-name?name=hello+world

200 OK
```

Query parameters

The following parameters can be used with queries.

Table 485. Query parameters

Parameter	Details and examples of parameters that can be added to queries
`approver`	This parameter is used to query items with a specific approver. A user ID must be specified when this parameter is used. For example: `?approver=userid`
`authoringtemplateid`	This parameter is used to query items with a specific authoring template ID. For example: `?authoringtemplateid=wcmrest:18cfc80c-a490-4d75-9057-fed3db89de53`
`author`	This parameter is used to query items with a specific author. A user UID must be specified when this parameter is used. For example: `?author=uid=WCMUT_Editor_A,o=defaultWIMFileBasedRealm`
`categoryid`	This parameter is used to query items with a specific category ID. For example: `?categoryid=wcmrest:18cfc80c-a490-4d75-9057-fed3db89de53`
`createdafter`	This parameter is used to query items that are created after a specific date and time. For example: `?createdafter=2011-01-11T11:43:29.0150Z`
`createdbefore`	This parameter is used to query items that are created before a specific date and time. For example: `?createdbefore=2011-01-11T11:43:29.0150Z`
`creator`	This parameter is used to query items with a specific creator. A user UID must be specified when this parameter is used. For example: `?creator=uid=WCMUT_Editor_A,o=defaultWIMFileBasedRealm`
`dateformat`	This parameter is used to define the date format of query parameters. For example: `?dateformat=mm-dd-yyyy&createdbefore=12-31-2011` If a date format not specified, then the default format *yyyy-MM-dd'T'HH:mm:ssz* is used.

Table 485. Query parameters (continued)

Parameter	Details and examples of parameters that can be added to queries
depth	This parameter is used with the parentid and is used to define whether to search for all descendants of a parent, or just the immediate children of a parent item. For example, to query only the immediate children of an item, you add &depth=CHILDREN to the query: ?parentid=wcmrest:18cfc80c-a490-4d75-9057-fed3db89de53&depth=CHILDREN To query all descendants of an item, you add &depth=DESCENDANTS to the query: ?parentid=wcmrest:18cfc80c-a490-4d75-9057-fed3db89de53&depth=DESCENDANTS
expireafter	This parameter is used to query items that are expired after a specific date and time. For example: ?expireafter=2011-01-11T11:43:29.0150Z
expirebefore	This parameter is used to query items that were expired before a specific date and time. For example: ?expirebefore=2011-01-11T11:43:29.0150Z
id	This parameter is used to query an item with a specific ID. For example: ?id=wcmrest:18cfc80c-a490-4d75-9057-fed3db89de53
keyword	This parameter is used to query items that are profiled with a specific keyword. For example: ?keyword=keywordValue
lastmodifiedafter	This parameter is used to query items that were last modified after a specific date and time. For example: ?lastmodifiedafter=2011-01-11T11:43:29.0150Z
lastmodifiedbefore	This parameter is used to query items that were last modified before a specific date and time. For example: ?lastmodifiedbefore=2011-01-11T11:43:29.0150Z
lastmodifier	This parameter is used to query items that were last modified by a specific user. A user UID must be specified when this parameter is used. For example: ?lastmodifier=uid=WCMUT_Editor_A,o=defaultWIMFileBasedRealm
libraryid	This parameter is used to query items that are stored in a specific library. For example: ?libraryid=wcmrest:18cfc80c-a490-4d75-9057-fed3db89de53

Table 485. Query parameters (continued)

Parameter	Details and examples of parameters that can be added to queries
`namelike`	This parameter is used as a wildcard query for items with names like the specified `namelike` parameter. For example: `?namelike=nameApproxValue%` **Note:** Libraries cannot be queried by using this parameter.
`name`	This parameter is used to query an item with a specific name. For example: `?name=nameValue` **Note:** Libraries cannot be queried by using this parameter.
`owner`	This parameter is used to query items with a specific owner. A user UID must be specified when this parameter is used. For example: `?owner=uid=WCMUT_Editor_A,o=defaultWIMFileBasedRealm`
`pagesize`	This parameter is used to restrict the number of items that are returned by a query to a set number. It can be used with the `page` parameter to return specific pages of results. For example, to restrict the number of queries to be returned to 5: `?type=PresentationTemplate&pagesize=5`
`page`	This parameter is used with the `pagesize` parameter to define what set of results to display. For example, if `pagesize` is set to 5, and the `page` parameter is set to 2, then only results 6 - 10 are displayed. For example: `?type=PresentationTemplate&pagesize=5&page=2`
`parentid`	This parameter is used to query items that are the children of a specific parent item. For example: `?parentid=wcmrest:18cfc80c-a490-4d75-9057-fed3db89de53` You can use the `depth` parameter to define whether to search for all descendants of a parent, or just the immediate children of a parent item.
`projectid`	This parameter is used to query items that are linked to a specific project. For example: `?projectid=wcmrest:18cfc80c-a490-4d75-9057-fed3db89de53`

Table 485. Query parameters (continued)

Parameter	Details and examples of parameters that can be added to queries
projectstate	This parameter is used to query items that are linked to a project with a specific state. The following values can be used with this parameter: • ACTIVE • SYNDICATING • PENDING • PUBLISHING • PUBLISHED • PUBLISHED_FAILED For example, to query items that are linked to projects with a state of "active" you would use the following query: ?projectstate=ACTIVE
publishafter	This parameter is used to query items that are published after a specific date and time. For example: ?publishafter=2011-01-11T11:43:29.0150Z
publishbefore	This parameter is used to query items that were published before a specific date and time. For example: ?publishbefore=2011-01-11T11:43:29.0150Z
sort	The sort parameter is appended to queries to determine how query results are sorted. The following values can be used with the sort parameter. • author • created • modified • name • title • parents • position The values _ascending or _descending are appended to the query to determine sort order. For example, to sort a presentation template query in ascending order of creation, you would use: ?type=PresentationTemplate&sort=created_ascending To sort a presentation template query in descending order of creation, you would use: ?type=PresentationTemplate&sort=created_descending If _ascending or _descending are not specified, the results as displayed in ascending order.

Table 485. Query parameters (continued)

Parameter	Details and examples of parameters that can be added to queries
`state`	This parameter is used to query items that are in a specific state. The following values can be used with this parameter: • `DRAFT` • `PUBLISHED` • `EXPIRED` For example: `?state=PUBLISHED`
`titlelike`	This parameter is used as a wildcard query for items with titles like the specified `titlelike` parameter. For example: `?titlelike=nameApproxValue%`
`title`	This parameter is used to query an item with a specific title. For example: `?title=titleValue`
`type`	This parameter is used to query items of a specific item type. For example, to query a list of components: `?type=LibraryHTMLComponent`
`workflowid`	This parameter is used to query items that use a specific workflow. For example: `?workflowid=wcmrest:8d25860b-7a5c-4015-9cd5-bdcc60ce14bb`
`workflowstageid`	This parameter is used to query items that are currently active within a specific workflow stage. For example: `?workflowstageid=wcmrest:18cfc80c-a490-4d75-9057-fed3db89de53`

How to use multiple parameters

- Multiple instances of the same parameter type in a query can be specified only as "OR" queries, with the following exceptions:

  Only one value allowed

  Only one instance of the following parameters can be used in a single query. If multiple instances are used, only the first instance is used by the query:

  - `dateformat`
  - `depth`
  - `page`
  - `pagesize`

  "AND" queries allowed

  The following queries can be used as "AND" queries:

  - `createdafter`
  - `createdbefore`
  - `expireafter`
  - `expirebefore`

- `lastmodifiedafter`
- `lastmodifiedbefore`
- `publishafter`
- `publishbefore`

Sort values

Sort values are comma-separated. For example:

```
?sort=created_ascending,title_descending
```

How to manage web content items by using REST

You can use the Web Content Manager REST Service to create, read, update, and delete the following item types.

"How to use REST with libraries" on page 3325
You can use the Web Content Manager REST service to create, read, update, and delete libraries.

"How to use REST with components" on page 3327
You can use the Web Content Manager REST service to create, read, update, and delete some types of components.

"How to use REST with elements before version 8.5 CF03" on page 3330
You can use the Web Content Manager REST service to create, read, update, and delete some types of elements that are stored in site areas and content items. All element types are supported.

"How to use REST with elements with version 8.5 CF03 or higher" on page 3332
You can use the Web Content Manager REST service to create, read, update, and delete elements.

CF06 "How to use REST with authoring templates" on page 3337
You can use the Web Content Manager REST service to create, read, update, and delete content templates and site area templates. You can also set default values for items that are created by using these authoring templates.

"How to REST with presentation templates" on page 3346
You can use the Web Content Manager REST service to create, read, update, and delete presentation templates.

"How to use REST with content items" on page 3348
You can use the Web Content Manager REST service to create, read, update, and delete content items.

"How to use REST with site areas" on page 3350
You can use the Web Content Manager REST service to create, read, update, and delete site areas.

"How to use REST with managed pages" on page 3352
You can use the Web Content Manager REST service to read managed pages.

"How to use REST with drafts and workflows" on page 3353
You can use the REST services for Web Content Manager to create drafts, approve items in a workflow, and move items through different stages of a workflow.

"How to use REST with workflow items" on page 3355
You can use the Web Content Manager REST service to create, read, update, and delete workflow items.

"How to use REST with workflow stages" on page 3357
You can use the Web Content Manager REST service to create, read, update, and delete workflow stages.

How to use REST with libraries

You can use the Web Content Manager REST service to create, read, update, and delete libraries.

Create

A library can be created by sending a POST request to the following URI:

```
/Library
```

For example:

```
HTTP/1.1 POST /wps/mycontenthandler/wcmrest/Library
Content-Type: application/atom+xml

<?xml version="1.0" encoding="UTF-8"?>
<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm/8.0">
    <wcm:name>My Library</wcm:name>
    <content type="application/vnd.ibm.wcm+xml">
        <wcm:library xmlns="http://www.ibm.com/xmlns/wcm/8.0">
            <allowDeletion>false</allowDeletion>
            <enabled>true</enabled>
            <language>en</language>
            <includeDefaultItems>true</includeDefaultItems>
        </wcm:library>
    </content>
</entry>

HTTP 201 Created
```

Update

An existing library can be updated by sending a PUT request to the following URI: `/Library/library-id`

For example:

```
HTTP/1.1 PUT /wps/mycontenthandler/wcmrest/Library/ff207ba6-ac9a-4b38-b831-99528ff5067c
Content-Type: application/atom+xml
Accept: application/atom+xml

<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm/8.0">
    <id>wcmrest:ff207ba6-ac9a-4b38-b831-99528ff5067c</id>
    <title>My New Library Title</title>
    <summary/>
    <wcm:name>my library</wcm:name>
    <wcm:type>Library</wcm:type>
    <updated>2014-10-09T03:18:02.303Z</updated>
    <link rel="self" href="/wps/mycontenthandler/wcmrest/Library/ff207ba6-ac9a-4b38-b831-99528ff5067c" xml:lang="en" label="Read"/>
    <link rel="edit" href="/wps/mycontenthandler/wcmrest/Library/ff207ba6-ac9a-4b38-b831-99528ff5067c" xml:lang="en" label="Edit"/>
    <link rel="delete" href="/wps/mycontenthandler/wcmrest/Library/ff207ba6-ac9a-4b38-b831-99528ff5067c" xml:lang="en" label="Delete"/>

    <link rel="edit-media" href="/wps/mycontenthandler/wcmrest/Library/ff207ba6-ac9a-4b38-b831-99528ff5067c" type="application/vnd.ibm.wcm+xml" xml:lang="en" label="Edit Media"/>
    <link rel="preset-folders" href="/wps/mycontenthandler/wcmrest/Library/ff207ba6-ac9a-4b38-b831-99528ff5067c/preset-folders"/>
    <content type="application/vnd.ibm.wcm+xml">
        <wcm:library xmlns="http://www.ibm.com/xmlns/wcm/8.0">
            <allowDeletion>true</allowDeletion>
            <enabled>true</enabled>
            <language>en</language>
        </wcm:library>
    </content>
</entry>
```

Read

An existing library can be read by sending a GET request to the following URI: `/Library/library-id`

For example:

```
HTTP/1.1 GET /wps/mycontenthandler/wcmrest/Library/ff207ba6-ac9a-4b38-b831-99528ff5067c
Accept: application/atom+xml

HTTP 200 OK

<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm/8.0">
    <id>wcmrest:ff207ba6-ac9a-4b38-b831-99528ff5067c</id>
    <title>My Library</title>
    <summary/>
    <wcm:name>my library</wcm:name>
    <wcm:type>Library</wcm:type>
    <updated>2014-10-09T03:18:02.303Z</updated>
    <link rel="self" href="/wps/mycontenthandler/wcmrest/Library/ff207ba6-ac9a-4b38-b831-99528ff5067c" xml:lang="en" label="Read"/>
    <link rel="edit" href="/wps/mycontenthandler/wcmrest/Library/ff207ba6-ac9a-4b38-b831-99528ff5067c" xml:lang="en" label="Edit"/>
    <link rel="delete" href="/wps/mycontenthandler/wcmrest/Library/ff207ba6-ac9a-4b38-b831-99528ff5067c" xml:lang="en" label="Delete"/>
    <link rel="access-control" href="/wps/mycontenthandler/ac/access:oid:Z6QReDe6JP43OS62BOCJM4C3BE2MMG62RCGJM8COPC2JM47P9D43SOC6BD03RS633" xml:lang="en" label="Access Control"/>
    <link rel="edit-media" href="/wps/mycontenthandler/wcmrest/Library/ff207ba6-ac9a-4b38-b831-99528ff5067c" type="application/vnd.ibm.wcm+xml" xml:lang="en" label="Edit Media"/>
    <link rel="preset-folders" href="/wps/mycontenthandler/wcmrest/Library/ff207ba6-ac9a-4b38-b831-99528ff5067c/preset-folders"/>
    <content type="application/vnd.ibm.wcm+xml">
        <wcm:library xmlns="http://www.ibm.com/xmlns/wcm/8.0">
            <allowDeletion>false</allowDeletion>
            <enabled>true</enabled>
            <language>en</language>
        </wcm:library>
    </content>
</entry>
```

Delete

An existing library can be deleted by sending a DELETE request to the following URI:

```
/Library/library-id
```

For example:

```
HTTP/1.1 DELETE /wps/mycontenthandler/wcmrest/Library/ff207ba6-ac9a-4b38-b831-99528ff5067c

HTTP 200 OK
```

Asynchronous Delete

An existing library can also be deleted asynchronously by using the following URI. The response contains a 'Content-Location' header, containing a URI that can be used to monitor the progress of the delete operation:

```
/Library/library-id?synchronous=true
```

For example:

```
HTTP/1.1 DELETE /wps/mycontenthandler/wcmrest/Library/ff207ba6-ac9a-4b38-b831-99528ff5067c?synchronous=true

HTTP 202 Accepted
Content-Location: /wps/mycontenthandler/wcmrest/Library/fd18e3a0-b96b-4a66-9bcc-f3d142c7837e/wcmTask:com.ibm.workplace.wcm.services.task.DeleteTask:ced02fae-abc7-4ff4-af4d-c08804b32811/delete-status
```

How to use REST with components

You can use the Web Content Manager REST service to create, read, update, and delete some types of components.

The following component types can be used with the Web Content Manager REST service.

Table 486. Component types

Component	API type
Authoring Tools Component	LibraryAuthoringToolsComponent
Date and time component	LibraryDateComponent
File resource component	LibraryFileComponent
HTML Component	LibraryHTMLComponent
Image component	LibraryImageComponent
JSP Component	LibraryJSPComponent
Link Component	LibraryLinkComponent
List Presentation Component	LibraryListPresentationComponent
Menu Component	LibraryMenuComponent
Navigator Component	LibraryNavigatorComponent
Number component	LibraryNumericComponent
Page Navigation Component	LibraryPageNavigationComponent
Personalization Component	LibraryPersonalizationComponent
Reference Component	LibraryReferenceComponent
Rich text component	LibraryRichTextComponent
Search Component	LibrarySearchComponent
Short text component	LibraryShortTextComponent
Stylesheet Component	LibraryStyleSheetComponent
Text component	LibraryTextComponent

Table 486. Component types (continued)

Component	API type
User Selection Component	LibraryUserSelectionComponent
Username Component	LibraryUserNameComponent

Create

A component can be created by sending a POST request to the following URI with an Atom entry that represents the component:

`/<library-component-api-type>`

For example:

```
POST /wps/mycontenthandler/wcmrest/LibraryNumericComponent HTTP/1.0
Content-Type: application/atom+xml

<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="wcm/namespace">
    <title>SampleNumericComponentTitle</title>
    <link rel="library" href="/wps/mycontenthandler/!ut/p/wcmrest/item/c98d11e1-7f2a-480e-9aac-40eb1949cbda"/>
    <wcm:name>SampleNumericComponentName</wcm:name>
    <wcm:description>SampleNumericComponentDescription</wcm:description>
</entry>

HTTP/1.0 201 Created
Content-type: application/atom+xml; type=entry
Content-location: /wps/mycontenthandler/!ut/p/wcmrest/LibraryNumericComponent/0d678334-69ae-4d3a-a525-91bb551e5a18

<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="wcm/namespace">
    <id>0d678334-69ae-4d3a-a525-91bb551e5a18</id>
    <title>SampleNumericComponentTitle</title>
    <link rel="edit" href="/wps/mycontenthandler/!ut/p/wcmrest/LibraryNumericComponent/0d678334-69ae-4d3a-a525-91bb551e5a18"/>
    <link rel="edit-media" type="text/plain" href="/wps/mycontenthandler/!ut/p/wcmrest/LibraryNumericComponent/0d678334-69ae-4d3a-a525-91bb551e5a18"/>
    <link rel="library" href="/wps/mycontenthandler/!ut/p/wcmrest/item/c98d11e1-7f2a-480e-9aac-40eb1949cbda"/>
    <link rel="create-draft" href="/wps/mycontenthandler/!ut/p/wcmrest/item/0d678334-69ae-4d3a-a525-91bb551e5a18/create-draft"/>
    <link rel="change-to-draft" href="/wps/mycontenthandler/!ut/p/wcmrest/item/0d678334-69ae-4d3a-a525-91bb551e5a18/change-to-draft"/>
    <link rel="versions" href="/wps/mycontenthandler/!ut/p/wcmrest/item/0d678334-69ae-4d3a-a525-91bb551e5a18/versions"/>
    <updated>2011-05-30T04:33:40.540Z</updated>
    <author>
        <wcm:distinguishedName>uid=wpsadmin,o=defaultWIMFileBasedRealm</wcm:distinguishedName>
        <uri>/wps/mycontenthandler/!ut/p/digest!6GVkh5U175Ln7DdEgvHm_g/um/users/profiles/Z9eAeH1C2JG561RC6JM47H9E4MMG6PHO6JM4C5JD0JMOC6BEEJS464JDG3I56K1</uri>
        <name>wpsadmin</name>
    </author>
    <wcm:owner>
        <wcm:distinguishedName>uid=wpsadmin,o=defaultWIMFileBasedRealm</wcm:distinguishedName>
        <uri>/wps/mycontenthandler/!ut/p/digest!6GVkh5U175Ln7DdEgvHm_g/um/users/profiles/Z9eAeH1C2JG561RC6JM47H9E4MMG6PHO6JM4C5JD0JMOC6BEEJS464JDG3I56K1</uri>
        <name>wpsadmin</name>
    </wcm:owner>
    <wcm:name>SampleNumericComponentName</wcm:name>
    <wcm:description>SampleNumericComponentDescription</wcm:description>
    <wcm:type>NUMERIC</wcm:type>
    <wcm:state>PUBLISHED</wcm:state>
</entry>
```

Update

A component can be updated by sending a PUT request to the following URI with an Atom entry that includes the fields of the item that need to be changed.

`/<library-component-api-type>/<itemuuid>`

For example:

```
PUT /wps/mycontenthandler/wcmrest/LibraryNumericComponent/c98d11e1-7f2a-480e-9aac-40eb1949cbda HTTP/1.0
Content-type : application/atom+xml

<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="wcm/namespace">
    <title>SampleNumericComponentTitleUpdated</title>
    <link rel="library" href="/wps/mycontenthandler/!ut/p/wcmrest/item/c98d11e1-7f2a-480e-9aac-40eb1949cbda"/>
    <wcm:name>SampleNumericComponentNameUpdated</wcm:name>
    <wcm:description>SampleNumericComponentDescriptionUpdated</wcm:description>
</entry>

HTTP/1.0 200 OK
Content-type: application/atom+xml; type=entry

<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="wcm/namespace">
    <id>0d678334-69ae-4d3a-a525-91bb551e5a18</id>
    <title>SampleNumericComponentTitleUpdated</title>
    <link rel="edit" href="/wps/mycontenthandler/!ut/p/wcmrest/LibraryNumericComponent/0d678334-69ae-4d3a-a525-91bb551e5a18"/>

```

Read

A component can be read by sending a GET request to the following URI:
`/<library-component-api-type>/<itemuuid>`

For example:

```
GET /wps/mycontenthandler/wcmrest/LibraryNumericComonent/0d678334-69ae-4d3a-a525-91bb551e5a18 HTTP/1.0

HTTP/1.0 200 OK
Content-type: application/atom+xml; type=entry

<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="wcm/namespace">
    <id>0d678334-69ae-4d3a-a525-91bb551e5a18</id>
    <title>SampleNumericComponentTitleUpdated</title>
    <link rel="edit" href="/wps/mycontenthandler/!ut/p/wcmrest/LibraryNumericComponent/0d678334-69ae-4d3a-a525-91bb551e5a18"/>
    <link rel="edit-media" type="text/plain" href="/wps/mycontenthandler/!ut/p/wcmrest/LibraryNumericComponent/0d678334-69ae-4d3a-a525-91bb551e5a18"/>
    <link rel="library" href="/wps/mycontenthandler/!ut/p/wcmrest/item/c98d11e1-7f2a-480e-9aac-40eb1949cbda"/>

    <link rel="change-to-draft" href="/wps/mycontenthandler/!ut/p/wcmrest/item/0d678334-69ae-4d3a-a525-91bb551e5a18/change-to-draft"/>
    <link rel="versions" href="/wps/mycontenthandler/!ut/p/wcmrest/item/0d678334-69ae-4d3a-a525-91bb551e5a18/versions"/>
    <updated>2011-05-30T04:38:49.522Z</updated>
    <author>
        <wcm:distinguishedName>uid=wpsadmin,o=defaultWIMFileBasedRealm</wcm:distinguishedName>
        <uri>/wps/mycontenthandler/!ut/p/digest!6GVkh5Ul75Ln7DdEgvHm_g/um/users/profiles/Z9eAeH1C2JG561RC6JM47H9E4MMG6PHO6JM4C5JD0JMOC6BEEJS464JDG3I56K1</uri>
        <name>wpsadmin</name>
    </author>
    <wcm:owner>
        <wcm:distinguishedName>uid=wpsadmin,o=defaultWIMFileBasedRealm</wcm:distinguishedName>
        <uri>/wps/mycontenthandler/!ut/p/digest!6GVkh5Ul75Ln7DdEgvHm_g/um/users/profiles/Z9eAeH1C2JG561RC6JM47H9E4MMG6PHO6JM4C5JD0JMOC6BEEJS464JDG3I56K1</uri>
        <name>wpsadmin</name>
    </wcm:owner>
    <wcm:name>SampleNumericComponentNameUpdated</wcm:name>
    <wcm:description>SampleNumericComponentDescriptionUpdated</wcm:description>
    <wcm:type>NUMERIC</wcm:type>
    <wcm:state>PUBLISHED</wcm:state>
</entry>
```

Delete

A component can be deleted by sending a DELETE request to the following URI:
`/<library-component-api-type>/<itemuuid>`

For example:

DELETE

```
HTTP/1.1 DELETE
http://host:port/wps/mycontenthandler/wcmrest/LibraryNumericComponent/<itemuuid>
```

Response

```
Status Code :200
Status Message : OK
```

Specifying raw data

The content of a component is accessed from the location that is specified in the HREF attribute of the edit-media link. The link also contains a TYPE attribute that contains the accepted media type for the content. For example:

```
<link rel="edit-media" type="text/plain"
href="/wps/mycontenthandler/!ut/p/wcmrest/LibraryTextComponent/0d678334-69ae-4d3a-a525-91bb551e5a18"/>
```

A complete list of media types are documented here: “Supported media types” on page 3392.

To update content of a library component PUT content in an accepted media type to the edit-media URL. For example:

```
PUT /wps/mycontenthandler/!ut/p/wcmrest/LibraryTextComponent/0d678334-69ae-4d3a-a525-91bb551e5a18 HTTP/1.0
Content-type: text/plain

This is some text to add to the component.

HTTP/1.0 200 OK
```

To retrieve content from a library component GET content from the edit-media URL. For example:

```
GET  /wps/mycontenthandler/!ut/p/wcmrest/LibraryTextComponent/0d678334-69ae-4d3a-a525-91bb551e5a18 HTTP/1.0
Accept: text/plain

HTTP/1.0 200 OK
Content-type: text/plain

This is some text to add to the component.
```

An alternative to specifying the media type in the HTTP accept header is to use the request parameter mime-type. You must URL encode the value. For example:

```
GET  /wps/mycontenthandler/!ut/p/wcmrest/LibraryTextComponent/0d678334-69ae-4d3a-a525-91bb551e5a18?mime-type=text%2Fplain HTTP/1.0

HTTP/1.0 200 OK
Content-type: text/plain

This is some text to add to the component.
```

Related concepts:

"REST content formats for components and elements" on page 3309
When you use REST with components or elements, use these content formats. These examples can be used as templates for your own REST solutions.

How to use REST with elements before version 8.5 CF03

You can use the Web Content Manager REST service to create, read, update, and delete some types of elements that are stored in site areas and content items. All element types are supported.

Create

An element can be created by sending a POST request to the following URI with an Atom entry that represents the title of the element:

```
/[Content|SiteArea]/<parent-uuid>/elements
```

Note: The type of the element to be created must be specified in the type field of the entry that is posted.

For example:

```
POST /wps/mycontenthandler/wcmrest/SiteArea/c6b00ee6-d628-4cbd-9e65-15c90f2093a6/elements HTTP/1.0
Content-type: application/atom+xml

<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="wcm/namespace">
    <title>Number Element Title</title>
    <wcm:name>numericElementName</wcm:name>
    <wcm:type>NumericComponent</wcm:type>
</entry>

HTTP/1.0 201 Created
Content-type: application/atom+xml; type=entry
Content-location: /wps/mycontenthandler/!ut/p/wcmrest/SiteArea/c6b00ee6-d628-4cbd-9e65-15c90f2093a6/elements/numericElementName

<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="wcm/namespace">
    <title>Number Element Title</title>
    <link rel="edit-media" type="text/plain" href="/wps/mycontenthandler/!ut/p/wcmrest/SiteArea/c6b00ee6-d628-4cbd-9e65-15c90f2093a6/elements/numericElementName"/>
    <link rel="edit" href="/wps/mycontenthandler/!ut/p/wcmrest/SiteArea/c6b00ee6-d628-4cbd-9e65-15c90f2093a6/elements/numericElementName"/>
    <wcm:name>numericElementName</wcm:name>
    <wcm:type>NumericComponent</wcm:type>
</entry>
```

Update

An element can be updated by sending a PUT request to the following URI with an Atom entry that includes the name and title of the element.

```
/[Content|SiteArea]/<parent-uuid>/elements/<element-name-encoded>
```

For example:

```
PUT /wps/mycontenthandler/wcmrest/SiteArea/c6b00ee6-d628-4cbd-9e65-15c90f2093a6/elements/numericComponentName HTTP/1.0
Content-type: application/atom+xml

<atom:entry xmlns:atom="http://www.w3.org/2005/Atom" xmlns:wcm="wcm/namespace">
    <title>numericElementTitleUpdated</title>
```

```
    <wcm:name>numericElementNameUpdated</wcm:name>
</atom:entry>

HTTP/1.0 200 OK
Content-type: application/atom+xml; type=entry

<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="wcm/namespace">
    <title>numericComponentTitleUpdated</title>
    <link rel="edit-media" type="text/plain" href="/wps/mycontenthandler/!ut/p/wcmrest/SiteArea/c6b00ee6-d628-4cbd-9e65-15c90f2093a6/elements/numericElementNameUpdated"/>
    <link rel="edit" href="/wps/mycontenthandler/!ut/p/wcmrest/SiteArea/c6b00ee6-d628-4cbd-9e65-15c90f2093a6/elements/numericElementNameUpdated"/>
    <wcm:name>numericElementNameUpdated</wcm:name>
    <wcm:type>NumericComponent</wcm:type>
</entry>
```

Read

An element can be read by sending a GET request to the following URI:
`/[Content|SiteArea]/<parent-uuid>/elements/<element-name-encoded>`

For example:

```
GET /wps/mycontenthandler/wcmrest/Content/c6b00ee6-d628-4cbd-9e65-15c90f2093a6/elements/numericElementName HTTP/1.0

HTTP/1.0 200 OK
Content-type: application/atom+xml; type=entry

<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="wcm/namespace">
    <title>numericElementTitleUpdated</title>
    <link rel="edit-media" type="application/vnd.ibm.wcm+xml" href="/wps/mycontenthandler/!ut/p/wcmrest/SiteArea/c6b00ee6-d628-4cbd-9e65-15c90f2093a6/elements/numericElementName"/>
    <link rel="edit" href="/wps/mycontenthandler/!ut/p/wcmrest/SiteArea/c6b00ee6-d628-4cbd-9e65-15c90f2093a6/elements/numericElementName"/>
    <wcm:name>numericElementName</wcm:name>
    <wcm:type>NumericComponent</wcm:type>
</entry>
```

Delete

An element can be deleted by sending a DELETE request to the following URI:
`/[Content|SiteArea]/<parent-uuid>/elements/<element-name-encoded>`

For example:

DELETE

```
HTTP/1.1 DELETE
http://host:port/wps/mycontenthandler/wcmrest/Content/<parent-uuid>/elements/<element-name-encoded>
```

Response

```
Status Code :200
Status Message : OK
```

Specifying raw data

The content of an element is accessed from the media resource that is specified in the HREF attribute of the edit-media link. The link also contains a TYPE attribute that contains the accepted media type of the content. For example:

```
<link rel="edit-media" type="text/html"
href="/wps/mycontenthandler/!ut/p/wcmrest/SiteArea/c6b00ee6-d628-4cbd-9e65-15c90f2093a6/elements/heading"/>
```

A complete list of media types are documented here: “Supported media types” on page 3392.

To update content of an element PUT content in an accepted media type to the edit-media URL. For example:

```
PUT /wps/mycontenthandler/!ut/p/wcmrest/SiteArea/c6b00ee6-d628-4cbd-9e65-15c90f2093a6/elements/heading HTTP/1.0
Content-type: text/html

<h1>Heading Text</h1>

HTTP/1.0 200 OK
```

To retrieve content from a library component GET content from the edit-media URL. For example:

```
GET  /wps/mycontenthandler/!ut/p/wcmrest/SiteArea/c6b00ee6-d628-4cbd-9e65-15c90f2093a6/elements/heading HTTP/1.0
Accept: text/html

HTTP/1.0 200 OK
Content-type: text/plain

<h1>Heading Text</h1>
```

An alternative to specifying the media type in the HTTP accept header, is to use the request parameter mime-type. You must URL encode the value. For example:

```
GET  /wps/mycontenthandler/!ut/p/wcmrest/SiteArea/c6b00ee6-d628-4cbd-9e65-15c90f2093a6/elements/heading?mime-type=text%2Fhtml HTTP/1.0

HTTP/1.0 200 OK
Content-type: text/plain

<h1>Heading Text</h1>
```

Related concepts:

"REST content formats for components and elements" on page 3309
When you use REST with components or elements, use these content formats. These examples can be used as templates for your own REST solutions.

How to use REST with elements with version 8.5 CF03 or higher

You can use the Web Content Manager REST service to create, read, update, and delete elements.

Create

You can use the Web Content Manager REST service to create, read, update, and delete all element types that belong to one of the following element container types:

- Content
- Site area
- The default content of a content template
- The default site area of a site area template

There are two ways to run these operations. The first is to address each element individually, and by using a URI and use the HTTP verbs (GET, PUT, POST, DELETE) to manipulate them. You can also update multiple elements with a PUT request.

An element can be created by sending a POST request to one of the following URIs with an Atom entry that represent the title of the element:

Content item
`/Content/content-id/elements`

Site area
`/SiteArea/site-area-id/elements`

The default content of a content template
`/ContentTemplate/template-id/Prototype/elements`

The default content of a site area template
`/SiteAreaTemplate/template-id/Prototype/elements`

Note: The type of the element to be created must be specified in the type field of the entry that is posted.

For example:

```
HTTP/1.1 POST /wps/mycontenthandler/wcmrest/ContentTemplate/12015598-24c4-40f6-9be0-68c52663c03f/Prototype/elements/

<?xml version="1.0" encoding="UTF-8"?>
<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm/8.0">
    <title>MyDateElement</title>
    <wcm:name>MyDateElement</wcm:name>
    <wcm:type>DateComponent</wcm:type>
    <content type="application/vnd.ibm.wcm+xml">
        <wcm:date type="DateTime">2014-08-05T06:01:07.152Z</wcm:date>
    </content>
</entry>

HTTP/1.1 201 Created
Content-Type: application/atom+xml
Content-Location: /wps/mycontenthandler/wcmrest/ContentTemplate/3f6311ae-d277-42d0-869c-eeb7a28ba754/Prototype/elements/MyDateElement

<?xml version="1.0" encoding="UTF-8"?>
<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm/8.0">
    <title>MyDateElement</title>
    <wcm:name>MyDateElement</wcm:name>
    <wcm:type>TextComponent</wcm:type>
    <link rel="self" href="/wps/mycontenthandler/wcmrest/ContentTemplate/3f6311ae-d277-42d0-869c-eeb7a28ba754/Prototype/elements/MyDateElement" xml:lang="en" label="Read"/>
    <link rel="edit-media" href="/wps/mycontenthandler/wcmrest/ContentTemplate/3f6311ae-d277-42d0-869c-eeb7a28ba754/Prototype/elements/MyDateElement" type="text/plain" xml:lang="en" label="Edit Media"/>
    <link rel="edit" href="/wps/mycontenthandler/wcmrest/ContentTemplate/3f6311ae-d277-42d0-869c-eeb7a28ba754/Prototype/elements/MyDateElement" xml:lang="en" label="Edit"/>
    <content type="application/vnd.ibm.wcm+xml">
        <wcm:date type="DateTime">2014-08-05T06:01:07.152Z</wcm:date>
    </content>
</entry>
```

Update

An element can be updated by sending a PUT request to one of the following URIs:

Content item
/Content/content-id/elements/element-name

Site area
/SiteArea/site-area-id/elements/element-name

The default content of a content template
/ContentTemplate/template-id/Prototype/elements/element-name

The default content of a site area template
/SiteAreaTemplate/template-id/Prototype/elements/element-name

For example:

```
HTTP/1.1 PUT /wps/mycontenthandler/wcmrest/ContentTemplate/3f6311ae-d277-42d0-869c-eeb7a28ba754/Prototype/elements/MyDateElement
Content-Type: application/atom+xml

<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm/8.0">
    <title xml:lang="en">MyDateElement</title>
    <wcm:name>MyDateElement with a new name</wcm:name>
    <wcm:type>DateComponent</wcm:type>
    <link rel="self" href="/wps/mycontenthandler/wcmrest/ContentTemplate/3f6311ae-d277-42d0-869c-eeb7a28ba754/Prototype/elements/MyDateElement" xml:lang="en" label="Read"/>
    <link rel="edit-media" href="/wps/mycontenthandler/wcmrest/ContentTemplate/3f6311ae-d277-42d0-869c-eeb7a28ba754/Prototype/elements/MyDateElement" type="application/vnd.ibm.wcm+xml" xml:lang="en" label="Edit Media"/>
    <link rel="edit" href="/wps/mycontenthandler/wcmrest/ContentTemplate/3f6311ae-d277-42d0-869c-eeb7a28ba754/Prototype/elements/MyDateElement" xml:lang="en" label="Edit"/>
    <content type="application/vnd.ibm.wcm+xml">
        <wcm:date type="DateTime">2013-08-05T06:01:07.152Z</wcm:date>
    </content>
</entry>

HTTP/1.1 200 OK
Content-Type: application/atom+xml

<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm/8.0">
    <title xml:lang="en">MyDateElement</title>
    <wcm:name>MyDateElement with a new name</wcm:name>
    <wcm:type>DateComponent</wcm:type>
    <link rel="self" href="/wps/mycontenthandler/wcmrest/ContentTemplate/3f6311ae-d277-42d0-869c-eeb7a28ba754/Prototype/elements/MyDateElement" xml:lang="en" label="Read"/>
    <link rel="edit-media" href="/wps/mycontenthandler/wcmrest/ContentTemplate/3f6311ae-d277-42d0-869c-eeb7a28ba754/Prototype/elements/MyDateElement" type="application/vnd.ibm.wcm+xml" xml:lang="en" label="Edit Media"/>
    <link rel="edit" href="/wps/mycontenthandler/wcmrest/ContentTemplate/3f6311ae-d277-42d0-869c-eeb7a28ba754/Prototype/elements/MyDateElement" xml:lang="en" label="Edit"/>
    <content type="application/vnd.ibm.wcm+xml">
        <wcm:date type="DateTime">2013-08-05T06:01:07.152Z</wcm:date>
    </content>
</entry>
```

Read

An element can be read by sending a GET request to one of the following URIs:

Content item
/Content/content-id/elements/element-name

Site area
/SiteArea/site-area-id/elements/element-name

The default content of a content template
/ContentTemplate/template-id/Prototype/elements/element-name

The default content of a site area template
/SiteAreaTemplate/template-id/Prototype/elements/element-name

For example:

```
HTTP/1.1 GET /wps/mycontenthandler/wcmrest/ContentTemplate/3f6311ae-d277-42d0-869c-eeb7a28ba754/Prototype/elements/MyDateElement
Accept: application/atom+xml

HTTP/1.1 200 OK
Content-Type: application/atom+xml

<?xml version="1.0" encoding="UTF-8"?>
<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm/8.0">
    <title xml:lang="en">MyDateElement</title>
    <wcm:name>MyDateElement</wcm:name>
    <wcm:type>DateComponent</wcm:type>
    <link rel="self" href="/wps/mycontenthandler/wcmrest/ContentTemplate/3f6311ae-d277-42d0-869c-eeb7a28ba754/Prototype/elements/MyDateElement" xml:lang="en" label="Read"/>
    <link rel="edit-media" href="/wps/mycontenthandler/wcmrest/ContentTemplate/3f6311ae-d277-42d0-869c-eeb7a28ba754/Prototype/elements/MyDateElement" type="application/vnd.ibm.wcm+xml" xml:lang="en" label="Edit Media"/>
    <link rel="edit" href="/wps/mycontenthandler/wcmrest/ContentTemplate/3f6311ae-d277-42d0-869c-eeb7a28ba754/Prototype/elements/MyDateElement" xml:lang="en" label="Edit"/>
    <content type="application/vnd.ibm.wcm+xml">
        <wcm:date type="DateTime">2014-08-05T06:01:07.152Z</wcm:date>
    </content>
</entry>
```

Delete

An element can be deleted by sending a DELETE request to one of the following URIs:

Content item
/Content/content-id/elements/element-name

Site area
/SiteArea/site-area-id/elements/element-name

The default content of a content template
/ContentTemplate/template-id/Prototype/elements/element-name

The default content of a site area template
/SiteAreaTemplate/template-id/Prototype/elements/element-name

For example:

```
HTTP/1.1 DELETE /wps/mycontenthandler/wcmrest/ContentTemplate/3f6311ae-d277-42d0-869c-eeb7a28ba754/Prototype/elements/MyDateElement

HTTP/1.1 200 OK
```

Read feed with multiple elements

Element feeds can be obtained by issuing a GET request to the following URIs:

Content item
/Content/content-id/elements/element-name

Site area
/SiteArea/site-area-id/elements/element-name

The default content of a content template
/ContentTemplate/template-id/Prototype/elements/element-name

The default content of a site area template
/SiteAreaTemplate/template-id/Prototype/elements/element-name

For example:

```
HTTP/1.1 GET /wps/mycontenthandler/wcmrest/Content/4f9dfaa1-a823-4964-9583-8bbd69504595/elements
Accept: application/atom+xml

HTTP/1.1 200 OK

<?xml version="1.0" encoding="UTF-8"?>
<feed xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm/8.0">
    <title xml:lang="en">Elements Feed</title>
    <updated>2014-08-08T04:50:01.839Z</updated>
    <link rel="parent" href="/wps/mycontenthandler/wcmrest/Content/4f9dfaa1-a823-4964-9583-8bbd69504595" xml:lang="en" label="Parent"/>
    <entry>
        <title xml:lang="en">MyRichTextElement</title>
        <wcm:name>MyRichTextElement</wcm:name>
        <wcm:type>RichTextComponent</wcm:type>
        <link rel="alternate" href="/wps/mycontenthandler/wcmrest/Content/4f9dfaa1-a823-4964-9583-8bbd69504595/elements/MyRichTextElement" xml:lang="en" label="Read"/>
        <content type="text/html"><![CDATA[<p dir="ltr">This is some rich text</p>
]]&gt;</content>
    </entry>
    <entry>
        <title xml:lang="en">MyDateComponent</title>
        <wcm:name>MyDateComponent</wcm:name>
        <wcm:type>DateComponent</wcm:type>
        <link rel="alternate" href="/wps/mycontenthandler/wcmrest/Content/4f9dfaa1-a823-4964-9583-8bbd69504595/elements/MyDateComponent" xml:lang="en" label="Read"/>
        <content type="application/vnd.ibm.wcm+xml">
            <wcm:date type="DateTime">2014-08-06T15:00:00.000Z</wcm:date>
        </content>
    </entry>
```

```
    <entry>
        <title xml:lang="en">MyTextComponent</title>
        <wcm:name>MyTextComponent</wcm:name>
        <wcm:type>TextComponent</wcm:type>
        <link rel="alternate" href="/wps/mycontenthandler/wcmrest/Content/4f9dfaa1-a823-4964-9583-8bbd69504595/elements/MyTextComponent" xml:lang="en" label="Read"/>
        <content type="text/plain">This is some text</content>
    </entry>
</feed>
```

Read inline with multiple elements

Element within an entry can be obtained by issuing a GET request to the following URIs:

Content item
/Content/content-id/

Site area
/SiteArea/site-area-id/

The default content of a content template
/ContentTemplate/template-id/Prototype/

The default content of a site area template
/SiteAreaTemplate/template-id/Prototype/

For example:

```
HTTP/1.1 GET /wps/mycontenthandler/wcmrest/Content/4f9dfaa1-a823-4964-9583-8bbd69504595
Accept: application/atom+xml

HTTP/1.1 200 OK

<?xml version="1.0" encoding="UTF-8"?>
<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm/8.0">
    <id>wcmrest:4f9dfaa1-a823-4964-9583-8bbd69504595</id>
    <title xml:lang="en">MyContentItem</title>
    <summary xml:lang="en"></summary>
    <wcm:name>MyContentItem</wcm:name>
    <wcm:type>Content</wcm:type>
    ... some content elided ...
    <content type="application/vnd.ibm.wcm+xml">
        <wcm:content xmlns="http://www.ibm.com/xmlns/wcm/8.0">
            <elements xmlns:atom="http://www.w3.org/2005/Atom">
                <element name="MyRichTextElement">
                    <title xml:lang="en">MyRichTextElement</title>
                    <type>RichTextComponent</type>
                    <data type="text/html"><![CDATA[<p dir="ltr">This is some rich text</p>]]&gt;</data>
                </element>
                <element name="MyDateComponent">
                    <title xml:lang="en">MyDateComponent</title>
                    <type>DateComponent</type>
                    <data type="application/vnd.ibm.wcm+xml">
                        <date type="DateTime">2014-08-06T15:00:00.000Z</date>
                    </data>
                </element>
                <element name="MyTextComponent">
                    <title xml:lang="en">MyTextComponent</title>
                    <type>TextComponent</type>
                    <data type="text/plain">This is some text</data>
                </element>
            </elements>
        </wcm:content>
    </content>
</entry>
```

Update multiple elements

An item that contains elements can have elements added, removed, or updated by issuing a PUT request, specifying the elements that should be present on the item. Any elements that don't exist on the item are added. Any elements that are not specified in the request will be removed. Any existing elements will be updated.

The elements of an item can be modified by issuing a PUT request to the following URIs:

Content item
/Content/content-id/

Site area
/SiteArea/site-area-id/

The default content of a content template
/ContentTemplate/template-id/Prototype/

The default content of a site area template

/SiteAreaTemplate/template-id/Prototype/

For example:

```
HTTP/1.1 GET /wps/mycontenthandler/wcmrest/Content/4f9dfaa1-a823-4964-9583-8bbd69504595
Accept: application/atom+xml

HTTP/1.1 200 OK

<?xml version="1.0" encoding="UTF-8"?>
<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm/8.0">
    <id>wcmrest:4f9dfaa1-a823-4964-9583-8bbd69504595</id>
    <title xml:lang="en">MyContentItem</title>
    <summary xml:lang="en"></summary>
    <wcm:name>MyContentItem</wcm:name>
    <wcm:type>Content</wcm:type>
    ... some content elided ...
    <content type="application/vnd.ibm.wcm+xml">
        <wcm:content xmlns="http://www.ibm.com/xmlns/wcm/8.0">
            <elements xmlns:atom="http://www.w3.org/2005/Atom">
                <element name="MyRichTextElement">
                    <title xml:lang="en">MyRichTextElement</title>
                    <type>RichTextComponent</type>
                    <data type="text/html"><![CDATA[<p dir="ltr">This is some rich text</p>]]&gt;</data>
                </element>
                <element name="MyDateComponent">
                    <title xml:lang="en">MyDateComponent</title>
                    <type>DateComponent</type>
                    <data type="application/vnd.ibm.wcm+xml">
                        <date type="DateTime">2014-08-06T15:00:00.000Z</date>
                    </data>
                </element>
                <element name="MyTextComponent">
                    <title xml:lang="en">MyTextComponent</title>
                    <type>TextComponent</type>
                    <data type="text/plain">This is some text</data>
                </element>
            </elements>
        </wcm:content>
    </content>
</entry>
```

This response is used to perform the following modifications:

1. Remove *MyTextComponent*.
2. Modify *MyRichTextElement*.
3. Add an element named *MyNewTextElement*.

```

How to use REST with authoring templates

You can use the Web Content Manager REST service to create, read, update, and delete content templates and site area templates. You can also set default values for items that are created by using these authoring templates.

CF06 "How to use REST with content templates"
You can use the Web Content Manager REST service to create, read, update, and delete content templates. You can also set default values for items that are created by using these content templates.

CF06 "How to use REST with site area templates" on page 3341
You can use the Web Content Manager REST service to create, read, update, and delete site area templates. You can also set default values for items that are created by using these site area templates.

How to use REST with content templates:

You can use the Web Content Manager REST service to create, read, update, and delete content templates. You can also set default values for items that are created by using these content templates.

Create

A content template can be created by sending a POST request to the following URI with an Atom entry that represents the content template:

`/ContentTemplate`

For example:

```
POST /wps/mycontenthandler/wcmrest/ContentTemplate
Content-Type : application/atom+xml

<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm/8.0">
    <title>SampleContentTemplateTitle</title>
    <wcm:name>SampleContentTemplateName</wcm:name>
    <summary xml:lang="en">SampleContentTemplateDescription</summary>
    <link rel="library" href="/wps/mycontenthandler/wcmrest/Library/91d0b849-7e9b-4053-a267-d4b84be29062" label="Library"/>
</entry>

HTTP/1.0 201 Created
Content-type: application/atom+xml; type=entry
Content-location: /wps/mycontenthandler/!ut/p/wcmrest/ContentTemplate/e15bb37f-6eba-42f4-8470-e54431b69fb3

<?xml version="1.0" encoding="UTF-8"?><entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm/8.0">

Update

A content template can be updated by sending a PUT request to the following URI with an Atom entry that includes the fields on the item that need to be changed.

`/ContentTemplate/item-uuid`

For example:

```
PUT /wps/mycontenthandler/wcmrest/ContentTemplate/d19db2ce-87dc-484f-937a-203139818fbd
Content-Type: application/atom+xml

<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="wcm/namespace">
    <title>SampleContentTemplateTitleUpdated</title>
    <link rel="library" href="/wps/mycontenthandler/!ut/p/wcmrest/Library/91d0b849-7e9b-4053-a267-d4b84be29062"/>
    <wcm:name>SampleContentTemplateNameUpdated</wcm:name>
    <summary xml:lang="en">SampleContentTemplateDescriptionUpdated</summary>
</entry>

HTTP/1.0 200 OK
Content-type: application/atom+xml; type=entry

Delete

A content template can be deleted by sending a DELETE request to the following URI:

`/ContentTemplate/item-uuid`

For example:

```
DELETE /wps/mycontenthandler/wcmrest/ContentTemplate/d19db2ce-87dc-484f-937a-203139818fbd

Response:
Status Code :200
Status Message : OK
```

CF06 "How to set default content values for content templates by using REST"
You can update and read default content values for content items that are created by using a content template.

CF06 "How to set default properties for content templates by using REST" on page 3340
You can update and read the default properties of content items that are created by using a content template.

How to set default content values for content templates by using REST:

You can update and read default content values for content items that are created by using a content template.

These values include:

- Elements
- Default workflow
- Presentation template override

Update

You can update the default content values of a content template by sending a PUT request to the following URI:

`/ContentTemplate/item-uuid/Prototype`

For example:

```
PUT /wps/mycontenthandler/wcmrest/ContentTemplate/d19db2ce-87dc-484f-937a-203139818fbd/Prototype
Content-Type: application/atom+xml

</entry>
```

How to set default properties for content templates by using REST:

You can update and read the default properties of content items that are created by using a content template.

These properties include:

- Default presentation template
- Selected locations
- Create content under new site area
- Single site area option
- Enable or disable workflow

Update

You can update the default properties of a content template by sending a PUT request to the following URI:

`/ContentTemplate/item-uuid/Prototype/properties`

For example:

```
PUT /wps/mycontenthandler/wcmrest/ContentTemplate/d19db2ce-87dc-484f-937a-203139818fbd/Prototype/properties
Content-Type: application/vnd.ibm.wcm+xml

<?xml version="1.0" encoding="UTF-8"?>
<content-properties xmlns="http://www.ibm.com/xmlns/wcm/8.0" xmlns:atom="http://www.w3.org/2005/Atom">
    <workflow-control>
        <option name="ENABLE_WORKFLOW" enabled="false"/>
        <option name="HIDE_WORKFLOW_SECTION" enabled="true"/>
    </workflow-control>
    <createNewParent>true</createNewParent>
    <placement>FIRST_CHILD</placement>
    <location-options allowedLocation="ALL_AVAILABLE" contentLink="NONE"/>
    <link rel="default-presentation" href="/wps/mycontenthandler/wcmrest/PresentationTemplate/37d77b82-c3fb-4ee8-ba88-3ce0a2c1443f" label="Default Presentation"/>
</content-properties>

HTTP/1.0 200 OK
Content-type: application/atom+xml

<?xml version="1.0" encoding="UTF-8"?>
<content-properties xmlns="http://www.ibm.com/xmlns/wcm/8.0" xmlns:atom="http://www.w3.org/2005/Atom">
    <workflow-control>
        <option name="ENABLE_WORKFLOW" enabled="false"/>
```

```
        <option name="HIDE_WORKFLOW_SECTION" enabled="true"/>
    </workflow-control>
    <link rel="default-presentation" href="/wps/mycontenthandler/!ut/p/wcmrest/PresentationTemplate/37d77b82-c3fb-4ee8-ba88-3ce0a2c1443f" type="application/vnd.ibm.wcm+xml" label="Default Presentation"/>
    <createNewParent>true</createNewParent>
    <placement>FIRST_CHILD</placement>
    <location-options allowedLocation="ALL_AVAILABLE" contentLink="NONE"/>
</content-properties>
```

Read

The default properties of a content template can be read by sending a GET request to the following URI:

`/ContentTemplate/item-uuid/Prototype/properties`

For example:

```
GET /wps/mycontenthandler/wcmrest/ContentTemplate/d19db2ce-87dc-484f-937a-203139818fbd/Prototype/properties

HTTP/1.0 200 OK
Content-type: application/vnd.ibm.wcm+xml

<?xml version="1.0" encoding="UTF-8"?>
<content-properties xmlns="http://www.ibm.com/xmlns/wcm/8.0" xmlns:atom="http://www.w3.org/2005/Atom">
    <workflow-control>
        <option name="ENABLE_WORKFLOW" enabled="true"/>
        <option name="HIDE_WORKFLOW_SECTION" enabled="false"/>
    </workflow-control>
    <createNewParent>false</createNewParent>
    <placement>LAST_CHILD</placement>
    <location-options allowedLocation="ALL_AVAILABLE" contentLink="NONE"/>
</content-properties>
```

Format of properties values

Workflow options:

```
<workflow-control>
        <option name="ENABLE_WORKFLOW" enabled="false"/>
        <option name="HIDE_WORKFLOW_SECTION" enabled="true"/>
</workflow-control>
```

Default presentation template:

```
<link rel="default-presentation"
href="/wps/mycontenthandler/wcmrest/PresentationTemplate/<item-uuid>"
label="Default Presentation"/>
```

Create content under a new site area:

```
<createNewParent>true</createNewParent>
```

Valid values: true, false.

Default placement of new item:

```
<placement>FIRST_CHILD</placement>
```

Valid values: FIRST_CHILD, LAST_CHILD.

Selected locations:

When all available locations are allowed:

```
<location-options allowedLocation="ALL_AVAILABLE" contentLink="NONE"/>
```

When only selected locations are allowed:

```
<location-options allowedLocation="SELECTED" contentLink="NONE">
            <location href="/wps/mycontenthandler/!ut/p/wcmrest/SiteArea/<item-uuid>"/>
            <location href="/wps/mycontenthandler/!ut/p/wcmrest/SiteArea/<item-uuid>"/>
</location-options>
```

Valid values for `allowedLocation`: ALL_AVAILABLE, SELECTED.

Valid values for `contentLink`: SINGLE, MULTIPLE, NONE.

How to use REST with site area templates:

You can use the Web Content Manager REST service to create, read, update, and delete site area templates. You can also set default values for items that are created by using these site area templates.

Create

A site area template can be created by sending a POST request to the following URI with an Atom entry that represents the site area template:

`/SiteAreaTemplate`

For example:

```
POST /wps/mycontenthandler/wcmrest/SiteAreaTemplate
Content-Type : application/atom+xml

<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm/8.0">
    <title>SampleSiteAreaTemplateTitle</title>
    <wcm:name>SampleSiteAreaTemplateName</wcm:name>
    <summary xml:lang="en">SampleSiteAreaTemplateDescription</summary>
    <link rel="library" href="/wps/mycontenthandler/wcmrest/Library/91d0b849-7e9b-4053-a267-d4b84be29062" label="Library"/>
</entry>

HTTP/1.0 201 Created
Content-type: application/atom+xml; type=entry
Content-location:/wps/mycontenthandler/!ut/p/wcmrest/SiteAreaTemplate/7f1055db-29ac-43ea-88b8-c6b23019b6b9

<?xml version="1.0" encoding="UTF-8"?>
<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm/8.0">
    <id>wcmrest:7f1055db-29ac-43ea-88b8-c6b23019b6b9</id>
    <title xml:lang="en">SampleSiteAreaTemplateTitle</title>
    <summary xml:lang="en">SampleSiteAreaTemplateDescription</summary>

Update

A site area template can be updated by sending a PUT request to the following URI with an Atom entry that includes the fields on the item that need to be changed.

`/SiteAreaTemplate/item-uuid`

For example:

```
PUT /wps/mycontenthandler/!ut/p/wcmrest/SiteAreaTemplate/7f1055db-29ac-43ea-88b8-c6b23019b6b9
Content-Type: application/atom+xml

<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="wcm/namespace">
    <title>SampleSiteAreaTemplateTitleUpdated</title>
    <link rel="library" href="/wps/mycontenthandler/!ut/p/wcmrest/Library/91d0b849-7e9b-4053-a267-d4b84be29062"/>
    <wcm:name>SampleSiteAreaTemplateNameUpdated</wcm:name>
    <summary xml:lang="en">SampleSiteAreaTemplateDescriptionUpdated</summary>
</entry>

HTTP/1.0 200 OK
Content-type: application/atom+xml; type=entry

<?xml version="1.0" encoding="UTF-8"?>
<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm/8.0">

</entry>
```

Delete

A site area template can be deleted by sending a DELETE request to the following URI:

`/SiteAreaTemplate/item-uuid`

For example:

```
DELETE /wps/mycontenthandler/wcmrest/SiteAreaTemplate/7f1055db-29ac-43ea-88b8-c6b23019b6b9

Response:
Status Code :200
Status Message : OK
```

CF06 “How to set default site area values for site area templates by using REST”
You can update and read default site area values for site areas that are created by using a site area template.

CF06 “How to set default properties for site area templates by using REST” on page 3345
You can update and read the default properties of site areas that are created by using a site area template.

How to set default site area values for site area templates by using REST:

You can update and read default site area values for site areas that are created by using a site area template.

These values include:

- Elements
- Setting workflow
- Child template mappings
- Rendering behavior
- Presentation override
- Child default content

Update

You can update the default site area values a of site area template by sending a PUT request to the following URI:

`/SiteAreaTemplate/item-uuid/Prototype`

For example:

```
PUT /wps/mycontenthandler/wcmrest/SiteAreaTemplate/7f1055db-29ac-43ea-88b8-c6b23019b6b9/Prototype
Content-Type: application/atom+xml

Read

The default site area values of a site area template can be read by sending a GET request to the following URI:

`/SiteAreaTemplate/item-uuid/Prototype`

For example:

```
GET /wps/mycontenthandler/wcmrest/SiteAreaTemplate/7f1055db-29ac-43ea-88b8-c6b23019b6b9/Prototype

HTTP/1.0 200 OK
Content-type: application/atom+xml; type=entry

<?xml version="1.0" encoding="UTF-8"?><entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm/8.0">
    <id>wcmrest:a2fd2e1d-d8da-44de-9ce3-17c8ab614208</id>
    <title/>

```

Dependencies of Presentation Override and Default Content on Rendering Behavior

The availability of the **Presentation Override** and **Default Content** fields depend on the value of rendering behavior field.

Table 487. Presentation Override and Default Content on Rendering Behavior

Rendering Behavior	Presentation Override	Default Content
RENDER_DEFAULT_CONTENT_AS_CHILD	No.	Yes.
REDIRECT_TO_DEFAULT_CONTENT	No.	Yes.
RENDER_SITE_AREA_DIRECTLY	Yes.	No.
RENDER_FIRST_CHILD_CONTENT	No.	No.
RENDER_FIRST_CHILD	No.	No.

How to set default properties for site area templates by using REST:

You can update and read the default properties of site areas that are created by using a site area template.

These properties include:

- Default presentation template
- Enable or disable workflow

Update

You can update the default properties of a site area template by sending a PUT request to the following URI:

`/SiteAreaTemplate/item-uuid/Prototype/properties`

For example:

```
PUT /wps/mycontenthandler/wcmrest/SiteAreaTemplate/7f1055db-29ac-43ea-88b8-c6b23019b6b9/Prototype/properties
Content-Type: application/vnd.ibm.wcm+xml

<?xml version="1.0" encoding="UTF-8"?>
<sitearea-properties xmlns="http://www.ibm.com/xmlns/wcm/8.0" xmlns:atom="http://www.w3.org/2005/Atom">
    <workflow-control>
        <option name="ENABLE_WORKFLOW" enabled="true"/>
        <option name="HIDE_WORKFLOW_SECTION" enabled="true"/>
    </workflow-control>
    <link rel="default-presentation" href="/wps/mycontenthandler/wcmrest/PresentationTemplate/37d77b82-c3fb-4ee8-ba88-3ce0a2c1443f"  label="Default Presentation"/>
</sitearea-properties>

HTTP/1.0 200 OK
Content-type: application/atom+xml

<?xml version="1.0" encoding="UTF-8"?>
<sitearea-properties xmlns="http://www.ibm.com/xmlns/wcm/8.0">
    <workflow-control>
        <option name="ENABLE_WORKFLOW" enabled="true"/>
        <option name="HIDE_WORKFLOW_SECTION" enabled="true"/>
    </workflow-control>
    <link rel="default-presentation" href="/wps/mycontenthandler/!ut/p/wcmrest/PresentationTemplate/37d77b82-c3fb-4ee8-ba88-3ce0a2c1443f" type="application/vnd.ibm.wcm+xml"  label="Default Presentation"/>
</sitearea-properties>
```

Read

The default properties of a site area template can be read by sending a GET request to the following URI:

`/SiteAreaTemplate/item-uuid/Prototype/properties`

For example:

```
GET /wps/mycontenthandler/wcmrest/SiteAreaTemplate/7f1055db-29ac-43ea-88b8-c6b23019b6b9/Prototype/properties

HTTP/1.0 200 OK
Content-type: application/vnd.ibm.wcm+xml

<?xml version="1.0" encoding="UTF-8"?>
<sitearea-properties xmlns="http://www.ibm.com/xmlns/wcm/8.0">
    <workflow-control>
        <option name="ENABLE_WORKFLOW" enabled="false"/>
        <option name="HIDE_WORKFLOW_SECTION" enabled="false"/>
    </workflow-control>
</sitearea-properties>
```

How to REST with presentation templates

You can use the Web Content Manager REST service to create, read, update, and delete presentation templates.

Create

A presentation template can be created by sending a POST request to the following URI with an Atom entry that represents the presentation template:

`/PresentationTemplate`

For example:

```
POST /wps/mycontenthandler/wcmrest/PresentationTemplate HTTP/1.0 POST
Content-Type : application/atom+xml

<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="wcm/namespace">
    <title>SamplePresentationTemplateTitle</title>
    <link rel="library" href="/wps/mycontenthandler/!ut/p/wcmrest/item/c98d11e1-7f2a-480e-9aac-40eb1949cbda"/>
    <wcm:name>SamplePresentationTemplateTitleName</wcm:name>
    <wcm:description>SamplePresentationTemplateDescription</wcm:description>
</entry>

HTTP/1.0 201 Created
Content-type: application/atom+xml; type=entry
Content-location: /wps/mycontenthandler/!ut/p/wcmrest/PresentationTemplate/02da6e9d-20ca-4c54-ae4a-f1114fa8e948

<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="wcm/namespace">
    <id>02da6e9d-20ca-4c54-ae4a-f1114fa8e948</id>
    <title>SamplePresentationTemplateTitle</title>
    <link rel="edit" href="/wps/mycontenthandler/!ut/p/wcmrest/PresentationTemplate/02da6e9d-20ca-4c54-ae4a-f1114fa8e948"/>
    <link rel="edit-media" type="text/html" href="/wps/mycontenthandler/!ut/p/wcmrest/PresentationTemplate/02da6e9d-20ca-4c54-ae4a-f1114fa8e948"/>
    <link rel="library" href="/wps/mycontenthandler/!ut/p/wcmrest/item/c98d11e1-7f2a-480e-9aac-40eb1949cbda"/>
    <link rel="create-draft" href="/wps/mycontenthandler/!ut/p/wcmrest/item/02da6e9d-20ca-4c54-ae4a-f1114fa8e948/create-draft"/>
    <link rel="change-to-draft" href="/wps/mycontenthandler/!ut/p/wcmrest/item/02da6e9d-20ca-4c54-ae4a-f1114fa8e948/change-to-draft"/>
    <link rel="versions" href="/wps/mycontenthandler/!ut/p/wcmrest/item/02da6e9d-20ca-4c54-ae4a-f1114fa8e948/versions"/>
    <link rel="add-attachment" href="/wps/mycontenthandler/!ut/p/wcmrest/PresentationTemplate/02da6e9d-20ca-4c54-ae4a-f1114fa8e948/attachments"/>
    <updated>2011-05-30T04:46:34.811Z</updated>
    <author>
        <wcm:distinguishedName>uid=wpsadmin,o=defaultWIMFileBasedRealm</wcm:distinguishedName>
        <uri>/wps/mycontenthandler/!ut/p/digest!6GVkh5Ul75Ln7DdEgvHm_g/um/users/profiles/Z9eAeH1C2JG561RC6JM47H9E4MMG6PHO6JM4C5JD0JMOC6BEEJS464JDG3I56K1</uri>

    </author>
    <wcm:owner>
        <wcm:distinguishedName>uid=wpsadmin,o=defaultWIMFileBasedRealm</wcm:distinguishedName>
        <uri>/wps/mycontenthandler/!ut/p/digest!6GVkh5Ul75Ln7DdEgvHm_g/um/users/profiles/Z9eAeH1C2JG561RC6JM47H9E4MMG6PHO6JM4C5JD0JMOC6BEEJS464JDG3I56K1</uri>
        <name>wpsadmin</name>
    </wcm:owner>
    <wcm:name>SamplePresentationTemplateTitleName</wcm:name>
    <wcm:description>SamplePresentationTemplateDescription</wcm:description>
    <wcm:type>PresentationTemplate</wcm:type>
    <wcm:state>PUBLISHED</wcm:state>
</entry>
```

Update

A presentation template can be updated by sending a PUT request to the following URI with an Atom entry that includes the fields on the item that need to be changed.

`/PresentationTemplate/<itemuuid>`

For example:

```
PUT /wps/mycontenthandler/wcmrest/PresentationTemplate/02da6e9d-20ca-4c54-ae4a-f1114fa8e948 HTTP/1.0
Content-Type: application/atom+xml

<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="wcm/namespace">
    <title>SamplePresentationTemplateTitleUpdated</title>
    <link rel="library" href="/wps/mycontenthandler/!ut/p/wcmrest/item/c98d11e1-7f2a-480e-9aac-40eb1949cbda"/>
    <wcm:name>SamplePresentationTemplateTitleNameUpdated</wcm:name>
    <wcm:description>SamplePresentationTemplateDescriptionUpdated</wcm:description>
</entry>

HTTP/1.0 200 OK
Content-type: application/atom+xml; type=entry

<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="wcm/namespace">

    <link rel="edit-media" type="text/html" href="/wps/mycontenthandler/!ut/p/wcmrest/PresentationTemplate/02da6e9d-20ca-4c54-ae4a-f1114fa8e948"/>
    <link rel="library" href="/wps/mycontenthandler/!ut/p/wcmrest/item/c98d11e1-7f2a-480e-9aac-40eb1949cbda"/>
    <link rel="create-draft" href="/wps/mycontenthandler/!ut/p/wcmrest/item/02da6e9d-20ca-4c54-ae4a-f1114fa8e948/create-draft"/>
    <link rel="change-to-draft" href="/wps/mycontenthandler/!ut/p/wcmrest/item/02da6e9d-20ca-4c54-ae4a-f1114fa8e948/change-to-draft"/>
    <link rel="versions" href="/wps/mycontenthandler/!ut/p/wcmrest/item/02da6e9d-20ca-4c54-ae4a-f1114fa8e948/versions"/>
    <link rel="add-attachment" href="/wps/mycontenthandler/!ut/p/wcmrest/PresentationTemplate/02da6e9d-20ca-4c54-ae4a-f1114fa8e948/attachments"/>
    <updated>2011-05-30T04:51:39.260Z</updated>
    <author>
        <wcm:distinguishedName>uid=wpsadmin,o=defaultWIMFileBasedRealm</wcm:distinguishedName>
        <uri>/wps/mycontenthandler/!ut/p/digest!6GVkh5Ul75Ln7DdEgvHm_g/um/users/profiles/Z9eAeH1C2JG561RC6JM47H9E4MMG6PHO6JM4C5JD0JMOC6BEEJS464JDG3I56K1</uri>
        <email></email>
        <name>wpsadmin</name>
    </author>
    <wcm:owner>
        <wcm:distinguishedName>uid=wpsadmin,o=defaultWIMFileBasedRealm</wcm:distinguishedName>
        <uri>/wps/mycontenthandler/!ut/p/digest!6GVkh5Ul75Ln7DdEgvHm_g/um/users/profiles/Z9eAeH1C2JG561RC6JM47H9E4MMG6PHO6JM4C5JD0JMOC6BEEJS464JDG3I56K1</uri>
        <email></email>
        <name>wpsadmin</name>
    </wcm:owner>
    <wcm:name>SamplePresentationTemplateTitleNameUpdated</wcm:name>
    <wcm:description>SamplePresentationTemplateDescriptionUpdated</wcm:description>
    <wcm:type>PresentationTemplate</wcm:type>
    <wcm:state>PUBLISHED</wcm:state>
</entry>
```

Delete

A presentation template can be deleted by sending a DELETE request to the following URI:

`/PresentationTemplate/<itemuuid>`

For example:

DELETE

```
HTTP/1.1 DELETE
http://host:port/wps/mycontenthandler/wcmrest/PresentationTemplate/<itemuuid>
```

Response:

```
Status Code :200
Status Message : OK
```

Specifying raw data

The content of a presentation template is accessed from the media resource that is specified in the HREF attribute of the edit-media link. The link also contains a TYPE attribute that contains the accepted media type for presentation templates, which is text/html. For example:

```
<link rel="edit-media" type="text/html"
href="/wps/mycontenthandler/!ut/p/wcmrest/PresentationTemplate/02da6e9d-20ca-4c54-ae4a-f1114fa8e948"/>
```

To update content of a presentation template PUT content of type text/html type to the edit-media URL. For example:

```
PUT /wps/mycontenthandler/!ut/p/wcmrest/PresentationTemplate/02da6e9d-20ca-4c54-ae4a-f1114fa8e948 HTTP/1.0
Content-type: text/html

<html>
    <body>
        [Component name="story"]
    </body>
</html>

HTTP/1.0 200 OK
```

To retrieve content from a library component GET content from the edit-media URL. For example:

```
GET  /wps/mycontenthandler/!ut/p/wcmrest/PresentationTemplate/02da6e9d-20ca-4c54-ae4a-f1114fa8e948 HTTP/1.0
Accept: text/html

HTTP/1.0 200 OK
Content-type: text/html

<html>

    </body>
</html>
```

How to use REST with content items

You can use the Web Content Manager REST service to create, read, update, and delete content items.

Create

A content item can be created by sending a POST request to the following URI with an Atom entry used to represent the content item:

`/Content`

- A library or parent link relation must be used to define the location of the hierarchical item that is being created.
- An authoring template must be specified to set what authoring template to use when the item is created.

For example:

POST

```
HTTP/1.1 POST
http://host:port/wps/mycontenthandler/wcmrest/Content/
Content-Type: application/atom+xml
  <atom:entry xmlns:atom="http://www.w3.org/2005/Atom" xmlns:wcm="wcm/namespace">
   <wcm:name>Content Name</wcm:name>
   <atom:title>Content Title</atom:title>
   <atom:link atom:rel="parent" atom:href="/wps/mycontenthandler/wcmrest/item/49f4ed95-a99f-434c-a415-77c341fa4893"/>
   <atom:link atom:rel="workflow" atom:href="/wps/mycontenthandler/wcmrest/item/abae799b-4cca-47ae-aad8-b3d8204deefb"/>
   <atom:link atom:rel="content-template" atom:href="/wps/mycontenthandler/wcmrest/item/588127d0-a4f8-44b5-87a4-5fe3f7bd3da7"/>
  </atom:entry>
```

Response:

```
201 Created
```

Create from a skeleton

A "skeleton" representation of a content item that is created from a content template can be obtained to aid in the creation of content items. This can be obtained by using a GET request to the following URI. When the skeleton is obtained and completed a POST request can be made by using this data to create the item.

`/ContentTemplate/`*`template-uuid`*`/new-content`

For example:

```
HTTP/1.1 GET http://host:port/wps/mycontenthandler/wcmrest/ContentTemplate/b7b8b3fb-8fa1-4eb3-915e-ce7514f7067f/new-content

Response
200 OK
```

```

        <name>wpsadmin</name>
    </wcm:owner>
    <link label="Library" rel="library" href="/wps/mycontenthandler/!ut/p/digest!PQo5Yhy68oeppWcEz2sddA/wcmrest/item/a423287f-b0ce-4ee3-9c95-aa0939382228" lang="en"/>
    <link label="Content Template" rel="content-template" href="/wps/mycontenthandler/!ut/p/digest!PQo5Yhy68oeppWcEz2sddA/wcmrest/Content/b7b8b3fb-8fa1-4eb3-915e-ce7514f7067f" lang="en"/>
    <content type="application/vnd.ibm.wcm+xml">
        <content xmlns="http://www.ibm.com/xmlns/wcm">
            <elements>
                <element name="Body">
                    <title lang="en">Body</title>
                    <type>RichTextComponent</type>
                    <data type="text/html"></data>
                </element>
            </elements>
        </content>
    </content>
</entry>
```

Update

A content item can be updated by sending a PUT request to the following URI with an Atom entry that specifies the fields on the item that need to be changed.

`/Content/`*`item-uuid`*

For example:

PUT

```
HTTP/1.1 PUT
http://host:port/wps/mycontenthandler/wcmrest/Content/abae799b-4cca-47ae-aad8-b3d8204deefb
Content-Type: application/atom+xml
<atom:entry xmlns:atom="http://www.w3.org/2005/Atom" xmlns:wcm="wcm/namespace">
    <wcm:name>Updated Content Name</wcm:name>
    <atom:title>Updated Content Title</atom:title>
</atom:entry>
```

Response:

200 OK

Read

A content item can be read by sending a GET request to the following URI:

`/Content/`*`item-uuid`*

For example:

GET

```
HTTP/1.1 GET
http://host:port/wps/mycontenthandler/wcmrest/Content/fa2bfd32-7b2f-4394-a5ab-2e150c5ed8aa

<atom:entry xmlns:atom="http://www.w3.org/2005/Atom" xmlns:wcm="wcm/namespace">
    <atom:id>fa2bfd32-7b2f-4394-a5ab-2e150c5ed8aa</atom:id>
    <wcm:name>content name145805586</wcm:name>
    <atom:title>content title145805586</atom:title>
    <wcm:type>Content</wcm:type>
    <atom:updated>2011-04-27T04:06:32.643Z</atom:updated>
    <atom:link atom:rel="edit" atom:href="/wps/mycontenthandler/wcmrest/Content/fa2bfd32-7b2f-4394-a5ab-2e150c5ed8aa"/>
    <atom:link atom:rel="library" atom:href="/wps/mycontenthandler/wcmrest/item/957a67f2-9d70-469f-9d43-f63f78508e48"/>
    <atom:link atom:rel="parent" atom:href="/wps/mycontenthandler/wcmrest/item/49f4ed95-a99f-434c-a415-77c341fa4893"/>
    <atom:link atom:rel="workflow-stage" atom:href="/wps/mycontenthandler/wcmrest/item/f659d3af-7d45-4fc0-ad37-86e407caf2b6"/>
    <atom:link atom:rel="workflow" atom:href="/wps/mycontenthandler/wcmrest/item/abae799b-4cca-47ae-aad8-b3d8204deefb"/>
    <atom:link atom:rel="versions" atom:href="/wps/mycontenthandler/wcmrest/item/fa2bfd32-7b2f-4394-a5ab-2e150c5ed8aa/versions"/>
    <atom:link atom:rel="content-template" atom:href="/wps/mycontenthandler/wcmrest/item/588127d0-a4f8-44b5-87a4-5fe3f7bd3da7"/>
    <atom:link atom:rel="elements" atom:href="/wps/mycontenthandler/wcmrest/Content/fa2bfd32-7b2f-4394-a5ab-2e150c5ed8aa/elements"/>
</atom:entry>
```

Response:

200 OK

Delete

A content item can be deleted by sending a DELETE request to the following URI:
`/Content/item-uuid`

For example:

DELETE

```
HTTP/1.1 DELETE
http://host:port/wps/mycontenthandler/wcmrest/Content/fa2bfd32-7b2f-4394-a5ab-2e150c5ed8aa/
```

Response:

```
200 OK
```

How to use REST with site areas

You can use the Web Content Manager REST service to create, read, update, and delete site areas.

Create

A site area can be created by sending a POST request to the following URI with an Atom entry that represents the site area:
`/SiteArea`

- A library or parent link relation must be specified. This tells the REST service the location of the hierarchical item being created.
- An authoring template must be specified. This tells the REST service what authoring template to use when creating the item.
- Template mappings can also be specified.

For example:

```
POST /wps/mycontenthandler/wcmrest/SiteArea HTTP/1.0
Content-type : application/atom+xml

<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="wcm/namespace">
    <title>SampleSiteAreaTitle</title>
    <link rel="parent" href="/wps/mycontenthandler/!ut/p/wcmrest/item/ae6a3632-a1b5-456a-866e-e9baab84fe29"/>
    <wcm:name>SampleSiteAreaName</wcm:name>
    <wcm:description>SampleSiteAreaDescription</wcm:description>
</entry>

HTTP/1.0 201 Created
Content-type : application/atom+xml; type=entry
Content-location: /wps/mycontenthandler/!ut/p/wcmrest/SiteArea/18001a8c-2117-45d2-be1c-baea28a41769

<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="wcm/namespace">

        <name>wpsadmin</name>
    </wcm:owner>
    <link label="Sitearea Template" rel="sitearea-template" href="/wps/mycontenthandler/!ut/p/digest!PQo5Yhy68oeppWcEz2sddA/wcmrest/SiteArea/72456e6a-198c-47f3-8611-659b0ec6624c" lang="en"/>
    <content type="application/vnd.ibm.wcm+xml">
        <siteArea xmlns="http://www.ibm.com/xmlns/wcm">
            <elements>
                <element name="summary">
                    <title lang="en-US">Summary</title>
                    <type>TextComponent</type>
                    <data type="text/plain"><![CDATA[Text inside the element]]&gt;</data>
                </element>
                <element name="body">
                    <title lang="en-US">Body</title>
                    <type>HTMLComponent</type>
                    <data type="text/html"><![CDATA[<p>
Lorem ipsum dolor sit amet, consectetuer adipiscing elit.
]]&gt;</data>
                </element>
            </elements>
        </siteArea>
    </content>
</entry>
```

Update

A site area can be updated by sending a PUT request to the following URI with an Atom entry that includes the fields on the item that need to be changed.

`/SiteArea/`*`item-uuid`*

For example:

```
PUT /wps/mycontenthandler/wcmrest/SiteArea/18001a8c-2117-45d2-be1c-baea28a41769 HTTP/1.0
Content-Type : application/atom+xml

<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="wcm/namespace">
    <title>SampleSiteAreaTitleUpdated</title>
    <wcm:name>SampleSiteAreaNameUpdated</wcm:name>
    <wcm:description>SampleSiteAreaDescriptionUpdated</wcm:description>
</entry>

HTTP/1.0 200 OK
Content-type: application/atom+xml; type=entry

<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="wcm/namespace">
    <id>18001a8c-2117-45d2-be1c-baea28a41769</id>

    <wcm:description>SampleSiteAreaDescriptionUpdated</wcm:description>
    <wcm:type>SiteArea</wcm:type>
    <wcm:state>PUBLISHED</wcm:state>
</entry>
```

Delete

A site area can be deleted by sending a DELETE request to the following URI: /SiteArea/*item-uuid*

For example:

```
DELETE /wps/mycontenthandler/wcmrest/SiteArea/18001a8c-2117-45d2-be1c-baea28a41769 HTTP/1.0

HTTP/1.0 200 OK
```

How to use REST with managed pages

You can use the Web Content Manager REST service to read managed pages.

Read

A managed page can be read by sending a GET request to the following URI: /PortalPage/<itemuuid>

For example:

```
GET /wps/mycontenthandler/wcmrest/PortalPage/6c523449-e919-41a8-a8d0-f8b1ea207af1 HTTP/1.0
HTTP/1.0 200 OK
Content-type: application/atom+xml; type=entry
<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="wcm/namespace">
    <atom:id>wcmrest:6c523449-e919-41a8-a8d0-f8b1ea207af1</atom:id>
    <atom:title>RestPortalPage1</atom:title>
   <atom:link atom:rel="edit" atom:href="/wps/mycontenthandler/!ut/p/wcmrest/PortalPage/6c523449-e919-41a8-a8d0-f8b1ea207af1"/>
    <atom:link atom:rel="library" atom:href="/wps/mycontenthandler/!ut/p/wcmrest/item/d07f0a12-3801-465e-bc20-eaec2cecf5cb"/>

        <atom:name>wpsadmin</atom:name>
    </atom:owner>
</atom:entry>
```

How to use REST with drafts and workflows

You can use the REST services for Web Content Manager to create drafts, approve items in a workflow, and move items through different stages of a workflow.

Creating a draft of an item that does not use a workflow

You can create a draft of items that do not use workflows.

To do that, specify explicitly the draft workflow state in the request entry data. For example, to create a link component as draft:

```
HTTP/1.1 POST

http://host:port/wps/mycontenthandler/wcmrest/LibraryLinkComponent
<atom:entry xmlns:atom="http://www.w3.org/2005/Atom" xmlns:wcm="wcm/namespace">
    <wcm:name>linkDraft_E</wcm:name>
    <atom:link atom:rel="library" atom:href="/wps/mycontenthandler/!ut/p/wcmrest/item/d07f0a12-3801-465e-bc20-eaec2cecf5cb"/>
    <category label="Draft" scheme="wcmrest:workflowState" term="DRAFT"/>
</atom:entry>

201 Created
```

Creating a draft in a workflow

You can use the REST service to create a new draft item. This is equivalent to using the **Create Draft** button in the authoring portlet.

A new draft of an item can be created by sending a POST request to the following URI:

`/item/`*`item-uuid`*`/create-draft`

For example:

```
HTTP/1.1 POST
http://host:port/wps/mycontenthandler/wcmrest/item/item-uuid/create-draft

201 Created
```

Moving an item to the next stage

You can use the REST service to move an item to the next stage of a workflow. This is equivalent to using the **Next Stage** button in the authoring portlet.

An item can be moved to the next stage by sending a POST request to the following URI:

`/item/`*`item-uuid`*`/next-stage`

For example:

```
HTTP/1.1 POST
http://host:port/wps/mycontenthandler/wcmrest/item/<item-uuid>/next-stage

201 Created
```

Moving an item to the previous stage

You can use the REST service to move an item to the previous stage of a workflow. This is equivalent to using the **Previous Stage** button in the authoring portlet.

An item can be moved to the previous stage by sending a POST request to the following URI:

`/item/item-uuid/previous-stage`

For example:

```
HTTP/1.1 POST
http://host:port/wps/mycontenthandler/wcmrest/item/item-uuid/previous-stage

201 Created
```

Approving an item within a workflow

You can use the REST service to move an item to the next stage of a workflow by approving it. This is equivalent to using the **Approve** button in the authoring portlet.

An item can be approved by sending a POST request to the following URI:

`/item/item-uuid/approve`

For example:

```
HTTP/1.1 POST
http://host:port/wps/mycontenthandler/wcmrest/item/item-uuid/approve

201 Created
```

Rejecting an item within a workflow

You can use the REST service to reject an item in a workflow. This is equivalent to using the **Reject** button in the authoring portlet.

An item can be rejected by sending a POST request to the following URI:

`/item/item-uuid/reject`

For example:

```
HTTP/1.1 POST
http://host:port/wps/mycontenthandler/wcmrest/item/item-uuid/reject

201 Created
```

Restarting a workflow

You can use the REST service to restart a workflow. This is equivalent to using the **Restart** button in the authoring portlet.

An item can be restarted by sending a POST request to the following URI:

`/item/item-uuid/restart`

For example:

```
HTTP/1.1 POST
http://host:port/wps/mycontenthandler/wcmrest/item/item-uuid/restart

201 Created
```

Workflow Comments

To ensure that comments are added to workflow stages that require comments, a GET request must be issued to the associated link. This will return an HTML form indicating whether a comment is required.

To add the comment you either submit the form, or perform an HTTP Post request with a content type of `text/plain`. For example:

```
HTTP GET /wps/mycontenthandler/wcmrest/item/84e35979-d7c4-429a-b2ab-eb79abc5debc/next-stage
 Accept: text/html

 <html>
<b>Next Stage</b><br><br>
<form action="/wps/mycontenthandler/!ut/p/digest!hp5aUN2TU2D-7ziKYRo2-g/wcmrest/item/84e35979-d7c4
   <label for="comment"><b>*</b>Enter Comment</label>
   <input id="comment" name="comment" type="text" required/><br>
   <input type="submit" value="Submit"></input>
</form>
</html>
```

How to use REST with workflow items

You can use the Web Content Manager REST service to create, read, update, and delete workflow items.

Create

A workflow item can be created by sending a POST request to the following URI with an Atom entry that represents the workflow item:

`/Workflow`

Note: A library link is required to specify the location to create the workflow.

For example:

```
HTTP/1.1 POST /wps/mycontenthandler/wcmrest/Workflow
Content-Type: application/atom+xml

<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm/8.0">
    <wcm:name>MyWorkflow</wcm:name>
    <link rel="library" href="/wps/mycontenthandler/wcmrest/Library/be3ca1cd-f482-4715-9972-8e683fd0be85"/>
    <content type="application/vnd.ibm.wcm+xml">
        <wcm:workflow xmlns="http://www.ibm.com/xmlns/wcm/8.0" xmlns:atom="http://www.w3.org/2005/Atom">

        <draftCreation>ALLOW_EXCLUSIVE_DRAFTS_ONLY</draftCreation>
    </wcm:workflow>
</content>
</entry>
```

Update

A workflow item can be updated by sending a PUT request to the following URI with an Atom entry that includes the fields on the item that need to be changed.

`/Workflow/itemuuid`

For example:

```
HTTP/1.1 PUT /wps/mycontenthandler/wcmrest/Workflow/b9c05b29-66ac-48fa-9ed7-43e3912f3c54
Content-Type: application/atom+xml

<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm/8.0">
    <wcm:name>MyWorkflow With A New Name</wcm:name>
    ... some content elided ...
    <content type="application/vnd.ibm.wcm+xml">
        <wcm:workflow xmlns="http://www.ibm.com/xmlns/wcm/8.0" xmlns:atom="http://www.w3.org/2005/Atom">
            <stages>
                <stage href="/wps/mycontenthandler/wcmrest/WorkflowStage/9fdaec77-e342-43a1-beb7-1c7ab21ee35f"/>
                <stage href="/wps/mycontenthandler/wcmrest/WorkflowStage/8eba94a5-dda2-46c4-a9f9-bba5ebac05a2"/>
                <stage href="/wps/mycontenthandler/wcmrest/WorkflowStage/9fbbe443-63f5-49ad-905d-aa54102f377a"/>
            </stages>
            <draftCreation>ALLOW_MULTIPLE_DRAFTS</draftCreation>
        </wcm:workflow>
    </content>
</entry>

HTTP/1.1 200 OK
Content-Type: application/atom+xml

<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm/8.0">
    <wcm:name>MyWorkflow With A New Name</wcm:name>
    ... some content elided ...
    <content type="application/vnd.ibm.wcm+xml">

```

Delete

A workflow item can be deleted by sending a DELETE request to the following URI:

```
/Workflow/itemuuid
```

For example:

```
HTTP/1.1 DELETE /wps/mycontenthandler/wcmrest/Workflow/b9c05b29-66ac-48fa-9ed7-43e3912f3c54

HTTP/1.1 200 OK
```

How to use REST with workflow stages

You can use the Web Content Manager REST service to create, read, update, and delete workflow stages.

Create

A workflow stage is created by sending a POST request to the following URI with an Atom entry that represents the workflow item:

```
/WorkflowStage
```

For example:

```
HTTP/1.1 POST /wps/mycontenthandler/wcmrest/WorkflowStage
Content-Type: application/atom+xml

<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm/8.0">
    <wcm:name>WorkflowStage Create With Access Control Test</wcm:name>
    <link rel="library" href="/wps/mycontenthandler/!ut/p/digest!_Nw2dNJ9qG0BrJuC97Bijw/wcmrest/Library/3e22085a-2ebb-423d-89c2-53d3c4aa593f"/>
    <content type="application/vnd.ibm.wcm+xml">

```

Update

A workflow stage is updated by sending a PUT request to the following URI with an Atom entry that includes the fields on the item that need to be changed.

`/WorkflowStage/workflow-stage-id`

For example:

```
HTTP/1.1 PUT /wps/mycontenthandler/wcmrest/WorkflowStage/141793eb-afa7-428e-bb7b-070a25ee3d7c
Content-Type: application/atom+xml

<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm/8.0">
    ... some content elided ...
    <content type="application/vnd.ibm.wcm+xml">
        <wcm:workflowStage xmlns="http://www.ibm.com/xmlns/wcm/8.0" xmlns:atom="http://www.w3.org/2005/Atom">
            <option name="ENABLE_PREVIOUS_STAGE_FOR_REVIEWERS" enabled="false"/>
            <option name="REQUIRE_COMMENT_ON_APPROVAL" enabled="false"/>
            <actions>
                <entering href="/wps/mycontenthandler/wcmrest/item/a9198c77-b5fa-4205-aa1a-e12d4a7ad832"/>
            </actions>
            <jointApproval enabled="false"/>
            <workflowDefinedAccess>
                <role name="User" inheritance="true" propagation="true"/>
                <role name="PrivilegedUser" inheritance="true" propagation="true"/>
                <role name="MarkupEditor" inheritance="true" propagation="true"/>
                <role name="Reviewer" inheritance="true" propagation="true"/>
                <role name="DraftCreator" inheritance="true" propagation="true"/>
                <role name="Contributor" inheritance="true" propagation="true"/>
                <role name="Editor" inheritance="true" propagation="true"/>
                <role name="Manager" inheritance="true" propagation="true"/>
                <role name="SecurityAdmin" inheritance="true" propagation="true"/>
                <role name="Admin" inheritance="true" propagation="true"/>

```

Delete

A workflow item can be deleted by sending a DELETE request to the following URI:

```
/WorkflowStage/workflow-stage-id
```

For example:

```
HTTP/1.1 DELETE /wps/mycontenthandler/wcmrest/WorkflowStage/b9c05b29-66ac-48fa-9ed7-43e3912f3c54

HTTP/1.1 200 OK
```

How to use REST with workflow actions

You can use the Web Content Manager REST service to create, read, update, and delete all workflow action types.

"How to use REST with workflow publish, expire, or version actions" on page 3360
The properties of publish actions, expire actions and version actions are identical. Only the URI used to run the actions are different.

"How to use REST with scheduled move workflow actions" on page 3362
You can use the Web Content Manager REST service to create, read, update, and delete scheduled move workflow actions.

"How to use REST with email workflow actions" on page 3364
You can use the Web Content Manager REST service to create, read, update, and delete email workflow actions.

"How to use REST with custom workflow actions" on page 3366
You can use the Web Content Manager REST service to create, read, update, and delete custom workflow actions.

How to use REST with workflow publish, expire, or version actions:

The properties of publish actions, expire actions and version actions are identical. Only the URI used to run the actions are different.

Create

A publish action can be created by sending a POST request to the following URI with an Atom entry that represents the action:

`/PublishAction`

An expire action can be created by sending a POST request to the following URI with an Atom entry that represents the action:

`/ExpireAction`

A version action can be created by sending a POST request to the following URI with an Atom entry that represents the action:

`/VersionAction`

In this example, the type `PublishAction` can be replaced with `ExpireAction` or `VersionAction` when needed.

```
HTTP/1.1 POST /wps/mycontenthandler/wcmrest/PublishAction
Content-Type: application/atom+xml

<?xml version="1.0" encoding="UTF-8"?>
<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm/8.0">
    <title>My Publish Action</title>
    <summary>This action publishes content to the live site</summary>
    <wcm:name>My Publish Action</wcm:name>
    <link rel="library" href="/wps/mycontenthandler/!ut/p/digest!muAe8T8GIzS4EJeiF9a_sw/wcmrest/Library/03da7ddc-1bc9-47cd-ab69-b06f23a3f284" />
</entry>

HTTP/1.1 201 Created
Content-Type: application/atom+xml
Content-Location: /wps/mycontenthandler/wcmrest/PublishAction/9c1d8e5b-0e0d-467b-8f1d-58ed550f4236

<?xml version="1.0" encoding="UTF-8"?>

```

Update

A publish action can be updated by sending a PUT request to the following URI with an Atom entry that includes the fields on the item that need to be changed.

`/PublishAction/action-id`

An expire action can be updated by sending a PUT request to the following URI with an Atom entry that includes the fields on the item that need to be changed.

/ExpireAction/action-id

A version action can be updated by sending a PUT request to the following URI with an Atom entry that includes the fields on the item that need to be changed.
/VersionAction/action-id

In this example, the type PublishAction can be replaced with ExpireAction or VersionAction when needed.

```

```

Delete

A publish action can be deleted by sending a DELETE request to the following URI:

`/PublishAction/action-id`

A expire action can be deleted by sending a DELETE request to the following URI:

`/ExpireAction/action-id`

A version action can be deleted by sending a DELETE request to the following URI:

`/VersionAction/action-id`

In this example, the type `PublishAction` can be replaced with `ExpireAction` or `VersionAction` when needed.

```
HTTP/1.1 DELETE /wps/mycontenthandler/wcmrest/PublishAction/7b40f5b6-bf52-4b9e-8062-b0755aaf1f80

HTTP/1.1 200 OK
```

How to use REST with scheduled move workflow actions:

You can use the Web Content Manager REST service to create, read, update, and delete scheduled move workflow actions.

Create

A scheduled move action can be created by sending a POST request to the following URI with an Atom entry that represents the action:

`/ScheduledMoveAction`

For example:

```
HTTP/1.1 POST /wps/mycontenthandler/wcmrest/ScheduledMoveAction
Content-Type: application/atom+xml

<?xml version="1.0" encoding="UTF-8"?>
<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm/8.0">
    <wcm:name>My Scheduled Move Action</wcm:name>
    <content type="application/vnd.ibm.wcm+xml">
        <wcm:scheduledMoveAction xmlns="http://www.ibm.com/xmlns/wcm/8.0">
            <dateType>LIVE_DATE</type>
            <offset unit="DAY" amount="3" direction="AFTER">
                <time-of-day>15:42:12</time-of-day>
            </offset>
        </wcm:scheduledMoveAction>
    </content>
</entry>

HTTP/1.1 201 Created

<?xml version="1.0" encoding="UTF-8"?>
<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm/8.0">
    <wcm:name>My Scheduled Move Action</wcm:name>
    ... some content elided ...
    <link rel="library" href="/wps/mycontenthandler/wcmrest/Library/624ca7c0-86ac-4e17-9167-25004c84aeca" xml:lang="en" label="Library"/>
    <content type="application/vnd.ibm.wcm+xml">
        <wcm:scheduledMoveAction xmlns="http://www.ibm.com/xmlns/wcm/8.0">
            <dateType>LIVE_DATE</type>
            <offset unit="DAY" amount="3" direction="AFTER">
                <time-of-day>15:42:12</time-of-day>
            </offset>
        </wcm:scheduledMoveAction>
    </content>
</entry>
```

Update

A scheduled move action can be updated by sending a PUT request to the following URI:

`/ScheduledMoveAction/action-id`

For example:

```
HTTP/1.1 PUT /wps/mycontenthandler/wcmrest/ScheduledMoveAction/abc4c24a-3540-4ae3-8ba6-f2f82a977046
Content-Type: application/atom+xml

<?xml version="1.0" encoding="UTF-8"?>
<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm/8.0">
    ... some content elided ...
    <content type="application/vnd.ibm.wcm+xml">
        <wcm:scheduledMoveAction xmlns="http://www.ibm.com/xmlns/wcm/8.0">
            <dateType>LIVE_DATE</type>
            <offset unit="HOUR" amount="1" direction="BEFORE">
                <time-of-day>15:42:12</time-of-day>
            </offset>
        </wcm:scheduledMoveAction>
    </content>
</entry>

HTTP/1.1 200 OK
```

Read

A scheduled move action can be read by sending a GET request to the following URI:

`/ScheduledMoveAction/action-id`

For example:

```
HTTP/1.1 GET /wps/mycontenthandler/wcmrest/ScheduledMoveAction/abc4c24a-3540-4ae3-8ba6-f2f82a977046
Accept: application/atom+xml

HTTP/1.1 200 OK

<?xml version="1.0" encoding="UTF-8"?>
<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm/8.0">
    <id>wcmrest:abc4c24a-3540-4ae3-8ba6-f2f82a977046</id>
    <title xml:lang="en">My Scheduled Move Action</title>

    <link rel="access-control" href="/wps/mycontenthandler/ac/access:oid:Z6QReDelJO66QCC1D2MMC6L1D0JMG61BP6JM072BOCJMOCIHPG3P4CPPDE3OG6M1" xml:lang="en" label="Access Control"/>
    <link rel="library" href="/wps/mycontenthandler/wcmrest/Library/624ca7c0-86ac-4e17-9167-25004c84aeca" xml:lang="en" label="Library"/>
    <link rel="versions" href="/wps/mycontenthandler/wcmrest/item/abc4c24a-3540-4ae3-8ba6-f2f82a977046/versions" xml:lang="en" label="Versions"/>
    <link rel="edit-media" href="/wps/mycontenthandler/wcmrest/ScheduledMoveAction/abc4c24a-3540-4ae3-8ba6-f2f82a977046" type="application/vnd.ibm.wcm+xml" xml:lang="en" label="Edit Media"/>
    <category scheme="wcmrest:workflowState" term="PUBLISHED" label="Published" xml:lang="en"/>
    <category scheme="wcmrest:favorite" term="false" xml:lang="en"/>
    <content type="application/vnd.ibm.wcm+xml">
        <wcm:scheduledMoveAction xmlns="http://www.ibm.com/xmlns/wcm/8.0">
            <dateType>LIVE_DATE</type>
            <offset unit="DAY" amount="3" direction="AFTER">
                <time-of-day>15:42:12</time-of-day>
            </offset>
        </wcm:scheduledMoveAction>
    </content>
</entry>
```

Delete

A scheduled move action can be deleted by sending a DELETE request to the following URI:

`/ScheduledMoveAction/action-id`

For example:

```
HTTP/1.1 DELETE /wps/mycontenthandler/wcmrest/ScheduledMoveAction/abc4c24a-3540-4ae3-8ba6-f2f82a9770
```

```
HTTP/1.1 200 OK
```

How to use REST with email workflow actions:

You can use the Web Content Manager REST service to create, read, update, and delete email workflow actions.

Create

An email action can be created by sending a POST request to the following URI:
`/EmailAction`

For example:

```
HTTP/1.1 POST /wps/mycontenthandler/wcmrest/EmailAction
Content-Type: application/atom+xml

<?xml version="1.0" encoding="UTF-8"?>
<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm/8.0">
    <wcm:name>My Email Action</wcm:name>
    <link rel="library" href="/wps/mycontenthandler/wcmrest/Library/1f5955c8-38e7-41f9-9029-5c4c0b151976" xml:lang="en" label="Library"/>
    <content type="application/vnd.ibm.wcm+xml">
        <wcm:emailAction xmlns="http://www.ibm.com/xmlns/wcm/8.0" xmlns:atom="http://www.w3.org/2005/Atom">
            <dateType>GENERAL_DATE_ONE</dateType>
            <offset unit="MONTH" amount="1" direction="AFTER">
                <time-of-day>11:53:00</time-of-day>
            </offset>
            <recipients>
                <stageApprovers>true</stageApprovers>
                <authors of-item="true" of-referencing-items="true"/>
                <owners of-item="true" of-referencing-items="true"/>
                <additional>
                    <distinguishedName>uid=WCMUT_Editor_A,o=defaultWIMFileBasedRealm</distinguishedName>
                    <atom:name>uid=WCMUT_Editor_A,o=defaultWIMFileBasedRealm</atom:name>
                </additional>
            </recipients>
            <emailText>this is some email text</emailText>
        </wcm:emailAction>
    </content>
</entry>

HTTP/1.1 201 Created

<?xml version="1.0" encoding="UTF-8"?>
<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm/8.0">
    ... some content elided ...
    <wcm:name>My Email Action</wcm:name>
    ... some content elided ...
    <content type="application/vnd.ibm.wcm+xml">
        <wcm:emailAction xmlns="http://www.ibm.com/xmlns/wcm/8.0" xmlns:atom="http://www.w3.org/2005/Atom">
            <dateType>GENERAL_DATE_ONE</dateType>
            <offset unit="MONTH" amount="1" direction="AFTER">
                <time-of-day>11:53:00</time-of-day>
            </offset>
            <recipients>

                    <atom:name>WCMUT_Editor_A WCMUT_Editor_A</atom:name>
                </additional>
            </recipients>
            <emailText>this is some email text</emailText>
        </wcm:emailAction>
    </content>
</entry>
```

Update

An email action can be updated by sending a PUT request to the following URI:
`/EmailAction/action-id`

For example:

```
HTTP/1.1 PUT /wps/mycontenthandler/wcmrest/EmailAction/abc4c24a-3540-4ae3-8ba6-f2f82a977046
Content-Type: application/atom+xml

<?xml version="1.0" encoding="UTF-8"?>
<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm/8.0">
    ... some content elided ...
    <content type="application/vnd.ibm.wcm+xml">
        <wcm:emailAction xmlns="http://www.ibm.com/xmlns/wcm/8.0" xmlns:atom="http://www.w3.org/2005/Atom">
            <dateType>DATE_ENTERED</dateType>
            <recipients>
                <stageApprovers>false</stageApprovers>
                <authors of-item="false" of-referencing-items="false"/>
                <owners of-item="false" of-referencing-items="false"/>
                <additional>
                    <distinguishedName>uid=WCMUT_Contributor_A,o=defaultWIMFileBasedRealm</distinguishedName>
                    <atom:uri>/wps/mycontenthandler/um/users/profiles/Z9eAeJHPGJP86M9EAMMG6K9PAMMG62RDGJM4C1JP0JM06IHP4JPK61RDCMIP6K1</atom:uri>

        </wcm:emailAction>
    </content>
</entry>
```

Delete

An email action can be deleted by sending a DELETE request to the following URI: `/EmailAction/action-id`

For example:

```
HTTP/1.1 DELETE /wps/mycontenthandler/wcmrest/ScheduledMoveAction/abc4c24a-3540-4ae3-8ba6-f2f82a97

HTTP/1.1 200 OK
```

How to use REST with custom workflow actions:

You can use the Web Content Manager REST service to create, read, update, and delete custom workflow actions.

Locating Installed Actions

To create a custom workflow action, you need to first identify the installed action that is run by that workflow action. There are two ways to do locate installed actions.

1. List all the installed custom workflow actions by sending a GET request to the following URI:

   Note: Each entry has a link with the "alternate" relation. This link can be used to specify the action to use when you create a custom workflow action.

   `/CustomWorkflowAction/available-actions`

   For example:

```
HTTP/1.1 GET /wps/mycontenthandler/wcmrest/CustomWorkflowAction/available-actions

HTTP 200 OK

<?xml version="1.0" encoding="UTF-8"?>
<feed xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm/8.0">
    <id>wcmrest:CustomWorkflowAction/available-actions</id>
    <title xml:lang="en">All Custom Workflow Actions</title>
    <updated>2014-06-26T01:17:46.022Z</updated>
    <entry>

    <entry>
        <title xml:lang="en">ML Next Stage</title>
        <summary xml:lang="en">Used to move a document to the next stage in the workflow</summary>
        <wcm:name>com.ibm.workplace.wcm.ml.workflowactions.NextStageWorkflowAction</wcm:name>
        <link rel="alternate" href="/wps/mycontenthandler/wcmrest/CustomWorkflowActionFactory/MLCustomWorkflowActionFactory/actions/com.ibm.workplace.wcm.ml.workflowactions.NextStageWorkflowAction" label="Read"/>
    </entry>
</feed>
```

2. List all the installed custom workflow action factories, and in turn the custom actions that are handled by that factory.

   The list of available custom workflow action factories can be obtained by sending a GET request to the following URI. Each entry in the returned feed provides a description of the factory, and a link to all the custom actions associated with that factory that uses the "actions" link relation.

   `/CustomWorkflowActionFactory`

For example:

```
HTTP/1.1 GET /wps/mycontenthandler/wcmrest/CustomWorkflowActionFactory

HTTP 200 OK

<?xml version="1.0" encoding="UTF-8"?>
<feed xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm/8.0">
    <id>wcmrest:CustomWorkflowActionFactory</id>
    <title xml:lang="en">Custom Workflow Action Factories</title>
    <updated>2014-06-26T01:26:38.340Z</updated>
    <entry>
        <id>wcmrest:MLCustomWorkflowActionFactory</id>
        <title xml:lang="en">ML Custom Workflow Action Factory</title>
        <wcm:name>MLCustomWorkflowActionFactory</wcm:name>
        <link rel="actions" href="/wps/mycontenthandler/wcmrest/CustomWorkflowActionFactory/MLCustomWorkflowActionFactory/actions"/>
        <content/>
    </entry>
</feed>
```

The list of actions that are associated with a custom workflow action factory are obtained by sending a GET request to the following URI.

Note: Each entry has a link with the "alternate" relation. This link is used to specify the action when you create a custom workflow action.

`/CustomWorkflowActionFactory/name-of-the-factory/actions`

For example:

```
HTTP/1.1 GET /wps/mycontenthandler/wcmrest/CustomWorkflowActionFactory/MLCustomWorkflowActionFactory/actions

HTTP 200 OK

<?xml version="1.0" encoding="UTF-8"?>
<feed xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm/8.0">
    <id>wcmrest:CustomWorkflowActionFactory/MLCustomWorkflowActionFactory/actions</id>
    <title xml:lang="en">ML Custom Workflow Action Factory</title>
    <updated>2014-06-26T01:30:16.491Z</updated>
    <entry>
        <title xml:lang="en">ML Localize</title>
        <summary xml:lang="en">
           Notifies the base locale owner of changes to localized copies and performs
           automatic localization of modified base locale documents
        </summary>
        <wcm:name>com.ibm.workplace.wcm.ml.workflowactions.LocalizeMLCustomWorkflowAction</wcm:name>
        <link rel="alternate" href="/wps/mycontenthandler/wcmrest/CustomWorkflowActionFactory/MLCustomWorkflowActionFactory/actions/com.ibm.workplace.wcm.ml.workflowactions.LocalizeMLCustomWorkflowAction" label="Read"/>
    </entry>
    ... some entries omitted ...
</feed>
```

Create

Custom workflow actions can be created by sending a POST request to the following URI:

`/CustomWorkflowAction`

For example:

```
HTTP/1.1 POST /wps/mycontenthandler/wcmrest/CustomWorkflowAction

<?xml version="1.0" encoding="UTF-8"?>
<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm/8.0">
    <title>MLS Next Stage Workflow Action</title>
    <wcm:name>MLS Next Stage Workflow Action</wcm:name>
    <link rel="library" href="/wps/mycontenthandler/!ut/p/digest!muAe8T8GIzS4EJeiF9a_sw/wcmrest/Library/03da7ddc-1bc9-47cd-ab69-b06f23a3f284" />
    <content type="application/vnd.ibm.wcm+xml">
        <wcm:customAction xmlns="http://www.ibm.com/xmlns/wcm/8.0">
            <action href="/wps/mycontenthandler/wcmrest/CustomWorkflowActionFactory/MLCustomWorkflowActionFactory/actions/com.ibm.workplace.wcm.ml.workflowactions.NextStageWorkflowAction"/>
        </wcm:customAction>
    </content>
</entry>

HTTP/1.1 201 Created

<?xml version="1.0" encoding="UTF-8"?>
<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm/8.0">
    <id>wcmrest:33b378f9-78be-4457-a5ec-20c9f2848000</id>
    <title xml:lang="en">MLS Next Stage Workflow Action</title>
    <summary xml:lang="en"></summary>
    <wcm:name>MLS Next Stage Workflow Action</wcm:name>
    <wcm:type>CustomWorkflowAction</wcm:type>
    ... some content elided ...
    <content type="application/vnd.ibm.wcm+xml">
        <wcm:customAction xmlns="http://www.ibm.com/xmlns/wcm/8.0" xmlns:atom="http://www.w3.org/2005/Atom">
            <dateType>CUSTOM_ACTION_DATE</dateType>
            <action href="/wps/mycontenthandler/wcmrest/CustomWorkflowActionFactory/MLCustomWorkflowActionFactory/actions/com.ibm.workplace.wcm.ml.workflowactions.NextStageWorkflowAction"/>
        </wcm:customAction>
    </content>
</entry>
```

Update

A custom workflow action can be updated by sending a PUT request to the following URI:

`/CustomWorkflowAction/action-id`

For example:

```
HTTP/1.1 PUT /wps/mycontenthandler/wcmrest/CustomWorkflowAction/abc4c24a-3540-4ae3-8ba6-f2f82a977046
Content-Type: application/atom+xml

<?xml version="1.0" encoding="UTF-8"?>
<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm/8.0">
    ... some content elided ...
     <content type="application/vnd.ibm.wcm+xml">
        <wcm:customAction xmlns="http://www.ibm.com/xmlns/wcm/8.0" xmlns:atom="http://www.w3.org/2005/Atom">
            <dateType>SPECIFIED_DATE</dateType>
            <date>2014-06-26T01:48:00.000Z</date>
            <action href="/wps/mycontenthandler/wcmrest/CustomWorkflowActionFactory/MLCustomWorkflowActionFactory/actions/com.ibm.workplace.wcm.ml.workflowactions.NextStageWorkflowAction"/>
        </wcm:customAction>
    </content>
</entry>

HTTP/1.1 200 OK
```

Read

Custom workflow actions can be read by sending a GET request to the following URI:

`/CustomWorkflowAction/action-id`

For example:

```
HTTP/1.1 GET /wps/mycontenthandler/wcmrest/CustomWorkflowAction/33b378f9-78be-4457-a5ec-20c9f2848000
Accept: application/atom+xml

HTTP/1.1 200 OK

<?xml version="1.0" encoding="UTF-8"?>
<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm/8.0">
    <id>wcmrest:33b378f9-78be-4457-a5ec-20c9f2848000</id>
    <title xml:lang="en">My Test Action</title>
    <summary xml:lang="en"></summary>

            <action href="/wps/mycontenthandler/wcmrest/CustomWorkflowActionFactory/MLCustomWorkflowActionFactory/actions/com.ibm.workplace.wcm.ml.workflowactions.NextStageWorkflowAction"/>
        </wcm:customAction>
    </content>
</entry>
```

Delete

A custom action can be deleted by sending a DELETE request to the following URI:

`/CustomWorkflowAction/action-id`

For example:

```
HTTP/1.1 DELETE /wps/mycontenthandler/wcmrest/CustomWorkflowAction/abc4c24a-3540-4ae3-8ba6-f2f82a977(

HTTP/1.1 200 OK
```

How to use REST with projects

You can use the REST services for Web Content Manager to create and work with projects.

Creating a project

To create a project, send a POST request that contains the appropriate data to the following URI.

`/project/`

For example:

```
POST /wps/mycontenthandler/wcmrest/Project HTTP/1.0
Content-type : application/atom+xml

<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="wcm/namespace">
    <title>SampleProjectTitle</title>
    <wcm:name>SampleProjectName</wcm:name>
    <wcm:description>SampleProjectDescription</wcm:description>
</entry>

HTTP/1.0 Created
Content-type: application/atom+xml; type=entry
Content-location: /wps/mycontenthandler/!ut/p/wcmrest/Project/80d503aa-fec5-477c-a8b2-372897982af

<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="wcm/namespace">
    <id>80d503aa-fec5-477c-a8b2-372897982afe</id>
    <title>SampleProjectTitle</title>
    <link rel="edit" href="/wps/mycontenthandler/!ut/p/wcmrest/Project/80d503aa-fec5-477c-a8b2-372897982afe"/>
    <link rel="add-item" href="/wps/mycontenthandler/!ut/p/wcmrest/Project/80d503aa-fec5-477c-a8b2-372897982afe/additem"/>
    <link rel="remove-item" href="/wps/mycontenthandler/!ut/p/wcmrest/Project/80d503aa-fec5-477c-a8b2-372897982afe/removeitem"/>
    <updated>2011-05-30T06:15:29.952Z</updated>
    <author>
        <wcm:distinguishedName>uid=wpsadmin,o=defaultWIMFileBasedRealm</wcm:distinguishedName>
        <uri>/wps/mycontenthandler/!ut/p/digest!6GVkh5Ul75Ln7DdEgvHm_g/um/users/profiles/Z9eAeH1C2JG561RC6JM47H9E4MMG6PHO6JM4C5JD0JMOC6BEEJS464JDG3I56K1</uri>
        <name>wpsadmin</name>
    </author>
    <wcm:owner>
        <wcm:distinguishedName>uid=wpsadmin,o=defaultWIMFileBasedRealm</wcm:distinguishedName>
        <uri>/wps/mycontenthandler/!ut/p/digest!6GVkh5Ul75Ln7DdEgvHm_g/um/users/profiles/Z9eAeH1C2JG561RC6JM47H9E4MMG6PHO6JM4C5JD0JMOC6BEEJS464JDG3I56K1</uri>
        <name>wpsadmin</name>
    </wcm:owner>
    <wcm:name>SampleProjectName</wcm:name>
    <wcm:description>SampleProjectDescription</wcm:description>
    <wcm:type>Project</wcm:type>
</entry>
```

Reading a project

To read a project, send a GET request that contains the appropriate data to the following URI.

`/project/item-uuid`

For example:

```
GET /wps/mycontenthandler/wcmrest/Project/80d503aa-fec5-477c-a8b2-372897982afe HTTP/1.1

HTTP/1.0 200 OK
Content-type: application/atom+xml; type=entry

<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="wcm/namespace">
    <id>80d503aa-fec5-477c-a8b2-372897982afe</id>
    <title>SampleProjectTitle</title>
    <link rel="edit" href="/wps/mycontenthandler/!ut/p/wcmrest/Project/80d503aa-fec5-477c-a8b2-372897982afe"/>
    <link rel="add-item" href="/wps/mycontenthandler/!ut/p/wcmrest/Project/80d503aa-fec5-477c-a8b2-372897982afe/additem"/>
    <link rel="remove-item" href="/wps/mycontenthandler/!ut/p/wcmrest/Project/80d503aa-fec5-477c-a8b2-372897982afe/removeitem"/>
    <updated>2011-05-30T06:15:29.952Z</updated>
    <author>
        <wcm:distinguishedName>uid=wpsadmin,o=defaultWIMFileBasedRealm</wcm:distinguishedName>
        <uri>/wps/mycontenthandler/!ut/p/digest!6GVkh5Ul75Ln7DdEgvHm_g/um/users/profiles/Z9eAeH1C2JG561RC6JM47H9E4MMG6PHO6JM4C5JD0JMOC6BEEJS464JDG3I56K1</uri>
        <email></email>
        <name>wpsadmin</name>
    </author>
    <wcm:owner>
        <wcm:distinguishedName>uid=wpsadmin,o=defaultWIMFileBasedRealm</wcm:distinguishedName>
        <uri>/wps/mycontenthandler/!ut/p/digest!6GVkh5Ul75Ln7DdEgvHm_g/um/users/profiles/Z9eAeH1C2JG561RC6JM47H9E4MMG6PHO6JM4C5JD0JMOC6BEEJS464JDG3I56K1</uri>
        <email></email>
        <name>wpsadmin</name>
    </wcm:owner>
    <wcm:name>SampleProjectName</wcm:name>
    <wcm:description>SampleProjectDescription</wcm:description>
    <wcm:type>Project</wcm:type>
</entry>
```

Deleting a project

To delete a project, send a DELETE request that contains the appropriate data to the following URI.

`/project/item-uuid`

For example:

```
HTTP/1.1 DELETE
http://host:port/wps/mycontenthandler/wcmrest/Project/35b9120a-17d0-4dcb-b0ba-b034e34b50a6
Accept-Type: application/atom+xml

200 OK
```

Updating a project

To update a project, send a PUT request that contains the appropriate data to the following URI.

```
/project/item-uuid
```

For example:

```
HTTP/1.1 PUT
http://host:port/wps/mycontenthandler/wcmrest/Project/35b9120a-17d0-4dcb-b0ba-b034e34b50a6
Accept-Type: application/atom+xml

200 OK
```

Adding an item to a project

To add an item to a project, update the item by using a PUT request that specifies a link with relation "project" specifying the project to add the item to. For example:

```
HTTP/1.1 PUT
http://host:port/wps/mycontenthandler/!ut/p/digest!MetYLHV_M5sJbvslxI8twA/
wcmrest/LibraryTextComponent/fd34a8bf-7ca1-499c-80ab-acdc2f33cf3e</a>
Accept-Type: application/atom+xml

<?xml version="1.0" encoding="UTF-8"?>
<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm">
    ... data ...
<link rel="project" href="/wps/mycontenthandler/wcmrest/Project/77d08cf6-88f6-4577-a929-34d43a8e150e
... data...
</entry>

200 OK
```

Note: If you use REST inside a Portal project context, posting to the create-draft link relation creates the draft in a project.

Removing an item from a project

To remove an item from a project, update the item by using a PUT request without specifying the project link relation. For example:

```
HTTP/1.1 PUT
http://host:port/wps/mycontenthandler/!ut/p/digest!MetYLHV_M5sJbvslxI8twA/
wcmrest/LibraryTextComponent/fd34a8bf-7ca1-499c-80ab-acdc2f33cf3e</a>
Accept-Type: application/atom+xml

200 OK
```

Submitting a project for review

Editors of a project can submit a project for review by sending a POST request that contains the appropriate data to the following URI:

```
/project/project-uuid/submit-for-review
```

For example:

```
HTTP/1.1 POST
http://host:port/wps/mycontenthandler/wcmrest/Project/PROJECT-UUID/submit-for-review
Accept-Type: application/atom+xml

201 Created
```

Withdrawing a project from review

Editors of a project can withdraw a project from review by sending a POST request that contains the appropriate data to the following URI:

```
/project/project-uuid/withdraw-from-review
```

For example:

```
HTTP/1.1 POST
http://host:port/wps/mycontenthandler/wcmrest/Project/PROJECT-UUID/withdraw-from-review
Accept-Type: application/atom+xml

201 Created
```

When withdrawn, the project returns to an active state.

Approving a project

Approvers of a project can approve a project by sending a POST request that contains the appropriate data to the following URI:

```
/project/project-uuid/approve
```

For example:

```
HTTP/1.1 POST
http://host:port/wps/mycontenthandler/wcmrest/Project/PROJECT-UUID/approve
Accept-Type: application/atom+xml

201 Created
```

When approved, the project is ready to be published.

Rejecting a project

Approvers of a project can reject project approval by sending a POST request that contains the appropriate data to the following URI:

```
/project/project-uuid/reject
```

For example:

```
HTTP/1.1 POST
http://host:port/wps/mycontenthandler/wcmrest/Project/PROJECT-UUID/reject
Accept-Type: application/atom+xml

201 Created
```

When rejected, the project returns to an active state.

Withdrawing approval for a project

Approvers of a project can withdraw approval for a project by sending a POST request that contains the appropriate data to the following URI:

```
/project/project-uuid/withdraw-approval
```

For example:

```
HTTP/1.1 POST
http://host:port/wps/mycontenthandler/wcmrest/Project/PROJECT-UUID/withdraw-approval
Accept-Type: application/atom+xml

201 Created
```

Withdrawing approval does not change the state of the project, which remains in review.

How to use REST with folders

You can use the Web Content Manager REST service to create, read, update, and delete folders. You can also use the WWeb Content Manager REST service to query for the preset folders in a library.

Query For Preset Folders

A list of the preset folders in a library can be obtained by sending a GET request to the following URI:

```
/Library/library-id/preset-folders
```

For example:

```
HTTP/1.1 /wps/mycontenthandler/wcmrest/Library/
Accept: application/atom+xml

HTTP/1.1 200 OK
Content-Type: application/atom+xml

<?xml version="1.0" encoding="UTF-8"?>

```

Create

A folder can be created by sending a POST request to the following URI with an Atom entry that represents the folder:

```
/Folder
```

For example:

```
HTTP/1.1 POST /wps/mycontenthandler/wcmrest/Folder
Content-Type: application/atom+xml

<?xml version="1.0" encoding="UTF-8"?>
<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm/8.0">
    <wcm:name>Design Components</wcm:name>
    <link rel="parent" href="/wps/mycontenthandler/wcmrest/Folder/17fe1ab3-ba6a-4769-b5f0-a2cb2f91ebb5-10"/>
</entry>

HTTP/1.1 200 OK

<?xml version="1.0" encoding="UTF-8"?>
<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm/8.0">
    <id>wcmrest:5def4f6f-0dd9-49ca-b954-706f8ceb7373</id>
    <title xml:lang="en">test create components folder</title>
    <summary xml:lang="en"></summary>
    <wcm:name>test create components folder</wcm:name>
    <wcm:type>Folder</wcm:type>
    <updated>2014-06-27T02:39:58.735Z</updated>
    <wcm:created>2014-06-27T02:39:58.733Z</wcm:created>
```

```
    <wcm:lastModifier>
        <wcm:distinguishedName>uid=wpsadmin,o=defaultWIMFileBasedRealm</wcm:distinguishedName>

    <link rel="edit" href="/wps/mycontenthandler/wcmrest/Folder/5def4f6f-0dd9-49ca-b954-706f8ceb7373" xml:lang="en" label="Edit"/>
    <link rel="delete" href="/wps/mycontenthandler/wcmrest/Folder/5def4f6f-0dd9-49ca-b954-706f8ceb7373" xml:lang="en" label="Delete"/>
    <link rel="access-control" href="/wps/mycontenthandler/ac/access:oid:Z6QReDeL1PA6JH66JDCMM0643PIJMG6PPO2MM8CP9D8JMS6GHDC6SCC5JOEJPS6J1" xml:lang="en" label="Access Control"/>
    <link rel="library" href="/wps/mycontenthandler/wcmrest/Library/17fe1ab3-ba6a-4769-b5f0-a2cb2f91ebb5" xml:lang="en" label="Library"/>
    <link rel="parent" href="/wps/mycontenthandler/wcmrest/Folder/17fe1ab3-ba6a-4769-b5f0-a2cb2f91ebb5-10" xml:lang="en" label="Parent"/>
    <link rel="versions" href="/wps/mycontenthandler/wcmrest/item/5def4f6f-0dd9-49ca-b954-706f8ceb7373/versions" xml:lang="en" label="Versions"/>
    <category scheme="wcmrest:favorite" term="false" xml:lang="en"/>
</entry>
```

Update

A folder can be updated by sending a PUT request to the following URI with an Atom entry that includes the fields on the item that need to be changed:

`/Folder/folder-id`

For example:

```
HTTP/1.1 PUT /wps/mycontenthandler/wcmrest/Folder/5def4f6f-0dd9-49ca-b954-706f8ceb7373
Content-Type: application/atom+xml

<?xml version="1.0" encoding="UTF-8"?>
<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm/8.0">
    ... some content elided ...
    <wcm:name>The Folder Name has Chenged</wcm:name>
    <!-- Note that the parent has changed. This will cause the folder to be moved. -->
    <link rel="parent" href="/wps/mycontenthandler/wcmrest/Folder/aceaf85a-48a8-45f7-a6cc-343ace84f337" xml:lang="en" label="Parent"/>
    ... some content elided ...
</entry>
```

Read

A folder can be read by sending a GET request to the following URI:

`/Folder/folder-id`

For example:

```
HTTP/1.1 GET /wps/mycontenthandler/wcmrest/Folder/5def4f6f-0dd9-49ca-b954-706f8ceb7373
Accept: application/atom+xml

HTTP/1.1 200 OK

<?xml version="1.0" encoding="UTF-8"?>
<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm/8.0">
    <id>wcmrest:5def4f6f-0dd9-49ca-b954-706f8ceb7373</id>

    <category scheme="wcmrest:favorite" term="false" xml:lang="en"/>
</entry>
```

Delete

A folder can be deleted by sending a DELETE request to the following URI:

`/Folder/folder-id`

```
HTTP/1.1 DELETE /wps/mycontenthandler/wcmrest/Folder/5def4f6f-0dd9-49ca-b954-706f8ceb7373

HTTP/1.1 200 OK
```

How to use REST with taxonomies

You can use the Web Content Manager REST service to create, read, update, and delete taxonomies.

Create

A taxonomy can be created by sending a POST request to the following URI with an Atom entry that represents the item:
`/Taxonomy`

For example:

```
HTTP/1.1 POST /wps/mycontenthandler/wcmrest/Taxonomy
Content-Type: application/atom+xml

<?xml version="1.0" encoding="UTF-8"?>
<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm/8.0">
    <wcm:name>Marketing Taxonomy</wcm:name>
    <title>Marketing Taxonomy</title>
    <link rel="library" href="/wps/mycontenthandler/!ut/p/digest!muAe8T8GIzS4EJeiF9a_sw/wcmrest/Library/94a8214d-322c-4724-acc3-b6c217d1bc5f" label="Library"/>
</entry>

HTTP/1.1 201 Created
Content-Type: application/atom+xml

<?xml version="1.0" encoding="UTF-8"?>
<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm/8.0">

    <category scheme="wcmrest:favorite" term="false" xml:lang="en"/>
</entry>
```

Update

A taxonomy can be updated by sending a PUT request to the following URI:
`/Taxonomy/taxonomy-id`

For example:

```
HTTP/1.1 PUT /wps/mycontenthandler/wcmrest/Taxonomy/501a4ab8-48c3-41fc-b1fd-6dbe0acba1d4
Content-Type: application/atom+xml

<?xml version="1.0" encoding="UTF-8"?>
<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm/8.0">
    <wcm:name>Marketing Taxonomy Has Been Changed</wcm:name>
    ... some content elided ...
</entry>

HTTP/1.1 200 OK
```

Read

A taxonomy can be read by sending a GET request to the following URI:
`/Taxonomy/taxonomy-id`

For example:

```
HTTP/1.1 GET /wps/mycontenthandler/wcmrest/Taxonomy/501a4ab8-48c3-41fc-b1fd-6dbe0acba1d4
Accept: application/atom+xml

HTTP/1.1 200 OK

<?xml version="1.0" encoding="UTF-8"?>

    <link rel="versions" href="/wps/mycontenthandler/wcmrest/item/501a4ab8-48c3-41fc-b1fd-6dbe0acba1d4/versions" xml:lang="en" label="Versions"/>
    <category scheme="wcmrest:workflowState" term="PUBLISHED" label="Published" xml:lang="en"/>
    <category scheme="wcmrest:favorite" term="false" xml:lang="en"/>
</entry>
```

Delete

A taxonomy can be deleted by sending a DELETE request to the following URI:

`/Taxonomy/taxonomy-id`

In this example, the type `PublishAction` can be replaced with `ExpireAction` or `VersionAction` when you work with those workflow action types.

```
HTTP/1.1 DELETE /wps/mycontenthandler/wcmrest/Taxonomy/7b40f5b6-bf52-4b9e-8062-b0755aaf1f80

HTTP/1.1 200 OK
```

How to use REST with categories

You can use the Web Content Manager REST service to create, read, update, and delete categories.

Create

A category can be created by sending a POST request to the following URI with an Atom entry that represents the item:

`/Category`

For example:

```
HTTP/1.1 POST /wps/mycontenthandler/wcmrest/Category
Content-Type: application/atom+xml

<?xml version="1.0" encoding="UTF-8"?>
<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm/8.0">
    <wcm:name>Product Marketing Category</wcm:name>
    <link rel="parent" href="/wps/mycontenthandler/wcmrest/Taxonomy/5b4c58a2-68fb-45e2-9907-ef58ad95cc2f"/>
</entry>

HTTP/1.1 201 Created
Content-Type: application/atom+xml

<?xml version="1.0" encoding="UTF-8"?>
<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm/8.0">
    <id>wcmrest:525900ec-0ae0-40f7-9edd-4bddc7af154f</id>

```
    <link rel="edit" href="/wps/mycontenthandler/wcmrest/Category/525900ec-0ae0-40f7-9edd-4bddc7af154f" xml:lang="en" label="Edit"/>
    <link rel="delete" href="/wps/mycontenthandler/wcmrest/Category/525900ec-0ae0-40f7-9edd-4bddc7af154f" xml:lang="en" label="Delete"/>
    <link rel="change-to-draft" href="/wps/mycontenthandler/wcmrest/item/525900ec-0ae0-40f7-9edd-4bddc7af154f/change-to-draft" xml:lang="en" label="Change To Draft"/>
    <link rel="create-draft" href="/wps/mycontenthandler/wcmrest/item/525900ec-0ae0-40f7-9edd-4bddc7af154f/create-draft" xml:lang="en" label="Create Draft"/>
    <link rel="access-control" href="/wps/mycontenthandler/ac/access:oid:Z6QReDeLHCAJS06G9P6MM061BP0JMG6GHPEJM4753P8MMG623P8MHT61JP2JQG663" xml:lang="en" label="Access Control"/>
    <link rel="library" href="/wps/mycontenthandler/wcmrest/Library/078dc9ce-3cde-4eec-ab7c-2bdc0043deb7" xml:lang="en" label="Library"/>
    <link rel="parent" href="/wps/mycontenthandler/wcmrest/Taxonomy/5b4c58a2-68fb-45e2-9907-ef58ad95cc2f" xml:lang="en" label="Parent"/>
    <link rel="versions" href="/wps/mycontenthandler/wcmrest/item/525900ec-0ae0-40f7-9edd-4bddc7af154f/versions" xml:lang="en" label="Versions"/>
    <category scheme="wcmrest:workflowState" term="PUBLISHED" label="Published" xml:lang="en"/>
    <category scheme="wcmrest:favorite" term="false" xml:lang="en"/>
</entry>
```

Update

A category can be updated by sending a PUT request to the following URI `/Category/category-id`

For example:

```
HTTP/1.1 PUT /wps/mycontenthandler/wcmrest/Category/525900ec-0ae0-40f7-9edd-4bddc7af154f
Content-Type: application/atom+xml

<?xml version="1.0" encoding="UTF-8"?>
<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm/8.0">
    <wcm:name>Marketing Category Has Been Changed</wcm:name>
    ... some content elided ...
</entry>

HTTP/1.1 200 OK
```

Read

A category can be read by sending a GET request to the following URI: `/Category/category-id`

For example:

```
HTTP/1.1 GET /wps/mycontenthandler/wcmrest/Category/501a4ab8-48c3-41fc-b1fd-6dbe0acba1d4
Accept: application/atom+xml

HTTP/1.1 200 OK

<?xml version="1.0" encoding="UTF-8"?>
<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm/8.0">
    <id>wcmrest:525900ec-0ae0-40f7-9edd-4bddc7af154f</id>
    <title xml:lang="en">Product Marketing Category</title>
    <summary xml:lang="en"></summary>

    <category scheme="wcmrest:favorite" term="false" xml:lang="en"/>
</entry>
```

Delete

A category can be deleted by sending a DELETE request to the following URI: `/Category/category-id`

In this example, the type `PublishAction` can be replaced with `ExpireAction` or `VersionAction` when working with those workflow action types.

```
HTTP/1.1 DELETE /wps/mycontenthandler/wcmrest/Category/525900ec-0ae0-40f7-9edd-4bddc7af154f

HTTP/1.1 200 OK
```

How to use REST to work with item identity controls

The way identity controls are used with REST depend on whether a text provider is enabled or not for an item.

Creating, updating, or reading identity controls with no text provider enabled

When no text provider is enabled on an item, identity controls work this way:

Table 488. REST tags with no text provider enabled

REST Tag	Item field
`<wcm:name>text</wcm:name>`	Name
`<atom:title>text</atom:title>`	Display title
`<atom:summary>text</atom:summary>`	Description

Enabling updating or reading text provider controls

To either enable, update or read text provider controls, you add the following parameters to the title tag:

Table 489. REST tags for text providers

REST Tag	Text provider field
`<wcm:title TextProviderName>text</ wcm:title TextProviderName>`	Title name
`<wcm:title TextProviderKey>text</ wcm:title TextProviderKey>`	Title key
`<wcm:desc TextProviderName>text</ wcm:desc TextProviderName>`	Description name
`<wcm:desc TextProviderKey>text</wcm:desc TextProviderKey>`	Description key

Creating, updating, or reading identity controls with a text provider enabled

When a text provider is enabled on an item, identity controls work this way:

Table 490. REST tags with a text provider enabled

REST Tag	Item field
`<wcm:name>text</wcm:name>`	Name
`<wcm:displayTitle>text</ wcm:displayTitle>`	Display title
`<atom:title lang="language code" >text</atom:title>` For example:`<atom:title lang="fr" >text</atom:title>`	Localized title **Note:** When a text provider is enabled, only the localized title can be read by the REST service. You need to update the text provider plug-in directly to change the localized title.
`<wcm:description>text</wcm:description>`	Description

Table 490. REST tags with a text provider enabled (continued)

REST Tag	Item field
<atom:summary lang="language code" >text</atom:summary> For example:<atom:summary lang="fr" >text</atom:summary>	Localized description **Note:** When a text provider is enabled, only the localized description can be read by the REST service. You need to update the text provider plug-in directly to change the localized description.

Note: The language code that is required for the localized tags must be an IETF BCP47 compliant language code.

How to use REST with access controls

The access control section in an Atom entry or JSON entry that is generated by the REST service for Web Content Manager links to resources from the Portal Access Control REST API.

An example of how the access controls are displayed:

```
<link rel="access-control"
href="/wps/mycontenthandler/!ut/p/digest!ZXqvndUckPlBBgMoHkgcCA/ac/
access:oid:Z6QReDeOHP0JQK62BO4JM462RO6JMG64JC2JM07K1D6JM07MHCE3QKCH1D86I9633"/>
```

You can send a GET request to the URI and obtain the access control information of an item that is generated by the "Portal Access Control REST API" on page 2923.

How to use REST to work with author and owner parameters

Information for the author and owner of an item can be specified by using the REST service.

The following attributes are used:

- `name`
- `distinguishedName`
- A URI to fetch detailed information of the author or owner by using the PUMA REST SPI

You can also specify such information in the entry in the same format for a POST or PUT operation to Create or Update an item with the information you specified.

Example

This example is in application/atom+xml format:

```
<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="wcm/namespace">
   ...
    <author>
        <wcm:distinguishedName>uid=wpsadmin,o=defaultWIMFileBasedRealm</wcm:distinguishedName>
        <uri>/wps/mycontenthandler/!ut/p/digest!6GVkh5Ul75Ln7DdEgvHm_g/um/users/profiles/Z9eAeH1C2JG561RC6JM47H9E4MMG6PHO6JM4C5JD0JMOC6BEEJS464JDG3I56K1</uri>
        <name>wpsadmin</name>
    </author>
    <wcm:owner>
        <wcm:distinguishedName>uid=wpsadmin,o=defaultWIMFileBasedRealm</wcm:distinguishedName>
        <uri>/wps/mycontenthandler/!ut/p/digest!6GVkh5Ul75Ln7DdEgvHm_g/um/users/profiles/Z9eAeH1C2JG561RC6JM47H9E4MMG6PHO6JM4C5JD0JMOC6BEEJS464JDG3I56K1</uri>
        <name>wpsadmin</name>
    </wcm:owner>
   ...
</entry>
```

How to use REST with versions

Item versions can be listed and read by using the REST service.

Retrieving a list of versions

To retrieve a list of versions, you use a GET request to the following URI:

/item/*item-uuid*/versions

A feed is returned containing the identifying information of each version, along with a relation "versioned-item" that links to the specified version.

Version link relations

```
<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="wcm/namespace">
  ...
    <link rel="versions" href="/wps/mycontenthandler/!ut/p/wcmrest/item/0d678334-69ae-4d3a-a525-91bb551e5a18/versions"/>
  ...
</entry>
```

Versions feed

```
<feed xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="wcm/namespace">
    <entry>
        <link rel="versioned-item" href="/wps/mycontenthandler/!ut/p/wcmrest/item/0d678334-69ae-4d3a-a525-91bb551e5a18/version/2"/>
        <content>
            <wcm:versionContent>
                <wcm:versionName>2</wcm:versionName>
                <wcm:versionDate>2011-05-30T04:38:49.540Z</wcm:versionDate>
            </wcm:versionContent>
        </content>
    </entry>
    <entry>
        <link rel="versioned-item" href="/wps/mycontenthandler/!ut/p/wcmrest/item/0d678334-69ae-4d3a-a525-91bb551e5a18/version/1"/>
        <content>
            <wcm:versionContent>
                <wcm:versionName>1</wcm:versionName>
                <wcm:versionDate>2011-05-30T04:33:40.677Z</wcm:versionDate>
            </wcm:versionContent>
        </content>
    </entry>
</feed>
```

Viewing the details of a version

To view the details of a specified version, you use a GET request in the following format:

/item/*item-uuid*/version/*version-name*

For example:

```
GET HTTP/1.0
/wps/mycontenthandler/wcmrest/item/8f055ba2-1bc3-4d21-8443-86274e14dd2c/version/1
Host: www.example.com
Accept: application/atom+xml

HTTP/1.0 200 OK

<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="wcm/namespace">
    <id>0d678334-69ae-4d3a-a525-91bb551e5a181</id>
    <title>SampleNumericComponentTitle</title>
    <link rel="edit" href="/wps/mycontenthandler/!ut/p/wcmrest/LibraryNumericComponent/0d678334-69ae-4d3a-a525-91bb551e5a181"/>
    <link rel="edit-media" type="text/plain" href="/wps/mycontenthandler/!ut/p/wcmrest/LibraryNumericComponent/0d678334-69ae-4d3a-a525-91bb551e5a181"/>
    <link rel="library" href="/wps/mycontenthandler/!ut/p/wcmrest/item/c98d11e1-7f2a-480e-9aac-40eb1949cbda"/>
    <link rel="create-draft" href="/wps/mycontenthandler/!ut/p/wcmrest/item/0d678334-69ae-4d3a-a525-91bb551e5a181/create-draft"/>
    <link rel="change-to-draft" href="/wps/mycontenthandler/!ut/p/wcmrest/item/0d678334-69ae-4d3a-a525-91bb551e5a181/change-to-draft"/>
    <link rel="versions" href="/wps/mycontenthandler/!ut/p/wcmrest/item/0d678334-69ae-4d3a-a525-91bb551e5a181/versions"/>
    <updated>2011-05-30T06:42:10.244Z</updated>
    <author>
        <wcm:distinguishedName>uid=wpsadmin,o=defaultWIMFileBasedRealm</wcm:distinguishedName>
        <uri>/wps/mycontenthandler/!ut/p/digest!6GVkh5Ul75Ln7DdEgvHm_g/um/users/profiles/Z9eAeH1C2JG561RC6JM47H9E4MMG6PHO6JM4C5JD0JMOC6BEEJS464JDG3I56K1</uri>
        <email></email>

    </wcm:owner>
    <wcm:name>SampleNumericComponentNameUpdated</wcm:name>
    <wcm:description>SampleNumericComponentDescription</wcm:description>
    <wcm:type>LibraryNumericComponent</wcm:type>
    <wcm:state>PUBLISHED</wcm:state>
    <versionContent>
        <wcm:versionName>1</wcm:versionName>
        <wcm:versionDate>2011-05-30T04:33:40.677Z</wcm:versionDate>
    </versionContent>
</entry>
```

Using REST to work with recent items

You can use REST service to display a list of recently accessed items. This is the equivalent of the **Recent Items** view in the library explorer.

Note: By default, items accessed through the REST service are added to the recent items list. To stop items accessed through the REST service appearing in the list of recent items, change the *rest.default.add-recent* parameter to false in the `WCM WCMConfigService` service using the WebSphere Integrated Solutions Console. The *rest.default.add-recent* parameter can be overridden on a per-request basis by specifying `recent=true` or `recent=false` in the query string.

URI: `/recent-items`

Example:

```
HTTP 1.1 GET /wps/mycontenthandler/wcmrest/recent-items

<feed xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm">
    <id>wcmrest:recent-items</id>
    <title>wcmrest:recent-items</title>
    <updated>2011-09-28T02:51:47.228Z</updated>
    <link rel="next-page" href="/wps/mycontenthandler/!ut/p/wcmrest/recent-items?page=2"/>
    <entry>
        <id>wcmrest:8b629b12-e16a-4afa-bbf5-a37ebee5a5b8</id>
        <title xml:lang="en">Articles List</title>
        <summary xml:lang="en"></summary>
        <wcm:name>Articles List</wcm:name>
        <wcm:description xml:lang="en"></wcm:description>
        <wcm:type>LibraryMenuComponent</wcm:type>
        <updated>2011-09-21T06:21:11.701Z</updated>
        <wcm:lastAccessed>2011-09-26T05:41:50.874Z</wcm:lastAccessed>
        <wcm:lastModifier>
            <wcm:distinguishedName>Replicator</wcm:distinguishedName>
        </wcm:lastModifier>
        <link rel="edit" href="/wps/mycontenthandler/!ut/p/wcmrest/item/8b629b12-e16a-4afa-bbf5-a37ebee5a5b8"/>
        <link rel="library" href="/wps/mycontenthandler/!ut/p/wcmrest/item/8c01ede8-4ccd-410e-9e21-c4c37114f5f2"/>
        <wcm:displayTitle xml:lang="en">Articles List</wcm:displayTitle>
        <category label="Published" scheme="wcmrest:workflowState" term="PUBLISHED" xml:lang="en"/>
    </entry>
    <entry>
        <id>wcmrest:4ffeefcc-5539-4271-936a-7bd0ddf1644d</id>
        <title xml:lang="en">Article Toolbar</title>
        <summary xml:lang="en"></summary>
        <wcm:name>Article toolbar</wcm:name>
        <wcm:description xml:lang="en"></wcm:description>
        <wcm:type>LibraryAuthoringToolsComponent</wcm:type>
        <updated>2011-09-21T06:21:21.452Z</updated>
        <wcm:lastAccessed>2011-09-26T05:41:55.544Z</wcm:lastAccessed>
        <wcm:lastModifier>
            <wcm:distinguishedName>Replicator</wcm:distinguishedName>
        </wcm:lastModifier>
        <link rel="edit" href="/wps/mycontenthandler/!ut/p/wcmrest/item/4ffeefcc-5539-4271-936a-7bd0ddf1644d"/>
        <link rel="library" href="/wps/mycontenthandler/!ut/p/wcmrest/item/8c01ede8-4ccd-410e-9e21-c4c37114f5f2"/>
        <wcm:displayTitle xml:lang="en">Article toolbar</wcm:displayTitle>
        <category label="Published" scheme="wcmrest:workflowState" term="PUBLISHED" xml:lang="en"/>
    </entry>
</feed>
```

There is one additional field present in each of the entries when a recent items query is performed. This field is the last accessed date of the item. This indicates the date and time at which the item was last viewed or edited through the authoring portlet. For example:

```
<wcm:lastAccessed>2011-09-26T05:41:55.544Z</wcm:lastAccessed>
```

Parameters

The following parameters, along with mime-type, are the only parameters that will work with the returned feed. All other parameters will be ignored.

Table 491. Parameters

Parameter	Details
sort	The `sort` parameter is appended to queries to determine how query results are sorted. The following values can be used with the `sort` parameter. • `accessed` • `author` • `created` • `modified` • `name` • `title` The values `_ascending` or `_descending` are appended to the query to determine sort order. For example, to sort a presentation template query in ascending order of creation, you would use: `/recent-items?type=PresentationTemplate&sort=created_ascending` To sort a presentation template query in descending order of creation, you would use: `/recent-items?type=PresentationTemplate&sort=created_descending` If `_ascending` or `_descending` are not specified, the results as displayed in ascending order.
type	This parameter is used to query items of a specific item type. For example, to query a list of components: `/recent-items?type=LibraryHTMLComponent`
page	This parameter is used with the `pagesize` parameter to define what set of results to display. For example, if `pagesize` is set to 5, and the `page` parameter is set to 2, then only results 6 - 10 are displayed. For example: `/recent-items?type=PresentationTemplate&pagesize=5&page=2`
pagesize	This parameter is used to restrict the number of items that are returned by a query to a set number. It can be used with the `page` parameter to return specific pages of results. For example, to restrict the number of queries to be returned to 5: `/recent-items?type=PresentationTemplate&pagesize=5`

How to use REST to work with favorite items

You can use REST service to display a list of favorite items. This function is the equivalent of the **Favorite Items** view in the library explorer.

URI: `/favorite-items`

Example:

```
<?xml version="1.0" encoding="UTF-8"?>
<feed xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm">
    <id>wcmrest:favorite-items</id>
    <title>wcmrest:favorite-items</title>
    <updated>2012-01-31T01:19:00.564Z</updated>
    <entry>

```

Parameters

The following parameters, along with mime-type, are the only parameters that work with the returned feed. All other parameters are ignored.

Table 492. Parameters

Parameter	Details
sort	The `sort` parameter is appended to queries to determine how query results are sorted. The following values can be used with the `sort` parameter. • `author` • `created` • `modified` • `name` • `title` The values `_ascending` or `_descending` are appended to the query to determine sort order. For example, to sort a presentation template query in ascending order of creation, you would use: `/favorite-items?type=PresentationTemplate&sort=created_ascending` To sort a presentation template query in descending order of creation, you would use: `/favorite-items?type=PresentationTemplate&sort=created_descending` If `_ascending` or `_descending` are not specified, the results as displayed in ascending order.
type	This parameter is used to query items of a specific item type. For example, to query a list of components: `/favorite-items?type=LibraryHTMLComponent`
page	This parameter is used with the `pagesize` parameter to define what set of results to display. For example, if `pagesize` is set to 5, and the `page` parameter is set to 2, then only results 6 - 10 are displayed. For example: `/favorite-items?type=PresentationTemplate&pagesize=5&page=2`
pagesize	This parameter is used to restrict the number of items that are returned by a query to a set number. It can be used with the `page` parameter to return specific pages of results. For example, to restrict the number of queries to be returned to 5: `/favorite-items?type=PresentationTemplate&pagesize=5`

Adding and removing favorite items

For item types that have an explicit REST URI, such as types that can be created or updated, the item can be added by performing an HTTP PUT to update the item, with the PUT request containing the favorites category.

For example:

```
HTTP 1.1 PUT /wps/mycontenthandler/wcmrest/LibraryHTMLComponent/47018149-fc6b-46af-a54d-1eab89a6fe
<?xml version="1.0" encoding="UTF-8"?>
<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="http://www.ibm.com/xmlns/wcm">
  ... data ...
    <category scheme="wcmrest:favorite" term="true" lang="en"/>
    ... data ...
</entry>
```

- `term="true"` will add an item to the list of favorite items.
- `term="false"` will remove an item from the list of favorite items.
- If the "term" parameter is not present, the item will be removed from the list of favorite items.

For items that do not have an explicit REST URI, an HTTP POST request can be made specifying the generic URI of the item. For this to work the item must be created already.

For example:

Adding:

```
HTTP 1.1 POST /wps/mycontenthandler/wcmrest/favorite-items/additem?item-uri=/wps/mycontenthandler/!ut/p/digest!yGIcBv5sO9Vb0EY9LLhJyQ/wcmrest/item/65a46943-ed1c-4f5d-b497-03c18886ca8e
```

Removing:

```
HTTP 1.1 POST /wps/mycontenthandler/wcmrest/favorite-items/removeitem?item-uri=/wps/mycontenthandler/!ut/p/digest!yGIcBv5sO9Vb0EY9LLhJyQ/wcmrest/item/65a46943-ed1c-4f5d-b497-03c18886ca8e
```

Note: The item-uri parameter specifies the item to add, and can be in the expanded form, as shown in the previous examples, or the compact form. For example:

```
wcmrest:item/65a46943-ed1c-4f5d-b497-03c18886ca8e
```

REST: Attachments

You can use the REST service to attach images to some item types. This is equivalent to using the **Insert An Image** button in the authoring portlet.

An attachment is an image resource that is associated with another item that contains HTML, and can be referenced from within that item. Attachments are a special item type in the REST service because they cannot be directly referenced. This is because there is no URI associated with an attachment when it is created. An attachment cannot be read or updated, but can be deleted indirectly by running an update on the parent item.

Attachments can be added to the following item types:

- Presentation templates
- Rich text components
- HTML components

Note: You must create the item and add a rich text or HTML element before you create the attachment.

Creating

```
/ITEM-TYPE/ITEM-UUID/attachments
Content-Type: image/*
```

When you create an attachment, the binary data, but not encoding, of an image is sent to the attachments collection of an item. The Content-Type header field is set to the appropriate image type. For example: `image/jpg`, `image/png`

Example:

```
HTTP/1.1 POST
http://host:port/wps/mycontenthandler/wcmrest/LibraryHTMLComponent/ITEM-UUID/attachments
Content-Type: image/jpg
(... binary data ... )

201 Created
```

Reading

Not supported.

Updating

Not supported.

Deleting

An attachment cannot be directly referenced through the REST service, which means it cannot be directly deleted. However, it can be deleted indirectly by running an update operation on the parent item.

For example, this is some markup that is stored in an HTML component:

```
<h1> Example Delete </h1>
<img src='/wps/wcm/myconnect/65132264-fd8b-461c-b6ec-ccdd22524ea6/image.jpg?MOD=AJPERES'
 alt='' title='' border='0'  />
```

To remove the image, you would make the following update request:

```
HTTP/1.1 PUT
http://host:port/wps/mycontenthandler/wcmrest/LibraryHTMLComponent/ITEM-UUID/
Content-Type: text/html

<h1> Example Delete </h1>

200 OK
```

Generic reading by using REST services for Web Content Manager

Although not all item types are handled by the REST service, all item types can be read in a generic fashion by using the REST service.

You can send a GET request to any web content item by using the following URI:

```
/item/{item-uuid}
```

Example

```
GET /wps/mycontenthandler/wcmrest/item/c98d11e1-7f2a-480e-9aac-40eb1949cbda HTTP/1.0

HTTP/1.0 200 OK

<entry xmlns="http://www.w3.org/2005/Atom" xmlns:wcm="wcm/namespace">
    <id>c98d11e1-7f2a-480e-9aac-40eb1949cbda</id>
```

```
    <title>Web Content</title>
    <link rel="edit" href="/wps/mycontenthandler/!ut/p/wcmrest/item/c98d11e1-7f2a-480e-9aac-40eb1949cbda"/>
    <link rel="library" href="/wps/mycontenthandler/!ut/p/wcmrest/item/c98d11e1-7f2a-480e-9aac-40eb1949cbda"/>
    <updated>2011-05-16T20:42:29.979Z</updated>

Reference material for the Web Content Manager REST service

Reference material for REST response codes, links, media types, and attachments.

"Response codes for the Web Content Manager REST service"
These response codes are generated by the Web Content Manager REST service.

"Link relations" on page 3386
These definitions provide information on how different requests can be linked.

"Supported media types" on page 3392
The following media types are supported by the Web Content Manager REST service.

"REST Item Types" on page 3397
These item types are supported by the Web Content Manager REST service.

Response codes for the Web Content Manager REST service

These response codes are generated by the Web Content Manager REST service.

Table 493. Response codes

Response code	Message	Description
200	OK	The operation completed successfully.
201	Created	The resource was successfully created.
301	Moved Permanently	The resource addressed is known, however, its URI has changed.
400	Bad Request	Generic client side error. The request data is invalid in some way.
403	Forbidden	The request is formed correctly, but the server cannot carry out the operation.
404	Not Found	The URI specified is unknown to the REST service.
405	Method Not Allowed	The addressed resource does not support the HTTP method used.
406	Not Acceptable	The client specified an unsupported accept type.
409	Conflict	The request attempted to put the resource in an impossible or inconsistent state.
415	Unsupported Media Type	The server did not recognize the specified media type.

Table 493. Response codes (continued)

Response code	Message	Description
423	Locked	Unable to perform the requested operation, as the resource is locked.
500	Internal Server Error	An internal error occurred.

Link relations

These definitions provide information on how different requests can be linked.

Link relation purpose and operation

CF06 **access-control**

Purpose: The access settings of an item.

Supported Operation to the Link HREF: GET

Settable for PUT and POST operation: NO

add-attachment

Purpose: Add attachment to the item (array component only, such as HTML, RichText component/element, and PresentationTemplate).

Supported Operation to the Link HREF: POST

Settable for PUT and POST operation: NO

approve

Purpose: Approve the item in current stage and move it into next stage in the worklfow.

Supported Operation to the Link HREF: POST

Settable for PUT and POST operation: NO

change-to-draft

Purpose: Go to the draft of the item.

Supported Operation to the Link HREF: POST

Settable for PUT and POST operation: NO

content-template

Purpose: The content template of the item.

Supported Operation to the Link HREF: GET

Settable for PUT and POST operation: YES

create-draft

Purpose: Create a draft of the item. It also adds an item to a project if created within a portal project context.

Supported Operation to the Link HREF: POST

Settable for PUT and POST operation: NO

CF06 **default-presentation**

Purpose: The template set as the default presentation template for the item that is created from an authoring template.

Supported Operation to the Link HREF: GET

Settable for PUT and POST operation: YES

CF06 **delete**

Purpose: Delete an item.

Supported Operation to the Link HREF: DELETE

Settable for PUT and POST operation: NO

draft-of

Purpose: The published item link of the draft item.

Supported Operation to the Link HREF: GET

Settable for PUT and POST operation: NO

draft

Purpose: The draft link of the published item.

Supported Operation to the Link HREF: GET

Settable for PUT and POST operation: NO

edit-media

Purpose: Pointing to the item itself with raw data type specified in the 'type' attribute. Designed to be used for 'Raw Data' Read and Update.

Supported Operation to the Link HREF: PUT, GET

Settable for PUT and POST operation: NO

edit

Purpose: Pointing to item itself.

Supported Operation to the Link HREF: PUT, POST, GET, DELETE

Settable for PUT and POST operation: NO

elements

Purpose: All the elements in the content/sitearea.

Supported Operation to the Link HREF: GET

Settable for PUT and POST operation: NO

library

Purpose: The library that the item is stored in.

Supported Operation to the Link HREF: GET

Settable for PUT and POST operation: YES

CF06 **new-content**

Purpose: Link to the new content item to be created from this content template.

Supported Operation to the Link HREF: GET

Settable for PUT and POST operation: NO

CF06 **new-project**

Purpose: Link to the new project to be created from this project template.

Supported Operation to the Link HREF: GET

Settable for PUT and POST operation: NO

CF06 **new-projecttemplate**

Purpose: Link to the new project template.

Supported Operation to the Link HREF: GET

Settable for PUT and POST operation: NO

CF06 **new-sitearea**

Purpose: Link to the site area to be created from this site area template.

Supported Operation to the Link HREF: GET

Settable for PUT and POST operation: NO

next-stage, expire, publish, submit-for-review

Purpose: Move item to next stage in the workflow.

Supported Operation to the Link HREF: POST

Settable for PUT and POST operation: NO

parent

Purpose: The parent of the item.

Supported Operation to the Link HREF: GET

Settable for PUT and POST operation: YES, overrides the library if both specified

CF06 **presentation-override**

Purpose: The presentation template set as the presentation override on the item that is created from the authoring template.

Supported Operation to the Link HREF: GET

Settable for PUT and POST operation:

preview

Purpose: Used to preview content items and site areas.

Supported Operation to the Link HREF: GET

Settable for PUT and POST operation: NO

previous-stage, withdraw-from-review

Purpose: Move item to previous stage in the workflow.

Supported Operation to the Link HREF: POST

Settable for PUT and POST operation: GET

project

Purpose: The project that the item belongs to, if it is a draft in a project.

Supported Operation to the Link HREF: GET

Settable for PUT and POST operation: YES

CF06 **project-items**

Purpose: List the items associated with a project.

Supported Operation to the Link HREF: GET

Settable for PUT and POST operation: NO

CF06 **prototype**

Purpose: The default content properties of an authoring template.

Supported Operation to the Link HREF: GET

Settable for PUT and POST operation: YES

CF06 **prototype-properties**

Purpose: The default properties of an authoring template.

Supported Operation to the Link HREF: GET

Settable for PUT and POST operation: YES

reject

Purpose: Decline the item in current stage and move it back to previous stage in the workflow.

Supported Operation to the Link HREF: POST

Settable for PUT and POST operation: NO

restart

Purpose: Restart the workflow for the item and move to the draft stage.

Supported Operation to the Link HREF: POST

Settable for PUT and POST operation: NO

CF06 **self**

Purpose: Read-only link back to item itself.

Supported Operation to the Link HREF: GET

Settable for PUT and POST operation: NO

sitearea-template

Purpose: The site area template of the item.

Supported Operation to the Link HREF: GET

Settable for PUT and POST operation: YES

versioned-item

Purpose: The individual version of the item.

Supported Operation to the Link HREF: GET

Settable for PUT and POST operation: NO

versions

Purpose: All versions of the item.

Supported Operation to the Link HREF: GET

Settable for PUT and POST operation: NO

workflow-stage

Purpose: The workflow stage of the item

Supported Operation to the Link HREF: GET

Settable for PUT and POST operation: NO

workflow

Purpose: The workflow of the item.

Supported Operation to the Link HREF: GET

Settable for PUT and POST operation: YES

REST Item Types

These item types are supported by the Web Content Manager REST service.

Level of support

Basic Basic support means that the create, read, update operations operate only on those fields that are common to all items. This includes fields such as name, title, description, text providers, and workflow.

Item Specific
Item Specific support means that the item type has support for fields beyond those fields common to all item types. For example, the element on a content item can be accessed, or the HTML element in an HTML component can be modified. Not all fields in each item type are handled.

Table 496. Item support levels

How to display data from external sources

You display data from external sources by using the same methods as you would when you create a website.

Displaying data

You can display content from external sources by using standard Java tag libraries and a JSP element. Java code that uses standard Java APIs or tag libraries can be used to display and format data from databases, LDAP repositories, or send email.

If you use a rendering portlet to display web content on a portal page, you can also use other IBM WebSphere Portal Express portlets on the same portal page to display data.

Web page aggregation

Content from external websites and IBM Web Content Manager can be displayed together on a portal page by using standard WebSphere Portal portlets for displaying content from external websites. Refer to the web Page portlet and Web Clipping portlet sections of this IBM Knowledge Center for information about creating and configuring these portlets.

This function is only available when you display content in WebSphere Portal. These portlets are not accessible from the Web Content Manager servlet, though standard Java API or tag libraries can be used with a JSP element to achieve the same result.

Instrumenting web content for Active Site Analytics

You can collect information from web content for Active Site Analytics.

About this task

For collecting information about the web content that the portal renders, use the following microformat tags:

asa.wcm.content_item.path
Use this tag to identify the content path. The tag contains the unique identifier of the content item in IBM Web Content Manager.

asa.wcm.content_item.title
Use this tag to identify the content title. The tag contains the display title of the content item.

asa.wcm.content_item.authors
Use this tag to identify the authors of the content. The tag contains one of the authors of the content item.

asa.wcm.content_item.lastmodified
Use this tag to identify the last modification date of the content. The tag contains the date on which the content item was last modified.

Web Content Manager provides the following methods for collecting information about web content:

- Using the analytics data rendering plug-in tag.

- Using the sample HTML component for Active Site Analytics that is provided with Web Content Manager.
- Using the default microformat tags that are supported by web content viewers.

"Using the sample HTML component for Active Site Analytics"
The HTML – Analytics component is a sample HTML component that you can use to instrument web content for Active Site Analytics. You can use this component to insert the supported microformat tags for web content into your content or presentation templates.

"Enabling default microformat support in Web Content Viewers"
Web Content Viewers provide support for Active Site Analytics microformats by default. You can use this support to inject microformats into your content design or presentation templates.

Related tasks:

"Setting up site analysis for the Web Content Viewer" on page 411
To track usage data for the Web Content Viewer, you can configure the portal for site analysis logging for the Web Content Viewer.

Related information:

Using the analytics data rendering plug-in tag

Using the sample HTML component for Active Site Analytics

The HTML – Analytics component is a sample HTML component that you can use to instrument web content for Active Site Analytics. You can use this component to insert the supported microformat tags for web content into your content or presentation templates.

About this task

The HTML – Analytics component is located in the Web Content Templates library. You can adapt this sample to the requirements of your aggregator and Active Site Analytics setup. By default, the sample inserts the following microformat tags:

- asa.wcm.content_item.path
- asa.wcm.content_item.title
- asa.wcm.content_item.id
- asa.wcm.content_item.authors
- asa.wcm.content_item.lastmodified

Procedure

Insert the HTML – Analytics component in your content or presentation template design by adding the [Component] tag.
For example:

```
[Component name="Web Content Templates/HTML - Analytics"]
```

Enabling default microformat support in Web Content Viewers

Web Content Viewers provide support for Active Site Analytics microformats by default. You can use this support to inject microformats into your content design or presentation templates.

About this task

The viewer supports the following microformat tags:

- asa.wcm.content_item.title

- asa.wcm.content_item.path

Procedure

Edit the portlet preferences for the Web Content Viewer, and set the value of the **WCM_ENABLE_ASA_TAGS** preference to `true`. By default, the preference value is `false`.

Note: The default viewer has the unique name of ibm.portal.Web.Content.Viewer.Jsr286.

- To use the administration user interface to set the preference for all instances of the viewer, complete these steps:
  1. Click the **Administration menu** icon. Then, click **Portlet Management** > **Portlets**..
  2. Locate the Web Content Viewer from the list.
  3. Click the **Configure portlet** icon, and set the preference value.
- To set the preference for all instances or only a single instance of the viewer, you can also use the XML configuration interface.

Results

After you set the preference, the viewer automatically inserts the microformat tags into each piece of content that it renders.

Java messaging services for web content

Web Content Manager supports for the notification of events such as item state changes, or services starting and stopping. These notifications can be delivered as messages to the Java messaging service.

About this task

The event classes can be delivered as messages to the Java messaging service:

Item events:

- Item created
- Item updated
- Item moved
- Item deleted

Syndication events:

- Starting
- Stopping

Pre-render events:

- Starting
- Stopping

Procedure

1. Configure the messaging services parameters in the `WCM MessagingService` service by using the WebSphere Integrated Solutions Console.
2. Run the following command from the *wp_profile_root*`/ConfigEngine` directory:

Windows

```
ConfigEngine.bat create-wcm-jms-resources
-DPortalAdminId=username -DPortalAdminPwd=password
-DuseRemoteEndPoints=true/false
```

Linux

```
./ConfigEngine.sh create-wcm-jms-resources
-DPortalAdminId=username -DPortalAdminPwd=password
-DuseRemoteEndPoints=true/false
```

IBM i

```
ConfigEngine.sh create-wcm-jms-resources -DPortalAdminId=username
-DPortalAdminPwd=password -DuseRemoteEndPoints=true/false
```

Note: An administrator user name and password is not needed if you specify the portal administrator user name and password by using the `PortalAdminId` and `PortalAdminPwd` settings in the `wkplc.properties` file.

Note: The `-DuseRemoteEndPoints` parameter is only used on clustered systems. If set to true, the task uses all node end points on the current setup. If set to "false", the task uses the end points of the current node.

3. Restart WebSphere Portal.

Results

The `create-wcm-jms-resources` command creates a topic space that is named `IWK.Topic.Space` and the topics `IWKTopics_Items`, `IWKTopics_PreRender`, and `IWKTopics_Syndication` in that space for the different events.

The messages are sent with no expiration time and need to be consumed, otherwise the queue fills up.

Note: There is a default limit of 50.000 messages per queue topic. When that limit is reached messages cannot be stored anymore in the queue and exceptions are logged in the Portal server log file.

For information about the default implementation of the WebSphere Application Server JMS implementation and choices of message providers, read Types of messaging providers.

Related tasks:

"Setting service configuration properties" on page 283
IBM WebSphere Portal Express comprises a framework of services to accommodate the different scenarios that portals need to address. Services are available for both WebSphere Portal Express and IBM Web Content Manager. You can configure some of these services.

"Web Content Manager service configuration" on page 353
Configuration services for IBM Web Content Manager contain settings for the general operation of the web content system, including settings for messaging, pre-rendering, and searching.

Developing basic PAA file applications

Solution developers can create their own Portal Application Archive (PAA) files. The developers can then use the configuration wizard to add on their applications to their IBM WebSphere Portal Express environment.

About this task

Review the following requirements before you create your own Portal Application Archive (PAA) file:

"Checking server dependency"
When you install a Portal Application Archive (PAA) file, you must verify that the file is compatible with the current version of IBM WebSphere Portal Express.

"PAA dependencies for deployment and removal" on page 3405
The deployment and removal of a Portal Application Archive (PAA) file might depend on deployment of other PAA applications. You can specify the PAA dependencies for a PAA file in the assembly level `sdd.xml` file.

"Create a Portal Application Archive (PAA) file" on page 3407
Use the Portal Application Archive (PAA) file format to install applications with the Solution Installer. The PAA file is a customized compressed file that contains an application. This application is installed on IBM WebSphere Portal Express with the ConfigEngine.

Related concepts:

"Install and uninstall add-ons using the Configuration Wizard" on page 212
You can install add-on functionality to your WebSphere Portal Express with the solution installer through the Configuration Wizard. The add-ons that are accepted by the configuration options are `.paa` files. For more information, see the solution installer documentation.

Related tasks:

"Accessing the Configuration Wizard" on page 235
The home page of the Configuration Wizard provides access to common configuration tasks. Supported tasks include setting up a stand-alone server, setting up a cluster, transferring from Apache Derby to another supported database, migrating your server, installing add-ons, and more.

Checking server dependency

When you install a Portal Application Archive (PAA) file, you must verify that the file is compatible with the current version of IBM WebSphere Portal Express.

About this task

The Solution Installer uses the following two methods to check for dependencies:

Dependency checking for PAA files
The Solution Installer can check dependencies for the PAA file. To define the dependencies for a PAA file, you must edit the assembly level `sdd.xml` file in the PAA directory. Open the `sdd.xml` file and search for the `<rootIU>` tag. Add the `<serverVersionDependency>` tag to the `<rootIU>` tag with the following attributes:

- **`name`**: This attribute must be set to `PortalServer`
- **`lowerVersion`**: This attribute is optional. Only one WebSphere Portal Express version value is acceptable for this attribute.
- **`higherVersion`**: This attribute is optional. Only one WebSphere Portal Express version value is acceptable for this attribute.
- **`versions`**: This attribute is optional. You can add multiple WebSphere Portal Express version values for this attribute as a comma-separated list.

For example, you might add the following information to your sdd.xml file:

```
<serverVersionDependency name="PortalServer" lowerVersion="6.0.0.0"
                         higherVersion="8.5.0.0" versions="7.0.0.1,7.0.0.2" />
```

If you want to add dependencies for a specific fix level, you must add the following attributes to the <server> subelement within the <serverVersionDependency> element:

- **version**: This value is the version of WebSphere Portal Express where you want to set the level restriction.
- **fixlevel**: This attribute is optional. This attribute is compared against the current installation fix level to determine any dependencies. If the attribute is not set, then it is ignored.
- **lower**: This attribute is optional. Set this value to true if the **fixlevel** is the lowest version for the current server.
- **higher**: This attribute is optional. Set this value to true if the **fixlevel** is the highest version for the current server.

For example, you might add the following information to your sdd.xml file:

```
<serverVersionDependency name="PortalServer" lowerVersion=""
                         higherVersion="" versions="" >
<server version="8.5.0.0" fixlevel="CF02" lower="true"
     higher="false" />
</serverVersionDependency>
```

The Solution Installer uses the following rules to determine whether a PAA file is compatible with the current WebSphere Portal Express version:

- The Solution Installer assumes that the file is compatible in the following situations:
  - If the <serverVersionDependency> tag is not found in the assembly level sdd.xml file
  - If the <serverVersionDependency> tag exists but has no attributes that are defined
- The Solution Installer installs the PAA file if the following information is true:
  - The **lowerVersion** attribute is set and the value is equal to or greater than the current version of WebSphere Portal Express.
  - The **higherVersion** attribute is set and the current version of WebSphere Portal Express is less than or equal to its value.
- If the **versions** attribute is set, the Solution Installer installs the PAA file if the current WebSphere Portal Express matches one of the values.
- If a <server> element is included, the PAA file is installed if the following information is true:
  - If **version** and **fixlevel** are equal to the current server information
  - If **lower** is true, any fix pack level that is greater than **fixlevel**
  - If **higher** is true, any fix pack level that is less than or equal to **fixlevel**

Black list to block deploying PAA files that must not be deployed

The Solution Installer checks the blacklist.txt file in the /WebSphere/PortalServer/solutioninstaller/wp.si directory. The blacklist.txt file contains a list of PAA files that WebSphere Portal Express cannot deploy. The format for the blacklist.txt file is *assemblyname*: *version_number*. Multiple versions are allowed as a semicolon-separated list; for example: *assemblyname*: *version_number1*;*version_number2*.

When you install a PAA file, the Solution Installer reads the assembly name and version from the assembly level `sdd.xml` file. The Solution Installer then looks for the matching information in the `blacklist.txt` file. If the Solution Installer finds a match in the `blacklist.txt` file, the PAA file is not installed.

PAA dependencies for deployment and removal

The deployment and removal of a Portal Application Archive (PAA) file might depend on deployment of other PAA applications. You can specify the PAA dependencies for a PAA file in the assembly level `sdd.xml` file.

Add PAA dependencies for deploying a PAA file

The deployment of a PAA file might depend on deployment of other PAA applications. You can specify the PAA dependencies for deploying a PAA file in the assembly level `sdd.xml` file.

To define the PAA dependencies for a PAA file, you must edit the assembly level `sdd.xml` file in the PAA directory. Open the `sdd.xml` file and search for the `<rootIU>` tag. Add the `<paaDependencies>` tag to the `<rootIU>` tag. Also, add the `<paaDependency>` tag for each PAA dependency in the `<paaDependencies>` tag. The `<paaDependency>` tag has the following attributes:

`name`
This attribute is required. Set the value to the name of the PAA dependency.

`lowerVersion`
This attribute is optional. Only one PAA dependency version value is acceptable for this attribute.

`higherVersion`
This attribute is optional. Only one PAA dependency version value is acceptable for this attribute.

`versions`
This attribute is optional. You can add multiple PAA dependency version value for this attribute as a comma-separated list.

You can specify more than one `<paaDependency>` tag in the `<paaDependencies>` tag. For example, you might add the following information to your `sdd.xml` file:

```
<paaDependencies>
 <paaDependency name="Dependency1" lowerVersion="8.0.0.0" higherVersion="8.0.0.1" versions="8.5.0.
 <paaDependency name="Dependency2" lowerVersion="8.0.0.0" higherVersion="8.0.0.1" versions="8.5.0.
</paaDependencies>
```

All the PAA dependencies that are specified in the `<paaDependencies>` tag must be deployed on the Portal server. The version of each PAA dependency must match the values that are specified in `<paaDependencies>` tag. Then, the PAA file can be deployed into the Portal server.

The Solution Installer uses the following rules to determine whether a PAA file can be deployed:

- The Solution Installer assumes the PAA dependency requirement is satisfied in the following situations:
  - If the `<paaDependency>` tag is not found in the assembly level `sdd.xml` file
  - If the `<paaDependency>` tag exists but has no attributes that are defined

- All the PAA dependencies that are specified in the <paaDependencies> tag satisfy the requirement. The requirement is, for each of the PAA dependencies that are specified in a <paaDependency> tag, at least one of the following is true:
  - The PAA dependency is deployed. The **lowerVersion** attribute is set and the value is equal to or greater than the current version of PAA dependency.
  - The PAA dependency is deployed. The **higherVersion** attribute is set and the current version of PAA dependency is less than or equal to its value.
  - The PAA dependency is deployed. The **versions** attribute is set and the current version of PAA dependency matches one of the values.

Add PAA dependencies for removing a PAA file

The removal of a PAA file might depend on removal of other PAA applications. You can specify the PAA dependency for removing a PAA file in the assembly level sdd.xml file.

To define the PAA dependencies for a PAA file, you must edit the assembly level sdd.xml file in the PAA directory. Open the sdd.xml file and search for the <rootIU> tag. Add the <paaDependencies> tag to the <rootIU> tag. And add <removePaaDependency> tag for each PAA dependency in the <paaDependencies> tag. The <removePaaDependency> tag has the following attributes:

name
This attribute is required. Set the value to the name of the PAA dependency.

lowerVersion
This attribute is optional. Only one PAA dependency version value is acceptable for this attribute.

higherVersion
This attribute is optional. Only one PAA dependency version value is acceptable for this attribute.

versions
This attribute is optional. You can add multiple PAA dependency version value for this attribute as a comma-separated list.

You can specify more than one <paaDependency> tag in the <paaDependencies> tag. For example, you might add the following information to your sdd.xml file:

```
<paaDependencies>
 <removePaaDependency name="Dependency1" lowerVersion="8.0.0.0" higherVersion="8.0.0.1" versions="8.5
 <removePaaDependency name="Dependency2" lowerVersion="8.0.0.0" higherVersion="8.0.0.1" versions="8.5
</paaDependencies>
```

The Solution Installer uses the following rules to determine whether a PAA file can be removed:

- The Solution Installer assumes the PAA dependency requirement is satisfied in the following situations:
  - If the <removePaaDependency> tag is not found in the assembly level sdd.xml file
  - If the <removePaaDependency> tag exists but has no attributes that are defined
- All the PAA dependencies satisfy the requirement. The requirement is, for each of the PAA dependencies that are specified in a <removePaaDependency> tag, the PAA dependency is not deployed, or not any of the following is true:
  - The PAA dependency is deployed. The **lowerVersion** attribute is set and the value is less than the current version of PAA dependency.

- The PAA dependency is deployed. The **higherVersion** attribute is set and the value is greater than the current version of PAA dependency.
- The PAA dependency is deployed. The **versions** attribute is set and the current version of PAA dependency matches any one of the values.

Create a Portal Application Archive (PAA) file

Use the Portal Application Archive (PAA) file format to install applications with the Solution Installer. The PAA file is a customized compressed file that contains an application. This application is installed on IBM WebSphere Portal Express with the ConfigEngine.

Many steps might be required to install and configure the individual resources of an application to IBM WebSphere Portal Express. This fact is especially true when you deploy applications with many resource types. The Solution Installer automates many of these deployment tasks. The Solution Installer uses resources that are contained in a Portal Application Archive (PAA) file. The PAA file is a ZIP compression file that has a specific directory structure. The PAA format informs Solution Installer how to install the application and provides the installable artifacts.

Currently, the Solution Installer focus is on installing applications to WebSphere Portal Express. Potentially in the future, IBM WebSphere Application Server solutions might be supported. The Solution Installer relies on the ConfigEngine, which is not specific to WebSphere Portal Express.

The PAA format can be employed to handle deployments that range from applications with only a few configuration steps to large-scale enterprise portal solutions. The directory structure of the PAA file is important to Solution Installer when you determine how to install a specific artifact, for example, how to handle shared library files. In addition, the software definition descriptor (`sdd.xml`) files also play a significant role in determining the installation steps. All required extension points for installation must be specified in an `sdd.xml` file local to the component. The component level `sdd.xml` file can now be generated automatically during the installation phase.

The PAA format can reduce the work that is required to create a deployable solution. Many deployment tasks can use a default configuration that is found in the Solution Installer. For complex applications, extra work is required to provide custom installation features. Using the PAA format with the Solution Installer reduces the production time for creating a deployable solution for your application.

A number of sample files that demonstrate the overall structure and usage of the PAA file format are included in the *PortalServer_root*`/doc/paa-samples` directory. These examples act as reference material for the remainder of the file specification documentation.

"PAA file structure overview" on page 3408
Each PAA file is a structured ZIP compression file. Because the Solution installer uses Ant tasks to expand or parse the PAA file, it needs to be a ZIP compression file that can be decoded by the `java.util.zip` class.

"Installation tasks" on page 3417
Solution installer supports the auto generation of deployment tasks for specific resource types. The creation of these tasks occurs during the installation or registration phase for the PAA file with the Solution Installer and the ConfigEngine.

"Order of installation of scripts and artifacts" on page 3419
Often the order that scripts are run or artifacts that are deployed is important for the success of the installation. This information is both true for artifacts or scripts in a single component and the order in which scripts contained in multiple components are installed.

"The sdd.xml file" on page 3420
The sdd.xml files perform a number of different roles in the PAA file structure. They allow the developer to control, with ConfigEngine extension points, how an application is installed. They also inform the ConfigEngine of the type of installation to be processed. It also determines, in terms of the ConfigEngine, where the deployable files are stored after registration with the ConfigEngine.

"Property files" on page 3427
Two different types of properties are contained within a PAA distribution. They can be classified as being either user editable that is requiring user input, for example a database URL, or as developer-provided settings required for a component to function. However, for user convenience, a separation between user properties from those settings that are supplied by the developer is advised.

"Database properties for the Solution Installer" on page 3428
Some Portal Application Archive (PAA) files require access to an external database. The database properties are stored in either the assemblyName.properties file for the assembly or in the componentName.properties file of the component requiring database support.

"Virtual portals in the PAA file" on page 3431
There are many situations where a user might want to install the applications that are contained in a Portal Application Archive (PAA) file directly to a virtual portal.

PAA file structure overview

Each PAA file is a structured ZIP compression file. Because the Solution installer uses Ant tasks to expand or parse the PAA file, it needs to be a ZIP compression file that can be decoded by the java.util.zip class.

At the top level of a PAA file is the root directory. There are no restrictions on the name of this directory; however, use something that is unique and does not clash with other registered PAA files or assemblies. There must be only one root directory in a PAA file. The name of this directory is significant because it is the reference name for your PAA content. It is the same value as the assemblyName when you create the assembly level sdd.xml file. Read "The sdd.xml file" on page 3420 for information.

You can find a sample top-level directory in the *PortalServer_root*/doc/paa-samples/sample1.paa file. The root directory contains the documentation and components directories and an sdd.xml file.

The sdd.xml file has the following roles:

- It informs the ConfigEngine about the assembly of components.
- It provides the ConfigEngine with the list of components and their locations within the directory structure.
- It points to each component sdd.xml file so that the installation function can process the installation of the individual components.

  "Documentation directory" on page 3409
  Place all documents and ID-related artifacts for the application in the documentation directory.

"Components directory"
The components directory and its subdirectories in the PAA file archive are where all deployable artifacts must be stored. If you examine the content of the components directory in the *PortalServer_root*/doc/paa-samples/Sample1.paa file, you see one component, sample1. There is always at least one component that is contained in a PAA file. However, there is no limit on the number of extra components that you can include.

Documentation directory:

Place all documents and ID-related artifacts for the application in the documentation directory.

The PAA package developer must organize the documentation directory per the relationship between the documents and the flow of content information. The Solution Installer copies the content to the correct location in the expanded archive under the PAA offering directory; for example, *wp_profile_root*\paa\sample_paa\documentation*.*.

Note: The documentation directory is the only recommended place for documentation that is related to the application. There is no provision within the PAA format to provide documentation at the component level.

Components directory:

The components directory and its subdirectories in the PAA file archive are where all deployable artifacts must be stored. If you examine the content of the components directory in the *PortalServer_root*/doc/paa-samples/Sample1.paa file, you see one component, sample1. There is always at least one component that is contained in a PAA file. However, there is no limit on the number of extra components that you can include.

The number of available components depends on how you want to organize your deployable artifacts. Potentially all the deployable artifacts can be stored in a single component. However, if there are multiple stand-alone applications to be stored in the PAA file, create a component for each application. Also, if you want to be able to reuse components across PAA file distributions, then it makes sense to separate artifacts into multiple components.

There is no limit on the type of artifacts that can be contained within a specific component. There is a limitation on where the artifacts can be placed within the component directory sub tree structure.

A component can include artifacts and configuration details for an entire application. It can also contain only artifacts that relate to a certain part of the application. For example, you might include all your theme-related artifacts in one component, and your XML access scripts to create the pages for your site in another. The Solution Installer is not concerned with the approach selected. It processes each component based on the dependencies that are listed in the sdd.xml file. However, it might make sense to have some separation to handle reusability of components.

Using the *PortalServer_root*/doc/paa-samples/sample1.paa example, open the components/Sample1 directory. The following directories must be present with the component level sdd.xml file:

config This directory contains includes and templates directories. Both directories

are important if you plan to add custom tasks to aid the installation or configuration of the component artifacts.

includes
This directory is where the ConfigEngine looks for tasks that implement the extension points that are listed in the component level `sdd.xml` file. The name of the xml file that contains the Ant tasks is not hardcoded, so the ConfigEngine automatically loads any XML files that are found in this directory. The Ant tasks do not have to be stored in a single file. They can be spread over multiple files that are all picked up by the ConfigEngine.

templates
This directory is where extra script files are stored for configuration tasks. For example, if you deploy a WAR file and want to run portlet configuration tasks, you can place the XML scripts in this directory. Copy the war file to the `profile_dir/installableApps` directory with your custom task implementation and reference this location in your XMLAccess script.

Note: The Solution Installer does not automatically run the scripts that are stored in this location. Instead, the custom tasks are responsible for calling these scripts.

content
This directory is where you can store IBM Web Content Manager libraries and other content related artifacts for import. The `component/content` directory contains the following subdirectories:

jcr This directory contains JCR-related artifacts and a directory structure of nodes. Each entry is either a file or a directory, with associated metadata (title, last modified, permissions). Content that is found in this directory must be installed with custom code. The Solution Installer does not auto-generate any tasks to handle resources that are found in this location.

jsp Place any JSP files that you want to package as part of your application in this directory. Usually, the custom code handles resources in this location. However, Web Content Manager related JSP files are treated as a special case. Place such files in a sub folder that is called `wcm` under the `jsp` directory, for example, `jsp/wcm`. The Solution Installer copies all files and folders to the relevant location on the server: `${WasUserHome}/installedApps/${NodeName}/WCM_EXTENSION.ear/wp.wcmextension.war/jsp/wcm/content`.

Note: The Solution Installer does not run any default tasks to handle other JSP content, excluding those tasks that are found in the `jsp/wcm` directory. A developer must provide a custom task to ensure that this content is copied to the correct location.

wcm This directory contains Web Content Manager libraries. Each subdirectory of the `wcm` directory represents a separate library. These libraries are a specialized form of JCR artifacts. Web Content Manager libraries are separated into their own directory due to the process required to install them with the default function. For

example, if you have a library that is called lib1, you might place the content in the `content/wcm/lib1` directory; for example, `content/wcm/lib1/554ee7f5`.

Multiple Web Content Manager libraries that are contained within a single subdirectory are supported. However, it places a limitation on the Solution Installer's ability to delete and replace libraries. That is, the task that Solution installer relies upon to import takes everything within a supplied subdirectory and attempts to import to the server. Therefore, to be able to successfully replace all the libraries in the directory, they must all be marked for deletion. Where libraries are allocated to their own subdirectory, they can be replaced on the system individually when there are no interlibrary dependencies. Another existing library does not have a dependency on items in the library that is selected for deletion.

webdav This directory and its sub tree structure contain artifacts that must be uploaded to the WebDAV file store. There are four possible subdirectories. Each one is named to reflect the type of function that is provided in the files supplied. The following options are available:

iwidgets
Place `.zip` files that contain iWidgets that must be uploaded to the WebDAV file store and registered with WebSphere Portal Express. The Solution Installer automatically uploads any `.zip` files that are found in this directory to the `dav:fs-type1/iwidgets/` directory. Extra work is necessary to have the iWidget definitions that are registered with WebSphere Portal Express. The installer must know about the widget definition files to register with WebSphere Portal. A properties file called `iwidgets.properties` must be included in the `iwidgets` directory in the PAA. The properties are generated with the `.zip` file name that contains the definition file as the name of the property. It also supplies a comma-separated list of definition files that are contained in this file as the value.

layout-templates
Place `.zip` files that contain layout-templates in this directory. When such files are detected by the installer, code is generated to automatically upload such content to the `dav:fs-type1/layout-templates/` directory in the WebDAV file store.

skins Place any `.zip` files that contains skins not specific to a theme in this directory. The content is automatically uploaded to the `dav:fs-type1/skins/` directory in the WebDAV file store.

themes Place `.zip` files that contain static theme content in this directory. They are automatically uploaded to the `dav:fs-type1/themes/` directory in the WebDAV file store.

Note: If your theme contains dynamic content, include them in a WAR file that is deployed at run time.

The Solution Installer uploads WebDAV content with the `dav:fs-type1/*.* WebDAV` entry point. The themes and skins are

not automatically made available through the themelist or skinlist entry points. To ensure that they are available through the administration pages, an XMLAccess script must be created to register the resources with WebSphere Portal Express. The context root, where the content of the individual `.zip` files is installed, is set in the following manner:

- The root directory is contained within the `.zip` file. For example, all the content is enclosed within a directory. Then, it is appended to the `TargetURI`. For example, a `.zip` file in the `componentName/content/webdav/themes` directory with a root directory of sample would result in `TargetURI 'dav:fs-type1/themes/sample/'`.
- No root directory is contained in the `.zip` file. All the items are in the parent level. Then, the name of the `.zip` file minus the '`.zip`' suffix is used. For example, a `.zip` file with the name `sample1.zip` would result in `TargetURI 'dav:fs-type1/themes/sample1/'`. The upload task for the `.zip` files to the WebDAV file system is set to replace the current directory with the new content. However, the Solution Installer alters this function to merge the content by default instead. When the **`UpdateMode`** parameter is set to `replace`, which is the default, the upload replaces all content found at the `TargetURI`. For example, if you upload a `.zip` file to `dav:fs-type1/themes/`, it does not replace the equivalent content that is stored in the directory. It replaces everything in this directory. Therefore, it was decided that it would be better to have the content that is set to merge with the existing content as the default behavior. If you do require **`UpdateMode`** set to `replace`, then you must add a properties file to the directory. For example, if you want to replace all the themes, you would place the `webdav.properties` file in the `componentName/content/webdav/themes` directory. There is just one property available in this file: `webdav.replace=list of .zip files`. The value of the `webdav.replace` property is a comma-separated list of files that tells the Solution Installer which files must be uploaded.

`xmlaccess`
Stores any component level XML access scripts. This directory differs from the `component/config/templates` directory that stores scripts to be called by custom Ant tasks. Any scripts that must be run by default, are placed in the `content/xmlaccess` directory. This directory has two subdirectories to aid in the distinction between installation and uninstall scripts. The scripts that are required for installation are in the `/content/xmlaccess/install` directory and the uninstall scripts are placed in the `/content/xmlaccess/uninstall` directory. The type of scripts in the `component/content/xmlaccess` directory can include scripts to register a theme or create pages and assign portlets. Other examples are scripts to create a set of users and groups or a credential slot in the WebSphere Portal Express credential vault. All the scripts that are found by Solution Installer in these directories are automatically run.

`database`
This directory contains any database scripts for creating tables and pre-populating the tables with any relevant data. Solution Installer

can generate Ant tasks to create the relevant configuration settings on the underlying WebSphere Application Server. For details of the required properties, go to "Database properties for the Solution Installer" on page 3428.

There are two directories in the `database` directory in the PAA file: `install` and `uninstall`. The PAA file developer must place the following scripts in these directories:

- `.ddl` and `.sql` scripts to create and populate tables in the `install` directory
- `.ddl` and `.sql` scripts for dropping tables in the `uninstall` directory

Where multiple scripts are required, include an `order.properties` file in the appropriate directory to specify the correct order for installation.

If you are providing setup scripts for different database types in a single PAA file, there is an extra step. Run this step during the PAA creation phase. For each database type, a properties file must be added to the `components/componentName/content/database/install` directory.

- For Derby scripts, call the `scripts.derby.properties` file.
- For DB2 scripts, call the `scripts.db2.properties` file.
- For Oracle scripts, call the `scripts.oracle.properties` file.
- For SQL Server scripts, call the `scripts.sql.properties` file.

Add a comma-separated list of scripts to the properties file in the order that they must be run for a specific database type. The Solution Installer determines at run time, which set of scripts to run for the database type requested.

pzn PZN-related artifacts, such as JAR files that contain business rules and personalization `.nodes` files are in this directory. The Solution installer automatically copies any JAR files that contain custom Java classes to the correct location under the `profile` directory and upload any `.nodes` files to the server.

installableApps

The `installableApps` directory is where any artifacts that must be installed to WebSphere Portal Express or directly to the application server are to be stored. Solution Installer copies the relevant files across to the *wp_profile_root*`/installableApps` directory automatically when the default implementation tasks are used. The artifacts are stored in the PAA file in subdirectories of the `installableApps` directory. The subdirectories are based on their resource type to allow for default code to be easily generated to manage installation and deployment of artifacts. However, when the artifacts are copied to the *wp_profile_root*`/installableApps` directory, it is just the content of the subdirectories that is copied and not the directories themselves. The following is a list of currently supported resource sub directories:

ear Contains any EAR files that must be deployed to the application server. Wrap `.war` files that do not contain any portlets and must be installed to the application server in an EAR file. The reason for this is that the default scripts used to deploy artifacts require specific information to run the installation. For example, the display name and context root for the application. This information

can be found in the application.xml file of an EAR file. The context root information would not be available with just a WAR file. An example of a WAR file that must be wrapped in this way is a theme.war file. If you are providing a custom Ant deployment script, it is unnecessary because you can provide the required information in the script or a properties file.

EAR files are deployed automatically to the server. However, if a WAR file that contains a portlet is wrapped inside of an EAR file, the developer must supply an extra script to register the portlets with WebSphere Portal Express. It is the responsibility of the developer to ensure that the portlets are registered in the correct manner.

portlets

Place any WAR files that contain JSR portlets into the portlets directory. IBM legacy portlets are not handled automatically by the installer. They require custom code to install and must not be placed in this directory. The reason for separating these WAR files from those files that contain servlets or other application types is due to the installation method required. Those files that contain JSR portlets are typically installed and deployed with an XML access script. Those files that need to be installed directly to the application server are deployed with a ConfigEngine Ant task or with a wsadmin script. The Solution Installer can then read the portlets directory and install the WAR files automatically and does not need to worry that it might encounter a non-portlet WAR. However, if there is extra configuration setup for a portlet, then overwrite the default installation task with an Ant task with a custom XMLAccess script to do the installation. Add a <SCU> element to the sdd.xml file for the **deploy-portlets-applySIFeaturePack** extension point and add an Ant task that implements this extension point in the config/includes directory. This Ant task must call the **XMLAccess** task to run any supplied XMLAccess script against the portal server.

The automatic installation uses the unique ID from the <portlet-app> element that is found in the *warfile*/WEB-INF/portlet.xml file, and the location of the WAR file itself to enable the deployment. If the unique ID is not available, the name of the WAR file is used. The WAR file is automatically copied over to the *wp_profile_root*/installableApps directory. The following is a sample XMLAccess script that shows how the information is used to drive the installation.

```
<?xml version="1.0" encoding="UTF-8"?>
<request xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.0.xsd" type="update"
  create-oids="true">
  <portal action="locate">
   <web-app action="update" active="true"
    uid="portletXmlUniqueId.webmod">
    <url>file:///$profile_dir$/installableApps/warfile.war</url>
   </web-app>
  </portal>
</request>
```

WAR files that are placed at this location also have unique names that are automatically generated for the individual portlets during installation. The generation of unique name values is based on the

scheme *componentName.portletName*. The following is a sample XMLAccess script that shows how the unique name values are specified:

```
<?xml version="1.0" encoding="UTF-8"?>
<request xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.0.xsd" type="update" create-oids
  <portal action="locate">
   <web-app action="locate" domain="rel" objectid="WebAppID.webmod"
uid="WebAppId.webmod">
   <portlet-app action="update" domain="rel" name="PortletAppId"
uid="PortletAppId">
   <portlet action="update" domain="rel" name="PortletName"
uniquename="componentName.PortletName"/>
   </portlet-app>
  </web-app>
 </portal>
</request>
```

Prefix the component name to the WAR file name with the *componentName.WARname*.war scheme. Although not essential, it allows the user to easily track which WAR files were installed with the Solution Installer.

war This directory contains any WAR files that the developer does not want to automatically install. The developer extends the extension point with a custom Ant task to install the artifacts. An example is if the WAR file contains legacy IBM portlets. Alternatively, the WAR file does not contain any portlets and the developer does not want to wrap it in an EAR. Also, extra customization steps might be required for the configuration of the deployed artifacts. Therefore, a custom script is necessary. The installer generally ignores this directory apart from copying the files to the *wp_profile_root*/installableApps directory and then starting any custom code that is provided to handle these artifacts.

zip This directory contains any .zip file content that you must include for a component. For example, you might have some artifacts that must be copied and installed to a server that currently is not supported by Solution Installer. Solution Installer does not automatically process the content of this directory. The individual files remain in their compressed state after the PAA file is extracted. Instead, any processing of these files is completed by either custom Ant tasks that are provided by the developer or through manual steps.

shared When you deploy an application to WebSphere Portal Express, often extra shared libraries are required for the application to function correctly. These libraries can be at different levels of scope for the application. If stored in the WAR file itself, then only classes within that WAR file are able to access the library files. The second situation is when a set of libraries are solution-specific. That is, the classes in the shared library are available only to the overall solution. The WAR file option is not appropriate as it might mean a number of separate applications that work together as a larger solution, all requiring access to the library. The third level of scope is global, meaning that many applications on the server can access these classes. The first situation where the library JAR files are stored in the WAR file is out of scope for this document. However, the ability to handle the other two situations is provided by the Solution Installer.

For globally available JAR files, place the JAR files into either the component/shared/app or component/shared/ext directories. These files are not copied to the equivalent directories under the *PortalServer_root* directory. Instead, a task is run to register all the JAR files found in the shared/app and shared/ext directories of the components. When objects are found in these directories, they are registered directly with a Solution Installer-specific set of shared libraries that are inside the profile. This action makes the libraries profile-specific thus different versions of the same files might be installed to different profiles.

JAR files that are registered in the component/shared/app directory are registered in the Solution Installer-specific shared.app.jar file. Similarly, for the .jar files in componentName/shared/ext directory, these files are registered with a profile-specific shared.ext.jar file. These files can be found under the *wp_profile_root*/PortalServer/solutionInstaller directory sub tree. The specific library 'SiSharedLib' is registered at the cell or node level of the profile. A reference is then added to the class path of the application server to ensure that the files are available at run time. Only the shared.app.jar file is loaded automatically by the SiSharedLib library. When the registration of these files is finished, a server restart is required to reload the libraries and make the classes available on the class path. When complete, the library-specific classes are now available globally to that server for an application to access.

To allow a library scope that is limited to a specific solution, place the relevant JAR files in the component/shared/common directory. Files in this directory are not copied to a location inside of the profile directory. Instead, a shared library for this component that points to this directory are added to the WebSphere Application Server. This shared library then must be associated with either the application or made available on the server-wide class path so it is available to all applications. A properties file called shared-library.properties is in the component/shared/common directory. This file contains information on the scope to which the shared library must be registered. It also provides information on any required class loader properties, such as class loading precedence. The following properties are available in the shared-library.properties file:

```
# set whether the library should be at the server scope or application scope
# Can have the following values:
# cell, cluster, node, server
library-scope=server
# specify whether the library should be added to the server class path
# or associated with a specific application.
Library-ref=application
# Set the name of the application(s) to which the library is to be associated.
# name of application(s) found in the integrated administration
# console/applications/enterprise applications.
applicationName=# your application name
# Set class loading preference, options are either
# 'PARENT_FIRST' or 'PARENT_LAST'.
classLoadingMode=PARENT_FIRST
```

If multiple applications are associated with the library, specify a comma-separated list of application name; for example: **applicationName=**AppName1,AppName2,AppName3, where AppName1,AppName2,AppName3 represent the applications to which the library is associated.

template

The template directory is where a developer can place files to create a website template. The template is based on one or more of the components

that are supplied in the PAA distribution. One or more subdirectories might be contained within the `template` directory, one for each template that you want to provide. The default directory name is reserved by Solution Installer as the content of this directory is always run.

The default directory and any subsequent template directories have their content split into two further subdirectories to aid in the distinction between installation and uninstallation scripts. The installation scripts are in the `/component/template/template_Name/install` directory and the uninstallation scripts are placed in the `/component/template/template_Name/uninstall` directory. The scripts that are contained in the default directory are always run. Therefore, if you are offering multiple templates and do not want one to be installed by default, leave this directory structure empty. In general the content of the default, or template-specific directories, include XMLAccess scripts to create pages, put portlets on the pages, and create users. That is, any task that is site-related and not covered by the other directories or components. For example, do not place an XMLAccess script to install a WAR file here. Instead, if this file is required, place it in the `component/config/templates` directory if a custom Ant task is required or in the `component/content/xmlaccess/install` directory otherwise.

To use a different template to the default, set the **templateName** property in the `componentName.properties` file. The value of the **templateName** property should reflect the name of the template to be used. For example: **templateName=**`template2`.

Note: Store any site-wide template-related artifacts in a single component separate from the components on which they depend. This placement allows the overall site presentation to be separate from the underlying technologies they surface and it makes it easier for the installer to handle updates in the future. It also makes it much easier to manage the provision of multiple site templates in a single PAA distribution. Store sample or demonstration pages for a single component local to that component.

version

The `component/version` directory contains a single `.component` file with the application version information. The file contains build date, build version, name, and spec-version. This file is what tells the ConfigEngine the version of the application. Knowledge of the version that is already installed is necessary to facilitate updates to an application. The following is an example of a `.component` file:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE component PUBLIC "componentId" "component.dtd">
<component build-date="6/10/14" build-version="20140610-1200" name="components/sample1" sp
```

Installation tasks

Solution installer supports the auto generation of deployment tasks for specific resource types. The creation of these tasks occurs during the installation or registration phase for the PAA file with the Solution Installer and the ConfigEngine.

At this stage, analysis is done on the PAA content after expansion to the *wp_profile_root*`/paa` directory to determine which resources are included. When complete, the Solution Installer generates the code to deploy the artifacts. The developer might decide that the default code is not robust enough to handle the deployment of their artifacts. Or the developer might decide that extra configuration that is not covered by the Solution Installer is required. The

developer can overwrite the code generation step for the specific resources. The developer must provide an implementation task for the extension point that is mapped to that resource directory. For information, read “Developing advanced PAA file applications” on page 3431.

The Solution installer determines what resources are available and looks up the mapping between individual resource types and their assigned extension point. Then, it checks the `config/includes` directory of the current component to determine whether a task exists for the extension point that is related to the resource type. If one is found, then it is assumed that all resources in the directory are covered by the task. No attempt is made to auto-generate code to deploy those resources. No code inspection is done on the implementation task to establish if all resources are covered.

The naming scheme for tasks is important for recognizing which tasks implement extension points. The naming scheme is `'action-' + '%extension point' + '-componentname'`.

The extension points that are started by the Solution Installer differ from the portal core extension points. They have the suffix 'applySIFeaturePack' or 'removeSIFeaturePack' appended to the end of the core extension point name.

Take for example two ear files that are provided in the `components/sample1/installableApps/ear` directory. The Solution Installer checks if a task called **`action-create-ear-applySIFeaturePack-components/sample1`** exists. The `'action-'` *`extension point name`* + *`componentName`*`'` is the pattern that is used to determine that a task implements an extension point. If such a task is found, then the Solution Installer adds the task name to the list of implemented extension points and moves on to the next resource type. Otherwise, it implements a task to cover the deployment of both ear files.

The ConfigEngine runs the installation of the set of components by extension point and controls the order in which they are run. For example, all component tasks that implement the **`create-ear-applySIFeaturePack`** extension point are run together. Portlet deployments are done at the same time. If you need an artifact of a component that is installed before you install another, then you must create a dependency in the `sdd.xml` file. The dependency works on an extension point basis because you can specify that artifacts covered by that extension point can have an order. For example, you can specify that the EAR file in component1 is installed before the EAR file in component2. Read “Component level `sdd.xml` file overview” on page 3424 for information.

Any extra Ant tasks that are found in the `config/includes` directory that do not comply with the naming scheme for extension point tasks are not run. Instead, these tasks must be called directly by extension point tasks or they are not run.

In earlier versions of the Solution Installer, it was necessary to add an `SCU` element to the component level `sdd.xml` file to register any developer-provided extension point implementation tasks. However, it is no longer necessary because `SCU` elements are now added for all recognized extension point tasks.

Developers can also implement extra configuration extension points that are not directly related to deploying resources in the PAA file. An example is a task to create a resource environment custom property. Read the “Developing advanced PAA file applications” on page 3431 for information. Tasks to implement these extension points can also be added to an XML file in the `config/includes`

directory. When they follow the naming scheme pattern, they are registered in the component level sdd.xml file with the SCU elements and automatically run at run time. In this way, the Solution Installer can handle both auto-generated and developer-provided code.

Order of installation of scripts and artifacts

Often the order that scripts are run or artifacts that are deployed is important for the success of the installation. This information is both true for artifacts or scripts in a single component and the order in which scripts contained in multiple components are installed.

At the component level all the scripts or artifacts in a directory are installed or deployed by a single task with one of the extension points. Therefore, if there are multiple scripts or resources, the Solution installer needs a mechanism to determine the correct order to run the scripts. If a custom task is provided, then there is no problem as it is assumed that the task runs all the scripts in the expected order. However, an issue arises when the Solution Installer auto-generated code is used to handle the deployment of the resources.

To solve this issue, a properties file called order.properties can be added to any of the directories within the component hierarchy that contain artifacts that must be run or installed. For example, an order.properties file can be added to the components/componentN/content/xmlaccess/install directory to handle the order of two or more XMLAccess scripts. This file contains a comma-separated list of the file names in the correct order that they are to be deployed.

When the **install-paa** task is run for the Portal Application Archive (PAA) file, a new Ant task is created. It runs the scripts in the order that is outlined in the order.properties file. If no order.properties file exists, the Solution Installer works on the assumption that the order of installation is not important.

The previous solution covers multiple artifacts for an extension point in a component. However, multiple components might require the same extension point and might have a dependency on the resources of one of these components to be deployed or configured before deployment. The strategy that is used by ConfigEngine and therefore Solution Installer is to collect all the different implementations of an extension point in the PAA file and run them consecutively. For example, all implementations of the create-ear-applySIFeaturePack extension point are run before you move on to the next extension point type. The Solution Installer determines the order in which the extension points are run. Each extension point is run in a preset order that is based on the type of function required. Where there are multiple implementations for an extension point across components, it might be necessary to have an order that is placed on when they are started.

These dependencies between the component extension points are set in the component level sdd.xml file. Add a requirements element to the SCU element for the extension point. This requirements element must point to the component on which it depends. Read "Component level sdd.xml file overview" on page 3424 for information.

Starting with version 8.5, the dependencies can be automatically created between extension points of different components with the **install-paa** task. Add an order.properties file to the /components directory of a PAA file. This file contains a comma-separated list of components in the order in which they are to be installed. The components that can be run outside of this order do not need to be

added to the list. After the Solution Installer creates default code and adds the SCU elements for the extension points, it analyses the components in the order.properties file. It sets the requirements elements on the relevant SCU elements to add dependencies between the shared extension points of these components.

Note: The full component name must be used in the order.properties file, Take for example a PAA file with two components components/component1 and components/component2. The line in the order.properties file is components/component1,components/component2.

Important: The Solution Installer adds only a requirements element where one does not exist. Therefore, it does not overwrite any developer-provided settings.

For the removal of the resources from the portal with the **remove-paa** task, the order that the Solution Installer uses is the reverse of what is found in the order.properties file.

The sdd.xml file

The sdd.xml files perform a number of different roles in the PAA file structure. They allow the developer to control, with ConfigEngine extension points, how an application is installed. They also inform the ConfigEngine of the type of installation to be processed. It also determines, in terms of the ConfigEngine, where the deployable files are stored after registration with the ConfigEngine.

The ConfigEngine takes a granular approach to the installation and deployment of an application. The sdd.xml file controls the granularity to the ConfigEngine. There are three different levels of installation:

- Offering level: Large applications such as WebSphere Portal Express are offering level deployments.
- Assembly level: An assembly is usually a group of applications that can be stand-alone or form the basis of a much larger application. An example of an assembly is the ap or base directories under WebSphere Portal Express.
- Component level: The component level is the finest level of granularity. A component can be an application or can be one of many small applications that make up a much larger application.

An assembly is made up of one or more components and an offering is made up of one or more assemblies.

The Solution Installer includes all the PAA files in a higher-level PAA offering. The directory structure for the Solution Installer and any offering setup details that are applied to the ConfigEngine are processed automatically. It is easier to manage the installation of the different components when they are installed under one hierarchy.

Each PAA file is treated as a separate assembly. The top-level sdd.xml contains installation information for the ConfigEngine relating to the assembly and its components. A PAA file that contains an update has the same assembly name in its sdd.xml file. The Solution Installer checks that the assembly exists before it adds each new component or update to the current assembly.

The assembly can be made up of one or more components, each requiring a component level sdd.xml file that can be automatically generated. The number of components depends on how the developer structures the application to be installed. Every artifact can potentially be included in a single component,

although it might not be the most practical approach. However, you might want to separate larger applications into multiple components that contain related artifacts to facilitate reuse. Because a component might be required by multiple PAA distributions, this approach allows it to be reused with little extra work for the developer.

"The assembly level sdd.xml file"
When you create a Portal Application Archive (PAA) file, it might be necessary to add an assembly level sdd.xml file. This file registers the PAA content with the ConfigEngine.

"Component level sdd.xml file overview" on page 3424
For most installation scenarios, generation of the component level sdd.xml file is automated. However, there are still occasions where it might be necessary to create it manually. The component level sdd.xml file contains the information on how to install the artifacts of the component. It lists the extension points that need to be processed. The extension points ensure that the resources can be installed and configured on the server. Ant tasks complete the deployment and configuration work.

The assembly level sdd.xml file:

When you create a Portal Application Archive (PAA) file, it might be necessary to add an assembly level sdd.xml file. This file registers the PAA content with the ConfigEngine.

The information in the sdd.xml file informs the Solution Installer about the name and type of the application to install. It also includes information about the versions of IBM WebSphere Portal Express to which installation of the PAA content is compatible. In addition, the sdd.xml tells Solution Installer the names and locations of the components to be installed. The different elements of the assembly level sdd.xml file are described in terms of how they are required for the Solution Installer. You can edit a sample sdd.xml file with the required information to ensure that the sdd.xml file is complete and accurate.

Starting with Version 8.5, a basic version of the assembly level sdd.xml file can be automatically generated. Solution installer uses the name of the root directory in the PAA file as the assembly name and can add any components that are found in the /components/ directory. Each component is added based on the names of the sub directories that are found in the /components directory. Each components/ subdirectory is recognized as a separate component. However, there might be cases where a developer does not want to have a component included in the assembly level sdd.xml file. For example, an extra component that contains files that should not be deployed is included. Then, the developer might need a mechanism to restrict the list of components. You can place a limitation on the components that you want to include. Create an order.properties file in the components directory. Populate it with a comma-separated list of the components in the order in which they should be installed. If there is a components/order.properties file, the Solution Installer restricts the list of components added to the sdd.xml file to only those components that are listed in the order.properties file. This order has other meanings for automatically creating dependencies between the components so it is important to ensure that the components can be successfully installed following

this order. See the section 'Order of installation of scripts and artifacts' for more details on how the ordering of artifacts is handled. The mechanism in which the dependencies are created is described in *The component level `sdd.xml` file* section in the advanced development documentation.

Although the assembly level `sdd.xml` file can be auto-generated, there are many circumstances where this option is not a viable solution. For example, there are restrictions on server versions on which the PAA file can be installed. It is necessary to include a `<ServerVersionDependencies>` element to illustrate the versions. This information is not handled automatically by the Solution Installer so you must generate the file manually. If you added a `/components/order.properties` file and do not want to limit the list to only those components in the `order.properties` file, add the additional `<containedPackage>` elements for each component to the file.

Note: In the `PortalServer_root/doc/paa-samples` directory, some sample files illustrate the PAA directory structure. You can use the assembly level `sdd.xml` file of the `sample1.paa` file as an example. This file can be used as a starting point for developers to create their own working `sdd.xml` files. This sample PAA file is an installable application. It can be registered with the ConfigEngine. However, it is not a working PAA file because there are no installable resources. The structure is provided so that a developer can use it to create their own PAA files.

The following is an example of an assembly level `sdd.xml` file:

```
<?xml version="1.0" encoding="UTF-8"?>

h<iudd:iudd
 xmlns:iudd="http://www.ibm.com/xmlns/prod/autonomic/solutioninstall/IUDD"
 xmlns:iurtype="http://www.ibm.com/xmlns/prod/autonomic/resourcemodel/IU/resourcetypes"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xmlns:OSRT="http://www.ibm.com/xmlns/prod/autonomic/resourcemodel/OS/resourcetypes"
 xsi:schemaLocation="http://www.ibm.com/xmlns/prod/autonomic/solutioninstall/IUDD ../iudd/iudd.xsd "
 schemaVersion="2.0.0" buildID="MySoln-IUDD-1.0" buildDate="2006-01-19T12:00:00">

 <packageIdentity contentType="Assembly">
  <name>sample_paa</name>
  <version>8.5.0.0</version>
  <displayName key="d0001" default="sample_paa" />
  <manufacturer>
   <displayName key="DU_01" default="IBM" />
  </manufacturer>
 </packageIdentity>

 <topology>
  <resource type="OSRT:OperatingSystem" id="OS" />
 </topology>

 <content xsi:type="iudd:RootIUContent">
  <rootIU id="sample_paa" targetRef="OS">
   <identity>
    <name>sample_paa</name>
   </identity>

   <containedPackage id="components/componentN" pathname="components/componentN/sdd.xml" />

   <serverVersionDependency name="PortalServer" lowerVersion="6.0.0.0" higherVersion="8.5.0.0" versi

  </rootIU>
 </content>
</iudd:iudd>
```

Inside the root <iudd:iudd> element, the following three subelements are required for installation with the Solution Installer:

The <packageIdentity> element

The first element is the <packageIdentity> element; for example:

```
<packageIdentity contentType="Assembly">
  <name>sample_paa</name>
  <version>8.5.0.0</version>
  <displayName key="d0001" default="sample_paa" />
  <manufacturer>
   <displayName key="DU_01" default="IBM" />
  </manufacturer>
 </packageIdentity>
```

The <packageIdentity> element informs the Solution Installer and the ConfigEngine of the type of application to be installed. In this case, the **contentType** attribute equals Assembly. An assembly is a grouping of one or more components. The Solution Installer considers each PAA file as an assembly, even though it might contain only one component. Do not edit this attribute.

The <packageIdentity> element contains a number of subelements that provide information about the content. The name and version elements need to be altered to suit the application you are installing. The <displayName> element can also be edited to include the assembly name, but is not required.

Important: The name element that is provided for an assembly must match the name of the PAA file root directory. For example, a name of sample_paa requires the root directory to also be called sample_paa.

The <topology> element

The next subelement is the <topology> element. This element does not require any alterations. For example:

```
<topology>
  <resource type="OSRT:OperatingSystem" id="OS" />
 </topology>
```

The <content> element

The final element block is the <content> element. This element provides the Solution Installer and the ConfigEngine with the information about what to install and on which servers. The <rootIU> element is where the actual information is included. Set the 'ID' attribute of the <rootIU> element to the name of the application as used in the <name> element of the <packageIdentity> element.

```
<content xsi:type="iudd:RootIUContent">
  <rootIU id="sample_paa" targetRef="OS">
  <identity>
    <name>sample_paa</name>
   </identity>

   <containedPackage id="components/componentN" pathname="components/componentN/sdd.xml" /

   <serverVersionDependency name="PortalServer" lowerVersion="6.0.0.0" higherVersion="8.5.

  </rootIU>
 </content>
```

The <identity> element contains the <name> subelement. Set this element to the name of the assembly found in the <packageIdentity> name element.

Although there is only one <containedPackage> element in this example, there can be a number of these elements. One for each component included in the PAA file. This element allows for ConfigEngine to register the components and informs it on where to find the component level sdd.xml file. The Solution Installer can auto-generate the component level sdd.xml file during the **install-paa** command. The developer does not need to add this file for a basic PAA file. However, when the developer needs to provide specific component dependencies outside of an order.properties file, then the component level sdd.xml file must be provided.

There are two attributes for the <containedPackage> element. The ID must equal the path of the component relative to the assembly level sdd.xml file. For example, as the PAA file puts all components in the components directory, a component name needs to also include the components/. For example, a component that is called 'componentN' would have the id="components/componentN". The path name contains the path from the assembly sdd.xml file to the component level sdd.xml file. Continuing with the previous example, the pathname element is pathname="components/componentN/sdd.xml".

The final element is the <serverVersionDependency> element. This element informs the Solution Installer of the WebSphere Portal Express versions on which the content can be installed. Not all the attributes that are shown are required. Go to the *Checking server dependency* section for more details.

```

See "The component level sdd.xml file" on page 3432 for information about editing the sdd.xml file.

Syntax information for component names

The syntax for naming the component is important. There are dependencies within the PAA file that determine part of the component name that is registered in the `sdd.xml` file. You are free to name your components as you like; however, the component names must be unique. The ConfigEngine and by extension Solution Installer impose a restriction that a component name not clash with an existing component in the ConfigEngine registry. This restriction is not limited to an assembly, but is registry wide. Therefore, if a component has the same name as an existing component, it is not automatically installed. If the user wants to install this new component, they can use the **update-paa-components** task. This task removes the existing version and installs the new component as part of the new assembly.

When you register the names in the `sdd.xml` files, you must adhere to the following syntax: `components/componentName`. This syntax is necessary for the Solution Installer to resolve the component name. It must contain the full path from the directory that contains the assembly level `sdd.xml` file, usually the root directory, to the component level `sdd.xml` file.

Looking at the *PortalServer_root*`/doc/paa-samples/sample1.paa` file, it contains one component in the components directory called '`Sample1`'. Therefore, The component name would appear in the `sdd.xml` file as follows: `components/Sample1`. It is the full path relative to the directory that contains the assembly level `sdd.xml` file.

The Solution Installer follows the feature pack approach that is provided by the ConfigEngine to install the individual components. The advantage of this approach is that the ConfigEngine manages the installation order of the individual components. Using the feature pack approach ensures a distinction between portal core extension points and those points that are used to install the PAA content. This approach reduces the risk of a user accidentally removing portal core components when you run a remove extension point.

The ConfigEngine runs the installation of the set of components by extension point and controls the order in which they are run. For example, all EAR files are installed together; all portlet deployments are done at the same time. If there is a need to have an artifact of a component that is installed before another, then you need to create a dependency in the `sdd.xml` file. The dependency works on an extension point basis in that you can specify that artifacts covered by that extension point can have an order. For example, you can specify that the EAR file in component1 is installed before the EAR file in component2.

Note: The value of the **FunctionalArea** parameter is set to featurepackSI. This value is important so the Solution Installer can determine that the components are to be installed with the Solution Installer specific feature pack. See the `sdd.xml` file example at the beginning of this file for how to implement the feature pack approach.

In the sample `sdd.xml` file, there are two `SCU` elements. The first one shows how to register the extension point to deploy a portlet and the second one demonstrates how to remove the portlets.

```
<SCU id="deploy-portlets-applySIFeaturePack" targetRef="OS">
 <identity>
 <name>Do Configuration Task</name>
 <version>1.0.0.0</version>
  <displayName key="keyInBundle" default="Executes Configuration for this component" />
  <description key="keyInBundle" default="This section runs configuration for this
   component" />
```

```
 </identity>
 <unit>
 <configArtifact type="ConfigEngine">
 <parameters>
  <parameter name="targetName" value="deploy-portlets-applySIFeaturePack" />
  </parameters>
  </configArtifact>
 </unit>
  <!–register a dependency on a previous component-->
  <requirements>
   <requirement name=" deploy-portlets-applySIFeaturePack">
   <alternative name="dependentComponent"/>
  </requirement>
  </requirements>
</SCU>
```

The `SCU` element example notifies the Solution Installer about the task you want to run. The extension point in this case is called **`deploy-portlets-applySIFeaturePack`**. It deviates from the core extension points for portal by adding 'applySIFeaturePack' to the end of the extension point. With an uninstall task, 'removeSIFeaturePack' is appended instead. It allows the Solution Installer to distinguish between installation and uninstall tasks. Append these strings to the extension point names to create a definite distinction between core extension points and those points included for the Solution Installer to handle a PAA distribution. The Solution Installer expects and runs only extension points that conform to this format.

To provide an implementation task for an extension point, read "Installation tasks" on page 3417 for information.

Property files

Two different types of properties are contained within a PAA distribution. They can be classified as being either user editable that is requiring user input, for example a database URL, or as developer-provided settings required for a component to function. However, for user convenience, a separation between user properties from those settings that are supplied by the developer is advised.

In general custom Ant tasks that are provided by the developer handle such properties. The exception is when properties for connecting to an external database are included. The other exception is a selection property for cases when the user wants to install a template other than the default template in the PAA templates directory is required. However, there are cases where properties required by the Solution Installer might also need to be set. In this case, they need to be included with user editable properties.

Users might need to edit such content before they run the installation. Therefore, it makes sense to consolidate such properties in the one place instead of having the user edit multiple files in different locations. However, there is a trade-off with keeping all the properties required by a component together to allow for component reuse. Therefore, a number of approaches to storing properties in the PAA file are allowed.

User editable properties can be defined in the properties file specific to a component, `component_name.properties`, which can be found in the top-level directory of a component. The naming scheme of this file is important because the Solution Installer loads it automatically. When the PAA file is expanded, users are free to edit them as needed. They can then rerun any ConfigEngine function that is

associated with the component to take account of these new values. The values in this file are the defaults for the properties and can be overwritten by parent properties files.

There are two ways in which the properties in the component level properties files can be overwritten by parent properties. The properties files that contain user editable properties for the components of the PAA assembly can be consolidated into one properties file. They are placed in the top-level directory of the PAA file. It is called `assembly_name.properties`. The user can edit this file to set any values that are required for the installation to ConfigEngine and IBM WebSphere Portal Express to run smoothly. When the user starts the installation process for the ConfigEngine, these properties are read first. The values in the default properties files are redundant because the Ant properties cannot be overwritten, unless they are out of scope.

Alternatively, the user editable properties can be passed in on the command line as parameters to the Solution Installer tasks. Individual property **`name=value`** pairs can be typed on the command line with a **`-D`** prefix to inform solution installer and the ConfigEngine that they are to be treated as Ant properties. Alternatively a properties file containing all of the user editable properties can be passed in on the command line with the Ant **`-propertyfile`** parameter.

The Solution Installer checks the command line to establish if properties were passed in when the task was started. If so, the properties are loaded by the installer and the values of the properties set are the ones that are used during the deployment to WebSphere Portal Express. Similarly, if a properties file is not received on the command line, then it looks in the highest level directory of the PAA distribution for such files. When found, these values are loaded as the values for the properties. If there are extra properties in the assembly level file, then these properties are also read. If no properties file is found, values from the component level property files are used. Otherwise, it is assumed that no user editable properties are required and the installation continues.

Property files that contain developer-provided settings must be at the component level. To aid reuse of components across multiple PAA files, keep required settings local to a component.

When you decide on property names, take great care. A limitation of Ant means that when a property is created in a run of the scripts, it cannot be overwritten. Therefore, if you install multiple components that have a setting with the same name but different values, the first one to be created is used throughout the installation. It can cause unexpected results. Employ a pattern for naming the properties to ensure that property names across components do not clash. For example, a property name might have the name of the component to which it relates, prefixed to the name to ensure uniqueness.

Database properties for the Solution Installer

Some Portal Application Archive (PAA) files require access to an external database. The database properties are stored in either the `assemblyName.properties` file for the assembly or in the `componentName.properties` file of the component requiring database support.

The Solution Installer uses the following database properties:

dbName
The name of the database created to store tables required by the PAA file.

Ideally, this should be specified in the `default.properties` file, especially if the name of the database is explicitly included in the table population scripts.

DbPort
Specify the database port number. The following examples are default port numbers for each database, but your server port number might be different if you changed the port values:

- Derby: `1527`
- DB2: `50000`
- Oracle: `1521`
- SQL Server : `1433`

DbHostname
The host name or IP address of the server hosting the database.

dbType
The type of database. Use the following valid database types:

- Derby: `derby`
- DB2: `db2`
- Oracle: `oracle`
- SQL Server : `SQL Server`

dbProviderName
The name of jdbc provider to be used. Use the following example jdbc provider names:

- Derby: `wpdbJDBC_derby`
- DB2: `wpdbJDBC_db2`
- Oracle: `wpdbJDBC_oracle`
- SQL Server : `wpdbJDBC_sqlserver`

dbDriverType
Connection pool data source

dbUsername
The username for connecting to the database.

dbPassword
The password for connecting to the database.

dbDriverName
The name of database driver. Use the following valid driver names:

- Derby: `org.apache.derby.jdbc.EmbeddedDriver`
- DB2: `com.ibm.db2.cc.DB2Driver`
- Oracle: `oracle.jdbc.driver.OracleDriver`
- SQL Server : `com.microsoft.sqlserver.jdbc.SQLServerDriver`

dbDriverPath
The path to the database driver. Use one of the following examples with values specific to your database:

- Derby: `${WasHome}/derby/lib`
- DB2: `${WasHome}/deploytool/itp/plugins/${dbPlugin}/driver`
- Oracle: `{$ORACLE_HOME}/jdbc/lib/`

  Note: ORACLE_HOME is the environment variable specified during the installation of the Oracle database.

- SQL Server : *installation_directory*/sqljdbc_2.0/enu

dbClasspath
The database class path value. Use one of the following examples with values specific to your database:

- Derby: ${dbDriverPath}/derby.jar:${dbDriverPath}/derbyclient.jar:${dbDriverPath}/derbytools.jar:${dbDriverPath}/derbynet.jar
- DB2: ${dbDriverPath}/db2jcc4.jar:${dbDriverPath}/db2jcc_license_cisuz.jar:${dbDriverPath}/db2jcc_license_cu.jar
- Oracle: ${dbDriverPath}/ojdbc6.jar
- SQL Server : *installation_directory*/sqljdbc_2.0/enu/sqljdbc4.jar

dbUrl The database URL value. Use one of the following examples with values specific to your database:

- Derby: jdbc:${dbType}:${dbName}
- DB2: jdbc:${dbType}://${dbHostname}:${dbPort}/${dbName}
- Oracle: jdbc:${dbType}:thin:@${dbHostname}:${dbPort}:${dbName}
- SQL Server : jdbc:sqlserver://*hostname*:${DbPort};SelectMethod=cursor;DatabaseName=tbmesg

dbJndiName
Specify the JNDI name that will be used for a component.

dsTemplateName
The data source template name. Use one of the following examples with values specific to your database:

- Derby: Derby JDBC Driver DataSource
- DB2: DB2 Universal JDBC Driver DataSource
- Oracle: Oracle JDBC Driver DataSource
- SQL Server : Microsoft SQL Server JDBC Driver - XA DataSource

jpTemplateName
Use one of the following examples with values specific to your database:

- Derby: Derby JDBC Provider
- DB2: DB2 Universal JDBC Driver Provider
- Oracle: Oracle JDBC Driver Provider
- SQL Server : Microsoft SQL Server JDBC Driver

dsDbDriverType
The type of the database driver that the data source connects to. Valid values are 2 and 4.

dataSourceName
Specifies the Data Source name will be used for the component.

dbAuthDataAlias
Specifies the Authentication Alias.

db.connectionTimeout
The interval, in seconds, after which a connection request times out and a ConnectionWaitTimeoutException is thrown. Default value is 180.

db.maxConnections
The maximum number of physical connections that you can create in this pool. Default value is 30.

db.reapTime
The interval, in seconds, between runs of the pool maintenance thread. Default value is 120.

db.agedTimeout
The interval in seconds before a physical connection is discarded. Default value is 1800.

Virtual portals in the PAA file

There are many situations where a user might want to install the applications that are contained in a Portal Application Archive (PAA) file directly to a virtual portal.

No additional configuration steps are needed when you create the PAA file. The Solution Installer takes advantage of the virtual portal-related properties that are available in the `wkplc.properties` file when it connects to the portal server. The Solution Installer checks the value of the **`VirtualPortalHostName`** and **`VirtualPortalContext`** properties. If one or more of these properties are set, then their values are used when it creates a connection. However, if neither of these properties are set, it is assumed that the PAA file content is installed to the base WebSphere Portal Express. These properties can be set in the `wkplc.properties` file or included on the command line with a prefix of **`-D`** when you run the deployment. For example, `-D`**`VirtualPortalContext`**`=testVP`. In addition, when you remove resources from a virtual portal, these properties must also be set.

Note: The properties and parameters must be set before you run the installer to deploy the PAA application. There is no facility to install individual components of the PAA file to different virtual portals during a single run of the **`deploy-paa`** task. Therefore, run the deployment for the specific components that are required for each virtual portal separately. All components that are listed for deployment are installed to the same location.

If you deploy a PAA file to more than one Virtual Portal, some components are not deployed on the other Virtual Portals. Therefore, items such as Libraries are not created on the second Virtual Portal. If you downloaded the PAA file from the IBM WebSphere Portal Business Solutions Catalog, refer to the associated documentation for instructions on how to deploy to Virtual Portals. If the PAA file is not from the IBM WebSphere Portal Business Solutions Catalog, choose one of the following options:

- Open the *wp_profile_root*`/paa/`*paaName*`/components.properties` file. Set the components that you want to deploy to true. Then, run the **`deploy-paa`** task.
- Run the **`deploy-paa`** task with the `-DforceDeploy=true` option. This parameter tells the Solution Installer to ignore the `components.properties` file.

Developing advanced PAA file applications

Developers can create their own advanced Portal Application Archive (PAA) file. The advanced PAA file contains custom content. The developers can then use the configuration wizard to add on their applications to their IBM WebSphere Portal Express environment.

About this task

Review the following requirements before you create your own advanced Portal Application Archive (PAA) file:

"The component level `sdd.xml` file" on page 3432
When you run the **`install-paa`** task, the Solution Installer examines each

component to verify whether an `sdd.xml` file is included for that component. If an `sdd.xml` file is not found, one is generated with the information gathered from the directory parsing step.

"Add custom code to a Portal Application Archive (PAA) file" on page 3437
Solution developers can create applications that use resource types that the Solution Installer does not automatically generate. The Solution Installer handles many resource types. However, there are some resource types that have no mechanism for accurate installation procedures. Your application might require additional configuration settings for installation. Those applications require custom code for the installation.

"Updating a Portal Application Archive (PAA) file" on page 3438
Before Version 8.5, updating the PAA file content in the portal server was not a simple task. It usually involved removing and uninstalling the previous version, then installing or deploying an updated version of the PAA file. This work can lead to a number of problems because it might break existing links between pages or portlets that were created outside of the PAA file deployment. Since Version 8.5, the Solution Installer can handle this type of function. Only some of the PAA file resources might change. Therefore, it does not make sense to overwrite the full set of resources on the system, but only those resources that changed since the new PAA file was released.

"ConfigEngine extension points for the Solution Installer" on page 3440
Some ConfigEngine extension points are required when you install an application from a Portal Application Archive (PAA) file.

"Tasks and extension points for custom code" on page 3442
You can use the following tasks and extension points when you create custom code to work with the ConfigEngine framework.

Related concepts:

"Install and uninstall add-ons using the Configuration Wizard" on page 212
You can install add-on functionality to your WebSphere Portal Express with the solution installer through the Configuration Wizard. The add-ons that are accepted by the configuration options are `.paa` files. For more information, see the solution installer documentation.

Related tasks:

"Developing basic PAA file applications" on page 3402
Solution developers can create their own Portal Application Archive (PAA) files. The developers can then use the configuration wizard to add on their applications to their IBM WebSphere Portal Express environment.

"Accessing the Configuration Wizard" on page 235
The home page of the Configuration Wizard provides access to common configuration tasks. Supported tasks include setting up a stand-alone server, setting up a cluster, transferring from Apache Derby to another supported database, migrating your server, installing add-ons, and more.

The component level `sdd.xml` file

When you run the **`install-paa`** task, the Solution Installer examines each component to verify whether an `sdd.xml` file is included for that component. If an `sdd.xml` file is not found, one is generated with the information gathered from the directory parsing step.

The type of data that is gathered from the components directory structure includes information on the different resource types. For example, the list of resources that are included in the individual sub directories and any custom extension point implementation tasks. It also uses the name of the directory when it generates the

component name. After it gathers the information, it can generate the sdd.xml file. The file includes the information on the extension points for registration with the Solution Installer or ConfigEngine. The Solution Installer can add any information about extension points whether auto-generated or custom implementations to the sdd.xml file. There is no longer a need to manually register any custom tasks with <SCU> elements.

The ability to automatically generate dependencies between components was added. Include an order.properties file in the /components directory of the Portal Application Archive (PAA) file. Read *Order of installation of scripts and artifacts* for more information.

For most situations, the SDD automation is enough to allow the PAA files to be deployed successfully. However, there are still some situations where the developer needs to overwrite the function of the sdd.xml file. One example might be in the ordering of components where the order.properties file does not meet the requirements for the PAA file. For example, a component contains extension points that have dependencies on 2 or more different components.

This information outlines the different pieces of the component level sdd.xml file in terms of their use. In addition, steps on how to create your own custom sdd.xml file and where to include relevant information on the component for successful deployment are also covered.

Note: If you are providing a component level sdd.xml file, you do not need to provide information for all the resources included in the PAA file. Provide information only where you are overwriting the function of the Solution Installer.

The following is an example component level sdd.xml file:

```
<?xml version="1.0" encoding="UTF-8"?>

<iudd:iudd
 xmlns:iudd="http://www.ibm.com/xmlns/prod/autonomic/solutioninstall/IUDD"

 xsi:schemaLocation="http://www.ibm.com/xmlns/prod/autonomic/solutioninstall/IUDD ../iudd/iudd.xsd
 schemaVersion="2.0.0" buildID="112220" buildDate="2006-01-19T12:00:00">

 <packageIdentity contentType="Component">
  <name>components/componentN</name>
  <version>8.0.0.0</version>
  <displayName key="d0001" default="components/componentN" />
  <manufacturer>
   <displayName key="AC_01" default="IBM" />
  </manufacturer>
 </packageIdentity>

 <topology>
  <resource type="OSRT:OperatingSystem" id="OS" />
 </topology>

 <content xsi:type="iudd:RootIUContent">
  <rootIU id="components/componentN">
   <variables>
    <parameters>
     <parameter name="installLocation" defaultValue="/usr/dummy.offr.1" />
    </parameters>
   </variables>
```

```
   <SCU id="deploy-portlets-applySIFeaturePack" targetRef="OS">
    <identity>
     <name>Do Configuration Task</name>
     <version>8.0.0.0</version>
     <displayName key="keyInBundle"
      default="Executes Configuration for this component" />
     <description key="keyInBundle"
      default="This section runs configuration for this component" />
    </identity>
    <unit>ts-applySIFeaturePack" />
      </parameters>
     </configArtifact>
    </unit>
   </SCU>
   <SCU id="remove-portlets-applySIFeaturePack" targetRef="OS">
    <identity>
     <name>Do Configuration Task</name>
     <version>1.0.0.0</version>
     <displayName key="keyInBundle"
      default="Executes Configuration for this component" />
     <description key="keyInBundle"
      default="This section runs configuration for this component" />
    </identity>
    <unit>
     <configArtifact type="ConfigEngine">
      <parameters>
       <parameter name="targetName" value="remove-portlets-applySIFeaturePack" />
      </parameters>
     </configArtifact>
    </unit>
   </SCU>
  </rootIU>
 </content>

</iudd:iudd>
```

Inside the root <iudd:iudd> element the following important subelements are required for installation by the Solution Installer:

The <packageIdentity> element

The first element is the <packageIdentity> element; for example:

```
<packageIdentity contentType="Component">
  <name>components/componentN</name>
  <version>8.5.0.0</version>
  <displayName key="d0001" default="components/componentN" />
  <manufacturer>
   <displayName key="AC_01" default="IBM" />
  </manufacturer>
 </packageIdentity>
```

The <packageIdentity> element informs Solution Installer and the ConfigEngine of the type of application to be installed. In this case, the **contentType** attribute equals "component". A component is the lowest level of granularity that is used by the ConfigEngine and thus Solution Installer for grouping application resources. One or more components are grouped in an assembly. This grouping is the next level of granularity for grouping resources that are recognized by the ConfigEngine or the Solution Installer. Each PAA file is considered by Solution Installer as an assembly, even though it might contain only one component. With the PAA file, a component must have a higher-level assembly that is associated with it. Read *The assembly level sdd.xml file* for information.

If you look at the <packageIdentity> element, a number of the subelements provide information on the content that is being installed. The

<name> and <version> element need to be altered to suit the application that is being installed. The <displayName> element can also be edited to include the component name but is not required.

The <name> element must equal the path of the component relative to the assembly level sdd.xml file. For example, as the PAA file puts all components in the components directory, a component name needs to also include the components/. For example, a component that is called 'componentN' would have a component name of 'components/componentN'.

The <topology> element

The next sub element is the <topology> element. This element does not require any alterations. For example:

```
<topology>
  <resource type="OSRT:OperatingSystem" id="OS" />
 </topology>
```

The <content> element

The final element block is the <content> element. This element provides the Solution Installer and the ConfigEngine with the information on what is being installed and on which servers the package can be installed on. The <rootIU> element is where the actual information is included. Set the **id** attribute of the <rootIU> element to the name of the component as used in the <name> element of the <packageIdentity> element. For example:

```
<content xsi:type="iudd:RootIUContent">
  <rootIU id="components/componentN">
   <variables>
    <parameters>
     <parameter name="installLocation" defaultValue="/usr/dummy.offr.1" />
    </parameters>
   </variables>

   <SCU id="deploy-portlets-applySIFeaturePack" targetRef="OS">
    <identity>
     <name>Do Configuration Task</name>
     <version>1.0.0.0</version>
     <displayName key="keyInBundle"
      default="Executes Configuration for this component" />
     <description key="keyInBundle"
      default="This section runs configuration for this component" />
    </identity>
    <unit>
     <configArtifact type="ConfigEngine">
      <parameters>
       <parameter name="targetName" value="deploy-portlets-applySIFeaturePack" />
      </parameters>
     </configArtifact>
    </unit>
   </SCU>
  </rootIU>
 </content>
```

The ConfigEngine requires the <variables> element for processing the content. You do not need to edit this code section. Include it in the component level sdd.xml file per the previous example.

The <SCU> element is the element of the file that is of most relevant to adding custom code to your PAA file. Each <SCU> element represents a ConfigEngine extension point. These extension points govern how and when resources are installed or uninstalled on the server during the **deploy-paa** task. Each extension point has an equivalent implementation task that needs to be added to an XML file

in the components/componentN/config/includes directory. Read *ConfigEngine extension points for the Solution Installer* for a list of exported extensions and how they map to directories. For details on extension points and how they are used, read *Component level sdd.xml file overview*.

The Solution Installer automatically adds the correct <SCU> element to the sdd.xml file after it detects an extension point implementation task. The Solution Installer first examines the components/componentName/config/includes directory for xml files that contain any custom Ant tasks. Any tasks that meet the extension point implementation criteria are then registered in the sdd.xml file where an existing <SCU> element for the extension point does not exist. However, you can register the <SCU> elements manually, especially where you need to set dependencies between multiple components on different extension points.

In the previous example, there are two places to changes. The first place is the **id** attribute of the <SCU> element. Set the ID to the name of the required extension point with **applySIFeaturePack** appended to the end. For example: deploy-apps-applySIFeaturePack. The second to change is the nested <parameter> element. Set the value attribute of this element to the extension point string. For example, set it to deploy-apps-applySIFeaturePack.

For each extension point, a separate <SCU> element is required by the Solution Installer or ConfigEngine. Therefore, an extra <SCU> element is required to provide an equivalent remove-apps-removeSIFeaturePack extension.

A second and rather important role is assigned to the <SCU> element. These elements also influence the order in which components are installed. You might have a PAA file with two components, where the second component is installed before the first component. A mechanism is necessary to ensure that the correct order is imposed on the deployment. This action can be done by adding a <requirements> element to the <SCU> element as shown in the following example:

```
<SCU id="deploy-portlets-applySIFeaturePack" targetRef="OS">
  <identity>
    <name>Do Configuration Task</name>
    <version>1.0.0.0</version>
    <displayName key="keyInBundle" default="Executes Configuration for this component" />
    <description key="keyInBundle" default="This section runs configuration for this component" />
  </identity>
  <unit>
    <configArtifact type="ConfigEngine">
      <parameters>
        <parameter name="targetName" value="deploy-portlets-applySIFeaturePack" />
      </parameters>
    </configArtifact>
  </unit>
<!—register a dependency on a previous component-->
<requirements>
<requirement name=" deploy-portlets-applySIFeaturePack">
<alternative name="dependentComponent"/>
</requirement>
</requirements>
</SCU>
```

The <requirements> element can contain one or more <requirement> elements, each one representing a component on which the current component depends on being previously installed. The name attribute of the <requirement> element can be set to whatever value the developer chooses. The name attribute of the <alternative> element must equal the full name of the component on which the current extension point depends. The dependency link is between extension points.

If you add the <requirements> element to the <SCU> element for the deploy-apps-applySIFeaturePack, register an equivalent deploy-apps-applySIFeaturePack extension point for the dependent component.

Not all extension points allow for a component dependency to be set. The extension points that are called as part of the deploy-apps-applySIFeaturePack, such as **install-content-xmlaccess**, apply the <requirements> element to the deploy-apps-applySIFeaturePack extension point. Read *ConfigEngine extension points for the Solution Installer* for the full list of extension points that are supported by the Solution Installer and whether they can handle component dependencies.

Add custom code to a Portal Application Archive (PAA) file

Solution developers can create applications that use resource types that the Solution Installer does not automatically generate. The Solution Installer handles many resource types. However, there are some resource types that have no mechanism for accurate installation procedures. Your application might require additional configuration settings for installation. Those applications require custom code for the installation.

Where to place custom code in the Portal Application Archive (PAA) file

An example of a PAA file is located in the *PortalServer_root*/doc/paa-samples/sample1.paa directory. This example contains a sample component file: sample1/components/sample1. The sample component file contains the config/include and config/templates directories. Custom code and Solution Installer generated code are stored in these two directories. The config/templates directory should contain any additional scripts that are required for installation. An example of an additional script is one that configures a .war file. The config/include directory should contain any custom ANT task. Any scripts in the config/include directory are picked up at run time.

How to name custom code files

There are no restrictions on how to name files containing custom code. The Solution Installer adds automatically generated code to the file. It uses the portion of the component name following the / combined with the string _cfg.xml. Using the sample_paa/components/componentN component example, the component name is components/componentN. Therefore, the file is called componentN_cfg.xml.

For WAR file installations from the installableApps/portlets directory, install and uninstall XML access scripts are generated with file names using the following strings:

- -portlets-install.xml
- -portlets-uninstall.xml
- -portletDataGen.xml

For example, if you have a WAR file called MyWar.war, the following files are created:

- MyWar.war-portlets-install.xml
- MyWar.war-portlets-uninstall.xml
- MyWar.war-portletDataGen.xml

You should name your files that contain custom ANT tasks so you avoid situations where the Solution Installer overwrites it.

Component level sdd.xml file

The component level sdd.xml file is located in the component directory. Using the sample_paa/components/componentN example, the sdd.xml file is located in the componentN directory. The sdd.xml file is only required if you have custom code; otherwise, the Solution Installer generates it.

Add an <scu> element to your component level sdd.xml file to register your code with the ConfigEngine.

Sample custom code

The following sample code uses the <scu> element for the extension point **create-ear**. The code tells the Solution Installer to overwrite the **create-ear** functionality. The full name of the extension is **create-ear-applySIFeaturePack**. The **create-ear** part tells the ConfigEngine what type of installation functionality is used to group the tasks to run. The **-applySIFeaturePack** part allows the Solution Installer to invoke functionality of the ConfigEngine for components that conform to this naming scheme. Hence it reduces the likelihood that other components, for example core portal components, from being removed during uninstallation.

```
<SCU id="create-ear-applySIFeaturePack" targetRef="OS">
 <identity>
  <name>create-ear-applySIFeaturePack</name>
  <version>1.0.0</version>
  <displayName key="deploy-apps-applySIFeaturePack" default="Executes
   Configuration for this component" />
  <description key="deploy-apps-applySIFeaturePack" default="Executes
   Configuration for this component" />
 </identity>
 <unit>
  <configArtifact type="ConfigEngine">
  <parameters>
  <parameter name="targetName" value="create-ear-applySIFeaturePack" />
  </parameters>
  </configArtifact>
 </unit>
</SCU>
```

After registering the extension point with the sdd.xml file, an implementation task must be created to overwrite the default functionality. The task should reside in the config/includes directory of the component. There is a specific naming convention required for the task so that it is directly associated with the <scu> element in the sdd.xml file. Use the following naming convention:

```
'action;' + extension point name = '-' = componentname
```

For example: action-create-ear-applySIFeaturePack-components/componentN.

Tip: Use the full path of the component as the component name.

Updating a Portal Application Archive (PAA) file

Before Version 8.5, updating the PAA file content in the portal server was not a simple task. It usually involved removing and uninstalling the previous version, then installing or deploying an updated version of the PAA file. This work can lead to a number of problems because it might break existing links between pages

or portlets that were created outside of the PAA file deployment. Since Version 8.5, the Solution Installer can handle this type of function. Only some of the PAA file resources might change. Therefore, it does not make sense to overwrite the full set of resources on the system, but only those resources that changed since the new PAA file was released.

In addition, some resource types are difficult to update without removing the existing version and redeploying the new resource. For example, IBM Web Content Manager libraries. The developer must decide whether the library needs to be replaced or whether the existing version is good. A number of new Solution Installer tasks handle the update of a PAA file. Read *Managing your existing Portal Application Archive (PAA) file* for information on the tasks.

The **install-paa-update** task verifies that an existing PAA file is installed to the ConfigEngine and creates a backup of the current set of files that are placed in the `profile_dir/paa/backup` directory. The existing PAA file is removed from the ConfigEngine registry and most of the files from the expanded PAA file directory are deleted. The auto-generated code files are not replaced during this step because the PAA files might be different. Therefore, the removal tasks are still available to the Solution Installer and called by the custom code.

After this step completes, the Solution Installer continues with the regular **install-paa** task. However, it registers that the new PAA file is an update and records the location of the previous backed up version. It is this information that allows the **deploy-paa** task to run only the update-related tasks and not all the Ant tasks that are registered for the PAA file.

It would be difficult for the Solution Installer to establish what pieces of the PAA file are deployed as part of the update. Therefore, as the developer is in the best position to provide this input, the Solution Installer does not attempt to generate any default installation code for the update tasks. Instead, when the **deploy-paa** task detects that a PAA file is an update, it runs only extension point implementation tasks that meet certain naming criteria. For deploying an update, the extension point uses the `updateSIFeaturePack` suffix instead of the `applySIFeaturePack` suffix. For example, the **deploy-apps-applySIFeaturePack** in terms of an update would be **deploy-apps-updateSIFeaturePack**.

The content of these tasks is up to the developer of the PAA file. However, the existing Solution Installer generated tasks are present. The developer can start this code as part of any tasks they add. The Solution Installer does not overwrite any extension point implementation tasks during the **install-paa-update** task. If more resources are added, for example another ear file is created in the `components/componentName/installableApps/ear` directory, it must be deployed with custom code.

Although these update tasks are not automatically generated, the Solution Installer can automatically register them with the `sdd.xml` file for the component. Read *The component level `sdd.xml` file* for information on how to register the extension points. After an extension point implementation task is provided, read *Add custom code to a Portal Application Archive (PAA) file*. The Solution Installer automatically registers the task. The following is an example task for the 'componentN' component and the **deploy-apps-updateSIFeaturePack** task:

```
<target name="action-deploy-apps-updateSIFeaturePack-components/componentN">
</target>
```

In a similar fashion, the rollback of the update with the **remove-paa-update** task runs the extension points with the `rollbackSIFeaturePack` suffix. This task removes all the update PAA resources and restore the artifacts from the backup. When complete, the Solution Installer runs any extension point with the `rollbackSIFeaturePack` suffix. It is the developers responsibility to generate the tasks that can remove the resources and then deploy the previous versions. The original Ant tasks both custom and auto-generated are available and can be called from the custom Ant tasks. The following is an example of a rollback task:

```
<target name="action-remove-apps-rollbackSIFeaturePack-components/componentN">
</target>
```

Tasks with the `updateSiFeaturePack` and `rollbackSIFeaturePack` suffix are run only when the PAA file is registered as an update during the **install-paa-update** task. If the installation is on a fresh system, only the `applySIFeaturePack` and `removeSIFeaturePack` extension points are run.

ConfigEngine extension points for the Solution Installer

Some ConfigEngine extension points are required when you install an application from a Portal Application Archive (PAA) file.

Table 497. ConfigEngine extension points

PAA directory	Extension point name	Description
Config		No extension points required
Content		
Database	**create-jdbc-provider-applySIFeaturePack**	Create the JDBC provider for Solution Installer
Database	**remove-jdbc-provider-removeSIFeaturePack**	Remove the JDBC provider for Solution Installer
Database	**create-j2c-auth-applySIFeaturePack**	Create J2C authentication alias
Database	**remove-j2c-auth-removeSIFeaturePack**	Remove J2C authentication alias
Database	**create-dataSource-applySIFeaturePack**	Create the datasource for Solution Installer
Database	**remove-dataSource-removeSIFeaturePack**	Remove the datasource for Solution Installer
Database	**create-database-applySIFeaturePack**	Runs script to create the database structures, e.g. db schema, tables buffers etc.
Database	**setup-database-applySIFeaturePack**	Runs script to populate the database with sample data
Database	**remove-database-removeSIFeaturePack**	Runs scripts to remove the database structures from the db, e.g. drops all tables.
Database	**create-cmp-connection-factory-applySIFeaturePack**	Creates cmp connection factory for container management. This extension point does not exist so it needs to be created.

Table 497. ConfigEngine extension points (continued)

PAA directory	Extension point name	Description
Database	**remove-cmp-connection-factory-removeSIFeaturePack**	Removes cmp connection factory for container management. This extension point does not exist so it needs to be created.
JCR		No extension points available because this is custom code
JSP		No extension points available because this is custom code
Personalization	**create-personalisation-rules-applySIFeaturePack**	Creates the personalization rules for the library
Personalization	**remove-personalisation-rules-removeSIFeaturePack**	Currently not available.
WCM	**import-wcm-applySIFeaturePack**	Imports WCM Library
XMLAccess	**install-content-xmlaccess-applySIFeaturePack**	Runs XML install scripts in install/configure application
XMLAccess	**remove-content-xmlaccess-removeSIFeaturePack**	Run XML scripts to remove application
webdav	**Import-webdav-applySIFeaturePack**	Uploads WebDav artefacts to the IBM WebSphere Portal Express WebDav file system
InstallableApps		
EAR	**create-ear-applySIFeaturePack**	Installs EAR file
EAR	**remove-ear-removeSIFeaturePack**	Removes EAR file
Portlets	**deploy-portlets-applySIFeaturePack**	Deploy portlets from WAR file
Portlets	**remove-portlets-removeSIFeaturePack**	Removes portlets from portal
WAR	**Copy-war-files-applySIFeaturePack**	Copy war files to the Profile dir directory
WAR	**Delete-war-files-applySIFeaturePack**	Delete the war files copied across by the copy-warfiles extension point implementation
ZIP	No extension points	
Shared	No extension points	
App	No extension points	
Common	**create-library-applySIFeaturePack**	Creates shared library
Common	**remove-library-removeSIFeaturePack**	Removes shared library
Common	**create-application-library-references-applySIFeaturePack**	Creates shared library references

Table 497. ConfigEngine extension points (continued)

PAA directory	Extension point name	Description
Common	**remove-application-library-references-applySIFeaturePack**	Removes shared library references
Common	**create-app-server-library-references-applySIFeaturePack**	Adds shared library to server classpath
Common	**remove-app-server-library-references-applySIFeaturePack**	Removes shared library to server classpath
Ext	No extension points	
Templates	**deploy-pages-applySIFeaturePack**	Deploys pages in this template
Templates	**remove-pages-applySIFeaturePack**	Removes pages in this template
Templates	**add-templates-applySIFeaturePack**	Installs template
Templates	**delete-templates-applySIFeaturePack**	Removes templates

Tasks and extension points for custom code

You can use the following tasks and extension points when you create custom code to work with the ConfigEngine framework.

Common Properties

These attributes are a reflection of similar attributes present on the **WsAdmin** task. Not all attributes on the **WsAdmin** task are used and some have a restricted range of values. None of these values are written into the dynamic profile.

Table 498. Common WPLC properties. This table displays a list of the common properties that you can use with your extension points.

Attribute	Description	Required	Scope
wasuser	Contains the user ID to authenticate with the server.	Yes	Global
waspassword	Contains the password that is associated with the **wasuser** user ID to authenticate with the server.	Yes	Global
conntype	Specifies the type of server connection. The following values are allowed: • SOAP: Establishes a SOAP connection. This value is the default. • NONE: No server connection is used. Instead, a direct connection to the local WebSphere Application Server configuration repository is used.	No	Global

Table 498. Common WPLC properties (continued). This table displays a list of the common properties that you can use with your extension points.

Attribute	Description	Required	Scope
properties	Java properties file containing attributes to set in the JVM System properties. The default is `${EngineInstallLocation}/config/work/was/jacl.properties`.	No	Global
script	Provides the location of the deployment script file. This file contains a set of commands to be passed to the **WsAdmin** script processor. Set the **lang** attribute to determine the script processor. If not specified, each deployment task assigns a default script location. It is built from the home directory of the configuration engine and a name specific to the task. For example, `wplc_deployEar`. Refer to the individual task for this name. Set the **lang** attribute to determine the file extension.	No	Global
lang	Contains the language to be used to interpret scripts. The supported values are as follows: • `jacl`: Use the Jacl interpreter. This value is the default. • `jpython`: Use the Java Python interpreter.	No	Global

Framework-specific Attributes

These attributes provide information about the runtime environment that is associated with the configuration engine.

Table 499. Framework-specific attributes. Runtime environment attributes.

Attribute	Description	Required	Scope
engineinstalllocation	The location of the configuration engine home directory. This location is used as the root when you construct many of the default locations. It defaults to the setting of the Ant property: **engineInstallLocation**.	No	Global
engineinstalllocation	The location of a deployment file that contains some or all of the deployment attributes of the targeted resource. This file is an XML file whose syntax mirrors that of the Ant task that references the file.	No	not applicable

Embedded Markup Tag

The following markup tags are supported.

Comment markup tag

Use the comment markup tag to embed a comment into a task value. The comment text is displayed during the task output trace, which is enclosed by parentheses. It is not included in the value that is passed to the task execution. Use <c> or <comment> to begin a comment. This tag has no attributes.

Default markup tag

Use the default markup tag to force a default value for a task value. The default is chosen if the target value resolves to an empty string. Otherwise, it is ignored. Use <d> or <default> to delimit text that is defaulted. This tag has the following single attribute:

`value`: The default value. This attribute is required.

<lower> markup tag

Use the lower markup tag to force text to lowercase. Use `<l>` or `<lower>` to delimit lowercase text. This tag has no attributes.

Password markup tag

Use the password markup tag to indicate a portion of text that is to remain hidden (or obscured) whenever the text value is logged. Use `<p>`, `<pw>`, or `<password>` to indicate the beginning of password text. This tag has no attributes. The default is to substitute the string, PASSWORD_REMOVED, for the text value during logging. You can override this value with the log attribute.

`log`: The value that is substituted for the real password during logging of the task. Defaults to PASSWORD_REMOVED. This attribute is not required.

Upper markup tag

Use the upper markup tag to force text to uppercase. Use `<u>` or `<upper>` to delimit uppercase text. This tag has no attributes.

Examples

The following example illustrates the use for each of the supported tags. The last instance embeds an undefined tag. This tag causes the parsing to stop and results in a value that is unchanged.

```
<wplc-create-variable server="server"
      node="node"
      wasuser="${WasUserid}"
      waspassword="${WasPassword}"
      testbeanclass="com.ibm.wplc.deploy.tasks.impl.TestAdminBeanImpl">
      <resource name="r1" value="&lt;cValue for r1&lt;/>v1"/>
    <resource name="r2" value="&lt;dvalue=&quot;xxx&quot;> &lt;/>"/>
    <resource name="r3" value="<u>uPpEr</u>"/>
    <resource name="r4" value="<l>LoWeR</l>"/>
    <resource name="r5" value="<p>password</p>"/>
    <resource name="r6" value="<p log="SECRET">password</p>"/>
    <resource name="r7" value="<undefined attr="Attribute">password</undefined>"/>
</wplc-create-variable>
```

Running the previous task results in the following trace. The second set of output for each instance is produced by the test bean class. This bean class is a dummy bean implementation that is used to echo the output that is passed in to a bean for each WPLC task.

```

wplc-create-application-library-ref

Definition and usage

Use this Ant task to create or modify the specified library reference.

Required parameters

The following parameters are required:

- **appName**: The name of the application with required library reference. The scope is instance.
- **libraryName**: The name of the library reference. The scope is instance.

Optional parameters

The following parameters are optional:

- **mode**: The mode of the class loader. The scope is instance.
- **sharedClassloader**: Boolean - specifies whether to use a shared class loader. The scope is instance.

Parameters that are specified as nested elements

attribute - a generic attribute for this resource. Users can use this attribute to specify any additional name-value pairs that are not already covered by the **wplc** task.

- **name**: The name of the attribute.
- **value**: The value of the attribute.

Implementation bean

The **com.ibm.wplc.deploy.tasks.impl.ApplicationLibraryRefCreateImpl** class implements this task.

wplc-remove-application-library-ref

Definition and usage

Use this Ant task to remove the specified library reference.

Required parameters

The following parameters are required:

- **appName**: The name of the application with required library reference. The scope is instance.
- **libraryName**: The name of the library reference. The scope is instance.

Optional parameters

The following parameter is optional:

- **mode**: The mode of the class loader. The scope is instance.

Parameters that are specified as nested elements

attribute - a generic attribute for this resource. Users can use this attribute to specify any additional name-value pairs that are not already covered by the **wplc** task.

- **name**: The name of the attribute.
- **value**: The value of the attribute.

Implementation bean

The **com.ibm.wplc.deploy.tasks.impl.ApplicationLibraryRefRemoveImpl** class implements this task.

wplc-create-app-server-classloader

Description and usage

Use this Ant task to create the specified application server class loader.

Required parameters

The following parameters are required:

- **mode**: The mode to operate the application server class loader in. The scope is instance.

Optional parameters

The following parameters are optional:

- **cell**: Cell scope of resource action. The scope is global.
- **node**: The node scope of resource action. The scope is global.
- **server**: Server scope of resource action. The scope is global.

Parameters that are specified as nested Elements

A generic **attribute** parameter for this resource. Users can use this attribute to specify any additional name-value pairs that are not already covered by the **wplc** task.

- **name**: The name of the attribute.
- **value**: The value of the attribute.

Implementation bean

The **com.ibm.wplc.deploy.tasks.impl.ApplicationServerClassloaderCreateImpl** class implements this task.

wplc-remove-app-server-classloader

Description and usage

Use this Ant task to create the specified application server class loader.

Required parameters

The following parameters are required:

- **mode**: The mode to operate the application server class loader in. The scope is instance.

Optional parameters

The following parameters are optional:

- **cell**: Cell scope of resource action. The scope is global.
- **node**: The node scope of resource action. The scope is global.
- **server**: Server scope of resource action. The scope is global.

Parameters that are specified as nested Elements

A generic **attribute** parameter for this resource. Users can use this attribute to specify any additional name-value pairs that are not already covered by the **wplc** task.

- **name**: The name of the attribute.
- **value**: The value of the attribute.

Implementation bean

The **com.ibm.wplc.deploy.tasks.impl.ApplicationServerClassloaderCreateImpl** class implements this task.

wplc-create-app-server-custom-property

Description and usage

Use this Ant task to create or modify a custom property.

Required parameters

The following parameters are required:

- **name**: The name of the property to create. The scope is instance.
- **value**: The value of the property to create. The scope is instance.

Optional parameters

The following parameters are optional:

- **cell**: Cell scope of resource action. The scope is global.
- **description**: The description of the property you are creating. The scope is instance.
- **node**: Node scope of resource action. The scope is global.
- **required**: Boolean - specifies whether the property is required or not. The scope is instance.
- **server**: Server scope of resource action. The scope is global.

Parameters that are specified as nested Elements

attribute - a generic attribute for this resource. Users can use this attribute to specify any additional name-value pairs that are not already covered by the **wplc** task.

- **name**: The name of the attribute.
- **value**: The value of the attribute.

Implementation bean

The **com.ibm.wplc.deploy.tasks.impl.ApplicationServerCustomPropertyCreateImpl** class implements this task.

wplc-remove-app-server-custom-property

Description and usage

Use this Ant task to remove a custom property.

Required parameters

The following parameter is required:

- **name**: The name of the property to remove. The scope is instance.

Optional parameters

The following parameters are optional:

- **cell**: Cell scope of resource action. The scope is global.
- **node**: The node scope of resource action. The scope is global.
- **server**: Server scope of resource action. The scope is global.

Parameters that are specified as nested Elements

A generic **attribute** parameter for this resource. Users can use this attribute to specify any additional name-value pairs that are not already covered by the **wplc** task.

- **name**: The name of the attribute.
- **value**: The value of the attribute.

Implementation bean

The **com.ibm.wplc.deploy.tasks.impl.ApplicationServerCustomPropertyRemoveImpl** class implements this task.

wplc-create-app-server-library-ref

Description and usage

Use this Ant task to create or modify the specified reference.

Required parameters

The following parameters are required:

- **libraryName**: Tells what library reference to add. The scope is instance.
- **mode**: The mode of the class loader. The scope is instance.

Optional parameters

The following parameters are optional:

- **cell**: Cell scope of resource action. The scope is global.
- **node**: Node scope of resource action. The scope is global.
- **server**: Server scope of resource action. The scope is global.

Parameters that are specified as nested Elements

attribute - a generic attribute for this resource. Users can use this attribute to specify any additional name-value pairs that are not already covered by the **wplc** task.

- **name**: The name of the attribute.
- **value**: The value of the attribute.

Implementation bean

The **com.ibm.wplc.deploy.tasks.impl.ApplicationServerLibraryRefCreateImpl** class implements this task.

wplc-remove-app-server-library-ref

Description and usage

Use this Ant task to remove the specified library reference.

Required parameters

The following parameters are required:

- **libraryName**: Tells what library reference to remove. The scope is instance.
- **mode**: The mode of the class loader. The scope is instance.

Optional parameters

The following parameters are optional:

- **cell**: Cell scope of resource action. The scope is global.
- **node**: Node scope of resource action. The scope is global.
- **server**: Server scope of resource action. The scope is global.

Parameters that are specified as nested Elements

attribute - a generic attribute for this resource. Users can use this attribute to specify any additional name-value pairs that are not already covered by the **wplc** task.

- **name**: The name of the attribute.
- **value**: The value of the attribute.

Implementation bean

The **com.ibm.wplc.deploy.tasks.impl.ApplicationServerLibraryRefRemoveImpl** class implements this task.

wplc-create-cmp-connection-factory

Description and usage

Use this Ant task to add a data source to the specified CMP J2CResourceAdaptor.

Required parameters

The following parameters are required:

- **authDataAlias**: The AuthAlias used this binding procedure. The scope is instance.
- **datasourcename**: Name of the data source. The scope is instance.
- **j2cresourceadaptorname**: The J2C Resource adapter name. The scope is instance.
- **jdbcprovidername**: Name of the JDBC provider that identifies this resource. The scope is instance.

Optional parameters

The following parameters are optional:

- **cell**: Cell of the resource action. The scope is global.
- **containerauthalias**: Authorization alias for container. The scope is instance.
- **containermappingalias**: Mapping alias for container. The scope is instance.
- **description**: A description of the data source. The scope is instance.
- **forceScope**: Set to true if do not want to scope to the existing cluster. The scope is instance.
- **node**: Node of the resource action. The scope is global.
- **server**: Server of the resource action. The scope is global.
- **usecontainer**: Use the container. The value must be set to `true` or `false`. The scope is instance.

Parameters that are specified as nested Elements

attribute - a generic attribute for this resource. Users can use this attribute to specify any additional name-value pairs that are not already covered by the **wplc** task.

- **name**: The name of the attribute.
- **value**: The value of the attribute.

customproperty - used to create a custom property under this data source.

- **name**: The name of the custom property.
- **value**: The value of the custom property.

connectionpool - used to set the connection pool properties for this data source.

- **name**: The name of the connection pool.
- **value**: The value of the connection pool.

relationalresourceadapter - used to set the Relational Resource adapter properties for this data source.

- **name**: The name of the relational resource adapter.
- **value**: The value of the relational resource adapter.

Implementation bean

The **com.ibm.wplc.deploy.tasks.impl.CMPConnectionFactoryCreateImpl** class implements this task.

wplc-remove-cmp-connection-factory

Description and usage

Use this Ant task to remove a data source to the specified CMP J2CResourceAdaptor.

Required parameters

The following parameters are required:

- **containermappingalias**: The mapping alias for the container.
- **datasourcename**: Name of the data source. The scope is instance.
- **j2cresourceadaptorname**: The J2C Resource adapter name. The scope is instance.
- **jdbcprovidername**: Name of the JDBC provider that identifies this resource. The scope is instance.

Optional parameters

The following parameters are optional:

- **cell**: Cell of the resource action. The scope is global.
- **containerauthalias**: Authorization alias for container. The scope is instance.
- **containermappingalias**: Mapping alias for container. The scope is instance.
- **description**: A description of the data source. The scope is instance.
- **forceScope**: Set to true if do not want to scope to cluster, if exists. The scope is instance.
- **node**: Node of the resource action. The scope is global.
- **server**: Server of the resource action. The scope is global.
- **usecontainer**: Use the container. The value must be set to `true` or `false`. The scope is instance.

Parameters that are specified as nested Elements

attribute - a generic attribute for this resource. Users can use this attribute to specify any additional name-value pairs that are not already covered by the **wplc** task.

- **name**: The name of the attribute.
- **value**: The value of the attribute.

customproperty - used to create a custom property under this data source.

- **name**: The name of the custom property.
- **value**: The value of the custom property.

connectionpool - used to set the connection pool properties for this data source.

- **name**: The name of the connection pool.
- **value**: The value of the connection pool.

relationalresourceadapter - used to set the Relational Resource adapter properties for this data source.

- **name**: The name of the relational resource adapter.
- **value**: The value of the relational resource adapter.

Implementation bean

The **com.ibm.wplc.deploy.tasks.impl.CMPConnectionFactoryRemoveImpl** class implements this task.

wplc-create-datasource

Description and usage

Use this Ant task to create a data source at the target scope.

Required parameters

The following parameters are required:

- **datasourcename**: Name of the data source. The scope is instance.
- **jdbcprovidername**: Name of the JDBC provider that identifies this resource. The scope is instance.

Optional parameters

The following parameters are optional:

- **cell**: Cell scope of resource action. The scope is global.
- **containerauthalias**: Authorization alias for container. The scope is instance.
- **containermappingalias**: Mapping alias for container. The scope is instance.
- **DbDriverType**: Specifies the driver type for this data source. Can be the type 2 or type 4 driver for this database. The scope is instance.
- **DbType**: The database type for this data source. Use this parameter to specify the database type; for example: `db2`, `oracle`, `sqlserver`, `db2 for z0S`. The scope is instance.
- **DbUrl**: The database URL. Use the data source to connect to the database. The database name displays in this URL. The scope is instance.
- **description**: A description of the data source. The scope is instance.
- **forceScope**: Set to `true` if do not want to scope to existing cluster. The scope is instance.
- **isPortalDatasource**: Specifies whether this parameter is a Portal data source domain. Portal data source domains are governed by special rules for config-split and database domain function in Portal. If your data source is not governed by these rules, enter `false`. The default for this property is `true`. The scope is instance.
- **node**: Node of the resource action. The scope is global.
- **portalDomain**: Required only for WebSphere Portal domain-based data sources. This setting tells the name of the domain of the data source. The scope is instance.
- **server**: Server of the resource action. The scope is global.
- **templatename**: Name of the WebSphere template to follow when you create the data source. The scope is instance.
- **usecontainer**: Use the container. The value must be set to `true` or `false`. The scope is instance.
- **useXA**: Specify whether this data source uses XA connections or not. The value must be set to `true` or `false`. The scope is instance.

Parameters that are specified as nested Elements

attribute - a generic attribute for this resource. Users can use this attribute to specify any additional name-value pairs that are not already covered by the **wplc** task.

- **name**: The name of the attribute.
- **value**: The value of the attribute.

customproperty - used to create a custom property under this data source.

- **name**: The name of the custom property.
- **value**: The value of the custom property.

connectionpool - used to set the connection pool properties for this data source.

- **name**: The name of the connection pool.
- **value**: The value of the connection pool.

relationalresourceadapter - used to set the Relational Resource adapter properties for this data source.

- **name**: The name of the relational resource adapter.
- **value**: The value of the relational resource adapter.

Implementation bean

The **com.ibm.wplc.deploy.tasks.impl.DataSourceCreateImpl** class implements this task.

wplc-modify-datasource

Description and usage

Use this Ant task to modify a data source at the target scope.

Required parameters

The following parameters are required:

- **datasourcename**: Name of the data source. The scope is instance.
- **jdbcprovidername**: Name of the JDBC provider that identifies this resource. The scope is instance.

Optional parameters

The following parameters are optional:

- **cell**: Cell scope of resource action. The scope is global.
- **containerauthalias**: Authorization alias for container. The scope is instance.
- **containermappingalias**: Mapping alias for container. The scope is instance.
- **description**: A description of the data source. The scope is instance.
- **forceScope**: Set to `true` if do not want to scope to existing cluster. The scope is instance.
- **node**: Node of the resource action. The scope is global.
- **server**: Server of the resource action. The scope is global.
- **usecontainer**: Use the container. The value must be set to `true` or `false`. The scope is instance.

Parameters that are specified as nested Elements

attribute - a generic attribute for this resource. Users can use this attribute to specify any additional name-value pairs that are not already covered by the **wplc** task.

- **name**: The name of the attribute.
- **value**: The value of the attribute.

customproperty - used to create a custom property under this data source.

- **name**: The name of the custom property.
- **value**: The value of the custom property.

connectionpool - used to set the connection pool properties for this data source.

- **name**: The name of the connection pool.
- **value**: The value of the connection pool.

relationalresourceadapter - used to set the Relational Resource adapter properties for this data source.

- **name**: The name of the relational resource adapter.
- **value**: The value of the relational resource adapter.

Implementation bean

The **com.ibm.wplc.deploy.tasks.impl.DataSourceModifyImpl** class implements this task.

wplc-remove-datasource

Description and usage

Use this Ant task to remove a data source at the target scope.

Required parameters

The following parameters are required:

- **datasourcename**: Name of the data source. The scope is instance.
- **jdbcprovidername**: Name of the JDBC provider that identifies this resource. The scope is instance.

Optional parameters

The following parameters are optional:

- **cell**: Cell scope of resource action. The scope is global.
- **forceScope**: Set to `true` if do not want to scope to existing cluster. The scope is instance.
- **node**: Node of the resource action. The scope is global.
- **portalDomain**: Required only for WebSphere Portal domain-based data sources. This setting tells the name of the domain of the data source. The scope is instance.
- **server**: Server of the resource action. The scope is global.

Implementation bean

The **com.ibm.wplc.deploy.tasks.impl.DataSourceRemoveImpl** class implements this task.

wplc-create-host-alias

Description and usage

Use this Ant task to create the specified Host Alias.

Required parameters

The following parameters are required:

- **host**: The host name for the host alias. The scope is instance.
- **port**: The port number for this host alias. The scope is instance.
- **virtualHostName**: The virtual host name to use for this host alias. The scope is instance.

Optional parameters

The following parameter is optional:

- **cell**: The cell scope of resource action. The scope is global.

Parameters that are specified as nested Elements

attribute - a generic attribute for this resource. Users can use this attribute to specify any additional name-value pairs that are not already covered by the **wplc** task.

- **name**: The name of the attribute.
- **value**: The value of the attribute.

Implementation bean

The **com.ibm.wplc.deploy.tasks.impl.HostAliasCreateImpl** class implements this task.

wplc-remove-host-alias

Description and usage

Use this Ant task to remove the specified Host Alias.

Required parameters

The following parameters are required:

- **host**: The host name for the host alias. The scope is instance.
- **port**: The port number for this host alias. The scope is instance.
- **virtualHostName**: The virtual host name to use for this host alias. The scope is instance.

Optional parameters

The following parameter is optional:

- **cell**: The cell scope of resource action. The scope is global.

Parameters that are specified as nested Elements

attribute - a generic attribute for this resource. Users can use this attribute to specify any additional name-value pairs that are not already covered by the **wplc** task.

- **name**: The name of the attribute.
- **value**: The value of the attribute.

Implementation bean

The **com.ibm.wplc.deploy.tasks.impl.HostAliasRemoveImpl** class implements this task.

wplc-create-j2c-auth

Description and usage

Use this Ant task to create an entry in the security table of the target cell. This entry can be used as a user-password pair for your configuration.

Required parameters

The following parameters are required:

- **alias**: The alias that is used to identify this authentication data. The scope is instance.
- **password**: The password that is associated with this user ID.
- **user**: The user name that is used to create a connection with this authentication data.

Optional parameters

The following parameters are optional:

- **cell**: The name of the cell where this J2C authentication data is created, removed, or modified. The scope is global.

- **description**: A description of what this authentication data is used for and what it connects to. The scope is instance.

Implementation bean

The **com.ibm.wplc.deploy.tasks.impl.J2CAuthCreateImpl** class implements this task.

wplc-modify-j2c-auth

Description and usage

Use this Ant task to modify an entry in the security table of the target cell. This entry can be used as a user-password pair for your configuration.

Required parameters

The following parameters are required:

- **alias**: The alias that is used to identify this authentication data. The scope is instance.
- **password**: The password that is associated with this user ID.
- **user**: The user name that is used to create a connection with this authentication data.

Optional parameters

The following parameters are optional:

- **cell**: The name of the cell where this J2C authentication data is created, removed, or modified. The scope is global.
- **description**: A description of what this authentication data is used for and what it connects to. The scope is instance.

Implementation bean

The **com.ibm.wplc.deploy.tasks.impl.J2CAuthModifyImpl** class implements this task.

wplc-remove-j2c-auth

Description and usage

Use this Ant task to remove an entry in the security table of the target cell.

Required parameters

The following parameter is required:

- **alias**: The alias that is used to identify this authentication data. The scope is instance.

Optional parameters

The following parameter is optional:

- **cell**: The name of the cell where this J2C authentication data is created, removed, or modified. The scope is global.

Implementation bean

The **com.ibm.wplc.deploy.tasks.impl.J2CAuthRemoveImpl** class implements this task.

wplc-create-jvm-custom-property

Description and usage

Use this Ant task to create or update a custom JVM property in the WebSphere Application Server environment.

Required parameters

The following parameters are required:

- **name**: The name of the JVM custom property. The scope is instance.
- **value**: The value of the property to create.

Optional parameters

The following parameters are optional:

- **cell**: The cell scope of the resource action. The scope is global.
- **description**: A description of the JVM custom property. The scope is instance.
- **node**: The node scope of the resource action.
- **required**: The Boolean value that is used to tell WebSphere if this property is required or not.
- **server**: The server scope of the resource action.

Implementation bean

The **com.ibm.wplc.deploy.tasks.impl.JVMCustomPropertyCreateImpl** class implements this task.

wplc-remove-jvm-custom-property

Description and usage

Use this Ant task to remove a custom JVM property in the WebSphere Application Server environment.

Required parameters

The following parameters are required:

- **name**: The name of the JVM custom property. The scope is instance.
- **value**: The value of the property to create.

Optional parameters

The following parameters are optional:

- **cell**: The cell scope of the resource action. The scope is global.
- **node**: The node scope of the resource action.
- **server**: The server scope of the resource action.

Implementation bean

The **com.ibm.wplc.deploy.tasks.impl.JVMCustomPropertyRemoveImpl** class implements this task.

wplc-create-jdbc-provider

Description and usage

Use this Ant task to create a JDBC provider resource on the target scope.

Required parameters

The following parameter is required:

- **jdbcprovidername**: The name of the JDBC provider that identities this resource. The scope is instance.

Optional parameters

The following parameters are optional:

- **cell**: Cell scope of resource action. The scope is global.
- **DbDriverType**: Specifies the driver type for this JDBC Provider. Can be the type 2 or type 4 driver for this database. The scope is instance.
- **DbType**: The database type for this JDBC Provider. Use this parameter to specify the database type; for example: `db2`, `oracle`, `sqlserver`, `db2 for z0S`. The scope is instance.

- **DbUrl**: The database URL. This JDBC Provider is used to connect to the database. The database name displays in this URL. The scope is instance.
- **forceScope**: Set to `true` if do not want to scope to an existing cluster. The scope is instance.
- **implementationClassName**: The class name that is used to create this JDBC Provider. The scope is instance.
- **node**: The node of the resource action. The scope is global.
- **server**: The server of the resource action. The scope is global.
- **templatename**: Name of the template to follow when you create the JDBC Provider. The scope is instance.
- **useXA**: Specify whether this JDBC Provider uses XA connections or not. Set to `true` or `false`. The scope is instance.

Parameters that are specified as nested Elements

attribute - a generic attribute for this resource. Users can use this attribute to specify any additional name-value pairs that are not already covered by the **wplc** task.

- **name**: The name of the attribute.
- **value**: The value of the attribute.

Implementation bean

The **com.ibm.wplc.deploy.tasks.impl.JDBCProviderCreateImpl** class implements this task.

wplc-modify-jdbc-provider

Description and usage

Use this Ant task to create a JDBC provider resource on the target scope.

Required parameters

The following parameter is required:

- **jdbcprovidername**: The name of the JDBC provider that identities this resource. The scope is instance.

Optional parameters

The following parameters are optional:

- **cell**: Cell scope of resource action. The scope is global.
- **forceScope**: Set to `true` if do not want to scope to an existing cluster. The scope is instance.
- **node**: The node of the resource action. The scope is global.
- **server**: The server of the resource action. The scope is global.

Parameters that are specified as nested Elements

attribute - a generic attribute for this resource. Users can use this attribute to specify any additional name-value pairs that are not already covered by the **wplc** task.

- **name**: The name of the attribute.
- **value**: The value of the attribute.

Implementation bean

The **com.ibm.wplc.deploy.tasks.impl.JDBCProviderModifyImpl** class implements this task.

wplc-remove-jdbc-provider

Description and usage

Use this Ant task to remove a JDBC provider resource on the target scope.

Required parameters

The following parameter is required:

- **jdbcprovidername**: The name of the JDBC provider that identities this resource. The scope is instance.

Optional parameters

The following parameters are optional:

- **cell**: Cell scope of resource action. The scope is global.
- **forceScope**: Set to `true` if do not want to scope to an existing cluster. The scope is instance.
- **node**: The node of the resource action. The scope is global.
- **server**: The server of the resource action. The scope is global.

Implementation bean

The **com.ibm.wplc.deploy.tasks.impl.JDBCProviderRemoveImpl** class implements this task.

wplc-create-library

Description and usage

Use this Ant task to create or modify the specified library.

Required parameters

The following parameter is required:

- **name**: The name of the library. The scope is instance.

Optional parameters

The following parameters are optional:

- **cell**: The cell of the resource action. The scope is global.
- **classpath**: Tells what class path entries to add. The scope is instance.
- **node**: The node of the resource action. The scope is global.
- **server**: The server of the resource action. The scope is global.

Parameters that are specified as nested Elements

attribute - a generic attribute for this resource. Users can use this attribute to specify any additional name-value pairs that are not already covered by the **wplc** task.

- **name**: The name of the attribute.
- **value**: The value of the attribute.

Implementation bean

The **com.ibm.wplc.deploy.tasks.impl.LibraryCreateImpl** class implements this task.

wplc-remove-library

Description and usage

Use this Ant task to remove the specified library.

Required parameters

The following parameter is required:

- **name**: The name of the library. The scope is instance.

Optional parameters

The following parameters are optional:

- **cell**: The cell of the resource action. The scope is global.
- **node**: The node of the resource action. The scope is global.
- **server**: The server of the resource action. The scope is global.

Parameters that are specified as nested Elements

attribute - a generic attribute for this resource. Users can use this attribute to specify any additional name-value pairs that are not already covered by the **wplc** task.

- **name**: The name of the attribute.
- **value**: The value of the attribute.

Implementation bean

The **com.ibm.wplc.deploy.tasks.impl.LibraryRemoveImpl** class implements this task.

wplc-create-res-env-custom-property

Description and usage

Use this Ant task to create or reassign a Resource Environment Provider custom property.

Required parameters

The following parameters are required:

- **name**: The name of the resource to create, update, or modify. The scope is instance.
- **providerName**: The name of the resource environment provider. The scope is instance.
- **value**: The value of the custom property. The scope is instance.

Optional parameters

The following parameters are optional:

- **cell**: The cell of the resource action. The scope is global.
- **description**: The description of the custom property. The scope is instance.
- **forceScope**: Set to `true` if do not want to scope to an existing cluster. The scope is instance.
- **node**: The node of the resource action. The scope is global.
- **required**: The Boolean value to specify whether this property is required or not. The scope is instance.
- **server**: The server of the resource action. The scope is global.

Implementation bean

The **com.ibm.wplc.deploy.tasks.impl.ResourceEnvProviderCustomPropertyCreateImpl** class implements this task.

wplc-retrieve-res-env-custom-property

Description and usage

Use this Ant task to return the value of a Resource Environment Provider custom property.

Required parameters

The following parameters are required:

- **name**: The name of the resource to create, update, or modify. The scope is instance.
- **propToSet**: The property that is set in the Ant project with the value retrieved from this property. The scope is instance.
- **providerName**: The name of the resource environment provider. The scope is instance.

Optional parameters

The following parameters are optional:

- **cell**: The cell of the resource action. The scope is global.
- **forceScope**: Set to `true` if do not want to scope to an existing cluster. The scope is instance.
- **node**: The node of the resource action. The scope is global.
- **server**: The server of the resource action. The scope is global.

Implementation bean

The **com.ibm.wplc.deploy.tasks.impl.ResourceEnvProviderCustomPropertyRetreiveImpl** class implements this task.

wplc-remove-res-env-custom-property

Description and usage

Use this Ant task to remove a Resource Environment Provider custom property.

Required parameters

The following parameters are required:

- **name**: The name of the resource to create, update, or modify. The scope is instance.
- **providerName**: The name of the resource environment provider. The scope is instance.

Optional parameters

The following parameters are optional:

- **cell**: The cell of the resource action. The scope is global.
- **forceScope**: Set to `true` if do not want to scope to an existing cluster. The scope is instance.
- **node**: The node of the resource action. The scope is global.
- **server**: The server of the resource action. The scope is global.

Implementation bean

The **com.ibm.wplc.deploy.tasks.impl.ResourceEnvProviderCustomPropertyRemoveImpl** class implements this task.

wplc-create-res-env-entry

Description and usage

Use this Ant task to create or modify a resource environment entry.

Prerequisites

Run the **wplc-create-res-referenceable** task before you run the **wplc-create-res-env-entry** task. The resource entry that is referenced in the **wplc-create-res-env-entry** task is not automatically created. Instead, the **wplc-create-res-referenceable** task creates the resource.

Required parameters

The following parameters are required:

- **jndiName**: The JNDI name. The scope is instance.
- **name**: The name of the resource to create, update, or modify. The scope is instance.
- **providerName**: The name of the resource environment provider. The scope is instance.
- **referenceable.Class**: The class of the resource environment provider. The scope is instance.
- **referenceable.FactoryClass**: The factory class of the resource environment provider. The scope is instance.

Optional parameters

The following parameters are optional:

- **category**: The name of the category. The scope is instance.
- **cell**: The cell of the resource action. The scope is global.
- **description**: The description of the resource action. The scope is instance.
- **forceScope**: Set to `true` if do not want to scope to an existing cluster. The scope is instance.
- **node**: The node of the resource action. The scope is global.
- **server**: The server of the resource action. The scope is global.

Implementation bean

The **com.ibm.wplc.deploy.tasks.impl.ResourceEnvEntryCreateImpl** class implements this task.

wplc-remove-res-env-entry

Description and usage

Use this Ant task to remove a resource environment entry.

Required parameters

The following parameters are required:

- **name**: The name of the resource to create, update, or modify. The scope is instance.
- **providerName**: The name of the resource environment provider. The scope is instance.

Optional parameters

The following parameters are optional:

- **cell**: The cell of the resource action. The scope is global.
- **forceScope**: Set to `true` if do not want to scope to an existing cluster. The scope is instance.
- **node**: The node of the resource action. The scope is global.
- **server**: The server of the resource action. The scope is global.

Implementation bean

The **com.ibm.wplc.deploy.tasks.impl.ResourceEnvEntryRemoveImpl** class implements this task.

wplc-create-res-env-entry-custom-property

Description and usage

Use this Ant task to create or reassign a custom SSL property in WebSphere Application Server security.

Required parameters

The following parameters are required:

- **entryName**: The name of the resource entry to update. The scope is instance.
- **name**: The name of the resource to create, update, or modify. The scope is instance.
- **providerName**: The name of the resource environment provider. The scope is instance.
- **value**: The value of the custom property. The scope is instance.

Optional parameters

The following parameters are optional:

- **cell**: The cell of the resource action. The scope is global.
- **description**: The description of the custom property. The scope is instance.
- **forceScope**: Set to `true` if do not want to scope to an existing cluster. The scope is instance.
- **node**: The node of the resource action. The scope is global.
- **required**: The Boolean value to specify whether this property is required or not. The scope is instance.
- **server**: The server of the resource action. The scope is global.

Implementation bean

The **com.ibm.wplc.deploy.tasks.impl.ResourceEnvEntryCustomPropertyCreateImpl** class implements this task.

wplc-remove-res-env-entry-custom-property

Description and usage

Use this Ant task to remove a custom SSL property in WebSphere Application Server security.

Required parameters

The following parameters are required:

- **entryName**: The name of the resource entry to update. The scope is instance.
- **name**: The name of the resource to create, update, or modify. The scope is instance.
- **providerName**: The name of the resource environment provider. The scope is instance.

Optional parameters

The following parameters are optional:

- **cell**: The cell of the resource action. The scope is global.
- **forceScope**: Set to `true` if do not want to scope to an existing cluster. The scope is instance.
- **node**: The node of the resource action. The scope is global.
- **server**: The server of the resource action. The scope is global.

Implementation bean

The **com.ibm.wplc.deploy.tasks.impl.ResourceEnvEntryCustomPropertyRemoveImpl** class implements this task.

wplc-create-resource-env-provider

Description and usage

Use this Ant task to create a resource environment provider at the specified scope.

Required parameters

The following parameter is required:

- **name**: The name of the resource to create, update, or modify. The scope is instance.

Optional parameters

The following parameters are optional:

- **cell**: The cell of the resource action. The scope is global.
- **description**: The description of the custom property. The scope is instance.
- **forceScope**: Set to `true` if do not want to scope to an existing cluster. The scope is instance.
- **node**: The node of the resource action. The scope is global.
- **server**: The server of the resource action. The scope is global.

Implementation bean

The **com.ibm.wplc.deploy.tasks.impl.ResourceEnvProviderCreateImpl** class implements this task.

wplc-remove-resource-env-provider

Description and usage

Use this Ant task to remove a resource environment provider at the specified scope and with the specified name.

Required parameters

The following parameter is required:

- **name**: The name of the resource to create, update, or modify. The scope is instance.

Optional parameters

The following parameters are optional:

- **cell**: The cell of the resource action. The scope is global.
- **forceScope**: Set to `true` if do not want to scope to an existing cluster. The scope is instance.
- **node**: The node of the resource action. The scope is global.
- **server**: The server of the resource action. The scope is global.

Implementation bean

The **com.ibm.wplc.deploy.tasks.impl.ResourceEnvProviderRemoveImpl** class implements this task.

wplc-create-res-referenceable

Description and usage

Use this Ant task to create or modify a resource entry that you can reference.

Important: Run this task before you run the **wplc-create-res-env-entry** task. The **wplc-create-res-referenceable** task creates the resource that is referenced in the **wplc-create-res-env-entry** task.

Required parameters

The following parameters are required:

- **providerName**: The name of the resource environment provider. The scope is instance.
- **referenceable.Class**: The reference class of the resource environment provider. The scope is instance.
- **referenceable.FactoryClass**: The reference factory class of the resource environment provider. The scope is instance.

Optional parameters

The following parameters are optional:

- **cell**: Cell of the resource action. The scope is global.
- **forceScope**: Set to true if do not want to scope to cluster, if exists. The scope is instance.
- **node**: Node of the resource action. The scope is global.
- **server**: Server of the resource action. The scope is global.

Implementation bean

The **com.ibm.wplc.deploy.tasks.impl.ResourceReferenceableCreateImpl** class implements this task.

wplc-remove-res-referenceable

Description and usage

Use this Ant task to remove a resource entry you can reference.

Required parameters

The following parameters are required:

- **providerName**: The name of the resource environment provider. The scope is instance.
- **referenceable.Class**: The reference class of the resource environment provider. The scope is instance.
- **referenceable.FactoryClass**: The reference factory class of the resource environment provider. The scope is instance.

Optional parameters

The following parameters are optional:

- **cell**: Cell of the resource action. The scope is global.
- **forceScope**: Set to `true` if do not want to scope to an existing cluster. The scope is instance.
- **node**: Node of the resource action. The scope is global.
- **server**: Server of the resource action. The scope is global.

Implementation bean

The **com.ibm.wplc.deploy.tasks.impl.ResourceReferenceableRemoveImpl** class implements this task.

wplc-create-variable

Description and usage

Use this Ant task to create or reassign a WebSphere Application Server environment variable and value.

Required parameters

The following parameters are required:

- **name**: The name of the variable. The scope is instance.
- **value**: The value that is assigned to the variable. The scope is instance.

Optional parameters

The following parameters are optional:

- **cell**: The cell of the resource action. The scope is global.
- **description**: The description of the variable.
- **node**: The node of the resource action. The scope is global.
- **server**: The server of the resource action. The scope is global.

Implementation bean

The **com.ibm.wplc.deploy.tasks.impl.VariableCreateImpl** class implements this task.

wplc-remove-variable

Description and usage

Use this Ant task to remove a WebSphere Application Server environment variable and value.

Required parameters

The following parameter is required:

- **name**: The name of the variable. The scope is instance.

Optional parameters

The following parameters are optional:

- **cell**: The cell of the resource action. The scope is global.
- **node**: The node of the resource action. The scope is global.
- **server**: The server of the resource action. The scope is global.

Implementation bean

The **com.ibm.wplc.deploy.tasks.impl.VariableRemoveImpl** class implements this task.

wplc-retrieve-variable

Description and usage

Use this Ant task to retrieve a WebSphere Application Server environment variable and value.

Required parameters

The following parameter is required:

- **name**: The name of the variable. The scope is instance.

Optional parameters

The following parameters are optional:

- **cell**: The cell of the resource action. The scope is global.
- **node**: The node of the resource action. The scope is global.
- **server**: The server of the resource action. The scope is global.

Implementation bean

The **com.ibm.wplc.deploy.tasks.impl.VariableRetrieveImpl** class implements this task.

wplc-create-res-env-directory

Description and usage
Use this Ant task to create RP file names in the directory.

Required parameters
The following parameter is required:

- **rpPropertyDirectoryName**: The property directory name. The scope is instance.

Optional parameters
The following parameters are optional:

- **cell**: Cell of the resource action. The scope is global.
- **forceScope**: Set to true if do not want to scope to an existing cluster. The scope is instance.
- **node**: Node of the resource action. The scope is global.
- **rpPrefix**: The name of the prefix. The scope is instance.
- **server**: Server of the resource action. The scope is global.

Implementation bean
The **com.ibm.wplc.deploy.tasks.impl.REProviderCreateByDirectoryImpl** class implements this task.

wplc-cluster-sync-all-node

Description and usage
Use this Ant task to sync all nodes in the cluster.

Optional parameters
The following parameters are optional:

- **cell**: Cell of the resource action. The scope is global.
- **node**: Node of the resource action. The scope is global.
- **server**: Server of the resource action. The scope is global.

Implementation bean
The **com.ibm.wplc.deploy.tasks.impl.ClusterSyncAllNodesImpl** class implements this task.

wplc-cluster-sync-single-node

Description and usage
Use this Ant task to sync a single cluster node.

Required parameters
The following parameter is required:

- **syncNode**: The name of the node to sync. The scope is instance.

Optional parameters
The following parameters are optional:

- **cell**: Cell of the resource action. The scope is global.
- **node**: Node of the resource action. The scope is global.
- **server**: Server of the resource action. The scope is global.

Implementation bean
The **com.ibm.wplc.deploy.tasks.impl.ClusterSyncSingleNodeImpl** class implements this task.

wplc-extract-ear-local-or-remote

Description and usage

Use this Ant task to extract ear files locally or remotely.

Required parameters

The following parameters are required:

- **appName**: The application name for the ear file. The scope is instance.
- **earFile**: The local directory and file where the ear file is exported to. The scope is instance.

Optional parameters

The following parameters are optional:

- **cell**: Cell of the resource action. The scope is global.
- **node**: Node of the resource action. The scope is global.
- **server**: Server of the resource action. The scope is global.

Implementation bean

The **com.ibm.wplc.deploy.tasks.impl.ExtractEarLocalOrRemoteImpl** class implements this task.

wplc-query-application-list

Description and usage

Use this Ant task to query a list of applications that are installed in the cell and to return a comma delimited string. The application list is placed in an Ant property called **${filteredAppList}**.

Optional parameters

The following parameters are optional:

- **cell**: Cell of the resource action. The scope is global.
- **filter**: The filter that is used for the application query; for example: PA_.
- **node**: Node of the resource action. The scope is global.
- **server**: Server of the resource action. The scope is global.

Implementation bean

The **com.ibm.wplc.deploy.tasks.impl.ApplicationsQueryImpl** class implements this task.

wplc-retrieve-datasource-custom-property

Description and usage

Use this Ant task to retrieve a value from the data source custom properties.

Required parameters

The following parameters are required:

- **datasourcename**: Name of the data source. The scope is instance.
- **jdbcprovidername**: Name of the JDBC provider that identifies this resource. The scope is instance.

Optional parameters

The following parameters are optional:

- **cell**: Cell of the resource action. The scope is global.
- **forceScope**: Set to true if do not want to scope to the existing cluster. The scope is instance.
- **node**: Node of the resource action. The scope is global.

- **propertyName**: The name of the custom property to retrieve the value from. The scope is instance.
- **propToSet**: The property that is set in the Ant project with the value retrieved from WebSphere Application Server. The scope is instance.
- **server**: Server of the resource action. The scope is global.

Implementation bean

The **com.ibm.wplc.deploy.tasks.impl.DataSourceRetrieveCustomPropertyValue** class implements this task.

wplc-wait-for-sync-to-complete

Description and usage

Use this Ant task to wait for the ear expansion and distribution to complete.

Optional parameters

The following parameters are optional:

- **cell**: Cell of the resource action. The scope is global.
- **maxAppTimeToWait**: The maximum time in minutes to wait for each application expansion process to complete.
- **maxTimeToWait**: The maximum time in minutes to wait for the expansion process to complete.
- **node**: Node of the resource action. The scope is global.
- **server**: Server of the resource action. The scope is global.
- **waitTime**: The time to wait between checks for the application to deploy.

Implementation bean

The **com.ibm.wplc.deploy.tasks.impl.ClusterWaitForSyncToCompleteImpl** class implements this task.

wplc-create-ear

Description and usage

Use this Ant task to deploy an EAR resource to the target Application or portal server.

Required parameters

The following parameters are required:

- **appname**: The name of the application for the EAR file.
- **earfile**: The location of the EAR file to deploy.

Optional parameters

The following parameters are optional:

- **cluster**: Defines the cluster name. Do not include spaces with this value. If not set, the value defaults to the context that is defined in the EAR file's `application.xml` file.
- **classloadermode**: Sets the class-loader delegation mode, also known as the class loader order. This value determines whether a class loader delegates the loading of classes to the parent class loader. The following values are supported:
  - `PARENT_FIRST`: Delegates the loading of classes to its parent before you load the class from its local path. This value is the default for the class-loader policy and for standard JVM class loaders.

– PARENT_LAST: Causes the class loader to attempt to load classes from its local class path before you delegate the class loading to its parent. Using this policy, an application class loader can override and provide its own version of a class that exists in the parent class loader.

- **startingweight**: Sets the starting weight for the application. The starting weight specifies the order in which applications are started when the server starts. The application with the lowest starting weight is started first.
- **server**: The name of the application server for WebSphere Portal Express.
- **node**: The name of the WebSphere Application Server node.
- **cell**: The name of the WebSphere Application Server cell.

Parameters that are specified as nested Elements

attribute - a generic attribute for this resource. Users can use this attribute to specify any additional name-value pairs that are not already covered by the **wplc** task. This parameter is used to pass any attribute that is associated with the resource action.

- **name**: The name of the attribute.
- **value**: The value of the attribute.

option - Not all available EAR deployment options are supported by the **wplc-create-ear** syntax as attributes. The **option** element passes more information to the underlying framework inside the **WsAdmin** profile. This feature is similar to how other parameters are passed into the **WsAdmin** script file. However, in this situation, the full set of options are assembled into a string corresponding to the syntax of the scripting language.
Do not code parameters that are included as attributes on the task as options. Use the corresponding attribute to avoid redundancy and to prevent runtime exception during the task parsing.
The syntax of the nested **option** element allows for the following three formats: keyword only, keyword/value pairing, or keyword with value list.

- **key**: The name of the option
- **value**: The value of the option. If no value is present and the option does not contain nested value elements, then this key does not take a value.

If a keyword can take a list of values, then a single nested **value** element is used for each value in the list.

Table 500. Examples of the keyword only, keyword/value pairing, or keyword with value list formats.. This table describes how to use the keyword only, keyword/value pairing, or keyword with value list formats for the **options** element.

Parameter type	Example (with AdminApp syntax)	Option element syntax
Keyword only	`-nodeployejb`	`<option key="nodeployejb"/>`
Keyword with simple value	`-custom value`	`<option key="custom" value="value"/>`
Keyword with list of values	`-MapresrefToEJB {{value1} {value2} {value3}}`	`<option key="MapResRefToEJB"/> <value>value1</value> <value>value2</value> <value>value3</value> </option>`

Implementation bean

The **com.ibm.wplc.deploy.tasks.EarCreate** class implements this task.

wplc-edit-ear

Description and usage

Use this Ant task to edit the attributes of the target application.

Required parameters

The following parameter is required:

- **appname**: The name of the application for the EAR file.

Parameters that are specified as nested Elements

option - Not all available EAR deployment options are supported by the **wplc-create-ear** syntax as attributes. The **option** element passes more information to the underlying framework inside the **WsAdmin** profile. This feature is similar to how other parameters are passed into the **WsAdmin** script file. However, in this situation, the full set of options are assembled into a string corresponding to the syntax of the scripting language.

Do not code parameters that are included as attributes on the task as options. Use the corresponding attribute to avoid redundancy and to prevent runtime exception during the task parsing.

The syntax of the nested **option** element allows for the following three formats: keyword only, keyword/value pairing, or keyword with value list.

- **key**: The name of the option
- **value**: The value of the option. If no value is present and the option does not contain nested value elements, then this key does not take a value.

If a keyword can take a list of values, then a single nested **value** element is used for each value in the list.

Table 501. Examples of the keyword only, keyword/value pairing, or keyword with value list formats.. This table describes how to use the keyword only, keyword/value pairing, or keyword with value list formats for the **options** element.

Parameter type	Example (with AdminApp syntax)	Option element syntax
Keyword only	`-nodeployejb`	`<option key="nodeployejb"/>`
Keyword with simple value	`-custom value`	`<option key="custom" value="value"/>`
Keyword with list of values	`-MapresrefToEJB {{value1} {value2} {value3}}`	`<option key="MapResRefToEJB"/> <value>value1</value> <value>value2</value> <value>value3</value> </option>`

Implementation bean

The **com.ibm.wplc.deploy.tasks.EarEdit** class implements this task.

wplc-update-ear

Description and usage

Use this Ant task to update an existing deployed EAR file with a new or modified version.

Required parameters

The following parameters are required:

- **appname**: The name of the application for the EAR file.
- **earfile**: The location of the EAR file to deploy.

Optional parameters

The following parameters are optional:

- **classloadermode**: Sets the class-loader delegation mode, also known as the class loader order. This value determines whether a class loader delegates the loading of classes to the parent class loader. The following values are supported:
  - PARENT_FIRST: Delegates the loading of classes to its parent before you load the class from its local class path. This value is the default for the class-loader policy and for standard JVM class loaders.
  - PARENT_LAST: Causes the class loader to attempt to load classes from its local class path before you delegate the class loading to its parent. Using this policy, an application class loader can override and provide its own version of a class that exists in the parent class loader.
- **startingweight**: Sets the starting weight for the application. The starting weight specifies the order in which applications are started when the server starts. The application with the lowest starting weight is started first.

Parameters that are specified as nested Elements

attribute - a generic attribute for this resource. Users can use this attribute to specify any additional name-value pairs that are not already covered by the **wplc** task. This parameter is used to pass any attribute that is associated with the resource action.

- **name**: The name of the attribute.
- **value**: The value of the attribute.

option - Not all available EAR deployment options are supported by the **wplc-create-ear** syntax as attributes. The **option** element passes more information to the underlying framework inside the **WsAdmin** profile. This feature is similar to how other parameters are passed into the **WsAdmin** script file. However, in this situation, the full set of options are assembled into a string corresponding to the syntax of the scripting language.
Do not code parameters that are included as attributes on the task as options. Use the corresponding attribute to avoid redundancy and to prevent runtime exception during the task parsing.
The syntax of the nested **option** element allows for the following three formats: keyword only, keyword/value pairing, or keyword with value list.

- **key**: The name of the option
- **value**: The value of the option. If no value is present and the option does not contain nested value elements, then this key does not take a value.

If a keyword can take a list of values, then a single nested **value** element is used for each value in the list.

Table 502. Examples of the keyword only, keyword/value pairing, or keyword with value list formats.. This table describes how to use the keyword only, keyword/value pairing, or keyword with value list formats for the **options** element.

Parameter type	Example (with AdminApp syntax)	Option element syntax
Keyword only	`-nodeployejb`	`<option key="nodeployejb"/>`
Keyword with simple value	`-custom value`	`<option key="custom" value="value"/>`
Keyword with list of values	`-MapresrefToEJB {{value1} {value2} {value3}}`	`<option key="MapResRefToEJB"/> <value>value1</value> <value>value2</value> <value>value3</value> </option>`

Implementation bean

The **com.ibm.wplc.deploy.tasks.EarUpdate** class implements this task.

wplc-modify-ear

Description and usage

Use this Ant task to modify a previously deployed EAR resource to the target application or Portal server instance.

Required parameters

The following parameters are required:

- **appname**: The name of the application for the EAR file.

Optional parameters

The following parameters are optional:

- **classloadermode**: Sets the class-loader delegation mode, also known as the class loader order. This parameter determines whether a class loader delegates the loading classes to the parent class loader. The following values are supported:
  - PARENT_FIRST: Delegates the loading of classes to its parent before you load the class from its local class path. This value is the default for the class-loader policy and for standard JVM class loaders.
  - PARENT_LAST: Causes the class loader to attempt to load classes from its local class path before you delegate the class loading to its parent. Using this policy, an application class loader can override and provide its own version of a class that exists in the parent class loader.
- **startingweight**: Set the starting weight for the application. The starting weight specifies the order in which applications are started when the server starts. The application with the lowest starting weight is started first.
- **server**: The name of the WebSphere Portal Express server.
- **node**: The name of the WebSphere Application Server node.
- **cell**: The name of the WebSphere Application Server cell.

Parameters that are specified as nested Elements

attribute - a generic attribute for this resource. Users can use this attribute to specify any additional name-value pairs that are not already covered by the **wplc** task.

- **name**: The name of the attribute.
- **value**: The value of the attribute.

option - Not all available EAR deployment options are supported by the **wplc-create-ear** syntax as attributes. The **option** element passes more information to the underlying framework inside the **WsAdmin** profile. This feature is similar to how other parameters are passed into the **WsAdmin** script file. However, in this situation, the full set of options are assembled into a string corresponding to the syntax of the scripting language.
Do not code parameters that are included as attributes on the task as options. Use the corresponding attribute to avoid redundancy and to prevent runtime exception during the task parsing.
The syntax of the nested **option** element allows for the following three formats: keyword only, keyword/value pairing, or keyword with value list.

- **key**: The name of the option

- **value**: The value of the option. If no value is present and the option does not contain nested value elements, then this key does not take a value.

If a keyword can take a list of values, then a single nested **value** element is used for each value in the list.

Table 503. Examples of the keyword only, keyword/value pairing, or keyword with value list formats.. This table describes how to use the keyword only, keyword/value pairing, or keyword with value list formats for the **options** element.

Parameter type	Example (with AdminApp syntax)	Option element syntax
Keyword only	`-nodeployejb`	`<option key="nodeployejb"/>`
Keyword with simple value	`-custom value`	`<option key="custom" value="value"/>`
Keyword with list of values	`-MapresrefToEJB {{value1} {value2} {value3}}`	`<option key="MapResRefToEJB"/> <value>value1</value> <value>value2</value> <value>value3</value> </option>`

Implementation bean

The **com.ibm.wplc.deploy.tasks.EarModify** class implements this task.

wplc-update-file-in-ear

Description and usage

Use this Ant task to update a file in the deployed ear.

Required parameters

The following parameters are required:

- **appname**: The name of the application for the EAR file.
- **classloadermode**: Sets the class-loader delegation mode, also known as the class loader order. This value determines whether a class loader delegates the loading of classes to the parent class loader. The following values are supported:
  - PARENT_FIRST: Delegates the loading of classes to its parent before you load the class from its local class path. This value is the default for the class-loader policy and for standard JVM class loaders.
  - PARENT_LAST: Causes the class loader to attempt to load classes from its local class path before you delegate the class loading to its parent. Using this policy, an application class loader can override and provide its own version of a class that exists in the parent class loader.
  - **startingweight**: Sets the starting weight for the application. The starting weight specifies the order in which applications are started when the server starts. The application with the lowest starting weight is started first.

Parameters that are specified as nested Elements

option - Not all available EAR deployment options are supported by the **wplc-create-ear** syntax as attributes. The **option** element passes more information to the underlying framework inside the **WsAdmin** profile. This feature is similar to how other parameters are passed into the **WsAdmin** script file. However, in this situation, the full set of options are assembled into a string corresponding to the syntax of the scripting language.

Do not code parameters that are included as attributes on the task as options. Use the corresponding attribute to avoid redundancy and to prevent runtime exception during the task parsing.

The syntax of the nested **option** element allows for the following three formats: keyword only, keyword/value pairing, or keyword with value list.

- **key**: The name of the option
- **value**: The value of the option. If no value attribute is present and the option does not contain value elements, then this key does not take a value.

If a keyword can take a list of values, then a single nested **value** element is used for each value in the list.

Add the following two <option> keys:

- An option element with a key of `contents` points to the location on disk of the file to update `option key="contents" value="locationOfFileOnDisk"/>`.
- An option element with a key of `contenturi` points to the location inside of an `.ear` file of the file to update `option key="contenturi" value="locationOfFileInEar"/>`

Implementation bean

The **com.ibm.wplc.deploy.tasks.EarCreate** class implements this task.

wplc-remove-ear

Description and usage

Use this Ant task to remove or uninstall an EAR resource from the target application or Portal server instance.

Required parameters

The following parameter is required:

- **appname**: The name of the application for the EAR file.

Implementation bean

The **com.ibm.wplc.deploy.tasks.EarRemove** class implements this task.

IBM UX Screen Flow Manager

The IBM UX Screen Flow Manager helps operators, developers, and dialog modelers develop fine-granular, small split portlets. Portlets provide the functions for the steps that are presented as screens. You can configure the sequence, transitions, and workflow of a set of screens. Screen flows work like wizards and process the screens to complete the task for the user. Screen flows are completed by a single user and have a short lifetime.

For example, screen flow modelers can model flows for processing the sequence of steps that are involved in booking a trip for a travel site. Booking for a trip might include steps such as gathering traveler information, booking flight, booking hotel, and booking car. Each of these steps might include substeps such as displaying the customer information, and updating customer information. Each of these steps is presented as screens and the functions behind them are provided by portlets. These portlets are interconnected and managed by IBM WebSphere Portal. The screen flow configurations route users along paths that interconnect user interface artifacts, such as forms or masks, to accomplish specific tasks. The mapping of individual screens to portlets affects both user experience and reusability. This approach provides both strict user guidance and high reusability.

Screen flows can be used together with business workflows. Long-running business processes that are run by a business workflow can trigger screen flows that are run by portal. After the screen flow completes, the portal gives the control

back to the business workflow. Data can be exchanged between the business workflow and the screen flow on the portal. If a user suspends a screen flow, the portal can hand over the processed data over to the business workflow to save it.

"Developing screen flows"
To develop screen flows you need to create user interface artifacts, interconnect the artifacts and deploy the artifacts.

"Advanced concepts" on page 3506
Learn about the advanced concepts of the IBM UX Screen Flow Manager.

CF05 "User interface components" on page 3518
In a default WebSphere Portal installation, the Dialog Stack and Dialog State Display portlets are deployed. The following topics describe how these portlets function.

"Configuration options" on page 3525
To change the overall behavior of the IBM UX Screen Flow Manager, several configuration options are available. You specify the options as Resource Environment Provider (REP) properties.

"Staging and migration" on page 3526
For staging or migration purposes, you can use the portal XML configuration interface (XMLAccess) to transfer IBM UX Screen Flow Manager related data from one system to another.

CF05 "Transitions reference" on page 3526
You can configure transitions in multiple ways. For example, with single portlets as source, you can configure it to transition to targets such as single portlets, multiple portlets through single or multiple transition endpoints, single page, or mixed resources. Similarly, you can configure single portlets, multiple portlets, single page, or mixed resources to become the source and transition to the target single portlet. The following reference topics show the code samples for these transitions.

"Sample screen flow application" on page 3534
The IBM UX Screen Flow Manager package can be downloaded from the Greenhouse site and includes a sample screen flow application that is ready to use. This sample guides a portal site visitor through a simple travel booking flow. It consists of a set of pages, portlets, and dialog definitions (DDs). For more details about DDs, go to Creating dialog definitions.

Product documentation

Developing screen flows

To develop screen flows you need to create user interface artifacts, interconnect the artifacts and deploy the artifacts.

About this task

To develop screen flows, do the following steps:

Procedure

1. Develop the necessary user interface artifacts that when combined define the appropriate screen flow. These user interface artifacts are usually portlets that can send and receive JSR 286 events.
2. Create the dialog definition that defines all interconnections between the user interface artifacts that were created in the previous step.
3. Deploy all user interface artifacts and the dialog definition.

"Developing user interface artifacts"
Every screen flow needs a starting point from which it can be triggered. The user interface components that you develop and their functions enable the screen flow to be triggered and processed. Independent of the type of user interface artifact you develop, it must send and receive JSR-286 events to enable a screen flow. Therefore, you must implement or reuse JSR-286 compliant portlets that send and receive such events.

"Creating dialog definitions" on page 3479
With the Screen Flow Manager, different teams or even third-party vendors can develop different types of user interface artifacts. The user puts together the correct set of user interface artifacts and creates the declarative model in XML known as the dialog definition. The dialog definition describes the specific screen flow that is also known as dialog, which consists of multiple steps and single steps referred to as subdialogs. The dialog definition contains all information about the subdialogs that participate and the transitions that route the user from one subdialog to another.

"Deploying user interface artifacts" on page 3505
Before you deploy the Screen Flow Manager dialog definitions, you must deploy all portal resources that are part of the dialog definitions, such as pages, and portlets. You can then deploy the dialog definitions by using the portal XML configuration interface (XMLAccess).

Developing user interface artifacts

Every screen flow needs a starting point from which it can be triggered. The user interface components that you develop and their functions enable the screen flow to be triggered and processed. Independent of the type of user interface artifact you develop, it must send and receive JSR-286 events to enable a screen flow. Therefore, you must implement or reuse JSR-286 compliant portlets that send and receive such events.

For example, assume in a travel site for a Flight booking page, the Passenger information portlet `portlet1` and the Calendar portlet `portlet2` are two portlets that you developed.

- The Passenger information portlet `portlet1` must be able to receive an event with the QName `e0` and to send an event with the QName `e1`.
- The Calendar portlet `portlet2` must be able to receive an event with the QName `e1` and to send an event with the QName `e2`.

When the Passenger information portlet `portlet1` sends the event `e1`, the user is routed from the Passenger information portlet `portlet1` to the Calendar portlet `portlet2`. For more information, go to *Transitions*.

To enable the Passenger information portlet `portlet1` to receive and send the mentioned events, you need to do the following two things:

- Specify the events in the `portlet.xml` file of the portlet.

```
<portlet id="portlet1">
 ...
  <supported-processing-event>
      <qname>e0</qname>
  </supported-processing-event>
  <supported-publishing-event>
      <qname>e1</qname>
  </supported-publishing-event>
 </portlet>

 <event-definition>
  <qname>e0</qname>
```

```
 <value-type>java.lang.String</value-type>
</event-definition>
<event-definition>
 <qname>e1</qname>
 <value-type>java.lang.String</value-type>
</event-definition>
```

- Include code in the portlet that can handle an incoming event and another code that can send an event.

```
@Override
public void processAction(ActionRequest request, ActionResponse response)
     throws PortletException, IOException {
 // ...

 response.setEvent(new QName("e1", "xyz"), new String());
}

@Override
public void processEvent(EventRequest request, EventResponse response)
     throws PortletException, IOException {

 final Event event = request.getEvent();
 // ...
```

Make similar changes to the Calendar portlet `portlet 2`.

```
<portlet id="portlet2">
 ...
 <supported-processing-event>
     <qname>e1</qname>
 </supported-processing-event>
 <supported-publishing-event>
     <qname>e2</qname>
 </supported-publishing-event>
</portlet>

<event-definition>
 <qname>e1</qname>
 <value-type>java.lang.String</value-type>
</event-definition>
<event-definition>
 <qname>e2</qname>
 <value-type>java.lang.String</value-type>
</event-definition>
```

```
@Override
public void processAction(ActionRequest request, ActionResponse response)
     throws PortletException, IOException {
 // ...

 response.setEvent(new QName("e2", "xyz"), new String());
}

@Override
public void processEvent(EventRequest request, EventResponse response)
     throws PortletException, IOException {

 final Event event = request.getEvent();
 // ...
```

If you want to integrate forms such as passenger information form or widgets such as calendar, you can use such a portlet as a wrapper for these artifacts. For more information about developing portlets, go to *Developing portlets in the WebSphere® Portal Version 8.0 product documentation.*

The portlets that can start screen flows are referred to as Dialog Instantiation and Initialization portlets (DIIPs). You can usually distinguish between two kinds of DIIPs:

- One type of DIIP triggers a new dialog instance by sending a well-defined start-event.
- The other type of DIIP triggers a new dialog that is based on the fact that a specific portlet emits a specific custom event.

In either case, the event emission causes a new screen flow to be started and initialized with some initial data that the event payload transmits.

With the Screen Flow Manager, different teams or even third-party vendors can develop different types of user interface (UI) artifacts. These artifacts are usually portlets, but can also be widgets or forms. For more details, go to *iWidgets Development in the IBM® Rational® Application Developer documentation*.

Related concepts:

"Transitions" on page 3487
Transitions define how to route a user from one subdialog to another. As subdialogs are represented by pages or portlets, they reference transition-endpoints. For example, in a travel site, a user can be routed from the Passenger information subdialog or portlet to the Calendar subdialog or portlet.

Related information:

Developing portlets

iWidget development overview

Creating dialog definitions

With the Screen Flow Manager, different teams or even third-party vendors can develop different types of user interface artifacts. The user puts together the correct set of user interface artifacts and creates the declarative model in XML known as the dialog definition. The dialog definition describes the specific screen flow that is also known as dialog, which consists of multiple steps and single steps referred to as subdialogs. The dialog definition contains all information about the subdialogs that participate and the transitions that route the user from one subdialog to another.

Dialogs

Dialogs, also known as dialog definitions, define all the artifacts of which a single dialog is comprised. They define the resources such as pages and portlets, also called transition endpoints, that are part of the specific dialog. Dialog definitions also define the transitions that route a user from one subdialog to another. For more information, go to *Transition endpoints* and *Transitions*. You can define dialog definitions by using a unique name. For example, in a travel site, the flight booking step can be described as a dialog, which defines artifacts such as Passenger information portlet, and Travel dates portlet.

```
<dialog-set>
    <dialog name="dialog1">
        <transition-endpoint name="portlet1">
            ...
        </transition-endpoint>
        <transition-endpoint name="portlet2">
            ...
        </transition-endpoint>
        <transition>
            ...
```

```
        </transition>
        <transition>
            ...
        </transition>
    </dialog>
</dialog-set>
```

During run time, dialog definitions form the templates from which concrete dialog instances are created. These instances are uniquely identified by `DialogInstanceIDs`.

Dialogs are scoped to virtual portals. This scoping means that a screen flow that is running in one virtual portal does not show in another virtual portal or vice versa.

Dialog sets

Dialog sets can contain one or more screen flow definitions. For example, in a travel site the Flight booking dialog and Car booking dialog that working together can be referred to as Dialog sets.

```
<dialog-set>
 <dialog name="dialog1">
     ...
 </dialog>
 <dialog name="dialog2">
     ...
 </dialog>
</dialog-set>
```

"Transition endpoints"
Resources that are part of a screen flow which marks an endpoint, that is, the source or target of a transition are referred to as transition endpoints. Resources can be pages and portlets and they can also wrap widgets or forms. A particular page or portlet that is the active step in a screen flow is referred to as the source and the potential next steps are referred to as targets.

"Transitions" on page 3487
Transitions define how to route a user from one subdialog to another. As subdialogs are represented by pages or portlets, they reference transition-endpoints. For example, in a travel site, a user can be routed from the Passenger information subdialog or portlet to the Calendar subdialog or portlet.

Related concepts:

"Transition endpoints"
Resources that are part of a screen flow which marks an endpoint, that is, the source or target of a transition are referred to as transition endpoints. Resources can be pages and portlets and they can also wrap widgets or forms. A particular page or portlet that is the active step in a screen flow is referred to as the source and the potential next steps are referred to as targets.

"Transitions" on page 3487
Transitions define how to route a user from one subdialog to another. As subdialogs are represented by pages or portlets, they reference transition-endpoints. For example, in a travel site, a user can be routed from the Passenger information subdialog or portlet to the Calendar subdialog or portlet.

Transition endpoints:

Resources that are part of a screen flow which marks an endpoint, that is, the source or target of a transition are referred to as transition endpoints. Resources can be pages and portlets and they can also wrap widgets or forms. A particular

page or portlet that is the active step in a screen flow is referred to as the source and the potential next steps are referred to as targets.

For example, in a travel site the Flight booking dialog contains resources such as the Passenger information portlet and Calendar portlet which wraps the Calendar widget. When the dialog defines a transition that route the user from entering Passenger information step to selecting the travel dates step, the Passenger information portlet and the Calendar portlet become the source and target of the transition.

A source can reference only one single transition-endpoint that is associated with only one single event. A target can reference multiple transition-endpoints that are associated with one or multiple events. There are different options available to reference resources.

CF05 "Referencing portlets"
A transition endpoint can reference portlets as the target of a screen flow transition.

CF05 "Reference pages" on page 3482
A transition endpoint can reference pages as the target of a screen flow transition.

CF05 "Referencing dialogs" on page 3484
A transition endpoint can reference dialog as the source of a screen flow transition.

"Referencing single resource across different dialogs" on page 3485
Often, a single resource is used across different dialogs. For example, such a resource can be a generic date selection portlet. In a travel site, such a page can be used to select the departure date and the return date for the Flight booking dialog and also for the Car booking dialog.

CF05 "Referencing through metadata markers" on page 3486
Pages and portlets can be referenced not only by their unique names but can also be referenced through metadata markers.

CF05 "Mixed referencing" on page 3487
The mechanisms for referencing a single page, a single portlet, multiple pages, or multiple portlets by unique names or metadata markers can be mixed.

CF05 "Limitations when referencing resources" on page 3487
Not all mechanisms for referencing resources are allowed to be used as part of both, a transitions source and a transitions target.

Referencing portlets:

A transition endpoint can reference portlets as the target of a screen flow transition.

Reference a single portlet

The simplest form of a transition endpoint that is used within a transitions source is a transition endpoint that references a single portlet. In that case, the portlet is referenced through its unique name. For example, in a travel site, the transition endpoint can reference a Calendar portlet as the target in a transition with Passenger information portlet as the source.

A transition with a source that points to a transition endpoint that references a single portlet is triggered. The transition is triggered when the particular portlet that is referenced emits the event that is defined as part of the transitions source. For more information, see *Transitions*.

```
<dialog name="dialog1">
 <transition-endpoint name="portlet1">
      <localedata locale="en">
           <title>Subdialog 1</title>
           <description>This is a subdialog</description>
       </localedata>
       <resource uniquename="uniquename.portlet1"/>
       <invocation type="static"/>
...
  </transition-endpoint>
```

Reference multiple portlets

It is also possible to reference multiple portlets as part of a single transition endpoint. For example, the transition with Passenger information portlet as the source can point to Calendar portlets, and Destination portlets as references in a transition endpoint.

A transition with a source that points to a transition endpoint that references multiple portlets is triggered. The transition is triggered when any of the referenced portlets emit the event that is defined as part of the transitions source.

```
<dialog name="dialog1">
 <transition-endpoint name="portlet1_2_3">
      <localedata locale="en">
          <title>Subdialog 1</title>
          <description>This is a subdialog</description>
       </localedata>
       <resource uniquename="uniquename.portlet1"/>
       <resource uniquename="uniquename.portlet2"/>
       <resource uniquename="uniquename.portlet3"/>
       <invocation type="static"/>
...
</transition-endpoint>
```

Related concepts:

CF05 "Transitions" on page 3487
Transitions define how to route a user from one subdialog to another. As subdialogs are represented by pages or portlets, they reference transition-endpoints. For example, in a travel site, a user can be routed from the Passenger information subdialog or portlet to the Calendar subdialog or portlet.

Reference pages:

A transition endpoint can reference pages as the target of a screen flow transition.

Reference a single page

A transition with a source that points to a transition endpoint that references a single page is triggered. The transition is triggered when any portlet on the particular page that is referenced emits the event that is defined as part of the transitions source. For example, in a travel site, in a Flight booking dialog the transition with Calendar portlet as the source can reference the departure date page as the target.

```
<dialog name="dialog1">
   <transition-endpoint name="page1">
        <localedata locale="page1">
```

```
            <title>Subdialog 1</title>
            <description>This is a subdialog</description>
        </localedata>
        <resource uniquename="uniquename.page1"/>
        <invocation type="static"/>
...
</transition-endpoint>
```

Reference multiple pages

As with portlets, it is also possible to reference multiple pages as part of a single transition-endpoint. For example, in a Flight booking dialog, the transition with Calendar portlet as the source can reference the departure date page and return date page as targets.

A transition with a source that points to a transition-endpoint that references multiple pages is triggered. The transition is triggered when any portlet on any of the pages that are referenced emits the event. The emitted event must be defined as part of the transitions source.

```
<dialog name="dialog1">
   <transition-endpoint name="page1_2_3">
         <localedata locale="en">
               <title>Subdialog 1</title>
               <description>This is a subdialog</description>
          </localedata>
          <resource uniquename="uniquename.page1"/>
          <resource uniquename="uniquename.page2"/>
          <resource uniquename="uniquename.page3"/>
          <invocation type="static"/>
...
</transition-endpoint>
```

Reference page hierarchies

A portlet can consist of a well-defined set of topologically connected pages. The pages are part of a connected graph. In some scenarios, you might want a transition to be triggered when any portlet on any page that is part of a connected graph emits the event. The event that is emitted must be defined as part of the transition's source.

To list all the pages, you can point to a page hierarchy by referencing the hierarchy's root page. You can reference the root page through its unique name and with the optional attribute `type` with value `hierarchy`.

A transition with a source that points to a transition-endpoint that references a page hierarchy is triggered. The transition is triggered when any page that is a direct or indirect child of the referenced root page emits the event. The event that is emitted must be defined as part of the transitions source.

For example, in a travel site, in a Flight booking dialog, the transition can point to the Destination portlet. The Destination portlet can consist of several pages that provide data on possible destination locations the user can choose. To list all the pages in the destination portlet the transition can reference the hierarchy root page, for example, Europe.

```
<dialog name="dialog1">
  <transition-endpoint name="pageHierarchy1">
       <localedata locale="en">
            <title>Subdialog 1</title>
            <description>This is a subdialog</description>
```

```
        </localedata>
        <resource uniquename="uniquename.page1" type="hierarchy" />
        <invocation type="static"/>
...
</transition-endpoint>
```

Referencing dialogs:

A transition endpoint can reference dialog as the source of a screen flow transition.

Reference a single dialog

It is possible to reference a single dialog as part of a transition-endpoint. For example, in a travel site, the steps that are needed to book a flight might represent a single dialog and booking a car might represent another dialog. A transition endpoint can reference the Flight booking dialog or the Car booking dialog.

If a transition defines a target that points to a transition-endpoint that references a dialog, the transition is referred to as outgoing transition. An outgoing transition represents a transition that starts when it leaves the calling dialog and enters the called one. For example, if the Car booking dialog is defined as the target in a transition and the Flight booking dialog is defined as the source, the Flight booking dialog would be the calling dialog and the Car booking dialog would be the called one. Therefore, an outgoing transition is one that starts when it leaves the Flight booking dialog and enters the Car booking dialog.

If a transition defines a source that points to a transition-endpoint that references a dialog, the transition is referred to as incoming transition. An incoming transition represents a transition that starts when it returns from the called dialog and continues with the calling one. For example, if the Flight booking dialog is referenced as the source, a transition that returns from the target Car booking, the called dialog to the source Flight booking, the calling dialog and continues with the steps then it is an incoming transition.

For more information about transitions, go to *Transitions* and for more information about starting dialogs from within other dialogs, go to *Dialog chaining and nesting*.

```
<dialog name="dialog1>
 <transition-endpoint name="dialog2">
      <localedata locale="en">
           <title>Dialog 2</title>
           <description>This is dialog 2</description>
      </localedata>
      <resource uniquename="dialog2"/>
      <invocation type="static"/>
...
 </transition-endpoint>
```

Related concepts:

CF05 "Transitions" on page 3487
Transitions define how to route a user from one subdialog to another. As subdialogs are represented by pages or portlets, they reference transition-endpoints. For example, in a travel site, a user can be routed from the Passenger information subdialog or portlet to the Calendar subdialog or portlet.

CF05 "Dialog chaining and nesting" on page 3494
Dialogs can start other dialogs. Dialogs that start other dialogs are referred to as calling dialogs and the dialogs that are being started are referred to as called dialogs. Two different options are available to complete this action such as dialog chaining and dialog nesting.

Referencing single resource across different dialogs:

Often, a single resource is used across different dialogs. For example, such a resource can be a generic date selection portlet. In a travel site, such a page can be used to select the departure date and the return date for the Flight booking dialog and also for the Car booking dialog.

Portlets can have only one dedicated title per locale. For example, the portlet might be called Calendar. Therefore, the dialog must make the descriptions clear to the site visitor who books a trip. The portlet must clearly show when this portlet is used for selecting the departure date, and when it is used for selecting the return date for the trip.

If no explicit titles and descriptions were specified for a transition endpoint as part of the dialog definition. The Dialog State Display (DSD) shows the step with the localized title of the referenced resource.

Thus the following applies:

- If the transition endpoint references a page, the localized page title is displayed.
- If the transition endpoint references a portlet, the localized portlet title is displayed.

But this fallback mechanism still does not provide possibilities for displaying different titles for the same resource during different steps. To resolve this problem, dialog modelers can also explicitly specify localized titles and descriptions for transition endpoints. The DSD then displays these titles and descriptions instead of the original title and description of the resource. Therefore, you can define two transition endpoints that point to the same resource but have different titles and descriptions or localized titles and descriptions for that resource.

The example references the same Calendar portlet twice as part of two separate transition endpoints. In one transition endpoint, the English title is set to `Date to leave`, in the other one to `Date to return`. This way, the DSD can display the same portlet with different titles or localized titles.

```
<dialog name="dialog1">
 <transition-endpoint name="calendar.leave">
     <localedata locale="en">
         <title>Date to leave</title>
         <description>Specify the date to leave</description>
     </localedata>
     <localedata locale="de">
         <title>Abreisedatum</title>
         <description>Geben Sie Ihr Abreisedatum an</description>
     </localedata>
     <resource uniquename="uniquename.calendar"/>
     <invocation type="static"/>
</transition-endpoint>
 <transition-endpoint name="calendar.return">
     <localedata locale="en">
        <title>Date to return</title>
         <description>Specify the date to return</description>
     </localedata>
     <localedata locale="de">
         <title>Rueckreisedatum</title>
         <description>Geben Sie Ihr Rueckreisedatum an</description>
     </localedata>
     <resource uniquename="uniquename.calendar"/>
     <invocation type="static"/>
 </transition-endpoint>
```

```
  ...
  <transition>
      <source>
          <transition-endpoint nameref="portlet1">
              <event qname="e1"/>
          </transition-endpoint>
      </source>
      <target>
          <transition-endpoint nameref="calendar.leave">
              <event qname="ecl"/>
          </transition-endpoint>
      </target>
  </transition>
  ...
  <transition>
     <source>
          <transition-endpoint nameref="portlet2">
              <event qname="e2"/>
          </transition-endpoint>
     </source>
      <target>
          <transition-endpoint nameref="calendar.return">
              <event qname="ecr"/>
          </transition-endpoint>
      </target>
  </transition>
  ...
 </dialog>
```

Referencing through metadata markers:

Pages and portlets can be referenced not only by their unique names but can also be referenced through metadata markers.

A transition has a source that points to a transition-endpoint. The transition-endpoint references one or multiple portlets through metadata markers. When the particular portlet or any of the portlets that are referenced emits the event, the transition is triggered. The event that is emitted is defined as part of the transition's source.

Alternatively, a transition has a source that points to a transition-endpoint. The transition-endpoint references one or multiple pages through metadata markers. When any portlet on the particular page or on any of the pages that are referenced emits the event, the transition is triggered. The event that is emitted is defined as part of the transitions source.

Code sample shows an example where resources, either pages or portlets, that are assigned metadata with keys *uxfm.marker.1* and *uxfm.marker.2* are being referenced.

```
<dialog name="dialog1">
  <transition-endpoint name="marked_resources">
      <localedata locale="en">
          <title>Subdialog 1</title>
          <description>This is a subdialog</description>
       </localedata>
       <resource metadat="uxfm.marker.1"/>
       <resource metadata="uxfm.marker.2"/>
       <invocation type="static"/>
...
</transition-endpoint>
```

Note: Marking portlet definitions instead of portlet windows lead to a different behavior. For more information, go to the topic *Dynamic pages and portlets*

Related concepts:

CF05 “Dynamic pages and portlets” on page 3516
The IBM UX Screen Flow Manager not only supports redirecting users between static portal resources, but also between dynamic resources. The WebSphere Portal feature Dynamic UI Management is used.

Mixed referencing:

The mechanisms for referencing a single page, a single portlet, multiple pages, or multiple portlets by unique names or metadata markers can be mixed.

Example of mixed referencing.

```
<dialog name="dialog1">
 <transition-endpoint name="mixed">
     <localedata locale="en">
           <title>Subdialog 1</title>
           <description>This is a subdialog</description>
      </localedata>
      <resource uniquename="uniquename.portlet1"/>
      <resource uniquename="uniquename.page1"/
```

Limitations when referencing resources:

Not all mechanisms for referencing resources are allowed to be used as part of both, a transitions source and a transitions target.

Table 1 provides an overview of what referencing mechanism is allowed and disallowed.

Table 504. Overview of referencing mechanisms

Referencing Mechanism	Allowed within a transitions's source	Allowed within a transitions target
Single portlet	✓	✓
Multiple portlets	✓	✓
Single page	✓	✓
Multiple pages	✓	
Page hierarchies	✓

Single dialog	✓	✓

Transitions:

Transitions define how to route a user from one subdialog to another. As subdialogs are represented by pages or portlets, they reference transition-endpoints. For example, in a travel site, a user can be routed from the Passenger information subdialog or portlet to the Calendar subdialog or portlet.

Transitions are consisted of two main subsections. One subsection defines a source and the other subsection defines a target. Sources and targets both reference transition-endpoints that are associated with events.

The following steps show how the user is routed from one subdialog to the other.

- The user is routed from the subdialog that is represented by the transition-endpoint. This transition-endpoint is referenced by the source.

- After the source's transition-endpoint emits the associated event, the user is routed from that subdialog.
- The user is routed to the subdialog that holds one or multiple transition-endpoints that are referenced by the target.
- The transition-endpoints that are routed from the source are then fed with the associated events of the target endpoints.

You can configure transitions in multiple ways, for example

- With single portlets as source, you can configure it to transition to targets such as single portlets, multiple portlets through single or multiple transition endpoints, single page, or mixed resources.
- Similarly you can configure single portlets, multiple portlets, single page or mixed resources to become the source and transition to the target single portlet.

For more information and example code samples of these transitions, see *Transitions reference* section.

"Start and end transitions" on page 3489
When the referenced transition endpoint and event matches the source of a start transition, dialogs are started. Start transitions differ from other transitions only in that they carry the attribute `type`, with the value `start`. Similarly, end transitions carry the attribute `type`, with the value `end`.

"Start transitions and wildcards" on page 3489
You can define a dialog to start if one of several source transition endpoints emits a specific event. In this case, the start of the dialog depends only on the event and not on the referenced transition endpoint and event.

"Start transitions and special events" on page 3490
You can define a dialog to starts if a special start event is emitted from a specific source or from an arbitrary source.

"End transitions and special events" on page 3491
Similar to the special start event, end transitions can emit a special end event.

"Other special transitions" on page 3492
IBM UX Screen Flow Manager supports several more special transitions, or more precisely, transition endpoints.

"Exclusive transitions or dialogs" on page 3494
Exclusive dialogs are special forms of dialogs. They are also referred to as null or one-step dialogs. They consist of a single transition only. You can use them to go into a dialog, run only one transition, and use it to end the dialog immediately afterward.

CF05 "Dialog chaining and nesting" on page 3494
Dialogs can start other dialogs. Dialogs that start other dialogs are referred to as calling dialogs and the dialogs that are being started are referred to as called dialogs. Two different options are available to complete this action such as dialog chaining and dialog nesting.

"Rules and restrictions" on page 3501
When you model a transition certain rules and restrictions apply.

CF05 "Execution priority" on page 3502
You can and must explicitly model and enforce a deterministic behavior for the transitions. Even if the entire set of dialogs is deterministic, the emission of an event by a particular portlet can trigger two different transitions of two different dialogs. Therefore, you must explicitly model the intended behavior of the transitions.

"Deploy dialog sets by using the XML configuration interface" on page 3504
You can use the portal XML configuration interface (XMLAccess) to work with dialog sets.

Related concepts:

"Transition endpoints" on page 3480
Resources that are part of a screen flow which marks an endpoint, that is, the source or target of a transition are referred to as transition endpoints. Resources can be pages and portlets and they can also wrap widgets or forms. A particular page or portlet that is the active step in a screen flow is referred to as the source and the potential next steps are referred to as targets.

Related reference:

CF05 "Transitions reference" on page 3526
You can configure transitions in multiple ways. For example, with single portlets as source, you can configure it to transition to targets such as single portlets, multiple portlets through single or multiple transition endpoints, single page, or mixed resources. Similarly, you can configure single portlets, multiple portlets, single page, or mixed resources to become the source and transition to the target single portlet. The following reference topics show the code samples for these transitions.

Start and end transitions:

When the referenced transition endpoint and event matches the source of a start transition, dialogs are started. Start transitions differ from other transitions only in that they carry the attribute `type`, with the value `start`. Similarly, end transitions carry the attribute `type`, with the value `end`.

To avoid transitions that can accidentally start or end a screen flow, dialog modelers need to define start and end transitions. Each dialog needs to define at least one start and at least one end transition.

```
<transition type="start">
    <source>
        ...
    </source>
    <target>
        ...
    </target>
</transition>
...
<transition type="end">
    <source>
        ...
    </source>
    <target>
        ...
    </target>
</transition>
```

Start transitions and wildcards:

You can define a dialog to start if one of several source transition endpoints emits a specific event. In this case, the start of the dialog depends only on the event and not on the referenced transition endpoint and event.

Syntactically, you describe an arbitrary source transition endpoint by referencing the transition endpoint with an asterisk (`*`). In this sample, the dialog `dialog1` is started whenever one of the participating portlets emits the event `e1`.

Note: Using this function increases the risk of modeling non-deterministic dialog sets. You must not use an event that is combined with an undetermined source as part of any other dialog's start transition source.

```
<transition>
    <source>
        <transition-endpoint nameref="*">
            <event qname="e1"/>
        </transition-endpoint>
    </source>
    <target>
        ...
    </target>
</transition>
```

Start transitions and special events:

You can define a dialog to starts if a special start event is emitted from a specific source or from an arbitrary source.

This special start event is identified by the following `QName:`

`{http://www.ibm.com/xmlns/prod/websphere/portal/v6.1.0/portal-pcm}StartDialog`

Its payload needs to implement the interface `com.ibm.portal.pcm.events.DialogStartPayload`.

This special start event provides extra ways to start dialogs or screen flows. For example, by implementing the methods of that interface, you can programmatically control the name of the dialog that you want to start.

The code sample shows a dialog definition that uses the special start event. In this sample, if a portlet emits the special start event, the dialog with the name returned by the `getDialogDefinitionName()` method is started.

Note: The central idea of the IBM UX Screen Flow Manager is to control transitions that are based on the declarative model. Therefore, use this more programmatic approach with care and only if you cannot implement your goal by other means.

```
<transition type="start">
    <source>
        <transition-endpoint nameref="*">
            <event qname="{http://www.ibm.com/xmlns/prod/websphere/portal/v6.1.0/portal-pcm}StartD
        </transition-endpoint>
    </source>
    <target>
        ...
    </target>
</transition>
```

It might happen that a JSR-286 event is emitted by a portlet that participates in a dialog, but is not defined as part of a transition. Events that occur outside of a screen flow transition are not affected by the IBM UX Screen Flow Manager. They are delivered as if IBM UX Screen Flow Manager was not present. The previous code sample shows as an example: If `portlet4` emits an event `eX`, a matching transition is found and therefore run. If `portlet4` emits an event `eY`, a matching transition cannot be found, and therefore no transition is run. Nevertheless, the emission of the event `eY` affects the screen flow. For example, `portlet4` might be on `page4`, together with another portlet `portlet5`. Then, if `portlet5` can receive the event `eY`. The event `eY` is delivered from `portlet4` to `portlet5`, as if the IBM UX Screen Flow Manager were not present. The central idea of the IBM UX Screen

Flow Manager is to control transitions that are based on the declarative model. Therefore, use this more programmatic approach with care and only if you cannot implement your goal by other means.

As you can start dialogs by specifying dedicated transition endpoints, undetermined transition endpoints, dedicated events, or special start events, several combinations are possible. The code sample shows the behavior and interplay of these combinations.

```
 <dialog name="dialog1">
  <transition type="start">
      <source>
          <transition-endpoint nameref="*">
              <event qname="{http://www.ibm.com/xmlns/prod/websphere/portal/v6.1.0/portal-pcm}Star
          </transition-endpoint>
      </source>
      ...
  </transition>
 </dialog>

<dialog name="dialog2">
  <transition type="start">
      <source>
         <transition-endpoint nameref="*">
              <event qname="eX"/>
          </transition-endpoint>
      </source>
      ...
  </transition>
 </dialog>

 <dialog name="dialog3">
  <transition type="start">
      <source>
          <transition-endpoint nameref="portlet3">
              <event qname="{http://www.ibm.com/xmlns/prod/websphere/portal/v6.1.0/portal-pcm}Star
          </transition-endpoint>
      </source>
      ...
  </transition>
 </dialog>

 <dialog name="dialog4">
  <transition type="start">
      <source>
          <transition-endpoint nameref="portlet4">
              <event qname="eX"/>
          </transition-endpoint>
      </source>
      ...
  </transition>
 </dialog>
```

End transitions and special events:

Similar to the special start event, end transitions can emit a special end event.

This special end event is identified by the following `QName:`

```
{http://www.ibm.com/xmlns/prod/websphere/portal/v6.1.0/portal-pcm}EndDialog
```

In contrast to the special start event, the special end event is not expected to carry a payload.

```
<transition type="end">
     <source>
         <transition-endpoint nameref="portlet1">
             <event qname="e1"/>
         </transition-endpoint>
     </source>
     <target>
         <transition-endpoint nameref="portlet2">
             <event qname="{http://www.ibm.com/xmlns/prod/websphere/portal/v6.1.0/portal-pcm}EndDia
         </transition-endpoint>
     </target>
 </transition>
```

Other special transitions:

IBM UX Screen Flow Manager supports several more special transitions, or more precisely, transition endpoints.

After a dialog ends, the user needs to be redirected to a page. The following options are available:

1. If the target of an end transition points to the special transition endpoint `DEFAULT_RETURN`, the screen flow manager redirects the user. The user is redirected to the resource referenced by the unique name that is specified for the configuration option `com.ibm.wps.pcm.dialog.default.return.uniquename`. For more details, go to *Configuration options*. The event that is associated with this target is transmitted to the referenced resource.

   ```
   <transition type="end">
        <source>
            <transition-endpoint nameref="portlet1">
                <event qname="e1"/>
            </transition-endpoint>
        </source>
        <target>
            <transition-endpoint nameref="DEFAULT_RETURN">
                <event qname="e2"/>
            </transition-endpoint>
        </target>
    </transition>
   ```

2. If the target of an end transition points to the special transition endpoint `PAGE_ORIGIN`, the user is redirected to the page from which the dialog is triggered.

   The event that is associated with this target is transmitted to all portlets on that page. This transmission is also called broadcasting.

   ```
    <transition type="end">
        <source>
            <transition-endpoint nameref="portlet1">
                <event qname="e1"/>
            </transition-endpoint>
        </source>
        <target>
            <transition-endpoint nameref="PAGE_ORIGIN">
                <event qname="e2"/>
            </transition-endpoint>
        </target>
    </transition>
   ```

3. If the target of an end transition points to the special transition endpoint `PORTLET_ORIGIN`, the user is redirected to the page that contains the portlet from which the dialog is triggered.

   The event that is associated with this target is transmitted to that specific portlet.

```
<transition type="end">
    <source>
        <transition-endpoint nameref="portlet1">
            <event qname="e1"/>
        </transition-endpoint>
    </source>
    <target>
        <transition-endpoint nameref="PORTLET_ORIGIN">
            <event qname="e2"/>
        </transition-endpoint>
    </target>
</transition>
```

Another special transition is available for standard transitions that are not end transitions. In this context, dialog modelers sometimes want to define a dialog as follows: after a specific source portlet emitted a specific event, the user is returned to the resource or portlet. This resource or portlet redirects the user to the resource that emitted the event. Therefore, you can reference the special transition endpoint named `CALLER`.

For example in the code, the first transition is triggered after `portlet1` emits event `e1`. Event `e1` causes the user to be redirected to `portlet2`. Then, after `portlet2` emits event `e2-2`, the user is redirected back to `portlet1`, which previously called `portlet2`.

Code sample

```
<transition>
    <source>
        <transition-endpoint nameref="portlet1">
            <event qname="e1"/>
        </transition-endpoint>
    </source>
    <target>
        <transition-endpoint nameref="portlet2">
            <event qname="e2-1"/>
        </transition-endpoint>
    </target>
</transition>
<transition>
    <source>
        <transition-endpoint nameref="portlet2">
            <event qname="e2-2"/>
        </transition-endpoint>
    </source>
    <target>
        <transition-endpoint nameref="CALLER">
            <event qname="e3"/>
        </transition-endpoint>
    </target>
</transition>
```

Related concepts:

"Configuration options" on page 3525
To change the overall behavior of the IBM UX Screen Flow Manager, several configuration options are available. You specify the options as Resource Environment Provider (REP) properties.

Exclusive transitions or dialogs:

Exclusive dialogs are special forms of dialogs. They are also referred to as null or one-step dialogs. They consist of a single transition only. You can use them to go into a dialog, run only one transition, and use it to end the dialog immediately afterward.

Code sample

```
<transition type="exclusive">
 <source>
     <transition-endpoint nameref="portlet1">
         <event qname="eX"/>
     </transition-endpoint>
 </source>
 <target>
     <transition-endpoint nameref="portlet2">
         <event qname="eX"/>
     </transition-endpoint>
 </target>
</transition>
```

Dialog chaining and nesting:

Dialogs can start other dialogs. Dialogs that start other dialogs are referred to as calling dialogs and the dialogs that are being started are referred to as called dialogs. Two different options are available to complete this action such as dialog chaining and dialog nesting.

With dialog chaining option, one dialog can start another dialog in a way that the calling dialog ends after the called one starts. Therefore, after the called one starts, there is no way to go back to the calling one anymore. For example, in a travel site, you can configure the Flight booking or the calling dialog to end after the Car booking or the called dialog starts. After the Car booking dialog starts the user cannot go back to the Flight booking dialog.

With the dialog nesting option, one dialog can start another dialog but the calling dialog does not end after the called dialog starts. Therefore, you can go back and forth between these nested dialogs. For example, in a travel site, you can configure the Flight booking or the calling dialog to pause after the Car booking or the called dialog starts. After the Car booking dialog starts the user cannot go back and forth between the Flight booking and car booking dialogs.

In both options, the calling dialog references the dialog to be called as target. The called dialog starts with the event the calling dialog emits.

A called dialog can start only by triggering one of its start transitions and can end only by triggering one of its end transitions. In the following code sample, `dialog2` must have a start transition, which is triggered by the emission of an event `eX`. The `dialog3` must have a start transition, which is triggered by the emission of an event `eY`.

```
...
<transition type="chained">
    <source>
        <transition-endpoint nameref="portlet1">
            <event qname="e1a"/>
        </transition-endpoint>
    </source>
    <target>
        <transition-endpoint nameref="dialog2">
```

```
            <event qname="eX"/>
        </transition-endpoint>
    </target>
</transition>
...
<transition type="nested">
    <source>
        <transition-endpoint nameref="portlet1">
            <event qname="e1b"/>
        </transition-endpoint>
    </source>
    <target>
        <transition-endpoint nameref="dialog3">
            <event qname="eY"/>
        </transition-endpoint>
    </target>
</transition>
```

CF05 "Valid and invalid definitions"
Whether you start a dialog in a chained or a nested fashion, the dialogs can be controlled through an attribute `type`. The attribute `type` is assigned to the transition-endpoint element. Valid values include `chained` and `nested`. If you do not specify the attribute, the default attribute value `chained` is applied.

CF05 "Multiple start transitions" on page 3497
In case the called dialog has multiple start transitions that can be triggered by the emission of an event, the start transition that needs to be triggered can be controlled. To control which of the potentially matching start transitions must be triggered, an attribute `entry-point` is assigned to the transition-endpoint element that references the dialog to be called.

CF05 "Incoming transitions" on page 3498
When the transitions return from the called dialog to the calling dialog, the incoming transitions can control how the transitions must continue.

CF05 "Multiple outgoing transitions" on page 3499
When the calling dialog has multiple outgoing transitions from which the called dialog can be started, you must define how the transition continues. When you return from the called dialog, you must define that the continuation of transitions within the calling dialog differs. The continuation of transitions differs depending on where you exited the calling dialog.

Valid and invalid definitions:

Whether you start a dialog in a chained or a nested fashion, the dialogs can be controlled through an attribute `type`. The attribute `type` is assigned to the transition-endpoint element. Valid values include `chained` and `nested`. If you do not specify the attribute, the default attribute value `chained` is applied.

The following code sample shows the relevant fragments of valid definitions for the calling dialog `dialog1` and the called dialogs `dialog2` and `dialog3`.

Code sample

```
<dialog name="dialog1">
  ...
  <transition type="chained">
      <source>
          <transition-endpoint nameref="portlet1">
              <event qname="e1a"/>
          </transition-endpoint>
      </source>
      <target>
          <transition-endpoint nameref="dialog2">
```

```
            <event qname="eX"/>
        </transition-endpoint>
    </target>
  </transition>
  ...
  <transition type="nested">
      <source>
          <transition-endpoint nameref="portlet1">
              <event qname="e1b"/>
          </transition-endpoint>
      </source>
      <target>
          <transition-endpoint nameref="dialog3">
              <event qname="eY"/>
          </transition-endpoint>
      </target>
  </transition>
  ...
</dialog>
...
<dialog name="dialog2">
  ...
  <transition type="start">
      <source>
          <transition-endpoint nameref="portlet1">
              <event qname="eX"/>
          </transition-endpoint>
      </source>
      <target>
          <transition-endpoint nameref="portlet2">
              <event qname="eX"/>
          </transition-endpoint>
      </target>
  </transition>
  ...
</dialog>
...
<dialog name="dialog3">
  ...
  <transition type="start">
      <source>
          <transition-endpoint nameref="portlet1">
              <event qname="eY"/>
          </transition-endpoint>
      </source>
      <target>
          <transition-endpoint nameref="portlet2">
              <event qname="eY"/>
          </transition-endpoint>
      </target>
  </transition>
  ...
</dialog>
```

The following code sample shows invalid definitions as `dialog2` has no start transition that is triggered by the event `eX`.

Code sample

```
<dialog name="dialog1">
  ...
  <transition type="chained">
      <source>
          <transition-endpoint nameref="portlet1">
              <event qname="e1a"/>
          </transition-endpoint>
      </source>
```

```
      <target>
          <transition-endpoint nameref="dialog2">
              <event qname="eX"/>
          </transition-endpoint>
      </target>
  </transition>
  ...
  <transition type="nested">
      <source>
          <transition-endpoint nameref="portlet1">
              <event qname="e1b"/>
          </transition-endpoint>
      </source>
      <target>
          <transition-endpoint nameref="dialog3">
              <event qname="eY"/>
          </transition-endpoint>
      </target>
  </transition>
  ...
</dialog>
...
<dialog name="dialog2">
  ...
  <transition type="start">
      <source>
          <transition-endpoint nameref="portlet1">
              <event qname="eZ"/>
          </transition-endpoint>
      </source>
      <target>
          <transition-endpoint nameref="portlet2">
              <event qname="eZ"/>
          </transition-endpoint>
      </target>
  </transition>
  ...
</dialog>
...
<dialog name="dialog3">
  ...
  <transition type="start">
      <source>
          <transition-endpoint nameref="portlet1">
              <event qname="eY"/>
          </transition-endpoint>
      </source>
      <target>
          <transition-endpoint nameref="portlet2">
              <event qname="eY"/>
          </transition-endpoint>
      </target>
  </transition>
  ...
</dialog>
```

Note: If the dialogs `dialog2` and `dialog3` are started in a chained or nested fashion, the transition endpoint that is referenced by the start transition's source becomes irrelevant.

Multiple start transitions:

In case the called dialog has multiple start transitions that can be triggered by the emission of an event, the start transition that needs to be triggered can be

controlled. To control which of the potentially matching start transitions must be triggered, an attribute `entry-point` is assigned to the transition-endpoint element that references the dialog to be called.

The following code sample shows an example.

In the sample `dialog1` calls `dialog2`. `Dialog2` has two start transitions, which are both triggered by the emission of the event `eX`. The transition that calls `dialog2` from within `dialog1` uses the `entry-point` attribute. The attribute points to the respective source transition-endpoint `portlet1` of the transition to be triggered.

For example, in a travel site, Flight booking dialog transitions to the Car booking dialog. The Car booking dialog can start either from the Renters information portlet or the Calendar portlet. The transition uses to the `entry-point` to point to the portlet that needs to be start.

```
<dialog name="dialog1">
  ...
  <transition type="nested">
      <source>
          <transition-endpoint nameref="portlet1">
              <event qname="e1a"/>
          </transition-endpoint>
      </source>
      <target>
          <transition-endpoint nameref="dialog2" entry-point="portlet1">
              event qname="eX"/>
          </transition-endpoint>
      </target>
  </transition>
  ...
</dialog>
  ...
  <transition type="start">
      <source>
          <transition-endpoint nameref="portlet1">
              <event qname="eX"/>
          </transition-endpoint>
      </source>
      <target>
          <transition-endpoint nameref="portlet3">
             <event qname="eX"/>
          </transition-endpoint>
      </target>
  </transition>
  <transition type="start">
      <source>
          <transition-endpoint nameref="portlet2">
              <event qname="eX"/>
          </transition-endpoint>
      </source>
      <target>
          <transition-endpoint nameref="portlet3">
             <event qname="eX"/>
          </transition-endpoint>
      </target>
  </transition>
  ...
</dialog>
```

Incoming transitions:

When the transitions return from the called dialog to the calling dialog, the incoming transitions can control how the transitions must continue.

The following code sample shows an example. In the following sample, `dialog1` is the calling dialog that called `dialog2`. After the called dialog `dialog2` ends, the transition returns to the calling dialog `dialog1`. Because `portlet3` emits event `eZ`, the shown incoming transition defines that `dialog1` must continue with `portlet5`. The `portlet5` is initialized with the event `eZ`.

Code sample

```
<dialog name="dialog1">
  ...
  <transition>
      <source>
          <transition-endpoint nameref="dialog2">
              <event qname="eZ"/>
          </transition-endpoint>
      </source>
      <target>
          <transition-endpoint nameref="portlet5">
              <event qname="eZ"/>
          </transition-endpoint>
      </target>
  </transition>
  ...
</dialog>
...
<dialog name="dialog2">
  ...
  <transition type="end">
      <source>
          <transition-endpoint nameref="portlet3">
              <event qname="eZ"/>
          </transition-endpoint>
      </source>
      <target>
          <transition-endpoint nameref="portlet4">
              <event qname="eZ"/>
          </transition-endpoint>
      </target>
  </transition>
  ...
</dialog>
```

The event that is associated with the target of the called dialog's end transition needs to match with the event of the calling dialog's incoming transition. In the sample, `dialog1` needs to have an incoming transition, which is triggered by the emission of an event `eZ` by `dialog2`. The transition endpoint that is referenced by the called dialogs end transitions target becomes irrelevant.

Multiple outgoing transitions:

When the calling dialog has multiple outgoing transitions from which the called dialog can be started, you must define how the transition continues. When you return from the called dialog, you must define that the continuation of transitions within the calling dialog differs. The continuation of transitions differs depending on where you exited the calling dialog.

To control how to continue with such transitions, an attribute `resume-point` is assigned to the transition-endpoint element that references the dialog from which the transition is returned. The `resume-point` attribute needs to reference a transition endpoint of the calling dialog that was active when another dialog was started.

In the following code sample, the dialog1 has two transitions from which dialog2 can be started. One transition references the transition endpoint portlet1 as its source, the other references the transition endpoint portlet2. Furthermore, dialog2 has two distinct incoming transitions. One transition carries the attribute resume-point with value portlet1, the other one with value portlet2.

When you exit dialog1 through the first transition, which references the endpoint portlet1, dialog1 would continue with portlet3 after dialog2 ends. The reason is that the transition that references the resume point with value portlet1 is triggered since portlet1 was active when you exited dialog1.

When you exit dialog1 through the second transition, which references the endpoint portlet2, dialog1 would continue with portlet4 after dialog2 ends. The reason is that the transition that references the resume point with value portlet2 is triggered since portlet2 was active when you exited dialog1.

Code sample

```
<dialog name="dialog1">
   ...
   <transition>
       <source>
           <transition-endpoint nameref="portlet1">
               <event qname="eX"/>
           </transition-endpoint>
       </source>
       <target>
           <transition-endpoint nameref="dialog2">
               <event qname="eX"/>
           </transition-endpoint>
       </target>
   </transition>
   <transition>
       <source>
           <transition-endpoint nameref="portlet2">
               <event qname="eX"/>
           </transition-endpoint>
       </source>
       <target>
           <transition-endpoint nameref="dialog2">
               <event qname="eX"/>
           </transition-endpoint>
       </target>
   </transition>
   ...
   <transition>
       <source>
           <transition-endpoint nameref="dialog2" resumepoint="portlet1">>
               <event qname="eZ"/>
           </transition-endpoint>
       </source>
       <target>
           <transition-endpoint nameref="portlet3">
               <event qname="eZ"/>
           </transition-endpoint>
       </target>
   </transition>
   <transition>
       <source>
           <transition-endpoint nameref="dialog2" resumepoint>
               <event qname="eZ"/>
           </transition-endpoint>
       </source>
       <target>
```

```
          <transition-endpoint nameref="portlet4">
              <event qname="eZ"/>
          </transition-endpoint>
      </target>
  </transition>
  ...
</dialog>
...
```

Rules and restrictions:

When you model a transition certain rules and restrictions apply.

The following are descriptions of the rules:

1. The entire set of dialogs, together with all their transitions, needs to be deterministic. That is the transitions need to produce the same results all times. To achieve this condition, the IBM UX Screen Flow Manager must always clearly determine the transition that is to be triggered. The transition is determined based on the transition endpoint that emits an event and the name (`QName`) of the event. The screenflow is not valid if the definition is not deterministic. For example, the definition of two dialogs as shown in code sample is not valid, as it is not deterministic: The Screen Flow Manager might not decide whether to trigger the first or the second transition after `portlet1` emits event `e1`.

   Code sample

   ```
   <transition>
       <source>
           <transition-endpoint nameref="portlet1">
               <event qname="e1"/>
           </transition-endpoint>
      </source>
       <target>
          <transition-endpoint nameref="portlet2">
               <event qname="e2"/>
           </transition-endpoint>
       </target>
   </transition>
   <transition>
       <source>
           <transition-endpoint nameref="portlet1">
               <event qname="e1"/>
           </transition-endpoint>
      </source>
       <target>
           <transition-endpoint nameref="portlet3">
               <event qname="e3"/>
          </transition-endpoint>
       </target>
   </transition>
   ```

2. A source cannot reference more than one single transition endpoint.
3. A target can reference one of the following portal resources:
   - A single portlet that can receive one or multiple events.
   - Multiple target portlets. All these portlets must be found on the same page. Each single portlet can receive one or multiple events.
   - A single target page. Each single portlet on that page can receive the same event or multiple events that are sent to the page. This action is also called broadcasting.

- One target page and one or multiple target portlets. All these portlets must be found on the target page. Each single portlet on that page can receive the following types of events:
  - The same event or multiple events that are sent to the page.
  - One or multiple dedicated events that are sent to the portlet itself.

Execution priority:

You can and must explicitly model and enforce a deterministic behavior for the transitions. Even if the entire set of dialogs is deterministic, the emission of an event by a particular portlet can trigger two different transitions of two different dialogs. Therefore, you must explicitly model the intended behavior of the transitions.

For example, when a `portlet1` emits an event `e1`, two different transitions T1 and T2 can be triggered. The transition T1 as part of an active dialog D1 and the start transition T2 as part of another dialog D2 both react on the same event `e1`. After `portlet1` emits `e1`, the transitions needs to determine whether to continue with D1 or to suspend D1 and start D2.

You can explicitly model the intended behavior of the transitions by using the optional attribute `priority`. The attribute `priority` is assigned to the element dialog. Valid values that you can use are `preserve` and `suspend`. The default value is set to `suspend` unless you configure the settings differently. For more information about configuring, go to *Configuration Options*.

The value `preserve` defines that the transition that is part of an active dialog always wins. For example, after `portlet1` emits the event `e1`, the transition continues with active dialog D1 instead of switching to another dialog D2.

The value `suspend` defines that start-transitions always win. For example, after `portlet1` emits the event `e1`, the transition suspends the active dialog D1 and starts another dialog D2. If the attribute is not specified, the default value is applied.

The following code samples show the outlined behavior under the assumption that `dialog1` is already active. In the following code sample, after `portlet1` emits the event `e1`, both the transitions shown theoretically fit. Since, for `dailog1` the attribute `priority` is set to `suspend`, the intended behavior is to prefer triggering matching start transitions. Matching start transitions are triggered even if they are part of the active dialog. Hence in this case `dialog1` is suspended and the user must continue with `dialog2` and is redirected to `portlet3`.

Code sample

```
<dialog name="dialog1" priority="suspend">
    ...
    <transition>
        <source>
            <transition-endpoint nameref="portlet1">
                <event qname="e1"/>
            </transition-endpoint>
        </source>
        <target>
            <transition-endpoint nameref="portlet2">
                <event qname="e2"/>
            </transition-endpoint>
        </target>
    </transition>
    ...
```

```
</dialog>
...
<dialog name="dialog2">
    ...
    <transition type="start">
        <source>
            <transition-endpoint nameref="portlet1">
                <event qname="e1"/>
            </transition-endpoint>
        </source>
        <target>
            <transition-endpoint nameref="portlet3">
                <event qname="e3"/>
            </transition-endpoint>
        </target>
    </transition>
    ...
</dialog>
```

In the following code sample, after `portlet1` emits the event `e1`, both transitions shown theoretically fit. Since for `dialog1` the attribute `priority` is set to `preserve`, the intended behavior is to prefer triggering a matching transition that is a part of the active dialog. Thus, in this case the user continues with `dialog1` and is redirected to `portlet2`.

Code sample

```
<dialog name="dialog1" priority="preserve">
    ...
    <transition>
        <source>
            <transition-endpoint nameref="portlet1">
                <event qname="e1"/>
            </transition-endpoint>
        </source>
        <target>
            <transition-endpoint nameref="portlet2">
                <event qname="e2"/>
            </transition-endpoint>
        </target>
    </transition>
    ...
</dialog>
...
<dialog name="dialog2">
    ...
    <transition type="start">
        <source>
            <transition-endpoint nameref="portlet1">
                <event qname="e1"/>
            </transition-endpoint>
        </source>
        <target>
            <transition-endpoint nameref="portlet3">
                <event qname="e3"/>
            </transition-endpoint>
        </target>
    </transition>
    ...
</dialog>
```

Note: In the context of dialog chaining or nesting, the attribute `priority` is not inherited. For example, when a dialog D1 calls another dialog D2, the attribute `priority`, which might be specified for D1 is not propagated to D2.

Related concepts:

CF05 “Configuration options” on page 3525
To change the overall behavior of the IBM UX Screen Flow Manager, several configuration options are available. You specify the options as Resource Environment Provider (REP) properties.

Deploy dialog sets by using the XML configuration interface:

You can use the portal XML configuration interface (XMLAccess) to work with dialog sets.

You can import dialog sets by specifying the value `create` for the `action` attribute.

Code sample

```
<request type="update" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xsi:noNamespaceSchemaL

 <portal action="create">
    <dialog-set>
        <dialog name="dialog1">
            ...
        </dialog>
        ...
     </dialog-set>
 </portal>
</request>
```

You can export dialog sets by specifying the value `export` for the `action` attribute. For example, you can use this option for staging or migration purposes. The following code sample shows how you can export a single dialog definition `dialog1`.

Code sample

```
<request type="update" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xsi:noNamespaceSchemaL

 <portal action="export">
    <dialog-set>
        <dialog name="dialog1">
    </dialog-set>
 </portal>
</request>
```

When you export dialog sets or definitions, you can use wildcards. The following code sample shows how to export all available dialog definitions.

Code sample

```
<request type="update" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xsi:noNamespaceSchemaL

 <portal action="export">
     <dialog-set>
         <dialog name="*">
     </dialog-set>
 </portal>
</request>
```

The following code sample shows how to export all dialog definitions with the name that starts with the string `toBeExported`.

Code sample

```
<request type="update" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xsi:noNamespaceSchemaLo

    <portal action="export">
```

```
       <dialog-set>
           <dialog name="toBeExported*">
       </dialog-set>
 </portal>
</request>
```

The following code sample shows how to export all dialog definitions with the name that ends with the string `toBeExported`.

Code sample

```
<request type="update" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xsi:noNamespaceSchem

 <portal action="export">
     <dialog-set>
         <dialog name="*toBeExported">
     </dialog-set>
 </portal>
</request>
```

The following code sample shows how to export all dialog definitions with the name that contains the string `toBeExported`.

Code sample

```
<request type="update" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xsi:noNamespaceSchem

 <portal action="export">
     <dialog-set>
         <dialog name="*toBeExported*">
     </dialog-set>
 </portal>
</request>
```

You can delete dialog sets by specifying the value `delete` for the `action` attribute. The following code sample shows how to delete a single dialog definition with the name `dialog1`. You can use the same wildcards as for exporting.

Code sample

```
<request type="update" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xsi:noNamespaceSchem

 <portal action="delete">
     <dialog-set>
         <dialog name="dialog1">
     </dialog-set>
 </portal>
</request>
```

Note: You cannot use the XML configuration interface to merge an updated dialog definition with an existing one that you imported earlier. The XMLAccess request type `update` overwrites the specified existing portal resource with the new one. Therefore, if you want to merge a previous dialog definition with a newer one, you need to manually merge the two XML scripts. To merge the two XML scripts, make sure that the new dialog definition contains both the new sections and the old sections that you want to preserve.

Deploying user interface artifacts

Before you deploy the Screen Flow Manager dialog definitions, you must deploy all portal resources that are part of the dialog definitions, such as pages, and portlets. You can then deploy the dialog definitions by using the portal XML configuration interface (XMLAccess).

You can import, export, update, or delete complete dialog sets by using the following command.

```
xmlaccess.{sh|bat} -in your_dialog_sets_file_name -user user_ID -password password -url http://host_
```

Advanced concepts

Learn about the advanced concepts of the IBM UX Screen Flow Manager.

"Retrieve and store event payload"
In a normal portal environment, the portlets in a single dialog can exchange data through a set of well-defined events. However, you might want to include third-party portlets or older portlets that are not aligned with the normal portal environment. You can include such portlets with the IBM UX Screen Flow Manager.

"Access control" on page 3515
You can use the Portal Access Control (PAC) to control what users can do when they are working with dialogs.

CF05 "Scoping session data and render parameters" on page 3516
The appearance of portlets heavily relies on the portlet session data and the render parameters. To better support the semi-parallel processing of dialogs, the portlet session data and the render parameters are stored in a scoped fashion.

"Dynamic pages and portlets" on page 3516
The IBM UX Screen Flow Manager not only supports redirecting users between static portal resources, but also between dynamic resources. The WebSphere Portal feature Dynamic UI Management is used.

Retrieve and store event payload

In a normal portal environment, the portlets in a single dialog can exchange data through a set of well-defined events. However, you might want to include third-party portlets or older portlets that are not aligned with the normal portal environment. You can include such portlets with the IBM UX Screen Flow Manager.

For example, in a travel site, a passenger information portlet `portlet1` can emit the ID of a passenger. It emits this ID by using a JSR-286 event with the `QName passengerID`. A second portlet, car renters information portlet `portlet2` can receive the ID of the passenger, but it expects this ID to be sent through a JSR-286 event with the `QName userID`. Without extra translation, the two portlets cannot communicate with each other because the events that they exchange use different `QNames`.

The Screen Flow Manager supports two mechanisms that enable such incompatible portlets to exchange data with each other:

- Event mappers. For more information, go to *Event Mappers*.
- The explicit specification of dialog context (DCX) keys when events are associated with referenced transition endpoints.

  CF05 "Dialog context keys" on page 3507
  The dialog context (DCX) acts like the transient memory of a dialog. It maintains contextual information that is passed from one portlet to subsequent portlets and provides the information to all subsequent portlets. Data that is stored in the dialog context (DCX) is stored only for the lifetime of a user session. If a user logs out of the portal or the user session times out, the current dialog instance, all suspended dialog instances, and all related data are lost.

"Event Mappers" on page 3508
In more complex scenarios, adapting only the event names or QNames might not be enough. Sometimes you might need to transform the payload.

CF05 "Dialog chaining and nesting DCX keys and event mappers" on page 3511
In context of dialog chaining or nesting, DCX keys and mappers never influence another dialogs DCX segment. When a transition part of a calling dialog uses a DCX key or a mapper it influences only the data that is stored in the calling dialog's DCX segment and not the called dialog's segment. Similarly, when a transition part of a called dialog uses a DCX key or a mapper it influences only the data that is stored in the called dialog's DCX segment and not the calling dialog's segment.

Related concepts:

"Event Mappers" on page 3508
In more complex scenarios, adapting only the event names or QNames might not be enough. Sometimes you might need to transform the payload.

Dialog context keys:

The dialog context (DCX) acts like the transient memory of a dialog. It maintains contextual information that is passed from one portlet to subsequent portlets and provides the information to all subsequent portlets. Data that is stored in the dialog context (DCX) is stored only for the lifetime of a user session. If a user logs out of the portal or the user session times out, the current dialog instance, all suspended dialog instances, and all related data are lost.

- The DCX is divided into segments where each segment holds data or contextual information of a single dialog instance.
- Normally, when you specify events, the QName defines how and under which key the corresponding payload is stored in the segment of the specific dialog instance.

  For example, the DCX contains the following information after you run the transition:

  – An entry with key = passengerID.
  – A value that matches the payload that was sent with the corresponding event.

  The car renters information portlet portlet2 is then initialized with the data stored in the DCX under the key userID. If no previous transition stored anything under the key userID, portlet2 does not receive any data.

  Code sample

```
<transition>
    <source>
        <transition-endpoint nameref="portlet1">
            <event qname="passengerID"/>
        </transition-endpoint>
    </source>
    <target>
        <transition-endpoint nameref="portlet2">
            <event qname="userID"/>
        </transition-endpoint>
    </target>
</transition>
```

DCX keys make it possible to specify under which key a portlet stores data in the DCX, or under which key a portlet reads data from the DCX.

To enable portlet1 to communicate with portlet2, you have the following two options:

- You can make portlet1 store its payload under the key userID, even though it emits an event with the QName passengerID. The following code sample shows how you can make portlet1 store data under userID.

  Code sample

```
<transition>
    <source>
        <transition-endpoint nameref="portlet1">
            <event qname="passengerID" dcx-key="userID"/>
        </transition-endpoint>
    </source>
    <target>
        <transition-endpoint nameref="portlet2">
            <event qname="userID"/>
        </transition-endpoint>
    </target>
</transition>
```

- You can make portlet2 read the key passengerID, even though it expects an event with the QName userID. The following code sample shows how you can make portlet2 read data under passengerID.

  Code sample

```
<transition>
    <source>
        <transition-endpoint nameref="portlet1">
            <event qname="passengerID"/>
        </transition-endpoint>
    </source>
    <target>
        <transition-endpoint nameref="portlet2">
            <event qname="userID" dcx-key="passengerID"/>
        </transition-endpoint>
    </target>
</transition>
```

Event Mappers:

In more complex scenarios, adapting only the event names or QNames might not be enough. Sometimes you might need to transform the payload.

For example, in a travel site, a passenger information portlet portlet1 emits a passenger ID under the key passengerID. The payload is of type Integer. A second portlet, a car renters information portlet portlet2 expects a passenger ID under the key userID, and sent as payload of type String.

As with DCX keys to enable the passenger information portlet portlet1 to communicate with the car renters information portlet portlet2, you have the following two options:

- You can make the passenger information portlet portlet1 store its payload under the key userID and as of type String, even though it emits an event with the QName employeeID and as of type Integer.
- You can make the car renters information portlet portlet2 read the key employeeID and as of type Integer, even though it expects an event with the QName userID and as of type String.

Mappers have full access to the DCX segment of the currently processed dialog instance and also to the payload that is being processed. Therefore, mappers are powerful tools, as they can run various transformations.

Implement MapperFactory to make the mappers available. You can register the MapperFactory with an Eclipse Extension Point. The advantage of this approach is that you can register new mappers without having to restart the server. This method is also called hot deployment. To use a MapperFactory, you need to implement the interface MapperFactory and return an object instance of type ContextToPayloadMapper or PayloadToContextMapper. This implementation depends on the concrete event mapper that is requested.

The following code sample shows an example of how a MapperFactory can look.

Code sample

```
public class MapperFactory implements com.ibm.portal.pcm.events.MapperFactory {

 public ContextToPayloadMapper getContextToPayloadMapper(String name) {
     ContextToPayloadMapper result = null;
     if (name.equals("myPackage.myMapper")) {
         result = new MyMapper();
     }

     return result;
 }

 public PayloadToContextMapper getPayloadToContextMapper(String name) {
     // ...
 }
}
```

The following code sample shows how you can register a MapperFactory with a plugin.xml file.

Code sample

```
<plugin
    id="com.ibm.wps.portlet.pcm.demo"
    name="Portlet Control Manager Demo"
    version="1.0.0"
    provider-name="IBM">

    <!-- Mapper Factory -->
    <extension point="com.ibm.portal.pcm.MapperFactory" id="PcmMapperFactory">
        <factory class="com.ibm.wps.pcm.demo.mapper.MapperFactory"/>
    </extension>
</plugin>
```

"Event mapper types"
IBM UX Screen Flow Manager supports the following two types of event mappers: PayloadToContextMappers and ContextToPayloadMappers.

"Packaging of event mappers and JAXB serialization" on page 3511
It is good practice to package event mappers in a shared library rather than together with the business portlets.

Event mapper types:

IBM UX Screen Flow Manager supports the following two types of event mappers: PayloadToContextMappers and ContextToPayloadMappers.

Consider the following example to understand how the two types of event mappers function.

Example: In a travel site, a passenger information portlet portlet1 emits a passenger ID under the key passengerID. The payload is of type Integer. A second

portlet, a car renters information portlet portlet2 expects a passenger ID under the key userID, and sent as payload of type String.

- PayloadToContextMappers mappers transform an event that is emitted by a transition source and influence the way that it is stored in the DCX segment. These mappers are started before data is stored in the DCX and therefore can control the key under which data is stored and the data type.

  The following code sample shows how you can use a PayloadToContextMapper to enable the passenger information portlet portlet1 and the car renters information portlet portlet2 in the example to communicate with each other.

  Code sample

  ```
  public void payloadToContext(final QName dcxKey, final Object payload, final DCXData dcxData) {
    // ...

    QName mappedDcxKey = new QName("userID");
    String transformedPayload = ((Integer)payload).toString();

    dcxData.put(mappedDcxKey, transformedPayload);
  }
  ```

  To use this mapper, you need to implement the interface PayloadToContextMapper. The input parameters carry information about the following two items:

  – The DCX key that is used to store the event as defined in association with the source, if it is not changed by the mapper.

  – The payload that is stored under this key, if it is not changed by the mapper.

  The input parameters also provide a reference to the DCX segment that belongs to a specific dialog instance. In this example, the mapper changes the DCX key where the payload is to be stored and the payload itself by transforming it from type Integer to type String.

  The following code sample shows how to register PayloadToContextMappers.

  Code sample

  ```
  <transition>
      <source>
          <transition-endpoint nameref="portlet1">
              <event qname="passengerID" mapper-class="myPackage.myMapper"/>
          </transition-endpoint>
      </source>
      <target>
          <transition-endpoint nameref="portlet2">
              <event qname="userID"/>
          </transition-endpoint>
      </target>
  </transition>
  ```

- ContextToPayloadMappers can transform an event before it is transmitted to a transition target. These mappers are started after data is read from the DCX and before it is transmitted to the target. This action means that these mappers can influence the payload before it is sent.

  The following code sample shows how you can use a ContextToPayloadMapper to enable the passenger information portlet portlet1 and the car renters information portlet portlet2 in the example to communicate with each other.

  Code sample

  ```
  public Serializable contextToPayload(final DCXData dcxData, final QName dcxKey, final Class<?> tar
    // ...
    Object payload = dcxData.get(dcxKey, targetClass);
  ```

```
    String transformedPayload = ((Integer)payload).toString();

    return (Serializable) transformedPayload;
}
```

To use this mapper, you need to implement the interface `ContextToPayloadMapper`. The input parameters carry information about the following two items:

- The DCX key or `QName` that is used to send the event as defined in association with the source.
- The payload is sent under this key - if it is not changed by the mapper.

The input parameters also provide a reference to the DCX segment that belongs to a specific dialog instance. In this example, the mapper changes the type of the payload that is to be sent by transforming it from type `Integer` to type `String`.

The following code sample shows how to register `ContextToPayloadMappers`.

Code sample

```
<transition>
    <source>
        <transition-endpoint nameref="portlet1">
            <event qname="passengerID"/>
        </transition-endpoint>
    </source>
    <target>
        <transition-endpoint nameref="portlet2">
            <event qname="userID" dcx-key="employeeID" mapper-class="myPackage.myMapper"/>
        </transition-endpoint>
    </target>
</transition>
```

Packaging of event mappers and JAXB serialization:

It is good practice to package event mappers in a shared library rather than together with the business portlets.

If you decide to package event mappers with more than one business portlets, the Screen Flow Manager runs JAXB-based marshalling and unmarshaling. This action prevents `ClassCastExceptions` caused by the use of one or more isolated classloaders. You can influence the behavior of the JAXB based marshalling by using specific configuration options. For more information, go to *Configuration Options*.

Related concepts:

"Configuration options" on page 3525
To change the overall behavior of the IBM UX Screen Flow Manager, several configuration options are available. You specify the options as Resource Environment Provider (REP) properties.

Dialog chaining and nesting DCX keys and event mappers:

In context of dialog chaining or nesting, DCX keys and mappers never influence another dialogs DCX segment. When a transition part of a calling dialog uses a DCX key or a mapper it influences only the data that is stored in the calling dialog's DCX segment and not the called dialog's segment. Similarly, when a transition part of a called dialog uses a DCX key or a mapper it influences only the data that is stored in the called dialog's DCX segment and not the calling dialog's segment.

Use of DCX keys and mappers in dialog chaining or dialog nesting is required to properly exchange data between the calling and called dialogs. In many cases, called dialogs are developed independently from calling dialogs, not intended to be part of another dialog.

For example, consider a travel booking screen flow. It consists of steps that allow to book a flight, a hotel, and a car after a particular date of travel, and destination is specified. Before the agent can start booking, the customer's personal data needs to be collected. Assume that another screen flow, a billing screen flow, is already modeled which allows the agent to look up this data through a customer ID. Thus the entire flow requires the booking to be started, the personal data to be collected and updated and finally the actual bookings to be done.

DCX keys

Assume the travel booking screen flow that carries the customer information under the key `travellerID` to be the blue screen flow. Assume the billing screen flow that carries the customer information under the key `customerID` to be the red screen flow.

1. During step 1, the `travellerID` is specified along with the date of travel, and destination. The red screen flow is started in a nested fashion.
2. During step 2, the red screen flow is supposed to display the customer information such as name, and address.
3. During step 3, the red screen flow must allow for updating the customer information. The red screen flow needs to be fed with the `travellerID` but expects it to be sent with an event with `QName customerID`.
4. The entire set of customer information such as name, and address, is packaged in a special customer object. This customer object is emitted by the red screen flow's end transition under the key `customerBean`.
5. The blue screen flow requires this data but expects it to be sent by an event with `QName travellerBean`. The `travellerID` needs to be converted to `customerID` and `travellerBean` to `customerBean`.

The following code sample shows an option to convert the event `Qnames`. The outgoing transition responsible for calling the red dialog assigned the attribute `dcx-key` with value `customerID` to the event element associated with this transition's source transition endpoint. Thus, even though the transition endpoint step_1 emits an event with `QName travellerID`, the information is stored in the blue dialog's DCX under the key `customerID`. Thus it can be sent to the red dialog through an event with `QName customerID` as the corresponding payload can be found in the blue dialog's DCX under exactly that key. The blue dialog's incoming transition receives the customer information through an event with `QName customerBean`, but stores the corresponding payload under the key `travellerBean`. Thus the customer information can be propagated with events with `QName travellerBean` as the corresponding payload can be found in the blue dialog's DCX under exactly that name.

Code sample

```
<dialog name="dialog blue">
  ...
  <transition type="nested">
      <source>
          <transition-endpoint nameref="step_1">
              <event qname="travellerID" dcx-key="customerID"/>
          </transition-endpoint>
```

```
      </source>
      <target>
          <transition-endpoint nameref="dialog red">
              <event qname="customerID"/>
          </transition-endpoint>
      </target>
  </transition>
  ...
  <transition>
      <source>
          <transition-endpoint nameref="dialog red">
              <event qname="customerBean" dcx-key="travellerBean"/>
          </transition-endpoint>
      </source>
      <target>
          <transition-endpoint nameref="step 4">
              <event qname="travellerBean"/>
          </transition-endpoint>
      </target>
  </transition>
  ...
</dialog>
...
<dialog name="dialog red">
 ...
  <transition type="start">
      <source>
          <transition-endpoint nameref="...">
              <event qname="customerID"/>
          </transition-endpoint>
      </source>
      <target>
          <transition-endpoint nameref="step_2">
              <event qname="customerID"/>
          </transition-endpoint>
      </target>
  </transition>
  ...
  <transition type="end">
      <source>
          <transition-endpoint nameref="step 3">
              <event qname="customerBean"/>
          </transition-endpoint>
      </source>
      <target>
          <transition-endpoint nameref="PAGE ORIGIN">
              <event qname="customerBean"/>
          </transition-endpoint>
      </target>
  </transition>
  ...
</dialog>
...
</dialog>
```

Event mappers

Assume the screen flow that carries the customer information under the key `travellerID` to be the blue screen flow. Assume the screen flow that carries the customer information under the key `customerID` to be the red screen flow. Assume the `travellerID` is of type `string` while the `customerID` is of type `Integer`. Also, assume that the beans `travellerBean` and `customerBean` differ not only by name but are also of different object type.

The following code sample shows an option to convert the keys and the bean. The mappers ensure that the events are properly renamed and the data types are properly transformed.

Code sample

```
<dialog name="dialog blue">
  ...
  <transition type="nested">
      <source>
          <transition-endpoint nameref="step 1">
              <event qname="travellerID" mapper-class="B2RMapper"/>
          </transition-endpoint>
      </source>
      <target>
          <transition-endpoint nameref="dialog red">
              <event qname="customerID"/>
          </transition-endpoint>
      </target>
  </transition>
  ...
  <transition>
      <source>
          <transition-endpoint nameref="dialog red">
              <event qname="customerBean" mapper-class="R2BMapper"/>
          </transition-endpoint>
      </source>
      <target>
          <transition-endpoint nameref="step 4">
              <event qname="travellerBean"/>
          </transition-endpoint>
      </target>
  </transition>
  ...
</dialog>
...
<dialog name="dialog red">
 ...
  <transition type="start">
      <source>
          <transition-endpoint nameref="...">
              <event qname="customerID"/>
          </transition-endpoint>
      </source>
      <target>
          <transition-endpoint nameref="step_2">
              <event qname="customerID"/>
          </transition-endpoint>
      </target>
  </transition>
  ...
  <transition type="end">
      <source>
          <transition-endpoint nameref="step 3">
              <event qname="customerBean"/>
          </transition-endpoint>
      </source>
      <target>
          <transition-endpoint nameref="PAGE ORIGIN">
              <event qname="customerBean"/>
          </transition-endpoint>
      </target>
  </transition>
  ...
</dialog>
...
</dialog>
```

Note: In the context of dialog chaining and dialog nesting, the definition of a mapper as part of an outgoing transition's target is invalid. The definition of a mapper as part of the called dialog's start transition's source is also invalid.

Access control

You can use the Portal Access Control (PAC) to control what users can do when they are working with dialogs.

You can assign users the following roles on the virtual resource PCM_DIALOGS:

- Administrator - An administrator has the rights and all tasks that are related to dialogs are done by the administrator.
- Security administrator - A security administrator can grant access on dialogs to other users.
- Manager - A manager can delete dialog definitions.
- User - A user can view a dialog definition and all its transition endpoints and transitions.
- Editor - An editor can create or edit a dialog definition. For example, an editor can add or remove transition endpoints or transitions.

These roles settings are inherited.

To assign users or user groups to these roles with the XML configuration interface (XMLAccess), run a script similar to the one shown in the following code sample.

Code sample

```
01 <virtual-resource action="update" domain="rel" name="PCM_DIALOGS">
02  <access-control externalized="false" owner="undefined" private="false">
03          <role actionset="User" update="set">
04              <mapping subjectid="all authenticated portal users" subjecttype="user_group" updat
05          </role>
06  </access-control>
07 </virtual-resource>
```

Processing a specific dialog depends on whether the user has sufficient rights on all pages and portlets that are part of the dialog. You specify access control settings on a dialog definition level. The following code sample shows an example.

Code sample

```
01 <dialog name="dialog1">
02  <access-control externalized="false" owner="undefined" private="false">
03      <role actionset="User" update="set">
04          <mapping subjectid="uid=wpsadmin,o=defaultWIMFileBasedRealm" subjecttype="USER" update
05      </role>
06      <role actionset="Editor" update="set">
07          <mapping subjectid="uid=wpsadmin,o=defaultWIMFileBasedRealm" subjecttype="USER" update
08      </role>
09  </access-control>
10  <transition-endpoint name="...">
11      ...
12  </transition-endpoint>
13  <transition>
14      ...
15  </transition>
16 </dialog>
```

Note: Assigning access on a specific dialog definition does not automatically assign access to all artifacts that are part of this dialog definition, such as pages, and portlets.

Scoping session data and render parameters

The appearance of portlets heavily relies on the portlet session data and the render parameters. To better support the semi-parallel processing of dialogs, the portlet session data and the render parameters are stored in a scoped fashion.

Storing the portlet session data and the render parameters in a scoped fashion avoids the active dialog from influencing the other dialogs. It also ensures that when the dialogs are resumed they appear exactly the way they appeared when they were suspended.

The data from an active dialog is stored in a different partition than the data that is stored when another dialog is active. Thus the data that is stored by one dialog cannot influence another dialog.

For example, in a travel site, when you start a Flight booking dialog D1, a partition p1 is created. When the Flight booking dialog D1 remains active, all portlet session data and render parameters of the dialog D1 are stored in partition p1. The partition p1 is not accessible or visible to any other partition. When the Flight booking dialog D1 is suspended, the partition P1 and all the data that is stored is also suspended.

When another dialog, a Car booking dialog D2 starts, another partition P2 is created. And when the Car booking dialog D2 remains active all data from dialog D2 is stored in partition P2. When the suspended Flight booking dialog D1 resumes, P1 resumes as well. This action ensures that when the Flight booking dialog D1 is active data is read from and written to P1 and when the Car booking dialog D2 remains active all data is read and written to P2. The partitions are deleted as soon as the dialog they belong to is canceled or ends.

Note: In the context of dialog nesting, a separate partition is created for any nested dialog. In other words, dialogs that call other dialogs read data from and write data to different partitions. This action ensures that the same portlets can be used as part of dialogs that call each other in a nested fashion without causing undesired interferences.

Dynamic pages and portlets

The IBM UX Screen Flow Manager not only supports redirecting users between static portal resources, but also between dynamic resources. The WebSphere Portal feature Dynamic UI Management is used.

You can use the Dynamic UI Management feature to create pages and portlets at run time. You can also use it to modify a user's content model and the navigation model, triggered by a user interaction.

In most cases, a dynamic page is a transient copy of a template page, often referred to as base page. This transient copy behaves like a snapshot of the base page from the time when the copy was created. It contains all portlets of the base page and all its properties. A dynamic portlet is a transient copy of a portlet definition. You can add dynamic portlets only to dynamic pages.

The benefit of using dynamic pages instead of static pages is that you can create multiple copies or instances of the base page. A user can then manually switch or be redirected between these instances.

Dynamic pages are always added to an extension node, a page to which a transformation is assigned.

During the processing of a dialog, single subdialogs can either be static or dynamic. If the subdialog is supposed to be dynamic, you can distinguish between the following two cases:

- If the transition endpoint references a page, the redirect requires a dynamic page. The dynamic page needs to be a transient copy, of the referenced base page that is to be started and to be added under the extension node.
- If the transition endpoint references a portlet, the redirect requires a dynamic portlet. The dynamic portlet needs to be a transient copy, of the referenced portlet definition that is to be started and to be added to an existing dynamic page. This case requires that a dynamic page is always created previously. The Screen Flow Manager ensures this requirement by starting an empty dynamic page. The dynamic portlet can then be added to that page.

You can use the dialog definition to control whether to start a resource dynamically. You can also specify in which extension node you want to add the dynamic copy. The following code sample shows an example.

Code sample

```
<dialog name="dialog1">
 <transition-endpoint name="page2">
     <resource uniquename="uniquename.page2"/>
     <invocation type="dynamic" extension-node="extensionNode1"/>
 </transition-endpoint>
 <transition-endpoint name="portlet1">
     <resource uniquename="uniquename.portlet1"/>
     <invocation type="static" extension-node="extensionNode1"/>
</transition-endpoint>
 <transition-endpoint name="portlet2">
     <resource uniquename="uniquename.portlet2"/>
     <invocation type="dynamic" extension-node="extensionNode1"/>
 </transition-endpoint>
 <transition>
     <source>
         <transition-endpoint nameref="portlet1">
             <event qname="e1-1"/>
         </transition-endpoint>
     </source>
     <target>
         <transition-endpoint nameref="page2">
             <event qname="e2"/>
         </transition-endpoint>
     </target>
 </transition>
 <transition>
     <source>
         <transition-endpoint nameref="portlet1">
             <event qname="e1-2"/>
         </transition-endpoint>
     </source>
     <target>
         <transition-endpoint nameref="portlet2">
             <event qname="e2"/>
         </transition-endpoint>
     </target>
 </transition>
</dialog>
```

In this sample, you can see two transitions: In both cases, `portlet1` exists on a static page.

- If the portlet emits the event `e1-1`, the user is redirected to `page2`. The `page2` is in turn expected to start dynamically in the extension node or page with the

unique name extensionNode1. The dynamic page is a transient copy of the base page with the unique name uniquename.page2.

- If portlet1 emits the event e1-2, the user is redirected to portlet2, which is also expected to start dynamically. A dynamic page is required to which this dynamic portlet can be added. Therefore, the screen flow manager creates an empty dynamic page in the extension node or page with the unique name extensionNode1 to which the portlet is then added.

The portal removes dynamic resources when they are no longer needed. For example, after a transition redirects a user from a dynamic page dpage1 to a dynamic page dpage2, dpage1 is removed and dpage2 is created.

User interface components

In a default WebSphere Portal installation, the Dialog Stack and Dialog State Display portlets are deployed. The following topics describe how these portlets function.

CF05 "Dialog Stack"
The Dialog Stack provides an overview of active and suspended dialogs. It allows for suspending, resuming, and canceling the dialogs.

CF05 "Dialog State Display" on page 3520
The Dialog State Display (DSD) displays a dialogs current state. You can move forward and backward or to jump to a dedicated step that was processed before. It is a generic navigation component that can be easily added to any page that participates in a dialog.

Dialog Stack

The Dialog Stack provides an overview of active and suspended dialogs. It allows for suspending, resuming, and canceling the dialogs.

The Dialog Stack displays the name of the current active dialog and the date and time when the dialog was started.

Consider for example, you are in a travel site and the screen flow is active. You are currently working on the Flight booking dialog. When you look at the Dialog Stack portlet, it would list the Flight booking dialog as active and the other dialogs in the travel site as suspended. For example, the Car booking and Hotel booking dialogs are listed as suspended.

The Dialog Stack also provides the option to return, suspend, or cancel the dialog. The functions of these options are as follows:

Return

When the user clicks Return, they are redirected to the currently active step of the currently active dialog from the Dialog Stack display screen.

For example, the user is redirected from the Dialog Stack portlet to the active Flight booking dialog.

Suspend

When the user clicks Suspend, it causes the active dialog to be suspended. After the dialog is suspended, it is no longer displayed as active and appears under the list of suspended dialogs.

Note: If the active dialog that is suspended is a dialog that is called by another dialog in a nested fashion, then the entire chain is suspended.

For example, the Flight booking dialog is suspended and listed under the suspended dialogs. And if the Flight booking dialog is called by the Car booking dialog and is nested both the dialogs are suspended.

Cancel

When the user clicks `Cancel`, the active dialog is canceled. The dialog is no longer available as active or suspended dialog and cannot be resumed.

Note: If the active dialog that is canceled is a dialog that is called by another dialog in a nested fashion, the entire chain is canceled.

For example, the Flight booking dialog is canceled and cannot be resumed. And if the Flight booking dialog is called by the Car booking dialog and is nested both the dialogs are canceled.

Cancel Nested

This option is only available if enabled.

When the user clicks `Cancel Nested`, the active dialog is canceled. But in contrast to the `Cancel` option, `Cancel Nested` option does not cause the entire chain of dependent dialogs to be canceled.

For example, if the Flight booking dialog called the Car booking dialog and the Car booking dialog is active. When the user clicks `Cancel` both the Flight booking and Car booking dialogs are canceled. When the user clicks `Cancel Nested` only the Car booking dialog is canceled; then, a redirect to the Flight booking dialog would occur. As the Flight booking dialog is the step that was active, when it was exited to call the Car booking dialog.

After the section that displays the current active dialog, the Dialog Stack displays a list of previously suspended dialogs by their name and start date. Each of these suspended dialogs can be canceled or resumed. When the user clicks `Resume` for the suspended dialog becomes active again.

Note: If another dialog is already active when the suspended dialog is resumed, the already active dialog is implicitly suspended.

CF05 "Configuration options for Dialog Stack"
Various configuration options are available for dialog stack. Two menus on the Dialog Stack provide the user with options to influence how dialogs are displayed.

Configuration options for Dialog Stack:

Various configuration options are available for dialog stack. Two menus on the Dialog Stack provide the user with options to influence how dialogs are displayed.

Consider the following example to better understand the configuration options available to you.

Assume a travel site with the following dialogs,

- Flight booking (dialog D1) consists of the following steps Passenger information(p1), Calendar(p2), and Destination(p3).
- Car booking(dialog D2) consists of the following steps Renters information (p4), Calendar (p5), and Vehicle type (p6).

The following are the available configuration options:

Display Initiating Screen Flow

When the user deals with only a single dialog and there is no nesting, the name of the dialog is displayed. For example, when the user works with the Flight booking dialog and the other dialogs are not nested, the name of the Flight booking dialog is displayed.

To understand how things work in a scenario where dialogs call other dialogs, consider the following example:

Assume that The Flight booking dialog D1 usually calls the Car booking dialog D2 from within the Calendar (p2) step and when the user returns from the Car booking dialog D2 to the Flight booking dialog D1 they usually end up in the Destination (p3) step. With the Display Initiating Screen Flow option, the Dialog Stack displays the dialogs as follows:

When in steps Passenger information(p1), Calendar(p2), Renters information (p4), Calend

Display Current Screen Flow

When the user deals with only a single dialog and there is no nesting, the name of the dialog is displayed. For example, when the user works with the Flight booking dialog and the other dialogs are not nested, the name of the Flight booking dialog is displayed.

In the example scenario where dialogs call other dialogs, with the Display Current Screen Flow option the dialog stack portlet displays the dialogs as follows:

When in steps Passenger information(p1), Calendar(p2), Renters information (p4), Calend

Display All Steps in Breadcrumb

When the user deals with only a single dialog and there is no nesting, the name of the dialog is displayed. For example, when the user works with the Flight booking dialog and the other dialogs are not nested, the name of the Flight booking dialog is displayed.

In the example scenario where dialogs call other dialogs, with the Display All Steps in Breadcrumb option the Dialog Stack displays the dialogs as follows:

When in steps Passenger information(p1), and Calendar(p2), the Flight booking dialog
When in step Renters information (p4), Flight booking D1 → Car booking D2 is display
When in steps Calendar (p5),and Vehicle type (p6), Flight booking D1 → Car booking D
When in step Destination(p3), the Flight booking dialog D1 is displayed.

Dialog State Display

The Dialog State Display (DSD) displays a dialogs current state. You can move forward and backward or to jump to a dedicated step that was processed before. It is a generic navigation component that can be easily added to any page that participates in a dialog.

Dialog State Display functions

The Dialog State Display Portlet displays the particular dialogs breadcrumb trail. For example, in a travel booking screen flow the dialog routes a user from a step to the other steps. For example, from a step that is called Flight Booking to steps called Hotel Booking, Car Booking, Insurance Booking, and Travel Summary. The currently active step is displayed in bold.

The Backward and Forward buttons trigger the following actions:

Backward

Clicking `Backward` redirects the user to the step that was active before the currently active one. To be more precise, it redirects to the step from which the currently active one was initially called. For example, if the Car booking dialog is currently active and was called from the Flight booking dialog, clicking `Backward` takes the user to Flight booking dialog which was previously active and called the Car booking dialog.

Forward

Clicking `Forward` redirects the user to the step that was active after the currently active one. To be more precise, it redirects to the step to which the currently active one redirected to last time. For example, the user goes from Car booking dialog to the Hotel booking dialog and returns to the Car booking dialog, which is currently active. Clicking `Forward` takes the user to the Hotel booking dialog.

Already processed steps can also be clicked to directly jump to them.

CF05 "Configuration options for Dialog State Display"
Various configuration options are available for Dialog State Display.

Configuration options for Dialog State Display:

Various configuration options are available for Dialog State Display.

Consider the following example to better understand the configuration options available to you.

Assume a travel site with the following dialogs,

- Flight booking (dialog D1) consists of the following steps Passenger information(p1), Calendar(p2), Destination(p3), Route (p4) and Airlines (p5).
- Car booking(dialog D2) consists of the following steps Renters information (p10), Calendar (p11), and Vehicle type (p12).
- Hotel booking (dialog D3) consists of the following steps Customer information (p20), Calendar (p21), and Room type (p22).
- Billing (dialog D4) consists of the following steps Account information (p30), Shopping cart (p31), and Check out (p32).

Previous Steps display preferences

You can influence how previous steps processed before the currently active step are displayed from the uppermost menu. The following are the available configuration options:

Display All Steps

All steps that are processed before the currently active step, are displayed without omitting one or more of them.

From the example, assume that the Destination (p3) step from the Flight booking dialog D1 is the active step. With this option selected the following steps are displayed.

`Passenger infromation → Calendar → Destination`

Display Custom Number of Steps

Displays the exact number of n steps that was processed most recently before the currently active step.

From the example, assume that the Destination (p3) step from the Flight booking dialog D1 is the active step . With this option selected and with n set to 1, the following steps are displayed.

`Calendar → **Destination**`

Next Steps display preferences

You can also influence how the steps that are to be processed after the currently active step are displayed from the second menu. The following are the available configuration options:

Display All Steps

All steps even those steps that are found on branches that can potentially be processed after the currently active step are being displayed without omitting one or more of them.

From the example,
Assume that the Car booking dialog D2 is called from the Flight booking dialog D1's C
Assume that the Hotel booking dialog D3 and the Billing dialog D4 are called from th
Assume that when you return from the Car booking D2, Hotel booking D3,and the Bil

Furthermore assume that you are currently in the active Passenger information(p1) and
Then, with this option selected the following steps are displayed.

```
Passenger information → Calendar → Destination → Route → Airlines
                                                    Renters information → Calendar→Vehicle
                                                         Customer information → Calendar →
                                                         Account information → Shopping ca
```

Display Custom Number of Steps

A definable number of steps even those steps that are on branches that can potentially be processed after the currently active step are being displayed.

Note: The number of steps is counted independently for each single branch.

With this option selected, two more configuration settings can be made:

Maximum Number of Steps per Branch. ***(s)***

This setting limits the total number of steps to be determined and thus displayed as the potential next steps. For example, if set to 5, the dialog state display shows no more than 5 steps per branch that are determined and displayed as the potential next steps.

Maximum Number of Branches per Step. ***(b)***

This setting limits the total number of branches to be displayed.

For example, the behavior can be described as follows:

- With b set to `unlimited` and with s set to 1 the following steps would be displayed:

  `**Passenger information** → Calendar`

  Reason: Passenger information (p1) is the active step. Potential next steps are Calendar (p2), Destination (p3), and so on. Following the path to Calendar (p2) costs one step (Calendar (p2) itself). Thus the Destination (p3) step that is also found on this branch cannot be displayed anymore as the value set for Maximum Number of Steps per Branch would be exceeded.
- With b set to `unlimited` and with s set to 2, the following steps are displayed

```
Passenger information → Calendar → Destination → Route → Airlines
                                                    Renters information → Calendar
                                                                Customer information → C
                                                                Account information → Sh
```

Reason: Passenger information (p1) is the active step. Potential next steps are Calendar (p2), Destination (p3), and so on. Following the path to Destination (p3) costs two steps Calendar(p2) and Destination (p3). The Destination (p3) step is a step that branches. Starting at Destination (p3) one can either be redirected to Route (p4) or to Renters information (p10). Following the path from Route (p4) to Airlines (p5) costs two steps Route (p4) and Airlines (p5). Thus these two steps can be displayed as it would not cause the value set for Maximum Number of Steps per Branch to be exceeded.

Following the path from Renters information (p10) to Calendar (p11) costs two steps (Renters information (p10) and Calendar (p11). Thus step Vehicle type (p12) also on this branch cannot be displayed anymore as it causes the value set for Maximum Number of Steps per Branch to be exceeded.

Route (p4) is a step that branches. Starting at Route (p4) one can either be redirected to Customer information (p20) or to Account information (p30). Following the path from Customer information (p20) to Calendar (p21) costs two steps (Customer information (p20) and Calendar (p21). Thus step Room type (p22) also on this branch cannot be displayed as it causes the value set for Maximum Number of Steps per Branch to be exceeded.

Following the path from Account information (p30) to Shopping cart (p31) costs 2 steps (Account information (p30) and Shopping cart (p31). Thus step Check out (p32) also on this branch cannot be displayed anymore as it causes the value set for Maximum Number of Steps per Branch to be exceeded.

- With b being set to 1 and with s being set to `unlimited`, the following steps are displayed.

  ```
  Passenger information → Calendar → Destination
  ```

  Reason: Passenger information (p1) is the active step. Potential next steps are Calendar (p2), Destination (p3) and so on. Destination (p3) is a step that branches. Starting at Destination (p3) one can either be redirected to Route (p4) or to Renters information (p10).Thus the number of branches that start from here is two, which does cause the value set for Maximum Number of Branches per Step to be exceeded. Thus the branches that start from Destination (p3) cannot be displayed anymore.

- With b being set to 2 and with s being set to `unlimited`, the following steps are displayed.

  ```
  Passenger information → Calendar → Destination → Route
                                                      Renters information → Calendar →
  ```

  Reason: Passenger information (p1) is the active step. Potential next steps are Calendar (p2), Destination (p3) , and so on. The step Destination (p3) is a step that branches. Starting at Destination (p3) one can either be redirected to Route (p4) or to Renters information (p10). Thus the number of branches that start from here is two, which does not cause the value set for Maximum Number of Branches per Step to be exceeded. Thus the branches that start from Destination (p3) can be displayed.

Route (p4) is a step that branches, too. Starting at Route (p4) one can either be redirected to Airlines (p5), Customer information (p20), or Account information (p30). Thus the number of branches that start from here is 3, which does cause the value set for Maximum Number of Branches per Step to be exceeded. Thus the branches that start from Route (p4) cannot be displayed anymore.

- With b being set to 3 and with s being set to `unlimited`, the following steps are displayed.

  Passenger information → Calendar → Destination → Route → Airlines
  Renters information → Calendar → Veh
  Customer information → Cale
  Account information → Shopp

  Reason: Passenger information (p1) is the active step. Potential next steps are Calendar (p2), Destination (p3) and so on. The step Destination (p3) is a step that branches. Starting at Destination (p3) one can either be redirected to Route (p4) or to Renters information (p10).Thus the number of branches that start from here is two, which does not cause the value set for Maximum Number of Branches per Step to be exceeded. Thus the branches that start from Destination (p3) can be displayed.

  Route (p4) is a step that branches, too. Starting at Route (p4) one can either be redirected to Airlines (p5), Customer information (p20), or Account information (p30). Thus the number of branches that start from here is 3, which does not cause the value set for Maximum Number of Branches per Step to be exceeded. Thus the branches that start from Route (p4) can be displayed.

Nested Dialog Display Preference

With the Nested Dialog Display Preference option, you can control how a nested non-active dialog is displayed. The following options are provided:

Display Nested Dialog Steps in Breadcrumb
With this option selected the single steps part of a nested dialog are represented as they are. They are not replaced by a single node that represents an entire nested dialog and all of its steps. For example, the following steps are displayed.

Passenger information → Calendar → Destination → Route → Airlines
Renters information → Calendar → Vehic
Customer information → Calenda
Account information → Shoppin

Display Nested Dialog as Single Step
With this option selected the single steps part of a nested dialog are represented by a single placeholder node. This single node is supposed to represent an entire nested dialog and all of its steps. For example, the following steps are displayed.

Passenger information → Calendar → Destination → Route → Airlines
Car booking
Hotel booking
Billing

Buttons to Display preference

With the check box underneath the label Buttons to Display, you can control whether extra Suspend and or Cancel buttons are to be displayed. These buttons

provide the option to cancel and suspend the current dialog the same way as in Dialog Stack.

Note: Though Dialog State Display can be used in a production scenario, it has more or less the character of a sample implementation. Depending on various factors such as the complexity of your dialogs, page design and layout, different visualizations or implementations might better satisfy your needs. Therefore, you can create your own custom, DSD implementation based on the APIs tailored to your requirements.

Configuration options

To change the overall behavior of the IBM UX Screen Flow Manager, several configuration options are available. You specify the options as Resource Environment Provider (REP) properties.

You can enable or disable the Screen Flow Manager by using a single configuration switch. The switch can be found in the REP WP_ConfigService for the portal configuration service

Property: `com.ibm.wps.pcm.enabled`
Values: `true, false`
Default: `true`
Description: If you set this property to `true`, the Screen Flow Manager is enabled. If you se

You can find all other properties that are listed here in the resource environment provider WP_PCMConfig.

Property: `com.ibm.wps.pcm.dialog.default.return.uniquename`
Value: A valid unique name of a page or portlet window
Default: None. Specify a unique name.
Description: Use this property to specify the default return target to which a user is redirect

Property: `com.ibm.wps.pcm.dialog.default.priority`
Value: `preserve, suspend`
Default: `suspend`
Description: Determines which default dialog execution priority is used if no priority is expl
The default execution priority implicitly suspends the active dialog, if a matching start trans

Property: `com.ibm.wps.pcm.dialog.default.dialogstep.display.endtransition`
Values: `true, false`
Default: `true`
Description: Use this property to determine whether the end transition is part of the set of

Property: `com.ibm.wps.pcm.dcx.jaxb.serialization.mode`
Values: `on, off, auto`
Default: `auto`
Description: Use this property to determine the JAXB marshalling mode of objects that are p

- The value `on` means that data to be stored in the DCX is always JAXB marshaled.
- The value `auto` means that the data is JAXB marshaled only if required. The decision is computed by analyzing the class loader hierarchy.
- The value `off` means that the data is never JAXB marshaled. For more information, read *Packaging of event mappers and JAXB serialization.*

Related concepts:

"Start transitions and special events" on page 3490
You can define a dialog to starts if a special start event is emitted from a specific source or from an arbitrary source.

"Packaging of event mappers and JAXB serialization" on page 3511
It is good practice to package event mappers in a shared library rather than together with the business portlets.

CF05 "Execution priority" on page 3502
You can and must explicitly model and enforce a deterministic behavior for the transitions. Even if the entire set of dialogs is deterministic, the emission of an event by a particular portlet can trigger two different transitions of two different dialogs. Therefore, you must explicitly model the intended behavior of the transitions.

Staging and migration

For staging or migration purposes, you can use the portal XML configuration interface (XMLAccess) to transfer IBM UX Screen Flow Manager related data from one system to another.

To transfer the data, run a full XMLAccess export of all dialogs that you want to transfer. Then, do an import of the exported data. For more information, go to *Deploy dialog sets by using the XML configuration interface*.

Related concepts:

"Deploy dialog sets by using the XML configuration interface" on page 3504
You can use the portal XML configuration interface (XMLAccess) to work with dialog sets.

Transitions reference

You can configure transitions in multiple ways. For example, with single portlets as source, you can configure it to transition to targets such as single portlets, multiple portlets through single or multiple transition endpoints, single page, or mixed resources. Similarly, you can configure single portlets, multiple portlets, single page, or mixed resources to become the source and transition to the target single portlet. The following reference topics show the code samples for these transitions.

CF05 "Transitions from portlets"
The following code samples show examples of the various transitions that you can configure from a single portlet as the source.

CF05 "Transitions from pages" on page 3531
The following code samples show examples of the various transitions that you can configure with the page as the source.

CF05 "Transitions from dialogs" on page 3532
The following code samples show examples of the various transitions that you can configure with the page as the source.

CF05 "Transitions from multiple resources" on page 3533
The following code sample shows a transition where the source points to multiple resources and the target points to single portlet. The multiple resources that the source points to can be pages or portlets or both pages and portlets that are marked with a particular metadata marker.

Transitions from portlets

The following code samples show examples of the various transitions that you can configure from a single portlet as the source.

Single portlet to single portlet

The transition from a single portlet to single portlet is the most simple transition. The code sample shows an example of such a transition.

The source points to a single transition endpoint a portlet, for example, in a travel site, a passenger information portlet and the target points to another single transition endpoint another portlet, for example, the Calendar portlet. After the source Passenger information portlet `portlet1` emits the event `e1`, the user is routed to the target Calendar portlet `portlet2`, which is fed with event `e2`.

Code sample

```
<transition>
    <source>
        <transition-endpoint nameref="portlet1">
             <event qname="e1"/>
         </transition-endpoint>
     </source>
     <target>
         <transition-endpoint nameref="portlet2">
              <event qname="e2"/>
          </transition-endpoint>
     </target>
</transition>
```

Single portlet to multiple portlets

This code sample shows a transition from a single portlet to multiple portlets where the target points to multiple portlets instead of a single one.

Some portlets are associated with different events than others. In the code sample, both the portlets that are referenced by the transition-endpoints `portlet2a` and `portlet2b` receive the event `e2a`. The portlet that is referenced by the transition endpoint `portlet2c` receives the event `e2c`.

Note: In case multiple portlets are referenced as part of a target, all portlets must be on the same page.

Code sample

```
<transition>
    <source>
        <transition-endpoint nameref="portlet1">
             <event qname="e1"/>
        </transition-endpoint>
    </source>
    <target>
        <transition-endpoint nameref="portlet2a">
              <event qname="e2a"/>
        </transition-endpoint>
        <transition-endpoint nameref="portlet2b">
              <event qname="e2a"/>
        </transition-endpoint>
        <transition-endpoint nameref="portlet2c">
              <event qname="e2c"/>
        </transition-endpoint>
    </target>
</transition>
```

Single portlet to page

This code sample shows a transition from a single portlet to a page instead of a portlet. This transition causes the event to be propagated to all portlets that are found on the page.

All portlets that are found on the page that is referenced by the transition-endpoint `page2` receives the event `e2`.

Code sample

```
<transition>
    <source>
        <transition-endpoint nameref="portlet1">
            <event qname="e1"/>
        </transition-endpoint>
    </source>
    <target>
        <transition-endpoint nameref="page2">
             <event qname="e2"/>
         </transition-endpoint>
     </target>
</transition>
```

Single portlet to a page and multiple portlets

This code sample shows a transition with the target that points to page and multiple portlets. The page and each portlet are associated with a different event. This transition causes each portlet to receive the event that is associated with the page and the event that is associated with the particular portlet.

In code sample, the portlet that is referenced by the transition-endpoint receives the events as follows

- Transition-endpoint `portlet2a` receives the events `e2` and `e2a`.
- Transition-endpoint `portlet2b` receives the events `e2` and `e2a`.
- Transition-endpoint `portlet2c` receives the events `e2` and `e2c`.

Note: If pages and portlets are both referenced as targets, all portlets must be on the referenced page.

Code sample:

```
<transition>
    <source>
        <transition-endpoint nameref="portlet1">
             <event qname="e1"/>
        </transition-endpoint>
     </source>
     <target>
          <transition-endpoint nameref="page2">
              <event qname="e2"/>
          </transition-endpoint>
          <transition-endpoint nameref="portlet2a">
               <event qname="e2a'/>
          </transition-endpoint>
          <transition-endpoint nameref="portlet2b">
               <event qname="e2a'/>
          </transition-endpoint>
          <transition-endpoint nameref="portlet2c">
```

```
            <event qname="e2c'/>
        </transition-endpoint>
     </target>
</transition>
```

The following code sample shows an alternative way to declare what is declared in the previous code sample. Two of the previously shown transition-endpoints are merged into a single one. Both notations lead to the same effect.

Code sample

```
<transition>
    <source>
        <transition-endpoint nameref="portlet1">
            <event qname="e1"/>
        </transition-endpoint>
     </source>
     <target>
          <transition-endpoint nameref="page2">
              <event qname="e2"/>
          </transition-endpoint>
          <transition-endpoint nameref="portlet2a 2b">
               <event qname="e2a'/>
          </transition-endpoint>
          <transition-endpoint nameref="portlet2c">
               <event qname="e2c'/>
          </transition-endpoint>
      </target>
</transition>
```

It is also possible to transmit multiple events to a single target transition-endpoint. In the following code sample, transition-endpoints are associated with events as shown

- The page that is referenced by the transition-endpoint `page2` is associated with the events `e2-1` and `e2-2`.
- The portlet that is referenced by the transition-endpoint `portlet2a` is associated with the events `e2a-1` and `e2a-2`.
- The portlet that is referenced by the transition-endpoint `portlet2b` is associated with the events `e2b-1`.

In this particular sample, `portlet2a` receives the events `e2-1`,`e2-2`, `e2a-1`, and `e2a-2` and `portlet2b` receives the events `e2-1`,`e2-2`, and `e2b-1`.

Note: Transmission of multiple events is supported only for targets.

Code sample

```
<transition>
    <source>
        <transition-endpoint nameref="portlet1">
            <event qname="e1"/>
        </transition-endpoint>
     </source>
     <target>
          <transition-endpoint nameref="page2">
              <event qname="e2-1"/>
              <event qname="e2-2"/>
          </transition-endpoint>
          <transition-endpoint nameref="portlet2a">
               <event qname="e2a-1"/>
               <event qname="e2a-2"/>
          </transition-endpoint>
          <transition-endpoint nameref="portlet2b">
```

```
            <event qname="e2b-1"/>
        </transition-endpoint>
    </target>
</transition>
```

Multiple portlets to single portlet

The following code sample shows a transition where the source points to multiple portlets and the target points to a single portlet.

When any of the referenced source portlets, `portlet1a` or `portlet1b`, emits the event `e1`, the user is routed to the target portlet `portlet2`, which is fed with event `e2`.

Note: For sources, it is not possible to alternatively reference multiple transition-endpoints as it was done with targets.

Code sample

```
<transition>
    <source>
        <transition-endpoint nameref="portlet1a_1b">
            <event qname="e1"/>
        </transition-endpoint>
    </source>
    <target>
        <transition-endpoint nameref="portlet2">
            <event qname="e2"/>
        </transition-endpoint>
    </target>
</transition>
```

Single portlet to another dialog

The following code sample shows a transition where the source points to a single portlet and the target to another dialog.

This transition represents the outgoing transition. When the transition is triggered, it starts the referenced dialog, which is initialized by the defined event. For more information about the outgoing transition, go to *Transition Endpoints*.

In this code sample, when `portlet1` emits the event `e1`, `dialog2` is started and initialized with event `eX`. From here, continuing to a particular step of `dialog2` depends on the transitions that are defined as part of `dialog2`. For more information, go to the topic *Dialog Chaining and Nesting*.

Code sample

```
<transition type="nested">
   <source>
       <transition-endpoint nameref="portlet1">
           <event qname="e1"/>
       </transition-endpoint>
    </source>
    <target>
        <transition-endpoint nameref="dialog2">
            <event qname="eX"/>
        </transition-endpoint>
    </target>
</transition>
```

Related concepts:

CF05 “Dialog chaining and nesting” on page 3494
Dialogs can start other dialogs. Dialogs that start other dialogs are referred to as calling dialogs and the dialogs that are being started are referred to as called dialogs. Two different options are available to complete this action such as dialog chaining and dialog nesting.

CF05 “Transition endpoints” on page 3480
Resources that are part of a screen flow which marks an endpoint, that is, the source or target of a transition are referred to as transition endpoints. Resources can be pages and portlets and they can also wrap widgets or forms. A particular page or portlet that is the active step in a screen flow is referred to as the source and the potential next steps are referred to as targets.

Transitions from pages

The following code samples show examples of the various transitions that you can configure with the page as the source.

Single page to single portlet

The following code sample shows a transition where the source points to a single page and the target points to single portlet.

When any portlet on the referenced page `page1` emits the event `e1`, the user is routed to the target portlet `portlet2`, which is fed with event `e2`.

Code sample

```
<transition>
    <source>
        <transition-endpoint nameref="page1">
            <event qname="e1"/>
         </transition-endpoint>
     </source>
     <target>
         <transition-endpoint nameref="portlet2">
              <event qname="e2"/>
          </transition-endpoint>
      </target>
</transition>
```

Multiple pages to single portlet

The following code sample shows a transition where the source points to multiple pages and the target points to a single portlet.

When any portlet on any of the referenced pages, `page1a` or `page1b`, emits the event `e1`, the user is routed to the target portlet `portlet2`. The target portlet `portlet2` is then fed with event `e2`.

Note: For sources, it is not possible to alternatively reference multiple transition endpoints.

Code sample

```
<transition>
   <source>
       <transition-endpoint nameref="page1a_1b">
            <event qname="e1"/>
       </transition-endpoint>
    </source>
    <target>
```

```
        <transition-endpoint nameref="portlet2">
            <event qname="e2"/>
         </transition-endpoint>
     </target>
</transition>
```

Page hierarchy to single portlet

The following code sample shows a transition where the source points to a page hierarchy and the target points to single portlet.

When any portlet on any page part of the referenced hierarchy emits the event `e1`, the user is routed to the target portlet `portlet2`. The target portlet `portlet2` is then fed with event `e2`.

Code sample

```
<transition>
   <source>
       <transition-endpoint nameref="pageHierarchy1">
            <event qname="e1"/>
       </transition-endpoint>
    </source>
    <target>
        <transition-endpoint nameref="portlet2">
            <event qname="e2"/>
         </transition-endpoint>
     </target>
</transition>
```

Transitions from dialogs

The following code samples show examples of the various transitions that you can configure with the page as the source.

Single dialog to single portlet

The following code sample shows a transition where the source points to a single dialog and the target to a single portlet.

The transition represents the incoming transition. When the transition is triggered, it causes the continuation of the dialog that the transition is returned to. For more information about incoming transitions, go to *Transition Endpoints*.

In this code sample, when `dialog2` emits the event `eX`, `dialog1` is continued and is initialized with event `e2`.

Code sample

```
<transition>
   <source>
       <transition-endpoint nameref="dialog2">
            <event qname="eX"/>
       </transition-endpoint>
    </source>
    <target>
        <transition-endpoint nameref="portlet2">
            <event qname="e2"/>
         </transition-endpoint>
     </target>
</transition>
```

Dialog to dialog

The following code sample shows a transition where the source and the target point to dialogs. This transition represents the dispatching transition.

A dispatching transition is triggered when the transition returns from one dialog and it causes another dialog to start. In this sample when `dialog2` emits the event `eX`, `dialog3` is started and is initialized with the event `eY`. For more information about dispatching transition, go to *Dialog Chaining and Nesting*.

Code sample

```
<transition type="nested">
   <source>
       <transition-endpoint nameref="dialog2">
            <event qname="eX"/>
       </transition-endpoint>
    </source>
    <target>
        <transition-endpoint nameref="dialog3">
            <event qname="eY"/>
         </transition-endpoint>
     </target>
</transition>
```

Related concepts:

CF05 "Dialog chaining and nesting" on page 3494
Dialogs can start other dialogs. Dialogs that start other dialogs are referred to as calling dialogs and the dialogs that are being started are referred to as called dialogs. Two different options are available to complete this action such as dialog chaining and dialog nesting.

CF05 "Transition endpoints" on page 3480
Resources that are part of a screen flow which marks an endpoint, that is, the source or target of a transition are referred to as transition endpoints. Resources can be pages and portlets and they can also wrap widgets or forms. A particular page or portlet that is the active step in a screen flow is referred to as the source and the potential next steps are referred to as targets.

Transitions from multiple resources

The following code sample shows a transition where the source points to multiple resources and the target points to single portlet. The multiple resources that the source points to can be pages or portlets or both pages and portlets that are marked with a particular metadata marker.

Multiple resources to single portlet

When any marked portlet or any portlet on a marked page emits the event `e1`, the user is routed to the target portlet `portlet2`. The target portlet `portlet2` is then fed with the event `e2`.

Code sample

```
<transition>
   <source>
       <transition-endpoint nameref="marked_resources">
            <event qname="e1"/>
       </transition-endpoint>
    </source>
    <target>
        <transition-endpoint nameref="portlet2">
```

```
            <event qname="e2"/>
          </transition-endpoint>
      </target>
</transition>
```

Sample screen flow application

The IBM UX Screen Flow Manager package can be downloaded from the Greenhouse site and includes a sample screen flow application that is ready to use. This sample guides a portal site visitor through a simple travel booking flow. It consists of a set of pages, portlets, and dialog definitions (DDs). For more details about DDs, go to Creating dialog definitions.

The sample includes the following components:

- The following main pages and portlets:
  - Travel Demo. This demonstration page is the root of the sample. The Travel Demo page provides entry fields where a site visitor can enter details about the intended travel. The IBM UX Screen Flow Manager then passes these details to the subsequent pages where the site visitor can book the appropriate flights, hotels, cars, and insurance.
  - Flight Booking
  - Hotel Booking
  - Car Booking
  - Insurance Booking
  - Travel Summary. The page provides a summary of the booking that is done by the site visitor.
- An exemplary Dialog State Display (DSD). It is shown on each page. The site visitor can use this DSD to go back and forth between the individual steps or to suspend or cancel the currently active dialog instance. For more information about DSDs, go to *Dialog State Display*.
- An extra page named Dialog Stack. It provides access to a Dialog Stack (DS). For more information about the Dialog Stack, go to *Dialog Stack*. The site visitor can use the Dialog Stack to view the currently active dialog instance and to return to it or to suspend or cancel it. It also provides an overview of all dialog instances that was previously suspended. The site visitor can resume or cancel these dialog instances.
- Three Dialog Definitions (DDs). The dialog definition that you use determines the order in which the IBM UX Screen Flow Manager routes the site visitor through the flow. By replacing the DD, you can easily change a screen flow without having to change code.

To install the sample, the following are the steps:

1. Deploy the sample application WAR file that is included with the installation package. The file contains the sample portlets that are mentioned before.
2. Create the pages that are mentioned before. To create the pages, run the following XML configuration interface (XMLAccess) command:

   Code sample

   ```
   xmlaccess.{sh|bat} -in deployPagesAndPortlets.xml -user userID  -password password  -url http://h
   ```
3. Import one of the Dialog Definitions included in the installation package. To import, run the appropriate XMLAccess command. The following code sample shows the syntax for the XMLAccess commands for all three dialog definitions.

Select the dialog definition that you import, depending on the order in which you want the IBM UX Screen Flow Manager to route the site visitor through the flow.

Code sample

```
xmlaccess.{sh|bat} -in dialogDefinitions_FlightCarHotel.xml -user userID  -password password -

xmlaccess.{sh|bat} -in dialogDefinitions_FlightHotelCar.xml -user userID -password password -u

xmlaccess.{sh|bat} -in dialogDefinitions_FlightHotelCarInsurance.xml -user userID -password pa
```

Related concepts:

"Creating dialog definitions" on page 3479
With the Screen Flow Manager, different teams or even third-party vendors can develop different types of user interface artifacts. The user puts together the correct set of user interface artifacts and creates the declarative model in XML known as the dialog definition. The dialog definition describes the specific screen flow that is also known as dialog, which consists of multiple steps and single steps referred to as subdialogs. The dialog definition contains all information about the subdialogs that participate and the transitions that route the user from one subdialog to another.

CF05 "Dialog State Display" on page 3520
The Dialog State Display (DSD) displays a dialogs current state. You can move forward and backward or to jump to a dedicated step that was processed before. It is a generic navigation component that can be easily added to any page that participates in a dialog.

CF05 "Dialog Stack" on page 3518
The Dialog Stack provides an overview of active and suspended dialogs. It allows for suspending, resuming, and canceling the dialogs.

Chapter 17. Troubleshooting

To help you resolve problems, use diagnostic tools such as IBM Support Assistant and tracing to capture system errors.

"Tools for troubleshooting and diagnostics"
A number of tools and resources are available to help you troubleshoot issues and resolve problems that users might encounter while using IBM WebSphere Portal Express. If you need further assistance, you can use the tools described here to identify and collect information to help IBM Support determine the underlying cause of a problem.

"Logging and tracing" on page 3541
If you are experiencing a problem, you might want to enable tracing and then re-create the problem to capture more log information. You can enable logging and tracing for software that is included with WebSphere Portal Express. Enabling tracing makes log output more verbose. For example, you can enable tracing within WebSphere Application Server to obtain information about application servers and other processes.

"Troubleshooting the Configuration Wizard" on page 3559
The configuration wizard provides tools for troubleshooting and recovering from errors, such as logs, step commands, and reset options.

"Error message codes" on page 3615
Each message code consists of a product identifier, component identifier, a unique number, and a message type identifier. The product identifier is EJP and there are many components. There are three message types: error, information, and warning.

"Contact support" on page 3615
For contact information, see to the IBM Software Support site.

Tools for troubleshooting and diagnostics

A number of tools and resources are available to help you troubleshoot issues and resolve problems that users might encounter while using IBM WebSphere Portal Express. If you need further assistance, you can use the tools described here to identify and collect information to help IBM Support determine the underlying cause of a problem.

"IBM Support Assistant" on page 3538
IBM Support Assistant (ISA) provides quick access to product, education, and support resources. These resources can help you answer questions and resolve problems with IBM Software products on your own, without needing to contact IBM Support. You can customize IBM Support Assistant for the particular

products that you installed with different product-specific plug-ins. IBM Support Assistant can also collect system data, log files, and other information to help IBM Support determine the cause of a particular problem.

"Data collection and symptom analysis" on page 3539
There is one method to collect data and analyze symptoms for problem determination scenarios. You run a task that can collect and optionally send the data for you. Starting with IBM WebSphere Portal Express version 8.5, there is now a task to collect the configuration wizard logs. This task is only necessary if the wizard fails before the steps to create the `wp_profile/ConfigEngine` instance.

"Portal version and history information" on page 3540
You can use the IBM WebSphere Portal Express version and history information tools to gather information about your portal installation. This information can be useful when you need a snapshot of your portal installation specifics, for example when you contact customer support. This information is automatically included in the automated data collection that is available when you use the IBM Support Assistant Lite for WebSphere Portal Express.

IBM Support Assistant

IBM Support Assistant (ISA) provides quick access to product, education, and support resources. These resources can help you answer questions and resolve problems with IBM Software products on your own, without needing to contact IBM Support. You can customize IBM Support Assistant for the particular products that you installed with different product-specific plug-ins. IBM Support Assistant can also collect system data, log files, and other information to help IBM Support determine the cause of a particular problem.

IBM Support Assistant is a utility to be installed on an administrator's workstation, not directly onto the WebSphere Portal Express or Web Content Manager server system itself. The memory and resource requirements for the Assistant might negatively impact the server's performance. The included portable diagnostic components are designed for minimal impact to the normal operation of a server.

You can use IBM Support Assistant to help you in the following ways:

- To search through IBM and non-IBM knowledge and information sources, across multiple IBM products to answer a question or solve a problem
- To find additional information through product-specific web resources. Including information from product and support home pages, customer news groups and forums, skills and training resources and information about troubleshooting and commonly asked questions
- To extend your ability to diagnose product-specific problems with targeted diagnostic tools available through the Support Assistant
- To simplify collection of diagnostic data. This action helps you and IBM resolve your problems (collecting either general or product/symptom-specific data)
- To help report problem incidents to IBM Support through a customized online interface. You can also attach the previous diagnostic data or any other information to new or existing incidents

Finally, you can use the built-in Updater facility to obtain support for more software products and capabilities as they become available.

More information, the download package, installation instructions, and the latest version of the IBM Support Assistant are available from the IBM Support Assistant web page at `www.ibm.com/software/support/isa/`.

IBM Support Assistant

Data collection and symptom analysis

There is one method to collect data and analyze symptoms for problem determination scenarios. You run a task that can collect and optionally send the data for you. Starting with IBM WebSphere Portal Express version 8.5, there is now a task to collect the configuration wizard logs. This task is only necessary if the wizard fails before the steps to create the `wp_profile/ConfigEngine` instance.

`wpcollector` tool

Complete the following steps:

1. If the support team requested tracing, enable it now as instructed and then re-create the problem. If no tracing is requested, skip to the next step.
2. Open a command prompt and change to the *wp_profile_root*`/PortalServer/bin/` directory.

   Attention: You must run the **`wpcollector`** task from the *wp_profile_root*`/PortalServer/bin/` directory. If you run the task from a different directory, the task fails.
3. Run the following script to collect data:
   - Linux : `./wpcollector.sh`
   - IBM i: `wpcollector.sh`
   - Windows: `wpcollector.bat`

   Tip: The `wpcollector` script can automatically FTP the logs to IBM so that you do not need to manually transfer them. To begin the collection and FTP the results to IBM correctly, use the `-Dpmr=`*`pmr_number`* parameter to identify the collection with your PMR (Problem Management Record) number. Format the number either with periods or commas. For example: `wpcollector.bat -Dpmr=`*`12345.xxx.000`*

   To collect files for the Deployment Manager profile, use the `-Ddmgr.root=`*`dmgr_root`* parameter either alone or with `-Dpmr=`*`pmr_number`*.
4. If you did not automatically FTP your results, locate the `wp.mustgather.zip` file or the *`pmr`*`-wp.mustgather-`*`timestamp`*`.zip` file in the *wp_profile_root*`/filesForAutoPD/` directory. Follow the instructions in "Exchanging information with IBM Technical Support for problem determination" to manually FTP your results.

Restriction: If you try to extract the `wp.mustgather.zip` file, some collections might not expand properly if the path name exceeds the 256 character limitation.

`cwcollector` tool

Complete the following steps if the configuration wizard failed before it created the `wp_profile/ConfigEngine` instance:

1. Open a command prompt and change to the *AppServer_root*`/ConfigEngine` directory.
2. Run the following task to collect the configuration wizard logs:

   Tip: The logs are compressed and placed into the *AppServer_root*`/filesForAutoPD` directory.

- Linux : `./ConfigEngine.sh collect-cw-logs -DPortalBinaryLocation=/opt/IBM/WebSphere/PortalServer -DWasPassword=password`
- IBM i: `ConfigEngine.sh collect-cw-logs -DPortalBinaryLocation=/QIBM/ProdData/WebSphere/PortalServer/V85/Server -DWasPassword=password`
- Windows: `ConfigEngine.bat collect-cw-logs -DPortalBinaryLocation=C:/IBM/WebSphere/PortalServer -DWasPassword=password`

Tip: The **collect-cw-logs** script can automatically FTP the logs to IBM so that you do not need to manually transfer them. To begin the collection and FTP the results to IBM correctly, use the `-Dpmr=pmr_number` parameter to identify the collection with your information. Format the number either with periods or commas. **Attention:** If the **collect-cw-logs** task fails, run the **stopserver server1** command from the *AppServer_root*`/bin` directory. Then, rerun the **collect-cw-logs** task.

3. If you did not automatically FTP your results, locate the `cw.mustgather.zip` file or the *pmr*`-cw.mustgather-`*timestamp*`.zip` file in the *AppServer_root*`/filesForAutoPD` directory. Follow the instructions in "Exchanging information with IBM Technical Support for problem determination" to manually FTP your results.

Portal version and history information

You can use the IBM WebSphere Portal Express version and history information tools to gather information about your portal installation. This information can be useful when you need a snapshot of your portal installation specifics, for example when you contact customer support. This information is automatically included in the automated data collection that is available when you use the IBM Support Assistant Lite for WebSphere Portal Express.

Version information

The portal version information tool is located in the following directory:

- Linux : *wp_profile_root*`/PortalServer/bin`
- IBM i: *wp_profile_root*`/PortalServer/bin`
- Windows: *wp_profile_root*`\PortalServer\bin`

You invoke the tool by using the following command:

- Linux : `./WPVersionInfo.sh`
- IBM i: `WPVersionInfo.sh`
- Windows: `WPVersionInfo.bat`

You can also generate a report in html format by executing the genVersionReport tool

- Linux : `./genVersionReport.sh`

- IBM i: `genVersionReport.sh`
- Windows: `genVersionReport.bat`

History information

The History information tool can be used to gather installation history for the WebSphere Portal Express product. The History information tool is located in the following directory:

- Linux : *wp_profile_root*`/PortalServer/bin`
- IBM i: *wp_profile_root*`/PortalServer/bin`
- Windows: *wp_profile_root*`\PortalServer\bin`

The History information tool can be invoked using the following command:

- Linux : `./WPHistoryInfo.sh`
- IBM i: `WPHistoryInfo.sh`
- Windows: `WPHistoryInfo.bat`

You can also generate a report in HTML format by executing the `genHistoryReport` tool:

- Linux : `./genHistoryReport.sh`
- IBM i: `genHistoryReport.sh`
- Windows: `genHistoryReport.bat`

Related concepts:

"Data collection and symptom analysis" on page 3539
There is one method to collect data and analyze symptoms for problem determination scenarios. You run a task that can collect and optionally send the data for you. Starting with IBM WebSphere Portal Express version 8.5, there is now a task to collect the configuration wizard logs. This task is only necessary if the wizard fails before the steps to create the `wp_profile/ConfigEngine` instance.

Logging and tracing

If you are experiencing a problem, you might want to enable tracing and then re-create the problem to capture more log information. You can enable logging and tracing for software that is included with WebSphere Portal Express. Enabling tracing makes log output more verbose. For example, you can enable tracing within WebSphere Application Server to obtain information about application servers and other processes.

Refer to the MustGather data collection lists used in troubleshooting various problems in WebSphere Portal Express and IBM Web Content Manager. Collecting MustGather data early, even before you open a PMR, helps IBM Product Support quickly determine whether

- Symptoms match known problems (rediscovery).
- A non-defect problem can be identified and resolved.
- A defect identifies a workaround to reduce severity.
- Locating the root cause can speed development of a code fix.

Simplify this process even more by using the IBM Support Assistant Lite for WebSphere Portal Express to automate the collection of the diagnostic data that is needed to troubleshoot most of these situations. You can use the information

gathered to help solve your own problems or to report an issue to IBM Product Support.

Links to important WebSphere Portal Express tracing questions

How do I turn on WebSphere Portal Express trace logging?
See "Trace logging" on page 3551 for information.

What are the different trace settings and where are they logged?
See "WebSphere Portal Express runtime logs" on page 3544 for information.

How do I change the location of my logs?
See "Changing the log file name and location" on page 3552

Use WebSphere Application Server log files and tracing to troubleshoot problems with WebSphere Portal Express.

"Configuration Wizard log files" on page 3550
The configuration wizard generates log files each time you run it. The log file can help you to debug problems.

"Enabling Virtual Member Manager tracing files" on page 3550
Enable WebSphere Application Server trace facilities to create trace information for Virtual Member Manager.

"System event logging" on page 3551
The system event logging facility of IBM WebSphere Portal Express enables the recording of information about the operation of WebSphere Portal Express.

"Web Content Manager tracing files" on page 3554
Enable the use of WebSphere Application Server trace facilities to create trace information for Web Content Manager. This tracing can be enabled either permanently or for just the current WebSphere Portal Express session.

"Logging and tracing client side rendering" on page 3557
Portal pages that are rendered in client side aggregation mode differ in their logging behavior from portal pages rendered in server side mode. For client side rendered pages, a considerable amount of code is written in JavaScript that is executed in the corresponding browser JavaScript engine rather than on the server. As a result, the corresponding logging and tracing information is collected in the browser and not on the server side.

Collecting Data (MustGather): Read first for IBM WebSphere Portal

Installation and migration logs

Learn about the different log files that WebSphere Portal Express provides to help administrators identify and correct problems with installation and migration.

Installation log files

The IBM Installation Manager controls the WebSphere Portal installation log files. The IBM Installation Manager records any errors or warnings that occur during the installation. The IBM Installation Manager stores all logs in a centralized location and the logs pertaining to WebSphere Portal can be found there. Typically these logs are found in the following directory:

- Linux : `/var/ibm/InstallationManager/logs`
- IBM i: `/QIBM/UserData/InstallationManager/logs`
- Windows: `C:\ProgramData\IBM\Installation Manager\logs`

The IBM Installation Manager retains logs from all installations and uninstallations that it does for all products. You can review your entire history. The IBM Installation Manager has a built-in function that you can use to view the logs. On the IBM Installation Manager main page, click **File** > **View log**. You can also use your web browser to view the `index.xml` file in the log directory.

Migration log files

Unless noted otherwise, migration log files are in the following directory:

- Linux : *wp_profile_root* `/logs`
- IBM i: *wp_profile_root*`/logs`

  Note: Files in this directory are stored only on the local System i5® workstation. You might be able to view them from a Windows workstation by mapping a network drive to the System i5 workstation.
- Windows: *wp_profile_root* `\logs`

The table lists each file, describes the file content, and recommends when to check the file for information that might help troubleshooting migration problems.

Table 505. Migration log files for IBM i Linux Windows

Log file name	Description	Problem symptoms
`ConfigTrace.log`	Contains information that is generated each time a ConfigEngine task is run, including trace information that is generated during migration. This file is in *wp_profile_root*`/ConfigEngine/log`.	Check this log if migration stops before successful completion.

Table 505. Migration log files for IBM i Linux Windows (continued)

Log file name	Description	Problem symptoms
upgradeConfigEngineTrace.log	Contains trace information that is generated when the ConfigEngine tool is upgraded. This file is in *wp_profile_root*/ConfigEngine/log	Check this log if errors occur when you run the upgradeConfigEngine tool.

To set tracing for the migration plug-in com.ibm.wp.was.plugin.jar file, which you use to migrate the Deployment Manager and nodes, specify com.ibm.wp.migration.*=all.

WebSphere Portal Express runtime logs

If tracing is enabled, IBM WebSphere Portal Express generates a log file during run time that contains messages and trace information.

The default runtime log file is shown:

- Linux : *wp_profile_root*/logs/WebSphere_Portal/trace.log
- IBM i (UserData): *wp_profile_root*/logs/WebSphere_Portal/trace.log
- Windows: *wp_profile_root*\logs\WebSphere_Portal\trace.log

See the topic on system event logging for details on how to configure logging and for information on the grammar of the "trace string" configuration key.

The following information describes trace loggers for particular situations and problem symptoms. Enabling the trace loggers can slow down WebSphere Portal Express.

Note: If there are problems with portal administration portlets, the error is not caused by the portlet code itself, but by the underlying function for which the portlet provides the UI. Therefore, the portlet trace strings are not listed here. If there are issues with these portlets, provide the trace strings of the underlying function. If you need traces or logs for portlets, you can learn how to obtain them from support personnel.

Access Control

When to use

Enable this tracer if you want permissions for resources to be explained in detail, need to verify the correctness of a permission, or need to isolate a defect in access control.

Trace String

com.ibm.wps.ac.*=all

Additional comments

The traces are easier to evaluate while WebSphere Portal Express usage is low.

Important: Enabling this logger creates large log files.

Authentication

Trace String

```
com.ibm.wps.services.puma.*=all:
com.ibm.wps.puma.*=all:
com.ibm.wps.auth.*=all:
com.ibm.wps.sso.*=all:
com.ibm.wps.um.*=all:
com.ibm.wps.services.authentication.*=all
```

Command

When to use

Use to turn on all command trace loggers.

Trace String

```
com.ibm.wps.commands.*=all
```

Layout Model

When to use

Enable these messages if you want to get more information on how pages are constructed, need to verify page lists that are displayed on WebSphere Portal Express for correctness, or need to isolate an error in the WebSphere Portal Express aggregation component.

Trace String

```
com.ibm.wps.model.*=all:
com.ibm.wps.composition.*=all
```

Additional comments

The traces are easier to evaluate while WebSphere Portal Express usage is low.

Important: Enabling this logger creates large log files.

Credential Vault

Trace String

```
com.ibm.wps.sso.credentialvault.*=all:
com.ibm.wps.command.credentialvault.*=all:
com.ibm.wps.portletservice.credentialvault.*=all:
com.ibm.wps.services.credentialvault.*=all:
com.ibm.portal.portlet.service.credentialvault.*=all
```

Database

When to use

Deals with generated SQL statements and the internal flow in the WebSphere Portal Express database layer.

Trace String

```
com.ibm.wps.datastore.*=all:
com.ibm.wps.services.datastore.*=all
```

Additional comments

Important: Enabling this logger creates large log files.

Engine

When to use

Use to enable all engine trace loggers.

Trace string

```
com.ibm.wps.engine.*=all
```

General

Trace string

```
com.ibm.wps.*=all
```

Note: If you want to use general tracing but do not want render times to be displayed for such portlets, you must selectively disable tracing by using the following trace string:

```
com.ibm.wps.pe.PortletRenderTimeLoggingHelper=info
```

Mail Service

When to use

Use to diagnose problems with the Mail Service.

Trace string

```
com.ibm.wps.services.mail.*=all
```

Mapping URLs

When to use

Use to diagnose problems with the user-defined mappings of URLs.

Trace string

```
com.ibm.wps.mappingurl.*=all:
com.ibm.wps.command.mappingurl.*=all
```

Personalization

Trace string

```
com.ibm.websphere.personalization.*=all:
com.ibm.dm.pzn.ui.*=all
```

Additional comments

When Personalization is installed outside of a WebSphere Portal Express server, Personalization logs by using WebSphere Application Server tracing with the same trace strings.

Portlet Container

Trace string

```
com.ibm.wps.pe.pc.*=all:
org.apache.jetspeed.portlet.Portlet=all:
javax.portlet.Portlet=all
```

Portlet Environment

Trace string

```
com.ibm.wps.pe.ext.*=all:
com.ibm.wps.pe.factory.*=all:
com.ibm.wps.pe.om.*=all:
com.ibm.wps.pe.util.*=all
```

Portlet Load Monitoring

When to use

Use to diagnose problems with Portlet Load Monitoring (PLM).

Trace string

```
com.ibm.wps.pe.pc.waspc.plm.*=all:
com.ibm.wps.command.plm.*=all
```

Deployment

Trace string

```
com.ibm.wps.pe.mgr.*=all:
com.ibm.wps.services.deployment.*=all:
com.ibm.wps.command.applications.*=all:
com.ibm.wps.command.portlets.*=all
```

Portlets

When to use

Use to diagnose problems with portlets.

Trace string

```
com.ibm.wps.portlets.*=all:
org.apache.jetspeed.portlet.PortletLog=all
```

Additional comments

Enables tracing for all portlets. Therefore, place the suspect portlet on a separate page for testing.

Scripting Interface

When to use

Use this trace string to diagnose problems with the Portal Scripting Interface, or with application interface scripting, and the execution of such scripts.

Trace string

```
com.ibm.wps.scripting.*=all
```

Additional comments

The traces are easier to evaluate while portal usage is low.

Note: Enabling this logger can create large log files fast.

Selfcare

When to use

Use to diagnose problems with user registration and profile editing.

Trace string

```
com.ibm.wps.services.puma.*=all:
com.ibm.wps.puma.*=all:
com.ibm.wps.um.*=all
```

Additional comments

Use this logger if there are errors in the sign-up, Edit My Profile, and the Manage Users and Groups portlets.

Services: EventBroker

Trace string

```
com.ibm.wps.services.registry.EventHandlerRegistry=all:
com.ibm.wps.services.events.*=all
```

Services: Finder

When to use

Use for debugging the resolution of file names.

Trace string

```
com.ibm.wps.services.finder.*=all
```

Services: Loader

When to use

Use to trace the dynamic class loading that is done by this service.

Trace string

```
com.ibm.wps.services.ServiceManager=all
```

ServicesNaming

When to use

Use to debug the lookup of objects by the naming service.

Trace string

```
com.ibm.wps.services.naming.*=all
```

ServicesNavigator

When to use

Use to diagnose problems with parts of page aggregation and display.

Trace string

```
com.ibm.wps.services.navigator.*=all
```

ServicesRegistry

When to use

Use to view the policies of the internal portlet object caching and watch it reload its content.

Trace string

```
com.ibm.wps.services.registry.*=all
```

Services

When to use

Use for turning on tracing for all services.

Trace string

```
com.ibm.wps.services.*=all
```

SSO

When to use

Use to turn on all SSO tracer loggers.

Trace string

```
com.ibm.wps.sso.*=all
```

Additional comments

Use this logger if errors occur when you use the Security Vault task on the Security page of the Administration pages.

WSRP administration

When to use

Use to diagnose problems that occur during the administration of Web Services for Remote Portlets (WSRP) with WebSphere Portal Express.

Trace string

```
com.ibm.wps.command.wsrp.*=all:
com.ibm.wps.wsrp.cmd.*=all
```

WSRP Consumer

When to use

Use to diagnose problems that occur during the use of WSRP with WebSphere Portal Express as a Consumer.

Trace string

```
com.ibm.wps.wsrp.consumer.*=all
```

WSRP Producer

When to use

Use to diagnose problems that occur during the use of WSRP with WebSphere Portal Express as a Producer.

Trace string

```
com.ibm.wps.wsrp.producer.*=all
```

XML configuration interface

When to use

Use to diagnose problems with the XML import/export of WebSphere Portal Express configurations.

Trace string

```
com.ibm.wps.command.xml.*=all
```

Verbose garbage collection in Java Virtual Machine (JVM) logs

Verbose garbage collection (verbosegc) logging is often required when tuning and debugging many issues, particularly memory problems, and has negligible impact on system performance.

The default WebSphere Portal Express installation enables verbosegc logging and configures the following generic JVM argument:

```
-Xverbosegclog:${SERVER_LOG_ROOT}/verbosegc.m%d.5/10/13M%S.
%pid.txt,20,10000
```

The verbosegc log file name is `verbosegc.m%d.5/10/13M%S.%pid.txt`. It includes a date/time stamp and the process ID (PID) of the WebSphere Portal Express instance.

The default WebSphere Portal Express installation redirects the verbosegc output to 20 rotating historical log files, each containing 10000 garbage collection (GC) cycles.

For more information about configuring the JVM through WebSphere Application Server, see the IBM WebSphere Application Server information centers at `www.ibm.com/software/webservers/appserv/was/library`.

WebSphere Application Server tracing and log files

Use WebSphere Application Server log files and tracing to troubleshoot problems with WebSphere Portal Express.

WebSphere Application Server has log files and a tracing function; however, whenever possible use the IBM Installation Manager installation logs to determine whether WebSphere Application Server was successfully configured for WebSphere Portal Express and whether WebSphere Portal Express was successfully started on WebSphere Application Server.

Configuration Wizard log files

The configuration wizard generates log files each time you run it. The log file can help you to debug problems.

The trace string for the Configuration Wizard is:
`com.ibm.wplc.config.wizard.*=all`.

The log files for the configuration wizard are located in the following directory:

- Windows: *AppServer_root*`\logs\server1`
- Linux : *AppServer_root*`/logs/server1`
- IBM i: *AppServer_root*`/logs/cw_profile`

Note: On IBM i, the *AppServer_root* refers to the UserData path.

You can view log files from the referenced directory. Log files are also generated that reflect the name of the task ran. These files are generated after the task has completed. They contain task-specific copies of the output in the configwizard log file and can be used to track output for one specific task when multiple tasks are run. The configwizard log file is generated at the task runs and remains in the `PortalServer/logs` directory. Each log file is backed up if a task is run again.

Enabling Virtual Member Manager tracing files

Enable WebSphere Application Server trace facilities to create trace information for Virtual Member Manager.

About this task

Virtual Member Manager uses the WebSphere Application Server trace facilities to create trace information. Complete the following steps to enable the Virtual Member Manager trace output to debug a problem:

Procedure

1. Log on to the WebSphere Integrated Solutions Console.
2. Go to section **Troubleshooting** > **Logs and Traces** > **WebSphere_Portal** > **Diagnostic Trace**.
3. Ensure the **File** radio button under **Trace Output** is selected.
4. Under the **Additional Properties** section, click **Change Log Detail Levels**. Enter the following trace string in the text box:

   ```
   com.ibm.ws.security.*=all:com.ibm.websphere.wim.*=all:
   com.ibm.wsspi.wim.*=all:com.ibm.ws.wim.*=all
   ```
5. Click **OK** and save the changes to the master configuration.
6. Restart WebSphere Portal Express.

Results

The resulting traces of Virtual Member Manager are written to:

- Windows: *wp_profile_root*\logs\WebSphere_Portal\trace.log
- Linux : *wp_profile_root*/logs/WebSphere_Portal/trace.log
- IBM i: *wp_profile_root*/logs/WebSphere_Portal/trace.log

System event logging

The system event logging facility of IBM WebSphere Portal Express enables the recording of information about the operation of WebSphere Portal Express.

Event logs provide administrators with information about important or abnormal events, especially errors that occur during the operation of the product. In addition, event logs gather debugging information that helps IBM support to resolve problems.

WebSphere Portal Express provides two types of logging: logging of messages and logging of debugging messages called traces.

For information about how to use log files and a list of trace logger strings refer to the topic about WebSphere Portal Express logs.

Message logging

Messages for WebSphere Portal Express are logged in the following files:

SystemOut.log
: Contains information that is useful to monitor the health of the WebSphere Portal Express server and all running processes.

System.err
: Contains exception stack trace information that is useful when problem analysis is done.

Locating the log files: Log files for WebSphere Portal Express, including SystemOut.log and System.err are in the following directory: *wp_profile_root*/logs/WebSphere_Portal

Trace logging

WebSphere Portal Express provides the logging of debugging messages called traces. These traces are useful for fixing problems. However, to save system resources, they are turned off by default.

Traces can be set for different durations:

Temporary
: Traces can be set for a temporary period by using the administration portlet **Enable Tracing** or the WebSphere Integrated Solutions Console. To set traces by using the portlet, complete the following steps:

1. Log in as the administrator.
2. Click the **Administration menu** icon. Then, click **Portal Analysis** > **Enable Tracing**. The Enable Tracing portlet displays.

3. Type the required trace string into the field **Append these trace settings:** For example, this string can be `com.ibm.wps.command.credentialvault.*=finest`
4. Click the **Add** icon. **Enable Tracing** updates the **Current trace settings** field.

Note: Restarting WebSphere Portal Express removes traces that were set by using the Enable Tracing Administration portlet.
To disable tracing, use either of the following methods:

- Select the current trace settings under **Current trace settings:** and click the **Remove** icon. For example, the current setting can be `com.ibm.wps.command.credentialvault.*=finest`.
- Type the trace string `*=info` into the field **Append these trace settings:** and click the **Add** icon. This trace string overwrites all settings that are listed under **Current trace settings:** and resets it to the default.

Extended

To enable trace settings for a longer period, that is, for more than one session, switch them on in the WebSphere Application Server configuration. Proceed by the following steps:

1. Access the WebSphere Integrated Solutions Console by using this URL: `http://hostname:`*`port_number`*`/ibm/console`
2. Go to **Servers** > **Server Types** > **WebSphere application servers**.
3. Select the application server.
4. Click **Troubleshooting** > **Change Log Detail Levels**.
5. Specify the required trace settings. For example, this setting can be `com.ibm.wps.command.credentialvault.*=finest`
6. Save your updates.
7. Restart the WebSphere_Portal server.
8. To disable tracing, specify `tracestring: *=info` and restart the WebSphere_Portal server.

Changing the log file name and location

You can change the locations of the log files by configuring them in the WebSphere Integrated Solutions Console. Go to **Troubleshooting** > **Logs and Trace** > **server_name** and select the logger type that you want to change. In the configuration dialog, change the path for the log file as required.

Changing the language used in the log file

By default, information in the log file is written in the language that was used for the WebSphere Portal Express installation. However, because WebSphere Portal Express supports a number of languages, you can choose to have the log file information that is written in a language other than that language used during installation.

To change the language that is used for the log file, edit the file `log.properties`. This file is in the following WebSphere Portal Express directory:

- Linux : *wp_profile_root*`/PortalServer/config/config`
- IBM i: *wp_profile_root*`/PortalServer/config/config`
- Windows: *wp_profile_root*`\PortalServer\config\config`

Add the following line:

`locale=xx`

Where *xx* is the two-letter abbreviation for the locale. For a list of the locale abbreviations that are used with WebSphere Portal Express, refer to the topic about Directory structure and go to the section about Directories for languages. For example, to have log information that is generated in English, you would add the following line:

```
locale=en
```

Reference: Log file format

If the logs are written to the log file of WebSphere Portal Express and not redirected to the logging facility WebSphere Application Server, the log file consists of a sequence log records that are separated by blank lines.

The log records have the following format:

```
timestamp classification classname method threadID
messagecode: logmessage
```

Where:

- The *timestamp* is the time (to the millisecond) when the log record was created.
- The *classification* is one of the following letters:

  E For error messages

  W For warning messages

  I For informational messages

  l For traces (low details)

  m For traces (medium details)

  h For traces (high details)
- The *classname* is the Java class that contains the code that triggered the log event.
- The *method* is the name of the Java method that contains the code that triggered the log event.
- The *messagecode* is a unique identifier for this message, to uniquely identify the specific message and refer to it when you are consulting documentation or support. The message code is only available for error, warning, or informational messages, and not for traces. It consists of:
  - A four-character identifier for the component that defines the message.
  - A four-digit number that identifies the message in the component.
  - A one-letter classification code, which can be E, W, or I.
- The *logmessage* is the actual log message that describes the logged event. Error, warning, and informational messages are translated into the system locale. Trace messages are not translated.
- The *threadID* is the identification of the thread that triggered the log event.

Note:

1. Traces are written only if the specific tracing facility is enabled; all other messages are written unconditionally.

2. The system locale is part of the general globalization features of WebSphere Portal Express and can be configured by using `LocalizerService`. For more information, see the topics about Setting service configuration properties and about the Portal configuration services.

Here is an example of a log record:

```
2011.05.16 13:36:14.449 W com.ibm.wps.services.datastore.DataStoreServiceImpl init 0000003a
DSTO0063W: The transaction isolation level is not set to READ_COMMITTED.

The current value is TRANSACTION_REPEATABLE_READ.
```

Related tasks:

"Starting and stopping servers, deployment managers, and node agents" on page 1216
Various installation and configuration tasks require you to start and stop IBM WebSphere Application Server and the IBM WebSphere Portal Express application servers, deployment managers, and node agents.

"Setting service configuration properties" on page 283
IBM WebSphere Portal Express comprises a framework of services to accommodate the different scenarios that portals need to address. Services are available for both WebSphere Portal Express and IBM Web Content Manager. You can configure some of these services.

Related reference:

"Portal service configuration" on page 289
IBM WebSphere Portal Express comprises a framework of configuration services to accommodate the different scenarios that portals of today need to address. You can configure some of these services.

"Localizer Service" on page 328
The portal Localizer Service provides access to the configured default locale and the system default locale. It also provides a list of supported bidirectional languages. Giving the system default locale is necessary because `Locale.getDefault()` is set to the default.

"Directory structure" on page 3618
The topic shows the naming conventions that are used to denote the location of files on the servers and the types of resources you can find in those directories.

WebSphere Application Server 8.5.:Log and trace settings

Web Content Manager tracing files

Enable the use of WebSphere Application Server trace facilities to create trace information for Web Content Manager. This tracing can be enabled either permanently or for just the current WebSphere Portal Express session.

IBM Web Content Manager uses the IBM WebSphere Application Server trace facilities to create trace information. If you need detailed trace output of Web Content Manager to debug a problem, follow these steps:

Permanently enable tracing

Procedure

1. Start WebSphere Application Server.
2. Open the WebSphere Integrated Solutions Console.
3. Go to section **Troubleshooting** > **Logs and Traces** > **WebSphere_Portal** > **Diagnostic Trace**.

4. Make sure that the check box **Enable Trace** is selected.
5. Enter any of the following in the **TraceSpecification** field:
   - com.ibm.workplace.wcm.*
   - com.aptrix.*
   - com.presence.*

   For example, to trace all events, enter the following value:

   ```
   com.ibm.workplace.wcm.*=all:com.aptrix.*=all:com.presence.*=all
   ```
6. Save the changes.
7. Restart IBM WebSphere Portal Express.

Enable tracing just for the current WebSphere Portal Express session

Procedure

1. Click the **Administration menu** icon. Then, click **Portal Analysis** > **Enable Tracing**.
2. Enter any of the following values in the **Append these trace settings** field:
   - com.ibm.workplace.wcm.*
   - com.aptrix.*
   - com.presence.*

   For example, to trace all events, enter the following value:

   ```
   com.ibm.workplace.wcm.*=all:com.aptrix.*=all:com.presence.*=all
   ```

   Here is a list of advanced trace settings:

   com.ibm.workplace.wcm.services.content.*
   This setting enables low level tracing for every item.

   com.ibm.workplace.wcm.domain.transformers.control. Controltype
   You can enable tracing for any of the following control types:
   - HistoryControlTransformer
   - IdentityControlTransformer
   - ProfileControlTransformer
   - SecurityControlTransformer
   - WorkflowControlTransformer

   com.ibm.workplace.wcm.domain.transformers.control.*
   This setting enables the tracing for all control types for all items.

   com.ibm.workplace.wcm.domain.transformers.controllable. Controllabletype
   You can enable tracing for any of the following controllable types:
   - AbstractControllableTransformer
   - AlternateDesignCmpntTransformer
   - AlternateLinkCmpntTransformer
   - ArrayCmpntTransformer
   - AttributeReferenceCmpntTransformer
   - BasePathCmpntTransformer
   - BaseReferenceCmpntTransformer
   - CategoryTransformer
   - CmpntReferenceTransformer
   - CmpntTransformer

- ConfigParamCmpntTransformer
- ContentLinkTransformer
- ContentSpotCmpntTransformer
- ContentTransformer
- ContextPathCmpntTransformer
- ControllableNodeValueTransformer
- ControllableTransformer
- DateCmpntTransformer
- EmailActionTransformer
- ExpireActionTransformer
- ExternalLinkTransformer
- FEDCmpntReferenceTransformer
- FEDCmpntTransformer
- FileResourceCmpntTransformer
- HistoryCmpntTransformer
- HTMLCmpntTransformer
- IDCmpntTransformer
- ImageResourceCmpntTransformer
- IndentCmpntTransformer
- IndexCmpntTransformer
- InlineEditCmpntTransformer
- InlineEditReferenceCmpntTransformer
- JSPCmpntTransformer
- LinkCmpntTransformer
- MenuCmpntTransformer
- NavigatorCmpntTransformer
- NoPrefixBasePathCmpntTransformer
- NoPrefixServletPathCmpntTransformer
- NumericCmpntTransformer
- ObjectSummaryTransformer
- OptionSelectionCmpntTransformer
- PageInfoCmpntTransformer
- PagingCmpntTransformer
- PDMCmpntReferenceTransformer
- PDMCmpntTransformer
- PlaceholderCmpntTransformer
- PlutoSubscriberTransformer
- PlutoSyndicatorTransformer
- PrefixPathCmpntTransformer
- ProfileCmpntTransformer
- PublishActionTransformer
- ResourceCmpntTransformer
- ScheduledMoveActionTransformer
- SearchCmpntTransformer
- SecurityCmpntTransformer

- ServletPathCmpntTransformer
- SiteAreaTransformer
- SiteTransformer
- StyleSheetCmpntReferenceTransformer
- StyleSheetCmpntTransformer
- StyleTransformer
- TaxonomyCmpntTransformer
- TaxonomyTransformer
- TemplateTransformer
- TextCmpntTransformer
- UsernameCmpntTransformer
- UserSelectionCmpntTransformer
- WCMURLCmpntTransformer
- WorkflowActionTransformer
- WorkflowCmpntTransformer
- WorkflowStageTransformer
- WorkflowTransformer

com.ibm.workplace.wcm.domain.transformers.controllable.*
This setting enables the tracing for all controllable types for all items.

Results

The resulting traces of Virtual Member Manager are written here.

- Linux : *wp_profile_root*/logs/WebSphere_Portal/trace.log
- IBM i: *wp_profile_root*/logs/WebSphere_Portal/trace.log
- Windows: *wp_profile_root*\logs\WebSphere_Portal\trace.log

Logging and tracing client side rendering

Portal pages that are rendered in client side aggregation mode differ in their logging behavior from portal pages rendered in server side mode. For client side rendered pages, a considerable amount of code is written in JavaScript that is executed in the corresponding browser JavaScript engine rather than on the server. As a result, the corresponding logging and tracing information is collected in the browser and not on the server side.

"Enabling client side logging and tracing"
To enable client-side logging and tracing for console loggers in client web browsers, modify the custom properties cc.isDebug and cc.traceConfig in the **WP CommonComponentConfigService**. This resource environment provider manages many of the configurable options for the common component.

"Capturing the log statements" on page 3558
Client side log statements are written to the JavaScript console of your browser.

"Enabling module tracing" on page 3559
Enable tracing to debug your module information to improve performance. You can enable a trace string so that debugging is enabled for all users. Or you can set a specific cookie so that debugging is only enabled for that user's cookie.

Enabling client side logging and tracing

To enable client-side logging and tracing for console loggers in client web browsers, modify the custom properties cc.isDebug and cc.traceConfig in the **WP**

CommonComponentConfigService. This resource environment provider manages many of the configurable options for the common component.

Procedure

1. Access the WebSphere Integrated Solutions Console.
2. Go to **Resources** > **Resource environment** > **Resource environment providers** > **WP CommonComponentConfigService**.
3. To view and edit the custom properties for this resource environment provider, click the **Custom Properties** link.
4. Set the value of the property `cc.isDebug` to `true`.
5. Set the value of the property `cc.traceConfig` property to a value that represents a correctly formatted JavaScript array of strings. Each string in the array is the name of the component that you want to trace. You can use the wildcard character asterisk (`*`) for multiple matching. Example:

   ```
   ["com.ibm.mashups.enabler.*","com.ibm.mashups.builder.model.ContextMenu"]
   ```

   This value adds client-side trace-logging for all components in the namespace `com.ibm.mashups.enabler` and the component `com.ibm.mashups.builder.model.ContextMenu`.
6. Save and persist the changes to the master configuration.
7. Restart the portal server.

Example

Examples: To activate all iWidget related logging and tracing, you use the following line:

```
traceConfig: ["com.ibm.mm.iwidget.*"]
```

To set multiple patterns, you separate them by commas like this example:

```
traceConfig: ["com.ibm.mm.iwidget.*", "com.ibm.portal.*", "com.ibm.portal.wps.*"]
```

What to do next

By alternative, you can also achieve the same result by using scripting tools that WebSphere Application Server provides. For more information, refer to the WebSphere Application Server information center under topic *configuring custom properties for resource environment providers by using wsadmin scripting*.

Related information:

Configuring custom properties for resource environment providers using wsadmin scripting

Capturing the log statements

Client side log statements are written to the JavaScript console of your browser.

About this task

There are various ways of accessing the data written to the JavaScript console, depending on the type of browser that you use. For example, in Microsoft Internet Explorer Version 8 you access the console by selecting **Tools** > **Developer Tools**. For FireFox, various plug-ins are available that provide access to the console, for example the Firebug plug-in.

Enabling module tracing

Enable tracing to debug your module information to improve performance. You can enable a trace string so that debugging is enabled for all users. Or you can set a specific cookie so that debugging is only enabled for that user's cookie.

Procedure

1. Enable tracing through trace string.
   a. To debug a module or theme, enable portal tracing with the following trace string.

      ```
      com.ibm.wps.resourceaggregator.CombinerDataSource.RemoteDebug=all
      ```

      This string loads the modules by using separate links and script tags, isolating each one independently. If the module definition defines a debug version, it also loads debug versions of each contribution. Typically, the debug version is an uncompressed version of the <script> tag that contains the same data as the normal version.

      Both using separate links and by using uncompressed <script> tags makes it easier to debug a running WebSphere Portal Express environment from the browser.
2. Enable tracing with cookies.
   a. Open WebSphere Integrated Solutions Console.
   b. Select **Resources** > **Resource Environment** > **Resource Environment Providers**.
   c. Select the **WP ConfigService** resource environment provider.
   d. Click **custom properties**.
   e. Change the **resourceaggregation.client.debug.mode.allowed** entry to `true`.
   f. Save the changes.
   g. Restart the WebSphere Portal Express server.

Results

When a user sets a cookie that is named **com.ibm.portal.resourceaggregator.client.debug.mode** to `true`, debug versions of module contributions are loaded if they are defined. Modules are loaded without using separate links and script tags. All resources are downloaded as a combined unit in that case.

Troubleshooting the Configuration Wizard

The configuration wizard provides tools for troubleshooting and recovering from errors, such as logs, step commands, and reset options.

If you encounter a failure during a configuration, do not go back to the Answer Questions or Customize Values pages. To recover from the failure and continue the configuration:

1. Click **View Results** for the step that failed to determine what caused the failure.
2. Save your selections in case you must reset the configuration process or start over. Click **Download Wizard Selections**.
3. Recovery steps vary based on the cause of the failure.
   - Update your configuration environment and run the step that failed again.
   - Reset the configuration steps and start over.

View Results to determine cause

When you encounter a problem, it is typically recorded in a log file. There are a number of log files. The two most frequently used log files are `ConfigTrace.log` and `SystemOut.log`. On the Configure page, use the **View Results** link to open the `ConfigTrace.log`. To inspect the `ConfigTrace.log`, use the following approach:

1. Search the log file for `BUILD FAILED`.
2. After you find `BUILD FAILED`, search for an error message that occurred before that message.
3. Most errors have a code and message. The code includes an E to indicate error, such as EJPXX1234E. Ideally the message indicates what failed, why, and what you need to do to recover. Some errors, especially from third-party applications, do not have error codes. For these errors, consult the application documentation.

Run Step to run a single step again

Depending on the failure and the action that you took, you might be able to run the step again. You can run the step again if the failure resulted from:

- Not being able to connect to the LDAP or database server because the server was not online. Start the server and when it is online, run the failed step again.
- Network communications instability. When network becomes stable, run the failed step again.

Reset Steps

The **Reset Steps** option forces you to start over. If you must reset all the steps, download your wizard selections to save time. After you click **Reset Steps**, return to the home page by clicking Cancel. Select your configuration options, and click **Upload Saved Selections**. After the XML file uploads, you can correct the settings that led to the error.

You need to reset the steps and start the configuration again if you:

- Provided an incorrect value for the profile path, administrator credentials, or another repeatedly used property.
- Completed manual steps only before the failure occurred.

Resetting the steps does not undo any tasks that the wizard completed before the failure occurred. Steps that you need to take to clean up depend on the configuration steps that the wizard ran before the failure occurred. See individual configuration troubleshooting topics for guidance.

After you correct the values, on the Configure page, click **Skip Step** for any steps that ran that you do not need to run again. If you completed a step in the previous attempt that did not use values that you changed, then you can skip the step.

"Troubleshooting: Database Transfer" on page 3561
Database transfer is part of setting up a stand-alone and cluster server topologies. Learn how to troubleshoot each step in your configuration for your target database.

"Troubleshooting: Enable federated security option" on page 3582
Enabling federated security is part of many environment setups. If you encounter a failure during the configuration process, determine whether you can run the step again, skip the step, or if you must clean up the step. For some failed steps, learn how to correct the issue and recover from the failure.

"Troubleshooting: Create a deployment manager" on page 3587
Create a deployment manager for clustered environments. If you encounter a failure during the configuration process, determine whether you can run the step again, skip the step, or if you must clean up the step. For some failed steps, learn how to correct the issue and recover from the failure.

"Troubleshooting: Create a cluster option" on page 3589
Creating a cluster is part of setting up a clustered environment.If you encounter a failure during the configuration process, determine whether you can run the step again, skip the step, or if you must clean up the step. For some failed steps, learn how to correct the issue and recover from the failure.

"Troubleshooting: Create an additional cluster node" on page 3591
Adding a node to a cluster is part of setting up a clustered environment. If you encounter a failure during the configuration process, determine whether you can run the step again, skip the step, or if you must clean up the step. For some failed steps, learn how to correct the issue and recover from the failure.

"Troubleshooting: Create a WebSphere Portal profile" on page 3594
View troubleshooting information for creating a WebSphere Portal Express profile.

"Troubleshooting: Remove a WebSphere Portal profile" on page 3598
View troubleshooting information for creating a WebSphere Portal Express profile.

"Troubleshooting: Migrate a stand-alone server" on page 3599
If you encounter a failure during the configuration process, determine whether you can run the step again, skip the step, or if you must clean up the step. For some failed steps, learn how to correct the issue and recover from the failure.

"Troubleshooting: Migrate the deployment manager profile for a cluster environment" on page 3605
If you encounter a failure during the configuration process, determine whether you can run the step again, skip the step, or if you must clean up the step. For some failed steps, learn how to correct the issue and recover from the failure.

"Troubleshooting: Migrate node profiles for a cluster environment" on page 3608
If you encounter a failure during the migration of the node profiles for a cluster environment, learn how to correct the issue and recover from the failure.

"Troubleshooting: Upgrade node profiles for a cluster environment" on page 3612
If you encounter a failure while upgrading the node profiles for a cluster environment, learn how to correct the issue and recover from the failure.

Related tasks:

"Accessing the Configuration Wizard" on page 235
The home page of the Configuration Wizard provides access to common configuration tasks. Supported tasks include setting up a stand-alone server, setting up a cluster, transferring from Apache Derby to another supported database, migrating your server, installing add-ons, and more.

DB2: Troubleshooting Database Transfer

If you encounter a failure during the configuration process, determine whether you can run the step again, skip the step, or if you must clean up the step. For some failed steps, learn how to correct the issue and recover from the failure.

Each potential step in the configuration is included. Because the steps vary depending on your selections, the steps are not numbered. Find the step that failed to learn more about correcting and recovering from the failure. If you need to change a value that you entered in the wizard, then you must run the configuration again.

Tip: If you must go through the wizard again, download the wizard selections that you made to save time. Then, cancel the configuration. Start the process over and upload your saved selections. Correct or enter values for the parameters that caused the failure.

Back up the properties files that the wizard uses during the configuration

About this task

During this step, the wizard attempts to back up the `wkplc.properties`, `wkplc_dbdomain.properties`, and `wkplc_dbtype.properties` files.

Table 506. Appropriate actions for step: Back up the properties files that the wizard uses during the configuration

Actions	Notes
Run the step again	You can run the step again without causing any harm. Alternatively, you can manually back up the properties files instead of running the step again.
Skip the step	If you already backed up your properties files before you started this configuration, you can skip this step. If this step is successful, you can skip it if you encounter a failure in a later step and need to run the configuration again.
Clean up step	None required

Manual Step: Create the database users and groups

About this task

During this step, you create the database configuration users and groups on the database server.

If you need a runtime user for day-to-day operations, you must create the runtime database users and groups on the database server.

Use the database user IDs and group names that are entered in the wizard when you create the database users and groups.

Table 507. Appropriate actions for step: Manual Step: Create the database users and groups

Actions	Notes
Run the step again	You cannot rerun a manual step, but you can perform the instructions for the step again without harm. If you realize later in the configuration that the database users and groups were not created correctly, you can repeat these instructions. For example, you might encounter a failure in the setup database step if the database users and groups are created incorrectly. You can repeat these instructions to correct the issue and then perform the setup database step again.
Skip the step	If you successfully created the database users and groups before you started this configuration, you can skip this step.If this step is successful, you can skip it if you encounter a failure in a later step and need to run the configuration again.
Clean up step	None required

Create your databases
About this task

Table 508. Appropriate actions for step: Create your databases

Actions	Notes
Run the step again	The type of failure that you encounter determines whether you can run the step again. Use the ERRORCODE and SQLSTATE associated with the error message in the `ConfigTrace.log` to determine the reason for the failure. You can run the step again if the reason for the failure does not affect any values that you entered in the wizard. For example, if you forgot to copy the JDBC JAR files from your database to the portal server, you can copy the files to the portal server. Then, you can run the step again. If you need to update wizard values to correct the issue, do not run the step again. You must create new scripts in the wizard. Upload your saved selections, update your values, and create scripts. Examples of issues that result in you updating your values include entering the wrong port number or entering an incorrect host name into the wizard.
Skip the step	If this step is successful, you can skip it if you encounter a failure in a later step and need to run the configuration again.
Clean up step	None required. If the step fails because you entered incorrect values in the wizard, remove the database manually, enter correct values to create your scripts, then run the configuration again.

Manual Step: Download the script and run it on the database server to create your database

About this task

During this step, you download a script to create your database.

Table 509. Appropriate actions for step: Manual Step: Download the script and run it on the database server to create your database

Actions	Notes
Run the step again	You cannot rerun a manual step, but you can perform the instructions for the step again without harm. In this step, you download a script to run. The type of failure you encounter determines whether you can run the script again. Use the ERRORCODE and SQLSTATE associated with the error message in the `ConfigTrace.log` to determine the reason for the failure. You can run the step again if the reason for the failure does not affect any values that you entered in the wizard. For example, if you forgot to copy the JDBC JAR files from your database to the portal server, you can copy the files to the portal server. Then, you can run the step again. If you need to update wizard values to correct the issue, do not run the step again. You must create new scripts in the wizard. Upload your saved selections, update your values, and create scripts. Examples of issues that result in you updating your values include entering the wrong port number or entering an incorrect host name into the wizard.
Skip the step	If this step is successful, you can skip it if you encounter a failure in a later step and need to run the configuration again.
Clean up step	Not applicable

Set up your database

About this task

Use the ERRORCODE and SQLSTATE associated with the error message in the `ConfigTrace.log` to determine the source of the problem.

Table 510. Appropriate actions for step: Set up your database

Actions	Notes
Run the step again	The type of failure that you encounter determines whether you can run the step again. You can run the step again if the issue for the failure does not affect any values that you entered in the wizard. If you need to update values, you must create new scripts in the wizard. Upload your saved selections, change the affected values, and create new scripts to run. For example, if you entered the wrong path to your database library, you must upload your saved selections, correct the path, and then configure your system with new scripts.
Skip the step	If this step is successful, you can skip it if you encounter a failure in a later step and need to run the configuration again.
Clean up step	None required

Manual Step: Download the script and run it on the database server to set up your database

About this task

During this step, you set permissions on your database.

Table 511. Appropriate actions for step: Manual Step: Download the script and run it on the database server to set up your database

Actions	Notes
Run the step again	You cannot rerun a manual step, but you can perform the instructions for the step again without harm. In this step, you download a script to run. The type of failure you encounter determines whether you can run the script again. Use the ERRORCODE and SQLSTATE associated with the error message in the `ConfigTrace.log` to determine the reason for the failure. You can run the downloaded script again if the issue for the failure does not affect any values that you entered in the wizard. For example, if you created database users and groups incorrectly on your database server, you can correct the issue and run the step again. If you need to update values, you must create new scripts in the wizard. Upload your saved selections, change the affected values, and create new scripts to run.
Skip the step	If this step is successful, you can skip it if you encounter a failure in a later step and need to run the configuration again.
Clean up step	None required

Manual Step: Set up JCR collation for correct language locale order

About this task

Table 512. Appropriate actions for step: Manual Step: Set up JCR collation for correct language locale order

Actions	Notes
Run the step again	You cannot rerun a manual step, but you can perform the instructions for the step again without harm.
Skip the step	If this step is successful, you can skip it if you encounter a failure in a later step and need to run the configuration again.
Clean up step	You must remove the database and create the database again.

Manual Step: Restart the DB2 server

About this task

During this step, you set global database default values that are required for the database that you created. These global values do not take effect until you restart your database server.

Table 513. Appropriate actions for step: Manual Step: Restart the DB2 server

Actions	Notes
Run the step again	You cannot rerun a manual step, but you can perform the instructions for the step again without harm.
Skip the step	If this step is successful, you can skip it if you encounter a failure in a later step and need to run the configuration again. If you already restarted your database server, you can skip this step.
Clean up step	None required

Validate the database connection and environment

About this task

During this step, you are validating that the database is still available and that you can successfully connect to the database.

Table 514. Appropriate actions for step: Validate the database connection and environment

Actions	Notes
Run the step again	You cannot rerun a manual step, but you can perform the instructions for the step again without harm.
Skip the step	If this step is successful, you can skip it if you encounter a failure in a later step and need to run the configuration again.
Clean up step	None required

Stop the portal server
About this task

Table 515. Appropriate actions for step: Stop the portal server

Actions	Notes
Run the step again	You can run the step again without causing any harm.
Skip the step	If you already stopped the portal server, you can skip this step.
Clean up step	None required

Transfer the database
About this task

Table 516. Appropriate actions for step: Transfer the database

Actions	Notes
Run the step again	The type of failure that you encounter determines whether you can run the step again. Use the ERRORCODE and SQLSTATE associated with the error message in the `ConfigTrace.log` to determine the reason for the failure. You might have a portal failure that does not have a SQLSTATE error code that is associated with the error message. You can run the step again if the issue for the failure does not affect any values that you entered in the wizard. If you need to update values in the wizard, you must create new scripts in the wizard. Upload your saved selections, change the affected values, and create new scripts to run. You do not need to run previous successful steps.
Skip the step	If this step is successful, you can skip it if you encounter a failure in a later step and need to run the configuration again.
Clean up step	None required

Grant privileges to the database runtime users.
About this task

Table 517. Appropriate actions for step: Grant privileges to the database runtime users.

Actions	Notes
Run the step again	The type of failure that you encounter determines whether you can run the step again. You can run the step again if the issue for the failure does not affect any values that you entered in the wizard. If you need to update values in the wizard, you must create new scripts in the wizard. Upload your saved selections, change the affected values, and create new scripts to run. You do not need to run previous successful steps.
Skip the step	If this step is successful, you can skip it if you encounter a failure in a later step and need to run the configuration again.
Clean up step	None required

Manual Step: Download the script and run it on the database server to grant privileges to the runtime user

About this task

Table 518. Appropriate actions for step: Manual Step: Download the script and run it on the database server to grant privileges to the runtime user

Actions	Notes
Run the step again	You cannot rerun a manual step, but you can perform the instructions for the step again without harm. In this step, you download a script to run. The type of failure you encounter determines whether you can run the script again. You can run the downloaded script again if the issue for the failure does not affect any values that you entered in the wizard. For example, if you created runtime users and groups incorrectly on your database server, you can correct the issue and run the script again. If you need to update values in the wizard, you must create new scripts in the wizard. Upload your saved selections, change the affected values, and create new scripts to run. You do not need to run previous successful steps.
Skip the step	If this step is successful, you can skip it if you encounter a failure in a later step and need to run the configuration again.
Clean up step	None required

Configure the JCR domain to support large files

About this task

Table 519. Appropriate actions for step: Configure the JCR domain to support large files

Actions	Notes
Run the step again	You cannot rerun a manual step, but you can perform the instructions for the step again without harm.
Skip the step	If this step is successful, you can skip it if you encounter a failure in a later step and need to run the configuration again.
Clean up step	None required

Start the portal server

About this task

Table 520. Appropriate actions for step: Start the portal server

Actions	Notes
Run the step again	You can run the step again without causing any harm
Skip the step	If you already started the portal server, you can skip this step.
Clean up step	None required

IBM DB2 for i: Troubleshooting Database Transfer

If you encounter a failure during the configuration process, determine whether you can run the step again, skip the step, or if you must clean up the step. For some failed steps, learn how to correct the issue and recover from the failure.

Each potential step in the configuration is included. Because the steps vary depending on your selections, the steps are not numbered. Find the step that failed to learn more about correcting and recovering from the failure. If you need to change a value that you entered in the wizard, then you must run the configuration again.

Tip: If you must go through the wizard again, download the wizard selections that you made to save time. Then, cancel the configuration. Start the process over and upload your saved selections. Correct or enter values for the parameters that caused the failure.

Back up the properties files that the wizard uses during the configuration

About this task

During this step, the wizard attempts to back up the `wkplc.properties`, `wkplc_dbdomain.properties`, and `wkplc_dbtype.properties` files.

Table 521. Appropriate actions for step: Back up the properties files that the wizard uses during the configuration

Actions	Notes
Run the step again	You can run the step again without causing any harm. Alternatively, you can manually back up the properties files instead of running the step again.
Skip the step	If you already backed up your properties files before you started this configuration, you can skip this step. If this step is successful, you can skip it if you encounter a failure in a later step and need to run the configuration again.
Clean up step	None required

Manual Step: Create the database user profile on IBM DB2 for i

About this task

During this step, you create the database user profile on the database server. Use the database user ID that you entered in the database configuration user field in the Configuration Wizard for the database user profile.

Table 522. Appropriate actions for step: Manual Step: Create the database user profile on IBM DB2 for i

Actions	Notes
Run the step again	You cannot rerun a manual step, but you can perform the instructions for the step again without harm. If you realize in the configuration that the database user profile was not created correctly, you can repeat these instructions.
Skip the step	If you successfully created the database user profile before you started this configuration, you can skip this step.If this step is successful, you can skip it if you encounter a failure in a later step and need to run the configuration again.
Clean up step	None required

Manual Step: Create the database runtime users and groups

About this task

During this step, you create the database runtime users on the database server. If you create database runtime users, you must also create database runtime groups.

Table 523. Appropriate actions for step: Manual Step: Create the database runtime users and groups

Actions	Notes
Run the step again	You cannot rerun a manual step, but you can perform the instructions for the step again without harm. If you realize later in the configuration that the database runtime user was not created correctly, you can repeat these instructions. For example, you might encounter a failure when you set up your database if the database runtime user is created incorrectly. You can repeat these instructions to correct the issue. Then, you can repeat the setup database step again.
Skip the step	If this step is successful, you can skip it if you encounter a failure in a later step and need to run the configuration again.
Clean up step	None required

Create your databases
About this task

Table 524. Appropriate actions for step: Create your databases

Actions	Notes
Run the step again	The type of failure that you encounter determines whether you can run the step again. Use the ERRORCODE and SQLSTATE associated with the error message in the `ConfigTrace.log` to determine the reason for the failure. You can run the step again if the reason for the failure does not affect any values that you entered in the wizard. For example, if you forgot to copy the JDBC JAR files from your database to the portal server, you can copy the files to the portal server. Then, you can run the step again. If you need to update wizard values to correct the issue, do not run the step again. You must create new scripts in the wizard. Upload your saved selections, update your values, and create scripts. Examples of issues that result in you updating your values include entering the wrong port number or entering an incorrect host name into the wizard.
Skip the step	If this step is successful, you can skip it if you encounter a failure in a later step and need to run the configuration again.
Clean up step	None required. If the step fails because you entered incorrect values in the wizard, remove the database manually, enter correct values to create your scripts, then run the configuration again.

Validate the database connection and environment
About this task

During this step, you are validating that the database is still available and that you can successfully connect to the database.

Table 525. Appropriate actions for step: Validate the database connection and environment

Actions	Notes
Run the step again	You cannot rerun a manual step, but you can perform the instructions for the step again without harm.
Skip the step	If this step is successful, you can skip it if you encounter a failure in a later step and need to run the configuration again.
Clean up step	None required

Stop the portal server
About this task

Table 526. Appropriate actions for step: Stop the portal server

Actions	Notes
Run the step again	You can run the step again without causing any harm.
Skip the step	If you already stopped the portal server, you can skip this step.
Clean up step	None required

Transfer the database
About this task

Table 527. Appropriate actions for step: Transfer the database

Actions	Notes
Run the step again	The type of failure that you encounter determines whether you can run the step again. Use the ERRORCODE and SQLSTATE associated with the error message in the `ConfigTrace.log` to determine the reason for the failure. You might have a portal failure that does not have a SQLSTATE error code that is associated with the error message. You can run the step again if the issue for the failure does not affect any values that you entered in the wizard. If you need to update values in the wizard, you must create new scripts in the wizard. Upload your saved selections, change the affected values, and create new scripts to run. You do not need to run previous successful steps.
Skip the step	If this step is successful, you can skip it if you encounter a failure in a later step and need to run the configuration again.
Clean up step	None required

Grant privileges to the database runtime users.
About this task

Table 528. Appropriate actions for step: Grant privileges to the database runtime users.

Actions	Notes
Run the step again	The type of failure that you encounter determines whether you can run the step again. You can run the step again if the issue for the failure does not affect any values that you entered in the wizard. If you need to update values in the wizard, you must create new scripts in the wizard. Upload your saved selections, change the affected values, and create new scripts to run. You do not need to run previous successful steps.
Skip the step	If this step is successful, you can skip it if you encounter a failure in a later step and need to run the configuration again.
Clean up step	None required

Start the portal server
About this task

Table 529. Appropriate actions for step: Start the portal server

Actions	Notes
Run the step again	You can run the step again without causing any harm
Skip the step	If you already started the portal server, you can skip this step.
Clean up step	None required

DB2 for z/OS: Troubleshooting Database Transfer

If you encounter a failure during the configuration process, determine whether you can run the step again, skip the step, or if you must clean up the step. For some failed steps, learn how to correct the issue and recover from the failure.

Each potential step in the configuration is included. Because the steps vary depending on your selections, the steps are not numbered. Find the step that failed to learn more about correcting and recovering from the failure. If you need to change a value that you entered in the wizard, then you must run the configuration again.

Tip: If you must go through the wizard again, download the wizard selections that you made to save time. Then, cancel the configuration. Start the process over and upload your saved selections. Correct or enter values for the parameters that caused the failure.

Back up the properties files that the wizard uses during the configuration

About this task

During this step, the wizard attempts to back up the `wkplc.properties`, `wkplc_dbdomain.properties`, and `wkplc_dbtype.properties` files.

Table 530. Appropriate actions for step: Back up the properties files that the wizard uses during the configuration

Actions	Notes
Run the step again	You can run the step again without causing any harm. Alternatively, you can manually back up the properties files instead of running the step again.
Skip the step	If you already backed up your properties files before you started this configuration, you can skip this step. If this step is successful, you can skip it if you encounter a failure in a later step and need to run the configuration again.
Clean up step	None required

Manual Step: Create the database configuration users on DB2 for z/OS

About this task

During this step, you download RACF commands. Review the RACF commands with your RACF administrator. If you encounter a failure, you might need to edit the RACF commands before you run the RACF commands again.

Table 531. Appropriate actions for step: Manual Step: Create the database configuration users on DB2 for z/OS

Actions	Notes
Run the step again	You cannot rerun a manual step, but you can perform the instructions for the step again without harm.
Skip the step	If this step is successful, you can skip it if you encounter a failure in a later step and need to run the configuration again. If you have database IDs that are already defined, review the RACF commands before you skip this step. You might need to edit the RACF commands. For example, the RACF administrator might need to remove the ADDUSER commands if you already have database user IDs that are defined in your RACF.
Clean up step	None required

Manual Step: Download the script and view instructions to delete existing databases

About this task

Table 532. Appropriate actions for step: Manual Step: Download the script and view instructions to delete existing databases

Actions	Notes
Run the step again	You can run this step only under certain conditions. • If you have previously run the database transfer option, you need to delete the databases that you created before you rerun the create database and transfer database steps. • You can run the commands in this step only once when you use the database transfer option. If you run this step multiple times, you might delete databases that must exist for your configuration.
Skip the step	If you have never run the transfer database step, you can skip this step.
Clean up step	None required

Manual Step: Download the script and view instructions to create your databases

About this task

Table 533. Appropriate actions for step: Manual Step: Download the script and view instructions to create your databases

Actions	Notes
Run the step again	You cannot rerun a manual step, but you can perform the instructions for the step again without harm. Use the SQLSTATE associated with the error message to determine the source of the problem.
Skip the step	If this step is successful, you can skip it if you encounter a failure in a later step and need to run the configuration again.
Clean up step	If you need to update wizard values to correct the issue, do not run the commands in this step again. You must create new scripts in the wizard. Upload your saved selections, update your values, and create scripts. In the next configuration attempt, you must delete existing databases before you create databases. Do not skip the following step: Manual Step: Download the script and view instructions to delete existing databases

Validate the database connection and environment

About this task

During this step, you are validating that the database is still available and that you can successfully connect to the database.

Table 534. Appropriate actions for step: Validate the database connection and environment

Actions	Notes
Run the step again	You cannot rerun a manual step, but you can perform the instructions for the step again without harm.
Skip the step	If this step is successful, you can skip it if you encounter a failure in a later step and need to run the configuration again.
Clean up step	None required

Stop the portal server

About this task

Table 535. Appropriate actions for step: Stop the portal server

Actions	Notes
Run the step again	You can run the step again without causing any harm.
Skip the step	If you already stopped the portal server, you can skip this step.
Clean up step	None required

Transfer the database

About this task

Table 536. Appropriate actions for step: Transfer the database

Actions	Notes
Run the step again	The type of failure that you encounter determines whether you can run the step again. Use the ERRORCODE and SQLSTATE associated with the error message in the `ConfigTrace.log` to determine the reason for the failure. You might have a portal failure that does not have a SQLSTATE error code that is associated with the error message. You can run the step again if the issue for the failure does not affect any values that you entered in the wizard. If you need to update values in the wizard, you must create new scripts in the wizard. Upload your saved selections, change the affected values, and create new scripts to run. You do not need to run previous successful steps.

Table 536. Appropriate actions for step: Transfer the database (continued)

Actions	Notes
Skip the step	If this step is successful, you can skip it if you encounter a failure in a later step and need to run the configuration again.
Clean up step	If you need to update wizard values to correct the issue, do not run the commands in this step again. You must create new scripts in the wizard. Upload your saved selections, update your values, and create scripts. In the next configuration attempt, you must delete existing databases before you create databases. Do not skip the following step: Manual Step: Download the script and view instructions to delete existing databases.

Grant privileges to the database runtime users.

About this task

Table 537. Appropriate actions for step: Grant privileges to the database runtime users.

Actions	Notes
Run the step again	The type of failure that you encounter determines whether you can run the step again. You can run the step again if the issue for the failure does not affect any values that you entered in the wizard. If you need to update values in the wizard, you must create new scripts in the wizard. Upload your saved selections, change the affected values, and create new scripts to run. You do not need to run previous successful steps.
Skip the step	If this step is successful, you can skip it if you encounter a failure in a later step and need to run the configuration again.
Clean up step	None required

Connect to your databases

About this task

Table 538. Appropriate actions for step: Connect to your databases

Actions	Notes
Run the step again	The type of failure that you encounter determines whether you can run the step again. Use the ERRORCODE and SQLSTATE associated with the error message in the `ConfigTrace.log` to determine the reason for the failure. You can run the step again if the issue for the failure does not affect any values that you entered in the wizard. If you need to update values in the wizard, you must create new scripts in the wizard. Upload your saved selections, change the affected values, and create new scripts to run. You do not need to run previous successful steps.
Skip the step	If you need to run the configuration again, you must repeat this step if you need to run the transfer database step again. If this step is successful, you can skip it if you encounter a failure in a later step and need to run the configuration again. If this step is successful, you can skip it if you encounter a failure in a later step.
Clean up step	None required

Manual Step: Download the script and view instructions to reset the check pending status on portal table spaces

About this task

Table 539. Appropriate actions for step: Manual Step: Download the script and view instructions to reset the check pending status on portal table spaces

Actions	Notes
Run the step again	You cannot rerun a manual step, but you can perform the instructions for the step again without harm.
Skip the step	If this step is successful, you can skip it if you encounter a failure in a later step and need to run the configuration again.
Clean up step	None required

Reset the web content manager event log
About this task

Table 540. Appropriate actions for step: Reset the web content manager event log

Actions	Notes
Run the step again	You can run this step repeatedly without causing harm.
Skip the step	If this step is successful, you can skip it if you encounter a failure in a later step and need to run the configuration again.
Clean up step	None required

Start the portal server
About this task

Table 541. Appropriate actions for step: Start the portal server

Actions	Notes
Run the step again	You can run the step again without causing any harm
Skip the step	If you already started the portal server, you can skip this step.
Clean up step	None required

SQL Server: Troubleshooting Database Transfer

If you encounter a failure during the configuration process, determine whether you can run the step again, skip the step, or if you must clean up the step. For some failed steps, learn how to correct the issue and recover from the failure.

Each potential step in the configuration is included. Because the steps vary depending on your selections, the steps are not numbered. Find the step that failed to learn more about correcting and recovering from the failure. If you need to change a value that you entered in the wizard, then you must run the configuration again.

Tip: If you must go through the wizard again, download the wizard selections that you made to save time. Then, cancel the configuration. Start the process over and upload your saved selections. Correct or enter values for the parameters that caused the failure.

Back up the properties files that the wizard uses during the configuration
About this task

During this step, the wizard attempts to back up the `wkplc.properties`, `wkplc_dbdomain.properties`, and `wkplc_dbtype.properties` files.

Table 542. Appropriate actions for step: Back up the properties files that the wizard uses during the configuration

Actions	Notes
Run the step again	You can run the step again without causing any harm. Alternatively, you can manually back up the properties files instead of running the step again.
Skip the step	If you already backed up your properties files before you started this configuration, you can skip this step. If this step is successful, you can skip it if you encounter a failure in a later step and need to run the configuration again.
Clean up step	None required

Create your databases
About this task

Table 543. Appropriate actions for step: Create your databases

Actions	Notes
Run the step again	The type of failure that you encounter determines whether you can run the step again. Use the ERRORCODE and SQLSTATE associated with the error message in the `ConfigTrace.log` to determine the reason for the failure. You can run the step again if the reason for the failure does not affect any values that you entered in the wizard. For example, if you forgot to copy the JDBC JAR files from your database to the portal server, you can copy the files to the portal server. Then, you can run the step again. If you need to update wizard values to correct the issue, do not run the step again. You must create new scripts in the wizard. Upload your saved selections, update your values, and create scripts. Examples of issues that result in you updating your values include entering the wrong port number or entering an incorrect host name into the wizard.
Skip the step	If this step is successful, you can skip it if you encounter a failure in a later step and need to run the configuration again.
Clean up step	None required. If the step fails because you entered incorrect values in the wizard, remove the database manually, enter correct values to create your scripts, then run the configuration again.

Manual Step: Download the script and run it on the database server to create your database
About this task

Table 544. Appropriate actions for step: Manual Step: Download the script and run it on the database server to create your database

Actions	Notes
Run the step again	You cannot rerun a manual step, but you can perform the instructions for the step again without harm. In this step, you download a script to run. The type of failure you encounter determines whether you can run the script again. Use the ERRORCODE and SQLSTATE associated with the error message in the `ConfigTrace.log` to determine the reason for the failure. You can run the step again if the reason for the failure does not affect any values that you entered in the wizard. For example, if you forgot to copy the JDBC JAR files from your database to the portal server, you can copy the files to the portal server. Then, you can run the step again. If you need to update wizard values to correct the issue, do not run the step again. You must create new scripts in the wizard. Upload your saved selections, update your values, and create scripts. Examples of issues that result in you updating your values include entering the wrong port number or entering an incorrect host name into the wizard.
Skip the step	If this step is successful, you can skip it if you encounter a failure in a later step and need to run the configuration again.
Clean up step	None required

Set up your database
About this task

Use the ERRORCODE and SQLSTATE associated with the error message in the `ConfigTrace.log` to determine the source of the problem.

Table 545. Appropriate actions for step: Set up your database

Actions	Notes
Run the step again	The type of failure that you encounter determines whether you can run the step again. You can run the step again if the issue for the failure does not affect any values that you entered in the wizard. If you need to update values, you must create new scripts in the wizard. Upload your saved selections, change the affected values, and create new scripts to run. For example, if you entered the wrong path to your database library, you must upload your saved selections, correct the path, and then configure your system with new scripts.
Skip the step	If this step is successful, you can skip it if you encounter a failure in a later step and need to run the configuration again.
Clean up step	None required

Manual Step: Download the script and run it on the database server to set up your database

About this task

During this step, you set permissions on your database.

Table 546. Appropriate actions for step:

Actions	Notes
Run the step again	You cannot rerun a manual step, but you can perform the instructions for the step again without harm. In this step, you download a script to run. The type of failure you encounter determines whether you can run the script again. Use the ERRORCODE and SQLSTATE associated with the error message in the `ConfigTrace.log` to determine the reason for the failure. You can run the downloaded script again if the issue for the failure does not affect any values that you entered in the wizard. For example, if you created database users and groups incorrectly on your database server, you can correct the issue and run the step again. If you need to update values, you must create new scripts in the wizard. Upload your saved selections, change the affected values, and create new scripts to run.
Skip the step	If this step is successful, you can skip it if you encounter a failure in a later step and need to run the configuration again.
Clean up step	None required

Validate the database connection and environment

About this task

During this step, you are validating that the database is still available and that you can successfully connect to the database.

Table 547. Appropriate actions for step: Validate the database connection and environment

Actions	Notes
Run the step again	You cannot rerun a manual step, but you can perform the instructions for the step again without harm.
Skip the step	If this step is successful, you can skip it if you encounter a failure in a later step and need to run the configuration again.
Clean up step	None required

Stop the portal server

About this task

Table 548. Appropriate actions for step: Stop the portal server

Actions	Notes
Run the step again	You can run the step again without causing any harm.
Skip the step	If you already stopped the portal server, you can skip this step.
Clean up step	None required

Transfer the database
About this task

Table 549. Appropriate actions for step: Transfer the database

Actions	Notes
Run the step again	The type of failure that you encounter determines whether you can run the step again. Use the ERRORCODE and SQLSTATE associated with the error message in the `ConfigTrace.log` to determine the reason for the failure. You might have a portal failure that does not have a SQLSTATE error code that is associated with the error message. You can run the step again if the issue for the failure does not affect any values that you entered in the wizard. If you need to update values in the wizard, you must create new scripts in the wizard. Upload your saved selections, change the affected values, and create new scripts to run. You do not need to run previous successful steps.
Skip the step	If this step is successful, you can skip it if you encounter a failure in a later step and need to run the configuration again.
Clean up step	None required

Grant privileges to the database runtime users.
About this task

Table 550. Appropriate actions for step: Grant privileges to the database runtime users.

Actions	Notes
Run the step again	The type of failure that you encounter determines whether you can run the step again. You can run the step again if the issue for the failure does not affect any values that you entered in the wizard. If you need to update values in the wizard, you must create new scripts in the wizard. Upload your saved selections, change the affected values, and create new scripts to run. You do not need to run previous successful steps.
Skip the step	If this step is successful, you can skip it if you encounter a failure in a later step and need to run the configuration again.
Clean up step	None required

Manual Step: Download the script and run it on the database server to grant privileges to database runtime users
About this task

Table 551. Appropriate actions for step: Manual Step: Download the script and run it on the database server to grant privileges to database runtime users

Actions	Notes
Run the step again	You cannot rerun a manual step, but you can perform the instructions for the step again without harm. In this step, you download a script to run. The type of failure you encounter determines whether you can run the script again. You can run the downloaded script again if the issue for the failure does not affect any values that you entered in the wizard. For example, if you created runtime users and groups incorrectly on your database server, you can correct the issue and run the script again. If you need to update values in the wizard, you must create new scripts in the wizard. Upload your saved selections, change the affected values, and create new scripts to run. You do not need to run previous successful steps.
Skip the step	If this step is successful, you can skip it if you encounter a failure in a later step and need to run the configuration again.
Clean up step	None required

Start the portal server
About this task

Table 552. Appropriate actions for step: Start the portal server

Actions	Notes
Run the step again	You can run the step again without causing any harm
Skip the step	If you already started the portal server, you can skip this step.
Clean up step	None required

Oracle: Troubleshooting Database Transfer
If you encounter a failure during the configuration process, determine whether you can run the step again, skip the step, or if you must clean up the step. For some failed steps, learn how to correct the issue and recover from the failure.

Each potential step in the configuration is included. Because the steps vary depending on your selections, the steps are not numbered. Find the step that failed to learn more about correcting and recovering from the failure. If you need to change a value that you entered in the wizard, then you must run the configuration again.

Tip: If you must go through the wizard again, download the wizard selections that you made to save time. Then, cancel the configuration. Start the process over and upload your saved selections. Correct or enter values for the parameters that caused the failure.

Back up the properties files that the wizard uses during the configuration
About this task

During this step, the wizard attempts to back up the `wkplc.properties`, `wkplc_dbdomain.properties`, and `wkplc_dbtype.properties` files.

Table 553. Appropriate actions for step: Back up the properties files that the wizard uses during the configuration

Actions	Notes
Run the step again	You can run the step again without causing any harm. Alternatively, you can manually back up the properties files instead of running the step again.
Skip the step	If you already backed up your properties files before you started this configuration, you can skip this step. If this step is successful, you can skip it if you encounter a failure in a later step and need to run the configuration again.
Clean up step	None required

Manual Step: Create your Oracle database
About this task

Table 554. Appropriate actions for step: Manual Step: Create your Oracle database

Actions	Notes
Run the step again	You cannot rerun a manual step, but you can perform the instructions for the step again without harm. The type of failure that you encounter determines whether you can run the step again. You can repeat the instructions again if the issue for the failure does not affect the values that you entered in the wizard. For example, if you forgot to copy the JDBC JAR files from your database to the portal server, you can copy the files to the portal server. Then, repeat the step without harm. If you need to update wizard values to correct the issue, you must create new scripts in the wizard. Upload your saved selections, update your values, and create scripts. Examples of issues that result in you updating your values include entering the wrong port number or entering an incorrect host name into the wizard.

Table 554. Appropriate actions for step: Manual Step: Create your Oracle database (continued)

Actions	Notes
Skip the step	If this step is successful, you can skip it if you encounter a failure in a later step and need to run the configuration again.
Clean up step	None required

Manual Step: Create the data directory, `data`, and the index directory, `index`, on your database server

About this task

Table 555. Appropriate actions for step: Manual Step: Create the data directory, `data`, and the index directory, `index`, on your database server

Actions	Notes
Run the step again	You cannot rerun a manual step, but you can perform the instructions for the step again without harm.
Skip the step	If you already created these directories, skip this step. If this step is successful, you can skip it if you encounter a failure in a later step and need to run the configuration again.
Clean up step	None required

Set up your database

About this task

Use the ERRORCODE and SQLSTATE associated with the error message in the `ConfigTrace.log` to determine the source of the problem.

Table 556. Appropriate actions for step: Set up your database

Actions	Notes
Run the step again	The type of failure that you encounter determines whether you can run the step again. You can run the step again if the issue for the failure does not affect any values that you entered in the wizard. If you need to update values, you must create new scripts in the wizard. Upload your saved selections, change the affected values, and create new scripts to run. For example, if you entered the wrong path to your database library, you must upload your saved selections, correct the path, and then configure your system with new scripts.
Skip the step	If this step is successful, you can skip it if you encounter a failure in a later step and need to run the configuration again.
Clean up step	None required

Manual Step: Download the script and run it on the database server to set up your database

About this task

During this step, you set permissions on your database.

Table 557. Appropriate actions for step: Manual Step: Download the script and run it on the database server to set up your database

Actions	Notes
Run the step again	You cannot rerun a manual step, but you can perform the instructions for the step again without harm. In this step, you download a script to run. The type of failure you encounter determines whether you can run the script again. Use the ERRORCODE and SQLSTATE associated with the error message in the `ConfigTrace.log` to determine the reason for the failure. You can run the downloaded script again if the issue for the failure does not affect any values that you entered in the wizard. If you need to update values, you must create new scripts in the wizard. Upload your saved selections, change the affected values, and create new scripts to run. For example, if you entered the wrong path to your database library, you must upload your saved selections, correct the path, and then configure your system with new scripts.
Skip the step	If this step is successful, you can skip it if you encounter a failure in a later step and need to run the configuration again.
Clean up step	None required

Validate the database connection and environment

About this task

During this step, you are validating that the database is still available and that you can successfully connect to the database.

Table 558. Appropriate actions for step: Validate the database connection and environment

Actions	Notes
Run the step again	You cannot rerun a manual step, but you can perform the instructions for the step again without harm.
Skip the step	If this step is successful, you can skip it if you encounter a failure in a later step and need to run the configuration again.
Clean up step	None required

Stop the portal server

About this task

Table 559. Appropriate actions for step: Stop the portal server

Actions	Notes
Run the step again	You can run the step again without causing any harm.
Skip the step	If you already stopped the portal server, you can skip this step.
Clean up step	None required

Transfer the database
About this task

Table 560. Appropriate actions for step: Transfer the database

Actions	Notes
Run the step again	The type of failure that you encounter determines whether you can run the step again. Use the ERRORCODE and SQLSTATE associated with the error message in the `ConfigTrace.log` to determine the reason for the failure. You might have a portal failure that does not have a SQLSTATE error code that is associated with the error message. You can run the step again if the issue for the failure does not affect any values that you entered in the wizard. For example, if your data and index directories are not created in the correct location, this step might fail. (Automatic Storage Management Users only): After you run the setup database script, you must manually create JCR table spaces to prevent a database transfer failure . Go to "Oracle: Creating JCR table spaces (Automatic Storage Management)" on page 554 to perform additional manual instructions. After you perform these instructions, run the transfer database step again. (Automatic Storage Management Users only): If you manually downloaded a script to set up your database, you must edit the script for your Automatic Storage Management environment to prevent a database transfer failure. After you run the edited script, you can run the transfer database step again. If you need to update values in the wizard, you must create new scripts in the wizard. Upload your saved selections, change the affected values, and create new scripts to run. You do not need to run previous successful steps.
Skip the step	If this step is successful, you can skip it if you encounter a failure in a later step and need to run the configuration again.
Clean up step	None required

Grant privileges to the database runtime users.
About this task

Table 561. Appropriate actions for step: Grant privileges to the database runtime users.

Actions	Notes
Run the step again	The type of failure that you encounter determines whether you can run the step again. You can run the step again if the issue for the failure does not affect any values that you entered in the wizard. If you need to update values in the wizard, you must create new scripts in the wizard. Upload your saved selections, change the affected values, and create new scripts to run. You do not need to run previous successful steps.
Skip the step	If this step is successful, you can skip it if you encounter a failure in a later step and need to run the configuration again.
Clean up step	None required

Manual Step: Download the script and run it to grant the database runtime user the appropriate privileges to work with database tables

About this task

Table 562. Appropriate actions for step: Manual Step: Download the script and run it to grant the database runtime user the appropriate privileges to work with database tables

Actions	Notes
Run the step again	You cannot rerun a manual step, but you can perform the instructions for the step again without harm. In this step, you download a script to run. The type of failure you encounter determines whether you can run the script again. You can run the downloaded script again if the issue for the failure does not affect any values that you entered in the wizard. For example, if you created runtime users and groups incorrectly on your database server, you can correct the issue and run the script again. If you need to update values in the wizard, you must create new scripts in the wizard. Upload your saved selections, change the affected values, and create new scripts to run. You do not need to run previous successful steps.
Skip the step	If this step is successful, you can skip it if you encounter a failure in a later step and need to run the configuration again.
Clean up step	None required

Manual Step: Improve database response time for your database that contains the JCR domain

About this task

Table 563. Appropriate actions for step: Manual Step: Improve database response time for your database that contains the JCR domain

Actions	Notes
Run the step again	You cannot rerun a manual step, but you can perform the instructions for the step again without harm.
Skip the step	Not applicable.
Clean up step	None required

Start the portal server

About this task

Table 564. Appropriate actions for step: Start the portal server

Actions	Notes

Skip the step	If you already started the portal server, you can skip this step.
Clean up step	None required

Troubleshooting: Enable federated security option

Enabling federated security is part of many environment setups. If you encounter a failure during the configuration process, determine whether you can run the step again, skip the step, or if you must clean up the step. For some failed steps, learn how to correct the issue and recover from the failure.

Each potential step in the configuration is included. Because the steps vary depending on your selections, the steps are not numbered. Find the step that failed to learn more about correcting and recovering from the failure. If you need to change a value that you entered in the wizard, then you must run the configuration again.

Tip: If you must go through the wizard again, download the wizard selections that you made to save time. Then, cancel the configuration. Start the process over and

upload your saved selections. Correct or enter values for the parameters that caused the failure.
Attention: The Enable Federated Security option modifies the `wimconfig.xml` file. Make a backup copy of this file before you run any of the configuration tasks.

wp_profile_root`/config/cells/`*CellName*`/wim/config/wimconfig.xml`

Related tasks:

"Accessing the Configuration Wizard" on page 235
The home page of the Configuration Wizard provides access to common configuration tasks. Supported tasks include setting up a stand-alone server, setting up a cluster, transferring from Apache Derby to another supported database, migrating your server, installing add-ons, and more.

Manual Step: Retrieve the SSL certificate from the SSL port

About this task

Table 565. Appropriate actions for step: Manual Step: Retrieve the SSL certificate from the SSL port

Actions	Notes
Run the step again	Not applicable
Skip the step	Yes, if you completed this manual step successfully, you can skip the step in subsequent configuration attempts
Clean up step	None required

Create a backup of the WebSphere Portal Express profile before modifying cell security

CF07

About this task

Actions	Notes
Run step again	You can run the step repeatedly without causing any harm.
Skip step	If this step is successful, you can skip it if you run the configuration process again.
Clean up step	None required

Validate your LDAP server settings

During this step, the wizard attempts to connect to your LDAP server and authenticate by using the provided credentials and LDAP information.

About this task

Table 566. Appropriate actions for step: Validate your LDAP server settings

Actions	Notes
Run step again	You can run the step repeatedly without causing any harm.
Skip step	If this step is successful, you can skip it if you run the configuration process again.
Clean up step	None required

Procedure

Verify that the values used to connect with the LDAP were entered correctly. Click **View Step Command** to see which values are used.

Add an LDAP user registry to the default federated repository

During this step, the wizard attempts to add your LDAP to the federated repository. This step uses the same parameters as the step that validates the LDAP server settings.

About this task

Table 567. Appropriate actions for step: Add an LDAP user registry to the default federated repository

Actions	Notes
Run step again	You can run the step repeatedly without causing any harm.
Skip step	If this step is successful, you can skip it if you run the configuration process again.
Clean up step	Complete the following steps from the WebSphere Integrated Solutions Console to remove the configured repository: 1. Go to **Security** > **Global Security** > **Configure**. 2. Remove the repository from the realm. 3. Go to **Manage repositories** and delete the repository configuration.

Register the WebSphere Application Server scheduler tasks

About this task

Table 568. Appropriate actions for step: Register the WebSphere Application Server scheduler tasks

Actions	Notes
Run step again	You can run this step again after you clean up the issue.
Skip step	If this step is successful, you can skip it if you run the configuration process again.
Clean up step	Log in to the WebSphere Integrated Solutions Console. Go to **Resources** > **Schedulers** and delete the **WPSTaskScheduler**. If this task fails because of the administrator ID, change the **federated.ldap.bindDN** and optionally the **newAdminId** value. These values must be unique. Then, rerun this task. If this action does not resolve the issue, run the **wp-change-portal-admin-user** and **wp-change-was-admin-user** tasks. These tasks change the **PortalAdminId** and **WasUserId** so that the file system administrators are different from the LDAP users.

Replace the file-based WebSphere Portal and WebSphere Application Server users and groups with users and groups from your LDAP server

During this step, the wizard attempts to configure the portal to use the administrative user and user group that is stored in your LDAP server. The administrative ID and group must exist in your LDAP server. If the ID and group do not exist, create them and try the step again.

About this task

Table 569. Appropriate actions for step: Replace the file-based WebSphere Portal and WebSphere Application Server users and groups with users and groups from your LDAP server

Actions	Notes
Run step again	You can run the step repeatedly without causing any harm.
Skip step	If this step is successful, you can skip it if you run the configuration process again.

Table 569. Appropriate actions for step: Replace the file-based WebSphere Portal and WebSphere Application Server users and groups with users and groups from your LDAP server (continued)

Actions	Notes
Clean up step	You can log in to the WebSphere Integrated Solutions Console. However, the portal administrative user does not work as expected. You do not need to deactivate security with the file-based repository. If the WebSphere Application Server administrative user is not functional, it is likely that the WebSphere Integrated Solutions Console is not accessible. If you cannot log in to the WebSphere Integrated Solutions Console, disable security in the `security.xml` file in the *wp_profile_root*`/config/cells/`*`cellname`* directory. Restart WebSphere Application Server and log in. Then, complete the following steps: 1. Go to **Users and Groups** > **Administrative user roles**. 2. Validate the current administrative user ID or set a new user. 3. Go to **Resources** > **Resource Environment** > **Resource Environment Providers** > **WP AccessControlDataManagementService** > **Custom properties**. 4. Validate the values for the administrative users and groups of the different domains. If necessary, update the values to a valid user. **Valid users:** To find valid users, go to **Users and Groups** > **Manage Users** to search for valid users.

Update the user registry where new users and groups are stored

About this task

Table 570. Appropriate actions for step: Update the user registry where new users and groups are stored

Actions	Notes
Run step again	You can run the step repeatedly without causing any harm.
Skip step	If the current user repository is correct for new users and groups, you can skip this step.
Clean up step	Complete the following steps from the WebSphere Integrated Solutions Console to change the repository: 1. Go to **Security** > **Global Security** > **Federated repositories** > **Supported entity types**. 2. Click one of the following options to edit the **Base Entry for the Default Parent** to the specific Base Entry for your target repository: • **Group** • **OrgContainer** • **PersonAccount**

Recycle the servers after a security change

During this step, the wizard stops and starts the portal server.

About this task

Table 571. Appropriate actions for step: Recycle the servers after a security change

Actions	Notes
Run step again	Yes, run this step again under the following conditions. • If this step fails, run the step again. • If you are running the configuration again.
Skip step	If you are running the configuration again, you can skip this step only if you skipped all the previous steps.
Clean up step	None required

Update the search administration user

The wizard updates the user ID that is used to manage the search collections.

About this task

Table 572. Appropriate actions for step: Update the search administration user

Actions	Notes
Run step again	Yes, run this step again under the following conditions. • If this step fails, run the step again. • If you are running the configuration again.
Skip step	If you are running the configuration again, you can skip this step only if you skipped all the previous steps.
Clean up step	Log in to the WebSphere Integrated Solutions Console. Go to **Security** > **Global security** > **Java Authentication and Authorization Service** > **J2C authentication data**. Change the user ID and password for the **SearchAdminUser** and the alias.

After you change the security model, the servers need to be restarted

During this step, the wizard stops and starts the portal server.

About this task

Table 573. Appropriate actions for step: After you change the security model, the servers need to be restarted

Actions	Notes
Run step again	Yes, run this step again under the following conditions. • If this step fails, run the step again. • If you are running the configuration again.
Skip step	If you are running the configuration again, you can skip this step only if you skipped all the previous steps.
Clean up step	None required

Verify that all defined attributes are available in the configured LDAP user registry

About this task

Table 574. Appropriate actions for step: Verify that all defined attributes are available in the configured LDAP user registry

Actions	Notes
Run step again	Yes, run this step again under the following conditions: • If this step fails, run the step again. • If you are running the configuration again.
Skip step	If you are running the configuration again, you can skip this step if both of the following conditions are true: • The step completed successfully before • You did not change any attributes when you corrected other failures
Clean up step	None required

Manual Step: Update the appropriate `MemberFixerModule.properties` file with the values for your LDAP users

About this task

Table 575. Appropriate actions for step: Manual Step: Update the appropriate `MemberFixerModule.properties` file with the values for your LDAP users

Actions	Notes
Run step again	Not applicable
Skip step	Yes, if you previously modified the properties file, you can skip this step.
Clean up step	None required

Run the member fixer tool

During this step, the wizard runs the member fixer tool to clean up the entries in the portal server.

About this task

Table 576. Appropriate actions for step: Run the member fixer tool

Actions	Notes
Run step again	Yes, run this step again under the following conditions. • If this step fails, run the step again. • If you are running the configuration again.
Skip step	If you are running the configuration again, you can skip this step only if you skipped all the previous steps.
Clean up step	None required

Manual Step: Map attributes to ensure proper communication between WebSphere Portal and the LDAP server

About this task

Table 577. Appropriate actions for step: Manual Step: Map attributes to ensure proper communication between WebSphere Portal and the LDAP server

Actions	Notes
Run step again	Not applicable
Skip step	If you successfully completed the step before, then skip this step.
Clean up step	None required

Troubleshooting: Create a deployment manager

Create a deployment manager for clustered environments. If you encounter a failure during the configuration process, determine whether you can run the step again, skip the step, or if you must clean up the step. For some failed steps, learn how to correct the issue and recover from the failure.

Each potential step in the configuration is included. Because the steps vary depending on your selections, the steps are not numbered. Find the step that failed to learn more about correcting and recovering from the failure. If you need to change a value that you entered in the wizard, then you must run the configuration again.

Tip: If you must go through the wizard again, download the wizard selections that you made to save time. Then, cancel the configuration. Start the process over and upload your saved selections. Correct or enter values for the parameters that caused the failure.

Related tasks:

"Accessing the Configuration Wizard" on page 235
The home page of the Configuration Wizard provides access to common configuration tasks. Supported tasks include setting up a stand-alone server, setting up a cluster, transferring from Apache Derby to another supported database, migrating your server, installing add-ons, and more.

Manual Step: Install the deployment manager software

This is a manual step; any errors that occur are outside the context of the wizard.

About this task

Table 578. Appropriate actions for Manual Step: Install the deployment manager software

Actions	Notes
Run the step again	Not applicable
Skip the step	If you successfully completed the step before, then skip this step.
Clean up step	None required

Create the deployment manager profile

About this task

If the step fails, see the logs for the **manageprofiles** command to determine why the step failed. The wizard uses the portal profile templates to create the deployment manager profile. An error might result from a problem with the profile templates. The error message in the log provides more information.

The log files are in the *app_server_root*/logs/manageprofiles directory.

Table 579. Appropriate actions for step: Create the deployment manager profile

Actions	Notes
Run the step again	Run the step again, if it did not complete successfully before.
Skip the step	If this step was successful, you can skip it if you run the configuration process again.
Clean up step	If an unrecoverable error occurs and the create deployment manager profile step fails, remove the profile. 1. Use the **manageprofiles** command to remove the profile. The command file is in the app_server_root/bin directory. The command file is a script that is named manageprofiles.sh|bat. Example: `/opt/IBM/WebSphere/AppServer/bin/manageprofiles.sh -delete -profileName dmgr01` 2. Delete the profile directory. 3. Then, run the **Create a Deployment Manager Profile** step again.

Start the deployment manager server

About this task

If the step fails, check the systemout.log for the deployment manager. The log file is in the dmgr_profile/log/*dmgr01* directory.

Table 580. Appropriate actions for step: Start the deployment manager server

Actions	Notes
Run the step again	Run this step again if the deployment manager is not running.
Skip the step	Do not skip this step if the deployment manager is not running. You cannot successfully run the step to augment the profile unless the deployment manager is running.
Clean up step	None required

Augment the deployment manager profile with the portal profile template

About this task

If the step fails, see the logs for the **manageprofiles** command to determine why the step failed. The wizard uses the portal profile templates to create the deployment manager profile. An error might result from a problem with the profile templates. The error message in the log provides more information.

The log files are in the *app_server_root*/logs/manageprofiles directory.

Table 581. Appropriate actions for step: Augment the deployment manager profile with the portal profile template

Actions	Notes
Run the step again	Run the step again, if it did not complete successfully before.
Skip the step	If you successfully completed the step before, then skip this step.
Clean up step	If an unrecoverable error occurs and the augment deployment manager profile step fails, remove the profile. 1. Use the **manageprofiles** command to remove the profile. The command file is in the app_server_root/bin directory. The command file is a script that is named manageprofiles.sh|bat. Example: `/opt/IBM/WebSphere/AppServer/bin/manageprofiles.sh -delete -profileName dmgr01` 2. Delete the profile directory. 3. Then, run the **Create a Deployment Manger Profile** step again.

Stop the deployment manager

About this task

If the step fails, check the systemout.log for the deployment manager. The log file is in the dmgr_profile/log/*dmgr01* directory.

Table 582. Appropriate actions for step: Stop the deployment manager

Actions	Notes
Run the step again	You can run this step again.
Skip the step	Do not skip this step.
Clean up step	None required

Start the deployment manager after the profile augmentation is complete

About this task

If the step fails, check the systemout.log for the deployment manager. The log file is in the dmgr_profile/log/*dmgr01* directory.

Table 583. Appropriate actions for step: Start the deployment manager after the profile augmentation is complete

Actions	Notes
Run the step again	You can run this step again.
Skip the step	Do not skip this step.
Clean up step	None required

Troubleshooting: Create a cluster option

Creating a cluster is part of setting up a clustered environment.If you encounter a failure during the configuration process, determine whether you can run the step again, skip the step, or if you must clean up the step. For some failed steps, learn how to correct the issue and recover from the failure.

Each potential step in the configuration is included. Because the steps vary depending on your selections, the steps are not numbered. Find the step that failed to learn more about correcting and recovering from the failure. If you need to change a value that you entered in the wizard, then you must run the configuration again.

Tip: If you must go through the wizard again, download the wizard selections that you made to save time. Then, cancel the configuration. Start the process over and upload your saved selections. Correct or enter values for the parameters that caused the failure.

Manual Step: Verify that the portal node and deployment manager system clocks are within 5 minutes of each other

Manual step errors occur outside the context of the wizard.

About this task

Table 584. Appropriate actions for Manual Step: Verify that the portal node and deployment manager system clocks are within 5 minutes of each other

Actions	Notes
Run the step again	Not applicable
Skip the step	If you successfully completed the step before, then skip this step.
Clean up step	None required

Federate the node

When you federate the node, it becomes a managed node in the deployment manager cell.

About this task

If this step fails see the `addNode.log` to determine why the step failed. In most cases, you can correct the error condition and run the step again. You do not have to cancel or reset the configuration steps.

The log is in the `/wp_profile/logs` directory

Table 585. Appropriate actions for step: Federate the node

Actions	Notes
Run the step again	If the step did not complete successfully during the previous configuration, run it again.
Skip the step	If you successfully completed the step before, then skip this step.
Clean up step	Based on where the step failed during the **addNode** task, you might need to remove the node and run the step again. Run the **removeNode** command from the `wp_profile/bin` directory. Example: `wp_profile/bin/removeNode.sh`

Configure the dynamic cluster node

Applies to dynamic clusters only.

About this task

Table 586. Appropriate actions for step: Configure the dynamic cluster node

Actions	Notes
Run the step again	You can run this step repeatedly without causing harm.
Skip the step	If you successfully completed the step before, then skip this step.

Table 586. Appropriate actions for step: Configure the dynamic cluster node (continued)

Actions	Notes
Clean up step	None required

Prepare the node for clustering

If this step fails, click **View Results** to see the applicable section of the `ConfigTrace.log`.

About this task

Table 587. Appropriate actions for step: Prepare the node for clustering

Actions	Notes
Run the step again	You can run this step repeatedly without causing harm.
Skip the step	If you successfully completed the step before, then skip this step.
Clean up step	None required

Complete the cluster setup

About this task

Table 588. Appropriate actions for step: Complete the cluster setup

Actions	Notes
Run the step again	You can run this step repeatedly without causing harm.
Skip the step	If you successfully completed the step before, then skip this step.
Clean up step	None required

Troubleshooting: Create an additional cluster node

Adding a node to a cluster is part of setting up a clustered environment. If you encounter a failure during the configuration process, determine whether you can run the step again, skip the step, or if you must clean up the step. For some failed steps, learn how to correct the issue and recover from the failure.

Each potential step in the configuration is included. Because the steps vary depending on your selections, the steps are not numbered. Find the step that failed to learn more about correcting and recovering from the failure. If you need to change a value that you entered in the wizard, then you must run the configuration again.

Tip: If you must go through the wizard again, download the wizard selections that you made to save time. Then, cancel the configuration. Start the process over and upload your saved selections. Correct or enter values for the parameters that caused the failure.

Create the profile for the secondary portal node

About this task

If the step fails, see the logs for the **manageprofiles** command to determine why the step failed. The wizard uses the portal profile templates to create the deployment manager profile. An error might result from a problem with the profile templates. The error message in the log provides more information.

The log files are in the *app_server_root*/logs/manageprofiles directory.

Use the following table for manual instructions on recovering from a failure. If you prefer to use the Configuration Wizard option, **Remove the WebSphere Portal profile**, to remove the profile in the event of a failure, go to **More options** > **Remove the WebSphere Portal profile** and remove the profile. When the profile is removed successfully, you can run the **Create an Additional Cluster Node** configuration again.

Table 593. Appropriate actions for step: Create the profile for the secondary portal node

Actions	Notes
Run the step again	Run the step again, if it did not complete successfully before.
Skip the step	If this step was successful, you can skip it if you run the configuration process again.
Clean up step	If an unrecoverable error occurs and the create deployment manager profile step fails, remove the profile. 1. Use the **manageprofiles** command to remove the profile. The command file is in the app_server_root/bin directory. The command file is a script that is named manageprofiles.sh|bat. Example: /opt/IBM/WebSphere/AppServer/bin/manageprofiles.sh -delete -profileName *dmgr01* 2. Delete the profile directory. 3. Then, run the **Create an Additional Cluster Node** again.

Federate the node

About this task

If this step fails see the addNode.log to determine why the step failed. In most cases, you can correct the error condition and run the step again. You do not have to cancel or reset the configuration steps.

The log is in the /wp_profile/logs directory

Table 594. Appropriate actions for step: Federate the node

Actions	Notes
Run the step again	If the step did not complete successfully during the previous configuration, run it again.
Skip the step	If you successfully completed the step before, then skip this step.
Clean up step	Based on where the step failed during the **addNode** task, you might need to remove the node and run the step again. Run the **removeNode** command from the wp_profile/bin directory. Example: wp_profile/bin/removeNode.sh

Configure the dynamic cluster node

If this step fails, click **View Results** to see the applicable section of the ConfigTrace.log.

About this task

Table 595. Appropriate actions for step: Configure the dynamic cluster node

Actions	Notes
Run the step again	You can run this step repeatedly without causing harm.
Skip the step	If you successfully completed the step before, then skip this step.
Clean up step	None required

Add a secondary node to the cluster

About this task

Table 596. Appropriate actions for step: Add a secondary node to the cluster

Actions	Notes
Run the step again	You can run this step repeatedly without causing harm.
Skip the step	If you successfully completed the step before, then skip this step.
Clean up step	None required

Start the portal server

About this task

Table 597. Appropriate actions for step: Start the portal server

Actions	Notes
Run the step again	You can run this step repeatedly without causing harm.
Skip the step	Not applicable
Clean up step	None required

Troubleshooting: Create a WebSphere Portal profile

View troubleshooting information for creating a WebSphere Portal Express profile.

Each potential step in the configuration is included. Because the steps vary depending on your selections, the steps are not numbered. Find the step that failed to learn more about correcting and recovering from the failure. If you need to change a value that you entered in the wizard, then you must run the configuration again.

Tip: If you must go through the wizard again, download the wizard selections that you made to save time. Then, cancel the configuration. Start the process over and upload your saved selections. Correct or enter values for the parameters that caused the failure.

If you are on WebSphere Portal Express Version 8.5 without a combined cumulative fix applied, then you can use this option in the Configuration Wizard to create an additional profile.

Important: You cannot complete this configuration option, if you have CF01 or a later combined cumulative fix applied.

Related tasks:

"Accessing the Configuration Wizard" on page 235
The home page of the Configuration Wizard provides access to common configuration tasks. Supported tasks include setting up a stand-alone server, setting up a cluster, transferring from Apache Derby to another supported database, migrating your server, installing add-ons, and more.

Create the target profile for WebSphere Portal Express in the WebSphere Application Server

About this task

If the step fails, see the logs for the **manageprofiles** command to determine why the step failed. The wizard uses the portal profile templates to create the deployment manager profile. An error might result from a problem with the profile templates. The error message in the log provides more information.

The log files are in the *app_server_root*/logs/manageprofiles directory.

Important: WebSphere Application Server Version 8.5.5.5 requires that fix PI37248 is applied when creating the managed portal profile. This step fails if PI37248 is not installed.

Table 598. Appropriate actions for step: Create the target profile for WebSphere Portal Express in the WebSphere Application Server

Actions	Notes
Run the step again	If this step fails, you can run this step again after you clean up the issue.
Skip the step	If this step was successful, you can skip it if you run the configuration process again.
Clean up step	If an unrecoverable error occurs and this step fails, remove the profile. Use the **manageprofiles** command to remove the profile. The command file is in the app_server_root/bin directory. The command file is a script that is named manageprofiles.sh|bat. Example: `/opt/IBM/WebSphere/AppServer/bin/manageprofiles.sh -delete -profileName dmgr01` Delete the profile directory only if the **manageprofiles** command completes successfully. Then, run **Create the target profile for WebSphere Portal** again.

Install the ConfigEngine into the target WebSphere Portal Express profile

About this task

If you completed a binary installation, this is your first step.

Table 599. Appropriate actions for step: Install the ConfigEngine into the target WebSphere Portal profile

Actions	Notes
Run the step again	If this step fails, you can run this step again after you clean up the issue.
Skip the step	If this step was successful, you can skip it if you run the configuration process again.
Clean up step	If this step fails, look in configtrace.log for any failures.

Register the WebSphere Portal Express components with the ConfigEngine

About this task

Table 600. Appropriate actions for step: Register the components with the ConfigEngine

Actions	Notes
Run the step again	If this step fails, you can run this step again after you clean up the issue.
Skip the step	If this step was successful, you can skip it if you run the configuration process again provided you keep the same profile name.
Clean up step	If this step fails, look in configtrace.log for any failures.

Consolidate the properties files for WebSphere Portal Express components used in this configuration into a single properties file

About this task

Table 601. Appropriate actions for step: Consolidate the properties files for WebSphere Portal components used in this configuration into a single properties file

Actions	Notes
Run the step again	If this step fails, you can run this step again after you clean up the issue.
Skip the step	If this step was successful, you can skip it if you run the configuration process again.
Clean up step	If this step fails, look in `configtrace.log` for any failures.

Prepare the profile for basic configuration

About this task

Table 602. Appropriate actions for step: Prepare the profile for basic configuration

Run the step again	If this step fails, you can run this step again after you clean up the issue.
Skip the step	If this step was successful, you can skip it if you run the configuration process again.
Clean up step	If this step fails, look in `configtrace.log` for any failures.

Deploy the out-of-box pages and portlets to the portal

About this task

Table 607. Appropriate actions for step: Deploy the out-of-box pages and portlets to the portal

Actions	Notes
Run the step again	If this step fails, you can run this step again after you clean up the issue.
Skip the step	If this step was successful, you can skip it if you run the configuration process again.
Clean up step	If this step fails, look in `configtrace.log` for any failures.

Remove the application server (server1) from the profile

About this task

Table 608. Appropriate actions for step: Remove the application server (server1) from the profile

Actions	Notes
Run the step again	If this step fails, you can run this step again after you clean up the issue.
Skip the step	If you already removed server1, you do not need to run this step again.
Clean up step	If this step fails, look in `configtrace.log` for any failures.

Stop the portal server

About this task

Table 609. Appropriate actions for step: Stop the portal server

Actions	Notes
Run the step again	If this step fails, you can run this step again after you clean up the issue.
Skip the step	Do not skip this step, if you are running the configuration again.
Clean up step	Check for failures in the `systemout` and `systemerror` logs for starting or stopping the portal server.

Collect the deployment manager augmentation files and profile templates that are required to build a cell

About this task

Table 610. Appropriate actions for step: Collect the deployment manager augmentation files and profile templates that are required to build a cell

Actions	Notes
Run the step again	If this step fails, you can run this step again after you clean up the issue.
Skip the step	If this step was successful, you can skip it if you run the configuration process again.
Clean up step	If this step fails, look in `configtrace.log` for any failures.

Restart the WebSphere Portal Express server

About this task

Table 611. Appropriate actions for step: Restart the WebSphere Portal Server

Actions	Notes
Run the step again	If this step fails, you can run this step again after you clean up the issue.
Skip the step	Do not skip this step, if you are running the configuration again.
Clean up step	Check for failures in the `systemout` and `systemerror` logs for starting or stopping the portal server.

Troubleshooting: Remove a WebSphere Portal profile

View troubleshooting information for creating a WebSphere Portal Express profile.

Each potential step in the configuration is included. Because the steps vary depending on your selections, the steps are not numbered. Find the step that failed to learn more about correcting and recovering from the failure. If you need to change a value that you entered in the wizard, then you must run the configuration again.

Tip: If you must go through the wizard again, download the wizard selections that you made to save time. Then, cancel the configuration. Start the process over and upload your saved selections. Correct or enter values for the parameters that caused the failure.

Related tasks:

"Accessing the Configuration Wizard" on page 235
The home page of the Configuration Wizard provides access to common configuration tasks. Supported tasks include setting up a stand-alone server, setting up a cluster, transferring from Apache Derby to another supported database, migrating your server, installing add-ons, and more.

Manual Step: Prepare your system

About this task

Table 612. Appropriate actions for step: Prepare your system

Actions	Notes
Run the step again	Not applicable
Skip the step	If this step was successful, you can skip it if you run the configuration process again.
Clean up step	None required

Remove portal node from cluster

About this task

Table 613. Appropriate actions for step: Remove portal node from cluster

Actions	Notes
Run the step again	If this step fails, you can run this step again after you clean up the issue.
Skip the step	If this step was successful, you can skip it if you run the configuration process again.
Clean up step	Review `removeNode.log` in `wp_profile/logs` for any failures that are indicated by the words "exception" or "error."

Remove portal profile

About this task

Table 614. Appropriate actions for step: Remove portal profile

Actions	Notes
Run the step again	If this step fails, you can run this step again after you clean up the issue.
Skip the step	If this step was successful, you can skip it if you run the configuration process again.
Clean up step	1. Use the **manageprofiles** command to remove the profile. The command file is in the `app_server_root/bin` directory. The command file is a script that is named `manageprofiles.sh|bat`. Example: `/opt/IBM/WebSphere/AppServer/bin/manageprofiles.sh -delete -profileName profile_name` 2. Manually delete the profile directory only if the `manageprofiles -delete` command completes successfully. The **manageprofiles** command creates a log for every profile that it creates, deletes, or augments. If the `manageprofiles -delete` command does not complete successfully, review the logs that are named `profile_name_create.log` and `profile_name_augment.log` in `install_root/logs/manageprofiles`.

Stop the deployment manager

About this task

Table 615. Appropriate actions for step: Stop the deployment manager

Actions	Notes
Run the step again	Run this step again, only if you are running the configuration again and removing the deployment manager profile.
Skip the step	Do not skip this step, if you are running the configuration again to remove the deployment manager profile. The deployment manager must be stopped to remove the deployment manager profile.
Clean up step	None required You can check the status of the deployment manager by running `server-status.sh|bat`.

Remove the deployment manager profile

About this task

Table 616. Appropriate actions for step: Remove the deployment manager profile

Actions	Notes
Run the step again	If this step fails, you can run this step again after you clean up the issue.
Skip the step	If this step was successful, you can skip it if you run the configuration process again.
Clean up step	1. Use the **manageprofiles** command to remove the profile. The command file is in the `app_server_root/bin` directory. The command file is a script that is named `manageprofiles.sh|bat`. Example: `/opt/IBM/WebSphere/AppServer/bin/manageprofiles.sh -delete -profileName profile_name` 2. Manually delete the profile directory only if the `manageprofiles -delete` command completes successfully. The **manageprofiles** command creates a log for every profile that it creates, deletes, or augments. If the `manageprofiles -delete` command does not complete successfully, review the log named `delete.log` in `install_root/logs/dmgr_01`.

Troubleshooting: Migrate a stand-alone server

If you encounter a failure during the configuration process, determine whether you can run the step again, skip the step, or if you must clean up the step. For some failed steps, learn how to correct the issue and recover from the failure.

Each potential step in the configuration is included. Because the steps vary depending on your selections, the steps are not numbered. Find the step that failed to learn more about correcting and recovering from the failure. If you need to change a value that you entered in the wizard, then you must run the configuration again.

Tip: If you must go through the wizard again, download the wizard selections that you made to save time. Then, cancel the configuration. Start the process over and upload your saved selections. Correct or enter values for the parameters that caused the failure.

Related concepts:

"Migrate a stand-alone server" on page 842
Use the Configuration Wizard to migrate a stand-alone server environment. Use the following information to get familiar with the information that you must provide in the wizard and the configuration procedure that it generates.

Related tasks:

"Accessing the Configuration Wizard" on page 235
The home page of the Configuration Wizard provides access to common configuration tasks. Supported tasks include setting up a stand-alone server, setting up a cluster, transferring from Apache Derby to another supported database, migrating your server, installing add-ons, and more.

Manual Step: Install the latest fix packs

About this task

Since this is a manual step, any error that occurs is outside the context of the wizard.

Table 617. Appropriate actions for step: Install the latest fix packs

Actions	Notes
Run the step again	If this step fails, you can run this step again after you clean up the issue.
Skip the step	If this step was successful, you can skip it if you run the configuration process again.
Clean up step	If you encounter an issue when you are installing the fix, refer to the documentation for the fix.

Generate the files for remote migration

About this task

Table 618. Appropriate actions for step: Generate files for remote migration

Actions	Notes
Run the step again	If this step fails, you can run this step again after you clean up the issue.
Skip the step	If this step was successful, you can skip it if you run the configuration process again.
Clean up step	If this step fails, review the parameters and values that you entered in the Configuration Wizard, specifically the target temporary path and the application server path. If the parameter and values that you entered are correct, and the step fails again, use the wp-collector tool to gather the files that are needed to contact support for help. See "Data collection and symptom analysis" on page 3539 for information about using the wp-collector tool.

Manual Step: Copy the remote migration package to the source environment

About this task

Since this is a manual step, any error that occurs is outside the context of the wizard.

Table 619. Appropriate actions for step: Copy the remote migration package to the source environment

Actions	Notes
Run the step again	Not applicable
Skip the step	If this step was successful, you can skip it if you run the configuration process again.
Clean up step	None required

Create a backup of the remote source portal profile

About this task

Table 620. Appropriate actions for step: Create a backup of the remote source portal profile

Actions	Notes
Run the step again	If this step fails, you can run this step again after you clean up the issue.
Skip the step	If this step was successful, you can skip it if you run the configuration process again.
Clean up step	If this step fails, delete the path to the temporary backup profile, and run the step again. For more information about troubleshooting the WASPreUpgrade command, see the WebSphere Application Server documentation on Troubleshooting migration.

Create a backup profile of the source portal profile

About this task

Table 621. Appropriate actions for step: Create a backup of the source portal profile

Actions	Notes
Run the step again	If this step fails, you can run this step again after you clean up the issue.
Skip the step	If this step was successful, you can skip it if you run the configuration process again.
Clean up step	If this step fails, delete the path to the temporary backup profile, and run the step again. For more information about troubleshooting the WASPreUpgrade command, see the WebSphere Application Server documentation on Troubleshooting migration.

Manual Step: If the backup profile is larger than 2 GB, clean up the backup profile

About this task

Since this is a manual step, any error that occurs is outside the context of the wizard.

Table 622. Appropriate actions for step: If the backup profile is larger than 2 GB, clean up the backup profile

Actions	Notes
Run the step again	Not applicable
Skip the step	If you are running the configuration again, you can skip this step only if you skipped all the previous steps.
Clean up step	None required

Create a default profile

About this task

Table 623. Appropriate actions for step: Create a default profile

Actions	Notes
Run the step again	If this step fails, you can run this step again after you clean up the issue.
Skip the step	If this step was successful, you can skip it if you run the configuration process again.
Clean up step	If an unrecoverable error occurs and the create default profile step fails, remove the profile. 1. Use the **manageprofiles** command to remove the profile. The command file is in the `app_server_root/bin` directory. The command file is a script that is named `manageprofiles.sh|bat`. Example: `/opt/IBM/WebSphere/AppServer/bin/manageprofiles.sh -delete -profileName profile_name` 2. Delete the profile directory. 3. Then, run the **Create a default profile** step again.

Import backup profile

About this task

Table 624. Appropriate actions for step: Import backup profile

Actions	Notes
Run the step again	If this step fails, you can run this step again after you clean up the issue.
Skip the step	Do not skip this step, if you are running the configuration again. If you re-create the default profile from the **Create a default profile** step, then you must run this step again to import the new default profile.
Clean up step	If an unrecoverable error occurs and the import backup profile step fails, remove the profile. 1. Use the **manageprofiles** command to remove the profile. The command file is in the `app_server_root/bin` directory. The command file is a script that is named `manageprofiles.sh|bat`. Example: `/opt/IBM/WebSphere/AppServer/bin/manageprofiles.sh -delete -profileName profile_name` 2. Delete the profile directory. 3. Then, run the **Create a default profile** step again before you rerun this step.

Manual Step: If you cleaned up the backup profile, restore the JCR content

About this task

Since this is a manual step, any error that occurs is outside the context of the wizard.

Table 625. Appropriate actions for step: If you cleaned up the backup profile, restore the JCR content

Actions	Notes
Run the step again	Not applicable
Skip the step	Do not skip this step, if you are running the configuration again. You must restore the JCR content, if you completed the previous manual step to clean up the backup profile that is over 2 GB.
Clean up step	None required

Upgrade the ConfigEngine

About this task

Table 626. Appropriate actions for step: Upgrade the ConfigEngine

Actions	Notes
Run the step again	If this step fails, you can run this step again after you clean up the issue.
Skip the step	Do not skip this step, if you are running the configuration again.
Clean up step	If this step fails, review the parameters and values that you entered in the Configuration Wizard, specifically the new host name, passwords, port numbers, and the Portal server path. If the parameter and values that you entered are correct, and the step fails again, use the wp-collector tool to gather the files that are needed to contact support for help. See "Data collection and symptom analysis" on page 3539 for information about using the wp-collector tool.

Manual Step: Update the ports on the target environment

About this task

Since this is a manual step, any error that occurs is outside the context of the wizard.

Table 627. Appropriate actions for step: Update the ports on the target environment

Actions	Notes
Run the step again	Not applicable
Skip the step	Do not skip this step, if you are running the configuration again.
Clean up step	None required

Manual Step: Update database settings

About this task

Since this is a manual step, any error that occurs is outside the context of the wizard.

Table 628. Appropriate actions for step: Update database settings

Actions	Notes
Run the step again	Not applicable
Skip the step	Do not skip this step, if you are running the configuration again.
Clean up step	None required

Validate database settings

About this task

Table 629. Appropriate actions for step: Validate database settings

Actions	Notes
Run the step again	If this step fails, you can run this step again after you clean up the issue.
Skip the step	Do not skip this step, if you are running the configuration again.
Clean up step	Check your properties files to make sure that you have all of your parameters and values set correctly before you run the step again.

Connect to new database copies

About this task

Table 630. Appropriate actions for step: Connect to new database copies

Actions	Notes
Run the step again	If this step fails, you can run the step again.
Skip the step	Do not skip this step, if you are running the configuration again.
Clean up step	None required.

Manual Step: Review database schema changes

About this task

Since this is a manual step, any error that occurs is outside the context of the wizard.

Table 631. Appropriate actions for step: Review database schema changes

Actions	Notes
Run the step again	If this step fails, you can run this step again.
Skip the step	This step is optional. You can skip this step if you do not want to review the database schema changes.
Clean up step	None required

Upgrade the base portal database component

About this task

Table 632. Appropriate actions for step: Upgrade the base portal database component

Actions	Notes
Run the step again	If this step fails, you can run this step again after you clean up the issue.
Skip the step	Do not skip this step, if you are running the configuration again.
Clean up step	If this step fails, delete the database, create a new copy, and run the step again.

Manual Step: Remove check pending statuses from table spaces

About this task

Since this is a manual step, any error that occurs is outside the context of the wizard.

Table 633. Appropriate actions for step: Remove check pending statuses from table spaces

Actions	Notes
Run the step again	If this step fails, clean up the issue and start back with the **Upgrade the base portal database components** step, and then run this step again.
Skip the step	Do not skip this step, if you are running the configuration again.
Clean up step	If this step fails, delete the database, create a new copy, and rerun the **Upgrade the portal database component** step before you rerun this step again.

Upgrade the remaining portal databases

About this task

Table 634. Appropriate actions for step: Upgrade the remaining portal databases

Actions	Notes
Run the step again	If this step fails, clean up the issue and start back with the **Upgrade the base portal database components**.

Table 634. Appropriate actions for step: Upgrade the remaining portal databases (continued)

Actions	Notes
Skip the step	Do not skip this step, if you are running the configuration again. You must complete the **Upgrade the base portal database components** and **Remove check pending statuses from table spaces** steps before you run this step again.
Clean up step	If this step fails, delete the database, create a new copy, and rerun the **Upgrade the portal database component** and **Remove check pending statuses from table spaces** steps before you run this step again.

Upgrade the portal profile

About this task

Table 635. Appropriate actions for step: Upgrade the portal profile

Actions	Notes
Run the step again	If this step fails, you must contact support. **Note:** Contact support before you start the Portal server.
Skip the step	Do not skip this step, if you are running the configuration again.
Clean up step	Contact support.

When you run this step, the sub task that is named **`action-deploy-portlets-applyMIGStatic-wp.oob.full`** runs and completes successfully. However, the following error messages are shown. You can ignore these error messages:

- `EJPXA0161W: The web module ContactList could not be activated. Please see previous messages for reasons and possible corrective actions.`
- `EJPPH0048W: The synchronization mode of all nodes in the portal cluster is not consistently set. The portlet application PA_ContactList will not be started in the Application Server. Manual synchronization is assumed for all nodes. Manually start the application after all nodes were synchronized.`
- `EJPXA0067E: The following configuration data is needed to create a content-node resource: content-parentref.`

Troubleshooting: Migrate the deployment manager profile for a cluster environment

If you encounter a failure during the configuration process, determine whether you can run the step again, skip the step, or if you must clean up the step. For some failed steps, learn how to correct the issue and recover from the failure.

Each potential step in the configuration is included. Because the steps vary depending on your selections, the steps are not numbered. Find the step that failed to learn more about correcting and recovering from the failure. If you need to change a value that you entered in the wizard, then you must run the configuration again.

Tip: If you must go through the wizard again, download the wizard selections that you made to save time. Then, cancel the configuration. Start the process over and upload your saved selections. Correct or enter values for the parameters that caused the failure.

Related concepts:

"Cluster: Migrate the deployment manager profile" on page 847
Use the Configuration Wizard to migrate the deployment manager profile for a cluster environment. Use the following information to get familiar with the information that you must provide in the wizard and the configuration procedure that it generates.

Related tasks:

"Accessing the Configuration Wizard" on page 235
The home page of the Configuration Wizard provides access to common configuration tasks. Supported tasks include setting up a stand-alone server, setting up a cluster, transferring from Apache Derby to another supported database, migrating your server, installing add-ons, and more.

Manual Step: Disable automatic synchronization on all nodes in the cluster

About this task

Since this is a manual step, any error that occurs is outside the context of the wizard.

Table 636. Appropriate actions for step: Disable automatic synchronization on all nodes in the cluster

Actions	Notes
Run the step again	You can run this step again if it was not successful.
Skip the step	If this step was successful, you can skip it if you run the configuration process again.
Clean up step	None required

Manual Step: Install the latest fix packs

About this task

Since this is a manual step, any error that occurs is outside the context of the wizard.

Table 637. Appropriate actions for step: Install the latest fix packs

Actions	Notes
Run the step again	If this step fails, you can run this step again after you clean up the issue.
Skip the step	If this step was successful, you can skip it if you run the configuration process again.
Clean up step	If you encounter an issue when you are installing the fix, refer to the documentation for the fix.

Manual Step: Install the Portal and WebSphere binary files

About this task

Since this is a manual step, any error that occurs is outside the context of the wizard.

Table 638. Appropriate actions for step: Install the Portal and WebSphere binary files

Actions	Notes
Run the step again	If this step fails, you can run this step again after you clean up the issue.
Skip the step	If this step was successful, do not run this step again.
Clean up step	Complete an uninstall of the product, and delete the remaining file structure. Then, start the configuration from the beginning.

Manual Step: Copy required portal binary files to the target deployment manager

About this task

Since this is a manual step, any error that occurs is outside the context of the wizard.

Table 639. Appropriate actions for step: Copy required portal binary files to the target deployment manager

Actions	Notes
Run the step again	Not applicable
Skip the step	If this step was successful, you can skip it if you run the configuration process again.
Clean up step	None required

Manual Step: Generate files for remote migration on the deployment manager

About this task

Since this is a manual step, any error that occurs is outside the context of the wizard.

Table 640. Appropriate actions for step: Generate files for remote migration on the deployment manager

Actions	Notes
Run the step again	If this step fails, you can run this step again after you clean up the issue.
Skip the step	If this step was successful, you can skip it if you run the configuration process again. This step is optional. You do not need to complete this step, if the deployment manager is in the same binary as the primary node.
Clean up step	If this step fails, review the parameters and values that you entered in the Configuration Wizard, specifically the target temporary path and the application server path. If the parameter and values that you entered are correct, and the step fails again, use the wp-collector tool to gather the files that are needed to contact support for help. See "Data collection and symptom analysis" on page 3539 for information about using the wp-collector tool.

Manual Step: Copy the remote migration package to the source environment

About this task

Since this is a manual step, any error that occurs is outside the context of the wizard.

Table 641. Appropriate actions for step: Copy the remote migration package to the source environment

Actions	Notes
Run the step again	Not applicable
Skip the step	If this step was successful, you can skip it if you run the configuration process again.
Clean up step	None required

Manual Step: Create a backup of the source deployment manager

About this task

Since this is a manual step, any error that occurs is outside the context of the wizard.

Table 642. Appropriate actions for step: Create a backup of the source deployment manager

Actions	Notes
Run the step again	If this step fails, you can run this step again after you clean up the issue.
Skip the step	If this step was successful, you can skip it if you run the configuration process again.

Table 642. Appropriate actions for step: Create a backup of the source deployment manager (continued)

Actions	Notes
Clean up step	If this step fails, delete the path to the temporary backup profile, and run the step again. For more information about troubleshooting the WASPreUpgrade command, see the WebSphere Application Server documentation on Troubleshooting migration. **IBMi only:** If this step fails, remove the **oldProfile** parameter and run the step again.

Manual Step: Create a default deployment manager profile

About this task

Since this is a manual step, any error that occurs is outside the context of the wizard.

Table 643. Appropriate actions for step: Create a default deployment manager profile

Actions	Notes
Run the step again	If this step fails, you can run this step again after you clean up the issue.
Skip the step	If this step was successful, you can skip it if you run the configuration process again.
Clean up step	If an unrecoverable error occurs and the create default profile step fails, remove the profile. 1. Use the **manageprofiles** command to remove the profile. The command file is in the app_server_root/bin directory. The command file is a script that is named manageprofiles.sh|bat. Example: `/opt/IBM/WebSphere/AppServer/bin/manageprofiles.sh -delete -profileName profile_name` 2. Delete the profile directory. 3. Then, run the **Create a default deployment manager profile** step again.

Manual Step: Import the backup profile

About this task

Since this is a manual step, any error that occurs is outside the context of the wizard.

Table 644. Appropriate actions for step: Import the backup profile

Actions	Notes
Run the step again	If this step fails, you can run this step again after you clean up the issue.
Skip the step	Do not skip this step, if you are running the configuration again. If you re-create the default profile from the **Create a default deployment manager profile** step, then you must run this step again to import the new default profile.
Clean up step	If an unrecoverable error occurs and the import backup profile step fails, remove the profile. 1. Use the **manageprofiles** command to remove the profile. The command file is in the app_server_root/bin directory. The command file is a script that is named manageprofiles.sh|bat. Example: `/opt/IBM/WebSphere/AppServer/bin/manageprofiles.sh -delete -profileName profile_name` 2. Delete the profile directory. 3. Then, run the **Create a default deployment manager profile** step again before you rerun this step.

Troubleshooting: Migrate node profiles for a cluster environment

If you encounter a failure during the migration of the node profiles for a cluster environment, learn how to correct the issue and recover from the failure.

Each potential step in the migrate node profiles option is included. Since the steps vary, depending on your selections, the steps are not numbered. Find the step that failed to learn more about correcting and recovering from the failure.

Related tasks:

The home page of the Configuration Wizard provides access to common configuration tasks. Supported tasks include setting up a stand-alone server, setting up a cluster, transferring from Apache Derby to another supported database, migrating your server, installing add-ons, and more.

Manual Step: Stop the source deployment manager and node agents

About this task

Since this is a manual step, any error that occurs is outside the context of the wizard.

Table 645. Appropriate actions for step: Stop the source deployment manager and node agents

Actions	Notes
Run the step again	You can run this step again if it was not successful.
Skip the step	If this step was successful, you can skip it if you run the configuration process again.
Clean up step	None required

Manual Step: Start the target deployment manager

About this task

Since this is a manual step, any error that occurs is outside the context of the wizard.

Table 646. Appropriate actions for step: Start the target deployment manager

Actions	Notes
Run the step again	You can run this step again if it was not successful.
Skip the step	If this step was successful, you can skip it if you run the configuration process again.
Clean up step	None required

Generate the files for remote migration

About this task

Table 647. Appropriate actions for step: Generate the files for remote migration

Actions	Notes
Run the step again	If this step fails, you can run this step again after you clean up the issue.
Skip the step	If this step was successful, you can skip it if you run the configuration process again.
Clean up step	If this step fails, review the parameters and values that you entered in the Configuration Wizard, specifically the target temporary path and the application server path. If the parameter and values that you entered are correct, and the step fails again, use the wp-collector tool to gather the files that are needed to contact support for help. See "Data collection and symptom analysis" on page 3539 for information about using the wp-collector tool.

Manual Step: Copy the remote migration package to the source environment

About this task

Since this is a manual step, any error that occurs is outside the context of the wizard.

Table 648. Appropriate actions for step: Copy the remote migration package to the source environment

Actions	Notes
Run the step again	Not applicable
Skip the step	If this step was successful, you can skip it if you run the configuration process again.
Clean up step	None required

Create a backup of the source portal profile

About this task

Table 649. Appropriate actions for step: Create a backup of the source portal profile

Actions	Notes
Run the step again	If this step fails, you can run this step again after you clean up the issue.
Skip the step	If this step was successful, you can skip it if you run the configuration process again.
Clean up step	If this step fails, delete the path to the temporary backup profile, and run the step again. For more information about troubleshooting the WASPreUpgrade command, see the WebSphere Application Server documentation on Troubleshooting migration.

Manual Step: Create a backup of the remote source portal profile

About this task

Since this is a manual step, any error that occurs is outside the context of the wizard.

Table 650. Appropriate actions for step: Create a backup of the remote source portal profile

Actions	Notes
Run the step again	If this step fails, you can run this step again after you clean up the issue.
Skip the step	If this step was successful, you can skip it if you run the configuration process again.
Clean up step	If this step fails, delete the path to the temporary backup profile, and run the step again. For more information about troubleshooting the WASPreUpgrade command, see the WebSphere Application Server documentation on Troubleshooting migration.

Manual Step: Update the deployment manager settings

About this task

Since this is a manual step, any error that occurs is outside the context of the wizard.

Table 651. Appropriate actions for step: Update the deployment manager settings

Actions	Notes
Run the step again	Not applicable
Skip the step	If this step was successful, you can skip it if you run the configuration process again.
Clean up step	None required

Manual Step: If the backup profile is larger than 2 GB, clean up the backup profile

About this task

Since this is a manual step, any error that occurs is outside the context of the wizard.

Table 652. Appropriate actions for step: If the backup profile is larger than 2 GB, clean up the backup profile

Actions	Notes
Run the step again	Not applicable
Skip the step	If you are running the configuration again, you can skip this step only if you skipped all the previous steps.
Clean up step	None required

Create a default profile

About this task

Table 653. Appropriate actions for step: Create a default profile

Actions	Notes
Run the step again	If this step fails, you can run this step again after you clean up the issue.
Skip the step	If this step was successful, you can skip it if you run the configuration process again.
Clean up step	If an unrecoverable error occurs and the create default profile step fails, remove the profile. 1. Use the **manageprofiles** command to remove the profile. The command file is in the `app_server_root/bin` directory. The command file is a script that is named `manageprofiles.sh|bat`. Example: `/opt/IBM/WebSphere/AppServer/bin/manageprofiles.sh -delete -profileName profile_name` 2. Delete the profile directory. 3. Then, run the **Create a default profile** step again.

Import the backup profile

About this task

Table 654. Appropriate actions for step: Import the backup profile

Actions	Notes
Run the step again	If this step fails, you can run this step again after you clean up the issue.
Skip the step	Do not skip this step, if you are running the configuration again. If you re-create the default profile from the **Create a default profile** step, then you must run this step again to import the new default profile.
Clean up step	If an unrecoverable error occurs and the import backup profile step fails, remove the profile. 1. Use the **manageprofiles** command to remove the profile. The command file is in the `app_server_root/bin` directory. The command file is a script that is named `manageprofiles.sh|bat`. Example: `/opt/IBM/WebSphere/AppServer/bin/manageprofiles.sh -delete -profileName profile_name` 2. Delete the profile directory. 3. Then, run the **Create a default profile** step again before you rerun this step.

Manual Step: If you cleaned up the backup profile, restore the JCR content

About this task

Since this is a manual step, any error that occurs is outside the context of the wizard.

Table 655. Appropriate actions for step: If you cleaned up the backup profile, restore the JCR content

Actions	Notes
Run the step again	Not applicable
Skip the step	Do not skip this step, if you are running the configuration again. You must restore the JCR content, if you completed the previous manual step to clean up the backup profile that is over 2 GB.
Clean up step	None required

Troubleshooting: Upgrade node profiles for a cluster environment

If you encounter a failure while upgrading the node profiles for a cluster environment, learn how to correct the issue and recover from the failure.

Each potential step in the upgrade node profiles option is included. Since the steps vary, depending on your selections, the steps are not numbered. Find the step that failed to learn more about correcting and recovering from the failure.

Related concepts:

"Cluster: Upgrade node profiles" on page 853
Use the Configuration Wizard to upgrade the nodes profiles for a cluster environment. Use the following information to get familiar with the information you must provide in the wizard and the configuration procedure that it generates.

Related tasks:

"Accessing the Configuration Wizard" on page 235
The home page of the Configuration Wizard provides access to common configuration tasks. Supported tasks include setting up a stand-alone server, setting up a cluster, transferring from Apache Derby to another supported database, migrating your server, installing add-ons, and more.

Manual Step: Update the ports for the deployment manager and nodes

About this task

Since this is a manual step, any error that occurs is outside the context of the wizard.

Table 656. Appropriate actions for step: Update the ports for the deployment manager and nodes

Actions	Notes
Run the step again	You can run this step again if it fails.
Skip the step	If this step was successful, you can skip it if you run the configuration process again.
Clean up step	None required

Upgrade the ConfigEngine
About this task

Table 657. Appropriate actions for step: Upgrade the ConfigEngine

Actions	Notes
Run the step again	If this step fails, you can run this step again after you clean up the issue.
Skip the step	If this step was successful, you can skip it if you run the configuration process again. If you re-create your profile for any reason, you must run this step again.
Clean up step	If this step fails, review the parameters and values that you entered in the Configuration Wizard, specifically the new host name, passwords, port numbers, and the Portal server path. If the parameter and values that you entered are correct, and the step fails again, use the wp-collector tool to gather the files that are needed to contact support for help. See "Data collection and symptom analysis" on page 3539 for information about using the wp-collector tool.

Update database settings
About this task

Table 658. Appropriate actions for step: Update database settings

Actions	Notes
Run the step again	Not applicable
Skip the step	If this step was successful, you can skip it if you run the configuration process again. If you re-create your profile for any reason, you must run this step again.
Clean up step	None required

Validate the database settings
About this task

Table 659. Appropriate actions for step: Validate the database settings

Actions	Notes
Run the step again	If this step fails, you can run this step again after you clean up the issue.
Skip the step	If this step was successful, you can skip it if you run the configuration process again. If you re-create your profile for any reason, you must run this step again.
Clean up step	Check your properties files to make sure that you have all of your parameters and values set correctly before you run the step again.

Connect to new databases
About this task

Table 660. Appropriate actions for step: Connect to new databases

Actions	Notes
Run the step again	If this step fails, you can run the step again.
Skip the step	If this step was successful, you can skip it if you run the configuration process again. If you re-create your profile for any reason, you must run this step again.
Clean up step	None required

Manual Step: Review database schema changes
About this task

Since this is a manual step, any error that occurs is outside the context of the wizard.

Table 661. Appropriate actions for step: Review database schema changes

Actions	Notes
Run the step again	If this step fails, you can run this step again.
Skip the step	This step is optional. You can skip this step if you do not want to review the database schema changes.
Clean up step	None required

Upgrade the base portal database component
About this task

Table 662. Appropriate actions for step: Upgrade the base portal database component

Actions	Notes
Run the step again	If this step fails, you can run this step again after you clean up the issue.
Skip the step	Do not skip this step, if you are running the configuration again.
Clean up step	If this step fails, delete the database, create a new copy, and run the step again.

Manual Step: Remove check pending statuses from table spaces
About this task

Since this is a manual step, any error that occurs is outside the context of the wizard.

Table 663. Appropriate actions for step: Remove check pending statuses from table spaces

Actions	Notes
Run the step again	If this step fails, clean up the issue and start back with the **Upgrade the base portal database components** step, and then run this step again.
Skip the step	Do not skip this step, if you are running the configuration again.
Clean up step	If this step fails, delete the database, create a new copy, and run the **Upgrade the portal database component** step again before you rerun this step again.

Upgrade the remaining portal databases
About this task

Table 664. Appropriate actions for step: Upgrade the remaining portal databases

Actions	Notes
Run the step again	If this step fails, clean up the issue and start back with the **Upgrade the base portal database components**.
Skip the step	Do not skip this step, if you are running the configuration again. You must complete the **Upgrade the base portal database components** and **Remove check pending statuses from table spaces** steps before you run this step again.
Clean up step	If this step fails, delete the database, create a new copy, and rerun the **Upgrade the portal database component** and **Remove check pending statuses from table spaces** steps before you run this step again.

Upgrade the portal profile
About this task

Table 665. Appropriate actions for step: Upgrade the portal profile

Actions	Notes
Run the step again	If this step fails, you must contact support. **Note:** Contact support before you start the Portal server.
Skip the step	Do not skip this step, if you are running the configuration again.
Clean up step	Contact support.

When you run this step, the sub task that is named **`action-deploy-portlets-applyMIGStatic-wp.oob.full`** runs and completes successfully. However, the following error messages are shown. You can ignore these error messages:

- EJPXA0161W: The web module ContactList could not be activated. Please see previous messages for reasons and possible corrective actions.
- EJPPH0048W: The synchronization mode of all nodes in the portal cluster is not consistently set. The portlet application PA_ContactList will not be started in the Application Server. Manual synchronization is assumed for all nodes. Manually start the application after all nodes were synchronized.
- EJPXA0067E: The following configuration data is needed to create a content-node resource: content-parentref.

Error message codes

Each message code consists of a product identifier, component identifier, a unique number, and a message type identifier. The product identifier is EJP and there are many components. There are three message types: error, information, and warning.

Example

For the following message code EJPIC0001E:

- EJP is the product identifier
- IC is the component identifier, installation user interface
- 0001 is the unique message number
- E is the message type, error

During the last session, you clicked Start Configuration and the configuration was running automatically. To return to the automatic process, click Resume Configuration. Otherwise, click Cancel to run each remaining step manually.

Chapter 18. Reference

View information that helps you use the information center including directory conventions, terms of use, trademarks, a glossary, and more.

"Conventions"
Understand the conventions that are used in this documentation to use it more effectively.

"Directory structure" on page 3618
The topic shows the naming conventions that are used to denote the location of files on the servers and the types of resources you can find in those directories.

"Supported languages" on page 3622
The different user interfaces used to install, configure, and use IBM WebSphere Portal Express might not be available in all languages. Refer to the following table for the language codes and to see which areas of the product are available in your language. If your language is not supported currently, you might see the English version of the user interface.

"Updates using ReleaseBuilder" on page 3624
After setting up your initial staging and production servers, you can use ReleaseBuilder to make updates to your production server.

"Staging Personalization rules to production" on page 3629
Use the steps in this file to move Personalization rules from a staging system to a production system. There are a number of methods for moving rules between servers, each suitable for different situations.

"CF04 and earlier: Using friendly URLs without state information" on page 3631
By default, WebSphere Portal Express URLs include navigational state information. If you configure pages for friendly URLs, the portal appends the state information to the friendly URLs. Some scenarios require short and fully human readable URLs that omit the state information. For such scenarios, you can configure friendly URLs so that the portal does not show that state information.

"Terms of use" on page 3634
Understand the terms and conditions before you use this publication.

"Notices" on page 3634
This information was developed for products and services offered in the U.S.A. This material may be available from IBM in other languages. However, you may be required to own a copy of the product or product version in that language in order to access it.

"Glossary" on page 3637
This glossary includes terms and definitions for IBM WebSphere Portal Express.

Conventions

Understand the conventions that are used in this documentation to use it more effectively.

The following section provides conventions that can help you interpret the information that is provided in this documentation:

- File names, directories, and commands appear in `Courier` font. For example:
  - File name: `xmlaccess.bat` or `xmlaccess.sh`

  - Directory: `/opt/WebSphere/PortalServer`
  - Command: `startServer WebSphere_Portal`
- Variables are either italicized, enclosed in brackets, or both. For example: `http://`*`hostname.example.com`*`:`*`10039`*`/wps/portal`, where *hostname.example.com* is the fully qualified host name of the server where Portal is running and *10039* is the default transport port that is created by WebSphere Application Server. The port number might be different for your environment.
- Variables are used to indicate root installation directories. For more information, see "Directory structure."
- Directories are shown with forward slashes (/), unless operating-system specific information is provided. On Windows systems, you must use backward slashes (\) when typing at a command line, unless otherwise noted.
- Operating system-specific information is provided, for example:
  - Linux : **`./ConfigEngine.sh`** *task_name*
  - IBM i: **`ConfigEngine.sh`** *task_name*
  - Windows: **`ConfigEngine.bat`** *task_name*
- Links to reference information and external links are marked with the **For your reference** icon: .
- Most topics include a Related information section that links to other relevant topics.

Directory structure

The topic shows the naming conventions that are used to denote the location of files on the servers and the types of resources you can find in those directories.

PortalServer_root

Throughout this documentation, the installation location for the portal server component of IBM WebSphere Portal Express is noted as *PortalServer_root*.

For the IBM i operating system, an extra variable is used to indicate the user data directory. The user data directory is noted as *PortalServer_root_user*.

The following information shows the default location if it is not otherwise specified during installation:

IBM i

- `portal_server_root` (ProdData)
  - `/QIBM/ProdData/WebSphere/PortalServer/V85/<product offering>`

  Where *product offering* is Server or Express
- `PortalServer_root_user` (UserData)
  - WebSphere Application Server Version 8.5.5 for Network Deployment:

- /QIBM/UserData/WebSphere/AppServer/V85/ND/profiles/wp_profile/PortalServer

Linux /opt/IBM/WebSphere/PortalExpress/PortalServer

Windows
C:\Program Files\IBM\WebSphere\PortalExpress\PortalServer

wp_profile_root

Throughout this documentation, the profile location is noted as *wp_profile_root*. The following information shows the default profile location if another location is not specified during installation:

IBM i

- WebSphere Application Server Version 8.5 for Network Deployment:
  - /QIBM/UserData/WebSphere/AppServer/V85/ND/profiles/wp_profile

The *wp_profile* is the default profile name but is used here as an example since there can be multiple profiles with self described or incremental names (for example, wp_profile1, wp_profile2).

Linux /opt/IBM/WebSphere/PortalExpress/AppServer/profiles/wp_profile

Windows
C:\Program Files\IBM\WebSphere\wp_profile

ConfigEngine_root

Throughout this documentation, the installation location for the Configuration Engine component is noted as *ConfigEngine_root*.

IBM i /QIBM/ProdData/WebSphere/PortalServer/V85/ConfigEngine

Linux /opt/IBM/WebSphere/PortalExpress/AppServer/profiles/ConfigEngine

Windows
C:\Program Files\IBM\WebSphere\ConfigEngine

WebSphere Portal Express Configuration Engine profile directory

The Configuration Engine profile directory is the location of the **ConfigEngine** task.

IBM i

- WebSphere Application Server Version 8.5.5 for Network Deployment:
  - /QIBM/UserData/WebSphere/AppServer/V85/ND/profiles/wp_profile/ConfigEngine

The *wp_profile* is the default profile name but is used here as an example since there can be multiple profiles with self described or incremental names (for example, wp_profile1, wp_profile2).

Linux /opt/IBM/WebSphere/PortalExpress/AppServer/profiles/wp_profile/ConfigEngine

Windows
C:\Program Files\IBM\WebSphere\wp_profile\ConfigEngine

WebSphere Portal Express directory structure after installation

WebSphere Portal Express has the following directory structure after installation:

Note: On the Linux and IBM i operating systems, all directories are r/o.

```
PortalServer_root          Root directory for WebSphere Portal Express

AppServer_root

The following information shows the WebSphere Application Server installation directory:

WebSphere Portal Configuration profile directory *cw_profile_root*

Throughout this documentation, the configuration wizard profile location is noted as cw_profile_root. The following information shows the profile location:

IBM i WebSphere Application Server Version 8.5 for Network Deployment:/QIBM/UserData/WebSphere/AppServer/V8/ND/profiles/cw_profile

Linux /opt/IBM/WebSphere/AppServer/profiles/cw_profile

Windows
C:\Program Files\IBM\WebSphere\AppServer\profiles\cw_profile

IBM i The installation location for WebSphere Application Server is noted as *app_server_root* and refers to the UserData path, unless otherwise specified in the topic where you see it. The *profile_root* following variable refers to the name given to the WebSphere Application Server profile in use.

The following information shows the default WebSphere Application Server installation location if it is not otherwise specified during installation:

IBM i The installation location for WebSphere Application Server is noted as *app_server_root* and refers to the UserData path, unless otherwise specified in the topic where you see it. The *profile_root* following variable refers to the name given to the WebSphere Application Server profile in use.

Linux /opt/IBM/WebSphere/PortalExpress/AppServer

Windows
C:\Program Files\IBM\WebSphere\PortalExpress\AppServer

Directories for languages

The following table shows the languages that are supported by WebSphere Portal Express and the directories that are used for storing locale-specific resources. These directories are used in portlet web application directories and in the WebSphere Portal Express enterprise application (themes, skins, and other web application resources).

Table 666. Languages supported by WebSphere Portal Express

Language (locale)	Directory
Arabic	/ar
Danish	/da
English	/en
French	/fr
Italian	/it
Kazakh	/kk
Korean	/ko
Polish	/pl

Updates using ReleaseBuilder

After setting up your initial staging and production servers, you can use ReleaseBuilder to make updates to your production server.

"ReleaseBuilder"
To generate or stage follow-on releases of IBM WebSphere Portal Express portals, configurations, and artifacts need to be moved between systems. ReleaseBuilder enables management of release configurations independent of user configurations.

"Making updates with ReleaseBuilder" on page 3625
You can use ReleaseBuilder to compare the XML configuration files that describe your staging server (REV1) and your updated staging server (REV2). You can also use it to create an XML configuration file that contains the differences between the two servers. You can then use this output file to import only the differences from your staging server (REV2) onto the production server. Features that are unchanged from (REV1) on the staging server (REV2) are not affected by the import.

"Reference: ReleaseBuilder command syntax" on page 3628
The ReleaseBuilder command file is in the *wp_profile_root*`/PortalServer/bin` directory and has the following syntax:

ReleaseBuilder

To generate or stage follow-on releases of IBM WebSphere Portal Express portals, configurations, and artifacts need to be moved between systems. ReleaseBuilder enables management of release configurations independent of user configurations.

Release configuration data are exported to XML files that can be imported using the XML configuration interface (XmlAccess). Using ReleaseBuilder it is possible to stage release configurations between two portals. This allows you to track which configuration entities were removed, added, or changed compared to the previous release generated from a given portal and to apply these differential updates to another portal. Detecting the differences between one configuration and another of the same portal server creates differential updates. A third configuration or "diff", generated by ReleaseBuilder, represents the changes made between the two configurations. The third configuration can be used to apply not only addition and update modifications but also deletions to the target server. This allows two portal servers, for example, a staging server and a production server, to remain in synch. ReleaseBuilder is designed to eliminate the need to generate complete XmlAccess exports to move a partial configuration or to manually create XML response files to export a partial configuration. ReleaseBuilder also helps to prevent the problem of configuration bloat on the target server.

For staging virtual portals, ReleaseBuilder supports a virtual portal mode that allows the generation of difference configurations for virtual portal scoped resources only. This mode allows you to stage virtual portals.

Note: ReleaseBuilder is a configuration management tool. Do not use it for migration purposes.

Performance benefits

Massively parallel portal configuration tasks, for example hundreds of administrators working in parallel, can affect the user experience and portal performance. Such tasks can be distributed to independent portal systems.

ReleaseBuilder, together with the XML configuration interface, allows you to integrate the resulting configurations.

Usage notes

- ReleaseBuilder is installed when WebSphere Portal Express is installed along with the XML configuration interface. You can run ReleaseBuilder on the production server, although it can impact the WebSphere Portal Express performance.
- Unlike the XML configuration interface, ReleaseBuilder does not interact with the portal server runtime. You should run ReleaseBuilder on a separate, standalone machine. This system can be the staging system or a completely separate system where WebSphere Portal Express is installed.
- To maximize use of system resources, WebSphere Portal Express should not be running when executing ReleaseBuilder.

Making updates with ReleaseBuilder

You can use ReleaseBuilder to compare the XML configuration files that describe your staging server (REV1) and your updated staging server (REV2). You can also use it to create an XML configuration file that contains the differences between the two servers. You can then use this output file to import only the differences from your staging server (REV2) onto the production server. Features that are unchanged from (REV1) on the staging server (REV2) are not affected by the import.

Before you begin

Ensure that your development, test, and production environments are configured to allow all of the required artifacts and the configuration to be moved.

ReleaseBuilder is preferably run on an integration or staging server. Running ReleaseBuilder on the production server is not advised because ReleaseBuilder uses resources and affects portal services to users.

ReleaseBuilder uses XML configuration files to create an XML configuration file of the differences between the two servers. This XML configuration file is used to transfer the new portal configuration from your staging server to your production server. To export the configurations of the servers, use the XML configuration interface.

About this task

The XML files from your staging server (REV1) and from your updated staging server (REV2) refer to two exports that are taken from the SAME portal server. Building a release means to generate an XML file that contains the same modifications that are made to the staging server between REV1 and REV2. ReleaseBuilder is not designed to determine the differences between or changes that are made to two separate Portal servers.

Note: The following instructions describe the building of a release in installations, which do not use virtual portals. For instructions for staging virtual portals, refer to the topic about Building a Release for virtual portal installations.

Procedure

1. Complete the following steps to export the staging server configuration REV1:

Remember: Export the entire portal configuration REV1 of the staging server; do not include users, users' access control, or any other user configurations.

a. On the staging server change to the *wp_profile_root*/PortalServer/bin directory. This directory contains the portal tools.

b. Use the XML configuration interface to export the staging server REV1 configuration. A sample file is available, ExportRelease.xml.

   - HP-UX Linux : `./xmlaccess.sh -in ExportRelease.xml -user wpsadmin_user_ID -password wpsadmin_pwd -url "http://stagingserver.example.com:port/wps/config" -out stagingserverREV1_config.xml`
   - IBM i: `xmlaccess.sh -in ExportRelease.xml -user wpsadmin_user_ID -password wpsadmin_pwd -url "http://stagingserver.example.com:port/wps/config" -out stagingserverREV1_config.xml`
   - Windows: `xmlaccess.bat -in ExportRelease.xml -user wpsadmin_user_ID -password wpsadmin_pwd -url "http://stagingserver.example.com:port/wps/config" -out stagingserverREV1_config.xml`

   The exported configuration is stored in the stagingserverREV1_config.xml file.

2. Develop and test new functions and portlets on the staging server. This phase is where you add or delete functions. This phase can last for a long time. Ensure that the staging server is fully tested and the portal is ready.

3. Complete the following steps to export the staging server configuration REV2:

   Remember: Export the entire portal configuration REV2 of the staging server; do not include users, users' access control, or any other user configurations.

   a. On the staging server change to the *wp_profile_root*/PortalServer/bin directory. This directory contains the portal tools.

   b. Run the following task to export the staging server configuration REV2:

      Note: Use the XML configuration interface and the provided sample file that is called ExportRelease.xml.

      - HP-UX Linux : `./xmlaccess.sh -in ExportRelease.xml -user wpsadmin_user_ID -password wpsadmin_pwd -url "http://stagingserver.example.com:port/wps/config" -out stagingserverREV2_config.xml`
      - Windows: `xmlaccess.bat -in ExportRelease.xml -user wpsadmin_user_ID -password wpsadmin_pwd -url "http://stagingserver.example.com:port/wps/config" -out stagingserverREV2_config.xml`
      - IBM i: `xmlaccess.sh -in ExportRelease.xml -user wpsadmin_user_ID -password wpsadmin_pwd -url "http://stagingserver.example.com:port/wps/config" -out stagingserverREV2_config.xml`

      The exported configuration is stored in the stagingserverREV2_config.xml file.

4. If you installed extra portlets or applications, copy the necessary WAR files from the staging server to the *wp_profile_root*/PortalServer/deployed/archive installation directory on the production server.

   Note: The deployed/archive directory is always in the original *wp_profile_root* installation path, even if the production server is using an extra profile that is created after installation.

Note: As Windows limits the maximum path length to 260 characters, the name of the WAR file must be 25 characters or less. Installing a WAR file with a name that is more than 25 characters results in an error.

5. Complete the following steps to generate the differences between staging server configurations REV1 and REV2:

   Note: Complete these steps on the staging server and not on the production server. Computing a release difference produces a high load on the system and uses much memory for large releases. Therefore, do not complete them on the production system.

   a. Optional: Stop the portal server on the staging system. This option frees resources for computing the release difference.
   b. On the server where you just stopped the portal server, change to the *wp_profile_root*/PortalServer/bin directory.
   c. To generate the differences file containing the additions and deletions configuration file, enter one of the following commands:

Table 668. Differences file commands

Operating system	Command
Linux	./releasebuilder.sh -inOld *stagingserverREV1_config.xml* -inNew *stagingserverREV2_config.xml* -out *outputfile.xml*
Windows:	releasebuilder.bat -inOld *stagingserverREV1_config.xml* -inNew *stagingserverREV2_config.xml* -out *outputfile.xml*
IBM i:	releasebuilder.sh -inOld *stagingserverREV1_config.xml* -inNew *stagingserverREV2_config.xml* -out *outputfile.xml*

   The resulting output configuration file contains the additions and deletions to be imported onto your production server.

   d. Optional: Restart the portal server on the staging system, if you stopped it before.

6. Use the *outputfile*.xml, which contains the differences between REV1 and REV2 portal server to import these differences onto the production server.

Table 669. Task to import differences onto the production server

Operating system	Command
Linux	./xmlaccess.sh -in outputfile.xml -user *wpsadmin_user_ID* -password *wpsadmin_pwd* -url "http://*productionserver.example.com:port*/wps/config"
Windows:	xmlaccess.bat -in outputfile.xml -user *wpsadmin_user_ID* -password *wpsadmin_pwd* -url "http://*productionserver.example.com:port*/wps/config"

Table 669. Task to import differences onto the production server (continued)

Operating system	Command
IBM i:	`xmlaccess.sh -in outputfile.xml -user` *`wpsadmin_user_ID`* `-password` *`wpsadmin_pwd`* `-url "http://` *`productionserver.example.com:port`*`/wps/config"`

Notes:

a. If portlet parameters are deleted from a configuration, the output script that is generated by ReleaseBuilder does not remove those parameters on the target system.

b. XML files that are generated by ReleaseBuilder do not have any transaction levels set. To set a transaction level, edit the XML file that is generated by ReleaseBuilder and add the transaction level to the XML file.

Related reference:

"Sample XML configuration files" on page 1111
Sample files are provided for your reference to help illustrate how to use XML configuration for different portal configuration purposes. Before you use them, read the other topics about the XML configuration interface carefully. Many of the samples need to be modified with valid page or user name before they can be used.

Reference: ReleaseBuilder command syntax

The ReleaseBuilder command file is in the *wp_profile_root*`/PortalServer/bin` directory and has the following syntax:

NAME

`releasebuilder` - generate different configurations for a single staging server. The production server uses the configuration.

SYNOPSIS

`releasebuilder -inOld` *input file oldReleaseConfiguration* **`-inNew`** *input file newReleaseConfiguration* **`-out`** *output file* **`-virtualPortalMode`**

OPTIONS

The following options are supported:

- **`inOld`** *input file oldReleaseConfiguration*:

  Required. This option is used to specify the first of the two XML configuration files to compare. The *input file oldReleaseConfiguration* parameter must be an absolute or relative path of an accessible XML configuration file that is previously generated with the XML configuration interface command.

- **`inNew`** *input file newReleaseConfiguration*:

  Required. This option is used to specify the second of the two XML configuration files to compare. The *input file newReleaseConfiguration* parameter must be an absolute or relative path of an accessible XML configuration file that is previously generated with the XML configuration interface command.

- **`out`** *output file*:

  This option is used to specify the file in which the differential output is written. If not specified, the differential output is written to the System console. The *output file* parameter must be an absolute or relative path of an

accessible XML configuration file. If it does not exist, it is created. If it does exist, the existing information in the file is overwritten.

- **`virtualPortalMode`**:

  Use this option to specify that only virtual portal scoped resources are included in the configuration. This option enables the processing of a specific virtual portal. If you do not specify this parameter, the differential output includes unscoped resources as well.

- **`disableLogFile`**:

  Use this option if you do not want ReleaseBuilder to create a log file.

- **`logFileLocation`** *log output file*:

  ReleaseBuilder writes the log file to the specified location.

- **`debug`**

  Use this option to help you debug any errors that occur.

Staging Personalization rules to production

Use the steps in this file to move Personalization rules from a staging system to a production system. There are a number of methods for moving rules between servers, each suitable for different situations.

Choose one of the following methods to move rules:

Method: Export from source then import into destination

Steps	Advantages	Disadvantages	Users
1. Use the **Export** button in the Personalization Navigator portlet on the source to export a nodes file. 2. Use the **Import** button in the Personalization Navigator portlet on the target to import that file.	• This method is the easiest way to move rules. • Uses a familiar export and import paradigm.	• Cannot be scripted. • Requires Personalization Navigator portlet to be installed on the target server.	• Development teams. • Quick, ad-hoc changes in small deployments and test environments.

Method: Publish using the Personalization Navigator portlet

Steps	Advantages	Disadvantages	Users
Use the Publish menu options in the Personalization Navigator portlet to publish the entire workspace or to selectively publish	• Easy and quick to use. Once a publish server is configured, you can publish rules in two clicks. • This method does not require rules to be saved on the file system. • If publishing the entire workspace with smart delete, you can ensure two work spaces are the same.	• No intermediate file is produced by the process, so there is no record of what was published other than log files. • This approach is driven from a graphical user interface, so it is not scriptable.	Business users with rule authoring responsibilities.

Method: Export from the source and then publish into the destination

Steps	Advantages	Disadvantages	Users
1. Use the export button in the Personalization Navigator portlet on the source to export a nodes file. 2. Use the pznload command line utility (**pznload.sh** and **pznload.bat**) to publish the nodes file that you exported to the target.	• This method can an be scripted. • Allows your changes to be tracked, controlled, and the earlier versions to be reverted by maintaining copying of the nodes files and rerunning a script.	Requires use of a command line interface.	• Administrators • Moving between staging and production environments

Notes:

- If the rules are referenced by Personalization components, ensure the Personalization components are published and syndicated in Web Content Manager.
- If the rules are referenced in pages or portlets, move the page and portlet definitions with XML Access or Release Builder. This is related to attribute based administration.

Related concepts:

"Publishing personalization rules overview" on page 2298
WebSphere Portal Express Personalization sends published rules across HTTP to a servlet which resides on each personalization server. This servlet can receive publishing data or initiate new publishing jobs. When a user begins a publishing job from the personalization authoring environment, the local servlet is provided with the set of information necessary to complete the job. The local servlet contacts the destination endpoint servlet (which could be the same servlet) and sends its data to it. The destination servlet reports success or failure.

CF04 and earlier: Using friendly URLs without state information

By default, WebSphere Portal Express URLs include navigational state information. If you configure pages for friendly URLs, the portal appends the state information to the friendly URLs. Some scenarios require short and fully human readable URLs that omit the state information. For such scenarios, you can configure friendly URLs so that the portal does not show that state information.

About this task

The state information is an encoded aggregation of the navigational state of the portal, the page, and its components, for example, the portlets on the current page:

- The portal state includes page selection, expansions, label mapping, and action targets.
- The portlet state includes render parameters, window state, and portlet mode.

The representation of the navigational state within the URL enables characteristics of dynamic websites, such as usage of bookmarks or the **Back** button. For example, users can bookmark a page and later return to the exact same state of that page.

Some scenarios require short and fully human readable URLs that omit the state information. Examples:

- You do not want the URL to make the impression that it references dynamic content.
- You want the URL to contain only information that a human person can read and interpret.
- You want the URL to easily fit into the address field of the web browser.
- Internet search engines expect static URLs that reference only one resource or web page for the time that the page exists
- Internet search engines prefer short and friendly URLs.

For such scenarios you configure WebSphere Portal Express as follows:

- You configure themes to always display only short friendly URLs without the encoded navigational state.
- You configure pages that use that theme to display friendly URLs.

The configuration applies to all pages that use that theme and that are configured to display friendly URLs.

Notes:

- You can create friendly URLs for portal pages.
- If you configure your portal to show stateless friendly URLs, you gain improved URL readability at the cost of losing the state functionality. Example consequences are as follows:

- Portal URLs always point to the default state of a page, as they do not contain the state information.
- If a user clicks the **Back** button, or refreshes a page by clicking the **Refresh** button or the page title, the page moves back into the default View mode.
- If a user views a page, and then creates a bookmark, clicking the bookmark later opens the page in the default View mode.
- Stateless friendly URLs do not contain the usual information about the language of the page. The portal determines the language for the page by the following order:
  1. First, the portal looks for the user preference.
  2. If the user preference is not set, the portal looks for the preferred language that is set in the browser. If the page is a public page, the user is an anonymous user. In this case, the portal also looks for the preferred language that is set in the browser.
  3. If the portal cannot determine a preferred language setting for the portal or the browser, it applies the default language that is defined for the portal.

  For information about how to present language-specific portal pages with stateless friendly URLs, read the information at the end of the procedure that follows here.

Procedure

1. In the portal WP Configuration Service, set the custom property `friendly.redirect.enabled` to the value `false`. You do this step by editing the Resource Environment Provider (REP) WPConfigService in the WebSphere Integrated Solutions Console. If the property is not listed there, add it and set it to `false`. For information about this property and how to set it see the topics about the portal Configuration Service and Setting service configuration properties.
2. In the theme, that you want configure, for short stateless URLs, set the parameter `com.ibm.portal.theme.hasBaseURL` to `true`. You can update the theme parameter by using the XML configuration interface. Here is an example XML script:

```
<?xml version="1.0" encoding="UTF-8"?>

<request
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd"
   type="update">

   <!-- This sample sets the hasBaseURL Tag in the Portal 8.5 Theme. -->
   <portal action="locate">
      <theme action="update" uniquename="ibm.portal.85Theme" >
         <parameter name="com.ibm.portal.theme.hasBaseURL"
                    type="string" update="set">true</parameter>
      </theme>
   </portal>
</request>
```

3. Make sure that all generated URLs in the theme do not include the navigational state. In the default theme, you can do this step by modifying the `navigation.jsp` and `sideNavigation.jsp` files. To change the file `navigation.jsp`, proceed as follows:
   a. Change to the directory for the file `navigation.jsp`. You must update two copies of this file, one each in the following two directory locations.

- *PortalServer_root*\theme\wp.theme.themes\default85\installedApps\DefaultTheme85.ear\DefaultTheme85.war\themes\html\dynamicSpots
- *PortalServer_root*\theme\wp.theme.modules\webapp\installedApps\ThemeModules.ear\ThemeModules.war\themes\html\dynamicSpots

b. Open the file navigation.jsp with an editor.

c. Search for the string <a href="?uri=nm:oid:${wp.identification[node]}" class="wpthemeLeft${titleClass}"> and change it to the following code snippet:

```
<portal-navigation:urlGeneration contentNode="${wp.identification[node]}" keepNavigationalState="false">
<a href="<%wpsURL.write(out);%>" class="wpthemeLeft${titleClass}">
```

d. Locate the first tag after the updated string <a href="<%wpsURL.write(out);%>" and change it to the following code snippet:

```
</a>
</portal-navigation:urlGeneration>
```

To change the file sideNavigation.jsp, proceed as follows:

a. Change to the directory *PortalServer_root*\theme\wp.theme.themes\default85\installedApps\DefaultTheme85.ear\DefaultTheme85.war\themes\html\dynamicSpots.

b. Open the file sideNavigation.jsp with an editor.

c. Search for the string <a href="?uri=nm:oid:${wp.identification[node]}" class="<c:if test="${isSelectedNode}"> wpthemeSelected</c:if>${titleClass}"> and change it to the following code snippet:

```
<portal-navigation:urlGeneration contentNode="${wp.identification[node]}" keepNavigationalState="false">
<a href="<%wpsURL.write(out);%>" class="<c:if test="${isSelectedNode}">wpthemeSelected</c:if>${titleClass}">
```

d. Locate the first tag after the updated string <a href="<%wpsURL.write(out);%>" and change it to the following code snippet:

```
</a>
</portal-navigation:urlGeneration>
```

4. Edit the mobileNavigation.jsp file.

a. Change to the directory *PortalServer_root*\theme\wp.theme.themes\default85\installedApps\DefaultTheme85.ear\DefaultTheme85.war\themes\html\dynamicSpots.

b. Open the file mobileNavigation.jsp with an editor.

c. Search for the string <a href="?uri=nm:oid:${nodeID}"> and change it to the following code snippet:

```
<portal-navigation:urlGeneration contentNode="${nodeID}" keepNavigationalState="false">
<a href="<%wpsURL.write(out);%>"
```

d. Locate the first tag after the updated string <a href="<%wpsURL.write(out);%>" and change it to the following code snippet:

```
</a>
</portal-navigation:urlGeneration>
```

5. Optional: For IBM Web Content Manager: You might want the IBM Web Content Manager Rendering portlet to also display the friendly and stateless URLs. In this case, implement a plug-in that translates the IBM Web Content Manager URLs into the required custom format. For instructions and sample code for such a plug-in, see *Example 2, Generate a friendly URL for web content*.
6. Define friendly URL names for pages as required. For information about how to do this step, read *Using friendly URLs*.
7. Optional: You might want to present language-specific portal pages with stateless friendly URLs to your site visitors. In this case, structure your portal site to reflect which pages or pages are targeted for specific countries or regions. For example, you can create a node for a specific page, and then create language-specific child pages under that node. Example: In the node home, you create pages in English, French, and German. You can then give your site visitors the appropriate one of the following friendly URLs:

```
http://www.myco.com/wps/home/en/shop
http://www.myco.com/wps/home/fr/shop
http://www.myco.com/wps/home/de/shop
```

Results

The portal now no longer displays the state information with the URLs.

Terms of use

Understand the terms and conditions before you use this publication.

Permissions for the use of publications is granted subject to the following terms and conditions.

Personal Use: You may reproduce these publications for your personal, non commercial use provided that all proprietary notices are preserved. You may not distribute, display or make derivative work of these publications, or any portion thereof, without the express consent of IBM.

Commercial Use: You may reproduce, distribute and display these publications solely within your enterprise provided that all proprietary notices are preserved. You may not make derivative works of these publications, or reproduce, distribute or display these publications or any portion thereof outside your enterprise, without the express consent of IBM.

Except as expressly granted in this permission, no other permissions, licenses or rights are granted, either express or implied, to the publications or any information, data, software or other intellectual property contained therein.

IBM reserves the right to withdraw the permissions granted herein whenever, in its discretion, the use of the publications is detrimental to its interest or, as determined by IBM, the instructions are not being properly followed.

You may not download, export or re-export this information except in full compliance with all applicable laws and regulations, including all United States export laws and regulations.

U.S.A.

Such information may be available, subject to appropriate terms and conditions, including in some cases, payment of a fee.

The licensed program described in this document and all licensed material available for it are provided by IBM under terms of the IBM Customer Agreement, IBM International Program License Agreement or any equivalent agreement between us.

Any performance data contained herein was determined in a controlled environment. Therefore, the results obtained in other operating environments may vary significantly. Some measurements may have been made on development-level systems and there is no guarantee that these measurements will be the same on generally available systems. Furthermore, some measurements may have been estimated through extrapolation. Actual results may vary. Users of this document should verify the applicable data for their specific environment.

Information concerning non-IBM products was obtained from the suppliers of those products, their published announcements or other publicly available sources. IBM has not tested those products and cannot confirm the accuracy of performance, compatibility or any other claims related to non-IBM products. Questions on the capabilities of non-IBM products should be addressed to the suppliers of those products.

All statements regarding IBM's future direction or intent are subject to change or withdrawal without notice, and represent goals and objectives only.

This information contains examples of data and reports used in daily business operations. To illustrate them as completely as possible, the examples include the names of individuals, companies, brands, and products. All of these names are fictitious and any similarity to the names and addresses used by an actual business enterprise is entirely coincidental.

If you are viewing this information softcopy, the photographs and color illustrations may not appear.

Trademarks

IBM, the IBM logo, and ibm.com are trademarks or registered trademarks of International Business Machines Corp., registered in many jurisdictions worldwide. Other product and service names might be trademarks of IBM or other companies. A current list of IBM trademarks is available on the Web at “Copyright and trademark information” at www.ibm.com/legal/copytrade.shtml.

Adobe, the Adobe logo, PostScript, and the PostScript logo are either registered trademarks or trademarks of Adobe Systems Incorporated in the United States, and/or other countries.

Intel, Intel logo, Intel Inside, Intel Inside logo, Intel Centrino, Intel Centrino logo, Celeron, Intel Xeon, Intel SpeedStep, Itanium, and Pentium are trademarks or registered trademarks of Intel Corporation or its subsidiaries in the United States and other countries.

Linux is a registered trademark of Linus Torvalds in the United States, other countries, or both.

Microsoft, Windows and the Windows logo are trademarks of Microsoft Corporation in the United States, other countries, or both.

UNIX is a registered trademark of The Open Group in the United States and other countries.

Java and all Java-based trademarks and logos are trademarks or registered trademarks of Oracle and/or its affiliates.

Glossary

This glossary includes terms and definitions for IBM WebSphere Portal Express.

The following cross-references are used in this glossary:

1. See refers the reader from a term to a preferred synonym, or from an acronym or abbreviation to the defined full form.
2. See also refers the reader to a related or contrasting term.

To view glossaries for other IBM products, go to www.ibm.com/software/globalization/terminology.

A

access control. In computer security, the process of ensuring that users can access only those resources of a computer system for which they are authorized.

aggregation. The structured collection of data objects for subsequent presentation within a portal.

Ajax. A design approach and a set of techniques for delivering rich Internet applications (RIAs) using open web formats, for example, HTML, CSS and JavaScript; and rendering using a browser engine.

Ajax portlet. A normal server side portlet that uses lots of JavaScript and Ajax technologies and less Java and Java server pages.

anonymous user. A user who does not use a valid user ID and password to log into a site.

applet. A program that performs a specific task and is usually portable between operating systems. Often written in Java, applets can be downloaded from the Internet and run in a web browser.

application server. A server program in a distributed network that provides the execution environment for an application program.

Asynchronous JavaScript and XML. See Ajax.

authenticated user. A portal user who has logged in to the portal with a valid account (user ID and password). Authenticated users have access to all public places.

authentication. A security service that provides proof that a user of a computer system is genuinely who that person claims to be. Common mechanisms for implementing this service are passwords and digital signatures. Authentication is distinct from authorization; authentication is not concerned with granting or denying access to system resources.

authorization. The process of granting a user, system, or process either complete or restricted access to an object, resource, or function.

B

B2B. See business-to-business.

B2C. See business-to-consumer.

B2E. See business-to-employee.

bind. To establish a connection between software components on a network using an agreed-to protocol. In web services, the bind operation occurs when the service requestor invokes or initiates an interaction with the service at run time using the binding details in the service description to locate, contact, and invoke the service.

bookmark. A customizable, graphical link to databases, views, documents, web pages, and newsgroups.

business-to-business (B2B). Refers to Internet applications that exchange information or run transactions between businesses.

business-to-consumer (B2C). Refers to the subset of Internet applications that exchange information or run transactions between businesses and consumers.

business-to-employee (B2E). A business model that supports electronic communications between a business and its employees.

C

CA. See certificate authority.

card. WML document that provides user-interface and navigational settings to display content on mobile devices.

cascading style sheet (CSS). A file that defines a hierarchical set of style rules for controlling the rendering of HTML or XML files in browsers, viewers, or in print.

certificate authority (CA). A trusted third-party organization or company that issues the digital certificates. The certificate authority typically verifies the identity of the individuals who are granted the unique certificate.

client side aggregation (CSA). Aggregation based on JavaScript and XSLT transformations that are executed on the client.

cloud application. An application that is extended to be accessible through the Internet. Cloud applications use large data centers and powerful servers that host web applications and web services.

cloud computing. A computing platform where users can have access to applications or compute resources, as services, from anywhere through their connected devices. A simplified user interface and application programming interface (API) makes the infrastructure supporting such services transparent to users.

collaboration. The ability to connect customers, employees, or business partners to the people and processes in a business or organization, in order to facilitate improved decision-making. Collaboration involves two or more individuals with complementary skills interacting together to resolve a business problem.

collaborative components. UI-neutral API methods and tag libraries that allow developers to add IBM Lotus collaborative functionality to their portlets.

collaborative filtering. Personalization technology that calculates the similarity between users based on the behaviors of a number of other people and uses that information to make recommendations for the current user.

collaborative portal. A highly personalized desktop-to-web tool designed for specific audiences and communities of users that organizes information, applications, and services for effective community building at the corporate level and for personal use by individuals.

concrete portlet. A logical representation of a portlet object distinguished by a unique configuration parameter (PortletSettings).

confirmable methods. Interface methods that exist on each modifiable interface of a portal resource that allow users to determine whether a modification can be performed or not.

connector. A servlet that provides a portlet access to external sources of content, for example, a news feed from a website of a local television station.

consumer portal. A portal that uses the portlets that a producer portal provides.

content item. Web page content stored in the form of elements, equivalent to a web page in a traditional website. The look and feel of a content item when displayed in a website will depend on what authoring template is used to create the content item and what presentation template is used to display the content.

content management. Software designed to help businesses manage and distribute content from diverse sources.

content partner. See IBM content partner.

content provider. A source for content that can be incorporated into a portal page as a portlet.

controller. A modifiable instance of a portal model which allows to modify the topology of the model, create and delete resources, and create modifiable instances of existing resources.

cooperative portlets. Two or more portlets on the same web page that interact by sharing information.

creation context. A context that defines immutable properties of a resource that you can create

CSS. See cascading style sheet.

D

DB2. A family of IBM licensed programs for relational database management.

deck. An XML document that contains a collection of WML cards.

default portal page. The page that displays to a user at initial portal deployment and before the user completes enrollment. Sometimes used as a synonym for home page.

default public place. A place whose membership automatically includes all portal users and which appears in the Places selector for every user. A user is always a member of this place.

derived page. One or more child pages that have a shared layout that is inherited from the properties of the parent page.

differential page rendering (DPR). Renders only those parts of a portal page that were affected by the a user interaction.

document type definition (DTD). The rules that specify the structure for a particular class of SGML or XML documents. The DTD defines the structure with elements, attributes, and notations, and it establishes constraints for how each element, attribute, and notation can be used within the particular class of documents.

DTD. See document type definition.

dynamic layout. Standard portal layout that consists of rows or columns and is persisted in the database.

E

ECM. See Enterprise Content Management

embedded static page. A static page that is rendered in the content area of the portal.

enrollment. The process of entering and saving user or user group information in a portal.

Enterprise Content Management (ECM). Software and tools designed to enable companies to manage content and documents, optimize business processes, and enable compliance with an integrated infrastructure.

Enterprise Information Portal. Software developed by IBM that provides tools for advanced searching, and content customization and summarization.

Extensible Markup Language (XML). A standard metalanguage for defining markup languages that is based on Standard Generalized Markup Language (SGML).

Extensible Stylesheet Language (XSL). A language for specifying style sheets for XML documents. Extensible Stylesheet Language Transformation (XSLT) is used with XSL to describe how an XML document is transformed into another document.

F

federated search. A search capability that enables searches across multiple search services and returns a consolidated list of search results.

G

group.

1. A collection of users who can share access authorities for protected resources.
2. In places, two or more people who are grouped for membership in a place.

governance. The decision making processes in the administration of an organization. The rights and responsibilities of these processes are typically shared among the organization's participants, especially the management and stakeholders.

governance life cycle. A life cycle that represents the states and transitions that can exist in SOA deployment.

governance processes. A process that ensures that compliance and operational polices are enforced, and that change occurs in a controlled fashion and with appropriate authority as envisioned by the business design.

H

helper file. A properties file that WebSphere Portal Express provides to ensure that users specify the correct information that is needed to complete different types of configuration tasks such as configuring an LDAP user registry or a database user registry.

home page. The top-level web page of a portal.

HTML. See Hypertext Markup Language.

HTTP. See Hypertext Transfer Protocol.

HTTP over SSL (HTTPS). A web protocol for secure transactions that encrypts and decrypts user page requests and pages returned by the web server.

HTTPS. See HTTP over SSL.

Hypertext Markup Language (HTML). A markup language that conforms to the Standard Generalized Markup Language (SGML) standard and was designed primarily to support the online display of textual and graphical information, including hypertext links.

Hypertext Transfer Protocol (HTTP). An Internet protocol that is used to transfer and display hypertext and XML documents on the web.

I

i-mode. An Internet service for wireless devices.

IBM content partner (content partner). IBM partner that provides syndicated content for portals.

integrity. In computer security, assurance that the information that arrives at a destination is the same as the information that was sent.

iwidget. An open-source specification that allows for seamless interoperability across various platforms and products.

J

JavaScript. A web scripting language that is used in both browsers and web servers. (Sun)

JavaScript Object Notation. A lightweight data-interchange format that is based on the object-literal notation of JavaScript. JSON is programming-language neutral but uses conventions from languages that include C, C++, C#, Java, JavaScript, Perl, Python.

Jetspeed. The open-source portal that is part of the Jakarta project by Apache.

L

label. A node in a portal that cannot contain any content, but can contain other nodes. Labels are used primarily to group nodes in the navigation tree.

lazy application. An application whose initialization is deferred until first use.

LDAP. See Lightweight Directory Access Protocol.

LDAP directory. A type of repository that stores information on people, organizations, and other resources and that is accessed using the LDAP protocol. The entries in the repository are organized into a hierarchical structure, and in some cases the hierarchical structure reflects the structure or geography of an organization.

light mode. An operation method that enhances portal performance by improving start-up time and reducing memory consumption in production environments.

Lightweight Directory Access Protocol (LDAP). An open protocol that uses TCP/IP to provide access to directories that support an X.500 model and that does not incur the resource requirements of the more complex X.500 Directory Access Protocol (DAP). For example, LDAP can be used to locate people, organizations, and other resources in an Internet or intranet directory.

load balancing. The monitoring of application servers and management of the workload on servers. If one server exceeds its workload, requests are forwarded to another server with more capacity.

M

mandatory place. A shared place, either a public place or a restricted place, in which all portal users must be members. Only portal administrators can designate a shared place to be a mandatory place. Because membership is automatic and required, portal users cannot join or leave mandatory places.

membership. The state of being a portal user and a place member. Membership in the portal is controlled by the administrator during the installation and set up of portal servers. Membership in places is controlled by a place manager, who determines the level of access for each place member: participant, place designer, or place manager.

mashup. A graphical interface that features two or more reusable web applications (widgets) presenting seemingly disparate data in an understandable combination for a specific purpose.

meta search. A search across one or more search engines. A meta search engine provides a meaningful subset of search functionality through an abstraction layer that is generic enough to support a wide variety of search services.

messaging. A method for communication between programs. Messaging can be synchronous or independent of time.

middleware. Software that acts as an intermediate layer between applications or between client and server. It is used most often to support complex, distributed applications in heterogeneous environments.

model view controller (MVC). A software architecture that separates the components of the application: the model represents the business logic or data; the view represents the user interface; and the controller manages user input or, in some cases, the application flow.

modifiable. An interface for modifying portal resources that exist in the read only model.

MVC. See model view controller.

N

News Industry Text Format (NITF). An XML-based format that defines the structure and content of news articles.

News Markup Language (NewsML). An XML-based format for publishing news-related information.

NewsML. See News Markup Language.

NITF. See News Industry Text Format.

node. A logical group of managed servers.

O

OCS channel. See open content syndication channel.

open content syndication channel (OCS channel). An XML-based format for syndicated content.

P

page. A node in a portal that can contain content in addition to labels and other pages. Pages can contain child nodes, column containers, row containers, and portlets.

participant. A member of a portal place who can visit and use the place. By default, all portal users are participants in public places.

people awareness. The collaboration feature that provides access to people from various contexts. People awareness lets you see references to people and contact people by name through the Sametime online status indicator. Throughout the portal, wherever you see the name of a person, you can view the person's online status, send email, initiate a chat, or share an application via an electronic meeting.

people finder. A portlet that enables users to find, view information about, and contact individuals in their organization. Administrators can configure people finder to display information details such as email address, job title, and location.

person. An individual authenticated by the portal and having a person record in one or more corporate directories. Persons can be members of places, public groups within the organization's corporate directory, or personal groups that a user defines.

person card. An interface that displays information about a registered user such as phone number and online status (if Sametime is enabled), and additional details typically found on a business card. Available actions let you view the person's complete profile and, depending on how the portal is configured, send email, chat, and link to Lotus Connections features such as Communities, Activities, and Blogs.

person link. A reference to a person's name or a group name that appears with the Sametime online status indicator. The reference lets you view the person's online status, send an email, start a chat, or share an application using an electronic meeting, among other actions shown on the person link menu.

personal group. In Sametime Connect, a group of people designated by the user as a group. A user can choose individuals from the public Directory (public group) and create personal groups, which are then stored locally. Users can add and remove people from a personal group, whereas the membership of the public group is defined by the owner of the public Directory.

personalization. The process of enabling information to be targeted to specific users based on business rules and user profile information.

pervasive computing. The use of a computing infrastructure that supports information appliances from which users can access a broad range of network-based services, including Internet-based e-commerce services.

place designer. A member of a place who can edit place layout and bookmarks.

place manager. A member of a place who can edit place membership, layout, and bookmarks.

place member. A individual or group who has joined or been granted access to a place. Place members have three levels of access to a place: manager, designer, and participant.

place template. A format for use in creating a place. The portal provides a set of default templates for creating various types of places. Portal administrators may allow users to create, modify, and delete new templates.

policy. A set of rules and actions that are required to be performed when certain events or status conditions occur in an environment. Policies are implemented using the IPL.

port. An end point for communication between applications, generally referring to a logical connection. A port provides queues for sending and receiving data. Each port has a port number for identification.

port type. An element in a Web Services Description Language (WSDL) document that comprises a set of abstract operations, each of which refers to input and output messages that are supported by the web service.

portal. A single, secure point of access to diverse information, applications, and people that can be customized and personalized.

portal administration. The place where portal administrators set and maintain basic collaboration permissions, place records, place membership records, and server settings for companion products for advanced collaboration.

portal artifacts. Stored in the portal file system. All deliverables of software development are usually artifacts (otherwise referred to as software components).

portal configuration. The Portal Configuration is stored in the portal configuration database. It consists of configuration entities. Each portal resource is represented by one portal configuration entity in the portal database.

portal extension artifacts. Artifacts that belong to components that are installed together with the portal but are not core portal components.

portal farm. A series of identically configured, stand-alone portal server instances that offer a way to maintain a highly scalable and highly available server environment.

portal member. An individual or group who has a user record in the portal directory (LDAP or other directory) and can log in to the portal.

portal solution release. The solution that is developed by the customer and is based on WebSphere Portal. The solution consists of portal configurations, portal artifacts, and portal extension artifacts and is shared between multiple users.

portal theme. The style element that gives a place a particular look. The portal provides several themes, similar to virtual wallpaper, which can be chosen when creating a place.

portlet. A reusable web module that runs on a portal server. Portlets have predefined roles such as retrieving news headlines, searching a database, or displaying a calendar.

portlet API. The set of interfaces and methods that are used by Java programs running within the portal server environment to obtain services.

portlet application. A collection of related portlets that can share resources with one another.

portlet container. A column or row that is used to arrange the layout of a portlet or other container on a page.

portlet control. A portlet registry setting that renders the outer frame for a portlet.

portlet framework. The set of classes and interfaces that support Java programs running within the portal server environment.

portlet palette. A web module that enables users to browse available portlets organized by category, search for individual portlets, and add them to a portal page by dragging to the desired location.

pre-rendered site. A complete website saved to disk in HTML that can be used as a live site and displayed to users using either Web Content Manager or a web server.

presentation template. A template that determines the structure of each web page in the site and which elements and components are displayed on each page. HTML defines the default properties and layout of the template.

producer definition. A set of interfaces that are defined for the producer portal. The producer definition can include the producer service description, the producer portal URL, and the security setup.

producer portal. A portal that provides portlets as a service so that other portals, called consumer portals, can use the portlets and make the portlets available to their users.

property extension database. A database that is used to store additional attributes that cannot be stored in the LDAP user registry.

provisioning. The process of setting up and maintaining a user's access to a system.

PSTN. See public switched telephone network.

public group. A group of individuals, known to all portal users, that the administrator has created or that exists in the organization's corporate directory. Only administrators can modify and manage public groups.

public place. A shared place that is open to all portal users. The person who creates the place (and who automatically becomes the place manager) designates it as a public place during place creation.

public switched telephone network (PSTN). A communications common carrier network that provides voice and data communications services over switched lines.

pure server side portlet. A normal server side portlet that uses Java and Java server pages, but usually uses no JavaScript.

R

registered user. A portal user who has a user ID and password for logging in to a portal.

Representational State Transfer (REST). A software architectural style for distributed hypermedia systems like the World Wide Web. The term is also often used to describe any simple interface that uses XML (or YAML, JSON, plain text) over HTTP without an additional messaging layer such as SOAP.

REST. See Representational State Transfer.

restricted place. A shared place that is open to only those individuals and groups whom the place creator (or place manager) adds to the place's membership list. The person who creates the place (and who automatically becomes the place manager) designates the place as a restricted place during place creation.

Rich Site Summary (RSS). An XML-based format for syndicated web content that is based on the RSS 0.91 specification. The RSS XML file formats are used by Internet users to subscribe to websites that have provided RSS feeds.

role. A job function that identifies the tasks that a user can perform and the resources to which a user has access. A user can be assigned one or more roles.

RSS. See Rich Site Summary.

rules-based personalization. Personalization technology that enables you to customize web content based on user needs and preferences, and business requirements.

S

search center. A portlet that enables site users to search for keywords.

search collections. A searchable collection of documents that can span multiple content sources.

search service. A service that is used to define the configuration parameters for a search collection. A search service can be local, remote, inside the product, or outside the product.

SecureWay Directory. An LDAP directory that can store user-related data, such as the user ID, the user name, and passwords.

security. The protection of data, system operations, and devices from accidental or intentional ruin, damage, or exposure.

security manager. A component that is responsible for authenticating user logins.

server side aggregation (SSA). Aggregation based on Java server pages that are executed on the Server.

service. In service-oriented architecture, a unit of work accomplished by an interaction between computing devices.

service description. The description of a web service, which can be defined in any format such as WSDL, UDDI, or HTML.

service provider. A company or program that provides a business function as a service.

service requester. The application that initiates an interaction with a web service. The service requestor binds to the service using the published information and calls the service.

service-oriented architecture (SOA). A conceptual description of the structure of a software system in terms of its components and the services they provide, without regard for the underlying implementation of these components, services and connections between components.

session bean. An enterprise bean that is created by a client and that usually exists only for the duration of a single client/server session. (Sun)

shared place. A place created for a community of people with a common purpose. Shared places can be public or restricted. The place creator (who automatically becomes the place manager) specifies whether a place is public or restricted during place creation.

Short Message Service (SMS). A service that is used to transmit text to and from a mobile phone.

single sign-on (SSO). An authentication process in which a user can access more than one system or application by entering a single user ID and password.

site area. A component contained in a site framework as a way to group similar content items. There can be several site areas within one site framework.

site framework. A structure that consists of a single top-level intelligent page or site area beneath which are stored other intelligent pages, site areas, and content items. The hierarchical set of intelligent pages and site areas define the navigational structure of the website.

site template. A pre-built sample site that can be used to streamline the process of developing a custom portal.

SMS. See Short Message Service.

source portlet. The portlet that sends the information to other portlets.

SSO. See single sign-on.

staging. The process of moving solution releases from development to production.

stand-alone static page. A static page that renders the complete browser content.

static page. A portal page that references a static layout.

static layout. The layout of a page that is based on a plain HTML page that may contain references to portlets.

subscribe. To register to access data published by another application or system.

subscriber. The consumer of a business service.

T

TAI. See trust association interceptor.

target portlet. The portlet that receives the information from the source portlet

template library. The database, known as the Portal Template Catalog, that stores place template specifications and portlets forms, subforms, and profiles.

theme. The style element that gives a place a particular look. The portal provides several themes, similar to virtual wallpaper, from which you can choose when creating a place.

transcoding technology. Content adaptation to meet the specific capabilities of a client device.

transport. The process or protocol mechanism of transferring an XML message or document between parties as part of a meaningful, reliable exchange. The most common transports for web services are SOAP/HTTP, SOAP/HTTPs, and SOAP/JMS.

trust association interceptor (TAI). The mechanism by which trust is validated in the product environment for every request received by the proxy server. The method of validation is agreed upon by the proxy server and the interceptor.

U

Uniform Resource Identifier (URI). A unique address that is used to identify content on the web, such as a page of text, a video or sound clip, a still or animated image, or a program. The most common form of URI is the web page address, which is a particular form or subset of URI called a Uniform Resource Locator (URL). A URI typically describes how to access the resource, the computer that contains the resource, and the name of the resource (a file name) on the computer.

Uniform Resource Locator (URL). The unique address of an information resource that is accessible in a network such as the Internet. The URL includes the abbreviated name of the protocol used to access the information resource and the information used by the protocol to locate the information resource.

Universal Description, Discovery, and Integration (UDDI). A set of standards-based specifications that enables companies and applications to quickly and easily find and use web services over the Internet. See also Web service.

URI. See Uniform Resource Identifier.

URL. See Uniform Resource Locator.

user group. A group consisting of one or more defined individual users, identified by a single group name.

V

W

W3C. See World Wide Web Consortium.

WAP. See Wireless Application Protocol.

WAR. See Web archive.

WAR file. See Web archive.

Web archive (WAR). A compressed file format, defined by the Java EE standard, for storing all the resources required to install and run a web application in a single file.

Web content library. A library that stores items required for displaying or creating web content, such as workflow items, an authoring template, a presentation template, site areas, and content items. Most systems have at least two web content libraries, one for design items and one for web content.

Web crawler. A type of crawler that explores the web by retrieving a web document and following the links within that document.

Web service. A self-contained, self-describing modular application that can be published, discovered, and invoked over a network using standard network protocols. Typically, XML is used to tag the data, SOAP is used to transfer the data, WSDL is used for describing the services available, and UDDI is used for listing what services are available. See also Web Services Description Language.

Web service endpoint. An entity that is the destination for web service messages. A web service endpoint has a Uniform Resource Identifier (URI) address and is described by a Web Service Definition Language (WSDL) port element.

Web service interface. A group of operations described by the content of a Web Service Definition Language (WSDL) 1.1 port element. These operations can provide access to resource properties and metadata. (OASIS)

Web service semantics (WSDL-S). A technical specification that defines a mechanism to associate semantic annotations with web services that are described using Web Service Description Language (WSDL).

Web Services Description Language (WSDL). An XML-based specification for describing networked services as a set of endpoints operating on messages containing either document-oriented or procedure-oriented information. See also Web service.

Web Services Interoperability Organization (WSI). An open industry organization that promotes web services interoperability across platforms, operating systems, and programming languages.

Web Services Policy Framework (WS-Policy). A model and framework for describing the capabilities, requirements, and general characteristics of a web service as a policy assertion or a collection of policy assertions.

Web Services Resource Framework (WSRF). The set of specifications that define the specific rendering of a Web Services Resource (WS-Resource), the association of that resource with the web service interface, and the messages that define the querying and updating of the properties of that resource.

widget. A graphical interface that features two or more reusable web applications (widgets) presenting seemingly disparate data in an understandable combination for a specific purpose.

wire. To connect two or more components or cooperative portlets so that they work together. In an application, wiring identifies target services; for portlets changes in the source portlet automatically update the target portlets.

Wireless Application Protocol (WAP). An open industry standard for mobile Internet access that allows mobile users with wireless devices to easily and instantly access and interact with information and services.

Wireless Markup Language (WML). A markup language based on XML that is used to present content and user interfaces for wireless devices such as cellular phones, pagers, and personal digital assistants.

workflow. The sequence of activities performed in accordance with the business processes of an enterprise.

World Wide Web Consortium (W3C). An international industry consortium set up to develop common protocols to promote evolution and interoperability of the World Wide Web.

WML. See Wireless Markup Language.

WSDL. See Web Services Description Language.

WSDL-S. See Web service semantics.

WSI. See Web Services Interoperability Organization.

WSRF. See Web Services Resource Framework.

X

XML. See Extensible Markup Language.

XSL. See Extensible Stylesheet Language.
