You can schedule the FederationTaskHandler to periodically retrieve (import) Connections data. For more information about scheduling the FederationTaskHandler, see *Administering tag federation*.

Procedure

Using XML access, run
com.ibm.wps.cp.tagging.federation.taskhandler.FederationTaskHandler

Results

During the import of the tags if you exceed the number of available connections, increase the value for the configuration parameter `max-connections-per-host` for the corresponding policy in the Ajax Proxy configuration file `proxy-config.xml`

Related tasks:

"Administering tag federation" on page 1326
When tags from remote systems, such as IBM Connections are integrated into your WebSphere Portal Express site, you need to schedule tasks to retrieve tags and related data from the remote system, and later to clean them up from the portal. You can also redirect the rendering of federated resources to IBM Connections and add icons to federated resources.

Related reference:

"CP Configuration Service for tagging and rating" on page 312
The CP Configuration Service provides the properties for tagging and rating.

"Using the XML configuration interface to administer tags and ratings" on page 1343
You can use the XML configuration interface to manage tagging and rating in the portal. For example, you can move tagspaces and ratings between portal versions or for staging purposes.

IBM Connections: Installing the IBM Connections Portlets for IBM WebSphere Portal

Integrating IBM Connections files

To integrate files with your portal, register the Content Management Interoperability Services (CMIS) entry points with the WP FederatedDocumentsService resource environment provider. After this configuration is complete, content authors insert links to documents hosted on the Connections server. Using personalization, authors can also render inventories of folders that are hosted in files.

About this task

Authors can use the generic CMIS file picker dialog, in the IBM Web Content Manager rich text editor, to insert links to documents hosted on Connections files. Authors can also use the personalization component in Web Content Manager to render inventories of folders on the Connections server

"Determining the URL of the CMIS service document"
Connections Files offers a set of CMIS service documents that provide specific views of the content that is stored in files. Determine which CMIS API service document URL you need before starting the configuration.

"Set up predefined IBM Connection servers" on page 756
Configuring integration with files is similar to configuring other federated documents. You must specify the remote server URL, a display name, and the supported interface type of the remote server.

"Configure federated documents feature for files" on page 757
Complete the configuration of the federated documents feature to communicate with Connections.

Determining the URL of the CMIS service document

Connections Files offers a set of CMIS service documents that provide specific views of the content that is stored in files. Determine which CMIS API service document URL you need before starting the configuration.

About this task

The set of CMIS service documents includes service documents that define the following things:

- User-specific view for the currently logged in user
- Views for individual specific communities

Procedure

Determine the service document URL.
The CMIS service document location can be determined based on the following pattern: *base URL of files service*`/basic/cmis/`*CMIS Service Doc identifier*, where:

The *base URL of files service* denotes the entry URL to your Connections files service. The files service URL is typically the Connections base URL concatenated with the files service context root. The default context root is `/files` .

The *CMIS Service Doc identifier* identifies a specific CMIS service document. Information about individual Connections CMIS service document identifiers is available in the file CMIS API documentation.

For example, for an Connections server with the URL `www.example.com:9444` and that uses the default context root, the CMIS service document location is `https://www.example.com:9444/files/basic/cmis/my/servicedoc`

Related information:

Files CMIS API: Retrieving the Files CMIS API service document

Set up predefined IBM Connection servers

Configuring integration with files is similar to configuring other federated documents. You must specify the remote server URL, a display name, and the supported interface type of the remote server.

About this task

To specify the values, you must add custom properties. Each property includes a *suffix*. The value of the suffix is used to group related properties for each server. Use the same suffix value for properties that are related to the same server. The suffix can be any value if it is unique across the property keys.

Procedure

1. Log on to the WebSphere Integrated Solutions Console.
2. Click **Resources** > **Resource Environment** > **Resource Environment Providers**.
3. Click **WP FederatedDocumentsService**.
4. Under **Additional Properties**, click **Custom Properties**.
5. Register the CMIS service document with the federated documents feature.
   a. Click **New** and add this property and value:
   `wp.federated.documents.ic_personalized_sc.url=`*`https://www.example.com:9444/files/basic/cmis/my/servicedoc`*

   Replace *https://www.example.com:9444/files/basic/cmis/my/servicedoc* with your service document location.
   b. Click **New** and add this property and value:
   `wp.federated.documents.ic_personalized_sc.title.default=`*`Your Documents on IBM Connections`*
6. Specify the interface type.
   a. Click **New** and add this property: `wp.federated.documents.`*`suffix`*`.type`
   b. For the value, specify: `CMIS`

   You can also add more properties, such as:

   wp.federated.documents.ic_personalized_sc.nls.resources
   Value: The name of the resource bundle that contains the translated title and description used to identify this source server in the user interface. If this property is not defined, the default title is used. If no default title and no resource bundle are defined, the value of the **`wp.federated.documents.ic_personalized_sc.url`** property is used in the user interface.

   wp.federated.documents.ic_personalized_sc.vault.slot
   Value: The name of the credential vault slot that stores the credentials used for authentication with the remote server. Credential vault slots are set up and managed by the portal administrator. This property defines the default credential vault slot that is predefined in the user interface, although the user can also select a different slot if one is available. If this property is not defined, the user interface does not display a default credential vault slot, but you can still select a slot from the available list. This property is optional.

Note: The credential vault slot must contain the credentials that are required for authentication with the remote server.

wp.federated.documents.ic_personalized_sc.override.authentication.enabled
Value: `true` or `false`. When set to `true`, the user can change the authentication method for the server in the user interface. When set to `false`, the user interface does not display the field to change the authentication method. The default value is `true`.

Configure federated documents feature for files

Complete the configuration of the federated documents feature to communicate with Connections.

Procedure

1. Specify whether credential vaults slots are used for authentication with remote servers.

   Because you can access federated documents through either the personalization editor or the rich text editor that is provided with Web Content Manager, you can configure credential vault slots for each method independently.

   a. If you are accessing federated documents through the personalization editor, click **wp.federated.documents.pzn.vaultselection.enabled**. To enable credential vaults slots, set the value to `true`, or, to disable credential vault slots, set the value to `false`. By default, the value is `true`.

   b. If you are accessing federated documents through the rich text editor in Web Content Manager, click **wp.federated.documents.wcm.vaultselection.enabled**. To enable credential vaults slots, set the value to `true`, or, to disable credential vault slots, set the value to `false`. By default, the value is `true`.

   If you enable credential vault slots, users can select a credential vault slot in the user interface. You can also use the property **wp.federated.documents.*suffix*.vault.slot** to specify a default credential slot to be used with a given remote server.

2. If you enable credential vault slots, grant access to credential vault slots for all authenticated users.

   a. Log in to the portal as an administrator.

   b. Click the **Administration menu** icon. Then, click **Access** > **Resource Permissions**.

   c. From the list of resource types, click **Virtual Resources**.

   d. For the ADMIN_SLOTS resource, click the **Assign Access** icon.

   e. Edit the User role, and add the All Authenticated Portal Users group to the role.

3. Optional: Configure the amount of data that is returned for the summary metadata attribute of the document.

   a. Click **Resources** > **Resource Environment** > **Resource Environment Providers**.

   b. Click **WCM WCMConfigService**.

   c. Under **Additional Properties**, click **Custom Properties**.

   d. Click **wcm.pzn.ecm.max.field.length**, and enter the number of characters to be returned. If no value is specified, the default value is 128 characters.

4. Optional: Configure whether property changes are automatically loaded.

By default, the Federated Documents service automatically reloads properties at a specified interval, without requiring you to restart the portal. You can change the automatic reloading behavior or modify the reloading interval.

a. Click **Resources** > **Resource Environment** > **Resource Environment Providers**.
b. Click **WP FederatedDocumentsService**.
c. Under **Additional Properties**, click **Custom Properties**.
d. Click **wp.federated.documents.document.service.reload.disabled**, and specify a value of `true` to disable automatic reloading of properties. The default value is `false`.
e. Click **wp.federated.documents.document.service.reload.interval**, and specify the interval in seconds for reloading properties. The default value is 3 seconds.

5. Save your changes. The Federated Documents service automatically reloads any updated properties. If you disabled automatic reloading, restart the portal server.

Related tasks:

Inserting a link to remote content
You can insert links to remote content into elements that contain a rich text field by using the **Insert Link to Remote Document** button in the rich text editor. Only remote content that is configured remote server access can be selected by using this button.

"Personalizing federated documents" on page 1827
Portal Personalization provides the federated documents feature to retrieve metadata about documents that are stored in external content management systems or document repositories. Examples of these systems include IBM Content Manager, IBM FileNet® Content Manager, and Microsoft Sharepoint. You can use a personalization component in IBM Web Content Manager to display metadata from federated documents and to create links to download or open the documents.

Configuring community pages

Configure how you want community pages access to work in your portal site. For example you can configure community pages to automatically grant access to the page, how many child pages affected by community associations, and more.

About this task

Procedures in this section are not required. Complete only the configuration procedures that you need.

"Automatically grant page access to community members" on page 759
If you want community members to automatically be able to access the page, without explicitly configuring access, you must enable that feature. Community membership must be integrated with portal security before you can enable this feature.

"Overriding access control integration during community page instantiation" on page 760
The **Restrict view access to this page to community members** setting on a community page automatically grants access to the page to members of the associated community. When specified on a page template, the setting is also applied to any pages that are created from the template. However, you can override this setting on a page template by defining a page parameter.

"Configure limits for propagation of community associations" on page 760
You can control how many nested child pages that are affected by community associations and changed community associations.

"Configuring the number of retrieved communities" on page 761
You can define how many communities are retrieved from the Connections server when searching for communities in the Page Associations window.

Related information:

Single sign-on for authentication

Automatically grant page access to community members

If you want community members to automatically be able to access the page, without explicitly configuring access, you must enable that feature. Community membership must be integrated with portal security before you can enable this feature.

Before you begin

About this task

After this feature is enabled, you see a **Restrict view access to this page to community members** check box on the Page Associations window. If you selected the check box, community members have access to the page. This access is in addition to any access that you explicitly grant to the page. Community member access to the parent page is not automatically granted to the community page.

Procedure

1. From the portal server, log in to the WebSphere Integrated Solutions Console.
2. Click **Resources** > **Resource Environment** > **Resource Environment Providers**.
3. Click **WP ConnectionsIntegrationService**.
4. Under **Additional Properties**, click **Custom Properties**.
5. Update the value for the **community.group.mapper** property to the string `default`.
6. When integrating community membership and portal security, you can define the default access level that is granted to users.
   a. Edit the **community.member.access.level** property.
   b. Specify the role that is used to determine access. The default value is `Privileged User`.

      Depending on this role type, the set of role types that are blocked for inheritance on the page is defined as the set of all role types that are fully implied by the role type. For example, with the Privileged User role, the implied role types are Privileged User and User.

      For a list of available roles and information about the role types, see *Roles.*
7. Save your changes.
8. Restart the WebSphere_Portal server.

Results

The **Restrict view access to this page to community members** check box is available on the Page Association window.

Related concepts:

"Roles" on page 1533
Roles provide task permissions for users on resources. For example, Editor is a role that allows users to view, modify, and create resources. Roles are denoted as `Role@Resource`; for example, `Editor@Portal Page`.

Related information:

Integrating community membership with Portal security

Overriding access control integration during community page instantiation

The **Restrict view access to this page to community members** setting on a community page automatically grants access to the page to members of the associated community. When specified on a page template, the setting is also applied to any pages that are created from the template. However, you can override this setting on a page template by defining a page parameter.

Procedure

To override the **Restrict view access to this page to community members** setting for pages created from the template, set the **`ibm.portal.instantiation.community.access.control.integration`** parameter on the template.
You can set this parameter by editing the page properties in the user interface or by using the XML configuration interface (**`xmlaccess`** command).

Important: When specified, this parameter defines the behavior of the **Restrict view access to this page to community members** setting for pages that are created from the template. The corresponding setting in the Page Associations window for the page template is disregarded.
Specify one of the following values:

`true` The **Restrict view access to this page to community members** setting is enabled for all pages that are created from this template.

`false` The **Restrict view access to this page to community members** setting is disabled for all pages that are created from this template.

Configure limits for propagation of community associations

You can control how many nested child pages that are affected by community associations and changed community associations.

About this task

During this procedure modify the following properties in the WP_ConnectionsIntegrationService resource environment provider:

`child.page.propagation.levels`
The maximum number of page nesting levels that are affected when propagating a community association to child pages. The default value is `1`, which indicates that the association is propagated only to direct child pages of the current page.

To include all nested page levels, regardless of the number of levels, set the property value to `-1`.

To disable the propagation of a community association to child pages, set the property to `0`.

child.page.propagation.threshold

This threshold is based on how many child pages are affected by the propagation of a changed community association. If too many pages are updated, the operation might take too long and fail to complete. By setting this threshold, you can specify whether the control to copy the updated association is displayed in the user interface. If the number of pages to be updated is less than this threshold, the control is displayed. If the number of affected pages exceeds the threshold, the control is not displayed. The default value for this property is `50`.

The number of pages evaluated for this threshold also depends on the value of the **child.page.propagation.levels** property.

Procedure

1. On the portal server, log in to the WebSphere Integrated Solutions Console.
2. Click **Resources** > **Resource Environment** > **Resource Environment Providers**.
3. Click **WP ConnectionsIntegrationService**.
4. Under **Additional Properties**, click **Custom Properties**.
5. Update the values for the **child.page.propagation.levels** property and the **child.page.propagation.threshold** property.
6. Save the property changes.

Configuring the number of retrieved communities

You can define how many communities are retrieved from the Connections server when searching for communities in the Page Associations window.

About this task

During this procedure, modify the following property in the WP_ConnectionsIntegrationService resource environment provider:

community.picker.page.size

This value defines the maximum number of community entries to retrieve from the Connections server when searching for communities in the Page Associations window. The default value is `50`.

The value of this property also determines the number of communities that are retrieved the first time that the Page Associations window is used.

Performance note: If you increase this value too much, the response times of the Connections server can become slow.

Procedure

1. On the portal server, log in to the WebSphere Integrated Solutions Console.
2. Click **Resources** > **Resource Environment** > **Resource Environment Providers**.
3. Click **WP ConnectionsIntegrationService**.
4. Under **Additional Properties**, click **Custom Properties**.
5. Update the value for the **community.picker.page.size** property.
6. Save the property changes.

Configuring Portal to work with Connections in SmartCloud for Social Business

The Connections integration assets that are used to integrate WebSphere Portal Express with on-premise Connections can be used to integrate WebSphere Portal Express with IBM Connections in SmartCloud for Social Business as well.

CF03 "Known limitations for integrating WebSphere Portal Express with IBM Connections in SmartCloud for Social Business"
Some features that are available when you integrate WebSphere Portal Express with an on-premise IBM Connections server are not supported when you integrate WebSphere Portal Express with an Connections server that runs in the SmartCloud for Social Business.

CF03 "Establishing single sign-on (SSO) between the portal installation and IBM Connections in SmartCloud for Social Business" on page 763
Learn about the requirements that must be fulfilled in order to successfully integrate WebSphere Portal Express with IBM Connections in SmartCloud for Social Business. You can provide a user experience where a user logs in one time into WebSphere Portal Express and then automatically sees all integrated Connections information.

CF03 "Configuring a connection between WebSphere Portal Express and IBM Connections in SmartCloud for Social Business" on page 769
Learn how to configure the Connections integration assets to complete calls to IBM Connections in SmartCloud for Social Business.

Known limitations for integrating WebSphere Portal Express with IBM Connections in SmartCloud for Social Business

Some features that are available when you integrate WebSphere Portal Express with an on-premise IBM Connections server are not supported when you integrate WebSphere Portal Express with an Connections server that runs in the SmartCloud for Social Business.

Changes to features in IBM Connections in SmartCloud for Social Business

- The Connections business card on IBM Connections in SmartCloud for Social Business is not exposed to third-party applications.
- Connections Content Manager is not a part of IBM Connections in SmartCloud for Social Business
- Connections profiles reflect users of the same organization. Guests and visitors are ignored.
- Connections profiles API on IBM Connections in SmartCloud for Social Business no longer contains the deprecated board function.
- Seedlists for individual services are not exposed in IBM Connections in SmartCloud for Social Business.
- There is no public access to IBM Connections in SmartCloud for Social Business. A user must be logged in to access data.

The following services are available outside and within a community scope:

- Activity Stream
- Profiles
- Activities

All other services are available only within a community scope.

Changes to features in WebSphere Portal Express

Social Media Publisher
The Social Media Publisher does not support IBM Connections in SmartCloud for Social Business.

Social Rendering
Live names of authors and owners of social objects are not supported by SmartCloud for Social Business. Social rendering cannot be used on public pages, since access to IBM Connections in SmartCloud for Social Business is not possible without an authenticated user.

Community Membership Access Control Integration
The feature to restrict access to portal objects such as pages based on community membership is not supported by IBM Connections in SmartCloud for Social Business. Clear the check box **Limit access to this page to only community members** in the Community Picker Dialog in WebSphere Portal Express.

Portal Tag Cloud Federation
Portal Tag Cloud Federation with IBM Connections in SmartCloud for Social Business is not supported.

Search Integration
RCSS is the only available way to integrate Portal Search with IBM Connections in SmartCloud for Social Business to show both contents in one query, since seedlists are not exposed.

Enabling Portal Navigation in Connections by using Web Application Integrator (WAI)
This integration approach is not available for IBM Connections in SmartCloud for Social Business.

Visitors and Guests
The integration exposes only intra-organizational aspects. Nothing that is related to visitors or guests is exposed.

Connections Business Card
Connections business card in WebSphere Portal Express is not supported by SmartCloud for Social Business.

Establishing single sign-on (SSO) between the portal installation and IBM Connections in SmartCloud for Social Business

Learn about the requirements that must be fulfilled in order to successfully integrate WebSphere Portal Express with IBM Connections in SmartCloud for Social Business. You can provide a user experience where a user logs in one time into WebSphere Portal Express and then automatically sees all integrated Connections information.

Since SmartCloud for Social Business uses a specific user repository, the following requirements are established by using Identity Federation and Security Assertion Markup Language (SAML):

- Users do not have to maintain separate user names and passwords for WebSphere Portal Express and Connections.
- A user logs on one time in to your digital experience and can view:

  - Information from IBM Connections in SmartCloud for Social Business Rest APIs that are rendered by using portlets or IBM Web Content Manager rendering in WebSphere Portal Express.
  - The SmartCloud for Social Business Connections web user interface.
- The infrastructure to complete outbound calls must be configured to support SAML-based single sign-on (SSO), since single sign-on needs to be established for calls from the portal JVM to the Connections server in SmartCloud for Social Business APIs. To configure support for SAML-based single sign-on, you must use one of the following identity providers:
  - To use Tivoli Federated Identity Manager (TFIM) as your identity provider, view the information in *Configuration settings for Tivoli Federated Identity Manager (TFIM)* in the related links section.
  - CF05 To use Active Directory Federation Services (ADFS) as your identity provider, view the information in *Configuration settings for Active Directory Federation Services (ADFS)* in the related links.

  Notes:
  - SAML 2.0 is the only supported version.
  - Active Directory Federation Services (ADFS) is supported beginning with CF05 and later.

The infrastructure for your integrated system is as follows:

- There is an identity provider server in your local environment that uses the same user repository as your portal server.
- SSO between your portal server and the local identity provider system is established.
- The local identity provider server and the SmartCloud for Social Business infrastructure trust each other.

To establish trust between the local identity provider server and SmartCloud for Social Business, complete the steps that are outlined in the SmartCloud for Social Business documentation:

- For general information, see *Federated identity management* in the related links.
- For specifics of enabling federated Identity Management, see *Enabling federated identity management* in the related links.

CF03 "Configuring single sign-on (SSO) for backend calls to IBM Connections in SmartCloud for Social Business" on page 765
The Connections integration assets use a common infrastructure that is called HTTP Outbound to complete calls to the Connections backend server. Learn about the steps that are required to configure the HTTP outbound component to complete calls to IBM Connections in SmartCloud for Social Business.

CF03 "Configuring single sign-on (SSO) for browser-based access to IBM Connections in SmartCloud for Social Business" on page 768
Single sign-on (SSO) for browser-based access to IBM Connections in SmartCloud for Social Business is enabled by using Service Provider Initiated Authentication Flow. You can enable SSO for all links, including external URLs, custom markup, search results, and social portlets.

Related concepts:

"Configuration settings for Tivoli Federated Identity Manager (TFIM)" on page 3039

Federated identity management

Enabling federated identity management

Configuring single sign-on (SSO) for backend calls to IBM Connections in SmartCloud for Social Business

The Connections integration assets use a common infrastructure that is called HTTP Outbound to complete calls to the Connections backend server. Learn about the steps that are required to configure the HTTP outbound component to complete calls to IBM Connections in SmartCloud for Social Business.

Before you begin

If you have the default log level in the WebSphere Integrated Solutions Console set to `INFO` or lower, an increase in logged informational messages might occur when you establish an HTTP Outbound connection to IBM Connections in SmartCloud for Social Business. To disable the logging of informational messages so that only error and warning messages are logged, complete the following steps:

1. Log in to the WebSphere Integrated Solutions Console.
2. Click **Troubleshooting** > **Logs and trace** > **WebSphere_Portal**.
3. Click **Diagnostic trace** in the General Properties section.
4. Click **Change log detail levels** in the Additional Properties section.
5. Change the log detail level for `org.apache.commons.httpclient.*` to `WARNING` or higher. For example, if you are logging informational messages by default and therefore have `*=info` already specified, change the log detail level to `*=info:org.apache.commons.httpclient.*=WARNING`.
6. Click **Apply** > **OK**.
7. Restart your portal server for the changes to take effect.

Procedure

1. Set up a trust association between your portal server and the Connections server by using the SSL certificate. For detailed steps on how to do this, see *Import SSL certificate to set up trust association* in the related links.
2. Create a policy file that defines the URL and metadata that specifies the location of the Tivoli Federated Identity Manager server and which mapping to use. For complete instructions on how to complete this step, see *Configuration settings for Tivoli Federated Identity Manager (TFIM)* in the related links section. For example:

```
<?xml version="1.0" encoding="UTF-8"?>
<proxy-rules xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:noNamespaceSchemaLocation="http://www.ibm.com/xmlns/prod/sw/http/outbound/proxy-config/2.0
 <mapping contextpath="/proxy" url="*" name="proxy"/>
 <mapping contextpath="/myproxy" url="*" name="myproxy"/>

  <!-- todo: change the URL policy according to your need -->
  <policy name="Connections_Cloud_Global" url="https://apps.na.collabserv.lotus.com/*">
   <actions>
    <method>GET</method>
```

```

    <meta-data>
     <name>max-connections-per-host</name>
     <value>50</value>
    </meta-data>
   </policy>
</proxy-rules>
```

3. Push the policy to the WebSphere Portal Express policy store by running the **update-outbound-http-connection-config** task, where *XML_file* is the name of the policy file that you created in step 2:
   - AIX, HP-UX, Linux, Solaris: `./ConfigEngine.sh update-outbound-http-connection-config -DConfigFileName=XML_file -DOutboundProfileType=global`
   - IBM i: `ConfigEngine.sh update-outbound-http-connection-config -DConfigFileName=XML_file -DOutboundProfileType=global`
   - Windows: `ConfigEngine.bat update-outbound-http-connection-config -DConfigFileName=XML_file -DOutboundProfileType=global`

   Note: A preexisting Connections dynamic policy cannot be used for SmartCloud for Social Business. An error can occur if two policies exist. Verify that there is no value set for the **wp.proxy.config.urlreplacement.ibm_connections_policy** in the WP ConfigService Resource Environment Provider.
4. Verify the setup by logging in to WebSphere Portal Express and then calling the following URL: `http://<portalserver>:<portalserverport>/wps/myproxy/https/apps.na.collabserv.com/homeppage/web/updates/#imFollowing/all`.

   Note: You might need to change `apps.na.collabserv.com` to match the host name of your environment.
   If the setup is correct, Activity Stream markup displays without CSS styling. If the setup is incorrect, one of the following errors might occur:
   - A 403 error message displays, which means the proxy is not allowing the request.
   - Markup of the login page displays, which means that authentication failed.

   If an error occurs, check `SystemOut.log` for error messages, verify that the policy file is correct, and rerun the task.

Learn about establishing a single-sign on (SSO) connection for Active Directory Federation Services (ADFS).

Related tasks:

"Import SSL certificate to set up trust association" on page 749
To prevent security alert pop-up windows, add Connections certificates to your portal server. The signer certificate that is used by the Connections server must be trusted by the portal server. The instructions for deploying the IBM Connections portlets include a procedure to import the SSL certificate. If you did not complete that procedure, you must import the certificate to use community pages. For best results, follow the procedures that are provided in the IBM Connections documentation.

Configuring single sign-on (SSO) for browser-based access to IBM Connections in SmartCloud for Social Business

Single sign-on (SSO) for browser-based access to IBM Connections in SmartCloud for Social Business is enabled by using Service Provider Initiated Authentication Flow. You can enable SSO for all links, including external URLs, custom markup, search results, and social portlets.

About this task

By default, if an unauthenticated user is working within an Connections Integration Asset, such as a social rendering list, and clicks a URL that points to the web user interface for IBM Connections in SmartCloud for Social Business, the user is redirected to the Connections login screen. This redirect to the Connections login screen occurs if the user is not authenticated or if their authentication expired. Enabling Service Provider Initiated Authentication Flow prevents this redirect to the Connections login screen. Instead, the user is authenticated by using the Tivoli Federated Identity Manager server.

Procedure

1. Contact SmartCloud for Social Business support by emailing `cloudcsg@us.ibm.com`.
2. In your email, request to have Service Provider Initiated Authentication Flow enabled for your system.

Results

If you enable a Service Provider Initiated Authentication Flow, the following scenario occurs the first time that a user clicks a URL that points to the web user interface for IBM Connections in SmartCloud for Social Business:

Note: The user is not yet authenticated with IBM Connections in SmartCloud for Social Business.

1. In the prompt that opens, the user selects **Use My Organization's Login Page**.
2. The user specifies their email address.
3. The user is redirected to the local Tivoli Federated Identity Manager server and then back to the IBM Connections in SmartCloud for Social Business web user interface without any further user interaction.
4. The user is asked if they want to be remembered. The user specifies yes.
5. The requested content displays for the user.

If the user specifies that they want to be remembered and does not clear their browser's cookies, the following scenario occurs the next time that the user clicks a URL that points to the web user interface for IBM Connections in SmartCloud for Social Business:

Note: The user is not yet authenticated with IBM Connections in SmartCloud for Social Business.

1. The user is redirected to the local Tivoli Federated Identity Manager server and then back to the IBM Connections in SmartCloud for Social Business web user interface without any further user interaction.
2. The requested content displays for the user.

The automatic redirect to the local Tivoli Federated Identity Manager server and back to IBM Connections in SmartCloud for Social Business occurs because the portal server and the local Tivoli Federated Identity Manager server are in a single sign-on domain. Therefore, the Tivoli Federated Identity Manager server knows the user and can directly initiate a redirect back to the IBM Connections in SmartCloud for Social Business page without any user interaction.

Configuring a connection between WebSphere Portal Express and IBM Connections in SmartCloud for Social Business

Learn how to configure the Connections integration assets to complete calls to IBM Connections in SmartCloud for Social Business.

About this task

The instructions for deploying the Connections portlets include a procedure to configure the following settings. If you did not complete that procedure, you must complete the following steps.

Procedure

1. Configure the URL for the Connections server by completing the following steps. You must create a custom property that stores the URL for the Connections server. The URL must include the port number and specify the HTTPS protocol.
   a. Log in to the WebSphere Integrated Solutions Console.
   b. Click **Resources** > **Resource Environment** > **Resource Environment Providers**.
   c. Select **WP ConnectionsIntegrationService**.
   a. Within **Additional properties**, click **Custom properties**.
   b. Click **globalBaseURL** and update the value to the URL of the Connections server. For example:

      ```
      https://apps.na.collabserv.com
      ```

   c. Click **globalBaseURLUnsecured** and update the value to the URL of the Connections server. For example:

      ```
      https://apps.na.collabserv.com
      ```

2. Configure the Connections server type by setting the custom property **`server.type`** in the WP Connections Integration Service resource environment provider in the WebSphere Integrated Solutions Console. For detailed steps on how to set the **`server.type`** property, see *Configuring the IBM Connections server type* in the related links.

Related tasks:

Chapter 8. Backup and restore

Backup and recovery of data files and databases is an essential operation for any business system, particularly for data and applications that run in production environments. Create and follow a plan for backing up and recovering data on all tiers of your IBM WebSphere Portal Express deployment. IBM Installation Manager must also be included in backup and recovery planning. If you back up the WebSphere Portal Express file structure and then install a fix pack, the WebSphere Portal Express and IBM Installation Manager become out of sync after you restore the WebSphere Portal Express file system. This condition is not recoverable.

Backup and recovery include the WebSphere Portal Express file system and databases. Your backup and recovery plan needs to address each deployment tier: Complete system backup for catastrophic failures, back up of middleware such as WebSphere Portal Express and IBM WebSphere Application Server, and backup of individual applications that run on the middleware. Backup and recovery can be done on any or all of these tiers, depending on the needs of your portal deployment.

When you create a backup and recovery plan, consider these general questions:

- What procedure will you use to back up data?
- How often will you back up data?
- What are the trade-offs between online and offline backups?
- How does the scope of your portal deployment affect the backup and recovery strategy? For example, the number of users and the volume and importance of the data that is stored and used in applications affect your decisions about backup and recovery practices.
- Will you use IBM Tivoli Storage Manager or other utility to back up the file system?

Attention: Backing up and recovering a WebSphere Portal Express installation includes the WebSphere Application Server runtime environment and all applications that are deployed on WebSphere Portal Express. However, if applications use remote information sources outside of the WebSphere Portal Express databases and the LDAP directory, you need to consider these remote sources. Develop backup and recovery procedures for these remote sources as part of your comprehensive strategy.

"Guidelines for Idle Standby deployments" on page 772
If IBM WebSphere Portal Express is deployed in an Idle Standby topology, both a primary node and a secondary node are running in a cluster. The primary node is the active node, and the secondary node is the backup node. In this topology, there is no difference in database backup and restore because all cluster members use the same WebSphere Portal Express databases. However, you need to consider some additional factors when you back up and recover the file system in an Idle Standby deployment.

"Database considerations for backup and restore" on page 772
Before you back up IBM WebSphere Portal Express databases, determine whether you need to perform offline or online backup, what your requirements are for storage capacity and backup frequency, and your preferred utility.

"Backing up files, databases, and the LDAP server(s)" on page 774
Periodically run an automated backup procedure for the IBM WebSphere Portal

Express file system, databases, and LDAP server(s) using a backup and recovery utility of your choice. Remember to run the backup procedure before performing critical system-wide changes, such as upgrading to a new version of WebSphere Portal Express or installing interim fixes and fix packs.

"Restoring files, databases, and the LDAP server(s)" on page 779
When necessary, restore the IBM WebSphere Portal Express file system, databases, and LDAP server or servers that you backed up.

Guidelines for Idle Standby deployments

If IBM WebSphere Portal Express is deployed in an Idle Standby topology, both a primary node and a secondary node are running in a cluster. The primary node is the active node, and the secondary node is the backup node. In this topology, there is no difference in database backup and restore because all cluster members use the same WebSphere Portal Express databases. However, you need to consider some additional factors when you back up and recover the file system in an Idle Standby deployment.

About this task

In an Idle Standby deployment, adhere to these guidelines:

Procedure

1. Follow the file system backup and recovery procedures on both the primary and additional nodes.
2. Back up the file system of the Deployment Manager configuration, the master configuration repository for the cell, by using one of the following methods:
   - Use the simple commands that are provided by IBM WebSphere Application Server: `backupConfig` and `restoreConfig`.
   - Use IBM Tivoli Storage Manager or other utility to back up the Deployment Manager profile directory, where this configuration information resides.
3. When you restore WebSphere Portal Express databases and file systems, make sure to restore the Deployment Manager configuration at the same time that the primary node and secondary node file systems are restored. Then, complete a node synchronization of both nodes by using the Deployment Manager WebSphere Integrated Solutions Console. This step ensures that the configuration is identical on both nodes and is consistent with the restored databases.

Database considerations for backup and restore

Before you back up IBM WebSphere Portal Express databases, determine whether you need to perform offline or online backup, what your requirements are for storage capacity and backup frequency, and your preferred utility.

The backup method that you use depends on the type of deployment and the level of service that is being offered. Consider the following factors to determine whether to perform offline or online backup:

- Small or pilot deployments, including deployments with intermittent use, are best served by performing offline backups.

  Offline backups require that you stop all active applications that are connected to the database. When you perform an offline backup, the backup file that is created is a complete copy of all data stored in the database. Therefore, each offline backup requires the same amount of storage space as the entire database.

With small deployments, creating multiple full backups is more manageable than backing up larger systems with large amounts of data. Schedule regular downtime for backups during the organization's off-hours.

- Large deployments, including deployments that require continuous availability, are best served by performing online backups.

  Online backups can be performed while the database remains in service running applications; therefore, online backups require planning.

  As part of its normal operation, databases create logs that record changes to the database. Databases created with default parameters create *circular* logs, in which data is eventually overwritten. Setting up online backups requires that you store the logs on disk as *archive* logs. An online backup uses checkpoints in the log to back up incremental data or data changes rather than making a complete copy of the data as the offline backup process does. Because the logs grow in number and size over time as the database is used, you must ensure that the required storage is available. You will also need to back up the archived logs periodically because they are used during the data recovery and restoration process.

  For online backups, decide when to use incremental backups or delta backups. Both types of online backup are more space-efficient than full backups.

  – An *incremental backup* is a backup image that contains only portal pages that have been updated since the last full backup.
  – A *delta backup* is a copy of all database data that has changed since the last successful backup.

  A typical scheme is to schedule a full online backup on the first day of the week, followed by delta backups on the next two days, an incremental backup on the following day, delta backups on the next two days, and concluding with an incremental backup on the last day of the week.

Next, consider the data storage requirements and the resources and utilities that are available to you:

- Identify the resources needed for storing the backed-up database files.
- Determine a strategy for archiving the backed-up database files. For example, you may want to save a weekly full backup to tape and store the tape offsite.
- Decide which backup utilities to use.

  You can use IBM Tivoli Storage Manager to automate database backups and to organize and maintain the database backup files.

  You can also use tools and commands provided by your database to manage the backup procedures.

  Note if using DB2: For scheduling backup scripts, you can use either the DB2 Backup Wizard or the DB2 Task Center.

  – The Backup Wizard provides a simple, step-by-step user interface for configuring backup options, selecting a storage location for backup data files, and scheduling the backup.
  – The Task Center is an administrative component that allows you to create and schedule scripted functions.

Backing up files, databases, and the LDAP server(s)

Periodically run an automated backup procedure for the IBM WebSphere Portal Express file system, databases, and LDAP server(s) using a backup and recovery utility of your choice. Remember to run the backup procedure before performing critical system-wide changes, such as upgrading to a new version of WebSphere Portal Express or installing interim fixes and fix packs.

About this task

Perform the following tasks to back up the WebSphere Portal Express file system, databases, and LDAP server(s):

1. "Completing prerequisites for backup"
   Before you back up the WebSphere Portal Express installation, decide which utility to use and whether to perform online backup or offline backup.
2. "Backing up the WebSphere Portal Express file system"
   Periodically run an automated backup procedure for the IBM WebSphere Portal Express file system.
3. "Backing up the LDAP server(s)" on page 775
   If you have made system-wide changes and are using an LDAP user registry, back up your LDAP server.
4. "Backing up the WebSphere Portal Express database" on page 775
   Periodically run an automated backup procedure for the IBM WebSphere Portal Express databases.
5. "Backing up the IBM Installation Manager" on page 779
   IBM Installation Manager must also be included in backup and recovery planning. If you back up the WebSphere Portal Express file structure and then install a fix pack, the WebSphere Portal Express and IBM Installation Manager become out of sync after you restore the WebSphere Portal Express file system. This condition is not recoverable.

Completing prerequisites for backup

Before you back up the WebSphere Portal Express installation, decide which utility to use and whether to perform online backup or offline backup.

Before you begin

- Determine whether you want to use IBM Tivoli Storage Manager or another backup and recovery utility. Refer to the Tivoli Storage Manager documentation or the documentation for the utility that you choose to use.
- Determine whether you want to perform an online backup or an offline backup.
  - An online backup occurs while the portal servers are operational when you run the backup procedure.
  - An offline backup occurs when the portal servers are stopped prior to running the backup procedure.

  If you choose to use an online backup, make sure that the techniques and tools used for file system and database backup support the capturing of online backups where open files and database changes can be encountered during the backup procedure.

Backing up the WebSphere Portal Express file system

Periodically run an automated backup procedure for the IBM WebSphere Portal Express file system.

Procedure

1. If you are performing an online backup, go to Step 3.
2. If you are performing an offline backup, stop all servers.
   a. If applicable, stop all external HTTP servers.
   b. Stop all of the WebSphere Portal Express servers.
3. Back up all WebSphere Portal Express files and subdirectories under the directory *PortalServer_root*.
4. Back up all IBM WebSphere Application Server files under the directory *wp_profile_root* to capture the complete runtime environment.
5. Back up other WebSphere Application Server files under the directory *AppServer_root*.
6. Back up the IBM Installation Manager agent data location. This location contains information about the installed offerings and fixes. For details on the default location of this directory, see Agent Data Location in the Related information section.
7. Back up additional custom files outside of the `PortalServer`, profile, or `AppServer` directories; such as SSL certificates or shared libraries; that your WebSphere Portal Express server might use.

Related information:

Agent data location

Backing up the LDAP server(s)

If you have made system-wide changes and are using an LDAP user registry, back up your LDAP server.

About this task

Refer to the appropriate product documentation for information about how to back up the LDAP server:

- For IBM Directory Server, refer to IBM Directory Server Information Center.
- For IBM Domino, refer to the Directory Services topics in the Domino Administrator Help.
- For other LDAP servers, refer to that server documentation for instructions.

Related tasks:

"Completing prerequisites for backup" on page 774
Before you back up the WebSphere Portal Express installation, decide which utility to use and whether to perform online backup or offline backup.

Backing up the WebSphere Portal Express database

Periodically run an automated backup procedure for the IBM WebSphere Portal Express databases.

About this task

Note: The database backup should correspond to when you back up your file system.

Refer to the appropriate product documentation for information about how to back up the database server:

- For IBM DB2 Universal Database Enterprise Server Edition, refer to the DB2 documentation.
- For other database servers, refer to that database server documentation for instructions.

"Enabling logging"
Enable logging for the type of backup that you are performing.

"Using the DB2 Backup wizard" on page 778
Use the Backup wizard of IBM DB2 Universal Database Enterprise Server Edition to create online or offline backups. This sample scenario describes how to create a full offline backup of a IBM WebSphere Portal Express database.

Related tasks:

"Completing prerequisites for backup" on page 774
Before you back up the WebSphere Portal Express installation, decide which utility to use and whether to perform online backup or offline backup.

Enabling logging

Enable logging for the type of backup that you are performing.

"Enabling circular logging for offline backup"
Enable circular logging if you are performing offline backup of the database. Use the Configure Database Logging Wizard to specify the parameters that control circular logging.

"Enabling archive logging for online backup" on page 777
Enable archive logging if you are performing online backup of the database. Use the Configure Database Logging Wizard to specify the parameters that control archive logging.

Enabling circular logging for offline backup:

Enable circular logging if you are performing offline backup of the database. Use the Configure Database Logging Wizard to specify the parameters that control circular logging.

About this task

Note: This procedure refers to the *WPSDB* database, the default database name for the Release database domain.

To enable circular logging for an offline DB2 database backup, follow these steps:

Procedure

1. Open the DB2 Control Center: Click **General Administration Tools** > **Control Center**.
2. Select the *WPSDB* database from the navigation tree.
3. From the menu, choose **Selected** > **Configure Database Logging**.
4. In the Configure Database Logging Wizard, select **Circular Logging** for your logging type and click **Next**.
5. Accept the default values for the number and size of your log files and click **Next**.
6. Accept the default location for your log files or choose a new location.

   You can mirror your log files to store a copy of your log files in a second location, usually on a different drive. This is important for Idle Standby environments.

7. Click **Next**.
8. Select **Run now without saving history** and click **Next**.
9. Click **Finish** to execute the DB2 commands needed to update the logging configuration.
10. Select the *WPSDB* database from the navigation tree and, from the Control Center menu, choose **Selected** > **Configure Parameters**.
11. In the Recovery section, perform these steps:
    a. Set the value of the **TRACKMOD** parameter to *No*.
    b. Set the **LOG_RETAIN** parameter to *No* and click **OK**.
12. Restart DB2 to enable the changes.

Enabling archive logging for online backup:

Enable archive logging if you are performing online backup of the database. Use the Configure Database Logging Wizard to specify the parameters that control archive logging.

About this task

Note: This procedure refers to the *WPSDB* database, the default database name for the Release database domain.

To enable archive logging for an online DB2 database backup, follow these steps:

Procedure

1. Open the DB2 Control Center: Click **General Administration Tools** > **Control Center**.
2. Select the *WPSDB* database from the navigation tree.
3. From the menu, choose **Selected** > **Configure Database Logging**.
4. In the Configure Database Logging Wizard, select **Archive Logging** for your logging type and click **Next**.
5. Select **Use DB2 to automatically archive the log files** for the method of handling archived logs. Type a directory path for the **Primary archive log location** and **Failure archive log location** and click **Next**.
6. Accept the default values for the number and size of your log files and click **Next**.
7. Accept the default location for your log files or choose a new location.

   You can mirror your log files to store a copy of your log files in a second location, usually on a different drive. This is important for Idle Standby environments. If you do not mirror the log files, then you must back up the log files in addition to backing up the *WPSDB* database.
8. Click **Next**.
9. Type a directory path to store the initial backup. Because you are changing the logging method, this wizard automatically performs an initial backup.
10. Click **Next**.
11. Optional: Specify any options for the backup. Click **Next**.
12. Schedule the backup task for a later time or select the option **Run now without saving task history**. Click **Next**.
13. On the Summary screen, review the selections that you made with the wizard and click **Finish** to accept the changes and create the initial backup.

14. Select the *WPSDB* database from the navigation tree and, from the Control Center menu, choose **Selected** > **Configure Parameters**.
15. In the Recovery section, specify the following parameters:
    a. Set the value of the **TRACKMOD** parameter to *Yes*.
    b. Set the **LOG_RETAIN** parameter to *Recovery*.
    c. Click **OK** to save these settings.
16. To enable the changes, restart the DB2 instance for the WebSphere Portal Express server that you are backing up.

Using the DB2 Backup wizard

Use the Backup wizard of IBM DB2 Universal Database Enterprise Server Edition to create online or offline backups. This sample scenario describes how to create a full offline backup of a IBM WebSphere Portal Express database.

Before you begin

Before you perform an offline backup, stop all services that access the DB2 database: *WPSDB*, which is the default database for the Release database domain.

About this task

To perform a full offline backup of the *WPSDB* database, follow these steps:

Procedure

1. Stop the servers.
2. Open the DB2 Control Center: Click **General Administration Tools** > **Control Center**.
3. To open the Backup wizard, expand the object tree until you find the *WPSDB* database, display its menu, and select **Backup**.
4. After confirming that the details of your database are correct, click **Next**.
5. Select a storage location for the backup and click **Next**.
6. Select the backup type **Full backup** and an availability of **Offline**.
7. Unless you have configured a separate task to quiesce the database, select **Quiesce** to ensure that all users are disconnected from the database before the backup task begins.
8. Click **Next**.
9. If you are experiencing performance problems during backups, skip the next step and go to Step 11.
10. At Specify performance options for the backup, click **Next** to choose one of the following options:
    - To specify a schedule for the backup task, click **Change** and click **Next**.

      Important: Select a time when no users are working with the database or with applications that might be running on the server.
    - To perform a backup without setting a schedule, click **Run now without saving task history** and click **Next**.
11. Optional: Click **Show Command** to view the DB2 commands that the Backup wizard runs.

    Tip: You can copy these commands to use in the Task Center as an alternative to using the Backup wizard the next time you want to back up the database.

Note: The following example includes line breaks for readability. In actual practice, you need to type all commands, including the semicolons, on one line.

```
CONNECT TO WPSDB;QUIESCE DATABASE IMMEDIATE FORCE CONNECTIONS;CONNECT RESET;
BACKUP DATABASE WPSDB TO "D:\BackupFiles\DB2backup\" WITH 2 BUFFERS
BUFFER 1024 PARALLELISM 1 WITHOUT PROMPTING;CONNECT TO WPSDB;
UNQUIESCE DATABASE;CONNECT RESET;
```

12. When you are satisfied with your settings for the database backup, click **Finish** to start the backup task.

Results

DB2 displays a message confirming that the backup task has completed successfully or that the task encountered and logged problems that need to be fixed.

Backing up the IBM Installation Manager

IBM Installation Manager must also be included in backup and recovery planning. If you back up the WebSphere Portal Express file structure and then install a fix pack, the WebSphere Portal Express and IBM Installation Manager become out of sync after you restore the WebSphere Portal Express file system. This condition is not recoverable.

WebSphere Process Server V7 is now installed and maintained through IBM Installation Manager, which saves information on installed products in the agent data store and shared files. The damage or loss of shared files or IBM Installation Manager agent data can prevent the Installation Manager from working within your environment.

Without agent data files, you cannot change installed products or manage products and their components that you installed with the Installation Manager. For example, you cannot modify, update or install the products. Therefore, as part of your Disaster Recovery Plan, you need to have regular backups for the IBM Installation Manager agent and shared files.

For more information about the appdata locations for all versions of IBM Installation Manager, see *Backing up and restoring Installation Manager*.

Related tasks:

"Completing prerequisites for backup" on page 774
Before you back up the WebSphere Portal Express installation, decide which utility to use and whether to perform online backup or offline backup.

Agent data location

Restoring files, databases, and the LDAP server(s)

When necessary, restore the IBM WebSphere Portal Express file system, databases, and LDAP server or servers that you backed up.

Before you begin

Before you restore WebSphere Portal Express databases, remember to adhere to the following principles:

- Whenever you restore WebSphere Portal Express databases, you must restore the databases for all of the nonshared database domains to ensure consistency: Release, LikeMinds, Java Content Repository (JCR), and Feedback are the nonshared database domains.
- Restoring the databases of the shareable database domains is optional and might not be required when you do not want to lose recent user and community information: Customization and Community are the shareable database domains.
- Whenever you restore the WebSphere Portal Express databases, you must also restore the configuration and data files that were archived when the backup image was taken.
- Be sure that your database restoration rolls forward to the point when you performed the file system backup for the WebSphere Portal Express deployment. If you fail to do this step, the configuration and data files might not be synchronized with the information in the databases.
- The file system backup for WebSphere Portal Express includes directories that contain the configuration files.
- Consider whether you implemented separate databases for each database domain or multiple database domains by using the same database. For example, if all database domains were implemented by using a single WebSphere Portal Express database, then restoring this database restores the contents of all domains.
- If you are using IBM DB2 Universal Database Enterprise Server Edition, you should understand the basics of DB2 data backup.
- If you are using a different database management system (DBMS), refer to the DBMS documentation for backup instructions.

Procedure

1. Stop all servers.
   a. If applicable, stop all external HTTP servers.
   b. Stop all of the WebSphere Portal Express servers.
2. Move the backed up files to their original location.

   Refer to the documentation of the backup utility that you used for instructions on restoring files.

   WARNING: Do not overwrite the existing AppServer, PortalServer, or wp_profile root directories with the backed up files because you risk corrupting the WebSphere Portal Express file system. First, remove these old directories and then extract the backed up version in its place.
3. Restore the WebSphere Portal Express databases:
   - For IBM DB2 Universal Database Enterprise Server Edition, refer to the DB2 documentation.
   - For other database servers, refer to that database server documentation for instructions.
4. Optional: If necessary, restore your LDAP server.
   - For IBM Directory Server, refer to IBM Directory Server documentation.
   - For IBM Domino, refer to the Directory Services topics in the Domino Administrator Help.
   - For other LDAP servers, refer to the product documentation for instructions.

"Using the DB2 RESTORE DATABASE command"
Use the RESTORE DATABASE command of IBM DB2 Universal Database Enterprise Server Edition as an alternative to the DB2 Restore wizard to restore the databases that you backed up.

"Using the DB2 Restore wizard"
Use the Restore wizard of IBM DB2 Universal Database Enterprise Server Edition as an alternative to the DB2 RESTORE DATABASE command to restore the databases that you backed up.

Using the DB2 RESTORE DATABASE command

Use the RESTORE DATABASE command of IBM DB2 Universal Database Enterprise Server Edition as an alternative to the DB2 Restore wizard to restore the databases that you backed up.

About this task

To replace an existing *WPSDB* database with the backup copy using the **RESTORE DATABASE** command, follow these steps:

Procedure

1. Stop all application servers connected to the *WPSDB* database.
2. Determine which backup copy to use for the restoration by looking at the timestamp of the available backup files.
3. Run the **RESTORE DATABASE** command: This example refers to the *WPSDB* database, the default name for the Release database domain. **RESTORE DATABASE** *WPSDB* **FROM** *backup_directory_path* **TAKEN AT** *timestamp* **REPLACE EXISTING**
4. Roll the restored database forward by choosing the same point in time for the database. Consider these factors:
   - The time needs to be expressed as an ISO timestamp string in this format *YYYY-MM-DD-HH.MI.SS.NNNNNN*.
   - The time should be shortly after the completion of the backup.
   - The best way to determine this time is to use **Show History** in the Task Center to review the output saved for the backup commands.
   - Alternately, you can use the modification time of the saved backup file to determine when the backup task completed.

   For example, use the following roll-forward command when the last backup completed at 1:23 AM:ROLLFORWARD DATABASE *WPSDB* **TO** *2007-06-25-01.23.00.000000* **USING LOCAL TIME** AND **COMPLETE**

Using the DB2 Restore wizard

Use the Restore wizard of IBM DB2 Universal Database Enterprise Server Edition as an alternative to the DB2 RESTORE DATABASE command to restore the databases that you backed up.

About this task

To replace an existing *WPSDB* database with the backup copy using the DB2 Restore wizard, follow these steps:

Procedure

1. Stop all application servers connected to the *WPSDB* database.
2. Stop and start DB2 to make sure that there are no connections to the database.

3. In the DB2 Control Center, select **Tools** > **Wizards** > **Restore Wizard** from the list of available wizards to define and schedule the restoration of the database.
4. Select the database instance *DB2* and the database *WPSDB* to restore. If the *WPSDB* database does not display in the Database field, type `WPSDB` and click **OK**. A series of screens prompt you to specify information that controls how the database restoration is performed.
5. Choose one of the following options:
   - Select **Restore to an existing database** if you have an existing *WPSDB* database, but it is corrupted or does not contain recent data.

     For example, consider the case where both IBM WebSphere Portal Express and DB2 are installed on the same machine, and that machine suffered a disk failure. To get back to full functionality, you must reinstall DB2, reinstall WebSphere Portal Express, redeploy the server, and run the LDAP and DB2 transfer wizards. This operation would cause a new *WPSDB* database to be created in DB2. However, that database would not contain any data.
   - Select **Restore to a new database** if you no longer have an existing *WPSDB* database in DB2.

     For example, if you had two machines, one contained WebSphere Portal Express, and the second machine contained DB2 and the DB2 data. If the second machine failed, then you would need to reinstall DB2. You could then use the Restore Wizard to re-create the *WPSDB* database from a backed up *WPSDB* database.
6. Click **Next**.
7. If you selected to restore to a new database, type `WPSDB` as the name of the new database, and type the location of the database after the restore. Also, specify the location of the log files for the database after the restore.
8. Click **Next.**
9. Specify a backup image using one of the following options:
   - If you selected to **Restore to an existing database**, select the most recent backup file to use for the restore operation.
   - If you selected to **Restore to a new database**, type the media type, path, and date and time of the most recent backup.
10. Click **Next.**
11. On the Set your containers for a redirected restore screen, do not make any changes. Click **Next**.
12. On the Choose your restore options screen, do not enable **Datalink columns**. Click **Next**.
13. On the Select performance options for the restore screen, do not make any changes. Click **Next**.
14. On the Enabling the DB2 scheduling function screen, select one of these options:
    - Select **Run now without saving task history** to perform the restore immediately.
    - Select **Enable scheduler** to schedule the restore operation for a later time.
15. Click **Next.**
16. Optional: On the final screen that shows summary information, click the **Show Command** to view the DB2 commands that the Restore wizard will run. You can copy these commands to use in the DB2 Task Center as an alternative to using the Restore Wizard.

17. Click **Finish** to begin the restore process.
18. Stop and restart all DB2 services.
19. Restart all servers.

Chapter 9. Migrating

Successful migration requires significant planning and preparation, understanding the tools that are involved, and careful execution of the appropriate steps in the order provided.

"Migration overview"
Migration is the process of collecting configuration data and applications from an earlier installed version of IBM WebSphere Portal Express and merging them into a newer installed version. So that the new environment is identical to the earlier environment.

"Planning for migration" on page 787
Completing a thorough plan before migrating to the latest version of WebSphere Portal Express has a direct impact in the effort invested during the actual migration. Become familiar with the environment you are migrating to (target environment). Also, make sure that the environment you are migrating from (source environment) is up to date with fixes and meets the requirements for migration.

"Preparing your source environment" on page 814
Before you begin the steps for migration, you must perform some critical tasks on your source environment, such as creating back ups, installing the latest cumulative fix and one of the two most recent fix packs, and disabling automatic synchronization if you are migrating a cluster. Review the topics in this section, and perform the required tasks to ensure that your source environment remains functional and the migration completes successfully.

"Setting up the target environment" on page 831
The migration requires you to install the required Portal and WebSphere binary installations. To prepare your target environment, ensure that you have applied the latest cumulative fix and the most recent fix pack before you start migration. In addition, create new copies of the source databases for the target environment to use, and prepare the target environment for any custom applications that have dependencies or any other tasks that need to be performed for remote or cluster migrations.

"Migrate data using the configuration wizard" on page 841
For Version 8.5, data, applications, databases, property files, security settings, and configuration are migrated using the Configuration Wizard. Use the roadmaps for cluster and stand-alone environments to guide you through the process.

"Next steps" on page 856
To complete migration, you must first perform several post-migration steps that depend on how Portal is being used. After completing the post-migration steps, review the Enabling new functionality section to take advantage of the new tools available in IBM WebSphere Portal Express Version 8.5. Enabling new functionality should not be started until all post-migration steps have been completed.

Migration overview

Migration is the process of collecting configuration data and applications from an earlier installed version of IBM WebSphere Portal Express and merging them into a newer installed version. So that the new environment is identical to the earlier environment.

Migration is different from upgrading. With upgrading, you replace an existing installed out-of-date version of files with current files. With migration, you install the new version of a product alongside of the earlier version and then copy data from the earlier version to the new version. By migrating information from the earlier version to the new version, you can use that information in the new version without having to re-create it from scratch. Migration enables customizations to be carried forward that were implemented in the earlier portal so that you can continue to use them in the new portal.

WebSphere Portal Express also supports integration with additional products to extend core functionality. If the earlier portal environment is configured to work with one or more supported products that provided integrated features, you need to follow the migration procedures for the integrated product.

Migrated elements are not automatically upgraded to use features that are available in the new version. Taking advantage of new features that were not available in the earlier portal requires extra attention after migration is complete.

You can migrate to WebSphere Portal Express Version 8.5 from either Version 7.0 or 8.0. For additional information about supported migrations, see *Supported migration paths*.

Note: If you are migrating from IBM WebSphere Portal Express Version 8.0.0.1 on WebSphere Application Server Version 8.5.5.2 to WebSphere Portal Express Version 8.5, you must follow a different migration process. For more information, see *Migrating from Portal 8.0.0.1 on WebSphere Application Server 8.5.5.2*.

Migration to Version 8.5

For Version 8.5, data, applications, databases, property files, security settings, and configuration are migrated using the Configuration Wizard. Use the roadmaps for cluster and stand-alone migrations to guide you through planning, preparing your source environment, setting up your target environment, migrating data, and post-migration steps. For a high-level overview of this process, see the *Roadmaps for migration*.

Related concepts:

"Supported migration paths" on page 788
Migration is supported between equivalent offerings. For example, you can migrate from WebSphere Portal Enable Version 7.0 to WebSphere Portal Enable Version 8.5, but not from WebSphere Portal Express Version 7.0 to WebSphere Portal Extend Version 8.5.

"Migrating from Portal 8.0.0.1 on WebSphere Application Server 8.5.5.2" on page 800
If you are migrating from IBM WebSphere Portal Express Version 8.0.0.1 on WebSphere Application Server Version 8.5.5.2 to WebSphere Portal Express Version 8.5, you must follow a different migration process.

"What to expect after you complete migration" on page 811
During the migration process, your portal applications, portlets, and databases are updated to the IBM WebSphere Portal Express 8.5 versions. However, not all of the new WebSphere Portal Express Version 8.5 functionality and features are enabled by default. The following sections provide information on how various components are handled during migration, and what you can expect after the migration is complete.

Related tasks:

"Roadmaps for migration" on page 92
Choose the appropriate migration roadmap for your environment.

Planning for migration

Completing a thorough plan before migrating to the latest version of WebSphere Portal Express has a direct impact in the effort invested during the actual migration. Become familiar with the environment you are migrating to (target environment). Also, make sure that the environment you are migrating from (source environment) is up to date with fixes and meets the requirements for migration.

The following sections provide a starting point for your migration planning. Consider each migration planning unique to the environment you are migrating. Refer to the Roadmaps for migration when you are planning and completing the migration process for an high-level view of the process and direct links to important documentation resources.

Before you start the more detailed planning, here are some additional migration considerations:

- Take into account new development environment needs.
- Education and cultural changes.
- Contemplate different migration approaches and the impact on your business.
- What is contained within migration and what is not.
- Deprecated functionality.
- Vendor software unique to your environment and how it might interact with the new version of WebSphere Portal Express.

  "Supported migration paths" on page 788
  Migration is supported between equivalent offerings. For example, you can migrate from WebSphere Portal Enable Version 7.0 to WebSphere Portal Enable Version 8.5, but not from WebSphere Portal Express Version 7.0 to WebSphere Portal Extend Version 8.5.

  "Hardware considerations" on page 791
  There might be cases where you are completing a remote migration to a new hardware configuration. This new server might have different requirements from the current environment you are migrating from. Generally, here are some key points to consider.

  "Operating systems considerations" on page 791
  There might be cases where you upgrade not just to a newer version of WebSphere Portal Express but also to a different operating system version. In that case, there might be a different set of system requirements and considerations to keep in mind.

  "Migration considerations" on page 792
  There are a number of ways in which you can migrate WebSphere Portal Express to a newer version. Some migration scenarios might offer a higher availability percentage over another. There are some scenarios where the migration can be done in parallel while your source environment remains in production. Other scenarios might require the production system to be disconnected just before you go live with the newly migrated system. Depending on your needs on high availability systems, you might choose one approach or another.

  "Development considerations" on page 808
  The goal of the migration process is to ensure that the target environment

works similarly to the source environment. However, there are deprecated and unsupported features and changes in supported technical specifications that can prevent this transition from being seamless. Review the following topics for guidance on the development work that is required to maintain the functionality of the source environment and also begin preparation for enabling new features and functionality.

"What to expect after you complete migration" on page 811
During the migration process, your portal applications, portlets, and databases are updated to the IBM WebSphere Portal Express 8.5 versions. However, not all of the new WebSphere Portal Express Version 8.5 functionality and features are enabled by default. The following sections provide information on how various components are handled during migration, and what you can expect after the migration is complete.

Related concepts:

"What's changed" on page 16
WebSphere Portal Express includes changes to existing features.

"Unsupported and deprecated features for V8.5" on page 17
Review the features that were available in previous versions of IBM WebSphere Portal Express but are no longer available.

Related information:

WebSphere Portal V8.5 and V8.0 detailed system requirements

Supported migration paths

Migration is supported between equivalent offerings. For example, you can migrate from WebSphere Portal Enable Version 7.0 to WebSphere Portal Enable Version 8.5, but not from WebSphere Portal Express Version 7.0 to WebSphere Portal Extend Version 8.5.

The following table summarizes supported migration paths:

Table 100. Offerings and supported migration paths

Offering	WebSphere Portal Express Version 8.5	WebSphere Portal Version 8.5 (Server)	WebSphere Portal Version 8.5 (Enable, Extend)	Web Content Manager Version 8.5
WebSphere Portal Express Version 7.x	Supported	Not Supported	Not Supported	Not Supported
WebSphere Portal Server Version 7.x (Server)	Not Supported	Supported	Supported	Not Supported
WebSphere Portal Server Version 7.x (Enable, Extend)	Not Supported	Not Supported	Supported	Not Supported
Web Content Manager Version 7.x	Not Supported	Not Supported	Not Supported	Supported

Table 100. Offerings and supported migration paths (continued)

Offering	WebSphere Portal Express Version 8.5	WebSphere Portal Version 8.5 (Server)	WebSphere Portal Version 8.5 (Enable, Extend)	Web Content Manager Version 8.5
WebSphere Portal Express Version 8.0 on WebSphere Application Server Version 8.0	Supported	Not Supported	Not Supported	Not Supported
WebSphere Portal Server Version 8.0 (Server) on WebSphere Application Server Version 8.0	Not Supported	Supported	Supported	Not Supported
WebSphere Portal Server Version 8.0 (Enable, Extend) on WebSphere Application Server Version 8.0	Not Supported	Not Supported	Supported	Not Supported
Web Content Manager Version 8.0 on WebSphere Application Server Version 8.0	Not Supported	Not Supported	Not Supported	Supported
WebSphere Portal Server Version 8.0 (Server) on WebSphere Application Server Version 8.5.0	Not Supported	Supported	Supported	Not Supported
WebSphere Portal Server Version 8.0 (Enable, Extend) on WebSphere Application Server Version 8.5.0	Not Supported	Not Supported	Supported	Not Supported

Table 100. Offerings and supported migration paths (continued)

Offering	WebSphere Portal Express Version 8.5	WebSphere Portal Version 8.5 (Server)	WebSphere Portal Version 8.5 (Enable, Extend)	Web Content Manager Version 8.5
Web Content Manager Version 8.0 on WebSphere Application Server Version 8.5.0	Not Supported	Not Supported	Not Supported	Supported

You can also migrate from a Server install to the Enable or Extend versions of IBM WebSphere Portal Express.

Note for Version 6.1 customers: If you are currently on Version 6.1, you must perform a two-step migration from Version 6.1 to Version 8.0, and then from Version 8.0 to 8.5. Go to Migrating from WebSphere Portal 6.1 to Portal 8.5 for guidance on the two-step migration process.

Important Fix Pack Requirements: Migration is supported from the two most recent fix packs for WebSphere Portal Express Version 7.0.0.x and Version 8.0.0.x. However, you must apply the latest cumulative fix to your source environment. Your target environment must also have the latest cumulative fix and the most recent fix pack applied.

If you are not sure which earlier version is installed, run the following command on the earlier portal server:

Windows: *wp_profile_root*`\PortalServer\bin\WPVersionInfo.bat`

Linux: *wp_profile_root*`/PortalServer/bin/WPVersionInfo.sh`

IBM i: *wp_profile_root*`/PortalServer/bin/WPVersionInfo.sh`

When you migrate to Version 8.5, WebSphere Portal Express automatically migrates the following applications and configuration data:

- Security configuration
- Access control
- Portal behavior
- Portlet applications
- Customized portal resources, such as themes and skins, pages, and portlets
- Personalized content
- Virtual portals

Note: You cannot upgrade the source portal with a fix pack after migration if you intend to remigrate the JCR. For example, if your source portal is Version 7.0.0.4 and you migrate it to Version 8.5, you cannot then upgrade the source portal to Version 7.0.0.5 and remigrate the JCR. This path is not supported.

Related information:

WebSphere Portal detailed system requirements

Hardware considerations

There might be cases where you are completing a remote migration to a new hardware configuration. This new server might have different requirements from the current environment you are migrating from. Generally, here are some key points to consider.

Source environment:

- Revisit the hardware the software requirements for the platform you are migrating from. Ensure that you are still in a fully supported environment.
- Make sure that you are current with, at least, the last two maintenance levels for that platform.
- Be aware of the current overall performance and throughput. Know what the current activity is on your WebSphere Portal Express server.
- Make sure that you have detailed information about your entire environment.
  - Identify all the systems your WebSphere Portal Express server connects to.
  - Keep a detailed list of all the credentials and connection information as well as the services provided by the other systems.
  - If firewalls are involved, make sure that you note ports, IP addresses, and host names used.

Target environment:

- Review the system requirements for your new environment.
- Review the supported migration paths.
- Will this new system be dedicated as a WebSphere Portal Express server or it will be shared with other services?
  - If shared, be aware of potential resource conflicts such as ports as well as overall system performance.
- Make sure that you are at a supported maintenance level.
- Be mindful of the projected WebSphere Portal Express server activity. Once migrated, or even during the testing phase of your migration, you should be able to compare performance data between your current and new WebSphere Portal Express servers.

Architecture:

- Your target environment must be on the same system architecture than your source environment for migration. Migrating to a different architecture is not supported.

Related information:

WebSphere Portal detailed system requirements

Operating systems considerations

There might be cases where you upgrade not just to a newer version of WebSphere Portal Express but also to a different operating system version. In that case, there might be a different set of system requirements and considerations to keep in mind.

Important: Migrating between platforms (for example, migrating from Windows to Linux) is not supported.

Use the following list as a starting point.

- Review the supported migration paths.
- Review the system requirements for your new environment to make sure that you are migrating to a fully supported environment.
- Ensure that you applied all necessary fixes in preparation for migration.
- Get a complete understanding of the differences between the source and target environments. The following questions will help you get started.
  - Overall system administration. Are there any monitoring or administering tools in use today that might not work on the new environment?
  - Operating system security. Is there any security polices in effect that would require being ported to the new environment?
  - Will WebSphere Portal Express security implementation be any different?
  - File system. Will the files be placed in a different directory structure? Will those files require special permissions to run?

Migration considerations

There are a number of ways in which you can migrate WebSphere Portal Express to a newer version. Some migration scenarios might offer a higher availability percentage over another. There are some scenarios where the migration can be done in parallel while your source environment remains in production. Other scenarios might require the production system to be disconnected just before you go live with the newly migrated system. Depending on your needs on high availability systems, you might choose one approach or another.

Refer to the Server topologies section of this documentation for details on high availability installations.

"Backup and recovery" on page 793
Backup and recovery of data files and databases is an essential operation for any business system, particularly for data and applications that run in production environments. Create and follow a plan for backing up and recovering data on all tiers of your IBM WebSphere Portal Express deployment. IBM Installation Manager must also be included in backup and recovery planning. If you back up the WebSphere Portal Express file structure and then install a fix pack, the WebSphere Portal Express and IBM Installation Manager become out of sync after you restore the WebSphere Portal Express file system. This condition is not recoverable.

"Local or remote migration" on page 794
Review the considerations for local and remote migrations. Plan and review your options for an appropriate migration path that is based on your current environment.

"Automated or manual migration" on page 795
The IBM WebSphere Portal Express Knowledge Center documents the automated migration process that is the commonly used and supported method for migrating to a new version of WebSphere Portal Express. However, this approach might not be the ideal type of migration for all customers. Read the following considerations to determine which approach fits your needs.

"Portal farm migration" on page 797
The Portal farm migration consists of disabling farm mode and running the stand-alone migration. If you are migrating a unique installation farm configuration, you must migrate each farm member. If each farm instance is a clone, you can migrate one instance, and then create clones that are based on the migrated instance. When the migration is complete, you can re-enable farm mode.

Backup and recovery

Backup and recovery of data files and databases is an essential operation for any business system, particularly for data and applications that run in production environments. Create and follow a plan for backing up and recovering data on all tiers of your IBM WebSphere Portal Express deployment. IBM Installation Manager must also be included in backup and recovery planning. If you back up the WebSphere Portal Express file structure and then install a fix pack, the WebSphere Portal Express and IBM Installation Manager become out of sync after you restore the WebSphere Portal Express file system. This condition is not recoverable.

Backup and recovery include the WebSphere Portal Express file system and databases. Your backup and recovery plan needs to address each deployment tier: Complete system backup for catastrophic failures, back up of middleware such as WebSphere Portal Express and IBM WebSphere Application Server, and backup of individual applications that run on the middleware. Backup and recovery can be done on any or all of these tiers, depending on the needs of your portal deployment.

When you create a backup and recovery plan, consider these general questions:

- What procedure will you use to back up data?
- How often will you back up data?
- What are the trade-offs between online and offline backups?
- How does the scope of your portal deployment affect the backup and recovery strategy? For example, the number of users and the volume and importance of the data that is stored and used in applications affect your decisions about backup and recovery practices.

- Will you use IBM Tivoli Storage Manager or other utility to back up the file system?

Attention: Backing up and recovering a WebSphere Portal Express installation includes the WebSphere Application Server runtime environment and all applications that are deployed on WebSphere Portal Express. However, if applications use remote information sources outside of the WebSphere Portal Express databases and the LDAP directory, you need to consider these remote sources. Develop backup and recovery procedures for these remote sources as part of your comprehensive strategy.

Related tasks:

"Guidelines for Idle Standby deployments" on page 772
If IBM WebSphere Portal Express is deployed in an Idle Standby topology, both a primary node and a secondary node are running in a cluster. The primary node is the active node, and the secondary node is the backup node. In this topology, there is no difference in database backup and restore because all cluster members use the same WebSphere Portal Express databases. However, you need to consider some additional factors when you back up and recover the file system in an Idle Standby deployment.

"Backing up files, databases, and the LDAP server(s)" on page 774
Periodically run an automated backup procedure for the IBM WebSphere Portal Express file system, databases, and LDAP server(s) using a backup and recovery utility of your choice. Remember to run the backup procedure before performing critical system-wide changes, such as upgrading to a new version of WebSphere Portal Express or installing interim fixes and fix packs.

"Restoring files, databases, and the LDAP server(s)" on page 779
When necessary, restore the IBM WebSphere Portal Express file system, databases, and LDAP server or servers that you backed up.

Local or remote migration

Review the considerations for local and remote migrations. Plan and review your options for an appropriate migration path that is based on your current environment.

Local migration

There are a few migration combinations that can be considered local migration depending on the availability of the environment being migrated. At a minimum, you have two distinctive options with this migration path. You can perform a local migration by taking the source environment offline, or you can maintain both source and target environments coexisting. Depending on the migration path you choose, there might be additional factors to consider.

Note: IBM i supports local migration only.

Local migration without coexistence

Generally, local migration without coexistence is the simplest scenario. Both source and target WebSphere Portal Express installations are on the same system and resource conflicts are minimal.

There are still some directory structure considerations to keep in mind. You might want to use the same directory structure in you new WebSphere Portal Express installation to hold logs and backups for example.

Other configurations such as ports or virtual portals should not conflict. Both, source and target WebSphere Portal Express will not be running in parallel at the same time.

Local migration with coexistence

Coexistence is the process of running both the original and the newly migrated WebSphere Portal Express systems on the same system at the same time. This approach allows for maintaining your current production environment online while performing the migration to a newer version of WebSphere Portal Express. This statement is not exclusive of local migration with coexistence. You can also achieve this by performing a remote migration.

When you plan migration with coexistence you need to consider the hardware and software requirements for the new version of WebSphere Portal Express. Make sure the system currently running your production WebSphere Portal Express has enough resources to handle the new installation.

As you have two installations of WebSphere Portal Express you need to carefully plan to avoid resource conflicts. Default settings, like port assignments, require updating on the migrated WebSphere Portal Express.

Remote migration

In this scenario, you do not need to worry about resource conflicts as much as with the local migration with coexistence approach. However, being on a remote system you need consider factors outside the actual WebSphere Portal Express environment such as operating system accounts and security in general.

You also need to keep in mind that you must be able to move files between the source and the target environments. There are procedures that create files on the source WebSphere Portal Express environment that might need to be updated and placed in the new WebSphere Portal Express installation. So, once again, operating system security planning plays an important role in remote migrations.

Automated or manual migration

The IBM WebSphere Portal Express Knowledge Center documents the automated migration process that is the commonly used and supported method for migrating to a new version of WebSphere Portal Express. However, this approach might not be the ideal type of migration for all customers. Read the following considerations to determine which approach fits your needs.

The automated approach is intended to provide a one-size fits all migration that brings over the entire source site to the target environment. It takes into account all of the possible artifacts that a customer site might be using and packages them all to be brought over to the target environment. This is a great reproducible approach that satisfies the needs for most customers, but it can take longer because it attempts to move everything over.

However, it is also possible to migrate environments manually using administrative tools such as wsadmin, XMLAccess, and the ConfigEngine to move essential configurations, applications, and content from your existing source environment to the target environment.

Here are some factors to consider when deciding whether a manual approach is more effective:

- If you plan to re-create your site completely on the target version, you might not need to go through the automated migration process. You can start with a new 8.5 server, and then use the available administrative tools to bring over the configuration and artifacts from your source environment that you plan to preserve.
- If you are planning a two-step migration, from Version 6.1 to Version 8.0, and then Version 8 to Version 8.5, then review the deprecated and unsupported list for versions 7, 8, and 8.5 to determine whether your current site will work on Version 8.5 immediately after migration. In most cases, the theme must be re-created and many references to deprecated portlets and pages must be removed or updated. For this scenario, it might be more efficient to start with a new 8.5 installation and manually bring over the required artifacts from your source environment, and then update them as they are brought over.
- If you already have a well-documented deployment process, and you already know how to quickly create up a new environment that meets all of your requirements, then it is possible to use the core of that same process to create an equivalent version on the new version of Portal. There will be changes to the process, but it might be more efficient to use that process and update it for Version 8.5 as needed to redefine and use the process after migrating to Version 8.5.

If you plan to do a manual migration, review the following considerations first:

- IBM Support is limited if you choose to perform a manual migration.
  - XMLAccess imports are compatible with earlier versions of Portal. Therefore, it is reasonable to expect an XMLAccess script from a previous version of Portal to work in a newer version of Portal.
  - If there is a defect in the XMLAccess import process, you can contact IBM support. However, if the XMLAccess import fails and the failure is not defect related, then IBM Support will not be available to assist with troubleshooting or customizing the XMLAccess import file to make the import successful. Creating customized scripts is beyond the scope of the IBM Support.
  - IBM Services is available if assistance is needed with a manual migration, including customizing the XMLAccess import file.
- You need to manually copy over any files that are required by custom applications, third-party applications, or Portal add-ons that are required for your server to work properly.
- You can use wsadmin and jacl/jython scripts to bring over your custom applications and configuration.
  - The WebSphere Portal Express configurations such as security, performance tuning, datastore configurations, and more are not carried over. You need either a documented or scripted process to re-create these configurations in your new environment.
- You can use XMLAccess to bring over Portal artifacts such as portlets and pages:
  - There might be references to deprecated or unsupported portlets, pages, or features that prevent imports from working properly. You must correct these by removing the references or manually installing the feature if it is still available.
  - It is not recommend to bring any administrative features such as the admin portlets from the source system, but you can bring custom pages and applications.
  - For Virtual Portals, it is recommend to re-create them on the target system, and then manually moving the artifacts over from the source Virtual portal to the target system Virtual Portal.

  - If you customized the Virtual Portal creation scripts, you must redo the script customization for the 8.5 scripts
- You can use cross-version syndication from your source environment to the target environment to bring over JCR content:
  - You must apply the latest combined cumulative fix on your source environment in order to use cross-version syndication to your target environment.
  - You must disable managed pages on the target OOB installation before syndicating any changes.
  - From Version 6.1 and earlier, no cross-version syndication is possible
  - If you are performing a two-step migration from Version 6.1 to Version 8, and then Version 8 to Version 8.5, you must use the Version 8 content refresh task, and then use cross-version syndication to your Version 8.5 environment.
- You must manually bring over anything that is stored in WebDAV:
  - The WebDAV information is stored in JCR database, but is not brought over with cross-version syndication. It must be copied to the target environment manually.
- You lose customization and personalization during a manual migration:
  - There is not a process to preserve and bring this information to a new environment.

IBM Support handbook: How technical questions are handled by support

IBM Software Services Zone for WebSphere

Portal farm migration

The Portal farm migration consists of disabling farm mode and running the stand-alone migration. If you are migrating a unique installation farm configuration, you must migrate each farm member. If each farm instance is a clone, you can migrate one instance, and then create clones that are based on the migrated instance. When the migration is complete, you can re-enable farm mode.

Migrating a portal farm

1. Disable farm mode:
   - Deactivate all farm instances that share the required server's file system.
   - Stop sharing the required server's file system.
   - Run the following task to disable farm mode:
     - Linux : `./ConfigEngine.sh disable-farm-mode -DWasPassword=`*`password`* from the *wp_profile_root*`/ConfigEngine` directory
     - IBM i: `ConfigEngine.sh disable-farm-mode -DWasPassword=`*`password`* from the *wp_profile_root*`/ConfigEngine` directory
     - Windows: `ConfigEngine.bat disable-farm-mode -DWasPassword=`*`password`* from the *wp_profile_root*`\ConfigEngine` directory
2. Follow the steps that are covered in the Migrating a stand-alone environment roadmap.

   Note: If you are migrating a unique installation farm configuration, each farm member must be migrated. If you are migrating a clone installation farm configuration, you can migrate one farm member, and then clone the migrated instance.

3. Enable farm mode:
   - The **systemTemp** parameter specifies where the server-specific directory is located. This directory contains all directories and files that the running portal instance writes to, such as for logging and page compiling. Create the target directory path. For example:
     - Linux : `/var/log/was_tmp`
     - IBM i: `/var/log/was_tmp`
     - Windows: `C:\temp\was_tmp`
   - Run the following task to enable farm mode:
     - Linux : `./ConfigEngine.sh enable-farm-mode -DsystemTemp=/var/log/was_tmp -DWasPassword=`*password*
     - IBM i: `ConfigEngine.sh enable-farm-mode -DsystemTemp=/var/log/was_tmp -DWasPassword=`*password*
     - Windows: `ConfigEngine.bat enable-farm-mode -DsystemTemp=C:\temp\was_tmp -DWasPassword=`*password*

Related concepts:

"Roadmap: Migrating a stand-alone server environment" on page 92
Roadmaps provide a high-level overview of complex tasks such as migrating a stand-alone server environment to a new version of IBM WebSphere Portal Express.

Multiple tier environments

When you migrate multiple tier environments, you have two options for completing the migration process. You can choose to migrate each tier independently, or you can migrate the lowest tier and use staging to production techniques to build out the other tiers based on the migrated environment.

Choose from the two options when you are migrating multiple environments, and review the considerations for each:

Migrate tiers using staging to production techniques

The lowest level tier is migrated, and then that tier is moved to the next levels using staging to production techniques. For example, if you have Development, Authoring, and Production tiers, you can migrate the development environment and use staging to production to move that environment to the new authoring and production tier. This option might require less time than migrating tiers independently, but it is imperative that you take a disciplined approach to ensure that all artifacts and settings are properly moved to the next tiers.

Review the considerations for migrating tiers using staging to production techniques:

- Ensure managed pages enablement in the higher-level tiers matches. Migration from a version before Version 8.0 leaves the managed pages feature off. If you build new higher tiers using the Portal installer, then managed pages are turned on.
- Follow the Portal tuning guide to set up all tiers. Migration ensures that all settings in the lowest tier are migrated to the target environment, but since the higher tiers are newly built, they need to be tuned. Tuning might also be necessary on the lowest tier, if the tuning recommendation changed since the previous Portal version.
- Review and decide if you want to use the staging to production documentation to populate the higher tiers. You must ensure that all of

your custom applications and shared libraries are updated on the higher tiers, and plan for a test phase that validates your application before you move to the next tier.

Migrate tiers independently
Each tier is migrated independently. This option might require more time, but it ensures that all settings are migrated to the new environment.

Related concepts:

Chapter 15, "Staging to production," on page 2481
During portal solution development, the solution is initially developed, tested, and refined on one server or a limited number of servers. The solution is deployed later on live systems, referred to as the production environment. The process of moving the solution from the development environment to the production environment is called staging.

Multiple cluster environments

If you are migrating an environment with multiple clusters, you can run the **create-alias-multiple-cluster** task to support multiple clusters that use different credentials.

Supporting multiple clusters that use different database credentials

Using the same database user ID and password for each identically named domain/data source allows the existing JAAS Authentication Aliases to be functional. If a unique database user ID and password are required, extra manual configuration is needed to create new JAAS Authentication Aliases for each data source and map these accordingly.

Complete the following steps on the primary node of Cluster A:

1. Open a command line.
2. Change to the *wp_profile_root*/ConfigEngine directory.
3. Run the following task to create the JAAS Authentication Aliases:
   - Linux : `./ConfigEngine.sh create-alias-multiple-cluster -DauthDomainList=release,jcr -DWasPassword=`*dmgr_password*
   - IBM i: `ConfigEngine.sh create-alias-multiple-cluster -DauthDomainList=release,jcr -DWasPassword=`*dmgr_password*
   - Windows: `ConfigEngine.bat create-alias-multiple-cluster -DauthDomainList=release,jcr -DWasPassword=`*dmgr_password*

   Where **authDomainList** is set to a list of domains that use unique database user ID and passwords and those domain properties are set correctly in the wkplc_comp.properties file, including user ID and password.

Related concepts:

Adding secondary nodes to a clustered environment
The standard process of adding IBM WebSphere Portal Express server nodes to a cluster is to set up a stand-alone WebSphere Portal Express server with the correct database settings, and run the **enable-profiles** task to generate profile templates that can be used to create the secondary node profiles. However, there is a limitation with the enable-profiles task and it cannot be run in a clustered environment.

Migrating from Portal 8.0.0.1 on WebSphere Application Server 8.5.5.2

If you are migrating from IBM WebSphere Portal Express Version 8.0.0.1 on WebSphere Application Server Version 8.5.5.2 to WebSphere Portal Express Version 8.5, you must follow a different migration process.

Review the two different methods that you can use to migrate to Version 8.5 from Version 8.0.0.1 on WebSphere Application Server Version 8.5.5.2.

Use staging to production to set up a staging server, and migrate the staging server to WebSphere Portal Express 8.5.
: You can set up a staging server with a WebSphere Portal 8.0.0.1 and WebSphere Application Server 8.0.0.5 installation, and use the staging to production tools to create a new environment that is based on the source environment. Then, you can use the configuration wizard to migrate the staging environment. The benefit of this method is that your source environment stays in tact on WebSphere Portal Version 8, and it allows for the source and target environments to co-exist. It can require extra hardware, and these steps can take longer to complete.

Manually perform an in-place migration.
: You must manually uninstall and install the Portal binary files, and back up and restore the source Portal profile. This method might be faster, but you must update the source environment in-place, so you must have a backup and a plan for rolling back in case there is a failure. In addition, this procedure cannot be reversed, and when complete the Portal 8.0.0.1 version server is fully updated to WebSphere Portal Version 8.5.

"Using staging to production techniques to complete the migration"
Choose this option if you want to use staging to production techniques to migrate from IBM WebSphere Portal Express Version 8.0.0.1 on WebSphere Application Server Version 8.5.5.2 to WebSphere Portal Express Version 8.5.

"Performing a manual in-place migration" on page 801
If you proceed with this method of migration for IBM WebSphere Portal Express Version 8.0.0.1 on WebSphere Application Server Version 8.5.5.2, be aware that you cannot use the WebSphere remote migration tool because the WebSphere version of the source and target environments are the same. This migration is an in-place migration, and the source environment will no longer be available after the migration is complete.

Using staging to production techniques to complete the migration:

Choose this option if you want to use staging to production techniques to migrate from IBM WebSphere Portal Express Version 8.0.0.1 on WebSphere Application Server Version 8.5.5.2 to WebSphere Portal Express Version 8.5.

About this task

You can set up a staging server with a WebSphere Portal Express 8.0.0.1 and WebSphere Application Server 8.0.0.5 installation, and use the staging to production tools to create a new environment that is based on the source environment.

Procedure

1. Install WebSphere Portal Express 8.0.0.1 and WebSphere Application Server 8.0.0.5 on a staging server with the same operating system as the source server.

2. Use the WebSphere Portal Express staging to production tools to deploy a stand-alone server that is based on the source server.
3. Install the WebSphere Portal Express 8.5 and WebSphere Application Server 8.5.5.2 binary files on the target server.
4. Access the Configuration Wizard on the target server, and click **Migrate to a New Version** > **Migrate a Stand-alone Server**.
5. Optional: When you complete the migration of the stand-alone staging server, you can build it into a cluster if needed.

Related concepts:

"Configuration Wizard" on page 232
Use the Configuration Wizard to set up stand-alone servers and new deployments, create clusters, migrate and update to new versions, and add new capabilities to existing deployments.

Performing a manual in-place migration:

If you proceed with this method of migration for IBM WebSphere Portal Express Version 8.0.0.1 on WebSphere Application Server Version 8.5.5.2, be aware that you cannot use the WebSphere remote migration tool because the WebSphere version of the source and target environments are the same. This migration is an in-place migration, and the source environment will no longer be available after the migration is complete.

About this task

If you are performing an in-place update of a stand-alone server, complete steps 1 - 10. Then, continue with the **upgradeConfigEngine** step of the **Migrate a Stand-alone Server** option in the Configuration Wizard as it is detailed in steps 11 - 16.

If you are performing an in-place update of a cluster, the deployment manager should already have the WebSphere Application Server Version 8.5.5.2 installed. Therefore, you do not need to complete the **Migrate a Cluster Step 1: Migrate the Deployment Manager Profile** option in the Configuration Wizard. You can also skip **Migrate a Cluster Step 2: Migrate Node Profiles** option, but you must complete the following steps 1 - 9 on all nodes. Then, you must complete **Migrate a Cluster Step 3: Upgrade Node Profiles** on all nodes as detailed in steps 11 - 16.

Procedure

1. Back up your databases.
2. Clear out the `temp` and `wstemp` paths in *wp_profile_root*. If you do not complete this step, it can create long path names that prevent the **restoreProfile** task from working successfully.
3. Back up the *wp_profile_root* using `manageprofiles -backupProfile` from `AppServer/bin`. For example: `./manageprofiles.sh -backupProfile -profileName wp_profile -backupFile /tmp/wp_profile_bak`.
4. Uninstall WebSphere Portal Express Version 8 using the IBM Installation Manager. Do not uninstall WebSphere Application Server 8.5.5.
5. Delete the following files from the WebSphere Application Server AppServer path:
   - lib/ext/commons-codec-1.3.jar
   - lib/ext/commons-httpclient-3.0.1.jar
   - lib/ext/openid4java-full-0.9.5.jar

- lib/ext/wp.auth.base.sua_RedirectServletFilter.jar
- lib/ext/wp.auth.base.sua_loginmodule.jar
- lib/ext/wp.auth.tai.jar
- lib/wp.user.connections.jar
- lib/wp.wire.jar
- plugins/com.ibm.patch.was.plugin.jar
- plugins/com.ibm.wp.was.plugin.jar
- plugins/wp.ext.jar
- properties/jndi.properties

6. Ensure that the `wp_profile` and `cw_profile` are cleaned up and the paths are deleted.
7. Install only the Portal 8.5 binary. Do not create a Portal profile.
8. Test connecting to the Configuration Wizard in a browser. `http://your_server:10200/ibm/wizard`
9. Restore the *wp_profile_root* using `manageprofiles restoreConfig` from `AppServer/bin`. For example, `./manageprofiles.sh -restoreProfile -backupFile /tmp/wp_profile_bak`.

   Note: The *wp_profile_root* is restored to the original path.
10. If you are migrating a cluster, copy the `filesForDmgr.zip` in the *PortalServerRoot*`/filesForDmgr` path on your target primary node server to the existing WebSphere Application Server 8.5.5.2 deployment manager. Then, extract the files in the `AppServer` path.

    Note: This task is essential to update the deployment manager to user the portal 8.5 plug-ins. Complete this step once. Do not repeat this step on all nodes.

Complete the remaining steps for using the Configuration Wizard:

11. Access the Configuration Wizard. `http://your_server:10200/ibm/wizard`.
12. Click **Migrate to a New Version** > **Migrate a Stand-alone Server** or **Migrate to a New Version** > **Migrate a Cluster Step 3: Upgrade Node Profiles**.
13. Select **Same server** when you answer questions about your system.
14. Enter your properties with the correct values.
15. Mark all steps complete before **Upgrade the ConfigEngine**.
16. Start your configuration with the **Upgrade the ConfigEngine** step.

Related concepts:

"Configuration Wizard" on page 232
Use the Configuration Wizard to set up stand-alone servers and new deployments, create clusters, migrate and update to new versions, and add new capabilities to existing deployments.

Migration from Portal 7.0 server-only to Portal 8.5

When you migrate from a 7.0 server-only installation to WebSphere Portal Express Version 8.5, you must take extra steps that are not covered in the migration options completed using the Configuration Wizard. Instead of using the wizard to complete the final upgrade the Portal profile step, you must complete this step manually.

To complete a 7.0 server-only migration, follow the steps for stand-alone and cluster migrations that are available in the *Roadmaps for migration*. However, when

you use the Configuration Wizard options to **Migrate to a New Version**, complete all steps from the wizard except for the final **Upgrade the Portal Profile** step. You must run this step manually.

Manually run the two following ConfigEngine tasks from the *wp_profile_root*/ConfigEngine directory:

1. Run the **add-disabled-wcm-to-server** task:
   - Linux : `./ConfigEngine.sh add-disabled-wcm-to-server -DWasPassword=yourpassword -DPortalAdminPwd=yourpassword`
   - IBM i: `ConfigEngine.sh add-disabled-wcm-to-server -DWasPassword=yourpassword -DPortalAdminPwd=yourpassword`
   - Windows: `ConfigEngine.bat add-disabled-wcm-to-server -DWasPassword=yourpassword -DPortalAdminPwd=yourpassword`
2. Run the **upgrade-profile** task including the additional **-Dprevious.family.WPFamilyName=server** parameter:
   - Linux : `./ConfigEngine/ConfigEngine.sh upgrade-profile -DWasPassword=yourpassword -DPortalAdminPwd=yourpassword -javaoption -Xms512m -javaoption -Xmx2048m -Dwcm.transactionTimeout=1200 -Dprevious.family.WPFamilyName=server`
   - IBM i: `ConfigEngine/ConfigEngine.sh upgrade-profile -DWasPassword=yourpassword -DPortalAdminPwd=yourpassword -javaoption -Xms512m -javaoption -Xmx2048m -Dwcm.transactionTimeout=1200 -Dprevious.family.WPFamilyName=server`
   - Windows: `ConfigEngine/ConfigEngine.bat upgrade-profile -DWasPassword=yourpassword -DPortalAdminPwd=yourpassword -javaoption -Xms512m -javaoption -Xmx2048m -Dwcm.transactionTimeout=1200 -Dprevious.family.WPFamilyName=server`

   Note: If you encounter any problems running the **upgrade-profile** task and you need to restart the task using **-Dwp.migration.framework.resume=parameter**, then ensure that you continue to use the **-Dprevious.family.WPFamilyName=server** parameter.

Choose the appropriate migration roadmap for your environment.

Migrating from Web Content Manager version 7.0 or 8.0

These are the migration options available when migrating from Web Content Manager version 7.0.x or 8.0.x.

"Planning for changes to web content when migrating from Web Content Manager version 7.0" on page 804
Migration projects require careful planning to synchronize changes from the old production system with the new system. Content creation can still continue on the old system while the new system is installed. A typical migration plan includes time for provisioning, configuring, testing, and tuning infrastructure and software. Custom or third-party applications require their own migration procedures.

"IBM Portlet API Web Content Viewer and Remote Web Content Viewer" on page 805
If you use the Web Content Viewer portlet or the Remote Web Content Viewer portlet that are based on the IBM Portlet API, then you must plan for the replacement of those portlets when migrating.

"Cross version syndication" on page 806
Cross version syndication is the preferred method of refreshing web content after an initial migration. The portal migration process is used to migrate web content, however after the initial migration is complete, syndication is used to keep the migrated system synchronized with the older system.

"Managed pages options when migrating" on page 807
When you migrate your IBM WebSphere Portal Express to Version 8.5, here are some considerations with regards to managed pages.

"Library export and import options" on page 807
Web content libraries can be exported from one system and imported onto another. This tool can be used as part of a migration, but there are some limitations to the use of this tool.

Planning for changes to web content when migrating from Web Content Manager version 7.0:

Migration projects require careful planning to synchronize changes from the old production system with the new system. Content creation can still continue on the old system while the new system is installed. A typical migration plan includes time for provisioning, configuring, testing, and tuning infrastructure and software. Custom or third-party applications require their own migration procedures.

In addition to continuous content updates, many organizations plan to restructure their website, or introduce new websites or new sections and to have these changes go live with the migrated system. During migration planning and execution, it is important to understand how to manage structural change at the same time as keeping regular content updates synchronized.

Options for keeping data synchronized during migration

Cross-version syndication

Cross version syndication is supported on these versions:

- From Web Content Manager version 7.0.0.2 with CF26 or higher.
- From Web Content Manager version 8.0.0.1 with CF09 or higher.

On these systems, syndication is used to synchronize web content after an initial migration. Syndication replaces the existing function of a post migration data update. See "Cross version syndication" on page 806 for details.

Web content library export and import

A Web content library export and import can be used during migration. However, there are important limitations which preclude the usage of these tools in most migrations. A Web content library export and import can be used when updates are isolated to a small library on the source system. Export and import should only be used where simple modifications or additions are happening in the source system. A Web content library import must not be used to update content which has changed since the last import.

Syndication strategies

- Use cross-version syndication to keep the syndicator on your new system synchronized with the syndicator on your old system. These are usually your authoring servers.
- Updates that are applicable to both the old and new systems are made on the old syndicator.
- Updates that are only applicable to the new system should be made on the new syndicator.

Note: Any changes made on your old system will override changes made on your new system. If making updates on both systems, it is recommended that the items updated or added to the new system are unique to that system. If not, changes on your new system can be replaced by changes from the old system.

Recent items and favorites

Recent items and favorites are not preserved during migration. Lists of favorite items will need to be recreated post-migration. Users should make note of any favorite items prior to migration.

IBM Portlet API Web Content Viewer and Remote Web Content Viewer:

If you use the Web Content Viewer portlet or the Remote Web Content Viewer portlet that are based on the IBM Portlet API, then you must plan for the replacement of those portlets when migrating.

About this task

Both portlets were removed from Web Content Manager Version 8.5 and are no longer supported. You must replace them with the JSR 286 version of the Web Content Viewer portlet that is available.

If you already use only the JSR 286 version, then you do not need to plan for any additional steps for migration.

Procedure

Check which version you currently have installed on your source environment.

1. Click the **Administration menu** icon. Then, click **Portlet Management** > **Web Modules**.
2. Search for the following files names:

   ilwwcm-localrendering-portlet.war
   This file represents the IBM Portlet API Web Content Viewer portlet and its portlet clones. If you find this web module, you need to perform a conversion for the migration. For more information, see *Converting the IBM Portlet API Web Content Viewer to the JSR 286 Web Content Viewer*.

   ilwwcm-remoterendering-portlet.war
   This file represents the IBM Portlet API Remote Web Content Viewer portlet and its portlet clones. If you find this web module, you need to perform a conversion for the migration. For more information, see *Converting the IBM Portlet API Remote Web Content Viewer to the JSR 286 Web Content Viewer*.

ilwwcm-localrendering-portlet-jsr.war
This file represents the JSR 286 Web Content Viewer portlet and its portlet clones. A conversion of this portlet is not required for the migration.

Related tasks:

"Converting an IBM API Web Content Viewer to the JSR 286 API" on page 874
As installed by default, the Web Content Viewer is based on the JSR 286 API. If you have a Web Content Viewer that is based on the older IBM API, you can convert the viewer to the JSR 286 API. Use the **convert-wcm-rendering-portlet** task to convert the IBM API Web Content Viewer settings and instances to the JSR 286 Web Content Viewer portlet.

Cross version syndication:

Cross version syndication is the preferred method of refreshing web content after an initial migration. The portal migration process is used to migrate web content, however after the initial migration is complete, syndication is used to keep the migrated system synchronized with the older system.

Cross-version syndication is supported between the following releases. Syndication from a newer release to an older release is not supported:

- WebSphere Portal version 7.0.0.2 with CF26 or higher.
- WebSphere Portal 8.0.0.1 with CF09 or higher.
- WebSphere Portal 8.5 or higher.

There are no special steps required to configure syndication between releases. The procedure to enable syndication is the same no matter if the versions differ or not. When an existing subscriber is migrated, the existing pair continues to function normally. There are no additional limits to the kind of items or changes that can be updated between versions, although care must be taken whenever changes are made directly to the subscriber since this carries the risk of creating a conflict that can block items from syndicating.

Fix-pack upgrades

Cross version syndication can also be used to syndicate content between environments for the same release, but on different cumulative fix-packs. This allows individual environments, such as authoring and delivery, to be upgraded separately.

The upgrade can proceed in two ways: syndicator first or subscriber first. It might be preferable to upgrade the system with the least uses first, to lessen the impact of an unintended interruption of service. However the subscriber first approach is preferable because there is a greater degree of compatibility when syndicating from an older software level to a newer level.

- When upgrading a syndicator or subscriber, review the release notes of the new software level to check compatibility with the existing levels the server is syndicating to or subscribing from.
- The goal is to have an entire deployment running at the same level release and fix-pack. This capability is not intended to allow different release and fix-pack levels to coexist indefinitely.
- When syndicating from a newer level to an older level, it might be possible to use features on the syndicator that are not available on the subscriber. This should be avoided since it may result in syndication errors. If a failure is

encountered because of a new feature, the change must be reverted on the syndicator and then syndication of the affected items will resume. New features can be tried before the subscriber is upgraded, by saving content using the new features in a library that is not syndicated to an older software level.

- When a library is syndicated to another release level, that library must not be syndicated back to any server that it has already been syndicated from. Disable any reverse syndicator pairs before attempting a fix-pack upgrade.
- Syndicating from a newer software level to an older software level is only supported between different fix-pack levels of the same release. When syndicating between releases, only older to newer is supported.

  Restriction: CF07 The **Rebuild with mirror** option can only be used when syndicating between servers that use CF07 or higher.

Managed pages options when migrating:

When you migrate your IBM WebSphere Portal Express to Version 8.5, here are some considerations with regards to managed pages.

If you migrate from WebSphere Portal Express Version 8.0 to Version 8.5, the portal preserves the state of managed pages enablement:

- If you had managed pages enabled in your version 8.0 portal, managed pages remain enabled after migration.
- If you had managed pages disabled in your version 8.0 portal, managed pages remain disabled after migration.

If you migrate from WebSphere Portal Express Version 7.0, managed pages are not automatically enabled after migration. In this case, consider enabling managed pages after migration. With managed pages, you can take advantage of new features, such as syndication and versioning of pages, and the ability to manage pages in projects. When you migrate systems that access web content from virtual portals, you need to complete extra steps after you enable managed pages.

Portal Site Library

The Portal Site Library stores page-related web content items. The Portal Site Library, and related views in the authoring portlet, are only visible when managed pages are enabled.

Virtual portal isolation

When managed pages are disabled, web content is shared between all virtual portals. However, when managed pages are enabled, each virtual portal has its own unique and isolated workspace for web content. Before the migrated web content can be accessed from a virtual portal with managed pages, it must be syndicated from the base portal. Syndication between virtual portals is no different from syndication between stand-alone servers.

Library export and import options:

Web content libraries can be exported from one system and imported onto another. This tool can be used as part of a migration, but there are some limitations to the use of this tool.

Important: A library import must not be used to replace previously imported web content library if the previously imported library contains subsequent modifications.

Supported data

Only published and expired web content items are exported. The following data is not supported:

- Draft, deleted, purged web content items are not exported.
- Saved versions of web content items are not exported.
- Theme resources stored in WebDAV are not exported.
- Projects are not exported.

Performance

The library export and import tool is slower than the data migration tool because the library export and import tool creates copies of each item from the web content library. Data migration updates items in the database itself.

Port conflicts

During migration, it is possible that a port conflict might occur when starting up the target environment deployment manager, node agents, or IBM WebSphere Portal Express servers.

If you are completing a local migration, you might encounter a port conflict due to the source and target environments using the same ports. You can manually update the ports in the `serverindex.xml` located in the *`target_wp_profile`*`/config/cells/`*`cellname`*`/nodes/`*`nodename`* path to correct the port conflict issues.

You might also encounter a port conflict with the configuration wizard server. If this occurs, update the configuration wizard ports in the `serverindex.xml` located in *`cw_profile`*`/config/cells/`*`cellname`*`nodes/`*`nodename`*.

Related tasks:

"Using copies of source database domains to minimize downtime" on page 835
To keep the earlier portal environment in production and reduce the amount of downtime during migration copy the earlier portal server JCR and Release domains. Connect to the domain copies and then update the new portal server with the domain copies. The process of connecting to the domain copies must be done after you upgrade the ConfigEngine tool but before you upgrade the Portal profile.

Development considerations

The goal of the migration process is to ensure that the target environment works similarly to the source environment. However, there are deprecated and unsupported features and changes in supported technical specifications that can prevent this transition from being seamless. Review the following topics for guidance on the development work that is required to maintain the functionality of the source environment and also begin preparation for enabling new features and functionality.

"Deprecated features" on page 809
Review the features that were available in previous versions of IBM WebSphere Portal Express but are no longer available.

"Exploitation vs. toleration of applications and themes" on page 809
Toleration is the ability for the new version of IBM WebSphere Portal Express to

support and host the portal site of the source environment exactly the way it was on the previous version. And, exploitation is the enhancement of the source environment site to take advantage of the new functionality that is made available in the new version of Portal and WebSphere.

"Prepare applications and themes" on page 810
After the move to IBM WebSphere Portal Express Version 8.5, it is possible that applications and themes that depend on deprecated features will not function properly. To validate custom applications and themes, it is recommended to set up a basic stand-alone WebSphere Portal Express Version 8.5 server.

"Supported toolbar customization" on page 810
In Version 8.5, only specific customizations are allowed for the IBM WebSphere Portal Express site toolbar. Only the supported toolbar customizations can be migrated to the new version.

"Default changed for JavaServer Faces implementation" on page 811
The default JavaServer Faces (JSF) implementation has changed starting in WebSphere Application Server Version 8.

Deprecated features

Review the features that were available in previous versions of IBM WebSphere Portal Express but are no longer available.

After a migration, features that are no longer supported or are deprecated might result in unpredictable behavior. Remove unsupported and deprecated features before you start your migration. As they become available, links to more information are provided to help you move away from deprecated features. For more information on which features are deprecated for Version 8.5, see "Unsupported and deprecated features for V8.5" on page 17.

Exploitation vs. toleration of applications and themes

Toleration is the ability for the new version of IBM WebSphere Portal Express to support and host the portal site of the source environment exactly the way it was on the previous version. And, exploitation is the enhancement of the source environment site to take advantage of the new functionality that is made available in the new version of Portal and WebSphere.

The goal of the migration process is to carry over the portal site and all of its artifacts from the source environment to the target environment, while keeping everything in tact and functioning as it did in the previous version. Ideally, if everything is migrated perfectly, there will be no difference between the site hosted by the source and target environments other than the updated Portal and WebSphere versions that are hosting the site.

Toleration

The ability to support and host the source environment's portal site exactly the way it was on the previous source version. The migration process automates this process, but complete toleration cannot always be contained due to the adoption of new technical specifications, features, and specifications that are deprecated when updating to a new version. The steps that are not automated and that need to be performed following the migration process are documented in the "Post-migration activities" section of the product documentation. In many cases, deprecated features will be replaced by new features that provide equivalent or enhanced functionality, and these will either be included in the new version of WebSphere Portal Express or available in Content Template Catalog.

Exploitation

The enhancement of the source environment portal site to take advantage of the new functionality that is made available in the new version of Portal and WebSphere. There are many new features in Version 8.5 and since the goal is to replicate the original site during migration, none of the features are enabled by default during the migration process. They will need to be enabled by following the instructions in the "Enabling new features" section of the product documentation.

Related tasks:

"Post-migration activities" on page 857
After you migrate to IBM WebSphere Portal Express Version 8.5, you need to complete extra tasks depending on how you customized the source portal environment and which components you used. First, complete the **Applying the latest combined cumulative fix updates** task, then you can begin the post-migration tasks followed by enabling new functionality.

"Enabling new functionality in a migrated portal" on page 909
The migration process collects configuration data and applications from an earlier installed version of IBM WebSphere Portal Express and merges them into the newer installed version so that the new environment is identical to the earlier environment. Taking advantage of new functionality that was not available in the earlier portal requires additional attention after migration is complete.

Prepare applications and themes

After the move to IBM WebSphere Portal Express Version 8.5, it is possible that applications and themes that depend on deprecated features will not function properly. To validate custom applications and themes, it is recommended to set up a basic stand-alone WebSphere Portal Express Version 8.5 server.

The benefit of setting up a basic stand-alone server for validating the custom applications and themes is that the work of preparing the applications and themes for WebSphere Portal Express Version 8.5 can be done in parallel with migration, which can generally save time in the overall migration process.

This tactic can also be applied to any new custom applications or themes that are developed for Version 8.5. Rather than waiting for the WebSphere Portal Express Version 8.5 server migration to complete, you can begin development of the new applications and themes on a stand-alone server while the migration is taking place.

Supported toolbar customization

In Version 8.5, only specific customizations are allowed for the IBM WebSphere Portal Express site toolbar. Only the supported toolbar customizations can be migrated to the new version.

If you plan on migrating a customized, modularized Version 8.0 theme, review the "Preparing the site toolbar" on page 1900 section to understand what customizations of the toolbar are supported.

After you migrate your data, you can choose to enable the Version 8.5 toolbar, and remove the Version 8.0 toolbar on your modularized Version 8.0 theme. See the "Enabling new functionality" section of the documentation to enable the new toolbar or remove the older toolbar.

Related concepts:

"Migration - Add the version 8.5 site toolbar to a version 8.0 theme" on page 921
You can easily add the modularized site toolbar of WebSphere Portal Express Version 8.5 to a WebSphere Portal Express 8.0 theme. Or, you can add a toolbar to a custom theme that is derived from the WebSphere Portal Express 8.0 theme. The theme must be a modularized theme, which supports theme profiles and theme modules.

Related tasks:

Removing the WebSphere Portal Express 8.0 site toolbar from a WebSphere Portal Express 8.0 theme
To use the new site toolbar of WebSphere Portal Express 8.5 within a WebSphere Portal Express 8.0 theme, you must first remove the existing toolbar that comes with your WebSphere Portal Express 8.0 theme.

Default changed for JavaServer Faces implementation

The default JavaServer Faces (JSF) implementation has changed starting in WebSphere Application Server Version 8.

When you are migrating JSF portlets from an earlier version of IBM WebSphere Portal Express, be aware that WebSphere Application Server has changed the default JSF implementation starting in WebSphere Application Server Version 8. For more information, see *JavaServer Faces migration* in the WebSphere Application Server documentation.

Related information:

JavaServer Faces migration

What to expect after you complete migration

During the migration process, your portal applications, portlets, and databases are updated to the IBM WebSphere Portal Express 8.5 versions. However, not all of the new WebSphere Portal Express Version 8.5 functionality and features are enabled by default. The following sections provide information on how various components are handled during migration, and what you can expect after the migration is complete.

"Themes" on page 812
During the migration process, IBM WebSphere Portal Express moves your theme to your target environment without modifications. The pages in your target environment still reference the same theme that was used in the source environment.

"Site toolbar" on page 812
During migration, the IBM WebSphere Portal Express 8.5 theme is deployed. The 8.5 theme includes the site toolbar, but the toolbar is enabled only for the default virtual portal. For all other virtual portals, you must install the site toolbar separately.

"Virtual portals" on page 813
During the migration process, your existing virtual portals are moved over to your target environment without modification.

"WebSphere Portal and Web Content Manager administration" on page 814
In WebSphere Portal Express 8.5, the update of the IBM WebSphere Portal Express and Web Content Manager administration themes was automated. In previous versions of WebSphere Portal Express, the WebSphere Portal Express and Web Content Manager administration themes were not updated during migration.

"Page order" on page 814
If the page order was altered for IBM pages in the Applications,

Administration, or Hidden Pages areas on your source environment, then the page order might not be correct on the target environment after migration.

Themes

During the migration process, IBM WebSphere Portal Express moves your theme to your target environment without modifications. The pages in your target environment still reference the same theme that was used in the source environment.

If you are using standard portal pages, you must convert your pages to static pages. Then, create an WebSphere Portal Express Version 8.5 theme and the layouts that are required for your pages to take take advantage of the WebSphere Portal Express Version 8.5 theme features.

For more information about preparing and optimizing your applications and themes for migration, read the planning section of the product documentation. Also, see the following related links for information about developing themes and skins, troubleshooting modular themes, working with layouts, and converting standard portal pages to static pages by using the IBM WebSphere Portal Express Page Migration Tool.

Related concepts:

"Developing themes and skins" on page 2520
You can create themes using modules to contribute to separate areas of pages to provide flexibility, enhance the user experience, and maximize performance. To optimize themes on your website, use the theme optimization module framework. The framework separates feature-specific logic and capabilities from the theme code.

"Troubleshooting modular themes" on page 2600
You can debug your modules to improve performance.

"Layouts" on page 2677
You can apply ready-use layouts to your portal pages, modify the existing skins, or add your own custom layout to change how your pages display.

Related information:

IBM WebSphere Portal Page Migration Tool

Site toolbar

During migration, the IBM WebSphere Portal Express 8.5 theme is deployed. The 8.5 theme includes the site toolbar, but the toolbar is enabled only for the default virtual portal. For all other virtual portals, you must install the site toolbar separately.

The site toolbar contains artifacts that are not scoped to virtual portals. The global menus, such as the site menu, applications menu, and the administration menu, are displayed in virtual portals. However, the full site toolbar menu options, such as opening the toolbar, the project selector, as well as the edit mode switch, are hidden. To enable the full site toolbar, you must install and enable the toolbar for the respective virtual portal.

Related tasks:

"Enabling the 8.5 site toolbar" on page 878
During migration, the IBM WebSphere Portal Express Version 8.5 theme is deployed. The 8.5 theme includes the site toolbar, but the toolbar is enabled only for the default virtual portal. For all other virtual portals, including migrated and newly created virtual portals, you must install the site toolbar separately.

Virtual portals

During the migration process, your existing virtual portals are moved over to your target environment without modification.

The default sample virtual portal content scripts are not updated during migration. A new sample virtual portal script is available with each new version of WebSphere Portal Express. However, this script is not installed or made available during migration. If you create new virtual portals by using the Virtual Portal Manager portlet in the portal Administration area, the portal continues to use your existing virtual portal content scripts. If you want to create new virtual portals by using new scripts that you create based on the updated samples, configure the Virtual Portal Manager portlet to use these new scripts.

For more information about working with virtual portals, read the *Virtual portals* in the related links.

Adding a portal administrator to virtual portal realms

When you migrate an environment with virtual portals, the portal administrator must be added to the virtual portal realms. If the portal administrator is not added to the realms associated with the virtual portals, the migration fails.

Add the portal administrator to a virtual portal realm:

1. Enter a value for the following parameters in the `wkplc.properties` file in the VMM realm configuration section:
   - **`realmName=`***realmName*
   - **`addBaseEntry=`***o=BaseEntryName*
2. Open a command line.
3. Change to the *wp_profile_root*`/ConfigEngine` directory.
4. Run the following command:
   - AIX HP-UX Linux Solaris: `./ConfigEngine.sh wp-add-realm-baseentry -DWasPassword=`*`password`*
   - IBM i: `ConfigEngine.sh wp-add-realm-baseentry -DWasPassword=`*`password`*
   - Windows: `ConfigEngine.bat wp-add-realm-baseentry -DWasPassword=`*`password`*

Related concepts:

"Virtual portals" on page 1361
View information on how you can scope your WebSphere Portal Express to have multiple virtual portals.

Related tasks:

"Adding realm support" on page 582
A realm is a group of users from one or more user registries that form a coherent group within IBM WebSphere Portal Express. Realms allow flexible user management with various configuration options. A realm must be mapped to a Virtual Portal to allow the defined users to log in to the Virtual Portal. When you configure realm support, complete these steps for each base entry that exists in your LDAP and database user registry to create multiple realm support.

Related reference:

"Pre-configuring the default content for virtual portals" on page 1400
When you create the virtual portal by using the Virtual Portal Manager portlet, the virtual portal is pre-filled with default content. This default content is determined by the default XML script file for initializing virtual portals.

Related information:

"Tasks for administering virtual portals" on page 1389
Administering virtual portals and their content comprises the tasks described in the following topics.

WebSphere Portal and Web Content Manager administration

In WebSphere Portal Express 8.5, the update of the IBM WebSphere Portal Express and Web Content Manager administration themes was automated. In previous versions of WebSphere Portal Express, the WebSphere Portal Express and Web Content Manager administration themes were not updated during migration.

For more information about administering WebSphere Portal Express, read the *Administering* section of the product documentation.

Related concepts:

Chapter 11, "Administering," on page 1041
Use the administration tools that are provided with the portal to do various day-to-day administration tasks. There are two methods for editing portal setup: using the administration portlets or the XML configuration interface. The administration portlets are a convenient way to make real-time updates to the portal's configuration. While the XML configuration interface is suited to more advanced administration, including batch processing of updates.

Page order

If the page order was altered for IBM pages in the Applications, Administration, or Hidden Pages areas on your source environment, then the page order might not be correct on the target environment after migration.

You can adjust the page order of your pages using the Portal Administration menu or XMLAccess. If you want your pages to be listed first, then ensure that they have ordinal values less than 100. For more information, see the post-migration step for "Updating page order" on page 869.

Related tasks:

"Updating page order" on page 869
If the page order was altered for IBM pages in the Applications, Administration, or Hidden Pages areas on your source environment, then the page order might not be correct on the target environment after migration.

Preparing your source environment

Before you begin the steps for migration, you must perform some critical tasks on your source environment, such as creating back ups, installing the latest cumulative fix and one of the two most recent fix packs, and disabling automatic synchronization if you are migrating a cluster. Review the topics in this section, and perform the required tasks to ensure that your source environment remains functional and the migration completes successfully.

Before you begin

Important: If you are using *locahost* in the database URL, update the URL to use the actual database server host name before you continue with your migration.

For more details on preparing your source environment, review the following topics in this section and the Roadmaps for migration.

"Install fix packs on the source environment" on page 816
Periodically fix packs are released to integrate product code fixes. Between fix

pack releases, there are interim fixes to ensure product reliability and stability. You must apply the latest cumulative fix to the source environment. The *Recommended fixes* link provides links to fix pack and interim fix downloads. There is also information about what is recommended and what is required.

"Verifying property files" on page 816
Ensure that the existing portal environment is at the appropriate service level for migration.

"Backing up the system" on page 816
Make sure that you have a current backup and recovery policy before you alter the source environment. Follow the instructions in the Backup and restore section to ensure that you cover all the affected assets.

"Disabling automatic synchronization to protect your clustered source environment" on page 817
The target environment initially uses the same ports as the source environment. There are three important steps you must complete to ensure that the source and target environments do not become corrupted.

"Verifying that WebSphere Application Server Trust Association Interceptor is enabled" on page 818
The automated migration of the WebSphere Portal Express profile requires that the Trust Association Interceptor (TAI) is enabled so that you can configure content in WebDAV during migration.

"Preparing Web Content Manager content" on page 819
To migrate IBM Web Content Manager data, you must remove the locks on content and rename the content libraries.

"Migrating search components" on page 820
The search components in your source portal might require preparation steps and then extra steps on the target portal.

"Migrating from a 32-bit source environment to 64-bit target environment" on page 825
The 32-bit Portal installation is no longer supported in IBM WebSphere Portal Express Version 8.5. If you are migrating from a 32-bit source environment to a 64-bit Version 8.5 environment, you need to take extra steps to ensure that the **WASPreMigration** task completes successfully.

"Prepare UX Screen Flow Manager" on page 825
If you are migrating from Version 8.0.0.1 with the UX Screen Flow Manager (UXFM) enabled, then you must remove the dialog definitions, and then uninstall UXFM before you migrate to Version 8.5. Before you remove the dialog definitions and uninstall UXFM, it is highly recommended that you export your dialog definitions, and when migration is complete, you can import your dialog definitions into your upgraded system. If you do not export your dialog definitions, then your data will be lost.

"Removing WebSphere Commerce integration" on page 828
If you have WebSphere Commerce integrated with IBM WebSphere Portal Express, you must remove WebSphere Commerce from your source portal profile before you begin migration.

"Removing unsupported composite applications" on page 828
Composite applications are no longer supported. If you have a composite application in your system and you migrate to Version 8.5, the migration fails. Ensure that all composite applications are deleted before you start the migration. When you delete a composite application, you must also run the resource cleaner, otherwise pages can still exist in the database.

"Removing obsolete portlets from virtual portal scripts" on page 829
Some portlets were deprecated or removed in this release. If you have

references to deprecated or removed portlets in your virtual portal scripts, you must manually remove those references.

"Distinguished names" on page 829
If you are using LDAP in your source environment, make sure that the `wkplc.properties` file is properly configured. You might have a configuration that is working, but it might not be supported after migration. Short distinguished names (DN) are not supported. Make sure that the properties files in your source environment are set with the fully qualified distinguished names.

"Maximum open file descriptors for Unix-based platforms" on page 830
For Unix-based platforms, the default open file descriptor must be set to 200000 to allow the configuration wizard commands to run properly during migration.

"Disabling wsadmin client debug" on page 831
If you use either IBM WebSphere Application Server Version 8.5.5.4 or WebSphere Application Server Version 8.5.5.5, disable the wsadmin client trace to avoid a failure.

Install fix packs on the source environment

Periodically fix packs are released to integrate product code fixes. Between fix pack releases, there are interim fixes to ensure product reliability and stability. You must apply the latest cumulative fix to the source environment. The *Recommended fixes* link provides links to fix pack and interim fix downloads. There is also information about what is recommended and what is required.

Related information:

Recommended Updates for WebSphere Portal and IBM Web Content Manager

Verifying property files

Ensure that the existing portal environment is at the appropriate service level for migration.

Procedure

1. Open a command prompt and change to the *wp_profile_root*`/ConfigEngine` directory.
2. Run the following command to ensure that the `wkplc_comp.properties` file contains the correct information:
   - Linux : `./ConfigEngine.sh validate-database-connection`
   - IBM i: `ConfigEngine.sh validate-database-connection`
   - Windows: `ConfigEngine.bat validate-database-connection`

Backing up the system

Make sure that you have a current backup and recovery policy before you alter the source environment. Follow the instructions in the Backup and restore section to ensure that you cover all the affected assets.

About this task

Before you start the migration, make a fresh backup of your environment. At a minimum, you must back up the following information:

- Databases
- Directory structures of the source environment
- Security configurations

Related concepts:

Chapter 8, "Backup and restore," on page 771
Backup and recovery of data files and databases is an essential operation for any business system, particularly for data and applications that run in production environments. Create and follow a plan for backing up and recovering data on all tiers of your IBM WebSphere Portal Express deployment. IBM Installation Manager must also be included in backup and recovery planning. If you back up the WebSphere Portal Express file structure and then install a fix pack, the WebSphere Portal Express and IBM Installation Manager become out of sync after you restore the WebSphere Portal Express file system. This condition is not recoverable.

Disabling automatic synchronization to protect your clustered source environment

The target environment initially uses the same ports as the source environment. There are three important steps you must complete to ensure that the source and target environments do not become corrupted.

Procedure

1. Disable automatic synchronization on all nodes in the cluster.

   In a clustered environment, turn off automatic node synchronization before you start the migration. When the automatic synchronization is enabled, the node agent on each node automatically contacts the deployment manager every synchronization interval. As you migrate nodes, some of your migration-specific configuration for a node might get replicated in your clustered environment. For this reason, it is preferable to disable the automatic synchronization and manually sync.

   a. Start the WebSphere Integrated Solutions Console.
   b. Select **System Administration** > **Node Agents** in the navigation tree.
   c. Click **nodeagent** for the required node.
   d. Click **File Synchronization Service** under the **Additional Properties** section.
   e. Clear the **Enable service at server startup** check box selection to disable the synchronization service at startup.
   f. Clear the **Automatic Synchronization** check box selection to disable the automatic synchronization feature.
   g. Click **OK** and **Save**.
   h. Repeat these steps for all remaining nodes.
   i. Select **System Administration** > **Nodes** in the navigation tree.
   j. Select all nodes that must be manually synchronized, and click **Synchronize**.
   k. Select **System Administration** > **Node Agents** in the navigation tree.
   l. For the primary node, select the node agent and click **Restart**.
2. Stop the source deployment manager and node agents before you start your cluster migration.

   This step is required to ensure that the source and target environments do not become corrupted during the migration process. The application servers can continue to run, but administration is disabled until the ports for the target environment are changed in Migrate a Cluster Step 3: Upgrade nodes. Ensure that the source deployment manager and node agents do not start until you complete Migrate a Cluster Step 2: Migrate node profiles.

   a. Open the WebSphere Integrated Solutions Console.
   b. Click **System administration** > **Node agents**.

c. Select the check box for the node agents and click **Stop**.
d. Click **System administration** > **Deployment manager**.
e. On the **Configuration** tab of the deployment manager settings, click **Stop**.

3. Update the ports on the target environment.

   You will update the ports for the target environment in a step that is detailed in Migrate a Cluster Step 3: Upgrade node profiles. After you update the ports, the source deployment manager and node agents can be started.

Verifying that WebSphere Application Server Trust Association Interceptor is enabled

The automated migration of the WebSphere Portal Express profile requires that the Trust Association Interceptor (TAI) is enabled so that you can configure content in WebDAV during migration.

Procedure

Verify that TAI is enabled:

1. Log in to the WebSphere Integrated Solutions Console.
2. Go to **Security** > **Global security**.
3. Ensure that **Enable administrative security** and **Enable application security** are selected.
4. In the **Authentication** section, expand **Web and SIP security**. Click **Trust association**.
5. Ensure that **Enable trust assocation** is selected.

If TAI is not enabled, complete the following steps:

6. Open a command line and change to the directory where WebSphere Portal Express ConfigEngine is installed, on the corresponding operating system:
   - Linux: *wp_profile_root*`/ConfigEngine`
   - IBM i: *wp_profile_root*`/ConfigEngine`
   - Windows: *wp_profile_root*`\ConfigEngine`
7. Enter the following command:
   - Linux: `ConfigEngine.sh enable-http-basic-auth-tai-sitemgmt -DPortalAdminPwd=`*`password`* `-DWasPassword=`*`password`*
   - IBM i: `ConfigEngine.sh enable-http-basic-auth-tai-sitemgmt -DPortalAdminPwd=`*`password`* `-DWasPassword=`*`password`*
   - Windows: `ConfigEngine.bat enable-http-basic-auth-tai-sitemgmt -DPortalAdminPwd=`*`password`* `-DWasPassword=`*`password`*

   Use `-DPortalAdminPwd=`*`password`* `-DWasPassword=`*`password`* to specify the portal and WebSphere Application Server passwords.

   Note: This task uses the settings in the file `wkplc_comp.properties` to configure the TAI. Although the TAI settings are pre-configured to work without requiring adjustment, you can change the settings before you run the task if you need to configure the TAI differently.
8. Stop and restart the portal.
9. Optional: Perform this step if you have SSL configured. Establish trust between two WebSphere cells:
   a. For preparation, determine the URL to the administrative console of the client WebSphere cell. For example, the URL can be similar to `https://myclientserver.yourco.com:9043/ibm/console`.

b. Open the administrative console by using the URL that you obtained by the previous step.
c. Click **Security** > **SSL certificate and key management** > **Key stores and certificates**.
d. On the keystores and certificates panel click **CellDefaultTrustStore** or **NodeDefaultTrustStore**, depending on whether you have a cluster or single node configuration.
e. On the *xxx*DefaultTrustStore panel, locate the column Additional properties and click **Signer certificates**.
f. On the Signer certificates panel, click the button **Retrieve from port**.
g. Complete the fields and select the options as follows:

   Host The host name of the client server, for example `your_target_server.your_co.com`.

   Port The secure port on the client server, for example `9043`.

   SSL configuration for outbound connection
   Select the SSL configuration for the outbound connection, such as `CellDefaultSSLSettings` or `NodeDefaultSSLSettings`.

   Alias The alias name, for example `name_of_your_alias`.
h. Select **Retrieve signer information**. The signer information is displayed.

   Note: The error message `CWPKI0661E: Unable to get certificate signer information from host name "yourtargetserver.yourco.com" and port "9043". Verify host name and port are correct` might appear for one of two reasons:
   - A certificate has already been imported from the target location.
   - A previously deleted certificate has not timed out and been removed.
i. Click **OK**. Your alias is now shown in the list.
j. Click **Save**.
k. Stop and restart the portal.
l. Optional: At this time, if you have a clustered environment without automatic synchronization, you need to resynchronize the node agents.

Related tasks:

"Disabling TAI if disabled previously" on page 864
If TAI was disabled before you began migration, and you had to enable it in order to run the migration, then you might need to disable TAI on both the source and target environments as a post-migration step.

Preparing Web Content Manager content

To migrate IBM Web Content Manager data, you must remove the locks on content and rename the content libraries.

"Removing locks" on page 820
Before migrating, it is recommended that locks are removed on Web content items.

"Renaming web content libraries" on page 820
If the name of a web content library is the same as the URL context of a virtual portal, you can experience incorrect rendering behavior. To prevent this issue, rename the library to a different name before you start the migration.

"Preventing items from being expired during migration"
By default, items with no expiration date defined are automatically expired. Change this setting to prevent automatic expiration from occurring.

Removing locks

Before migrating, it is recommended that locks are removed on Web content items.

Procedure

1. Log on to IBM WebSphere Portal Express.
2. Click the **Administration menu** icon. Then, click **Portal Content** > **Web Content Libraries**.
3. Click **View locked items**.
4. Select all items, and then click **Unlock**.

Renaming web content libraries

If the name of a web content library is the same as the URL context of a virtual portal, you can experience incorrect rendering behavior. To prevent this issue, rename the library to a different name before you start the migration.

Procedure

1. Log in to IBM WebSphere Portal Express.
2. Click the **Administration menu** icon. Then, click **Portal Content** > **Web Content Libraries**.
3. For the library that you want to rename, click the **Edit Library** icon.
4. Enter a new name for the library that is distinct from the URL context of the virtual portal.

Preventing items from being expired during migration

By default, items with no expiration date defined are automatically expired. Change this setting to prevent automatic expiration from occurring.

1. Log in to the WebSphere Integrated Solutions Console.
2. Click **Resources** > **Resource Environment** > **Resource Environment Providers**.
3. Select **WCM WCMConfigService.**
4. In the **Additional Properties** section, select **Custom Properties**.
5. Locate the `expire.blankdate.immediately` setting.
   - If the setting does not exist, add it by clicking **New**. Enter `expire.blankdate.immediately` for **Name** and `false` for **Value.** Click **OK** to save the changes.
   - If the setting does exist, ensure that it is set to `false`. Click to edit the setting. Enter `false` for **Value.** Then, click **OK** to save the changes.

When you click **OK**, a message box appears that prompts you either to save your changes directly to your master configuration or to review your changes before you save them. Click **Save** to save your changes directly or **Review** to review them before saving.

Migrating search components

The search components in your source portal might require preparation steps and then extra steps on the target portal.

"Migrating portal search collections" on page 821
When you migrate or upgrade IBM WebSphere Portal Express to a later version, the data storage format and index structure of Portal Search is not

compatible with an earlier version. If you migrate your portal to a later version and want to continue using your search collections, you must preserve them before you migrate your portal and import them into the upgraded portal after the migration.

"Migrating web search collections" on page 823
You migrate web search collections to IBM WebSphere Portal Express Version 8.5 by exporting each web search collection from the earlier portal and then importing the web search collection into the new portal. You can also use the same functionality to move web search collections to a production portal after verifying them on a test portal, or to move web search collections to a configuration with remote search after verifying them locally on a portal.

"Migrating a remote search server" on page 824
If the source portal environment uses a remote search server, update the remote search server to work with the current portal environment.

"Removing JCR search collections" on page 824
In your source environment, there are JCR search collections that are prefixed with JCRCollection. Although search collections are covered in a separate section, JCRCollection prefixed collections must be handled differently.

Migrating portal search collections

When you migrate or upgrade IBM WebSphere Portal Express to a later version, the data storage format and index structure of Portal Search is not compatible with an earlier version. If you migrate your portal to a later version and want to continue using your search collections, you must preserve them before you migrate your portal and import them into the upgraded portal after the migration.

About this task

Search collections require manual migration; use the **Import or Export Collection** option of the Manage Search portlet to export and import the search collections. For more information about these tasks and the Manage Search portlet, see the portlet help.

Procedure

1. To include the security information when you export the search collection, add the **WS_KEY** parameter to the search service that contains the source search collection that you want to export. Complete the following steps:
   a. To open the **Manage Search** portlet, click the **Administration menu** icon. Then, click **Search Administration** > **Manage Search**.
   b. Click **Search Services**.
   c. Click the **Edit** icon for the search service that contains the search collection that you want to export.
   d. In the **Parameter key** field, enter `WS_KEY`.
   e. In the **New parameter value** field, enter `secret`.
   f. Click **Add Parameter**.
   g. Click **OK**.

   Note: If you do not export the security information when you export a search collection, you must manually add the user name and password to each content source after you import the search collection into the target portal.
2. Before you migrate your portal to a later version, export your search collections. This step exports the configuration data of your search collections.
   a. Click **Manage Search.**

b. Click **Search Collections**.
c. Click the **Import or Export Collection** icon for the collection that you want to export.
d. In the **Specify Location** field, enter the full directory path and XML file name to which you want to export the document collection and its data.
e. Click **Export**.

Notes:

a. Before you export a collection, make sure that the user who is running the portal application process has write access to the target directory location. Otherwise, you might get an error message, such as `File not found`.
b. When you specify the target directory location for the export, be aware that the export overwrites files in that directory.

3. For each collection, document the following data:
   - The target file names and directory locations to which you export the collection.
   - Location, name, description, and language.
   - Settings for the **Specify collection language** and **Remove common words from queries** options.
4. Delete the search collections from your existing portal. Otherwise, they can be corrupted by the import step that follows later.
5. Upgrade your WebSphere Portal Express as needed.
6. Create empty search collections that you can use later to hold the imported collections configuration. Complete the following fields and select the following options according to the information that you documented in step 2:

   Location of Collection
   The location can match the old setting, but does not have to match it.

   Name of Collection
   The name can match the old setting, but does not have to match it.

   Description of Collection
   The description can match the old setting, but does not have to match it.

   Specify Collection Language
   Select this field to match the old setting as documented in step 2.

   Select Summarizer
   The value is overwritten by the import process.

   Remove common words from queries (for example. in, of, on, and so on)
   Check or clear this setting to match the old setting as documented in step 2.

   You do not have to add content sources or documents, as that is completed by the import process.
7. To include the security information when you import the search collection, add the **WS_KEY** parameter to the search service that contains the target search collection. Complete the following steps:
   a. To open the **Manage Search** portlet, click the **Administration menu** icon. Then, click **Search Administration** > **Manage Search**.
   b. Click **Search Services**.

c. Click the **Edit** icon for the search service that contains the target search collection.
d. In the **Parameter key** field, enter `WS_KEY`.
e. In the **New parameter value** field, enter `secret`.
f. Click **Add Parameter**.

Note: If you do not import the security information when you import a search collection, you must manually add the user name and password to each content source after you import the search collection into the target portal.

8. Check that the target search collections that you created in step 6 are empty. Do not import collection data into a target collection that already contains sources or documents.
9. Import the search collection data into the portal. For the import source information, use your documented file names and directory locations to which you exported the collections before the portal upgrade.
10. Briefly review the content source's configuration settings to check whether information such as host name and security credentials are still valid or must be modified. Make any necessary changes to the content source's configuration settings.

    Note: When you import search collection data into a collection, most of the configuration data such as content sources, schedulers, filters, and language settings are also imported. If you configured such settings when you created the collection, they are overwritten by the imported settings.

Migrating web search collections

You migrate web search collections to IBM WebSphere Portal Express Version 8.5 by exporting each web search collection from the earlier portal and then importing the web search collection into the new portal. You can also use the same functionality to move web search collections to a production portal after verifying them on a test portal, or to move web search collections to a configuration with remote search after verifying them locally on a portal.

"Exporting search web collections"
Use the Manage Search portlet to export search web collections from a source portal. Before you export a collection, make sure that the user who is running the portal application process has write access to the target directory location.

Exporting search web collections:

Use the Manage Search portlet to export search web collections from a source portal. Before you export a collection, make sure that the user who is running the portal application process has write access to the target directory location.

Procedure

1. To include the security information when you export the search collection, add the **WS_KEY** parameter to the search service that contains the source search collection that you want to export. Complete the following steps:
   a. To open the **Manage Search** portlet, click the **Administration menu** icon. Then, click **Search Administration** > **Manage Search**.
   b. Click **Search Services**.
   c. Click the **Edit** icon for the search service that contains the search collection that you want to export.

d. In the **Parameter key** field, enter `WS_KEY`.
e. In the **New parameter value** field, enter `secret`.
f. Click **Add Parameter**.
g. Click **OK**.

Note: If you do not export the security information when you export a search collection, you must manually add the user name and password to each content source after you import the search collection into the target portal.

2. Click **Manage Search.**
3. Click **Search Collections**.
4. Click the **Import or Export Collection** icon for the collection that you want to export.
5. In the **Specify Location** field, enter the full directory path and XML file name to which you want to export the document collection and its data.
6. Click **Export**

Related tasks:

"Importing search web collections" on page 883
As a part of preparing your source environment, you exported web collections. After you export a search web collection from a source portal, you can import the data into a new, empty collection on the target portal. Importing a web collection retains most of the configuration data such as content sources, schedulers, filters, and language settings. If you configured such settings when creating the new collection, they are overwritten by the imported settings.

Migrating a remote search server

If the source portal environment uses a remote search server, update the remote search server to work with the current portal environment.

Procedure

1. Update IBM WebSphere Application Server on the remote search server to the supported version.

   To avoid port conflicts, ensure that the earlier installed version of WebSphere Application Server is up and running. Then install the current version of WebSphere Application Server to a different directory. After installation, check that both the earlier version and the newer version are running, and then continue configuring the remote server. For more information, see *Using remote search service*.
2. On the migrated portal, re-create the search collections for use with the updated remote search server.

Removing JCR search collections

In your source environment, there are JCR search collections that are prefixed with JCRCollection. Although search collections are covered in a separate section, JCRCollection prefixed collections must be handled differently.

About this task

When you migrate search collections, you usually export and delete them from the source environment. Then, proceed with the migration. Finally, import them into the target environment. These steps are covered in detail in the *Migrating Portal search collections* section.

For **JCRCollection** prefixed collections, the process is simpler. You do not need to export, migrate, and import later. Instead, you must delete the **JCRCollection** prefixed search collections from your source environment before you start with the migration. Migration automatically re-creates the JCR search collection as part of the post-migration activities.

Migrating from a 32-bit source environment to 64-bit target environment

The 32-bit Portal installation is no longer supported in IBM WebSphere Portal Express Version 8.5. If you are migrating from a 32-bit source environment to a 64-bit Version 8.5 environment, you need to take extra steps to ensure that the **WASPreMigration** task completes successfully.

About this task

The binary files that are used to run the **WASPreUpgrade** task on the source server are typically created on the target environment. However, the remote migration package includes a Java JRE that matches the 64-bit architecture of the target environment, and it cannot be run on the source environment. If you attempt to use the 64-bit remote migration package on the 32-bit source environment, you are prompted with an error message that states that the 64-bit JVM cannot run on 32-bit hardware.

Choose one of the following methods to resolve this issue:

1. Change the JAVA_HOME path that is used by the remote migration package to use the Java installed with source Portal server:
   a. Create the remote migration package as directed by the migration instructions in the Configuration Wizard.
   b. Copy the remote migration package to the source environment, and extract.
   c. Edit the *extracted remote migration package root*/bin/sdk/_setupsdk1.6_64.sh file, and update the **JAVE_HOME** property to be in the *Source AppServer root*/java path of the source environment.
   d. Continue with the rest of the migration process in the Configuration Wizard.
2. Copy the JRE from the source environment to the remote migration package:
   a. Create the remote migration package as directed by the migration instructions in the Configuration Wizard.
   b. Copy the remote migration package to the source environment, and extract.
   c. Move the Java folder from the remote migration package that is in *extracted remote migration package root*/java to another location.
   d. Copy the Java folder from your source that is in *Source AppServer root*/java to the Java folder in the remote migration package.
   e. Continue with the rest of the migration process in the Configuration Wizard.

Prepare UX Screen Flow Manager

If you are migrating from Version 8.0.0.1 with the UX Screen Flow Manager (UXFM) enabled, then you must remove the dialog definitions, and then uninstall UXFM before you migrate to Version 8.5. Before you remove the dialog definitions and uninstall UXFM, it is highly recommended that you export your dialog

definitions, and when migration is complete, you can import your dialog definitions into your upgraded system. If you do not export your dialog definitions, then your data will be lost.

1. "Exporting UXFM dialog definitions"
   Export and save your dialog definitions before you migrate to Version 8.5.
2. "Removing UXFM dialog definitions" on page 827
   Remove the UX Screen Flow Manager (UXFM) dialog definitions before uninstalling UXFM. This is a required step before you uninstall UXFM.
3. "Uninstalling UX Screen Flow Manager" on page 827
   If you are migrating from Version 8.0.0.1 with the UX Screen Flow Manager (UXFM) enabled, then you must uninstall UXFM before migrating to Version 8.5.

Exporting UXFM dialog definitions

Export and save your dialog definitions before you migrate to Version 8.5.

Procedure

1. Save the following example of code as *ExportSampleCode.xml* to use when exporting your dialog definitions.

```
<?xml version="1.0" encoding="UTF-8"?>
<request type="update" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:noNamespaceSchemaLocation="PCM_1.0.xsd">

    <!-- export all dialog definitions that are currently deployed -->
    <portal action="export">
        <dialog-set>
            <dialog name="*" />
        </dialog-set>
    </portal>
</request>
```

2. Run the following task from the *wp_profile_root*/PortalServer/bin directory to export your dialog definitions:
   - Linux : ./xmlaccess.sh -user *userID* -password *password* -url *http://local_host:local_port/wps/config* -in *ExportSampleCode.xml* -out export.xml
   - IBM i: xmlaccess.sh -user *userID* -password *password* -url *http://local_host:local_port/wps/config* -in *ExportSampleCode.xml* -out export.xml
   - Windows: xmlaccess.bat -user *userID* -password *password* -url *http://local_host:local_port/wps/config* -in *ExportSampleCode.xml* -out export.xml
3. Back up the file that contains the exported dialog definitions to a secure location. You can import your dialog definitions after you migrate to V8.5.

Related tasks:

"Importing UX Screen Flow Manager dialog definitions" on page 884
If you migrated from Version 8.0.0.1 with the UX Screen Flow Manager (UXFM) enabled, then you exported and removed your dialog definitions before migrating to Version 8.5. Run the following task to import the dialog definitions into your upgraded system.

"Uninstalling UX Screen Flow Manager" on page 827
If you are migrating from Version 8.0.0.1 with the UX Screen Flow Manager (UXFM) enabled, then you must uninstall UXFM before migrating to Version 8.5.

Related reference:

This topic lists the syntax elements for using the XML configuration interface command line client over an HTTP connection.

Removing UXFM dialog definitions

Remove the UX Screen Flow Manager (UXFM) dialog definitions before uninstalling UXFM. This is a required step before you uninstall UXFM.

Procedure

1. Save the following example of code as *RemoveSampleCode.xml* to use to remove your dialog definitions.

```
<?xml version="1.0" encoding="UTF-8"?>
<request type="update" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:noNamespaceSchemaLocation="PCM_1.0.xsd">

    <!-- remove all dialog definitions that are currently deployed -->
    <portal action="delete">
       <dialog-set>
            <dialog name="*" />
        </dialog-set>
    </portal>
</request>
```

2. Run the following task from the *wp_profile_root*/PortalServer/bin directory to remove your dialog definitions:
   - Linux : `./xmlaccess.sh -user userID -password password -url http://local_host:local_port/wps/config -in RemoveSampleCode.xml -out delete.xml`
   - IBM i: `xmlaccess.sh -user userID -password password -url http://local_host:local_port/wps/config -in RemoveSampleCode.xml -out delete.xml`
   - Windows: `xmlaccess.bat -user userID -password password -url http://local_host:local_port/wps/config -in RemoveSampleCode.xml -out delete.xml`

Related reference:

"Syntax elements for the XML configuration interface command line" on page 1067
This topic lists the syntax elements for using the XML configuration interface command line client over an HTTP connection.

Uninstalling UX Screen Flow Manager

If you are migrating from Version 8.0.0.1 with the UX Screen Flow Manager (UXFM) enabled, then you must uninstall UXFM before migrating to Version 8.5.

Before you begin

You must remove the dialog definitions before you uninstall UXFM. If you do not remove the dialog definitions prior to completing the uninstall, it can have a catastrophic effect on your system rendering it unusable.

Procedure

1. If UXFM portlets are installed, run the following task:
   - Linux : `./ConfigEngine.sh action-undeploy-pcm-portlets`
   - IBM i: `ConfigEngine.sh action-undeploy-pcm-portlets`
   - Windows: `ConfigEngine.bat action-undeploy-pcm-portlets`
2. Stop the Portal Server.

3. Run the following task:
   - Linux : `./ConfigEngine.sh uninstall-pcm`
   - IBM i: `ConfigEngine.sh uninstall-pcm`
   - Windows: `ConfigEngine.bat uninstall-pcm`

Related tasks:

"Exporting UXFM dialog definitions" on page 826
Export and save your dialog definitions before you migrate to Version 8.5.

IBM UX Screen Flow Manager: Installation and setup

Removing WebSphere Commerce integration

If you have WebSphere Commerce integrated with IBM WebSphere Portal Express, you must remove WebSphere Commerce from your source portal profile before you begin migration.

About this task

Complete the following steps on your source WebSphere Portal Express Version 8 profile.

Procedure

1. Run the following command:
   - Linux : `./ConfigEngine.sh remove-paa -DappName=wcm.wcs.integrator.paa`
   - IBM i: `ConfigEngine.sh remove-paa -DappName=wcm.wcs.integrator.paa`
   - Windows: `ConfigEngine.bat remove-paa -DappName=wcm.wcs.integrator.paa`
2. Run the following command:
   - Linux : `./ConfigEngine.sh uninstall-paa -DappName=wcm.wcs.integrator.paa`
   - IBM i: `ConfigEngine.sh uninstall-paa -DappName=wcm.wcs.integrator.paa`
   - Windows: `ConfigEngine.bat uninstall-paa -DappName=wcm.wcs.integrator.paa`
3. Delete the *Portal_V8_profile*/paa/wcm.wcs.integrator.paa directory.

What to do next

When migration is complete, you can install the 8.5 version of the PAA file.

Removing unsupported composite applications

Composite applications are no longer supported. If you have a composite application in your system and you migrate to Version 8.5, the migration fails. Ensure that all composite applications are deleted before you start the migration. When you delete a composite application, you must also run the resource cleaner, otherwise pages can still exist in the database.

Procedure

If you own or manage an application, you can delete it. The applications catalog is the only context where you can delete an application.

1. Use the following code sample to show the applications that you own or manage:

```
AppListString = Application.listall("applications")
if AppListString == '':
  print 'There are no composite applications.'
else:
  AppList = AppListString.split(' ')
  for app in AppList:
    print "- " + Application.nlsget(app,"title","en") + "(" + app + ")"
```

2. For each application that you want to delete, click the **Delete** icon.
3. Click **OK** to confirm the deletion.
4. Run the resource cleaner to ensure that no other pages exist in the database: "Scheduling the delayed cleanup of portal pages" on page 1079.

Related concepts:

"Unsupported and deprecated features for V8.5" on page 17
Review the features that were available in previous versions of IBM WebSphere Portal Express but are no longer available.

Removing obsolete portlets from virtual portal scripts

Some portlets were deprecated or removed in this release. If you have references to deprecated or removed portlets in your virtual portal scripts, you must manually remove those references.

In the virtual portal XML scripts, look for references to deprecated portlets such as,`Manage Seed List` and remove them.

- `<portlet action="locate" name="Manage Seed List" objectid="3_CGAH47L008DE402BK8543I1G63"></portlet>`
- `<p><portletinstance action="update" domain="rel" objectid="5_CGAH47L008DE402BK8543I18D4" portletref="3_CGAH47L008DE402BK8543I1G63" shareref="5_CGAH47L008DE402BK8543I18D4"></portletinstance></p>`

Note: Keep in mind that `objectid`, `portletref`, `shareref`, might vary in your installation.

You might also find references to `installer/wp.config/config/work` which is no longer valid and must be replaced to `installer/wp.config/config/templates`.

There might be other references to resources that do not exist in this new release of WebSphere Portal Express. Make sure that you update all those references as needed.

Distinguished names

If you are using LDAP in your source environment, make sure that the `wkplc.properties` file is properly configured. You might have a configuration that is working, but it might not be supported after migration. Short distinguished names (DN) are not supported. Make sure that the properties files in your source environment are set with the fully qualified distinguished names.

The following excerpt from the `wkplc.properties` file provides some examples of using fully qualified distinguished names (DN) for the **`PortalAdminId`** parameter.

`PortalAdminId`
This value is the user ID for the WebSphere Portal administrator. The installation program sets this value that is based on user input during installation. The user ID cannot contain a space: for example, `user ID`. The user ID cannot be longer than 200 characters.

(UNIX only) Some tasks might require you to enter the fully qualified user ID. If your fully qualified user ID contains a space; for example: `cn=wpsadmin,cn=users,l=SharedLDAP,c=US,ou=Lotus,o=Software Group,dc=ibm,dc=com`, then you must place the fully qualified user ID in the properties file or into a parent properties file instead of as a flag on the command line. To create a parent properties file called `mysecurity.properties`, enter the fully qualified user ID, and then run the following task: **`./ConfigEngine.sh task_name -DparentProperties=/opt/mysecurity.properties`**.

(Windows only) Some tasks might require you to enter the fully qualified user ID. If your fully qualified user ID contains a space; for example: `cn=wpsadmin,cn=users,l=SharedLDAP,c=US,ou=Lotus,o=Software Group,dc=ibm,dc=com`, then you must place quotations around the fully qualified user ID before you run the task, for example: `"cn=wpsadmin,cn=users,l=SharedLDAP,c=US,ou=Lotus,o=Software Group,dc=ibm,dc=com."`

Value: A valid user ID contains only ASCII characters and can contain the following characters:

Lowercase characters {a-z} and uppercase characters {A-Z}

Numbers {0-9}

Exclamation point {!}, Hyphen {-}, period {.}, question mark {?}, accent grave {`}, tilde {~}

Open parenthesis {(} and close parenthesis {)}

Open bracket {[} and close bracket {]}

Underscore {_}, which is the only special character that is allowed in IBM i

Examples: The following are example user IDs:

Development configuration without security: `PortalAdminId=uid=xyzadmin,o=defaultWIMFileBasedRealm`

IBM Tivoli Directory Server: { `uid=,cn=users,dc=yourco,dc=com` }

IBM Lotus Domino: { `cn=,o=yourco.com` }

Novell eDirectory: { `uid=,ou=people,o=yourco.com` }

Oracle Directory Server: { `uid=,ou=people,o=yourco.com` }

Windows Active Directory: { `cn=,cn=users,dc=yourco,dc=com` }

Windows Active Directory-Lightweight-Directory-Services: { `cn=,cn=users,dc=yourco,dc=com` }

Default: no default

Maximum open file descriptors for Unix-based platforms

For Unix-based platforms, the default open file descriptor must be set to 200000 to allow the configuration wizard commands to run properly during migration.

The default open file descriptor limit for the Unix user profile that is used to install and run the WebSphere Portal Express and configuration wizard servers should be set to 200000. Update this value in the user profile for any migrations that use the configuration wizard. The typical syntax is `ulimit -n 200000`. However, you can refer to the documentation specific to your platform to confirm.

If you run the migration commands manually, set the open file descriptor to 200000 prior to running the **`WASPreUpgrade.sh`** and **`WASPostUpgrade.sh`** commands.

Disabling wsadmin client debug

If you use either IBM WebSphere Application Server Version 8.5.5.4 or WebSphere Application Server Version 8.5.5.5, disable the wsadmin client trace to avoid a failure.

There is a known issue in wsadmin client connections to node agents on WebSphere Application Server Version 8.5.5.4 and WebSphere Application Server Version 8.5.5.5 that can cause wsadmin to fail if tracing is enabled.

Disable the wsadmin client trace:

- In *wp_profile_root*`/properties/wsadmin.properties`, comment out `com.ibm.ws.scripting.traceString`. For example:

  ```
  #com.ibm.ws.scripting.traceString=com.ibm.*=all=enabled
  ```

If the wsadmin client trace is needed, you can append the following line to the trace string to disable tracing for the MetaInfoCache class.

- Append `:com.ibm.ws.scripting.MetaInfoCache=off`. For example,

  ```
  com.ibm.ws.scripting.traceString=com.ibm.*=all=enabled:com.ibm.ws.scripting.MetaInfoCa
  ```

Setting up the target environment

The migration requires you to install the required Portal and WebSphere binary installations. To prepare your target environment, ensure that you have applied the latest cumulative fix and the most recent fix pack before you start migration. In addition, create new copies of the source databases for the target environment to use, and prepare the target environment for any custom applications that have dependencies or any other tasks that need to be performed for remote or cluster migrations.

About this task

Migration to a new release requires setting up a target environment. The target environment might be one of the following environments:

- A separate system
- A remote migration
- The same system if you choose a local migration path

Independently from the migration path that is chosen, the target environment requires a fresh, binary only, Portal installation. Meaning setting up the target environment without creating any profiles.

For more details on setting up the target environment, review the following topics in this section and the Roadmaps for migration.

"Target environment considerations" on page 832
Installation planning of the target environment must be part of your overall migration planning. There are some considerations to keep in mind when you install WebSphere Portal Express and you plan to do a migration from your existing installation.

"Installing Portal and WebSphere binary files" on page 833
On your target system, you must install the portal and WebSphere binary files.

"Installing fix packs on the target environment" on page 834
Periodically, fix packs are released to integrate product code fixes. Between fix pack releases, there are interim fixes to ensure product reliability and stability.

You must apply the latest available fix pack and cumulative fix to the target environment. The Recommended fixes link provides links to fix pack and interim fix downloads. There is also information about what is recommended and what is required.

"Copying portal binary files to the deployment manager" on page 834
Complete this task if the deployment manager is not sharing application binary files with a Portal install.

"Copying files for third party and custom applications" on page 835
The Portal migration attempts to install custom applications in the target environment, but it does not automatically copy the files required for those applications. If the files are not copied over, it is possible that the applications will fail to install or not work properly.

"Target environment: Maximum open file descriptors for Unix-based platforms" on page 835
For Unix-based platforms, the default open file descriptor must be set to 200000 to allow the configuration wizard commands to run properly during migration.

"Using copies of source database domains to minimize downtime" on page 835
To keep the earlier portal environment in production and reduce the amount of downtime during migration copy the earlier portal server JCR and Release domains. Connect to the domain copies and then update the new portal server with the domain copies. The process of connecting to the domain copies must be done after you upgrade the ConfigEngine tool but before you upgrade the Portal profile.

"Database considerations" on page 836
Depending on the type of database that you use, there might be extra considerations or tasks to complete before and after you migrate your data. Review the information that is tailored for your database type to ensure the migration process completes successfully.

Related information:

Recommended fixes and updates for WebSphere Portal and Web Content Management

WebSphere Portal detailed system requirements

Target environment considerations

Installation planning of the target environment must be part of your overall migration planning. There are some considerations to keep in mind when you install WebSphere Portal Express and you plan to do a migration from your existing installation.

Installing a brand new WebSphere Portal Express

When you install a new environment for migration, you must choose the binary-only option. This installation type does not create any profile that might conflict with the migration process. Refer to the Related information section for specific details on installing the target environment.

Installing the latest fix pack and cumulative fix

Ensure that you install the latest available fix pack and cumulative fix. They might include fixes and improvements to the migration process. Refer to Recommended fixes and updates for WebSphere Portal and Web Content Management for details.

Reserved user names and special characters

There are other considerations to keep in mind around the user IDs and passwords when compared to a regular installation. The `xyzadmin` is a reserved value and cannot be used as WebSphere Portal Express or WebSphere Application Server administrator name. You must change the administrator name from your source environment if you are using this name.

Related tasks:

"Replacing the WebSphere Portal Express administrator user ID" on page 1675
If you change your security configuration, you might need to replace your old IBM WebSphere Portal Express administrator user ID with a new WebSphere Portal Express administrator user ID.

"Replacing the WebSphere Application Server administrator user ID" on page 1674
If you change your security configuration, you might need to replace your old IBM WebSphere Application Server administrator user ID with a new WebSphere Application Server administrator user ID.

"Planning to install WebSphere Portal Express" on page 101
Before you install IBM WebSphere Portal Express in a production environment, you need to assess your hardware and software needs, possible database configurations, security options, and LDAP server options. Skipping this important step can lead to unexpected results and costly delays.

Related information:

"User IDs and passwords" on page 107
Understanding character limitations for user IDs and passwords is important because they are used throughout the system to provide access and secure content. The character limitations provided here apply to the IBM WebSphere Portal Express administrator, IBM WebSphere Application Server administrator, database administrator, LDAP server administrator, and user IDs. Database and LDAP servers can have more restrictive limitations than provided here. Therefore, check the database and LDAP server product documentation for restrictions. Failure to correctly define user IDs and passwords during the installation process can result in installation failure. In addition, your company might have more restrictive user ID and password requirements that you must also follow.

 Recommended fixes and updates for WebSphere Portal and Web Content Management

Installing Portal and WebSphere binary files

On your target system, you must install the portal and WebSphere binary files.

To effectively set up your target environment, install the Portal and WebSphere binary files on all target systems. Nodes and stand-alone servers require a binary Portal and WebSphere installation, while deployment managers require only a WebSphere binary installation.

IBM WebSphere Portal Express version 8.5 is packaged with IBM WebSphere Application Server version 8.5.5.2. There are some fixes in WebSphere Application Server version 8.5.5.4 and later that might prevent some problems from occurring during the migration. Therefore, when you install WebSphere Portal Express and the binary files, install the latest version of the WebSphere Application Server. Complete the following steps to install WebSphere Portal Express with the latest version of WebSphere Application Server:

1. Download the latest version of WebSphere Application Server from Passport Advantage.

2. Start the Installation Manager.
3. Go to **File** > **Preferences** > **Repositories**.
4. Add the repository for the latest version of WebSphere Application Server.
5. When you install WebSphere Portal Express, select the repositories for the latest version of WebSphere Application Server and the repository for WebSphere Portal Express.

The following high-level steps provide guidance for using the IBM Installation Manager. Refer to the Installing the Exceptional Digital Experience section for other installation alternatives.

Note: If you previously did a full Portal installation, you must remove all profiles.

1. Start the IBM Installation Manager.
2. Follow the IBM Installation Manager instructions through the different screens.
3. While on the **Features** screen, make sure that **Create a new Portal Server Profile** is not selected.
4. Proceed with the remaining instructions to complete the binary installation.

Related tasks:

"Installing the digital experience software" on page 167
IBM's Exceptional Digital Experience is designed to help create, manage, simplify, and integrate your processes into an engaging online experience. IBM WebSphere Portal and IBM Web Content Manager are a part of the Exceptional Digital Experience. The product documentation uses digital experience software as a shorthand for IBM WebSphere Portal and IBM Web Content Manager.

Installing fix packs on the target environment

Periodically, fix packs are released to integrate product code fixes. Between fix pack releases, there are interim fixes to ensure product reliability and stability. You must apply the latest available fix pack and cumulative fix to the target environment. The Recommended fixes link provides links to fix pack and interim fix downloads. There is also information about what is recommended and what is required.

Related information:

Recommended fixes and updates for WebSphere Portal and Web Content Management

Copying portal binary files to the deployment manager

Complete this task if the deployment manager is not sharing application binary files with a Portal install.

Procedure

Copy the required files (including the migration plug-in) from the IBM WebSphere Portal Express Version 8.5 binary installation to the target deployment manager system:

1. Copy the `filesForDmgr.zip` file to the remote deployment manager system.
2. Expand the `filesForDmgr.zip` file into the installation root directory of the deployment manager. For example, in the `C:\IBM\WebSphere\AppServer directory`.

If the deployment manager profile was not created in the default `AppServer/profiles/Dmgr01` directory, then the `metadata_wkplc.xml` file in the

AppServer/profiles/Dmgr01/config/.repository/metadata_wkplc.xml directory in the compressed file, must be copied into the config/.repository subdirectory under the deployment manager profile directory.
Failure to copy the migration plug-in files to the deployment manager can result in the following error when you try to upgrade
the ConfigEngine tool:com.ibm.websphere.management.exception.InvalidConfigDataTypeExcept
ADMG0007E: The configuration data type CellCompRegistryCollection is not valid.

Copying files for third party and custom applications

The Portal migration attempts to install custom applications in the target environment, but it does not automatically copy the files required for those applications. If the files are not copied over, it is possible that the applications will fail to install or not work properly.

Target environment: Maximum open file descriptors for Unix-based platforms

For Unix-based platforms, the default open file descriptor must be set to 200000 to allow the configuration wizard commands to run properly during migration.

The default open file descriptor limit for the Unix user profile that is used to install and run the WebSphere Portal Express and configuration wizard servers should be set to 200000. Update this value in the user profile for any migrations that use the configuration wizard. The typical syntax is `ulimit -n 200000`. However, you can refer to the documentation specific to your platform to confirm.

If you run the migration commands manually, set the open file descriptor to 200000 prior to running the **WASPreUpgrade.sh** and **WASPostUpgrade.sh** commands.

Using copies of source database domains to minimize downtime

To keep the earlier portal environment in production and reduce the amount of downtime during migration copy the earlier portal server JCR and Release domains. Connect to the domain copies and then update the new portal server with the domain copies. The process of connecting to the domain copies must be done after you upgrade the ConfigEngine tool but before you upgrade the Portal profile.

About this task

Review the following list before you begin.

Important:

- Copying the source portal JCR and Release domains is a recommendation but not a requirement. If you point the new portal server to the source portal domains, you cannot use the JCR and Release domains with the earlier portal server.
- During migration, the Community and Customization domains are upgraded to their new definitions required by the new WebSphere Portal Express release. This migration might break the compatibility with the source portal server. Carefully check the requirements for the source portal server if you plan to use the earlier portal server until migration is finished.

- If you are migrating from WebSphere Portal Express Version 7 to WebSphere Portal Express Version 8.5, be aware that there is a major schema change in the JCR database that may cause the JCR database to triple in size. Ensure that there is enough disk space for the new copies of the database when you create the new copies.
- DB2 only: When you migrate a source portal to a target portal that uses a different driver type, reconnect all of the affected domains. For example, the source portal is using DB2 with Type 2 drivers for all domains. You plan to use a Type 4 driver type for all of the domains in your target portal. In this case, you must reconnect all of the database domains that use the **connect-database** command.

Note: The **connect-database** configuration task does not preserve customizations to the data sources for the WebSphere Portal Express databases. If you previously tuned your data sources for the WebSphere Portal Express databases, make a note of the settings, run **connect-database**, and reapply the tuning after you run the configuration task.

Procedure

1. Use your Database tools to copy the source portal JCR domain and Release domain.

   Note: If you are using IBM DB2 Universal Database for z/OS, review the following considerations:
   - If you plan to use the DB2 Administration Tool to copy the database domains, make sure that APAR PM16847 is applied.
   - Make sure that you verify the databases are not in a `COPY PENDING` state before you connect to the database copies described in the following step.
2. DB2 only: On the database copies, verify that the Statement Heap size is set to at least 32k.
   a. List the database manager configuration parameters by running the following command **db2 get db cfg for** *dbname*.
   b. If the Statement Heap size is smaller than 32k, increase it by running the following command **db2 "UPDATE DB CFG FOR** *dbname* **USING stmtheap 32768"**

   Where *dbname* is the name of your WebSphere Portal Express database.
3. On the target portal, update the `wkplc_dbdomain.properties` file in the *wp_profile_root*`/ConfigEngine/properties` directory.
   a. Update the `jcr.*` and `release.*` database properties to point to the JCR and Release domain copies that you created in the previous step.

Database considerations

Depending on the type of database that you use, there might be extra considerations or tasks to complete before and after you migrate your data. Review the information that is tailored for your database type to ensure the migration process completes successfully.

"Configuring transaction logging space" on page 837
When you migrate from earlier versions of WebSphere Portal Express, certain portions of the actual database migration use database transactions that can contain large volumes of data change. In order for the database to accommodate these transaction changes, the amount of space available to the database transaction logs might need to be increased.

"Oracle: Disabling the auto space advisor background task" on page 839
To prevent deadlocks during migration, you must complete a task to disable the Oracle background task called "Auto Space Advisor" before your run the **upgrade-profile** task during migration using the Configuration Wizard. After you complete migration, you can enable "Auto Space Advisor" as a post-migration task.

"DB2" on page 840
Database migration is one of the most time consuming portions of the migration process. If you are migrating from DB2, review the following topics to improve the speed of the database migration process.

Configuring transaction logging space

When you migrate from earlier versions of WebSphere Portal Express, certain portions of the actual database migration use database transactions that can contain large volumes of data change. In order for the database to accommodate these transaction changes, the amount of space available to the database transaction logs might need to be increased.

About this task

There are certain database platforms that allow for the temporary usage of unlimited database transaction log space. It is advisable to enable that option during the migration to avoid any possible issues that are related to exhausting available transaction log space.

On platforms or environments where unlimited transaction logging is not an option, the following formula can be used to determine the amount of transaction log space that is required to complete the migration. Note that several of these queries can be long running (several minutes) depending on the amount of data in the Portal database.

Before you run the SQL commands, you need to replace the following references according to your environment.

- <*schema*> replace this token with the schema used in the JCR Domain database.
- <*ROOT_WSID*> replace this token with the result of `SELECT WSID FROM <schema>.ICMSTJCRWS WHERE WSNAME = 'ROOTWORKSPACE'`
- <*VER_WSID*> replace this token with the result of `SELECT WSID FROM <schema>.ICMSTJCRWS WHERE WSNAME = 'jcr:versioning'`

As you run the following steps, save the result as you need to do some computation to calculate the correct numbers for setting the transaction logging space.

Steps #1 - #8 are for calculating the space that is required to migrate hierarchy information for WebSphere Portal Express data that is stored in the JCR excluding all version information.

Steps #9 - #16 are for calculating the space that is required to migrate hierarchy information for version information of WebSphere Portal Express data.

Procedure

1. `SELECT COUNT(LID) FROM <schema>.ICMSTJCRLINKS WHERE WSID = <ROOT_WSID> AND INLEAFTREEFLAG = 1 AND SIID IN ( SELECT TIID FROM <schema>.ICMSTJCRLINKS WHERE INLEAFTREEFLAG = 0 AND WSID = <ROOT_WSID> )`

2. SELECT COUNT(LID) FROM <*schema*>.ICMSTJCRLINKS WHERE WSID = <*ROOT_WSID*> AND INLEAFTREEFLAG = 1 AND SIID IN (SELECT TIID FROM <schema>.ICMSTJCRLINKS WHERE WSID = <ROOT_WSID> AND INLEAFTREEFLAG = 1 AND SIID IN (SELECT TIID FROM <schema>.ICMSTJCRLINKS WHERE INLEAFTREEFLAG = 0 AND WSID = <*ROOT_WSID*>))
3. SELECT COUNT(LID) FROM <*schema*>.ICMSTJCRLINKS WHERE WSID = <*ROOT_WSID*> AND INLEAFTREEFLAG = 1
4. Run the following commands depending on your database
   - DB2 and SQL Server
     - WITH PATH (WSID , SIID, TIID, LVL) AS ((SELECT WSID, SIID, TIID, 1 AS LVL FROM <*schema*>.ICMSTJCRLINKS WHERE INLEAFTREEFLAG=1 AND WSID = <ROOT_WSID> AND SIID IN (SELECT TIID FROM <schema>.ICMSTJCRLINKS WHERE INLEAFTREEFLAG = 0 AND WSID = <*ROOT_WSID*>)) UNION ALL (SELECT L.WSID, L.SIID, L.TIID, P.LVL + 1 FROM PATH P, <*schema*>.ICMSTJCRLINKS L WHERE P.SIID = L.TIID AND P.LVL < 1000000 AND INLEAFTREEFLAG = 0 AND L.WSID = <*ROOT_WSID*>)) SELECT SUM(P1.LVL) FROM PATH P1, <*schema*>.ICMSTJCRWS WS WHERE P1.WSID = <*ROOT_WSID*> AND WS.WSID = <*ROOT_WSID*> AND P1.SIID = WS.ROOTIID
   - Oracle
     - SELECT SUM(LEV) FROM (SELECT WSID, SIID, TIID, LEVEL LEV FROM JCRPRODWCM.ICMSTJCRLINKS LINKS WHERE WSID = <*ROOT_WSID*> START WITH INLEAFTREEFLAG = 1 AND SIID IN (SELECT TIID FROM <*schema*>.ICMSTJCRLINKS WHERE INLEAFTREEFLAG = 0 AND WSID = <*ROOT_WSID*>) CONNECT BY PRIOR SIID = TIID AND INLEAFTREEFLAG = 0) P1, JCRPRODWCM.ICMSTJCRWS WS WHERE P1.WSID = <*ROOT_WSID*> AND WS.WSID = <*ROOT_WSID*> AND P1.SIID = WS.ROOTIID
5. Divide the value that is obtained in step #4 by the value of step #1 round up to nearest whole value and save that number.
6. Subtract the values that are obtained from steps #3, #2 and #1 and save that number.
7. Perform the following equation with the values previously calculated: ((value of #5 + 1) * value of #2) + ((value of #5 + 2) * value of #6) + value of #4
8. Multiply the value that is obtained in the previous step #7 by 700
9. SELECT COUNT(LID) FROM <*schema*>.ICMSTJCRLINKS WHERE WSID = <*VER_WSID*> AND INLEAFTREEFLAG = 1 AND SIID IN (SELECT TIID FROM <*schema*>.ICMSTJCRLINKS WHERE INLEAFTREEFLAG = 0 AND WSID = <*VER_WSID*>)
10. SELECT COUNT(LID) FROM <*schema*>.ICMSTJCRLINKS WHERE WSID = <*VER_WSID*> AND INLEAFTREEFLAG = 1 AND SIID IN (SELECT TIID FROM <*schema*>.ICMSTJCRLINKS WHERE WSID = <*VER_WSID*> AND INLEAFTREEFLAG = 1 AND SIID IN (SELECT TIID FROM <*schema*>.ICMSTJCRLINKS WHERE INLEAFTREEFLAG = 0 AND WSID = <*VER_WSID*>))
11. SELECT COUNT(LID) FROM <*schema*>.ICMSTJCRLINKS WHERE WSID = <*VER_WSID*> AND INLEAFTREEFLAG = 1
12. Run the following commands depending on your database
    - DB2 and SQL Server
      - WITH PATH (WSID , SIID, TIID, LVL) AS ((SELECT WSID, SIID, TIID, 1 AS LVL FROM <*schema*>.ICMSTJCRLINKS WHERE INLEAFTREEFLAG=1 AND WSID = <*VER_WSID*> AND SIID IN (SELECT TIID FROM <*schema*>.ICMSTJCRLINKS WHERE INLEAFTREEFLAG = 0 AND WSID = <*VER_WSID*>)) UNION ALL (SELECT L.WSID, L.SIID, L.TIID, P.LVL + 1 FROM PATH P, <*schema*>.ICMSTJCRLINKS L WHERE P.SIID = L.TIID AND

```
P.LVL < 1000000 AND INLEAFTREEFLAG = 0 AND L.WSID = <VER_WSID>) )
SELECT SUM(P1.LVL) FROM PATH P1, <schema>.ICMSTJCRWS WS WHERE
P1.WSID = <VER_WSID> AND WS.WSID = <VER_WSID> AND P1.SIID =
WS.ROOTIID
```

- Oracle
  - `SELECT SUM(LEV) FROM (SELECT WSID, SIID, TIID, LEVEL LEV FROM JCRPRODWCM.ICMSTJCRLINKS LINKS WHERE WSID = <VER_WSID> START WITH INLEAFTREEFLAG = 1 AND SIID IN (SELECT TIID FROM <schema>.ICMSTJCRLINKS WHERE INLEAFTREEFLAG = 0 AND WSID = <VER_WSID>) CONNECT BY PRIOR SIID = TIID AND INLEAFTREEFLAG = 0) P1, JCRPRODWCM.ICMSTJCRWS WS WHERE P1.WSID = <VER_WSID> AND WS.WSID = <VER_WSID> AND P1.SIID = WS.ROOTIID`

13. Divide the value that is obtained in step #12 by the value of #9 round up to nearest whole value and save that number.
14. Subtract the values that are obtained from steps #11, #10 and #9 and save that number.
15. Perform the following equation with the values previously calculated: ((value of #13 + 1) * value of #10) + ((value of #13 + 2) * value of #14) + value of #12
16. Multiply the value that is obtained in the previous step #15 by 700

Results

The estimated amount of database transaction log file space necessary in bytes is the greater of the two values that are determined in steps #8 and #16.

Oracle: Disabling the auto space advisor background task

To prevent deadlocks during migration, you must complete a task to disable the Oracle background task called "Auto Space Advisor" before your run the **upgrade-profile** task during migration using the Configuration Wizard. After you complete migration, you can enable "Auto Space Advisor" as a post-migration task.

Before you begin

You can check if the "Auto Space Advisor" task is enabled or disabled by entering the following command from SQL Plus:

```
SQL> select status from dba_autotask_client where client_name = 'auto space advisor';
```

Procedure

Enter the following SQL:

```
BEGIN
 dbms_auto_task_admin.disable(
  client_name => 'auto space advisor',
  operation  => NULL,
  window_name => NULL);
END;
/
```

Note: If you do not turn off the "Auto Space Advisor," it is possible for the migration to fail with the following Oracle error: `ORA-00060: deadlock detected while waiting for resource`.

What to do next

When you complete migrating your data using the Configuration Wizard, complete the post-migration step to enable the "Auto Space Advisor" Oracle background task.

Related tasks:

"Oracle: Enabling the auto space advisor background task" on page 896
If you use an Oracle database, you must complete a post-migration task to enable the Oracle background task called "Auto Space Advisor" after your run the **upgrade-profile** task during migration using the Configuration Wizard.

DB2

Database migration is one of the most time consuming portions of the migration process. If you are migrating from DB2, review the following topics to improve the speed of the database migration process.

"Update database statistics"
Statistics are information that is collected about the contents of the database tables and indexes. They are used by the cost-based optimizer in the database to influence the approach (query plan) that is used to run SQL queries. By collecting updated or new statistics, you provide the database optimizer the most up-to-date information about the tables and indexes. Therefore, the query execution plans are generated as efficiently as possible.

"Preparing DB2 for large data sets migration"
If you use DB2 and have a large amount of content in the JCR repository (for example, Web Content Manager data), prepare the DB2 for migration. You must update several settings that are related to performance.

Update database statistics:

Statistics are information that is collected about the contents of the database tables and indexes. They are used by the cost-based optimizer in the database to influence the approach (query plan) that is used to run SQL queries. By collecting updated or new statistics, you provide the database optimizer the most up-to-date information about the tables and indexes. Therefore, the query execution plans are generated as efficiently as possible.

This information is important during migration because there are several tables and indexes that are created and populated during this process. The default statistical information can lead query plans that show degrading performance as the migration progresses and can carry into the runtime performance.

JCR domain

Gather current statistics on all tables that are found in the JCR domain. If you are using DB2, you must run **reorgchk** and **runstats**.

Run the statistics on all the columns in all tables and indexes. Gather at least a minimum level of sampling and distribution. Refer to your database documentation for details on updating statistics.

Preparing DB2 for large data sets migration:

If you use DB2 and have a large amount of content in the JCR repository (for example, Web Content Manager data), prepare the DB2 for migration. You must update several settings that are related to performance.

About this task

These values are suggested starting points and were used successfully in IBM testing. Exact values can vary, depending on the size of the data set. Consult your database administrator as needed.

Important: The settings described here are optimized for migration rather than day-to-day operation. After migration completes successfully, you can revert any changes back to the values in use before migration.

Procedure

1. Update the lock list size for the database. A value of at least `10000` is recommended.
2. Disable all automatic maintenance on the database, including health monitoring.
3. Increase the package cache size. A value of at least `24000` is recommended.
4. Increase the statistics heap size. A value of at least `16384` is recommended.
5. Perform a complete reorganization of the tables and indexes on the database that is used for migration.
6. Collect detailed statistics with distribution for all tables and indexes.

   Note: While the migration is in progress, it might be necessary to collect detailed statistics to continue to allow the database optimizer to select efficient access plans.

Migrate data using the configuration wizard

For Version 8.5, data, applications, databases, property files, security settings, and configuration are migrated using the Configuration Wizard. Use the roadmaps for cluster and stand-alone environments to guide you through the process.

See the *Roadmaps for migration* section of the product documentation, and choose the roadmap that is specified for your environment for details on using the Configuration Wizard.

"Migrate a stand-alone server" on page 842
Use the Configuration Wizard to migrate a stand-alone server environment. Use the following information to get familiar with the information that you must provide in the wizard and the configuration procedure that it generates.

"Cluster: Migrate the deployment manager profile" on page 847
Use the Configuration Wizard to migrate the deployment manager profile for a cluster environment. Use the following information to get familiar with the information that you must provide in the wizard and the configuration procedure that it generates.

"Cluster: Migrate node profiles" on page 850
Use the Configuration Wizard to upgrade the node profiles for a cluster environment. Use the following information to get familiar with the information that you must provide in the wizard and the configuration procedure that it generates.

"Cluster: Upgrade node profiles" on page 853
Use the Configuration Wizard to upgrade the nodes profiles for a cluster environment. Use the following information to get familiar with the information you must provide in the wizard and the configuration procedure that it generates.

Related tasks:

"Accessing the Configuration Wizard" on page 235
The home page of the Configuration Wizard provides access to common configuration tasks. Supported tasks include setting up a stand-alone server, setting up a cluster, transferring from Apache Derby to another supported database, migrating your server, installing add-ons, and more.

Worksheet

To set up the migration, you answer questions about your wanted configuration. Some fields apply to migration configurations. Some fields are required based on your environment. The remaining fields are advanced and do not apply to most configurations.

Minimal required fields

The following table lists the fields that are unique to the migrate a stand-alone server configuration. You might be prompted for additional information about system or user IDs and passwords that you defined during the portal installation process.

Table 101. Minimal required fields

Field Label	Default	Your Value
Target operating system	Linux	
Target portal profile name	wp_profile	
Target portal profile home directory	/opt/IBM/WebSphere/wp_profile	
Is the target portal on the same server or a different server	Same server	
Database management software	Derby	
Target operating system		
WebSphere Application Server administrator	wpsadmin	
WebSphere Application Server administrator password		
Portal administrator password		
What is the portal profile name	wp_profile	
What is the cell name	CellName	
What is the portal node name	NodeName	
Where is the source application server installed **IBMi only:** Provide the path to the source profile directory instead of the application server directory.	/opt/IBM/WebSphere/AppServer	
What is the new host name		
Target portal soap port **Note:** Enter the same port number used for the source environment.	10033	
Where is the target application server installed	/opt/IBM/WebSphere/AppServer	
Where is the target portal installed	/opt/IBM/WebSphere/PortalServer	
Target temporary path	/opt/IBM/WebSphere/PortalServer	

Advanced fields

The following table lists the advanced fields that are unique to the migrate a stand-alone server configuration. Click **Advanced** on the Answer Questions page for the target system to see the advanced properties. Default values are provided for advanced fields that are required.

Table 102. Advanced fields

Field Label	Default	Your Value
JVM heap size	2048	

Migrate a stand-alone server option

After you answer questions and provide information about your migration, the wizard generates a custom configuration procedure.

About this task

Depending on your environment, the wizard generates a configuration process. The following steps reflect all possible steps in the configuration process. The steps do not represent a literal configuration. The steps are provided as a reference.

If you click **View Step Command**, you can see the task and properties that are associated with each step in the wizard.

Procedure

1. Manual Step: Install the latest fix packs

   Condition
   none

   ConfigEngine task
   none
2. Generate the files for remote migration

   Condition
   The target portal is on a different server than the source.

   ConfigEngine task
   none
3. Manual Step: Copy the remote migration package to the source environment

   Condition
   The target portal is on a different server than the source.

   ConfigEngine task
   none
4. Create a backup of the remote source portal profile

   Condition
   The target portal is on a different server than the source.

   ConfigEngine task
   none
5. Create a backup profile of the source portal profile

   Condition
   none

   ConfigEngine task
   none
6. Manual Step: If the backup profile is larger than 2 GB, clean up the backup profile

   Condition
   none

   ConfigEngine task
   none
7. Create a default profile

   Condition
   none

   ConfigEngine task
   none
8. Import backup profile

   Condition
   none

   ConfigEngine task
   none
9. Manual Step: If you cleaned up the backup profile, restore the JCR content

Condition
none

ConfigEngine task
none

10. Upgrade the ConfigEngine

    Condition
    none

    ConfigEngine task
    none

11. Manual Step: Update the ports on the target environment

    Condition
    none

    ConfigEngine task
    none

12. Manual Step: Update database settings

    Condition
    none

    ConfigEngine task
    none

13. Validate database settings

    Condition
    none

    ConfigEngine task
    `validate-database`

14. Connect to new database copies

    Condition
    none

    ConfigEngine task
    `connect-database`

15. Manual Step: Review database schema changes

    Condition
    none

    ConfigEngine task
    none

16. Upgrade the base portal database component

    Condition
    IBM z/OS

    DB2

    ConfigEngine task
    `grant-runtime-db-user-privileges`

    `upgrade-database`

17. Manual Step: Remove check pending statuses from table spaces

    Condition
    IBM z/OS

DB2

ConfigEngine task
none

18. Upgrade the remaining portal databases

    Condition
    IBM z/OS

    DB2

    ConfigEngine task
    grant-runtime-db-user-privileges

    upgrade-database

19. Upgrade the portal profile

    Condition
    none

    ConfigEngine task
    upgrade-profile

    Version 7.0 server-only migration: Do not complete the upgrade profile step using the Configuration Wizard. Instead you must run this task manually. For more information about running this task manually, see "Migration from Portal 7.0 server-only to Portal 8.5" on page 802.

    Note: When you run this step, the sub task that is named **action-deploy-portlets-applyMIGStatic-wp.oob.full** runs and completes successfully. However, the following error messages are shown. You can ignore these error messages:

    - `EJPXA0161W: The web module ContactList could not be activated. Please see previous messages for reasons and possible corrective actions.`
    - `EJPPH0048W: The synchronization mode of all nodes in the portal cluster is not consistently set. The portlet application PA_ContactList will not be started in the Application Server. Manual synchronization is assumed for all nodes. Manually start the application after all nodes were synchronized.`
    - `EJPXA0067E: The following configuration data is needed to create a content-node resource: content-parentref.`

What to do next

To complete migration, you must perform several post-migration tasks that depend on how you use WebSphere Portal Express.

1. Review the Next steps section of the product documentation.
   - Run the **PRE-APPLY-FIX** and **APPLY-FIX** tasks from Applying the latest combined cumulative fix updates.
   - Complete the post-migration activities that apply to how you are using WebSphere Portal Express before you move on to the next step. For example, if you are using a virtual portal, then complete the virtual portal post-migration steps.
   - Start the enabling new functionality tasks only after you complete the post-migration tasks.

Cluster: Migrate the deployment manager profile

Use the Configuration Wizard to migrate the deployment manager profile for a cluster environment. Use the following information to get familiar with the information that you must provide in the wizard and the configuration procedure that it generates.

Migrate a cluster step 2: Migrate node profiles option

After you answer questions and provide information about your migration, the wizard generates a custom configuration procedure.

About this task

Depending on your environment, the wizard generates a configuration process. The following steps reflect all possible steps in the configuration process. The steps do not represent a literal configuration. The steps are provided as a reference.

If you click **View Step Command**, you can see the task and properties that are associated with each step in the wizard.

Procedure

1. Manual Step: Stop the source deployment manager and node agents

Condition
none

ConfigEngine task
none

2. Manual Step: Start the target deployment manager

   Condition
   none

   ConfigEngine task
   none

3. Generate the files for remote migration

   Condition
   The target portal is on a different server than the source.

   ConfigEngine task
   none

4. Manual Step: Copy the remote migration package to the source environment

   Condition
   The target portal is on a different server than the source.

   ConfigEngine task
   none

5. Create a backup of the source portal profile

   Condition
   none

   ConfigEngine task
   none

6. Manual Step: Create a backup of the remote source portal profile

   Condition
   The target portal is on a different server than the source.

   ConfigEngine task
   none

7. Manual Step: Update the deployment manager settings

   Condition
   none

   ConfigEngine task
   none

8. Manual Step: If the backup profile is larger than 2 GB, clean up the backup profile

    Condition
    none

    ConfigEngine task
    none

Cluster: Upgrade node profiles

Use the Configuration Wizard to upgrade the nodes profiles for a cluster environment. Use the following information to get familiar with the information you must provide in the wizard and the configuration procedure that it generates.

Configuration Wizard

Select **Migrate to a New Version**, and choose the **Migrate a Cluster Step 3: Upgrade Node Profiles** option.

Related concepts:

"Troubleshooting: Upgrade node profiles for a cluster environment" on page 3612
If you encounter a failure while upgrading the node profiles for a cluster environment, learn how to correct the issue and recover from the failure.

"Configuration Wizard" on page 232
Use the Configuration Wizard to set up stand-alone servers and new deployments, create clusters, migrate and update to new versions, and add new capabilities to existing deployments.

"Roadmap: Migrating a clustered environment" on page 94
Roadmaps provide a high-level overview of complex tasks such as migrating a clustered environment to a new version of IBM WebSphere Portal Express.

Related tasks:

"Accessing the Configuration Wizard" on page 235
The home page of the Configuration Wizard provides access to common configuration tasks. Supported tasks include setting up a stand-alone server, setting up a cluster, transferring from Apache Derby to another supported database, migrating your server, installing add-ons, and more.

Worksheet

To set up the migration, you answer questions about your wanted configuration. Some fields apply to migration configurations. Some fields are required based on your environment. The remaining fields are advanced and do not apply to most configurations.

Minimal required fields

The following table lists the fields that are unique to the Migrate a cluster step 3: Upgrade node profiles configuration option. You might be prompted for additional information about system or user IDs and passwords that you defined during the portal installation process.

Table 107. Minimal required fields

Field Label	Default	Your Value
Target operating system	Linux	
Target portal profile name	wp_profile	
Target portal profile home directory	/opt/IBM/WebSphere/wp_profile	
Database management software	Derby	
WebSphere Application Server administrator	wpsadmin	
WebSphere Application Server administrator password		
Target deployment manager host name		
Target deployment manager soap port **Note:** Enter the same port number used for the source environment.	10033	
What is the new host name		
Where is the target portal installed	/opt/IBM/WebSphere/PortalServer	

Advanced fields

The following table lists the advanced fields that are unique to the Migrate a cluster step 3: Upgrade node profiles configuration option. Click **Advanced** on the Answer Questions page for the target node to see the advanced properties. Default values are provided for advanced fields that are required.

Table 108. Advanced fields

Field Label	Default	Your Value

   upgrade-database

10. Upgrade the portal profile

Condition
none

ConfigEngine task
upgrade-profile

Version 7.0 server-only migration: Do not complete the upgrade profile step using the Configuration Wizard. Instead you must run this task manually. For more information about running this task manually, see "Migration from Portal 7.0 server-only to Portal 8.5" on page 802.

Note: When you run this step, the sub task that is named **action-deploy-portlets-applyMIGStatic-wp.oob.full** runs and completes successfully. However, the following error messages are shown. You can ignore these error messages:

- `EJPXA0161W: The web module ContactList could not be activated. Please see previous messages for reasons and possible corrective actions.`
- `EJPPH0048W: The synchronization mode of all nodes in the portal cluster is not consistently set. The portlet application PA_ContactList will not be started in the Application Server. Manual synchronization is assumed for all nodes. Manually start the application after all nodes were synchronized.`
- `EJPXA0067E: The following configuration data is needed to create a content-node resource: content-parentref.`

What to do next

You must repeat the **Migrate a Cluster Step 3: Upgrade Node Profiles** steps on every node in the cluster. The task completes more quickly on the secondary nodes because it does not perform the same application and database upgrades that were performed on the primary node.

To complete migration, you must perform several post-migration tasks that depend on how you use WebSphere Portal Express.

1. Review the Next steps section of the product documentation.
   - Run the **PRE-APPLY-FIX** and **APPLY-FIX** tasks from Applying the latest combined cumulative fix updates.
   - Complete the post-migration activities that apply to how you are using WebSphere Portal Express before you move on to the next step. For example, if you are using a virtual portal, then complete the virtual portal post-migration steps.
   - Start the enabling new functionality tasks only after you complete the post-migration tasks.

Next steps

To complete migration, you must first perform several post-migration steps that depend on how Portal is being used. After completing the post-migration steps, review the Enabling new functionality section to take advantage of the new tools available in IBM WebSphere Portal Express Version 8.5. Enabling new functionality should not be started until all post-migration steps have been completed.

"Post-migration activities" on page 857
After you migrate to IBM WebSphere Portal Express Version 8.5, you need to complete extra tasks depending on how you customized the source portal

environment and which components you used. First, complete the **Applying the latest combined cumulative fix updates** task, then you can begin the post-migration tasks followed by enabling new functionality.

"Enabling new functionality in a migrated portal" on page 909
The migration process collects configuration data and applications from an earlier installed version of IBM WebSphere Portal Express and merges them into the newer installed version so that the new environment is identical to the earlier environment. Taking advantage of new functionality that was not available in the earlier portal requires additional attention after migration is complete.

Post-migration activities

After you migrate to IBM WebSphere Portal Express Version 8.5, you need to complete extra tasks depending on how you customized the source portal environment and which components you used. First, complete the **Applying the latest combined cumulative fix updates** task, then you can begin the post-migration tasks followed by enabling new functionality.

"Applying the latest combined cumulative fix updates"
This is a required task. After you migrate using the Configuration Wizard, you must run two tasks to ensure that all of the combined cumulative fix updates are applied to your system before you complete other post-migration or enablement tasks.

"Administrative tasks" on page 858
To ensure that your new environment functions properly, complete administrative tasks such as enabling automatic synchronization, migrating web server configurations, configuring a federated LDAP user registry, and more.

"Portal tasks" on page 866
Complete the post-migration tasks specific to the way that you use WebSphere Portal Express.

"Development tasks" on page 892
Complete the development tasks that are required after the migration to ensure that your environment functions properly.

"Database tasks" on page 894
There are different post-migration tasks that are required depending on the type of database that is used.

"Add-ons, features, and third-party integration tasks" on page 896
Complete the post-migration tasks that are required based on the way you use your WebSphere Portal Express environment.

Applying the latest combined cumulative fix updates

This is a required task. After you migrate using the Configuration Wizard, you must run two tasks to ensure that all of the combined cumulative fix updates are applied to your system before you complete other post-migration or enablement tasks.

Procedure

1. Stop the target environment:
   - If you migrated a stand-alone server, stop the WebSphere_Portal server.
   - If you migrated a cluster, stop the WebSphere_Portal server and node agent. Then, ensure that the deployment manager is started.
2. Run the **PRE-APPLY-FIX** task from the *wp_profile_root*/ConfigEngine directory:

Linux `./ConfigEngine.sh PRE-APPLY-FIX -DWasPassword=`*password* `-DPortalAdminPwd=`*password*

IBM i `ConfigEngine.sh PRE-APPLY-FIX -DWasPassword=`*password* `-DPortalAdminPwd=`*password*

Windows
`ConfigEngine.bat PRE-APPLY-FIX -DWasPassword=`*password* `-DPortalAdminPwd=`*password*

3. Run the **APPLY-FIX** task from the *wp_profile_root*`/ConfigEngine` directory:

   Important: If you are migrating to Portal 8.5 CF03 or CF04, you must specify the `-DForceRun=true` parameter when you run **APPLY-FIX**.

   Linux `./ConfigEngine.sh APPLY-FIX -DWasPassword=`*password* `-DPortalAdminPwd=`*password*

   IBM i `ConfigEngine.sh APPLY-FIX -DWasPassword=`*password* `-DPortalAdminPwd=`*password*

   Windows
   `ConfigEngine.bat APPLY-FIX -DWasPassword=`*password* `-DPortalAdminPwd=`*password*

4. **Cluster only:** Complete each step on every node in the cluster.

Related tasks:

"Starting and stopping servers, deployment managers, and node agents" on page 1216
Various installation and configuration tasks require you to start and stop IBM WebSphere Application Server and the IBM WebSphere Portal Express application servers, deployment managers, and node agents.

Administrative tasks

To ensure that your new environment functions properly, complete administrative tasks such as enabling automatic synchronization, migrating web server configurations, configuring a federated LDAP user registry, and more.

"Enabling automatic synchronization for a clustered environment" on page 859
Before you started migration, you disabled automatic synchronization to prevent the source and target environments from becoming corrupted. Now that the data migration is complete, it is safe to enable this feature on both the source and target environments.

"Enabling unprotected URI Authentication" on page 859
If Security Assertion Markup Language (SAML) is enabled, or if you plan to enable SAML, you must ensure that LTPA authentication works correctly with the web and proxy servers.

"Federating the LDAP user registry" on page 860
The stand-alone LDAP user registry configuration is deprecated. Instead, configure the federated LDAP user registry. Run the **wp-modify-federated-security** task to change to a federated LDAP user registry.

"Migrating web server configurations" on page 861
Migrate a web server so that it supports the latest version of WebSphere Application Server. The Application Migration Toolkit for WebSphere Application Server supports migrating applications from previous versions of WebSphere Application Server to the latest product version.

"Disabling TAI if disabled previously" on page 864
If TAI was disabled before you began migration, and you had to enable it in

order to run the migration, then you might need to disable TAI on both the source and target environments as a post-migration step.

"Reviewing and updating scheduled tasks" on page 865
After you complete the migration by using the Configuration Wizard, review your scheduled tasks to verify that the tasks are still valid for your current environment.

"Moving the personalization page" on page 865
After you migrate to IBM WebSphere Portal Express Version 8.5 and change your theme to Version 8.5, the Personalization welcome page is in the Content application area. You can run a task to move the Personalization welcome page back to the application level.

Enabling automatic synchronization for a clustered environment:

Before you started migration, you disabled automatic synchronization to prevent the source and target environments from becoming corrupted. Now that the data migration is complete, it is safe to enable this feature on both the source and target environments.

Procedure

1. Start the WebSphere Integrated Solutions Console for the deployment manager.
2. Select **System Administration** > **Node Agents**.
3. Click **nodeagent** for the required node.
4. Click **File Synchronization Service** in the **Additional Properties** section.
5. Ensure that **Enable service at server startup** is selected to enable the synchronization service at startup.
6. Ensure that **Automatic Synchronization** is selected to enable the automatic synchronization feature.
7. Click **OK** and **Save**.
8. Repeat these steps for all remaining nodes.
9. Select **System Administration** > **Node Agents**.
10. Select all nodes that previously had automatic synchronization disabled, and click **Restart**.

Related tasks:

"Disabling automatic synchronization to protect your clustered source environment" on page 817
The target environment initially uses the same ports as the source environment. There are three important steps you must complete to ensure that the source and target environments do not become corrupted.

Enabling unprotected URI Authentication:

If Security Assertion Markup Language (SAML) is enabled, or if you plan to enable SAML, you must ensure that LTPA authentication works correctly with the web and proxy servers.

About this task

The **Use available authentication data when an unprotected URI is accessed** setting must be enabled. Enabling this setting ensures that the security session stays active, if the browser context changes from protected to unprotected, for example from `/myportal` to `/portal`.

Procedure

1. Access the WebSphere Integrated Solutions Console.
2. Go to **Security** > **Global security** > **Web and SIP security** > **General settings**.
3. Select **Use available authentication data when an unprotected URI is accessed**.
4. Click **Apply**.
5. Click **Save**.
6. If you are using a stand-alone environment, restart the server. If you are using a cluster environment, synchronize the nodes, and then restart the servers.

Related information:

 Understanding the WebSphere Application Server SAML Trust Association Interceptor

Federating the LDAP user registry:

The stand-alone LDAP user registry configuration is deprecated. Instead, configure the federated LDAP user registry. Run the **wp-modify-federated-security** task to change to a federated LDAP user registry.

Before you begin

In a stand-alone server environment, you can complete the following task when the servers are either stopped or started. In a clustered environment, start the deployment manager and node agent. Then, verify that they are able to synchronize.

About this task

Remember: Starting with IBM WebSphere Portal Express Version 8.5, the stand-alone LDAP repository is deprecated. Change to the federated LDAP user repository.

Use the `wp_security_federated.properties` helper file that is in the *wp_profile_root*`/ConfigEngine/config/helpers` directory. It ensures that the correct properties are entered. In the following instructions, where the step refers to the `wkplc.properties` file, use your `wp_security_federated.properties` helper file.

Procedure

1. Go to the *wp_profile_root*`/ConfigEngine/properties` directory.
2. Open the `wkplc.properties` file with a text editor.
3. Update the following parameters in the `wkplc.properties` file under the VMM Federated repository properties heading:

   Note: Go to the properties file for specific information about the parameters.

   federated.primaryAdminId

   federated.realm

   federated.serverId

   federated.serverPassword
4. Open a command prompt.
5. Change to the *wp_profile_root*`/ConfigEngine` directory.

6. Run the following task to change the configuration to use a federated repository:
   - Linux : `./ConfigEngine.sh wp-modify-federated-security -DWasPassword=password -Dskip.ldap.validation=true`
   - IBM i: `ConfigEngine.sh wp-modify-federated-security -DWasPassword=password -Dskip.ldap.validation=true`
   - Windows: `ConfigEngine.bat wp-modify-federated-security -DWasPassword=password -Dskip.ldap.validation=true`

Important: If you have WebSphere Portal Express Version 8.5 with a CF05 or later fix pack applied, then you do not have to complete the following steps.

7. Stop and restart the appropriate servers to propagate the changes. For instructions, go to "Starting and stopping servers, deployment managers, and node agents" on page 1216.
8. Log in to WebSphere Portal Express as an administrator.
   a. Click **Administration**. Then, click **Virtual Portals** > **Manage Virtual Portals**.
   b. Edit each Virtual Portal using the pencil icon.
   c. Set **User realm** as blank.
   d. Click **OK**.
   e. Edit each Virtual Portal using the pencil icon.
   f. Set **User realm** to match the realm ID that you set for **federated.realm**.
   g. Click **OK**.

Migrating web server configurations:

Migrate a web server so that it supports the latest version of WebSphere Application Server. The Application Migration Toolkit for WebSphere Application Server supports migrating applications from previous versions of WebSphere Application Server to the latest product version.

You can upgrade IBM HTTP Server (IHS) from a previous version in two ways:

- Install the new version in a new directory
- Install the new version in the same directory as the previous version

For information about migrating applications, read more about the Application Migration Toolkit.

Related information:

Configuring a web server plug-in using the pct tool

Installing the new version of IBM HTTP Server in a new directory: Procedure

1. Install the Version 8.5 IBM HTTP Server in a new directory.
2. Optional: If you installed IBM HTTP Server into a new directory and retained your previous version of IBM HTTP Server, by default the administration server and the web server use the same ports as the previous version administration server and web server. If you ever run both versions of the IBM HTTP Server simultaneously, port conflicts occur unless you change the port numbers for one of the server versions. To modify the port numbers for one of the IBM HTTP Servers, edit the server configuration files for that IBM HTTP Server. These files are in the `http_server_install/conf` directory.

3. Optional: Migrate web server definitions. A web server definition is used to manage the web server from a stand-alone profile or the deployment manager.
   - If you updated IBM HTTP Server on the original host but in a new directory, update the path by selecting the web server: **Servers** > **Server Types** > **Web Servers in the WebSphere Application Server administration console**.
   - If the updated IBM HTTP Server is on a new host, follow the procedure in "Selecting a web server topology diagram and roadmap" to create a new web server definition. You can remove the old web server definition when you confirm that the new web server is working properly.
4. Install the latest IBM HTTP Server cumulative fix. Learn more about Recommended fixes for IBM HTTP Server.

Installing the new version of IBM HTTP Server in the same directory as the previous version:
Procedure

1. Migrate web server configurations.
   a. Stop the IBM HTTP Server and the IBM HTTP Server administration server.
   b. Copy the existing installation directory to a new location. This action preserves your configuration, keys, and content.
      - If you are using Linux, use the following command to copy the previous installation:

        ```
        cp –rp current_install_directory new_directory_name
        ```

      - If you are using Windows, use the following command to copy the previous installation:

        ```
        xcopy current_install_directory new_directory_name /s /e /k /i
        ```

   c. Uninstall the previous IBM HTTP Server version.
   d. Remove the previous installation directory. Because the uninstallation leaves behind some files, such as modified and added files, fix pack files, and uninstall files, you must manually remove the previous installation directory to complete the uninstallation process. If you had any uninstallation issues, review and backup the uninstall log files in the `http_server_install/logs/uninstall` directory before proceeding.
      - If you are using Linux, use the following command to remove the installation directory:

        ```
        rm -r  current_install_directory
        ```

      - If you are using Windows, use the following command to remove the installation directory:

        ```
        rd /s current_install_directory
        ```

   e. Install the Version 8.5 IBM HTTP Server in the same directory location as the previous version.
   f. Run the Plug-ins Configuration Tool, the pct tool, to configure your web server plug-ins. Refer to Configuring a web server plug-in using the pct tool for information on running the pct tool.
   g. Restore any custom configurations that were made to your previous version of IBM HTTP Server and IBM HTTP Server administration server.
      - Identify your previous customizations.

        If you used the `httpd.conf` configuration files that are provided with the previous version of IBM HTTP Server as the starting point for your configuration files, compare the content of each configuration file, with its corresponding `.default` file, within the directory that contains your previous IBM HTTP Server installation. For example, if you compare the

content of the `httpd.conf` file with the `httpd.conf.default` file, you can see any customizations that were made to the `httpd.conf` file since the original installation. Then, perform similar comparisons for the other configuration files.

If you did not use the `httpd.conf` configuration files that are provided with the previous version of IBM HTTP Server as the starting point for your configuration files, perform a manual analysis to determine your previous settings. In this situation, you might want to compare the settings in the `httpd.conf.default` file that is provided with the new IBM HTTP Server, with the settings in the `httpd.conf.default` file that is provided with the previous IBM HTTP Server version. Use this comparison to identify configuration differences in the two `httpd.conf.default` files. You can then use this information to modify your customized configuration file to work with the Version 8.5 IBM HTTP Server.

Compare the `bin/envars` file to the `bin/envars-std` file within the directory that contains your previous IBM HTTP Server installation. This comparison identifies any customizations that were made to this file.

- Merge the customizations into the newly installed IBM HTTP Server configuration and `envars` files.

  After you identify the configuration customizations that you made to your previous version of IBM HTTP Server, make these same changes, when applicable, to the configuration files for the Version 8.5 IBM HTTP Server.

  If the configuration files contain WebSphere Application Server plug-in statements from previous versions, remove them to prevent duplicates. If you do not remove these statements, when IBM HTTP Server attempts to start the Version 8.5 plug-in binary module, an error might occur that indicates that the module is already loaded.

  The configuration file might also contain duplicate entries for accessing WebSphere Application Server samples. Remove any aliases for previous versions and retain the Version 8.5 entries.

h. Restore HTML content. If your web page content was previously stored under your IBM HTTP Server installation directory, copy those content files from the directory that contains your prior version of IBM HTTP Server into the installation directory for the new version.

i. Copy any SSL KeyFiles that might be within the installation directory of the previous IBM HTTP Server into the new installation directory

2. Change port assignments for coexisting IBM HTTP Servers. To modify the port numbers for one of the IBM HTTP Servers, edit the server configuration files for that IBM HTTP Server. These files are in the `http_server_install/conf` directory.
3. Upgrade Apache plug-in modules.

   There are no Apache API (application programming interface) changes from the previous major release, so there should be no need to rebuild modules that worked with the previous release. However, if you use modules from third-party vendors, contact your vendors to verify that they support the module with the version of IBM HTTP Server to which you are upgrading.

   Apache plug-in modules from sources other than the Version 8.5 IBM HTTP Server must be built to support Apache 2.2. The distributors of modules that are used with older versions of IBM HTTP Server might need to recompile the modules to support Apache 2.2.

- WebSphere Application Server provides a new plug-in for Apache 2.2 and IBM HTTP Server 8.5.
- If you use modules from third-party vendors, contact your vendor for a version of the module that works with the Apache 2.2 API.
- If you use modules that were developed in-house, you must rebuild your modules to support Apache 2.2. The modules might also require some modifications.

4. Update the IBM HTTP Server service name in the WebSphere Application Server web server definition if the following conditions are true:
   - The server is a Windows server.
   - You installed IBM HTTP Server into the same directory where an earlier version was located.
   - You are using a web server definition from that prior installation.

   For an IBM HTTP Server on a Windows server system, use 'Services' to determine the name that is used for the new IBM HTTP Server service, and then update the web server definition to use this service name.
5. Migrate web server definitions. A web server definition is used to manage the web server from a stand-alone profile or the deployment manager.
   - If you updated IBM HTTP Server on the same host and in the same directory, no action is required. The current web server definition suffices.
   - If the updated IBM HTTP Server is on a new host, follow the procedure in Selecting a web server topology diagram and roadmap to create a new web server definition. You can remove the old web server definition when you confirm that the new web server is working properly.
6. Install the latest IBM HTTP Server cumulative fix. Learn more about Recommended fixes for IBM HTTP Server.

Disabling TAI if disabled previously:

If TAI was disabled before you began migration, and you had to enable it in order to run the migration, then you might need to disable TAI on both the source and target environments as a post-migration step.

Procedure

To disable TAI, complete the following task:

1. Log in to the WebSphere Integrated Solutions Console.
2. Go to **Security** > **Global security**.
3. Select **Enable administrative security** and **Enable application security**.
4. On the Global security page, locate the **Authentication** section and click **Web and SIP security** > **Trust association**.
5. Clear **Enable Trust Assocation**.
6. Click **Apply**.
7. Click **Save**.
8. If you have a cluster environment, synchronize the nodes.
9. Restart the server for a stand-alone environment, and restart all servers for a cluster environment.

Related tasks:

"Verifying that WebSphere Application Server Trust Association Interceptor is enabled" on page 818
The automated migration of the WebSphere Portal Express profile requires that the Trust Association Interceptor (TAI) is enabled so that you can configure content in WebDAV during migration.

Reviewing and updating scheduled tasks:

After you complete the migration by using the Configuration Wizard, review your scheduled tasks to verify that the tasks are still valid for your current environment.

About this task

If you performed a remote migration, then you must update the table prefix and **jdni** name for your schedulers, which are based on the host name. You can complete this update by running the **action-clean-scheduled-tasks** ConfigEngine task, which removes all schedulers. After you run this task, you must restart the Portal server, and then the schedulers are re-created with the correct table prefix and **jdni** name. Learn more about Configuring schedulers using the administration console.

Procedure

1. Review your scheduled tasks:
   a. Start the WebSphere Application Server administrative console.
   b. Select **Resources** > **Schedulers**.
2. Run the following task:
   - Linux : `./ConfigEngine.sh action-clean-scheduled-tasks -DWasPassword=`*`password`* `-Drelease.DbPassword=`*`password`*
   - IBM i: `ConfigEngine.sh action-clean-scheduled-tasks -DWasPassword=`*`password`* `-Drelease.DbPassword=`*`password`*
   - Windows: `ConfigEngine.bat action-clean-scheduled-tasks -DWasPassword=`*`password`* `-Drelease.DbPassword=`*`password`*
3. Restart the Portal server so that the default scheduled tasks that are required for operation are created.

Moving the personalization page:

After you migrate to IBM WebSphere Portal Express Version 8.5 and change your theme to Version 8.5, the Personalization welcome page is in the Content application area. You can run a task to move the Personalization welcome page back to the application level.

About this task

Important: This task is required only for versions before CF03.

Run this task to move the Personalization page to the application level. If you do not run this task, the Personalization welcome page remains in the Content application. If the personalization welcome page remains in the Content application, you cannot access the other existing pages in the Content application area.

Procedure

Run the following task using the ConfigEngine to move the Personalization welcome page:

- Linux : `./ConfigEngine.sh move-pzn-page`
- IBM i: `ConfigEngine.sh move-pzn-page`
- Windows: `ConfigEngine.bat move-pzn-page`

Portal tasks

Complete the post-migration tasks specific to the way that you use WebSphere Portal Express.

"Updating the default theme and skin" on page 867
You can add the Portal 8.5 theme and 8.5 skin to all new pages by default.

"Applying the new theme to your Portal pages" on page 868
Custom portal resources, such as themes and skins, are migrated automatically. The Portal 8.5 theme is also deployed when migration is complete. However, you must complete extra steps to apply the theme to your pages.

"Updating page order" on page 869
If the page order was altered for IBM pages in the Applications, Administration, or Hidden Pages areas on your source environment, then the page order might not be correct on the target environment after migration.

"Web Content Manager" on page 869
Extra migration steps are required for updating Web Content Manager after data migration is complete.

"Virtual Portal tasks" on page 876
If you configured WebSphere Portal Express to use virtual portal, there are some additional steps that are needed to complete the migration.

"Importing search web collections" on page 883
As a part of preparing your source environment, you exported web collections. After you export a search web collection from a source portal, you can import the data into a new, empty collection on the target portal. Importing a web collection retains most of the configuration data such as content sources, schedulers, filters, and language settings. If you configured such settings when creating the new collection, they are overwritten by the imported settings.

"Importing UX Screen Flow Manager dialog definitions" on page 884
If you migrated from Version 8.0.0.1 with the UX Screen Flow Manager (UXFM) enabled, then you exported and removed your dialog definitions before migrating to Version 8.5. Run the following task to import the dialog definitions into your upgraded system.

"WSRP" on page 885
If you use your IBM WebSphere Portal Express as a WSRP Consumer or Producer, you must complete additional steps to complete migration.

"Blogs and wikis" on page 887
After you migrate from WebSphere Portal Express Versions 7.0 or 8.0 to Version 8.5, you must run a configuration task to update the presentation templates that are used by blogs and wikis to apply the latest updates. You must run this task for content in your blogs and wikis to render properly.

"Tag and Search Center pages" on page 887
When you migrate to IBM WebSphere Portal Express Version 8.5, the migration process does not apply the Portal 8.5 theme to all portal pages. For example, this affects the Tag and Search Center pages. To continue to use your Tag

Center and Search Center pages, you must update the theme for the pages to the Version 8.5 theme. You must also update the profile of the pages to the Search and Tag Center profile.

"Removing Person Tag hidden pages" on page 888
Remove Person Tag hidden pages from migrated environments where Search for Portal Site was previously configured. If you migrated or updated to WebSphere Portal Express 8.5 CF04 or later, then you do not need to complete these steps.

"Updating URL mapping for personalization page" on page 889
If you migrated from Version 7.0 to Version 8.5 with a CF03 or earlier fix pack applied, then you must complete the following task to ensure that the Personalization page displays properly.

"Enabling vanity URL support after migration" on page 889
In a new WebSphere Portal Express Version 8.5 installation, vanity URL support is enabled. However, if you upgrade your WebSphere Portal Express from a previous version to Version 8.5, vanity URL support is disabled. You can enable and disable vanity URL support as required by using a portal configuration task.

"Enabling impersonation" on page 890
If you migrate to WebSphere Portal Express Version 8.5 and upgrade to fix pack level CF01-CF03, impersonation might not be enabled. If you plan to use the impersonation feature, which allows a selected user to preview and test new pages or portlets to help identify any potential issues, then you might need to enable this feature.

"Reinstalling the PortalTheme" on page 891
If you migrate from Version 7.0 to Version 8.5, when you apply the latest combined cumulative fix during post-migration, the PortalTheme from earlier WebSphere Portal Express versions is removed. If your system requires this theme, then you can manually reinstall it.

Updating the default theme and skin:

You can add the Portal 8.5 theme and 8.5 skin to all new pages by default.

About this task

After migration, a new theme is available for you to apply to your Portal pages. The name of the new theme is `Portal 8.5`. In addition, four new skins are available for the Portal 8.5 theme. For information about the new skins, see *Skins* in the Developing themes and skins section of the documentation.

Procedure

1. Click the **Administration menu** icon. Then, click **Portal User Interface** > **Themes and Skins**.
2. Select the **Portal 8.5** theme from the **Themes** list in the portlet.
3. Click **Set as default portal theme**.
4. Select the **Portal 8.5 Hidden** skin from the **Skins** list in the portlet.
5. Click **Set as default portal skin**.

Related concepts:

"Skins" on page 2682
You can apply ready-use skins to your portal pages, modify the existing skins, or add your own custom skin to change how your pages display.

Applying the new theme to your Portal pages:

Custom portal resources, such as themes and skins, are migrated automatically. The Portal 8.5 theme is also deployed when migration is complete. However, you must complete extra steps to apply the theme to your pages.

After migration, a new theme is available for you to apply to your Portal pages. The name of the new theme is `Portal 8.5`. In addition, four new skins are available for the Portal 8.5 theme. For information about the new skins, see *Skins* in the Developing themes and skins section of the documentation.

Creating a page and applying the theme

If you prefer to create a new set of pages and apply the theme, you can use the Manage Pages portlet or the XML configuration interface. It is possible that some migrated themes allow for inline page creation, and **Portal 8.5** would be an option to select in the process.

To use the Manage Pages portlet, complete the following steps:

1. To open the **Manage Pages** portlet, click the **Administration menu** icon. Then, click **Portal User Interface** > **Manage Pages**.
2. In the **Manage Pages** portlet, select the location in Portal to create the new page.
3. Click **New Page** in the portlet.
4. Define a name for the page and select the **Portal 8.5** option from the **Theme** menu.
5. After you complete these steps, the new page with the Portal 8.5 theme is created.

You can also create a page with the Portal 8.5 theme by using the XML configuration interface. This process is helpful for scripting the process across multiple pages. There are samples for modifying Portal resources with the XML configuration. For more information about using the XML configuration interface, see *Sample XML configuration files*.

When you create a new page and apply the Portal 8.5 theme, the new inline customization features are immediately available for use. Use the inline toolbar to create pages.

Related concepts:

"Skins" on page 2682
You can apply ready-use skins to your portal pages, modify the existing skins, or add your own custom skin to change how your pages display.

Related reference:

"Sample XML configuration files" on page 1111
Sample files are provided for your reference to help illustrate how to use XML configuration for different portal configuration purposes. Before you use them, read the other topics about the XML configuration interface carefully. Many of the samples need to be modified with valid page or user name before they can be used.

Updating page order:

If the page order was altered for IBM pages in the Applications, Administration, or Hidden Pages areas on your source environment, then the page order might not be correct on the target environment after migration.

About this task

You can adjust the page order of your pages using the Portal Administration menu or XMLAccess. If you want your pages to be listed first, then ensure that they have ordinal values less than 100. For more information about using XMLAccess to edit the ordinal values for your pages, see XMLAccess Frequently Asked Questions.

Procedure

1. Click **Administration**.
2. Click **Manage Pages**.
3. Use the **Move up** and **Move down** icons to adjust the order of your pages.

   Note: If you are rearranging the tree structure of your pages, then you can use the **Mark** icon to mark the page, and then move it.

Web Content Manager:

Extra migration steps are required for updating Web Content Manager after data migration is complete.

"Updates for Web Content Manager"
These are additional migration steps required for Web Content Manager after data migration is complete.

"Convert the IBM Portlet API Web Content Viewer to the JSR 286 Web Content Viewer" on page 870
If you use the IBM Portlet API Web Content Viewer portlet in your source environment, you must complete the following task after migration to convert to the JSR 286 Web Content Viewer.

"Convert the IBM Portlet API Remote Web Content Viewer to the JSR 286 Web Content Viewer" on page 871
If you use the IBM Portlet API Remote Web Content Viewer portlet in your source environment, you must complete the following task after migration to convert to the JSR 286 Web Content Viewer.

"Converting an IBM API Web Content Viewer to the JSR 286 API" on page 874
As installed by default, the Web Content Viewer is based on the JSR 286 API. If you have a Web Content Viewer that is based on the older IBM API, you can convert the viewer to the JSR 286 API. Use the **convert-wcm-rendering-portlet** task to convert the IBM API Web Content Viewer settings and instances to the JSR 286 Web Content Viewer portlet.

Updates for Web Content Manager:

These are additional migration steps required for Web Content Manager after data migration is complete.

Authoring portlet preferences

Authoring portlet preferences, such as configured libraries and default rich text editor, are not migrated. You must re-configure your authoring portlet after migration to restore your preferences.

JSP files and Web content plug-ins

- Any JSP files used on your old system must be manually copied to your new system.
- Any Web content plug-ins used on your old system, such as custom workflows, must be manually copied to your new system and enabled.

Syndication

If the hostname or context root of your migrated server is different to the original server, you will need to edit the syndicators or subscribers to use the new hostname or context root.

- Edit the Subscriber URL of any syndicators that are syndicating to the migrated server. See "Cross version syndication" on page 806 for details on what versions of WebSphere Portal support cross version syndication.
- Edit the Syndicator URL of any subscribers that are subscribing to the migrated server. See "Cross version syndication" on page 806 for details on what versions of WebSphere Portal support cross version syndication.

Convert the IBM Portlet API Web Content Viewer to the JSR 286 Web Content Viewer:

If you use the IBM Portlet API Web Content Viewer portlet in your source environment, you must complete the following task after migration to convert to the JSR 286 Web Content Viewer.

About this task

The Web Content Viewer portlet that is based on the IBM Portlet API was removed from IBM Web Content Manager Version 8.5 and is no longer supported. The migration process transfers the portlet and the portlet instances from your portal pages to the target environment. After migration, you must replace the IBM Portlet API Web Content Viewer portlet with the JSR 286 Web Content Viewer portlet. You can complete this task manually or with the conversion task as described in the following procedure.

Procedure

1. Check if you installed the IBM Portlet API Web Content Viewer portlet and identify potential portlet clones.
   a. Click the **Administration menu** icon. Then, click **Portlet Management** > **Web Modules**.
   b. Search for the web module with the file name `ilwwcm-localrendering-portlet.war`.
   c. If the search result is empty, then you do not have the IBM Portlet API Web Content Viewer, and you can skip this task.
   d. If the search result is not empty, then click **ilwwcm-localrendering-portlet.war** > **Web Content Management - Content Viewer**.
2. Check if you installed the JSR 286 Web Content Viewer portlet.

a. Click the **Administration menu** icon. Then, click **Portlet Management** > **Web Modules**.
b. Search for the web module with the file name `ilwwcm-localrenderingportlet-jsr`.
c. If the search result is empty, install the JSR 286 Web Content Viewer portlet from `PortalServer_root/pzn.ext/portlet.localrendering.jsr/localrendering.war/installableApps/ilwwcm-localrenderingportlet-jsr`.

3. To convert the instances of the IBM Portlet API Web Content Viewer portlet to the JSR 286 Web Content Viewer portlet, follow the steps that are given at "Converting an IBM API Web Content Viewer to the JSR 286 API" on page 874.

   Important: If you use clones of the IBM Portlet API Web Content Viewer portlet, you must also convert their instances.
4. After you replace all instances of the IBM Portlet API Web Content Viewer portlet and of its portlet clones, uninstall the `ilwwcm-localrendering-portlet.war` web module.

Convert the IBM Portlet API Remote Web Content Viewer to the JSR 286 Web Content Viewer:

If you use the IBM Portlet API Remote Web Content Viewer portlet in your source environment, you must complete the following task after migration to convert to the JSR 286 Web Content Viewer.

About this task

The Remote Web Content Viewer portlet that is based on the IBM Portlet API was removed from IBM Web Content Manager Version 8.5 and is no longer supported. The migration process transfers the portlet and the portlet instances from your portal pages to the target environment. After migration, you must replace the IBM Portlet API Remote Web Content Viewer portlet with the JSR 286 Web Content Viewer portlet.

Procedure

1. Check if you installed the IBM Portlet API Web Content Viewer portlet and identify potential portlet clones.
   a. Click the **Administration menu** icon. Then, click **Portlet Management** > **Web Modules**.
   b. Search for the web module with the file name `ilwwcm-remoterendering-portlet.war`.
   c. If the search result is empty, then you do not have the IBM Portlet API Remote Web Content Viewer, and you can skip this task.
   d. If the search result is not empty, then click **ilwwcm-remoterendering-portlet.war** > **Web Content Management - Remote Content Viewer**.

      Note: If you do not use clones of the portlet, the displayed table will contain only a single portlet with the title **Remote Web Content Viewer**.
2. If you use the IBM Portlet API Remote Web Content Viewer portlet, choose one of the following methods to deliver your web content after completing the post migration steps:

- Option 1: If you migrate from a source rendering portal that does not include IBM Web Content Manager to a target rendering portal that does not include IBM Web Content Manager, you must use the JSR 286 Web Content Viewer and the WSRP support in the portal.
- Option 2: If you migrate from a source rendering portal that does not include IBM Web Content Manager to a target rendering portal that includes IBM Web Content Manager, the preferred way to display your web content is to locally render it with the JSR 286 Web Content Viewer.
- Option 3: If your source rendering portal includes IBM Web Content Manager, the target rendering portal will also include IBM Web Content Manager. The preferred way to display your web content is to locally render it with the JSR 286 Web Content Viewer.

The following table summarizes the preferred options depending on the source and target rendering portal.

Table 109. Preferred way to display web content in your portal after migration

Source rendering portal	Target rendering portal	Preferred option
Includes the IBM Web Content Manager	Includes the IBM Web Content Manager	Option 3: Local web content rendering with JSR 286 Web Content Viewer
Includes the IBM Web Content Manager	Does not include the IBM Web Content Manager	Unsupported migration path
Does not include IBM Web Content Manager	Includes the IBM Web Content Manager	Option 2: Local web content rendering with JSR 286 Web Content Viewer
Does not include IBM Web Content Manager	Does not include the IBM Web Content Manager	Option 1: Remote web content rendering with JSR 286 Web Content Viewer via WSRP

Option 1: Remote web content rendering with JSR 286 Web Content Viewer via WSRP:

The source rendering portal of the migration does not contain the web content it delivers. Instead the IBM Portlet API Remote Web Content Viewer connects to another portal of your source environment to retrieve the web content.

About this task

As the target rendering portal does not include IBM Web Content Manager, you must continue displaying web content remotely. To perform remote rendering with IBM Web Content Manager version 8.5, you must configure your target environment to use the JSR 286 Web Content Viewer with WSRP.

The target rendering portal that does not include IBM Web Content Manager and still uses the IBM Portlet API Remote Web Content Viewer becomes the WSRP consumer. It consumes the JSR 286 Web Content Viewer from the target authoring portal that includes IBM Web Content Manager and contains the web content.

Procedure

1. To configure remote rendering, follow the instructions at "Enabling remote rendering with WSRP and the Web Content Viewer" on page 2069.
2. On the target rendering portal that acts as WSRP consumer:

a. Add instances of the consumed JSR 286 Web Content Viewer portlet to portal pages that contain instances of the IBM Portlet API Remote Web Content Viewer portlet.
b. Configure the consumed JSR 286 Web Content Viewer portlet instances to match the configuration of the IBM Portlet API Remote Web Content Viewer portlet instances on each of the portal pages.
c. After replacing all instances of the IBM Portlet API Remote Web Content Viewer portlet and of its portlet clones, uninstall the `ilwwcm-remoterendering-portlet.war` web module.

Note: This option has limitations that do not exist when rendering web content locally. For more information, see *Performing remote rendering with WSRP and the web content viewer*.

Options 2 and 3: Local web content rendering with JSR 286 Web Content Viewer:

The source rendering portal of the migration does not contain the web content it delivers. Instead the IBM Portlet API Remote Web Content Viewer connects to another portal of your source environment to retrieve the web content.

About this task

If you choose this option, you will change the web content delivery model from remote rendering to local rendering. After you make the web content libraries available on the target rendering portal, you can use the JSR 286 Web Content Viewer portlet for local rendering.

Procedure

1. To make the web content available on the target rendering portal, syndicate the web content libraries from the target authoring portal to the target rendering portal. For more information, see Syndication.
2. On the target rendering portal:
   a. Check if you installed the JSR 286 Web Content Viewer portlet.
      1) Click the **Administration menu** icon. Then, click **Portlet Management** > **Web Modules**.
      2) Search for the web module with the file name `ilwwcm-localrenderingportlet-jsr.war`.
      3) If the search result is empty, install the JSR 286 Web Content Viewer portlet from `PortalServer_root/pzn.ext/portlet.localrendering.jsr/localrendering.war/installableApps/ilwwcm-localrenderingportlet-jsr.war`.
   b. To convert the instances of the IBM Portlet API Remote Web Content Viewer portlet to the JSR 286 Web Content Viewer portlet, follow the steps given at Converting an IBM API web content viewer to the JSR 286 API.

      Important: If you use clones of the IBM Portlet API Remote Web Content Viewer portlet, you also need to convert their instances.
   c. After replacing all instances of the IBM Portlet API Web Content Viewer portlet and of its portlet clones, uninstall the `ilwwcm-localrendering-portlet.war` web module.

Converting an IBM API Web Content Viewer to the JSR 286 API:

As installed by default, the Web Content Viewer is based on the JSR 286 API. If you have a Web Content Viewer that is based on the older IBM API, you can convert the viewer to the JSR 286 API. Use the **convert-wcm-rendering-portlet** task to convert the IBM API Web Content Viewer settings and instances to the JSR 286 Web Content Viewer portlet.

About this task

The **convert-wcm-rendering-portlet** task converts portlet settings of the IBM API Web Content Viewer to portlet preferences of the JSR 286 Web Content Viewer. The task also converts instances of the IBM API Web Content Viewer to instances of the Web Content Viewer. User customized portlet data that is associated with the portlet instance is converted into portlet preferences.

Procedure

1. Update the file *wp_profile_root*/ConfigEngine/wkplc.properties. Confirm that the user IDs and passwords are set as required, or modify them if necessary.
2. Update or verify the properties in the file *wp_profile_root*/PortalServer/wcm/config/portletconversion.properties.

   Note: If the following conditions are true, no changes are required and you can use the default values in the properties file.
   - There are no clones of the IBM API Web Content Viewer.
   - You want to convert all instances of the portlet on all pages in the default virtual portal.

   For specific situations, you can update the additional properties that are described in the following table.

Scenario	Properties to modify
You want to convert instances of the portlet on specific pages in the default virtual portal.	**pages.uniquename** Specify a list of unique names of pages, separated by commas. If you specify this property, only portlets on those pages and their descendants are converted. If this property is empty or missing, instances of the IBM API Web Content Viewer on all pages are converted.
You want to convert instances of the portlet in a virtual portal that is not the default virtual portal.	**xmlaccess.url** Specify the URL of the virtual portal to the portal XML configuration interface servlet. You can use this property to run conversions for specific virtual portals. If this property is empty or missing, the default portal is used to run the conversion. Example: xmlaccess.url=http://www.example.com:10039/wps/config/vp1

Scenario	Properties to modify
You cloned the Web Content Viewer portlet and want to convert instances of the clone.	Identify the clone by specifying one of the following properties: • **ibmportlet.portletname** • **ibmportlet.uniquename** • **ibmportlet.objectid** Only one of the properties is required to identify the portlet. For a complete list of properties for the portlet conversion task, see *Converting portlet instances and settings from the IBM API to the standard API*.

3. Change to the directory *wp_profile_root*/ConfigEngine.
4. Run the task ConfigEngine convert-wcm-rendering-portlet.

   Windows

   ```
   ConfigEngine.bat convert-wcm-rendering-portlet
   ```

   AIX, HP-UX, Linux, Solaris

   ```
   ./ConfigEngine.sh convert-wcm-rendering-portlet
   ```

   IBM i `ConfigEngine.sh convert-wcm-rendering-portlet`
5. Verify the conversion by reviewing the console. The message Build successful indicates a successful conversion. If the message Build failed is displayed upon completion of the task, review the previous steps.
6. Verify the configuration of the converted Web Content Viewer. For more information about configuring a local Web Content Viewer, see the portlet help.
7. After the successful conversion, you can uninstall the IBM API Web Content Viewer.

What to do next

If you make the web content available on your delivery portal by using syndication, you can also convert instances of the IBM API Remote Web Content Viewer portlet to the JSR 286 portlet. When you make the web content available, you can transform your web content delivery model from remote rendering to local rendering. To convert instances and settings of the IBM API Remote Web Content Viewer portlet to the JSR 286 portlet, proceed by the following steps:

1. Edit the file wp_profile_root/PortalServer/wcm/config/portletconversion.properties.
2. Change the following parameters as described here:

   ibmwebapp.uid
   The default value for this parameter is the unique identifier of the IBM API Web Content Viewer. Change the value to match the unique identifier of the IBM API Remote Web Content Viewer: com.ibm.workplace.wcm.app.ui.portlet.RenderingPortlet.30f9cb100a340018159bfdc6578

   ibmportlet.portletname
   The default value for this parameter is the portlet name of the IBM API Web Content Viewer. Change the value to match the portlet name of the IBM API Remote Web Content Viewer: Remote Web Content Viewer.
3. Perform steps 1 - 5 of the procedure that is given earlier.

4. Verify the configuration of the converted Remote Web Content Viewer portlet. For further information on configuring a local Web Content Viewer portlet, read *Editing the settings of a web content viewer portlet*.
5. After the successful conversion, you can uninstall the IBM API Remote Web Content Viewer portlet.

Note: If you made clones of the IBM API Web Content Viewer portlet or of the IBM API Remote Web Content Viewer portlet, or if you renamed the portlets, you might need to modify the parameters in the file `wp_profile_root/PortalServer/wcm/config/portletconversion.properties` that identify the portlet that you use as the source for the conversion. For a complete reference of all parameters that the portlet conversion task supports, read *Converting portlet instances and settings from the IBM API to the standard API*.

Note: Note: In the version 8.5 user interface, the JSR 286 Web Content Viewer portlet has been renamed to Web Content Viewer.

Related concepts:

"Unsupported and deprecated features for V8.5" on page 17
Review the features that were available in previous versions of IBM WebSphere Portal Express but are no longer available.

Related tasks:

"Converting portlet instances and settings from the IBM API to the standard API" on page 3121
The portal provides a portlet conversion task that allows you to convert the settings and instances of IBM API portlets to the corresponding standard API portlets. This is useful when you intend to replace IBM API portlets by standard API portlets.

Related information:

Editing the settings of a Web Content Viewer Portlet

Virtual Portal tasks:

If you configured WebSphere Portal Express to use virtual portal, there are some additional steps that are needed to complete the migration.

"Updating administration themes in Virtual Portals" on page 877
During migration, the IBM WebSphere Portal Express Version 8.5 theme is deployed. However, only the administration themes on the default virtual portal are updated to the 8.5 version of the administration user interface. For all other virtual portals, you must manually update the administration themes.

"Enabling the 8.5 site toolbar" on page 878
During migration, the IBM WebSphere Portal Express Version 8.5 theme is deployed. The 8.5 theme includes the site toolbar, but the toolbar is enabled only for the default virtual portal. For all other virtual portals, including migrated and newly created virtual portals, you must install the site toolbar separately.

"Updating Web Content Manager pages theme" on page 879
Before using Web Content Manager in virtual portals that are created after migration by using default portal content from an older release, you must update the theme to ⌂Portal 8.5 theme. Otherwise, Web Content Manager related portlets do not work properly. If you upgraded or migrated to WebSphere Portal Express Version 8.5 CF04 or later, then you do not need to complete the following steps.

"Sharing Web Content Manager libraries between Virtual Portals" on page 880
When you created Web Content Manager libraries in the base portal of earlier versions of WebSphere Portal Express, these libraries were available in the virtual portals. In WebSphere Portal Express Version 8.0 and 8.5, a Web Content Manager library that you create in the base portal is not available in the virtual portals.

"Updating scripts and removing deprecated features" on page 880
To create new Virtual Portals with the same content as the portal from which you migrated, you must pre-configure the default content for creating the Virtual Portal. You must also remove or replace references to deprecated features.

"Enabling Tag and Search Center pages for virtual portals" on page 882
When you migrate to IBM WebSphere Portal Express Version 8.5, the migration process does not apply the Portal 8.5 theme to all portal pages for your virtual portals. This affects the Tag and Search Center pages. To use your Tag Center and Search Center pages, you must manually update the theme for the pages to the Version 8.5 theme. You must also update the profile of the pages to the Search and Tag Center profile.

Related tasks:

"Removing Person Tag hidden pages" on page 888
Remove Person Tag hidden pages from migrated environments where Search for Portal Site was previously configured. If you migrated or updated to WebSphere Portal Express 8.5 CF04 or later, then you do not need to complete these steps.

Related information:

"Administering virtual portals" on page 1386
View information to help you scope your WebSphere Portal Express to have multiple virtual portals.

"Tasks for administering virtual portals" on page 1389
Administering virtual portals and their content comprises the tasks described in the following topics.

Updating administration themes in Virtual Portals:

During migration, the IBM WebSphere Portal Express Version 8.5 theme is deployed. However, only the administration themes on the default virtual portal are updated to the 8.5 version of the administration user interface. For all other virtual portals, you must manually update the administration themes.

Procedure

Upgrade the administration pages theme:

1. Run the following commands from the *wp_profile_root*/ConfigEngine directory of your portal installation.

   For a context root based virtual portal:

   - AIX Linux Solaris: `./ConfigEngine.sh action-upgrade-theme-admin-oob -DWasPassword=`*`password`* `-DPortalAdminPwd=`*`password`* `-DVirtualPortalContext=`*`virtual_portal_context_url`*
   - Windows: `ConfigEngine.bat action-upgrade-theme-admin-oob -DWasPassword=`*`password`* `-DPortalAdminPwd=`*`password`* `-DVirtualPortalContext=`*`virtual_portal_context_url`*
   - IBM i: `ConfigEngine.sh action-upgrade-theme-admin-oob -DWasPassword=`*`password`* `-DPortalAdminPwd=`*`password`* `-DVirtualPortalContext=`*`virtual_portal_context_url`*

To find your virtual portal context, run the following command:

- AIX Linux Solaris: `./ConfigEngine.sh list-all-virtual-portals`
- Windows: `ConfigEngine.bat list-all-virtual-portals`
- IBM i: `ConfigEngine.sh list-all-virtual-portals`

2. If IBM Web Content Manager is installed, then run the following command to upgrade the Web Content Manager administration pages theme.

   For a context root based virtual portal:

   - AIX Linux Solaris: `./ConfigEngine.sh action-upgrade-wcm-theme-admin-oob -DWasPassword=`*`password`* `-DPortalAdminPwd=`*`password`* `-DVirtualPortalContext=`*`virtual_portal_context_url`*
   - Windows: `ConfigEngine.bat action-upgrade-wcm-theme-admin-oob -DWasPassword=`*`password`* `-DPortalAdminPwd=`*`password`* `-DVirtualPortalContext=`*`virtual_portal_context_url`*
   - IBM i: `ConfigEngine.sh action-upgrade-wcm-theme-admin-oob -DWasPassword=`*`password`* `-DPortalAdminPwd=`*`password`* `-DVirtualPortalContext=`*`virtual_portal_context_url`*

   To find your virtual portal context, run the following command:

   - AIX Linux Solaris: `./ConfigEngine.sh list-all-virtual-portals`
   - Windows: `ConfigEngine.bat list-all-virtual-portals`
   - IBM i: `ConfigEngine.sh list-all-virtual-portals`

Enabling the 8.5 site toolbar:

During migration, the IBM WebSphere Portal Express Version 8.5 theme is deployed. The 8.5 theme includes the site toolbar, but the toolbar is enabled only for the default virtual portal. For all other virtual portals, including migrated and newly created virtual portals, you must install the site toolbar separately.

About this task

The site toolbar requires a Portal 8.0 theme or a custom Portal 8.0 theme. The theme must be a modularized theme, which supports theme profiles and theme modules. For more information, see *Add the WebSphere Portal Version 8.5 site toolbar to a WebSphere Portal 8.0 theme*.

If you want to use the IBM WebSphere Portal Express Version 8.5 site toolbar on other migrated virtual portals, complete the following configuration task after you remove the old toolbar from your theme.

Cluster only: Complete this step only on the primary node.

Procedure

Go to the *wp_profile_root*`/ConfigEngine` directory of your portal installation and run:

- AIX HP-UX Linux Solaris: `./ConfigEngine.sh install-toolbar -DWasPassword=`*`password`* `-DPortalAdminPwd=`*`password`* `-DVirtualPortalContext=`*`virtual_portal_context_url`*
- IBM i: `ConfigEngine.sh install-toolbar -DWasPassword=`*`password`* `-DPortalAdminPwd=`*`password`* `-DVirtualPortalContext=`*`virtual_portal_context_url`*

- Windows: `ConfigEngine.bat install-toolbar -DWasPassword=password -DPortalAdminPwd=password -DVirtualPortalContext=virtual_portal_context_url`

Note: Run the **list-all-virtual-portals** ConfigEngine task to find your virtual portal context.

What to do next

You must restart the Portal server after you run the **install-toolbar** task.

For more information about using the 8.5 toolbar, see the site toolbar documentation.

Related concepts:

"Migration - Add the version 8.5 site toolbar to a version 8.0 theme" on page 921
You can easily add the modularized site toolbar of WebSphere Portal Express Version 8.5 to a WebSphere Portal Express 8.0 theme. Or, you can add a toolbar to a custom theme that is derived from the WebSphere Portal Express 8.0 theme. The theme must be a modularized theme, which supports theme profiles and theme modules.

Updating Web Content Manager pages theme:

Before using Web Content Manager in virtual portals that are created after migration by using default portal content from an older release, you must update the theme to ⌂Portal 8.5 theme. Otherwise, Web Content Manager related portlets do not work properly. If you upgraded or migrated to WebSphere Portal Express Version 8.5 CF04 or later, then you do not need to complete the following steps.

Procedure

1. Run the following configuration task from the *wp_profile_root*/ConfigEngine directory:

   Windows
   ```
   ConfigEngine.bat update-wcm-pages -DWasPassword=password
   -DPortalAdminPwd=password
   ```

   AIX Linux Solaris
   ```
   ./ConfigEngine.sh update-wcm-pages -DWasPassword=password
   -DPortalAdminPwd=password
   ```

   IBM i
   ```
   ConfigEngine.sh update-wcm-pages -DWasPassword=password
   -DPortalAdminPwd=password
   ```

2. Change the following pages to use Portal 8.5 Theme:
   - ⌂com.ibm.wps.hiddenpage.wcm.Authoring_Portlet
   - ⌂ibm.portal.Web.Content.Management
   - ⌂ibm.portal.Portal Content

   a. Log in to Portal as an administrator.
   b. To open the **Manage Pages** portlet, click the **Administration menu** icon. Then, click **Portal User Interface** > **Manage Pages**.
   c. In the **Search by** menu, select **Unique name contains**.
   d. In the **Search** field, enter the unique name of the page and click **Search**.
   e. Click **Edit Page Properties** for the Web Content Manager page.
   f. On the **Theme** field, select **Portal 8.5**.

g. Click **OK**.

Sharing Web Content Manager libraries between Virtual Portals:

When you created Web Content Manager libraries in the base portal of earlier versions of WebSphere Portal Express, these libraries were available in the virtual portals. In WebSphere Portal Express Version 8.0 and 8.5, a Web Content Manager library that you create in the base portal is not available in the virtual portals.

About this task

If you have managed pages enabled and want to share a Web Content Manager library between virtual portals, use syndication to replicate the library to the virtual portals.

Related concepts:

"Syndication" on page 448
Use syndication to replicate web content library data from one server to another server. Syndication is based on a syndicator and subscriber relationship. The syndicator has the current data. The subscriber received the current data from the syndicator.

Updating scripts and removing deprecated features:

To create new Virtual Portals with the same content as the portal from which you migrated, you must pre-configure the default content for creating the Virtual Portal. You must also remove or replace references to deprecated features.

About this task

When you migrate a Virtual Portal, WebSphere Portal Express treats all pages in the portal as custom, customer-created content. As a result, if the Virtual Portal contains pages that are associated with features that are not available in the new installed version, WebSphere Portal Express migrates those pages regardless.

For example, if you migrate a Virtual Portal that contains a Document Libraries page, WebSphere Portal Express preserves that page. You can remove these pages manually after you migrate the Virtual Portal.

Procedure

1. Register your *filename*.xml file that you used in the previous system to pre-configure the default content for creating the Virtual Portal.

   Note: The name of the file might change based on the release and editions of portal that you are using. The following are examples of file names: "InitVirtualContentPortal.xml, InitAdminVirtualPortal.xml."

Important: If you are migrating to WebSphere Portal Express 8.5 CF04 or later, you can skip the following steps.

2. Use the WebSphere Integrated Solutions Console to update the virtual portal XML scripts to remove references to Dynamic Person Tag portlet.

   Note: Your script can contain references to Dynamic Person Tag portlet. This portlet is no longer available and any reference to this portlet causes your script to fail.

   a. Go to the WebSphere Integrated Solutions Console.

b. Click **Applications** > **Application Types** > **Assets**.
c. Select `VirtualPortal.zip`, and click **Export**.
d. Remove the web-app sequence that includes the opening `<web-app...>` and the closing `</web-app>` tags, and everything in between.

   See the following example to see how the portlet is defined in a web-app sequence:

```
<web-app action="locate" uid="com.ibm.wkplc.people.portal.portlet.dynamicpersontag.web.app"
  <portlet-app action="locate" uid="com.ibm.wkplc.people.portal.portlet.dynamicpersontag.po
    <portlet action="locate" name="Dynamic Person Tag" objectid="3_CGAH47L008DE402BK8543I1C
  </portlet-app>
</web-app>
```

e. Remove the Person Tag page that includes the opening `<content-node...>` and the closing `</content-node>` tags, and everything in between. The object `ids`, `portletrefs`, `sharerefs`, and other references in the example might vary in your installation.

   See the following example of the page that is defined in the content-node sequence.

```
<content-node type="page" uniquename="ibm.portal.Person.Tag">
  <supported-markup markup="html" update="set"></supported-markup>
  <localedata locale="en">
<title>Person Tag</title>
<description>Person Tag portlet, which enables live names and information for names in IBM
  </localedata>
</content-node>
```

f. Select `VirtualPortal.zip`, and click **Update**.
g. Select the default value **Replace entire asset**.
h. Locate the updated file and upload the file.

3. Use the WebSphere Integrated Solutions Console to update the virtual portal XML scripts to remove references to CAI/TAI portlets. For example, the portlets are defined in a web-app sequence like the following examples.

   Note: Your script can contain references to the CAI/TAI portlets. These portlets are no longer available and any reference to these portlets cause your script to fail.

```
<web-app action="locate" uid="com.ibm.workplace.community.portal">
  <portlet-app action="locate" uid="com.ibm.workplace.community.portal.1">
    <portlet action="locate" name="Community" objectid="Z3_CGAH47L0008270I7MOUHLP18C5"/>
  </portlet-app>
</web-app>
```

```
<web-app action="locate" uid="com.ibm.workplace.builder.parameterPortlet.ParamConfigPortlet.40
  <portlet-app action="locate" uid="com.ibm.workplace.builder.parameterPortlet.ParamConfigPort
    <portlet action="locate" name="Parameters" objectid="Z3_CGAH47L0008270I7MOUHLP18O5"/>
  </portlet-app>
</web-app>
```

```
<web-app action="locate" uid="com.ibm.workplace.policystatus.PolicyStatus">
  <portlet-app action="locate" uid="com.ibm.workplace.policystatus.PolicyStatus.1">
    <portlet action="locate" name="Policy Status Portlet" objectid="Z3_CGAH47L0008270I7MOUHLP1
  </portlet-app>
</web-app>
```

```
<web-app action="locate" uid="com.ibm.workplace.builder.propertiesPortlet.portal">
  <portlet-app action="locate" uid="com.ibm.workplace.builder.propertiesPortlet.portal.1">
    <portlet action="locate" name="Properties portlet" objectid="Z3_CGAH47L0008270I7MOUHLP1845
  </portlet-app>
</web-app>
```

```
<web-app action="locate" uid="com.ibm.workplace.builder.manageroles.ManageRoles.50047239651b00181
  <portlet-app action="locate" uid="com.ibm.workplace.builder.manageroles.ManageRoles.50047239651
    <portlet action="locate" name="Roles portlet" objectid="Z3_CGAH47L0008270I7MOUHLP18K5"/>
  </portlet-app>
</web-app>
```

```
<web-app action="locate" uid="com.ibm.workplace.cdo.portal">
      <portlet-app action="locate" uid="com.ibm.workplace.cdo.portal.1">
        <portlet action="locate" name="Application Catalog" objectid="Z3_CGAH47L00OJ790IAH1AFAN10
      </portlet-app>
    </web-app>
```

```
<web-app action="locate" uid="com.ibm.workplace.tai.tc">
      <portlet-app action="locate" uid="com.ibm.workplace.tai.tc.1">
        <portlet action="locate" name="Template Catalog Manager" objectid="Z3_CGAH47L00OJ790IAH1A
      </portlet-app>
    </web-app>
```

The pages that reference these portlets in sequences like the following examples.

```
<component action="update" active="true" deletable="false" domain="rel" modifiable="undefined" ob
  <portletinstance action="update" domain="rel" objectid="Z5_CGAH47L0008270I7MOUHLP18E0" portletr
</component>
```

```
<component action="update" active="true" deletable="false" domain="rel" modifiable="undefined" ob
  <portletinstance action="update" domain="rel" objectid="Z5_CGAH47L0008270I7MOUHLP18I4" portletr
</component>
```

```
<component action="update" active="true" deletable="false" domain="rel" modifiable="undefined" ob
  <portletinstance action="update" domain="rel" objectid="Z5_CGAH47L0008270I7MOUHLP18U2" portletr
</component>
```

```
<component action="update" active="true" deletable="false" domain="rel" modifiable="undefined" ob
  <portletinstance action="update" domain="rel" objectid="Z5_CGAH47L0008270I7MOUHLP18Q1" portletr
</component>
```

```
<component action="update" active="true" deletable="false" domain="rel" modifiable="undefined" ob
  <portletinstance action="update" domain="rel" objectid="Z5_CGAH47L0008270I7MOUHLP1863" portletr
</component>
```

The `portletref` attribute of the `portletinstance` tag matches one of the `objectid` attributes from the portlet tags in the web-app section.

```
<portlet action="locate" name="Roles portlet" objectid="Z3_CGAH47L0008270I7MOUHLP18K5"/>
<portletinstance portletref="Z3_CGAH47L0008270I7MOUHLP18K5" ... />
```

Make sure to remove the web-app sequence that includes the opening `<web-app...>` and the closing `</web-app>` tags, and everything in between. Also, remove the components that reference the portlets. It includes the opening `<component ...>` and the closing `</component>` tags, and everything in between. The `object ids`, `portletrefs`, `sharerefs`, and other references in the example might vary in your installation.

Enabling Tag and Search Center pages for virtual portals:

When you migrate to IBM WebSphere Portal Express Version 8.5, the migration process does not apply the Portal 8.5 theme to all portal pages for your virtual portals. This affects the Tag and Search Center pages. To use your Tag Center and Search Center pages, you must manually update the theme for the pages to the Version 8.5 theme. You must also update the profile of the pages to the Search and Tag Center profile.

About this task

The Search and Tag Center profile is a hidden profile. Therefore, you must set this profile in the page properties.

Procedure

1. Update the theme and profile that is used for the Tag Center pages:
   a. Edit the existing page that is using the older theme.
   b. Go to **Page properties**.
   c. Set the Portal 8.5 theme for the page.
   d. Set the **resourceaggregation.profile** parameter to `profiles/profile_search_tag.json`.
   e. Save your changes.
2. If you created the Search Center pages using the Portal 8.5 theme, update the profile that is used for the Search Center pages:
   a. Go to **Page properties**.
   b. Set the **resourceaggregation.profile** parameter to `profiles/profile_search_tag.json`.
   c. Save your changes.

Importing search web collections:

As a part of preparing your source environment, you exported web collections. After you export a search web collection from a source portal, you can import the data into a new, empty collection on the target portal. Importing a web collection retains most of the configuration data such as content sources, schedulers, filters, and language settings. If you configured such settings when creating the new collection, they are overwritten by the imported settings.

Before you begin

When you import a web collection, a background process fetches, crawls, and indexes all documents that are listed by URL in the previously exported file. Therefore, be aware of the memory and time that is required for crawls. For more information, see *Hints and tips for using Portal search*.

About this task

Complete the following steps on the target portal, using the Manage Search portlet:

Procedure

1. If you are migrating to a remote server, copy the XML file that contains the exported web collection to the server where the new version of WebSphere Portal is installed.
2. In the **Search Collections** box, click **New Collection** to create an empty collection.
3. Specify the required information in the **Location of Collection**, **Name of Collection**, and **Description of Collection** fields, and then click **OK**.
4. To include the security information when you import the search collection, add the **WS_KEY** parameter to the search service that contains the target search collection. Complete the following steps:
   a. To open the **Manage Search** portlet, click the **Administration menu** icon. Then, click **Search Administration** > **Manage Search**.
   b. Click **Search Services**.
   c. Click the **Edit** icon for the search service that contains the target search collection.
   d. In the **Parameter key** field, enter `WS_KEY`.

e. In the **New parameter value** field, enter `secret`.
f. Click **Add Parameter**.

Note: If you do not import the security information when you import a search collection, you must manually add the user name and password to each content source after you import the search collection into the target portal.

5. Click the **Import or Export Collection** icon for the collection that you created.
6. In the **Specify Location** field, enter the full directory path and XML file name of the file that you exported.
7. Click **Import**.
8. Edit the Content Source Configuration details to ensure that the settings match your target environment:
   a. Select the imported search collection to edit.
   b. Click the **Edit Content Source** icon.
   c. On the General Parameters tab, update the **Collect documents linked from this URL** field to match your target environment. The update might require changing the name of the target server and the port information. When you import a collection from a version of WebSphere Portal Express before 8.0, you need to add the context root path of the portal application. For example, adding `/wps` to the URL following the port information.
   d. On the Security tab, update the **Security Realms** to match your target environment.
   e. Click **Save**.
9. Click the **Search and Browse the Collection** icon for the collection that you created.
10. Verify that the documents found are the same as the collection that you created on the earlier portal server, and that the links work as expected. Any inconsistencies between the exported document count and the imported document count should be resolved the next time the cleanup daemon runs.

Related tasks:

"Exporting search web collections" on page 823
Use the Manage Search portlet to export search web collections from a source portal. Before you export a collection, make sure that the user who is running the portal application process has write access to the target directory location.

"Hints and tips for using Portal Search" on page 714
View some useful tips for using Portal Search.

Importing UX Screen Flow Manager dialog definitions:

If you migrated from Version 8.0.0.1 with the UX Screen Flow Manager (UXFM) enabled, then you exported and removed your dialog definitions before migrating to Version 8.5. Run the following task to import the dialog definitions into your upgraded system.

Procedure

1. Save the following sample of code as *ImportSampleCode.xml* to use when importing your dialog definitions.

```
<?xml version="1.0" encoding="UTF-8"?>
<request type="update" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:noNamespaceSchemaLocation="PCM_1.0.xsd">
```

```
    <!-- import all dialog definitions that are currently deployed -->
    <portal action="import">
        <dialog-set>
            <dialog name="*" />
        </dialog-set>
    </portal>
</request>
```

2. Run the following task to import your dialog definitions:
   - Linux : `./xmlaccess.sh -user` *`userID`* `-password` *`password`* `-url` *`url`* `-in` *`ImportSampleCode.xml`* `-in import.xml`
   - IBM i: `xmlaccess.sh -user` *`userID`* `-password` *`password`* `-url` *`url`* `-in` *`ImportSampleCode.xml`* `-in import.xml`
   - Windows: `xmlaccess.bat -user` *`userID`* `-password` *`password`* `-url` *`url`* `-in` *`ImportSampleCode.xml`* `-in` *`ImportSampleCode.xml`* `-in import.xml`

Related tasks:

"Exporting UXFM dialog definitions" on page 826
Export and save your dialog definitions before you migrate to Version 8.5.

WSRP:

If you use your IBM WebSphere Portal Express as a WSRP Consumer or Producer, you must complete additional steps to complete migration.

"Updating a WSRP Producer"
After you complete the migration of your data, perform the following task if you use IBM WebSphere Portal Express as a WSRP Producer.

"Updating a WSRP Consumer" on page 886
After you complete the migration of your data, perform the following tasks if you use IBM WebSphere Portal Express as a WSRP Consumer.

Updating a WSRP Producer:

After you complete the migration of your data, perform the following task if you use IBM WebSphere Portal Express as a WSRP Producer.

Procedure

The WSRP web service security configuration of a Producer is not automatically migrated. After you complete the migration of a Producer portal, you must manually configure the WSRP Producer for security. For more information, see *Securing a WSRP Producer portal*.

Note: WebSphere Portal Express does not provide a default option for the configuration of web service security that uses signed user name tokens anymore. If you have used this security configuration on earlier versions of WebSphere Portal Express, see *Security for WSRP services* for available security options for WSRP.

Related concepts:

"Security for WSRP services" on page 1441
IBM WebSphere Portal Express supports two security mechanisms for WSRP.

Related tasks:

"Securing a WSRP Producer portal" on page 1447
To secure provided portlets, you can configure the WSRP Producer for web service message security, for example, for message authentication. If you configure

message authentication, you must also configure Portal Access Control.

Updating a WSRP Consumer:

After you complete the migration of your data, perform the following tasks if you use IBM WebSphere Portal Express as a WSRP Consumer.

Procedure

- Verify the web service security configuration for the WSRP ports of the Producer definitions. For more information about configuring and securing WSRP on a Consumer portal, see *Configuring security on the Consumer portal*.
- If you configured web services security using LTPA version 1 tokens for a WSRP port of a Producer definition, you must complete more steps. WebSphere Application Server Version 8.5.5 does not support creating LTPA version 1 tokens for immediate use. Your options depend on whether the Producer requires LTPA version 1 tokens or is able to accept LTPA version 2 tokens. For information about your options and the required configuration changes, see *Configuring WSRP Producer ports for Web Service Security on the Consumer portal*.

  Note: WebSphere Portal Express does not provide a default configuration option for web service security that uses signed user name tokens anymore. If you used this security configuration on earlier versions of WebSphere Portal Express, see *Configuring WSRP Producer ports for Web Service Security on the Consumer portal* for available security options for WSRP.

  Note: WebSphere Portal Express does not support to secure WSRP by Secure Socket Layer (SSL) with Client Certificate Authentication anymore. If you used this security configuration on earlier versions of WebSphere Portal Express, see *Security for WSRP services*.
- When you complete the migration of a Producer, verify the corresponding Producer definition on the WSRP Consumer. For details about working with Producer definitions, see *Working with Producer definitions*.

  Note: In particular, verify the WSDL URL of the Producer and the web service security configuration and the endpoint URLs of the Producer ports. If the context root of the Producer was changed, adapt the endpoint URLs of the WSRP ports.
- Configure the JVM setting for retrieving multiple transport headers from a JAX-WS web service response, as described in description of APAR PM91361. See *PM91361: MULTIPLE SET-COOKIE VALUES FROM AN HTTP TRANSPORT HEADER IN A JAX-WS WEB SERVICE RESPONSE ARE NOT RETRIEVED CORRECTLY*.

Related concepts:

"Security for WSRP services" on page 1441
IBM WebSphere Portal Express supports two security mechanisms for WSRP.

Related tasks:

"Configuring security on the Consumer portal" on page 1461
You can configure security for the WSRP Consumer. If you enable security, the WSRP Consumer sends a security token as part of the WSRP request message to the WSRP producer. The security token represents the identity of the user who is logged in to the Consumer Portal. The WSRP Producer uses the security token to process the WSRP requests under the user identity that is represented by the security token.

"Configuring WSRP Producer ports for Web Service Security on the Consumer portal" on page 1464
You can configure each WSRP port of a particular Producer definition for web service security by using LTPA or username tokens.

"Working with Producer definitions" on page 1473
To make a WSRP Producer known to your Consumer portal, you create a Producer definition for that WSRP Producer in your Consumer portal. You can also configure the Producer definition.

Related information:

 PM91361: MULTIPLE SET-COOKIE VALUES FROM AN HTTP TRANSPORT HEADER IN A JAX-WS WEB SERVICE RESPONSE ARE NOT RETRIEVED CORRECTLY

Blogs and wikis:

After you migrate from WebSphere Portal Express Versions 7.0 or 8.0 to Version 8.5, you must run a configuration task to update the presentation templates that are used by blogs and wikis to apply the latest updates. You must run this task for content in your blogs and wikis to render properly.

About this task

If you customized your blogs and wiki, you will lose your customizations and you must reapply those customizations after you run the task.

Procedure

1. Go to the *wp_profile_root*`/ConfigEngine` directory.
2. Run the following command:
   - Linux : `./ConfigEngine.sh configure-blog -DPortalAdminPwd=`*`password`* `-DWasPassword=`*`password`*
   - IBM i: `ConfigEngine.sh configure-blog -DPortalAdminPwd=`*`password`* `-DWasPassword=`*`password`*
   - Windows: `ConfigEngine.bat configure-blog -DPortalAdminPwd=`*`password`* `-DWasPassword=`*`password`*
3. Restart WebSphere Portal Express.

Results

Enabling blogs and wikis by running the **`configure-blog`** task also enables tag and rating widgets. Go to "Enabling the new tag and rating widgets after a portal upgrade" on page 917 to verify and finish enabling tag and rating widgets.

Related reference:

"The tag and rating widgets" on page 1310
The portal provides one widget each for tags and for ratings.

Tag and Search Center pages:

When you migrate to IBM WebSphere Portal Express Version 8.5, the migration process does not apply the Portal 8.5 theme to all portal pages. For example, this affects the Tag and Search Center pages. To continue to use your Tag Center and Search Center pages, you must update the theme for the pages to the Version 8.5 theme. You must also update the profile of the pages to the Search and Tag Center profile.

Before you begin

Ensure that the Portal 8.5 theme is set for your Tag and Search Center pages before completing the following procedure.

About this task

The Search and Tag Center profile is a hidden profile. Therefore, you must set this profile in the page properties.

Procedure

1. To create the Tag Center pages, or apply the correct theme in order to work with these pages, run the following configuration task. Go to the *wp_profile_root*/ConfigEngine directory and enter:
   - HP-UX Linux : `./ConfigEngine.sh cp-setup-tag-center`
   - IBM i: `ConfigEngine.sh cp-setup-tag-center`
   - Windows: `ConfigEngine.bat cp-setup-tag-center`
2. To update the profile for the Search Center pages, complete the following steps:
   a. Go to Page properties.
   b. Set the **resourceaggregation.profile** parameter to `profiles/profile_search_tag.json`.

Removing Person Tag hidden pages:

Remove Person Tag hidden pages from migrated environments where Search for Portal Site was previously configured. If you migrated or updated to WebSphere Portal Express 8.5 CF04 or later, then you do not need to complete these steps.

About this task

You might find errors that are captured in the `systemOut.log` file if the migrated system has Search for Portal Site configured and crawling runs. The following excerpt is provided as an example.

```
00000052 PortletContai E com.ibm.wps.pe.pc.legacy.PortletContainerImpl
         performBeginEvents EJPPG1122E:

         An error occurred during portlet event processing.
             javax.portlet.PortletException: javax.servlet.UnavailableException: SRVE0200E:

         Servlet [com.ibm.wkplc.people.portal.portlet.dynamicpersontag.DynamicPersonTagPortlet]: Could not
         find required class -  class java.lang.ClassNotFoundException: com.ibm.wkplc.people.portal.portlet.
         dynamicpersontag.DynamicPersonTagPortlet

         at com.ibm.wps.pe.pc.legacy.PortletContainerImpl.callPortletMethod(PortletContainerImpl.java:1308)
```

Procedure

Remove the hidden pages to avoid these errors in the `systemOut.log`.

1. Log in to Portal as an Administrator.
2. To open the **Manage Pages** portlet, click the **Administration menu** icon. Then, click **Portal User Interface** > **Manage Pages**.
3. Then, click **Context Root** > **Hidden Pages**.
4. Look for **Person Tag** with unique name **ibm.portal.Person.Tag**.
5. Delete this page.

Updating URL mapping for personalization page:

If you migrated from Version 7.0 to Version 8.5 with a CF03 or earlier fix pack applied, then you must complete the following task to ensure that the Personalization page displays properly.

Procedure

1. Log in to IBM WebSphere Portal Express.
2. Click **Administration**. Then, click **Portal Settings** > **URL Mapping**.
3. Delete the URL Mapping for **Personalization**.

   Note: Do not delete the **PZN** entry for PZN mapping on the list.

Enabling vanity URL support after migration:

In a new WebSphere Portal Express Version 8.5 installation, vanity URL support is enabled. However, if you upgrade your WebSphere Portal Express from a previous version to Version 8.5, vanity URL support is disabled. You can enable and disable vanity URL support as required by using a portal configuration task.

About this task

If vanity URL support is not enabled and a user tries to access a vanity URL, the portal gives a 404 return code.

Note: For vanity URLs to work, managed pages also must be enabled as a prerequisite. For more information, read *Enabling managed pages after migration*. If you disable managed pages, this step also disables vanity URLs. If you do not disable vanity URLs and you enable managed pages again, vanity URLs also work again.

Enabling vanity URL support

To enable vanity URL support, you use the configuration task **enable-vanityurl-support**. This task sets a new custom property in the Resource Environment Provider of the WP Configuration Service. The property name is **vanityurl.support.enabled**. When you run the configuration task, the property is set to the value `true`.

Note: It is mandatory to enable managed pages to have vanity URLs enabled. If managed pages support is not enabled, the task **enable-vanityurl-support** fails. In this case, run the task **enable-managed-pages** first.

Disabling vanity URL support

To disable vanity URL support, you use the configuration task **disable-vanityurl-support**. This task deletes the custom property **vanityurl.support.enabled** from the Resource Environment Provider of the WP Configuration Service. If the portal then receives a request to serve a vanity URL, it gives a 404 return code.

Syntax

You call these configuration tasks as follows:

IBM i

Enable: `ConfigEngine.sh enable-vanityurl-support -DPortalAdminPwd=`*`password`* `-DWasPassword=`*`password`*

Disable: `ConfigEngine.sh disable-vanityurl-support -DPortalAdminPwd=password -DWasPassword=password`

Linux

Enable: `./ConfigEngine.sh enable-vanityurl-support -DPortalAdminPwd=password -DWasPassword=password`

Disable: `./ConfigEngine.sh disable-vanityurl-support -DPortalAdminPwd=password -DWasPassword=password`

Windows

Enable: `ConfigEngine.bat enable-vanityurl-support -DPortalAdminPwd=password -DWasPassword=password`

Disable: `ConfigEngine.bat disable-vanityurl-support -DPortalAdminPwd=password -DWasPassword=password`

Remember: After you run the **enable-vanityurl-support** or **disable-vanityurl-support** task, restart the server. Go to "Starting and stopping servers, deployment managers, and node agents" on page 1216 for specific instructions.

Related tasks:

"Enabling managed pages" on page 913
After migration, you must manually enable support for managed pages. Without managed pages support, some features like the project menu are not available on the migrated server.

Enabling impersonation:

If you migrate to WebSphere Portal Express Version 8.5 and upgrade to fix pack level CF01-CF03, impersonation might not be enabled. If you plan to use the impersonation feature, which allows a selected user to preview and test new pages or portlets to help identify any potential issues, then you might need to enable this feature.

About this task

Note: If you applied CF04 or a later fix pack, then you do not need to complete the steps to enable impersonation.

Portal Access Control (PAC) controls the ability to impersonate another user. To impersonate another user, the **Can Run As User** role on the virtual resource users must be assigned. You must first enable the impersonation feature within WebSphere Portal Express. If you are unsure whether the impersonation feature is enabled, you can use the following instructions to verify that you have the correct settings.

Perform the following steps to enable the impersonation feature:

Procedure

1. Log on to the WebSphere Application Server Integrated Solutions Console or Network Deployment Administration Console.
2. Perform the following steps to enable the impersonation feature:
   a. Go to **Resources** > **Resource Environment** > **Resource environment Providers** > **WP Authentication Service** > **Custom Properties**.
   b. Click **New**.
   c. Enter `logout.explicit.filterchain` in the **Name** field.

d. Enter `com.ibm.wps.auth.impersonation.impl.ImpersonationLogoutFilter` in the **Value** field.
e. Click **Apply** , and then click **Save** to save the changes directly to the master configuration.
f. Go to **Resources** > **Resource Environment** > **Resource Environment Providers** > **WP PortletServiceRegistryService** > **Custom Properties**.
g. Click **New**.
h. Enter `com.ibm.wps.portletservice.impersonation.impl.ImpersonationServiceImpl` in the **Name** field.
i. Enter `com.ibm.wps.portletservice.impersonation.impl.ImpersonationServiceImpl` in the **Value** field.
j. Click **Apply** and then click **Save** to save the changes directly to the master configuration.

3. Stop and restart the WebSphere_Portal server.
4. Perform the following steps to assign the **Can Run As User** role to a user.
   a. Log on to WebSphere Portal Express as the administrator.
   b. Click **Administration** in the site toolbar.
   c. Click **Access** > **User and Group Permissions**.
   d. Click **Users**.
   e. Search for the user to which you want to assign the **Can Run As User** role.
   f. Click the **Select Resource Type** icon for the user.
   g. Click **Page Next**, and go to the page that contains the **Virtual Resources** option, and click that link.
   h. Go to the page that contains the **Users** option, and click the **Assign Access** icon.
   i. Select the **Explicitly Assign** check box for the **Can Run As User** role.
   j. Click **OK**.
   k. Verify that the user now has **User** and **Can Run As User** access.

   The users with the **Can Run As User** role can now impersonate another user.

Reinstalling the PortalTheme:

If you migrate from Version 7.0 to Version 8.5, when you apply the latest combined cumulative fix during post-migration, the PortalTheme from earlier WebSphere Portal Express versions is removed. If your system requires this theme, then you can manually reinstall it.

About this task

In Version 8.0, the PortalTheme was removed. Complete the following procedure only if your migrated system requires the PortalTheme from an earlier version.

Procedure

1. Run the following command to install the PortalTheme.
   - Linux : `./ConfigEngine.sh deploy-portal-theme -DPortalAdminPwd=`*`password`* `-DWasPassword=`*`password`*
   - IBM i: `ConfigEngine.sh deploy-portal-theme -DPortalAdminPwd=`*`password`* `-DWasPassword=`*`password`*

- Windows: `ConfigEngine.bat deploy-portal-theme -DPortalAdminPwd=password -DWasPassword=password`

2. Restart your portal server.

Development tasks

Complete the development tasks that are required after the migration to ensure that your environment functions properly.

"Updating portlets URL"
After migrating your portal environment, you must verify and update as needed the portlets URLs. In some cases, portlets have the incorrect URL after migration. URLs can be easily corrected using the XML configuration interface to export, update, and import the configurations.

"Updating custom theme Dojo references" on page 893
The default Dojo context root in WebSphere Portal Express is `/WpsContextRoot/portal_dojo`. You can find the value of `WpsContextRoot` in *wp_profile_root*`/ConfigEngine/properties/wkplc.properties`.

"Enabling and upgrading JavaServer Faces portlet applications" on page 894
You can enable or upgrade portlet projects that use JavaServer Faces 1.x to JavaServer Faces 2.0 Facelet-based portlet projects. Refer to the Rational Application Developer for WebSphere Software documentation for instructions on enabling and upgrading JavaServer Faces portlet applications.

Updating portlets URL:

After migrating your portal environment, you must verify and update as needed the portlets URLs. In some cases, portlets have the incorrect URL after migration. URLs can be easily corrected using the XML configuration interface to export, update, and import the configurations.

About this task

Perform the following steps in the newly migrated environment.

Procedure

Export the portlet configuration.

1. Change directory where the WebSphere Portal Express tools are contained:
   - IBM i Linux : *PortalServer_root*`/bin`
   - Windows: *PortalServer_root*`\bin`
2. Export the configuration using the provided sample file that is named `ExportAllPortlets.xml` by entering the following command:
   - Linux : `./xmlaccess.sh -in` *PortalServer_root*`/doc/xml-samples/ExportAllPortlets.xml -user` *wpsadmin* `-password` *wpsadminpwd* `-url http://`*server.example.com:port*`/wps/config -out` *Server_config.xml*
   - IBM i: `xmlaccess.sh -in` *PortalServer_root*`/doc/xml-samples/ExportAllPortlets.xml -user` *wpsadmin* `-password` *wpsadminpwd* `-url http://`*server.example.com:port*`/wps/config -out` *Server_config.xml*
   - Windows: `xmlaccess.bat -in` *PortalServer_root*`\doc\xml-samples\ExportAllPortlets.xml -user` *wpsadmin* `-password` *wpsadminpwd* `-url http://`*server.example.com:port*`/wps/config -out` *Server_config.xml*

   The exported configuration is stored in the XML file named `Server_config.xml`.

Verify output XML file and update URLs as needed.

3. Open the Server_config.xml file and verify that all URLs are valid. This means that all the files that are listed in the XML file must be present and accessible in the specified locations.
   a. If the URLs do not match the actual location in your environment, update those entries according to the actual location of the files.
   b. If the files specified in the URL field do not exist in the migrated environment or are no longer needed in the configuration, remove those entries.

   Note: If you are making the updates on a clustered environment, modify the XML file to remove the global-settings and services-settings entries if available in the file.

Import XML file with the updated URLs.

4. Change directory where the WebSphere Portal Express tools are contained:
   - IBM i Linux : *PortalServer_root*/bin
   - Windows: *PortalServer_root*\bin
5. Run the following command to import the updated configuration using the Server_config.xml file that you just updated:
   - Linux : ./xmlaccess.sh -in Server_config.xml -user *wpsadmin* -password *wpsadminpwd* -url http://*Server.example.com:port*/wps/config
   - IBM i: xmlaccess.sh -in Server_config.xml -user *wpsadmin* -password *wpsadminpwd* -url http://*Server.example.com:port*/wps/config
   - Windows: xmlaccess.bat -in *Server_config.xml* -user *wpsadmin* -password *wpsadminpwd* -url http://*Server.example.com:port*/wps/config
6. After the request is processed, make sure that the import process displays the following return message:

   ```
   <status element="all" result="ok">
   ```

For clustered environments only.

7. Resync the cluster from the Deployment Manager console.
8. Restart the Enterprise Applications from the Deployment Manager console.
9. Run the following command on the cluster primary node to activate the deployed portlets:
   - Linux : ./ConfigEngine.sh activate-portlets -DWasPassword=*password*
   - IBM i: From the UserData directory, ConfigEngine.sh activate-portlets -DWasPassword=*password*
   - Windows: ConfigEngine.bat activate-portlets -DWasPassword=*password*
10. Restart the portal.

Updating custom theme Dojo references:

The default Dojo context root in WebSphere Portal Express is /WpsContextRoot/portal_dojo. You can find the value of WpsContextRoot in *wp_profile_root*/ConfigEngine/properties/wkplc.properties.

About this task

You might find that migrated themes, including custom themes, have references to /portal_dojo without the WpsContextRoot prefix. You can look for these references in both the WAR file and in the WebDAV storage for the theme, and update it if needed.

See the following procedure for an example of how to search for these references in a Linux environment.

Procedure

1. Open a command line on your server.
2. Enter `WebSphere Portal Install Directory> grep -Hr "\"/portal_dojo".`

Related tasks:

"Using WebDAV with WebSphere Portal Express" on page 1351
WebSphere Portal Express provides a Web-based Distributed Authoring and Versioning (WebDAV) implementation that individual services can use by plugging into. WebDAV is a set of extensions to the HTTP protocol that allows you to collaborate on editing and managing files on remote Web servers. Caching Proxy supports WebDAV methods used by Microsoft Exchange Server, and user-defined (customized) methods. These methods are hard coded and managed by the Enable and Disable directives. Administrators can also use the corresponding method-mask defined in the PROTECT directive to authorize the use of these methods.

Enabling and upgrading JavaServer Faces portlet applications:

You can enable or upgrade portlet projects that use JavaServer Faces 1.x to JavaServer Faces 2.0 Facelet-based portlet projects. Refer to the Rational Application Developer for WebSphere Software documentation for instructions on enabling and upgrading JavaServer Faces portlet applications.

Go to Enabling and upgrading JavaServer Faces portlet applications for step-by-step instructions.

Database tasks

There are different post-migration tasks that are required depending on the type of database that is used.

"Updating the isolation level for SQL server databases"
If you are using an SQL Server, you must update the isolation level of your release, community, customization, and JCR databases to improve concurrency and efficiency of the databases.

"Updating DB2 self-tuning memory manager (STMM) settings" on page 895
With the Version 8.5 release, a number of the settings have been changed to be managed by the self-tuning memory manager (STMM) engine. Change your settings to the recommended values, if there are no specific needs for the current values.

"Oracle: Enabling the auto space advisor background task" on page 896
If you use an Oracle database, you must complete a post-migration task to enable the Oracle background task called "Auto Space Advisor" after your run the **upgrade-profile** task during migration using the Configuration Wizard.

Updating the isolation level for SQL server databases:

If you are using an SQL Server, you must update the isolation level of your release, community, customization, and JCR databases to improve concurrency and efficiency of the databases.

Before you begin

Ensure that the database is not in use.

Procedure

Run the command: `ALTER DATABASE database_name SET READ_COMMITTED_SNAPSHOT ON;`.

Updating DB2 self-tuning memory manager (STMM) settings:

With the Version 8.5 release, a number of the settings have been changed to be managed by the self-tuning memory manager (STMM) engine. Change your settings to the recommended values, if there are no specific needs for the current values.

Procedure

1. Stop the portal server.
2. Change your settings to the recommended values:

   UPDATE DBM CFG USING sheapthres 0;

   For each Portal database (release, community, customization, jcr, feedback, likeminds):

   - UPDATE DB CFG FOR *dbname* USING applheapsz automatic;
   - UPDATE DB CFG FOR *dbname* USING stmtheap automatic;
   - UPDATE DB CFG FOR *dbname* USING dbheap automatic;
   - UPDATE DB CFG FOR *dbname* USING locklist automatic;
   - UPDATE DB CFG FOR *dbname* USING avg_appls automatic;
   - UPDATE DB CFG FOR *dbname* USING PCKCACHESZ automatic;
   - UPDATE DB CFG FOR *dbname* USING AUTO_MAINT on;
   - UPDATE DB CFG FOR *dbname* USING SHEAPTHRES_SHR automatic;
   - UPDATE DB CFG FOR *dbname* USING SORTHEAP automatic;
   - UPDATE DB CFG FOR *dbname* USING SELF_TUNING_MEM ON;
   - Required only for the database that contains the JCR Domain: UPDATE DB CFG FOR *dbname* USING logfilsiz 16000;
   - Required only for the database that contains the JCR Domain: UPDATE DB CFG FOR *dbname* USING logprimary 20;
   - Required only for the database that contains the JCR Domain: UPDATE DB CFG FOR *dbname* USING logsecond 50;
   - Required only for the database that contains the JCR Domain: UPDATE DB CFG FOR *dbname* USING logbufsz 500;
3. Connect to your database.

   `db2 connect to dbdomain.DbName user dbdomain.DBA.DbUser using dbdomain.DBA.DbPassword`

   Note:

   - For *dbdomain.DbName*, enter the name of the portal domain database.
   - For *dbdomain.DBA.DbUser*, enter the name of the database administrator user ID for privileged access operations during database creation and setup.
   - For *dbdomain.DBA.DbPassword*, enter the database administrator password for privileged access operations during database creation.
4. Change your settings to the recommended bufferpool values:
   - ALTER BUFFERPOOL ICMLSFREQBP4 SIZE automatic;
   - ALTER BUFFERPOOL ICMLSVOLATILEBP4 SIZE automatic;

- ALTER BUFFERPOOL ICMLSMAINBP32 SIZE automatic;
- ALTER BUFFERPOOL CMBMAIN4 SIZE automatic;

Oracle: Enabling the auto space advisor background task:

If you use an Oracle database, you must complete a post-migration task to enable the Oracle background task called "Auto Space Advisor" after your run the **upgrade-profile** task during migration using the Configuration Wizard.

Procedure

Enter the following SQL:

```
BEGIN
 dbms_auto_task_admin.enable(
  client_name => 'auto space advisor',
  operation  => NULL,
  window_name => NULL);
END;
/
```

What to do next

To ensure that you enabled the "Auto Space Advisor" task, you can check whether the task is enabled or disabled by entering the following command from SQL Plus:

```
SQL> select status from dba_autotask_client where client_name = 'auto space advisor';
```

Related tasks:

"Oracle: Disabling the auto space advisor background task" on page 839
To prevent deadlocks during migration, you must complete a task to disable the Oracle background task called "Auto Space Advisor" before your run the **upgrade-profile** task during migration using the Configuration Wizard. After you complete migration, you can enable "Auto Space Advisor" as a post-migration task.

Add-ons, features, and third-party integration tasks

Complete the post-migration tasks that are required based on the way you use your WebSphere Portal Express environment.

"Content Template Catalog" on page 897
Content Template Catalog versions 3.x, 4.0.x, and 4.1.x are migrated along with all Web Content Manager data. These are additional migration steps that are required for Content Template Catalog after data migration is complete.

"Migrating Security Access Manager" on page 899
The IBM WebSphere Portal Express migration process migrates the security configurations. However, there is no provision for the automatic migration of any junction definitions that exist for the previous version of WebSphere Portal Express in WebSEAL. You must replace the old junction definitions with the new virtual host junction definitions.

"Migrating your PAA content" on page 901
If you installed a Portal Application Archive (PAA) file on a previous version of IBM WebSphere Portal Express, you can migrate the content to the current version of WebSphere Portal Express.

"Creating the analytics tag root label " on page 902
If you use site analytics on your migrated WebSphere Portal Express, you need to create the analytics tag root label.

Content Template Catalog:

Content Template Catalog versions 3.x, 4.0.x, and 4.1.x are migrated along with all Web Content Manager data. These are additional migration steps that are required for Content Template Catalog after data migration is complete.

Important post migration steps for Content Template Catalog versions 3.x, 4.0.x, and 4.1.x

As part of your migration to WebSphere Portal version 8.5 you must do all the migration steps and post-migration steps.

Using the WebSphere Portal version 8.5 default theme

If you want to use the new WebSphere Portal version 8.5 default theme, including all the new features that are included with that theme, such as the updated toolbar, you need to download and install Content Template Catalog version 4.2 or higher. Follow the upgrade procedures in the Content Template Catalog version 4.2 documentation.

Upgrading the Content Template Catalog 3.x theme to IBM WebSphere Portal 8.5

If you upgraded from IBM WebSphere Portal Express 7 to IBM WebSphere Portal Express 8.5, content and pages created with Content Template Catalog 3.x are migrated to WebSphere Portal Express 8.5 automatically.

The version of Content Template Catalog 3.x that ran on WebSphere Portal Express 7 was based on the PageBuilder2 theme. To run on WebSphere Portal Express 8.5, install the Mashup Integration `.ear` file, which installs additional required modules. Then, use the XML Access script that is provided to configure the Content Template Catalog 3.x theme on the WebSphere Portal Express 8.5 server.

1. On the WebSphere Portal Express 8.5 server, install the Mashup Integration `.ear` file by running the ConfigEngine batch or script file with the following arguments:

   Windows

   ```
   ConfigEngine.bat action-create-ear-wp.mmi.deploy
   ```

   AIX Linux

   ```
   ./ConfigEngine.sh action-create-ear-wp.mmi.deploy
   ```

2. Copy the following XML Access script and save it as an XML file:

```
<?xml version="1.0" encoding="UTF-8"?>
 <request type="update" version="8.5.0.0"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd">
   <portal action="locate">
    <theme action="update" active="true" context-root="/wps/PageBuilder2" default="false"
     domain="rel" resourceroot="PageBuilder2" uniquename="CTCTheme"/>
   </portal>
 </request>
```

3. Log in to WebSphere Portal Express as an administrator.
4. Click the **Administration menu** icon. Then, click **Portal Settings** > **Import XML**.
5. Import the file that is saved in Step 2.

Enabling inline editing for Content Template Catalog version 3.x

Inline editing for Content Template Catalog version 3.x is not enabled during migration. To enable inline editing:

1. Open the authoring portlet and go to the Content Template Catalog version 3.x Design library.
2. Open the Inline Editing folder and edit all the toolbar components.
3. Change the "On Editing" setting to "Edit live content".
4. Save each component.

Tagging and rating

If you use tagging and rating, then you must enable the new tag and rating widgets after migration. For more information, see "Enabling the new tag and rating widgets after a portal upgrade" on page 917.

Migrating Security Access Manager:

The IBM WebSphere Portal Express migration process migrates the security configurations. However, there is no provision for the automatic migration of any junction definitions that exist for the previous version of WebSphere Portal Express in WebSEAL. You must replace the old junction definitions with the new virtual host junction definitions.

About this task

The migration process migrates security configurations such as the user registry, VMM settings, and the IBM WebSphere Application Server security setup, including any Trust Association Interceptor (TAI) configurations. You must install the latest version of TAI on the current version of WebSphere Portal Express server. This installation configures the new WebSphere Portal Express instance for integration with Security Access Manager WebSEAL.

The WebSphere Portal Express migration process cannot change the junction definitions in WebSEAL to point to the new server. It cannot switch from standard non-transparent or transparent junctions to the new virtual host junctions. You must manually run these tasks within Security Access Manager. The Security Access Manager administrator staff often runs these tasks, which might be separate from the WebSphere Portal Express administrative staff.

Tip: Complete the following steps with the instructions in the *Security Access Manager eBusiness WebSEAL Administrative Guide*.

Attention: These steps describe that you create the new virtual host junction before you delete the old junctions. This approach assumes that there are no detected conflicts to prevent the new junction from coexisting with the old junctions. A conflict might arise if the **vhost_label** value is the same between the new and old junctions. Try to avoid or work around these conflicts. If you cannot avoid the conflict, delete the old junction before you create the new virtual host junction. Create a backup copy of the WebSEAL configuration file first so you can refer to it if necessary.

Procedure

1. Complete the following steps on the previous instance of WebSphere Portal Express:
   a. Open the WebSEAL configuration file.
   b. Search the file for stanzas that define the junctions. For example: `[junction:junction_name]`.
   c. Record the configuration value for each junction for future reference.
   d. Save a backup copy of the WebSEAL configuration file.
2. Create the new virtual host junctions that are based on the junctions from the previous instance:

   The general format for the `pdadmin` command to create a virtual host junction is

   ```
   pdadmin> server task WebSEAL-instance_name-webseald-WebSEAL-HostName virtualhost create -t typ
   ```

The following information describes the mandatory parameters in the `pdadmin` command:

- The *WebSEAL-instance_name*-webseald-*WebSEAL-HostName* has three parts, as documented in the WebSEAL Administration Guide:
  a. The configured name of a single WebSEAL instance, for example *web 1*
  b. The literal string `-websealed-`
  c. The host name, for example, *webseal.yourco.com*

  The resulting combination would be *web 1*-websealed-*webseal.yourco.com*. You can use the `pdadmin server list` command to display the correct format of the server name.
- The virtual host label (`vhost-label`) is the name for the virtual host junction.
  – Virtual host junctions are always mounted at the root of the WebSEAL object space.
  – You can refer to a junction in the `pdadmin` utility with this label.
  – The virtual host junction label must be unique within each instance of WebSEAL.
  – Because the label represents virtual host junctions in the protected object space, the label name must not contain the forward slash character (/).
- **`-t type`**: This parameter defines whether the junction is encrypted (`-t ssl`) or not encrypted (`-t tcp`). This parameter is mandatory when you create a virtual host junction. For more information about other possible values, see the *WebSEAL Administration Guide*.
- **`-h hostname`**: This parameter defines the backend server to which the junction connects. In most situations, the host name is the HTTP server that sits in front of WebSphere Portal Express. This parameter is mandatory when you create a virtual host junction.

The *[options]* includes the following parameters:

- **`-p port`**: This parameter defines the port number for the backend server to which the junction connects. If not specified, the default value is `80` for HTTP or `443` for HTTPS. It is best to specify this value explicitly in the junction creation command even if the default values are in use.
- **`-v vhost_name[:port]`**: This parameter is the virtual host name and port number that defines the junction. WebSEAL maps incoming requests to this host name and port to this junction. If not specified, the values default to the **`-h hostname`** and **`-p port`** values.
- **`-c header_type`**: This parameter inserts the Security Access Manager client identity in HTTP headers across the junction. The **`header_type`** argument can include any combination of the following Security Access Manager HTTP header types:
  – `{iv_user|iv_user-l}`
  – `iv_groups`
  – `iv_creds`
  – `all`

  The header types must be comma-separated, and cannot have a space between the types. For example: **`-c iv_user,iv_groups`**. Specifying **`-c all`** is the same as specifying **`-c iv_user,iv_groups,iv_creds`**. This parameter is valid for all junctions except for the type of local. The setting here depends on how you want your TAI running within WebSphere Application Server to operate. In certain modes, the TAI might be looking for the presence of one or more of these headers. The TAI looks for these headers to know that it

must claim the request when interrogated by WebSphere Application Server security. This setting must be set to match what the TAI is looking for. Consult your WebSphere system administrator if you are in doubt as to how the TAI is configured.

- **-b**: This option controls how WebSEAL passes authentication information to the backend server. Usually this setting depends on how you want the TAI to be configured in WebSphere to validate a trust relationship with WebSEAL. The usual option that is chosen is **-b supply**. For more information, see the *WebSEAL Administration Guide* or the *ETAI installation and configuration* documentation.
- **-k**: This option controls whether WebSEAL includes its own session cookie in the request to the backend server. In some situations, sending the WebSEAL session cookie to the backend server is necessary. This action is necessary to support single sign-on from WebSphere Portal Express to other backend services where WebSEAL also protects those backend services.
-

  Note: Junctions to WebSphere Portal Express whether direct or through an HTTP server does not support the **-q option** the query_contents function. Query_contents is not possible on WebSphere Portal Express

The following information is a sample command to create a virtual host TCP junction, on the *web 1* WebSEAL instance that is running on a host *webseal.yourco.com*, for the virtual host name *portalvhost.yourco.com* running on port 80 that requires a TAI in WebSphere Application Server. The virtual host junction is labeled *vhost_junction_portal_1*. The virtual host junction host name must be mapped in DNS to the WebSEAL server. The portal or http server is running on host *portal.yourco.com* and is using port 8080:

```
pdadmin> server task web1-webseald-webseal.yourco.com virtualhost create -t tcp -v portalvhost
```

3. Delete the old junctions with the appropriate administration commands. For example: `server task` *`instance_name`* `-webseal-`*`host_name`* `delete` *`junction_point`*

Related tasks:

"Configuring Security Access Manager for authentication only" on page 1631
IBM WebSphere Portal Express and IBM WebSphere Application Server support the Trust Association Interceptors (TAI) that IBM Security Access Manager provides. If you use Security Access Manager for authorization, you must also use Security Access Manager for authentication. Using Security Access Manager only for authorization is not supported.

"Configuring Security Access Manager for authentication, authorization, and the Credential Vault" on page 1644
You can configure Security Access Manager for authentication, authorization, and the vault adapter with one task.

Migrating your PAA content:

If you installed a Portal Application Archive (PAA) file on a previous version of IBM WebSphere Portal Express, you can migrate the content to the current version of WebSphere Portal Express.

About this task

Migration is supported from WebSphere Portal Express Version 7.0 to 8.5 and from Version 8.0 to 8.5.

Procedure

1. If you are migrating from Version 7.0 to Version 8.5, copy the PAA content from the directory of the previous release to the directory in the current release.

   Note: If you are migrating from Version 8.0.0.1 to Version 8.5, you can skip this step.

   Tip: Starting with version 8.0, the PAA directory is in the *wp_profile_root*/paa directory.

   Remember: Select only the expanded PAA file directories that you want to migrate to the new release.
2. Open a command prompt and change to the following directory:
   - IBM i: *wp_profile_root*/ConfigEngine
   - Windows: *wp_profile_root*\ConfigEngine
3. Run the following task to migrate the PAA content:

   This task deletes the auto-generated code and then re-creates it in the config/includes directory for each component. The task then registers the assembly and components with the current version ConfigEngine.
   - IBM i: ConfigEngine.sh migrate-paa -DWasPassword=*password* -DPortalAdminPwd=*password*
   - Windows: ConfigEngine.bat migrate-paa -DWasPassword=*password* -DPortalAdminPwd=*password*

Creating the analytics tag root label :

If you use site analytics on your migrated WebSphere Portal Express, you need to create the analytics tag root label.

About this task

To do this, proceed as follows in the newly migrated environment:

Procedure

1. Change to the following directory that contains the WebSphere Portal Express tools:
   - Linux : *PortalServer_root*/bin
   - IBM i: *PortalServer_root*/bin
   - Windows: *PortalServer_root*\bin
2. Create the analytics tag root label by running the following command:
   - Linux :

     ```
     ./xmlaccess.sh
     -url http://example_server.com:port/wps/config
     -user wpsadmin -password wpsadminpwd
     -in PortalServer_root/base/wp.asa.server.impl/config/templates/create_asa_tag_root.xml
     -out results.xml
     ```
   - IBM i:

     ```
     ./xmlaccess.sh
     -url http://example_server.com:port/wps/config
     -user wpsadmin -password wpsadminpwd
     -in PortalServer_root/base/wp.asa.server.impl/config/templates/create_asa_tag_root.xml
     -out results.xml
     ```
   - Windows:

```
xmlaccess.bat
-url http://example_server.com:port\wps\config
-user wpsadmin -password wpsadminpwd
-in PortalServer_root\base\wp.asa.server.impl\config\templates\create_asa_tag_root.xml
-out results.xml
```

As an alternative, you can also use the portal administration portlet **Import XML** to perform this import.

3. After the request has been processed, make sure that the import process has returned the following message: `<status element="all" result="ok">`

Results

Your site analytics tags are now ready for you to work.

Updating the web application bridge:

After you migrated to Version 8.5 and successfully tested it, update your migrated web application bridge content.

Procedure

1. Log in to IBM WebSphere Portal Express Version 8.5.
2. Click **Administration**. Then, click **Portlet management** > **Virtual Web Application Manager**.
3. View the user interface that lists the previous virtual web applications.
4. Click **Show Virtual Web Application** to display the list of previous virtual web applications.
5. Select the one of the previous virtual web applications that you want to create in the current version.
6. Click **Apply**. The screen to create the content provider profile displays.
7. Create the content provider profile.
8. Click **Next**. The screen to create the content provider profile policy displays.
9. Create the content provider profile policy.
10. Repeat these steps until all of the previous virtual web applications are converted to the current version.
11. Create the **Web Dock Application**.

Running post migration steps for the multilingual solution:

When you migrate the multilingual solution, you need to merge your configuration settings.

About this task

Note: If your current multilingual system uses synchronized publishing, it is recommended to move to the project-based synchronizing publishing extension. If you have existing documents in the pending-publish stage, then you temporarily leave the pending publish stage in your workflow until those items are published. The presence of the pending publish stage does not affect new items that use projects.

Procedure

1. Ensure that the **`WasPassword`** and **`PortalAdminPwd`** passwords are set in the `wkplc.properties` file.

2. Run the following registration command from the *wp_profile_root*/ConfigEngine directory:

   Windows
   ```
   ConfigEngine.bat register-wcm-mls
   ```

   Linux
   ```
   ./ConfigEngine.sh register-wcm-mls
   ```

   IBM i
   ```
   ConfigEngine.sh register-wcm-mls
   ```

3. Run the following deployment command from the *wp_profile_root*/ConfigEngine directory:

   Windows
   ```
   ConfigEngine.bat deploy-wcm-mls
   ```

   Linux
   ```
   ./ConfigEngine.sh deploy-wcm-mls
   ```

   IBM i
   ```
   ConfigEngine.sh deploy-wcm-mls
   ```

4. If your server contains virtual portals, you must also run the following task for each virtual portal on your server:

   Windows
   ```
   ConfigEngine.bat import-wcm-mls-data
   -DVirtualPortalHostName=VirtualPortalHostName
   -DVirtualPortalContext=virtual_portal_context_url
   ```

   Linux
   ```
   ./ConfigEngine.sh import-wcm-mls-data
   -DVirtualPortalHostName=VirtualPortalHostName
   -DVirtualPortalContext=virtual_portal_context_url
   ```

   IBM i
   ```
   ConfigEngine.sh import-wcm-mls-data
   -DVirtualPortalHostName=VirtualPortalHostName
   -DVirtualPortalContext=virtual_portal_context_url
   ```

5. Restart WebSphere Portal.
6. Repeat these steps on every server and cluster node.

Social Media Publisher:

The Social Media Publisher for Web Content Manager is an extension to Web Content Manager that allows businesses to promote their web content on social networks, and provide some basic statistics about the promoted content. When migrating the Social Media Publisher, you need to merge your configuration settings.

About this task

Procedure

1. Ensure that the **WasPassword** and **PortalAdminPwd** passwords are set in the wkplc.properties file.
2. Edit *wp_profile_root*/PortalServer/wcm/social/smp.properties to ensure that the configuration is correct for the current server or cluster node. Specifically, AUTHOR_DB_URL, AUTHOR_DB_NAME, AUTHOR_DB_SCHEMA and AUTHOR_DB_TYPE.

   Note: The parameter settings in smp.properties are case-sensitive.
3. Run the following registration command from the *wp_profile_root*/ConfigEngine directory:

   Windows
   ```
   ConfigEngine.bat register-wcm-social
   ```

Linux `./ConfigEngine.sh register-wcm-social`

IBM i `ConfigEngine.sh register-wcm-social`

4. Run the following deployment command from the *wp_profile_root*/ConfigEngine directory:

   Windows
   `ConfigEngine.bat deploy-wcm-social`

   Linux `./ConfigEngine.sh deploy-wcm-social`

   IBM i `ConfigEngine.sh deploy-wcm-social`
5. Restart WebSphere Portal.
6. Repeat these steps on every server and cluster node.

Social Lists:

After you migrate from a previous WebSphere Portal Version to Version 8.5, you must run a configuration task. The configuration task is run to deploy the new web content library and templates before you can use the Social Lists features. If you already used the social rendering feature from 8.0.0.1, your existing web content libraries and all portlet clones that were created during the enablement on 8.0.0.1 is not changed.

Before you begin

If you migrated from 7.0 to 8.5, then you must run the **action-install-wcm-localrender-portlet** task before you start the following procedure:

- Linux : `./ConfigEngine.sh action-install-wcm-localrender-portlet -DPortalAdminPwd=`*password* `-DWasPassword=`*password*
- IBM i: `ConfigEngine.sh action-install-wcm-localrender-portlet -DPortalAdminPwd=`*password* `-DWasPassword=`*password*
- Windows: `ConfigEngine.bat action-install-wcm-localrender-portlet -DPortalAdminPwd=`*password* `-DWasPassword=`*password*

Procedure

1. Go to the wp_profile_root/ConfigEngine directory. Run the **deploy-social-rendering** task:
   - Linux : `./ConfigEngine.sh deploy-social-rendering -DPortalAdminPwd=`*password* `-DWasPassword=`*password*
   - IBM i: `ConfigEngine.sh deploy-social-rendering -DPortalAdminPwd=`*password* `-DWasPassword=`*password*
   - Windows: `ConfigEngine.bat deploy-social-rendering -DPortalAdminPwd=`*password* `-DWasPassword=`*password*

   By default, the task is run on the base portal. To run this task on a different virtual portal, identify the virtual portal by adding one of the following parameters to the command line. Each parameter requires the prefix `-D` on the command line

   VirtualPortalHostName
   Specify the host name of the virtual portal. For example, `vp.example.com`

   VirtualPortalContext
   Specify the virtual portal context that identifies the virtual portal. For example, `vp1`.

   Example Commands:

```
./ConfigEngine.sh deploy-social-rendering -DPortalAdminPwd=password
-DWasPassword=password -DVirtualPortalContext=vp1
```

Note: If you plan to continue to use the old toolbar, you can use the following configuration task to deploy new social portlets to that toolbar.
```
./ConfigEngine.sh action-deploy-social-shelf-category-and-portlets
-DPortalAdminPwd=password -DWasPassword=password
```

2. Verify that the web content library Social Lists 1.1 was created. Click the **Administration menu** icon. Then, click **Portal Content** > **Web Content Libraries**.

Related concepts:

"Enabling social rendering in a virtual portal" on page 2133
Before you use social rendering in a virtual portal, you must deploy the new web content library and templates. The version and fix pack of your IBM WebSphere Portal Express determines how you do so.

Deploying and updating sample web content template items:

The sample web content template items are not installed or updated during migration. This sample content includes examples of web content template pages and predefined content items that you can add to pages to render content. You can add or update these items manually after migration.

Before you begin

Important: These instructions apply only if you installed an offering that includes the sample web content template items. These steps do not work with an offering that does not include the sample content.

About this task

When you add the sample content, the following artifacts are created:

- The `Template Page Content 3.0` and `Web Content Templates 3.0` web content libraries.
- The **Web Content** category in the site toolbar.
- The "Image," "Rich Text," "List of Articles," and "Article" content items. These content items are available from **Create** > **Content** tab of the site toolbar.
- The "Articles" web content page template.

Note: The "Articles" page template can be deployed only if the Portal 8.5 theme is available in your portal.

Procedure

1. Go to the *wp_profile_root*`/ConfigEngine` directory.
2. To install the sample web content template items, choose one of the following options that is based on your environment:
   - If the Portal 8.5 theme is available in your portal, run the following command to install the library, content items, and Articles sample page:
     - AIX Linux Solaris: `./ConfigEngine.sh deploy-content-templating-ui -DPortalAdminId=user_name -DPortalAdminPwd=password -DWasUserid=user_name -DWasPassword=password`

- Windows: `ConfigEngine.bat deploy-content-templating-ui -DPortalAdminId=user_name -DPortalAdminPwd=password -DWasUserid=user_name -DWasPassword=password`
- IBM i: `ConfigEngine.sh deploy-content-templating-ui -DPortalAdminId=user_name -DPortalAdminPwd=password -DWasUserid=user_name -DWasPassword=password`

- If the Portal 8.5 theme is not available in your portal, run the following command to install the library and the content items:
  - AIX Linux Solaris: `./ConfigEngine.sh deploy-content-templating-library -DPortalAdminId=user_name -DPortalAdminPwd=password -DWasUserid=user_name -DWasPassword=password`
  - Windows: `ConfigEngine.bat deploy-content-templating-library -DPortalAdminId=user_name -DPortalAdminPwd=password -DWasUserid=user_name -DWasPassword=password`
  - IBM i: `ConfigEngine.sh deploy-content-templating-library -DPortalAdminId=user_name -DPortalAdminPwd=password -DWasUserid=user_name -DWasPassword=password`

3. Optional: The sample web content template items include tagging and rating components. These components are functionally available from the web content libraries that are provided with the blogs and wikis feature of the portal. If you intend to use tagging and rating with the templating sample content, you must ensure that the blogs and wikis libraries are installed. For details on installing these libraries, see *Blogs and wikis* in the migration section of the documentation.

Related concepts:

"Creating content with sample web content template items" on page 2026
To illustrate how page templates, web content viewers, and content associations work together, IBM Web Content Manager provides sample web content. The sample content includes examples of web content template pages and predefined portlets that you can add to pages to render content.

Related tasks:

"Blogs and wikis" on page 887
After you migrate from WebSphere Portal Express Versions 7.0 or 8.0 to Version 8.5, you must run a configuration task to update the presentation templates that are used by blogs and wikis to apply the latest updates. You must run this task for content in your blogs and wikis to render properly.

Default changed for JavaServer Faces implementation:

The default JavaServer Faces (JSF) implementation has changed starting in WebSphere Application Server Version 8.

When you are migrating JSF portlets from an earlier version of IBM WebSphere Portal Express, be aware that WebSphere Application Server has changed the default JSF implementation starting in WebSphere Application Server Version 8. For more information, see *JavaServer Faces migration* in the WebSphere Application Server documentation.

Related information:

JavaServer Faces migration

Portlets no longer available:

Some portlets that were available on previous releases of WebSphere Portal Express are no longer including in Version 8.5. These portlets are not migrated as part of the WebSphere Portal Express migration process.

Choose one of the following methods to correct any references to unsupported portlets:

- Many of the portlets are now available for download from the IBM Lotus and WebSphere Portal Business Solutions Catalog. If these portlets are still required, installation and deployment instructions are provided with the portlet download.
- Some of the portlets have replacements that are installed during the migration, and the references to the old portlets can be updated to refer to the replacements.
- If you need to retain the original functionality, copy the war file to *wp_profile_root*`/PortalServer/deployed/archive/`, and follow the instructions from *Updating Portlets URLs* in the post-migration activities section.
- If the functionality is no longer needed, delete those portlet references or pages that contain the portlets.

See the What's new section for details on what changed and what features are deprecated in this release.

Related concepts:

"What's changed" on page 16
WebSphere Portal Express includes changes to existing features.

"Unsupported and deprecated features for V8.5" on page 17
Review the features that were available in previous versions of IBM WebSphere Portal Express but are no longer available.

Related tasks:

"Updating portlets URL" on page 892
After migrating your portal environment, you must verify and update as needed the portlets URLs. In some cases, portlets have the incorrect URL after migration. URLs can be easily corrected using the XML configuration interface to export, update, and import the configurations.

Related information:

IBM Lotus and WebSphere Portal Business Solutions Catalog

Mashup integration:

The mashup integration feature was removed in WebSphere Portal Express Version 8.0 and is not included in later releases. If you used this feature in a previous release and you want to continue using it in WebSphere Portal Express Version 8.5, you need to manually enable mashup integration after migration.

About this task

In previous versions of WebSphere Portal Express, the `MashupMaker_Integration.ear` was registered with the system in all cases. Even when it was only required in cases where the mashup integration feature was used actively in the system. To remove system overhead, the `.ear` file was removed from the portal configuration during migration.

Procedure

To enable the mashup integration feature, register the `.ear` file with the following command:

- Linux : `./ConfigEngine.sh action-create-ear-wp.mmi.deploy`
- IBM i: `./ConfigEngine.sh action-create-ear-wp.mmi.deploy`
- Windows: `ConfigEngine.bat action-create-ear-wp.mmi.deploy`

Navigation with consecutive labels is dynamic:

The secondary navigation is dynamic, and shows only two levels of navigation at a time. When a page on the last level of navigation is selected, only that level of navigation is displayed. It is possible to select a page where both the parent level of navigation and the grandparent level of navigation are both labels. In this case, the sibling navigation for the parent level is not accessible.

Related concepts:

"Side navigation" on page 2715
The Portal 8.5 theme includes a side navigation template that can be applied to render pages at the secondary level in a list with the main content. By default, this template is applied to the Administration section of your portal.

Enabling new functionality in a migrated portal

The migration process collects configuration data and applications from an earlier installed version of IBM WebSphere Portal Express and merges them into the newer installed version so that the new environment is identical to the earlier environment. Taking advantage of new functionality that was not available in the earlier portal requires additional attention after migration is complete.

"New Web Content Manager features"
You might need to update your old web content to take advantage of the new Web Content Manager features.

"Enabling managed pages" on page 913
After migration, you must manually enable support for managed pages. Without managed pages support, some features like the project menu are not available on the migrated server.

"Changing from Ajax proxy to outbound HTTP connection" on page 916
WebSphere Portal Express Version 8.5 provides a migration process for the change from the Ajax proxy of previous portal versions to the new outbound HTTP connection.

"Enabling the new tag and rating widgets after a portal upgrade" on page 917
If you upgrade your IBM WebSphere Portal Express from an earlier version to Version 8.5 and want to use the new tag and rating widgets, you must first enable blogs and wikis. Then, complete the following task to ensure that tag and rating widgets are enabled.

"Enabling new functionality in migrated themes" on page 918
When you migrate your themes, migration moves your existing themes to the new server. Migration does not upgrade themes from an earlier version to use new functions that are introduced in more recent versions of the product.

New Web Content Manager features

You might need to update your old web content to take advantage of the new Web Content Manager features.

Approver role

The Approver role is replaced by the Reviewer role and Draft Creator role. All users assigned the Approver role are automatically reassigned to the Reviewer and Draft Creator roles during migration to ensure that the behavior of the workflowed items remains unchanged on the new system. These new roles support inheritance and propagation, removing the need to set them explicitly on each item in the workflow stage.

The users that are assigned to the Reviewer role and Draft Creator role should be reviewed post migration because not all users need to be assigned to both roles. Enabling inheritance for these roles is also recommended, not just to reduce the effort of maintaining permissions on individual items, but to also improve overall system performance due to the reduction of explicit role assignments. The simplest way to enable inheritance is to assign users to the Reviewer role and Draft Creator role at the library level.

Restart workflow

The minimum resource access that is required for the restart workflow function has been raised from edit access to the library, to manager access to the library. If you need to maintain the old access level, then you can change the following property in the `WCM WCMConfigService` service to "false" in the WebSphere Integrated Solutions Console:

```
workflowrestart.requires.manager=false
```

Web content configuration changes

Note: This was new in Web Content Manager version 8.0. No action is required if migrating from Web Content Manager version 8.0 or higher.

You no longer use the `WCMConfigService.properties` file to update configuration settings for Web Content Manager. Instead, you now use the `WCM WCMConfigService` service to update configuration settings with the WebSphere Integrated Solutions Console. For more information, see “Setting service configuration properties” on page 283.

Web content tag format changes

Note: This was new in Web Content Manager version 8.0. No action is required if migrating from Web Content Manager version 8.0 or higher.

Web content tags now use brackets. This allows you to add web content tags directly into rich text fields.

For example, in previous versions the component tag was written as:

```
<component name="componentname" />
```

The component tag now uses brackets:

```
[component name="componentname" ]
```

Note:

- All web content tags are converted to the new format during migration.
- After migration, if a user enters a web content tag with the old format, it will be converted to the new format when saved.

New web content property tag

Note: This was new in Web Content Manager version 8.0. No action is required if migrating from Web Content Manager version 8.0 or higher.

The `IDCmpnt`, `HistoryCmpnt`, `ProfileCmpnt`, `WorkflowCmpnt`, and `SecurityCmpnt` tags are no longer supported. These features are retained and consolidated into a new property tag.

```
[Property field=" " context=" " type=" " name=" " key=" " format=" " link=" " separator=" "
htmlencode=" " awareness=" " ifEmpty=" " include=" " restrict=" " resolve=" "
start=" " end=" " ]
```

Note:

- These tags are converted to the new property tag during migration.
- After migration, if a user enters one of the deprecated tags, it will be converted to the new property tag when saved.

Autofill parameter in web content tags

Note: This was new in Web Content Manager version 8.0. No action is required if migrating from Web Content Manager version 8.0 or higher.

The behavior of the **`autofill`** parameter that is used in some web content tags is updated. If used in an item where **`autofill`** is not applicable, the tag instead uses the context of the current item.

If you do not want this behavior to be used, you can add the following property in the `WCM WCMConfigService` service in the WebSphere Integrated Solutions Console

```
renderAutoFillTagsAsCurrent=false
```

Federated content component and element

Note: This was new in Web Content Manager version 8.0. No action is required if migrating from Web Content Manager version 8.0 or higher.

The federated content component and element are no longer supported in version 8.0. To reference federated content in your website, use one of the following features:

- The Enterprise Content Manager window
- The Web Content Integrator
- The federated document feature of Personalization

Federated content components and elements are migrated from previous versions and are visible in the authoring portlet. These items can still be rendered in web pages, but you cannot create new federated content components or elements unless you enable this function.

To maintain older systems, enable federated content components and elements in your new system by adding the following property in the `WCM WCMConfigService` service in the WebSphere Integrated Solutions Console:

```
federatedcontent.enabled=true
```

Web content viewer portlet display title options

The standard Web Content Viewer portlet supports extra portlet and page display title options. You can now configure web content viewers to use the value of an element of the displayed content item as portlet and page display title.

Links and metadata for remote content

Note: This was new in Web Content Manager version 8.0. No action is required if migrating from Web Content Manager version 8.0 or higher.

The federated documents feature of Web Content Manager is used to insert links to content from a remote content system or document repository. Examples of supported repositories include IBM Content Manager, IBM FileNet Content Manager, and Microsoft SharePoint. This capability is provided by the rich text editors in Version 8.5:

- The default and advanced rich text editors include a toolbar button named **Insert Link to Remote Document**.
- In addition to the toolbar button, the advanced rich text editor includes a menu item named **Insert Link to Remote Document**.

You can also use the federated documents feature with Personalization to create selection rules. Personalization is used to retrieve metadata about documents that are stored in external content management systems or document repositories. With personalization components in Web Content Manager, you can display the metadata and create links to the documents in your web content. To select remote content in the Personalization Editor, the federated documents feature provides a wizard.

In Version 8.5, the capabilities of the portal theme determine whether the user interface features for Web Content Manager and Personalization are available.

To enable the **Insert Link to Remote Content** function after migration, ensure that the `wp_federated_documents_picker` theme module is available on the migrated portal. Any page that contains the authoring portlet must use a theme that integrates this theme module. In addition, to ensure that the module is loaded, the module profile that is used by the page must include the `wp_federated_documents_picker` theme module. If the feature is disabled when you use inline editing of web content, complete these steps:

- Apply a theme to the hidden authoring page that contains the `wp_federated_documents_picker` theme module. For example, you can apply the Portal 8.5 theme.
- Apply a module profile to the hidden authoring page that contains the `wp_federated_documents_picker theme` module. For example, you can apply the deferred profile of the Portal 8.5 theme.
- Apply a skin without decorations to the reserved authoring portlet instance on the hidden authoring page. For example, you can apply the "Portal 8.5 - No Skin" skin.

To enable the folder selection wizard in Personalization, ensure that the `wp_federated_documents_picker` theme module is available to the page that contains the Personalization Editor.

Related concepts:

Supported specifications for inserting links to remote content
The federated documents feature enables you to retrieve information about documents in a remote repository and insert links to those documents in your web content. Several types of feeds are supported for accessing remote content.

Related tasks:

"Configuring the reserved authoring portlet" on page 431
The reserved authoring portlet is essential to the proper operation of web content pages and the web content viewer, so it is important that the configuration of the reserved authoring portlet is similar to the configuration of other instances of the authoring portlet.

"Personalizing federated documents" on page 1827
Portal Personalization provides the federated documents feature to retrieve metadata about documents that are stored in external content management systems or document repositories. Examples of these systems include IBM Content Manager, IBM FileNet Content Manager, and Microsoft Sharepoint. You can use a personalization component in IBM Web Content Manager to display metadata from federated documents and to create links to download or open the documents.

Enabling managed pages

After migration, you must manually enable support for managed pages. Without managed pages support, some features like the project menu are not available on the migrated server.

About this task

When you enable managed pages after migration, several considerations apply:

- After migration, managed pages are initially disabled on the migrated server. In this case, there is a single workspace for storing IBM Web Content Manager content. All virtual portals on the server share this workspace. Although this single workspace simplifies the sharing of content between virtual portals, it can also lead to dependencies between content libraries and different virtual portals. Depending on your content environment, these dependencies can make it difficult for an administrator to determine which libraries to select for syndication to a syndicator.
- When you enable managed pages, a workspace is created for each virtual portal. This separation ensures that there are no cross-references between content items in different virtual portals. In addition, by selecting all libraries that are visible in a workspace, references are guaranteed to be resolved during syndication.

  Because of this separation of workspaces, extra syndication steps might be required on the migrated server for web content libraries:

  Libraries that are used only by a specific virtual portal
  You must syndicate the libraries from the default virtual portal to the specific virtual portal.

  Libraries that are shared by multiple virtual portals
  You must syndicate the shared libraries from the default virtual portal to each specific virtual portal.

  After you syndicate the libraries that are unique to specific virtual portals, you can delete the libraries from the default virtual portal.
- When supported, managed pages is enabled for a virtual portal, all pages in the virtual portal are copied into the Portal Site library in IBM Web Content Manager. However, the following pages are not treated as managed pages and are not copied:

- Administration pages, as identified by the label `ibm.portal.Administration` and its child pages
- Private pages

Each virtual portal has its own Portal Site library.

- In scenarios where the configured user realm does not contain the domain administrator, an alternative user must be provided. If you have a multi-realm configuration, see "Defining alternative administrators for multi-realm configurations" on page 436.

Note: To take advantage of the features available to managed pages in the user interface, your pages must use the Portal 8.5 theme.

Procedure

1. Start the portal server.
2. To enable support for managed pages, run the **enable-managed-pages** task from the *wp_profile_root*/ConfigEngine directory.

   Windows
   ```
   ConfigEngine.bat enable-managed-pages -DPortalAdminPwd=password
   -DWasPassword=password
   ```

   Linux
   ```
   ./ConfigEngine.sh enable-managed-pages -DPortalAdminPwd=password
   -DWasPassword=password
   ```

   IBM i
   ```
   ConfigEngine.sh enable-managed-pages -DPortalAdminPwd=password
   -DWasPassword=password
   ```

   After you run the **enable-managed-pages** task for the first time, the property **managed.pages** is created in the portal WP Configuration Service. The value of the property is set to `true`.
3. Restart the portal server.
4. To populate web content libraries with information about virtual portals in the system, run the **create-virtual-portal-site-nodes** task from the *wp_profile_root*/ConfigEngine directory. For each virtual portal, this task creates a library and a site area that is called `lost-found` for resources that cannot be properly located. If the library or site area exist, the task exits. By default, the task runs on all virtual portals in the system.

   Windows
   ```
   ConfigEngine.bat create-virtual-portal-site-nodes
   -DPortalAdminPwd=password -DWasPassword=password
   ```

   Linux
   ```
   ./ConfigEngine.sh create-virtual-portal-site-nodes
   -DPortalAdminPwd=password -DWasPassword=password
   ```

   IBM i
   ```
   ConfigEngine.sh create-virtual-portal-site-nodes
   -DPortalAdminPwd=password -DWasPassword=password
   ```
5. To populate web content libraries with information about the portal pages in the system, run the **create-page-nodes** task from the *wp_profile_root*/ConfigEngine directory.

   This task can also be used when portal pages and managed pages artifacts in Web Content Manager are not synchronized. In this case, the task attempts to resynchronize the portal artifacts and web content artifacts, giving precedence to the portal artifacts.

   Performance note: Depending on the amount of information in the system, the **create-page-nodes** task can take a long time to run. Because of the database

load of the task, do not run the task frequently. The initial run of the task requires the most time, while subsequent runs typically require less time.

Note: If you have many pages, then it might be necessary to increase the soap client timeout. Edit the *wp_profile_root*/properties/soap.client.props file to change the **com.ibm.SOAP.requestTimeout** to 60000.
Attention: If your virtual portals have different administrative accounts, you cannot run the **create-page-nodes** task directly. You must run the task for every virtual portal, including the base virtual portal. Use the **VirtualPortalHost** or **VirtualPortalContext** parameter with the **create-page-nodes** task. Run the **list-all-virtual-portals** task to get a list of all your virtual portals. When you run the create-page-nodes task on the base virtual portal, set the **VirtualPortalContext** value to __NO__VP__ID__.

Windows
```
ConfigEngine.bat create-page-nodes -DPortalAdminPwd=password
-DWasPassword=password
```

Linux
```
./ConfigEngine.sh create-page-nodes -DPortalAdminPwd=password
-DWasPassword=password
```

IBM i
```
ConfigEngine.sh create-page-nodes -DPortalAdminPwd=password
-DWasPassword=password
```

By default, this task is run on all pages in all virtual portals. To limit this task to a specific virtual portal, identify the virtual portal by adding one of the following parameters to the command line. Each parameter requires the prefix -D on the command line.

VirtualPortalHost
Specify the host name of the virtual portal. For example, vp.example.com.

Important: If the host name of the virtual portal is the same as the host name of the default virtual portal, you must also specify the **VirtualPortalContext** property. You can specify the **VirtualPortalHost** property by itself only if the host name is unique.

VirtualPortalContext
Specify the virtual portal context that identifies the virtual portal. For example, vp1.

You can customize the task with the following optional parameters on the command line. Each parameter requires the prefix -D on the command line.

RunParallel
Indicate whether you want the task to run with multiple threads. A value of false indicates a single thread and is the default setting.

A value of true indicates multiple threads, as specified by the work manager **wpsJcrSyncWorkManager** in the WebSphere Integrated Solutions Console. Each thread requires a database connection. For optimal performance, ensure that your database connection pool supports at least as many connections as there are threads in the pool.

Excluded
Specify a list of unique names of page nodes to exclude from the creation process. Excluding a page also excludes its child pages. By default, the portal administration pages (ibm.portal.Administration) are excluded.

6. Optional: If you used web content pages before you enabled managed pages, you can transfer the content for those pages to the Portal Site library. If you plan to use the default page templates and store your web content in the Portal Site library, transfer the content for the template pages to the Portal Site library. For more information, go to *Transferring content associations to the Portal Site library*.
7. Optional: Ensure that users have appropriate access to the Web Content Manager REST virtual resource so they can use **Edit mode**. For example, they have `user` access.

What to do next

After you migrate from Version 7.0 or Version 8.0, vanity URLs are not available. After you enable managed pages, you can enable vanity URL support. If you migrated from Version 7.0 or 8.0, go to "Enabling vanity URL support" on page 2100.

Related tasks:

"Transferring content associations to the Portal Site library" on page 380
When you enable manage pages, any web content pages that you have are converted to managed pages and added to the Portal Site library. However, the content that is associated with the web content pages remains in the original libraries. You can transfer this associated content to the Portal Site library with the `internalize-content-mappings` task.

"Enabling vanity URL support" on page 2100
In a new WebSphere Portal Express Version 8.5 installation, vanity URL support is enabled. If you upgrade your WebSphere Portal Express from a previous version to Version 8.5, vanity URL support is disabled. You can enable and disable vanity URL support as required by using a portal configuration task.

"Synchronizing the vanity URL database" on page 2104
Vanity URLs are stored as part of the page in the JCR database in the portal page site area of Web Content Manager. For performance reasons, the data is also stored in the WebSphere Portal Express database. When the data is modified, the portal synchronizes the data between both sides. However, under certain circumstances it can happen that the data is not synchronized. For such cases, the portal provides a configuration task that synchronizes the data.

Changing from Ajax proxy to outbound HTTP connection

WebSphere Portal Express Version 8.5 provides a migration process for the change from the Ajax proxy of previous portal versions to the new outbound HTTP connection.

If you upgrade your WebSphere Portal Express from a previous version to Version 8.5, the outbound HTTP connection infrastructure attempts to migrate existing Ajax proxy configuration settings to the outbound HTTP connection service configuration. It moves all settings from the Ajax proxy configuration into database settings for the outbound HTTP connection service. This migration takes place as follows:

Migration of global configuration settings:

In previous WebSphere Portal Express versions, global proxy configuration settings were in the `proxy-config.xml` file of the Ajax Proxy Configuration web module. The outbound HTTP connections infrastructure migrates global proxy configuration settings when the portal Version 8.5 outbound

HTTP connection service is accessed for the first time after the portal upgrade. The global configuration settings are updated in the system configuration profile.

Migration of customized global configuration settings:
In previous WebSphere Portal Express versions, custom global proxy configuration settings were in the WP Configuration Service Resource Environment Provider (REP) property named `proxy.config.file`. The outbound HTTP connections infrastructure migrates these custom global configuration settings when the portal Version 8.5 outbound HTTP connection service is accessed for the first time after the portal upgrade. Custom global configuration settings are updated into the global configuration profile.

Migration of application-specific proxy configurations
Application-specific configurations are imported into the outbound HTTP connection configuration when the web module for the application is deployed. The deployment program scans for the file `/WEB-INF/proxy-config.xml`. If this file exists, the migration program creates a scoped configuration profile that relates to the web module that is created.

Important: In previous WebSphere Portal Express versions, the `proxy-config.xml` file held the configuration of the Ajax proxy. Changes that you make to this file became effective when you restarted the web module. In contrast, the outbound HTTP connection infrastructure makes only the necessary updates to the `proxy-config.xml` file. Changes to this file do not become effective until one of the following events occur:

- For global or customized global configuration settings: The outbound HTTP connection service is started for the first time after the portal upgrade.
- For application-specific proxy configurations: The web module that contains the `proxy-config.xml` is deployed.
- One of the portal configuration tasks `create-outbound-http-connection-config` or `update-outbound-http-connection-config` is started.

Related concepts:

"Outbound HTTP connection" on page 2984
Applications in your IBM WebSphere Portal Express and the related user activities can require outbound HTTP connections to remote computer systems. The outbound HTTP connection service provides an administration infrastructure with a central point of administration for all outbound HTTP connections that are defined in the portal environment.

Related tasks:

"Configuring outbound HTTP connections by using configuration tasks" on page 3013
Programmers can create, read, update, or delete settings of the outbound HTTP connection by using the appropriate portal configuration engine tasks.

Enabling the new tag and rating widgets after a portal upgrade

If you upgrade your IBM WebSphere Portal Express from an earlier version to Version 8.5 and want to use the new tag and rating widgets, you must first enable blogs and wikis. Then, complete the following task to ensure that tag and rating widgets are enabled.

Before you begin

You must have blogs and wikis enabled before proceeding. Go to "Blogs and wikis" on page 887 for more information.

Procedure

1. Verify that the IBM Web Content Manager components are updated.
   a. Open the applications menu and go to **Content** > **Web Content Authoring** > **Libraries** > **Web Resources v70** > **Components**. If the Web Resources v70 library is not listed by default, add it. Open the applications menu and go to **Content** > **Web Content Authoring** > **Preferences** > **Edit Shared Settings** > **Library selection**. Select **Web Resources v70** and click **Add** and **OK**.
   b. Verify that the components **HTML-Tagging Widget Light- Tags** and **HTML-Rating Widget Light- Stars** are listed. If they are not listed, check the logs to determine whether the configuration task might have resulted in errors.
2. Turn on **Edit Mode**.
3. For the tag and rating widgets to render properly, go to **Menu** > **Edit Page Properties** and select the Portal 8.5 theme for your portal theme and click **Save**. The Portal 8.5 theme is now enabled.

   Note: Apply the Portal 8.5 theme to the page on which you want to use the tagging and rating widgets.
4. Go to **Edit Page Properties** and select the "Basic Content" profile for your portal profile.

Results

You and your portal site visitors can now use the new enhanced tag and rating widgets.

Enabling new functionality in migrated themes

When you migrate your themes, migration moves your existing themes to the new server. Migration does not upgrade themes from an earlier version to use new functions that are introduced in more recent versions of the product.

When migrating modular themes, the modular theme architecture makes it easy to enable new functions in your themes by turning on and off the modules or versions of the modules. For example, if you want to update your theme to use the current version of Dojo, replace the `dojo`*`xx`*`.json` file in the capabilities folder, where *xx* is the version number. Your Dojo meta-modules load the newer version of Dojo as specified in the `dojo`*`xx`*`.json` file.

WebSphere Portal Express provides an optimized, modular theme architecture from Version 7.0.0.2 onward. Non-modular Version 6.1, such as Portal, PortalWeb2, and Tab Menu - Page Builder themes were deprecated in Version 8.0 and are no longer supported in Version 8.5.

Non-modular version 7.0 (Page Builder) themes are still supported on version 8.5 but are also deprecated and will be unsupported in the next version of WebSphere Portal Express. It is either required (6.1 themes) or recommended (7.0 themes) that you upgrade to a modular theme. If you are starting a new project, you must start with a copy of the 8.5 theme. If you must migrate a previous project, the older

non-modular themes can physically be migrated. But, you must then manually update your themes to the modular architecture, which allows you to enable any new features.

"Device class support in a migrated theme"
You can use the new device classes and equation support to modify your themes from previous versions so they are more efficient.

"Migration - Removing the site toolbar in an 8.0 theme" on page 920
To use the new site toolbar of WebSphere Portal Express 8.5 within a WebSphere Portal Express 8.0 theme, you must first remove the existing toolbar that comes with your WebSphere Portal Express 8.0 theme.

"Migration - Add the version 8.5 site toolbar to a version 8.0 theme" on page 921
You can easily add the modularized site toolbar of WebSphere Portal Express Version 8.5 to a WebSphere Portal Express 8.0 theme. Or, you can add a toolbar to a custom theme that is derived from the WebSphere Portal Express 8.0 theme. The theme must be a modularized theme, which supports theme profiles and theme modules.

"Updating your theme to use simple context menus" on page 924
The theme context menu framework that is provided with the module `wp_theme_menus` in IBM WebSphere Portal Express 8.0 and earlier is relabeled and improved in WebSphere Portal Express 8.5. The new Simple Menu Framework is compatible with all previous versions of the `wp_theme_menus`.

Device class support in a migrated theme:

You can use the new device classes and equation support to modify your themes from previous versions so they are more efficient.

With the two new features, you can remove or modify certain aspects of a prior theme that you migrated. These changes are optional, but these new features are more powerful and simpler to use.

This version of Portal supports `ios`, `android`, `blackberry`, and `worklight` in addition to the `smartphone` and `tablet` themes it already supports. You can also use equation support to combine individual device classes to check for multiple client conditions.

For example, if you were manually integrating with MobileFirst in a previous version, and manually created some combination device classes, such as `smartphone-ios`, `tablet-ios`, `smartphone-android`, `tablet-android`, your combination device classes are no longer needed. The individual device classes can be combined in equations, such as `smartphone+ios`, `tablet+ios`. If you had a combination device class such as `hires-tablet-ios`, you can change to define the singular `hires` device class. Then, use equations to combine with the other default singular device classes, such as `hires+tablet+ios`. In these equations, use `+` for AND, `/` for OR, `!` for NOT and parentheses to group items together. For more information, see *Device Class Equations*.

In your `.jsp` logic, for example, you can change the previous version syntax with `<c:if>` against `deviceClass`. Here is an example of code from a previous version:

```
<c:set var="deviceClass" scope="request" value="${wp.clientProfile['DeviceClass']}" />
<c:set var="isMobile" scope="request" value="${deviceClass == 'tablet' || deviceClass == 'smartpho
<c:if test="${isMobile}">
...
</c:if>
```

You can change that to a new equation syntax with `<portal-logic:if>` with the new **deviceClass** parameter. For example:

```
<portal-logic:if deviceClass="tablet/smartphone">
...
</portal-logic:if>
```

You can now use device class equations in module subcontributions in theme contributions `.json` files. For example:

```
}, {
     "value":"/css/my_css_smartphone_ios.css",
     "type":"smartphone+ios"
    }, {
```

Dynamic content spots in theme templates can now also be varied entirely with device class equations. For example:

```
mvc:res:/hello.jsp,smartphone+ios@res:/hello_smartphone_ios.jsp,(smartphone/tablet)+android@res:/hel
```

In this example, you can use `res:/hello.jsp` as the default URI, `res:/hello_smartphone_ios.jsp` as the URI for iOS smartphones, and `res:/hello_mobile_android.jsp` as the URI for Android smartphones and tablets.

Migration - Removing the site toolbar in an 8.0 theme:

To use the new site toolbar of WebSphere Portal Express 8.5 within a WebSphere Portal Express 8.0 theme, you must first remove the existing toolbar that comes with your WebSphere Portal Express 8.0 theme.

About this task

All of the theme modules providing functions for editing and managing the site, which are also available in the new site toolbar, can be removed when you remove the toolbar. You cannot add the WebSphere Portal Express 8.5 site toolbar to a WebSphere Portal Express 8.0 theme while keeping the version 8.0 toolbar.

Procedure

1. Remove the theme modules from the WebSphere Portal Express 8.0 site toolbar from the theme profiles. Go through the theme profiles of your Portal 8.0 theme and remove the theme modules that are listed.
   - `wp_theme_edit`
   - `wp_project_menu`
   - `wp_preview`
   - `wp_toolbar`
   - `wp_project_menu_edit`
   - `wp_preview_menu`
   - `wp_pagebuilder_controls`
   - `wp_pagebuilder_dnd`
   - `mm_new_page_dialog`
   - `mm_builder_wiring`
   - `mm_move_page`
   - `mm_delete_page`
   - `mm_delete_control`
   - `mm_page_sharing_permission`

2. Remove the dynamic content spots of the WebSphere Portal Express 8.0 site toolbar from the theme templates. Edit the theme HTML templates of your WebSphere Portal Express 8.0 theme and remove the dynamic content spots with the following IDs.
   - `80theme_preview`
   - `80theme_projectMenu`
   - `80theme_toolbar`
   - `80theme_pageModeToggle`
3. For each of the dynamic content spots, look for HTML anchor elements that reference the spots with its ID in your templates.

   ```
   <a rel="dynamic-content" href="dyn-cs:id:spot-id"></a>
   ```
4. Remove the HTML anchor element from the template and save the template file. Depending on your theme, check if there is other decorating HTML markup which can be removed in addition to the anchor elements referencing the dynamic content spots. Verify that the changes are applied to the theme template of each locale.
5. In the default version 8.0 theme, the names of the theme template files are `theme.html` and `theme_sidenav.html`. The localized versions of `theme.html` can be found in the locale subfolder, `nls`. For example `theme_en.html`. The theme template `Plain.html` does not need to be edited.
6. In the `menuDefinitions` directory, remove `shelfActions.json` and `moreActions.json`.
7. In the `menuDefinitions` directory, you can optimize the menu definition `skinActions.json` by removing the menu contributions in `mm_builder_wiring`, `wp_pagebuilder_controls`, and `mm_delete_control`.
8. In the `system` directory, keep `layouts.json` and `styles.json`. Remove all other files.

Migration - Add the version 8.5 site toolbar to a version 8.0 theme:

You can easily add the modularized site toolbar of WebSphere Portal Express Version 8.5 to a WebSphere Portal Express 8.0 theme. Or, you can add a toolbar to a custom theme that is derived from the WebSphere Portal Express 8.0 theme. The theme must be a modularized theme, which supports theme profiles and theme modules.

You can add the site toolbar of WebSphere Portal Express Version 8.5 to an existing modularized theme. You can also remove the WebSphere Portal Express 8.0 site toolbar from it. In the WebSphere Portal Express Version 8.5 theme, the WebSphere Portal Express Version 8.5 site toolbar is available by default. If you migrate your system to WebSphere Portal Express Version 8.5, you need to install the site toolbar first by running a configuration task. For more information, *Enabling the 8.5 site toolbar*.

Note: You must add the Portal 8.5 toolbar to a migrated custom theme that you use. Adding the toolbar enables your content creators to take advantage of updates to the site manager and other updates in the maintenance of your portal including creating, reusing, deleting, copying, and moving pages and content items.

There are two ways to embed a WebSphere Portal Express Version 8.5 toolbar into your WebSphere Portal Express 8.0 theme.

1. You can embed the site toolbar by adding dynamic content spot to your theme HTML template. You must be familiar with theme templates and dynamic content spots to use this option. For more information, see *Dynamic content spots*.
2. You can embed the site toolbar dynamically without adding dynamic contents spots to your theme HTML. You must be familiar with theme modules and theme profiles to use this option. For more information, see *The module framework*.

Both options are valid. The dynamic content spots option provides a more customizable user experience. There are no flickering effects because of the dynamic content spot. However, the dynamic option offers integration without editing the theme HTML template. It is easier to implement. Both options require that you add a certain theme module to the theme profiles of your theme.

"Migration - Embedding a toolbar into a theme by adding a dynamic content spot to an HTML template"
Embedding a toolbar into a theme with a dynamic content spot provides an optimized user experience when compared to embedding it dynamically.

"Migration - Embedding the version 8.5 site toolbar dynamically without a dynamic content spot" on page 924
Embedding a toolbar into a theme dynamically integrates the toolbar without editing the theme HTML template.

Related concepts:

"Dynamic content spots" on page 2666
The static template files use dynamic content spots to reference JSP files or other dynamic resources. The dynamic resources are stored in a WAR file.

"The module framework" on page 2526
The module framework allows extensions to contribute to different areas of a page to provide flexibility, enhance the user experience, and maximize performance.

"Understanding the Portal Version 8.5 modularized theme" on page 2521
Modern websites and browsers enable incredible new capabilities that can greatly enhance your user's web experiences. However, these capabilities are not without cost in terms of large page sizes and more processing in the browser when each page is rendered. These capabilities are worth it when you need them, but removing them for an entire site or including them only on pages that take advantage of these capabilities provides for more flexibility.

"Customizing the theme" on page 2658
The module framework allows themes to be customized in order to provide flexibility, enhance the user experience, and maximize performance.

Related tasks:

"Enabling the 8.5 site toolbar" on page 878
During migration, the IBM WebSphere Portal Express Version 8.5 theme is deployed. The 8.5 theme includes the site toolbar, but the toolbar is enabled only for the default virtual portal. For all other virtual portals, including migrated and newly created virtual portals, you must install the site toolbar separately.

Migration - Embedding a toolbar into a theme by adding a dynamic content spot to an HTML template:

Embedding a toolbar into a theme with a dynamic content spot provides an optimized user experience when compared to embedding it dynamically.

Procedure

1. Configure the site toolbar. To add the site toolbar theme modules to the theme profiles of your theme, choose one of the three different theme modules.

   wp_toolbar_host
   The first level module of the WebSphere Portal Express 8.5 site toolbar. It groups all of the resources that are required to run the toolbar in your theme. It supports view mode and edit mode.

   wp_toolbar_host_view
   Contains all toolbar resources that are needed for view mode.

   wp_toolbar_host_edit
   Contains all toolbar resources that are needed for edit mode.

2. Use `wp_toolbar_host` alone, or combine `wp_toolbar_host_view` with the `wp_toolbar_host_edit` module.
   - If you have a theme profile which does not have a deferred section, you need to add the `wp_toolbar_host` theme module.

     ```
     {
     "moduleIDs" : [
     "getting_started_module",
     "wp_toolbar_host",
     ...
     ]
     ...
     }
     ```

   - If you have a theme profile with a non-deferred and a deferred section, it is recommended to combine the `wp_toolbar_host_view` with the `wp_toolbar_host_edit` module. In that case you must add the `wp_toolbar_host_view` to the non-deferred section and `wp_toolbar_host_edit` to the deferred section.

     ```
     {
     "moduleIDs" : [
     "getting_started_module",
     "wp_toolbar_host_view",
     ...
     ],
     "deferredModuleIDs" : [
     "wp_toolbar_host_edit",
     ...
     ],
     ...
     }
     ```

     The theme module `wp_toolbar_host_edit` will not be loaded until you enter edit mode.

3. Add the dynamic content spot of the version 8.5 toolbar to the theme templates. To integrate the new toolbar to your theme, you must add a dynamic content spot to the theme HTML templates of your theme. The ID of the dynamic content spot is `85toolbar`.
4. To add this dynamic content spot, create a HTML anchor element which references this dynamic content spot. Embed the dynamic content spot in the header of your page

   ```
   <div class="wpthemeFrame">
   <header role="banner">
   <a rel="dynamic-content" href="dyn-cs:id:85toolbar"></a>
   ...
   ```

5. Add this dynamic content spot to the locale-specific versions of your theme templates.

6. In the default version 8.0 theme, the names of the theme template files are `theme.html` and `theme_sidenav.html`. The localized versions of `theme.html` can be found in the locale subfolder, `nls`. For example `theme_en.html`.
7. After you embed a toolbar, you must either restart your portal server. Or, you must use the WebSphere Integrated Solutions Console to invalidate the resource aggregator cache. To invalidate your cache, click **Theme Analyzer** > **Utilities** > **Control Center** > **Invalidate Cache**. CF06 Auto invalidation recognizes your changes automatically for WebDAV based themes. No further action is required. For more information, see Utilities.

Migration - Embedding the version 8.5 site toolbar dynamically without a dynamic content spot:

Embedding a toolbar into a theme dynamically integrates the toolbar without editing the theme HTML template.

Procedure

1. Add `wp_toolbar_host_dynamic` to the non-deferred section of your theme profiles. This theme module contains both the resources for view mode and edit mode.

```
{
"moduleIDs" : [
"getting_started_module",
"wp_toolbar_host_dynamic",
...
]
...
}
```

2. See *Adding or removing a ready-to-use module to a theme* to add a module to your profile.
3. If you are not using WebDAV to connect to your theme resources, see *Setting a profile override on a page*.
4. After you embed a toolbar, you must either restart your portal server. Or, you must use the WebSphere Integrated Solutions Console to invalidate the resource aggregator cache. To invalidate your cache, click **Theme Analyzer** > **Utilities** > **Control Center** > **Invalidate Cache**. CF06 Auto invalidation recognizes your changes automatically for WebDAV based themes. No further action is required. For more information, see Utilities.

Updating your theme to use simple context menus:

The theme context menu framework that is provided with the module `wp_theme_menus` in IBM WebSphere Portal Express 8.0 and earlier is relabeled and improved in WebSphere Portal Express 8.5. The new Simple Menu Framework is compatible with all previous versions of the `wp_theme_menus`.

About this task

If you want to use the WebSphere Portal Express simple context menus, you must complete the following steps on your migrated theme.

Procedure

1. Update the existing module `wp_theme_menus` in *`WebDAV`*`/themes/`*`your_theme`*`/contributions/theme.json` and replace it with:

```
{
 "id":"wp_theme_menus",
 "prereqs":[{
  "id":"wp_simple_contextmenu_main"
}]
}
```

2. Copy the following artifacts from the Portal 8.5 theme to your migrated theme in the same directory:
   - *WebDAV*/themes/Portal 8.5/contributions/simple_contextmenu.json
   - *WebDAV*/themes/Portal 8.5/css/wp_simple_contextmenu.css
   - *WebDAV*/themes/Portal 8.5/css/wp_simple_contextmenu.css.uncompressed.css
   - *WebDAV*/themes/Portal 8.5/css/wp_simple_contextmenuRTL.css
   - *WebDAV*/themes/Portal 8.5/css/wp_simple_contextmenuRTL.css.uncompressed.css
   - *WebDAV*/themes/Portal 8.5/css/default/contextmenu.css
   - *WebDAV*/themes/Portal 8.5/css/default/contextmenu.css.uncompressed.css
   - *WebDAV*/themes/Portal 8.5/css/default/contextmenuCommon.css
   - *WebDAV*/themes/Portal 8.5/css/default/contextmenuCommon.css.uncompressed.css
   - *WebDAV*/themes/Portal 8.5/css/default/contextmenuRTL.css
   - *WebDAV*/themes/Portal 8.5/css/default/contextmenuRTL.css.uncompressed.css
   - *WebDAV*/themes/Portal 8.5/menuDefinitions/templates/simpleMenuTemplate.html
3. Click the **Administration menu** icon. Then, click **Portal Analysis** > **Theme Analyzer**. Then, click **Utilities** > **Control Center** > **Invalidate Cache** to invalidate the theme cache. You must invalidate the cache so that your profile and module changes are picked up by the Portal server. CF06 Auto invalidation recognizes your changes automatically for WebDAV based themes. No further action is required. For more information, see Utilities.

Chapter 10. Integrating

Integrate IBM WebSphere Portal Express with software such as IBM Sametime to enable your users to collaborate more easily. You can also use the unified task list portlet, available on the WebSphere Portal Express Solution Catalog to integrate WebSphere Portal Express with your backend business process software, such as IBM WebSphere Process Server.

"Integrate with collaboration software "
IBM WebSphere Portal Express integrates with collaboration software to provide you with more effective and cost-efficient ways of accessing information, sharing ideas, communicating and working together. Key software that WebSphere Portal Express integrates with includes IBM Domino, IBM Sametime, and IBM Connections.

"Integrating business processes" on page 967
Access relevant tasks and activities for multiple business process management solutions from a single user interface. The Unified Task List portlet provides a single point of integration between multiple systems and displays tasks that WebSphere Portal Express users must complete to advance workflows. The topics in this section provide information and instructions for developing and customizing the Unified Task List.

"Integrating with web applications" on page 977
The web application bridge uses reverse proxy technology to integrate web-based content providers, such as the Microsoft SharePoint server, with IBM WebSphere Portal Express. Administrators must first define the virtual web applications or content providers. A lightweight iFrame portlet renders the content from the backend applications. Users can then access the iFrame on a page without requiring direct network access to the backend application. A special engine maps Uniform Resource Identifier (URIs) on the iFrame portlet to real URIs from the content providers.

"Integrating with SAP NetWeaver Portal" on page 986
You can use IBM WebSphere Portal Express Integrator for SAP to integrate content from an SAP NetWeaver Portal into your IBM WebSphere Portal Express. You can integrate navigational structures and single content pieces.

"Integrating with IBM MobileFirst" on page 1002
You can integrate WebSphere Portal Express with MobileFirst to provide multi-channel support to your web communities. You can create a hybrid application that adds native device functions and a unified web experience on mobile device browsers and in mobile device native applications. You can use MobileFirst to create a hybrid application that adds native device functions to your portal.

"Integrating with Brightcove" on page 1032
If you are using videos as part of your website, integrate your portal with the Brightcove video streaming server.

Integrate with collaboration software

IBM WebSphere Portal Express integrates with collaboration software to provide you with more effective and cost-efficient ways of accessing information, sharing ideas, communicating and working together. Key software that WebSphere Portal Express integrates with includes IBM Domino, IBM Sametime, and IBM Connections.

"Finding users"
Use PeopleFinder or Directory Search to locate other WebSphere Portal users. The People Finder portlet can be added to a page through the Content menu, so that users can find people in any context. Directory Search is available to users as part of a larger task, such as sending mail. Directory Search also enables users to search for user groups in addition to individual users.

"Planning for collaborative servers and portlets" on page 943
Setting up a site with IBM Domino integration requires decisions about user directories, security, authentication, and performance. View some use cases that may help you make decisions leading to a successful Domino integration.

"Integrating with IBM Sametime" on page 953
Configuring the Sametime Community Server and Sametime portlets requires a set of tasks performed on both the Sametime Community Server and the portal server.

"Collaborative Services environment properties" on page 962
If your collaborative site requires optional configuration that is not accomplished by the tasks that you run on the IBM WebSphere Portal Express server to integrate IBM Domino and the collaboration products, you can modify the operation of the collaborative servers and portlets in various ways by manually editing the Lotus Collaborative Services environment properties file (`CSEnvironment.properties`) on the WebSphere Portal Express server.

Finding users

Use PeopleFinder or Directory Search to locate other WebSphere Portal users. The People Finder portlet can be added to a page through the Content menu, so that users can find people in any context. Directory Search is available to users as part of a larger task, such as sending mail. Directory Search also enables users to search for user groups in addition to individual users.

"People Finder"
The **People Finder** portlet provides both quick search and advanced search options for locating people and information about people. Once found, a person is visible to other users as a person link that indicates online presence and displays a menu of instant messaging and other options.

"Directory Search" on page 938
The Directory Search or "People Picker" portlet is a common embedded component that allows users to search for and select names of people (individual users) and groups for which the portal is configured.

People Finder

The **People Finder** portlet provides both quick search and advanced search options for locating people and information about people. Once found, a person is visible to other users as a person link that indicates online presence and displays a menu of instant messaging and other options.

Hovering over the person link provides an option to display the person's business card (also known as person card). To view the profile, select **Profile** on the business card. For more information on the business card, see the section "Person card" in the People Awareness topic.

You can add the People Finder portlet to a page in the same manner that you add any portlet. People Finder is then immediately available when the page is rendered. If you add **People Finder** to a page, you must configure the profile parameter of that page before you add the portlet.

1. Turn **Edit Mode** on.

2. Click **Page**.
3. On the **General** tab, click **Edit Page Properties**.
4. Click the **Advanced** tab.
5. Scroll to the **Theme Settings** section.
6. Select `Basic Content with Dojo` from the **Profile** menu.
7. Click **Save**.
8. Add the **People Finder** portlet to the page.

The **People Finder** portlet appears when users click the **Find a User** link that appears at the end of any IBM WebSphere Portal Express page when the back-end server is J2EE.

People Finder is supported as a remote WSRP service.

People Finder supports the Java Portlet Specification. For more information, read the information about developing portlets.

For information about the **People Finder** portlet, view the help that is available when you select Configure from the drop-down menu on the portlet title bar.

Using the People Finder portlet

Users interact with the People Finder portlet through the following features, which appear in one or more views of the portlet:

- Quick Search and Quick Search Results, including Business Card fields
- Advanced Search and Advanced Search Results
- Profile page, including Business Card fields
- Organization view, including Business Card fields

Setting up People Finder

Use the configuration mode to specify which fields to display in the **People Finder** portlet. The fields that are available for selection when configuring the portlet are based on a mapping of attributes from the user repository to the Member Manager component of WebSphere Portal Express. People Finder requires a mapping for the `uid` and `mail` attributes. To learn more about attribute mapping or how to determine which attributes are defined to the portal, see the section "Adding more attributes to VMM."

For People Finder, make sure your site meets the following client and server requirements.

Client requirements

This portlet supports browsers capable of rendering HTML markup.

Table 110. Minimum requirements for HTML

Item	Description
Markup level	HTML 4.01 Transitional
Java applet	n/a
JavaScript	n/a
<iframe>	No

Table 110. Minimum requirements for HTML (continued)

Item	Description
Style sheets	Portal styles only
Software	The People Finder portlet is compatible with specific Web browser software releases. For details, see the *WebSphere Portal Express hardware and software requirements*.
Accessibility	Yes

Server requirements

There are no special server requirements for the People Finder portlet.

Deployment/Installation

This portlet is installed automatically as part of WebSphere Portal Express installation.

Configuration parameters

Config_ResultSetLimit is the only parameter that you can edit. Use the **Configure** command. Do not modify any configuration parameter values for the **People Finder** portlet in the **Portlet Management**. Click the **Administration menu** icon. Then, click **Portlet Management** > **Portlets**. Use this interface only for viewing parameters when troubleshooting portlet configuration.

Table 111. Configuration parameters

Parameter	Value
ConfigHelpURI	The location and name of the JSP containing topics launched from the Help command when configuring People Finder. Default: `/help/pfind_config.jsp`
SearchHelpURI	The location and name of the JSP containing topics launched from the Help command in the Profile page of the People Finder. Topics in this JSP include Help for person links, Quick Search, Quick Search Results, Advanced Search, and Advanced Search Results. Default: `/help/pfind_view_search_for_people.jsp`
PersonRecordHelpURI	The location and name of the JSP containing topics launched from the Help command in the Profile page and Organization view of the People Finder. Default: `/help/pfind_view_display_person_info.jsp`
Config_PageIndexLimit	Specifies the maximum number of search results to be returned per page by Quick Search and Advanced Search. Default: 5

Table 111. Configuration parameters (continued)

Parameter	Value
Config_RecursionSetLimit	Specifies the maximum number of recursions performed by search and retrieval on the *manager* attribute for a given person. The limit of recursions performed on the *manager* attribute determines the number of managers responsible for the found person that appear in the Organization View.
Config_ActiveFields **Config_Active_Queries** **Config_VisualSets** **Config_Views** **Config_QuerySets** **Config_QueryViews** **Config_UpdateInfo** **Config_Complete**	These parameters appear in the portlet after fields are specified in configuration mode. Do not modify these parameters.

Related concepts:

"Developing portlets" on page 2931
Get an overview of the process of creating portlets, learn about the concepts of the APIs used to develop portlets, and view the samples to get you started. Also, learn about integrating features such as single sign-on, cooperative sharing of information using the property broker, and migrating Struts applications to the portlet environment.

"People awareness" on page 959
People awareness makes people's names appear as hyperlinks that users can click to display information about the individual and gain access to actions for contacting and working with him or her. If the administrator has configured an IBM Sametime server to work with WebSphere Portal Express, users can see each other's online presence in their person links according to the status options they have set in their Sametime client (for example, whether the person is active, away, offline, or does not want to be disturbed). The person's online status appears only if Sametime is enabled.

Related tasks:

"Adding more attributes to VMM" on page 568
After you install IBM WebSphere Portal Express and configuring your LDAP user registries, you must adapt the attribute configuration to match the configured LDAP servers and your business needs. However, do not complete these steps if you configured only a database user registry or the default federated file-based repository for out-of-box installations.

Related information:

"System requirements" on page 103
Before you install IBM WebSphere Portal Express, review the hardware and software requirements to ensure that you have the supported versions of prerequisite and corequisite software and the required hardware.

People Finder configuration reference:

The default fields of the People Finder portlet correspond to attributes defined by Member Manager, and enable the display of information about people in several views. As an administrator, you can determine the layout and content of portlet views by selecting and ordering the fields that appear in each view.

Note: If Member Manager is configured with Microsoft Active Directory, remove the fields *carLicense*, *secretary*, and *pager* from the People Finder configuration.

The configuration settings are stored in the file `apPDirConfig.xml`. You can return People Finder to its default configuration by selecting **Configure** from the portlet drop-down menu, and under XML Configuration, clicking **Reload Settings**.

For additional information on setting up the views of the People Finder portlet, while configuring People Finder, select Help from the drop-down menu on the portlet title bar.

Business Card fields

The following table lists the Member Manager attributes that appear as fields in the unlabelled Business Card section of the Profile in People Finder. By default, the Business Card section displays the following fields as lines in descending order. Business Card fields do not display labels, and fields that contain no information are not displayed. For each attribute listed, the field label and display type are identified, except for Photograph, whose attribute you can select from a separate list and is *jpegPhoto* by default. Unless noted, the default display type of an attribute is a text string.

Table 112. Member Manager attributes and Business Card fields

Member Manager attribute	Field label	Display type
jpegPhoto	Photo	N/A
cn	Name	Person Link
telephoneNumber	Phone number	N/A
ibm-primaryEmail	Email address	Email Address
ibm-jobTitle	Job title	N/A
localityName	City	N/A

Contact Information fields

The following table lists the Member Manager attributes that appear as fields in the **Contact Information** section of the Profile. For each attribute listed, the field label and display type are identified. Unless noted, the default display type of an attribute is a text string.

Table 113. Member Manager attributes and Contact Information fields

Member Manager attribute	Field label	Display type
ibm-personalTitle	Title	N/A
cn	Name	Person Link
uid	User ID	N/A
employeeNumber	Employee number	N/A

Table 113. Member Manager attributes and Contact Information fields (continued)

Member Manager attribute	Field label	Display type
ibm-primaryEmail	Email address	Email Address
telephoneNumber	Phone number	N/A
mobile	Mobile phone number	N/A
pager	Pager Number	N/A
postalAddress	Address	N/A
roomNumber	Room number	N/A
street	Street	N/A
localityName	City	N/A
stateOrProvinceName	State or province	N/A
postalCode	Postal Code	N/A
countryName	Country	N/A

Current Job fields

The following table lists the Member Manager attributes that appear as fields in the **Current Job** section of the Profile. For each attribute listed, the field label and display type are identified. Unless noted, the default display type of an attribute is a text string.

Table 114. Member Manager attributes and Current Job fields

Member Manager attribute	Field label	Display type
ibm-jobTitle	Job title	N/A
departmentNumber	Department Number	N/A
businessCategory	Business	N/A
employeeType	Employee Type	Member Link

Background fields

The following table lists the Member Manager attributes that appear as fields in the **Background** section of the Profile. For each attribute listed, the field label and display type are identified. Unless noted, the default display type of an attribute is a text string.

Table 115. Member Manager attributes and Background fields

Member Manager attribute	Field label	Display type
preferredLanguage	Preferred language	N/A
labeledURI	Personal web page	Web Page Link

Advanced Search Queries

Advanced Search criteria, by default, include most of the same fields that are available for the Profile. In general, only fields corresponding to attributes of data type *String* are available as search criteria. Attributes of data type *Numeric*, *Object*, or *MemberLink* are not available for search.

The following fields are not available for selection as Advanced Search criteria in the People Finder. Users cannot search for people using these fields because the attributes are not type String.

manager (data type = MemberLink)

seeAlso (data type = MemberLink)

secretary (data type = MemberLink)

Advanced Search Results fields

The following table lists the Member Manager attributes that appear as fields in the Advanced Search Results in People Finder. For each attribute listed, the field label and display type are identified. Unless noted, the default display type of an attribute is a text string.

Table 116. Member Manager attributes and Advanced Search Results fields

Member Manager attribute	Field label	Display type
cn	Name	Person Link
telephoneNumber	Phone number	N/A
ibm-jobTitle	Job title	N/A

Quick Search Queries

The following table lists the Member Manager attributes that appear by default in the **Search By** list in Quick Search. For each attribute listed, the field label and display type are identified. Unless noted, the default display type of an attribute is a text string.

Table 117. Member Manager attributes and Search By fields

Member Manager attribute	Field label	Display type
byName	Name	N/A
uid	User ID	N/A
ibm-primaryEmail	Email address	N/A
telephoneNumber	Phone number	N/A
ibm-jobTitle	Job title	N/A

Quick Search Results fields

The following table lists the Member Manager attributes that appear as fields in the Quick Search Results. For each attribute listed, the field label and display type are identified. Unless noted, the default display type of an attribute is a text string.

Table 118. Member Manager attributes and Quick Search Results fields

Member Manager attribute	Field label	Display type
cn	Name	Person Link
telephoneNumber	Phone number	N/A

Organization View fields

The following table lists the Member Manager attributes that appear as fields in the Organization View. For each attribute listed, the field label and display type are identified. Unless noted, the default display type of an attribute is a text string.

Table 119. Member Manager attributes and Organization fields

Member Manager attribute	Field label	Display type
cn	Name	Person Link
telephoneNumber	Phone number	N/A
ibm-jobTitle	Job title	N/A

Paginating search results in the People Finder:

You can configure the People Finder portlet to display a maximum number of results found per page.

Before you begin

About this task

Procedure

1. Select **Configure** from the People Finder drop-down menu.
2. Click **Configuration Basics**.
3. Type the value you want in the **Maximum number of items shown on a page in search results** field.
4. Click **OK**.
5. Click **Apply Changes Now**.

Example

What to do next

Enabling People Finder for anonymous users:

If you grant access to anonymous users for any page that contains the **People Finder** portlet, you must also grant them access to a hidden page, and to a dynamic person tag portlet that support awareness in **People Finder**. In addition, you must enable session use for anonymous users.

About this task

Perform the following steps:

Procedure

1. Log in to the portal as an Administrator.
2. Click the **Administration menu** icon. Then, click **Access** > **Resource Permissions**.
3. In the **Resource Types** list, click **Pages**.
4. Use Search to locate the page in your site where you added the **People Finder** portlet.
5. Click the key icon under **Assign Access**.

6. For the role User, click the pencil icon, and then click**Add**.
7. Select **Anonymous Portal User**, and then click **OK** as necessary to save the change.
8. Use Search to locate the **People Finder** portlet.
9. Repeat steps 6 - 8 to assign access for the portlet.
10. Click **Logout**.
11. Set the following property in the `WP NavigatorService` from the WebSphere Integrated Solutions Console. For more information, see the topic on setting configuration properties, and the Navigator Service section in the topic on Portal configuration services.

    ```
    public.session = true
    ```
12. Add the anonymous portal user to the user role on the USERS Virtual Resource:
    a. Click the **Administration menu** icon. Then, click **Access** > **Resource Permissions**.
    b. Under Resources Types, select **Virtual Resources**, locate **USERS** in the Resources list and then click the **Assign Access** icon.
    c. For the User role, click the **Edit Role** (pencil) icon.
    d. Click **Add**, then select **Anonymous Portal User** and click **OK** to save the change.

People Finder interaction with other portlets:

Other portlets can communicate with People Finder using URL addressability.

The Person tag uses URL addressability to communicate with the People Finder if People Finder is not on the current page. Other collaboration portlets can use URL addressability to programmatically integrate People Finder features. Portlets can display a link for the **Profile** action and thereby access People Finder functionality in their application contexts. Clicking **Profile** displays the Profile inside the People Finder.

Table 120. Parameters and values for implementing URL actions in portlets

URL Parameter	Possible Values
URLAction	URLShowPersonRecord, URLShowOrgView
URLMemberID	Member Manager memberUniqueIdentifier of the person whose Profile or Organization View is to be displayed. Alternatively, the following Member Manager attributes: • memberDN • any valid input for *byName* query • a valid entry of ibm-PersonAwarenessIdentifier attribute.

Note: In IBM WebSphere Portal Express, People Finder is a standard portlet and therefore does not support cooperative portlet methods.

Member Manager and People Finder:

Member Manager is the component of IBM WebSphere Application Server and IBM WebSphere Portal Express that provides the common schema of attributes used by People Finder for people and their Profile pages.

Prerequisites

To understand how Member Manager works, you should have a thorough understanding of WebSphere Portal Express security and authentication concepts, including user registries and user repositories.

Member Manager data types

You can select the display format of a People Finder field if the data type of the corresponding attribute in Member Manager is *string*. Attributes with data type *string* can have one of the following display formats:

- String (default)

  The People Finder field appears as text.
- Person link

  The People Finder field appears as a person name showing online presence and a person menu of actions.
- Email address

  The People Finder field appears as a mailto: link that launches an email message to the person.
- Web page link

  The People Finder field appears as a link to a web page

People Finder fields that correspond to Member Manager attributes that have data types other than *string* appear as fixed text. People Finder supports the following data types, but you cannot choose the display format for fields that correspond to attributes with these data types.

- Integer, Long, Double

  Display format is always Numeric.

  Examples:

  ibm-firstDayOfWeek

  ibm-firstWorkDayOfWeek
- MemberIdentifier

  Display format is always Member Link.

  Examples:

  manager (Employee's manager. Required to build Organization view.)

  secretary (Name of the person's secretary or assistant)

  seeAlso (Person who can be contacted when this person is not available)
- ByteArray

  Display format is always Image.

  Example: *jpegPhoto* (A jpeg format photograph)
- Object

  Display format is always Object.

Other data types such as Timestamp are not supported by People Finder.

People Finder attribute mapping:

The collaboration integration relies on a predefined set of Virtual Member Manager (VMM) user and group attributes to function properly, while your LDAP server may use a different set of predefined user and group attributes. If a portal attribute

is available under a different name on the LDAP server, you can map the portal attribute to the corresponding LDAP attribute. If you want to use an attribute as search attribute or you want to see its value in the search result, you must to map the attribute. Portal attributes that do not correspond to an LDAP attribute should be flagged as unsupported.

Before you begin

The collaboration products use these attributes:

- **displayName**
- **ibm-primaryEmail**
- **givenName**
- **dn**
- **cn**
- **sn**
- **uid**

About this task

Mapping the following attributes ensures that users see the appropriate values when People Finder displays an individual's User Profile, or when they search by attribute (for example, to find all users who have the same preferred language or whose telephone number starts with the same area code).

```
# name of the portal attribute
federated.ldap.attributes.mapping.portalName=ibm-primaryEmail,ibm-jobTitle,
stateOrProvinceName,countryName,localityName,street,employeeNumber,roomNumber,
preferredLanguage,labeledURI,ibm-personalTitle

# name of the LDAP attribute
federated.ldap.attributes.mapping.ldapName=mail,title,st,c,l,OfficeStreetAddress,
EmployeeID,physicalDeliveryOfficeName,preferredLanguage,url,
personalTitle
```

For more information, see *Adding more attributes to VMM*.

Directory Search

The Directory Search or "People Picker" portlet is a common embedded component that allows users to search for and select names of people (individual users) and groups for which the portal is configured.

Directory Search is different from People Finder in two ways:

- Users use Directory Search as part of a task, such as sending a document link to other people with access to the same document library. Users can search for user or group names and select them. Directory Search then tries to find the selection so that it can be used in the next step of the larger task.
- Users can search for groups and people.

Directory Search is supported as a remote WSRP service, and is available from all calling applications.

Using the Directory Search portlet

Directory Search opens in a window that is set to use the "no skin" skin so that it displays without a title bar. The portlet provides common controls for searching for people and groups.

Table 121. Portlet controls

Control	Description
Search for	The field where users enter all or part of a name for retrieval from the directory. Users can search for person names only, group names only, or person names and group names.
Search results	The list of names (persons and groups) that match the search text. By default, the application context and the type of directory determine the information that is displayed in the columns of the search results list. You can configure the search results to show information in 3 columns. Users can use the third column to distinguish between people whose name information in the first and second columns is identical.
Show details	Displays profile information for the selected name. If the search results include multiple users with the same displayed name, viewing a selected name's profile lets you check whether it is the one you want. **Tip:** As an alternative, you can hover over the selected name to see the profile information.

Starting Directory Search Portlet

Starting the Directory Search portlet requires the use of the IBM WebSphere Portal Express urlGeneration tag. This tag creates a URL to the Directory Search portlet. The following parameters are used with urlGeneration tag. This tag uses **`openModalDialog`** to pass a callback method, which is called when the portlet is closed, and contains the resulting people or groups that were selected:

- contentNode="PeopleConstants.IBM_PORTAL_DIRECTORY_SEARCH_PAGE"
- compositionNode="PeopleConstants.IBM_PORTAL_DIRECTORY_SEARCH_CONTROL"
- portletWindowState="solo"
- newWindow="true"

The parameters that are mentioned in the following table are used with the urlGeneration tag. The **`Lable`** and **`buckets`** parameters are required, while the other parameters are optional. Except for the following parameters, the urlGeneration tag accepts customized parameters.

Table 122.

Parameter	Possible values	Description
Label	default when parameter not specified: `Selected names:` `picker.mail.label=Recipients:` `str.calendar.label=Recipients:`	Resource key for the text string that the calling portlet requires; these resource keys are stored in the people picker property file. For example, the default is `Selected names` but the Mail portlet needs it to be `Recipients`.
dirs	default when parameter not specified: `WMM` `WMM=Organization Directory Adapter`	A comma delimited list that consists of the directory adapters that the picker should search.
searchScope	`peopleOnly` `groupsOnly` `all` If parameter is not specified, people and groups are searched (all)	Determines whether you can search for people only, groups only, or both people and groups. Also determines whether the **Show Group Member** button is displayed. If the value for this parameter is either `groupsOnly` or all, the **Show Group Member** button is displayed.
requireEmail	`true/false`	Determines whether the user can select the name of a person who does not have an email address. If the value for this parameter is true and the user tries to select a person who does not have an email address, an error message

Table 122. (continued)

Parameter	Possible values	Description
buckets	default when parameter not specified: Only one Search results list box is displayed, and the user can select only 1 name in it. `picker.mail.bucket1,picker.mail.bucket2,` `picker.mail.bucket3=To,cc,bcc`	The value is `0` or a comma-delimited list of resource keys for the text strings that the calling portlet requires. These resource keys are stored in the people picker property file. Determines the following: Whether the user can select only 1 name or more than 1 name. Whether a second list box is displayed. If the user can select multiple names, a second list box that holds the selected names is displayed. If the user can select only one name, the second list box bucket is not displayed. The number of **Add** buttons that are displayed, and the number of **buckets** in the second list box. Example: the default is one button that is labeled **Add** and no **buckets** in the second list box, but the Mail portlet has three buttons and buckets: To, cc, and bcc.

Setting up Directory Search

For Directory Search, make sure that your environment meets the following client and server requirements.

Note: The ability to search for users and groups in the Directory Search portlet requires the USER role on the USERS and USER GROUPS virtual resources.

Client requirements

This portlet supports browsers capable of rendering HTML markup. The following table provides detailed information.

Table 123. Minimum requirements for HTML

Item	Description
Markup level	HTML 4.01 Transitional
Java applet	No
JavaScript	Yes
<iframe>	No
Style sheets	Portal styles only
Software	The Directory Search portlet is compatible with specific web browser software releases. For details, refer to the *WebSphere Portal Express hardware and software requirements*.
Accessibility	Yes

Server requirements

There are no special server requirements for the Directory Search portlet.

Deployment/Installation

This portlet is installed automatically as part of WebSphere Portal Express installation.

Note: This portlet is supported as a remote WSRP service.

Configuring Directory Search

When you are searching for people and groups, Directory Search searches the repositories that are defined in the Member Manager component of the portal.

These repositories can include the default file repository, LDAP user registry, property extension database, database user registry, or custom user registry. For more information about configuring Member Manager, see the topic on User registry considerations.

The directory applies the `byName` query that is defined in Member Manager when retrieving person or group names. The `byName` query uses *cn* when it is retrieving a group name, and at least one of the following attributes when it is retrieving a person name:

- *cn*
- *givenName*
- *sn*
- *DisplayName*

For detailed information, refer to the attribute definition and mapping files and the configuration property files that are described in Member Manager documentation.

"Configuring display attributes in the directory search portlet" on page 942
You can configure the display attributes in the directory search dialog.

"Configuring search attributes in the directory search portlet" on page 942
You can configure the search attribute in the directory search dialog.

"Configuring the wildcard support in directory search queries" on page 943
You can use the wildcard character (*) in directory search queries.

Related information:

WebSphere Portal detailed system requirements

Changing the number of search results found:

By default, Member Manager limits the number of entries that are returned to 50 when you use the Directory Search window to search the organization directory for names. By modifying the `pickersettings.properties` file, you can change the number of search results returned.

Procedure

1. Edit the `pickersettings.properties` file in the following location:
   - Windows: `wp_profile\PortalServer\config\lotusworkplacelib\pickersettings.properties`
   - Linux : `wp_profile/PortalServer/config/lotusworkplacelib/pickersettings.properties`
   - IBM i: `wp_profile/PortalServer/config/lotusworkplacelib/pickersettings.properties`
2. Change the 50 at the end of the following content to the number of search results you want to display:

   ```
   people.view.1
   =WMM.1,com.ibm.workplace.people.picker.data.value.service,
   str.directory.name.wmm,com.ibm.wkplc.people.picker.workspace.
   WmmPickerAdapterFactory,50,2
   ```
3. Save the properties file.
4. Restart the IBM WebSphere Portal Express server.

Changing the minimum number of characters in names for searching:

By default, Member Manager requires users to enter a minimum of two characters when they use the Directory Search window to search the organization directory for names. This limit is not appropriate for all languages. By modifying the `pickersettings.properties` file, you can reduce the limit to one character.

Procedure

1. Edit the `pickersettings.properties` file in the following location:
   - Windows: `wp_profile\PortalServer\config\lotusworkplacelib\pickersettings.properties`
   - Linux : `wp_profile/PortalServer/config/lotusworkplacelib/pickersettings.properties`
   - IBM i: `wp_profile/PortalServer/config/lotusworkplacelib/pickersettings.properties`
2. Change the 2 at the end of the following content to a 1:

   ```
   people.view.1
   =WMM.1,com.ibm.workplace.people.picker.data.value.service,
   str.directory.name.wmm,com.ibm.wkplc.people.picker.workspace.
   WmmPickerAdapterFactory,50,2
   ```
3. Save the properties file.
4. Restart the IBM WebSphere Portal Express server.

Configuring display attributes in the directory search portlet:

You can configure the display attributes in the directory search dialog.

Procedure

1. Log on to the WebSphere Integrated Solutions Console.
2. Click **Resources** > **Resource Environment** > **Resource Environment Providers**.
3. Find and click the **WP PeopleService** resource environment provider. The resource environment provider name is case sensitive.
4. Click **custom properties**.
5. Click the custom properties page and configure the values for following property:

   pickerDisplayAttribute

   Governs the display attributes for the Portal People Picker UI.

   Use two attributes at a time, supported by both users and groups.

   default value : `cn,displayName`
6. Restart IBM WebSphere Portal Express server to reflect the changes.

Configuring search attributes in the directory search portlet:

You can configure the search attribute in the directory search dialog.

Procedure

1. Log on to the WebSphere Integrated Solutions Console.
2. Click **Resources** > **Resource Environment** > **Resource Environment Providers**.
3. Find and click the **WP PeopleService** resource environment provider. The resource environment provider name is case sensitive.

4. Click **custom properties**.
5. Click the custom properties page and configure the values for the following properties:

   pickerPeopleSearchAttribute
   Governs the Portal People Picker search attributes for a user. Use four attributes at a time.

   default value : `cn,displayName,sn,givenName`

   pickerGroupSearchAttribute
   Governs the Portal People Picker search attributes for a group. Use one attribute at a time.

   default value : `cn`
6. Restart IBM WebSphere Portal Express server to reflect the changes.

Configuring the wildcard support in directory search queries:

You can use the wildcard character (*) in directory search queries.

Procedure

1. Log on to WebSphere Integrated Solutions Console.
2. Go to **Resources** > **Resource Environment** > **Resource Environment Providers**.
3. Find the **WP PeopleService** resource.
4. Click the **WP PeopleService** resource link.
5. Click **Custom properties**.
6. Configure the value for the following property:

   pickerWildCardSearchEnable
   Controls whether to append the wildcard character (*) to search query or not. The default value is `true`.
7. Restart the IBM WebSphere Portal Express server to reflect the changes.

Planning for collaborative servers and portlets

Setting up a site with IBM Domino integration requires decisions about user directories, security, authentication, and performance. View some use cases that may help you make decisions leading to a successful Domino integration.

Performance considerations

When integrating Domino into your portal environment, consider performance when deciding how many and which servers you need.

For example, to use a Domino LDAP server as the user directory (repository) for the portal, install portal on a separate machine from the Domino LDAP server configured to support collaborative features in the portlets. The Domino LDAP server for the portal user directory should reside on a machine that is dedicated to serving the portal environment and all its users.

IBM i: It is recommended that a specific Domino server be created to run the collaborative components, and that it should reside on the same IBM i server as WebSphere Portal Express.

"Domino server installation and server setup reference" on page 944
View a roadmap to instructions for installation and first set up of an IBM

Domino server, including installation of the Domino Administrator client software that you can use to administer the server.

"Planning names for servers and users in a Domino site" on page 946
While installing and integrating Domino and collaboration products, you must decide on a naming scheme for your servers, plan for and create several important administrative users, and create passwords for those users. Learn about server naming and a table of identities you can use while installing and configuring servers, with recommendations for which names need to match for better performance.

"Determining the needs of your portal site" on page 949
The following general use cases are intended only to provide some recommendations for your decisions about directories when integrating collaboration product.

"Platform and user directory considerations" on page 951
There are unique considerations for operating systems that you should be aware of before you proceed with integrating collaboration software with WebSphere Portal Express. Also, in the context of collaboration integration, there are two types of user directories, Domino directory and then all other supported user directories.

"Security and user authentication considerations" on page 952
Correctly configuring authentication and security includes configuring single sign-on and setting up SSL.

Domino server installation and server setup reference

View a roadmap to instructions for installation and first set up of an IBM Domino server, including installation of the Domino Administrator client software that you can use to administer the server.

About Domino servers

A Domino server has several purposes in an IBM WebSphere Portal Express site. It can be a Domino Directory (LDAP) user registry server, a messaging/application server housing source data for Domino-based portlets. Or it can be a prerequisite server on an IBM Sametime server.

Because WebSphere Portal Express is compatible with many releases of Domino server software, this topic contains no step-by-step procedures for installation. Instead, you can access the following links to locate the correct procedure for your platform and for the release of Domino you intend to install. Documentation for specific releases and platforms is available over the Internet on the IBM website, for download and browsing. For information about the releases of Domino supported for use with WebSphere Portal Express, see the detailed system requirements.

The installation documentation covers the following basic tasks to complete a Domino server installation:

- Install the Domino server software.
- Run the Domino Server Set up program (with a wizard).
- Install the Domino Administrator client software. You can use this software for important tasks on the server.

  Tip: You can also want to install the Notes Client and Notes Designer clients for email and application development tasks.
- Set up the Domino Administrator client software (with a wizard).

- If this server is the first Domino server in your portal site, register ids for subsequent servers.

Usage restrictions: You are authorized to install and use Domino Directory solely and exclusively in connection with your use of Sametime. Consult the product license for details.

Where to find installation procedures

The IBM Lotus Documentation website lists all documentation for all releases of Domino.

The following table lists installation documentation pieces for the Domino 8.5.2 release. The documentation website is subject to change, so if any of these pieces are unavailable, check the Domino product pages for updates for your platform.

Table 124. Installation documentation

Platform	Documentation	Important topics	Comments
Windows	Lotus Domino 8 Administrator Help	Under *Installation*, *Server installation*,Installing Domino on Windows systems, and The Domino Server Set up program.	You can either view this documentation online or download a file.
Linux	Lotus Domino 8 Administrator Help	Under *Installation*, *Server installation*,Installing Domino on UNIX systemsInstalling Domino on Linux on zSeries systems, and The Domino Server Set up program.	You can either view this documentation online or download a file.
IBM i	Installing and Managing Domino 8 for System i	*Chapter 3 Installing Domino on your system*, *Chapter 6 Setting Up a First Domino Server*, and *Chapter 8 Setting Up an Additional Domino Server*.	You can either view this documentation online or download a file.

Critical choices for Domino in a portal site

The following table lists choices common to Domino installation on most or all platforms, with recommendations for use of Domino with the portal. Because specific installation steps differ between platforms, the descriptions of the choices are general. Do not expect to see the exact wording of the choice when installing for your platform and release. The options highlighted in this table are a subset of all choices you make during installation; in general, if not specified, accept default options.

Before installation, see the topic on planning for collaborative servers and portlets, which describes common types of collaborative portal sites, and includes considerations for platform, user directories, security, and performance.

Tip: Be sure to keep a record of all names and passwords you specify, and all directories where the installation programs installation software.

Table 125. Key decisions for Domino installation

Procedure	Decision point	Recommendations
Domino Server Set up program	First server versus additional server	Your Domino LDAP server must be a first server, and messaging/application servers or underlying Domino servers for Sametime are additional.
Domino Server Set up program	Organization name and certifier	See "Planning names for servers and users in a Domino site." Use the certifier id you create on the first Domino server to register subsequent Domino servers in the portal site.
Domino Server Set up program	Administrator name	See "Planning names for servers and users in a Domino site."
Domino Server Set up program	Services (servers)	Enable HTTP (or web browsers) and DIIOP on all Domino servers in your site, and LDAP on the Domino LDAP server. The DIIOP service can be with a Customize option in the server setup program.
Domino Administrator client software setup (wizard)	Administrator name	Use the same name you did for Domino server setup. See "Planning names for servers and users in a Domino site."

After you install and set up the first Domino server in your site, you must create certifier IDs to register subsequent Domino servers. For information, see the Lotus Domino 8 Administrator Help topic on server registration.

Lotus Domino Administrator Help, Server registration

Planning names for servers and users in a Domino site

While installing and integrating Domino and collaboration products, you must decide on a naming scheme for your servers, plan for and create several important administrative users, and create passwords for those users. Learn about server naming and a table of identities you can use while installing and configuring servers, with recommendations for which names need to match for better performance.

About server naming:

When your portal site contains multiple IBM Domino servers, their names should be reasonably short and should contain no spaces. The server names will be seen by your users, so make them descriptive when possible. If the Domino server name is not the same as the physical server name, you must make sure that the name is resolvable through DNS. For example, you could name a hub server in Chicago `acmehub`, which, combined with the server's domain, could yield a fully qualified host name of `acmehub.chicago.acme.com`. You would configure an entry in DNS for `acmehub.chicago.acme.com` to point to the physical IP address of the server. It is not a requirement to make the Domino server name the same as the physical server name, but if it is not, Server Connection documents are required in all other Domino servers and the Lotus Notes or Domino Administrator client software running on them.

Table of user identities

Some names in the following table are specified during the Domino Server Setup procedure you perform after installing the Domino LDAP server for the first time. If you later perform an upgrade installation, configuration choices from the first-time Server Setup will be used; you will not see screens presenting these choices again.

Table 126. User identities

Identity	Description	Recommendation
Organization name for a Domino LDAP server	This name is specified during the Domino Server Setup procedure.	See *About server naming*. Example: `dom_hub/chicago/renovationscorp`
Administrator of a Domino LDAP server	This administrative user identity is created during the Domino Server Setup procedure.	**Tip:** For convenience, you could make this the same as the user name of an administrator in WebSphere Portal Express (**`PortalAdminId`** in the `wkplc.properties` file)Example: `wpsadmin`
Bind user OR IBM WebSphere Application Server administrator OR both	This identity is used by IBM WebSphere Portal Express to access the LDAP directory. Both LDAP directory and security configuration for WebSphere Portal Express involve modifying values in the `wkplc.properties` file. This user identity is created during the Server Setup procedure.	Should be the same as the user ID of an administrator for the WebSphere Application Server (**`WasUserID`** in the `wkplc.properties` file)Example: `wpsbind` For information on how to create the Bind user or Admin user, use Search to find the topic on preparing a Domino Directory server on <*platform*> (for example, Preparing a Domino Directory server on Windows).

Table 126. User identities (continued)

Identity	Description	Recommendation
WebSphere Portal Express administrators group	You should manually edit the group `wpsadmins` to `wpsadmins/yourorgname`. This edit creates a fully distinguished LDAP name of `cn=wpsadmins/o=yourorgname`. This change must made when using a Domino LDAP directory, because Domino does not store groups in the hierarchical format that WebSphere Portal Express expects.	Should be the same as the group name of an administrator for all administrators for the WebSphere Portal Express server (**`PortalAdminGroupId`** in the `wkplc.properties` file)Example: `wpsadmins/renovationscorp` **Note:** In the ACL of the Domino Directory this group should have Author or Editor access, and the Role Types. These settings allow the administrator group to write and edit Person documents in the Domino Directory; these are necessary tasks in a portal that uses subscriber management.
Sametime server administrator	This user name has administrative access to the Sametime server and can modify Web pages on the server.	Example: `stadmin`
Sametime Web Conferencing administrator	This user name is created in the Domino Directory (`names.nsf`) on the Sametime Web Conferencing server and is used only for integration of Sametime. **Note:** In the ACL of the `STConfig.nsf` database, this user name is a Person/Manager, and has, at minimum, role(s) equivalent to those specified for the servlet entry of the meeting API in the `servlets.properties` file on the Domino server.	Example: `st_webconf_admin` Recommended: At least the [SametimeAdmin] role

Related tasks:

"Preparing a Domino Directory server" on page 159
If you plan to use a Domino Directory as an LDAP user registry, you must install and set up the server so that it communicates with IBM WebSphere Portal Express.

Determining the needs of your portal site

The following general use cases are intended only to provide some recommendations for your decisions about directories when integrating collaboration product.

To identify your use case, ask yourself two questions about your site:

1. What directory service are you already using, or do you want to use, for the user directory for WebSphere Portal Express? Possible answers are:
   A: LDAP directory other than Domino
   B: Domino LDAP directory
2. What directory service are you already using, or do you want to use, for the user directories for collaboration products, such as IBM Sametime? Possible answers are:
   A: LDAP directory other than Domino
   B: Domino LDAP directory
   C: Native (non-LDAP) Domino directory

Table 127. Use case: 1A+2A

Single directory (LDAP other than Domino) site	**Your decisions about Domino integration**
• You have WebSphere Portal Express installed and in active use. • Your portal site is configured with an LDAP directory other than Domino (for the purposes of these scenarios, assume IBM Directory Server, but any other LDAP has the same considerations) with a substantial user repository in active use. • You intend to integrate collaborative portlets • You want the Domino portlets to have online awareness features. • You want users to be able to work in portlets without authentication other than logging into the portal (that is, you need the single sign-on feature). In fact, you may already have single sign-on enabled on your portal server. • You do not yet have any collaboration products or servers installed, or if you have them, they are not yet configured for use with the portal. **Note:** If you have an existing Domino server you intend to integrate, make sure that its release is supported before you attempt to use it with the portal. See the Software for collaboration section in the *WebSphere Portal Express hardware and sofware requirements.* If the release is not supported, you must upgrade the Domino server before you can use it with the portal.	Your environment is typical of most portal customers. You must install and set up a Sametime server to support awareness. We recommend that you configure the server to authenticate against the LDAP directory already configured with your portal site. To enable single sign-on, configure it as a last task after installing and configuring new servers for collaboration products, to include all the new servers. Support for key features in the collaborative portlets such as auto-detection of users' mail files requires additional configuration in this environment.

Table 128. Use case: 1B+2B

Single directory (Domino LDAP) site	Your decisions about Domino integration
• You have installed WebSphere Portal Express • You have no LDAP user directory configured yet. • You intend to integrate collaborative portlets • You want the portlets to have online awareness features, and you want users to be able to work in portlets without authentication other than logging into the portal (that is, you need the single sign-on feature)	Your environment is recommended, especially for new portal sites, if you intend to make full use of Domino integration. Install and configure Domino as your LDAP directory for the portal. It is a best practice to use the directory configured for Sametime as the directory configured for the portal, and Domino LDAP is the best choice for Sametime; therefore, in a new site we recommend using Domino LDAP as the single directory.

Table 129. Use case: 1A + 2B

Dual directory-type site (LDAP other than Domino for portal with Domino LDAP for Sametime user directory)	Your decisions about Domino integration
• You already have a mature installation of Domino servers including Sametime or iNotes. Your Domino servers are upgraded to a release supported by WebSphere Portal Express. • You have newly installed WebSphere Portal Express or have the intention to deploy it. You may even have a mature portal site, but have not yet attempted to integrate it with your Domino installations. • You intend to integrate collaborative portlets, especially messaging portlets to support your existing Domino mail and calendar users. • You want the portlets to have online awareness features (your Domino users are accustomed to Sametime instant messaging), and you want users to be able to work in portlets without authentication other than logging into the portal (that is, you need the single sign-on feature).	Your environment is typical of many portal customers who have investments in both directories that must be maintained. See the following topics for tasks specific to reconciling directories: • "Auto-detecting user mail information from a secondary LDAP server" on page 964 • "People awareness" on page 959

Table 130. Use case: 1A + 2B + 2C

Multiple directory-type site (LDAP other than Domino for portal with a combination of other directories, most likely native Domino directory for Sametime	**Your decisions about Domino integration**
• You already have a mature installation of Domino servers including Sametime or iNotes. Your Domino servers are upgraded to a release supported by WebSphere Portal Express. • You have newly installed WebSphere Portal Express or have the intention to deploy it. You may even have a mature portal site, but have not yet attempted to integrate it with your Domino installations. • You have a native Domino Directory (non-LDAP) in active use. Sametime uses a native Domino Directory. • You intend to integrate collaborative portlets, especially messaging portlets, to support your existing Domino mail and calendar users. • You want the portlets to have online awareness features (your users are accustomed to Sametime instant messaging), and you want users to be able to work in portlets without authentication other than logging into the portal (that is, you need the single sign-on feature).	Your environment is typical of many customers with mature Domino installations and an investment in an extensive native Domino directory who want to integrate portal. To support SSO, you must reconcile authentication between user identifications in your native Domino directory and the portal LDAP directory. See the following topics for tasks specific to reconciling directories: • "Auto-detecting user mail information from a secondary LDAP server" on page 964 • "People awareness" on page 959

Related information:

WebSphere Portal hardware and software requirements

Platform and user directory considerations

There are unique considerations for operating systems that you should be aware of before you proceed with integrating collaboration software with WebSphere Portal Express. Also, in the context of collaboration integration, there are two types of user directories, Domino directory and then all other supported user directories.

Platform considerations

Depending upon platform, Domino servers in your environment have slightly different task and/or registry requirements:

- **All platforms:** Domino IIOP is used to pre-populate drop-down lists shown when users personalize the collaborative portlets.
- Windows: Any Domino data source servers must have HTTP, LDAP, and Domino IIOP enabled.
- Linux: Any Domino data source servers must have HTTP, LDAP, and Domino IIOP enabled.
- IBM i: Any Domino data source servers must have HTTP and Domino IIOP enabled, and must use an LDAP user registry.

User directory considerations

Directory considerations for Domino LDAP:

From the portal perspective, there are two types of Domino servers: the Domino server as a user repository (Domino Directory server as an LDAP server), and any Domino server that acts as a Domino data source for portlets: such a server is called a messaging/application server.

Because WebSphere Portal Express supports the use of Domino Directory as an LDAP server, you can set up the portal to use a Domino server as the user repository for users who access both the portal and any portlets that access Domino and collaboration products.

You can use a Domino server with LDAP enabled both as the user repository for the portal and for auto-detection of users' mail files, unless your portal user repository is so large that you want to use separate machines for performance reasons (see *Performance considerations*).

Directory considerations for Sametime :

If you will be using portlets for Domino and Sametime, the Sametime user directory can be any supported LDAP (including Domino) directory, or a native Domino directory. But it is recommended that Sametime use the same directory as the one configured for the portal, to avoid the additional configuration necessary to support both directories.

Security and user authentication considerations

Correctly configuring authentication and security includes configuring single sign-on and setting up SSL.

About security through SSL and other features

Whether your site includes single, dual, or multiple types of user directories, SSL is recommended, and you enable it the same way.

If your site will use IBM Security Access Manager or Computer Associates eTrust SiteMinder for additional security, set up such protection on servers in the following order: WebSphere Portal Express, Sametime, and then Domino servers. In addition, if you use eTrust SiteMinder, portlets such as Lotus Notes View will be unable to take advantage of features supported by DIIOP.

If your site will use Security Access Manager or another reverse proxy, or a load balancer, when installing Sametime, select the option "Allow HTTP Tunneling on a Sametime server with a single IP address." With this option selected, all Sametime client data, except A/V data, is tunneled to the Sametime server via HTTP on port 80. You also may need to enable this option if Sametime clients must connect to the server through a network that blocks TCP communications on ports 8081 and 1533.

About user authentication through Single Sign-On (SSO)

Single sign-on between the Domino environment and the portal environment allows users to log in to the portal, and then work in any of the collaborative portlets without having to authenticate a second time. Although enabling single

sign-on is not required to use all the collaborative portlets, it is strongly recommended as a way of improving the user experience. Lotus Notes View and iNotes require single sign-on support.

To support single sign-on, a Web SSO configuration document must exist for each Domino domain that includes Domino servers. The Web SSO configuration document is a domain-wide configuration document stored in the Domino Directory. This document, which you can replicate to all servers participating in the single sign-on domain, is encrypted for participating servers and administrators, and contains a shared secret key used by servers for authenticating user credentials.

In addition to the Web SSO configuration document for Domino servers, you must create, save, and export an LTPA key from WebSphere Application Server, and then import that WebSphere LTPA key into the Domino domain or domains. For each Domino domain that is set up for use with the portal, the same WebSphere LTPA key must be imported to support single sign-on. Verify that automatic LTPA key generation is disabled on each node of the single sign-on domain.

A best practice is to install and configure all servers prior to enabling single sign-on. For example, install and configure Sametime before you enable single sign-on.

If you complete the required single sign-on configuration between the Domino environment and portal environment, there is no procedure to disallow automatic login for a specific user. For example, if user A logs in to the portal, user A will always be logged in to the Domino environment.

Tip: Managing Single Sign-On and awareness when there are multiple types of directories. If there is an LDAP directory server other than Domino in place, for example IBM Directory Server, you could employ several strategies to integrate it with a native Domino Directory and therefore achieve single sign-on (SSO) and awareness across any collaborative portlets your organization uses. The Domino Directory Assistance functionality may provide a solution for name mapping across LDAP directories. Even when your organization, as a matter of policy, manages modifications primarily through an existing non-Domino LDAP directory, schema in the non-Domino directory can be customized and then work in concert with Directory Assistance, which can manage the name mapping for collaborative applications. For a number of creative multi-directory solutions, including information on supporting single-sign on for awareness through the Sametime servers if your organization uses it, see the IBM developerWorks article *Single Sign-on in a Multi-Directory World.*

Related information:

Single Sign-on in a Multi-Directory World

Integrating with IBM Sametime

Configuring the Sametime Community Server and Sametime portlets requires a set of tasks performed on both the Sametime Community Server and the portal server.

About this task

Important: Configuring a Sametime Community Server with secure socket layers (SSL) is not recommended when using a multiplexer server to manage traffic on the Sametime Community Server. If you configure SSL on the multiplexer,

WebSphere Portal Express will no longer be able to communicate through the multiplexer. For additional information, see Technote 1086354.

This topic lists the required procedures for configuring the Sametime Web 2.0 Contact List portlet to work with both the Sametime Community Server and the portal server:

Unless otherwise noted, all the procedures are required for all portlets.

1. "Sametime server installation reference"
   View a roadmap to instructions for installing an IBM Sametime server.
2. "Configuring Sametime Proxy" on page 957
   If IBM WebSphere Portal Express and IBM Sametime are both authenticating with the same LDAP server, SSO configuration is simple.
3. "People awareness" on page 959
   People awareness makes people's names appear as hyperlinks that users can click to display information about the individual and gain access to actions for contacting and working with him or her. If the administrator has configured an IBM Sametime server to work with WebSphere Portal Express, users can see each other's online presence in their person links according to the status options they have set in their Sametime client (for example, whether the person is active, away, offline, or does not want to be disturbed). The person's online status appears only if Sametime is enabled.

Related information:

Technote 1086354

Sametime server installation reference

View a roadmap to instructions for installing an IBM Sametime server.

About the Sametime server

A Sametime server is an IBM Domino server that has the Sametime server software installed and set up on it.

IBM WebSphere Portal Express is compatible with several releases of Sametime server software. Use the following links to locate the correct procedure for your platform and for the release of Sametime you intend to install. Documentation for specific releases and platforms is available on the IBM website for download and browsing. For information about the releases of Sametime supported for use with WebSphere Portal Express, see the *IBM WebSphere Portal Express detailed system requirements.*

The installation documentation covers the following basic tasks that you perform to complete a Sametime server before you begin to integrate it with your site:

- Install and set up the prerequisite underlying Domino server and its Domino Administrator client software.
- Install the Sametime server software.
- Set up the Sametime server software using a browser on the server home page.

Usage restrictions: You are authorized to install and use Domino Directory solely and exclusively with your use of Sametime. Consult the product license for details.

Where to find installation procedures

The IBM Lotus Documentation website lists all documentation for all releases of Sametime.

Table 131. Installation resources for recent Sametime releases

Platform	V8	V8.5	V9
Windows Linux	In the *IBM Sametime 8 documentation*, see Installing a Sametime server on Windows, AIX, Linux, or Solaris.	In the *IBM Sametime 8.5 documentation*, see Installing on AIX, Linux, Solaris, and Windows.	In the *IBM Sametime 9 documentation*, see the Deploying section. **Note:** Refer to the topics available in *Deploying instant messaging*. Details for each specific platform are available for each server installation option.
IBM i	In the *IBM Sametime 8 documentation*, see Installing Sametime server on i5/OS.	In the *IBM Sametime 8.5 documentation*, see Installing on IBM i.	

To install a Sametime proxy server, see *Installing a Sametime Proxy Server* in the Sametime documentation.

Critical choices for Sametime V8 in a WebSphere Portal Express site

The following table lists choices common to Sametime installation on most or all platforms, with recommendations for use of Sametime with WebSphere Portal Express. Because specific installation steps differ between platforms, the descriptions of the choices are general. Do not expect to see the exact wording of the choice when installing for your platform and release. The options that are highlighted in this table are a subset of all choices you make during installation; in general, if not specified, accept default options.

In addition, before installation, see the topic on planning for collaborative servers and portlets, which describes several common types of collaborative sites, and includes considerations that are related to platform, user directories, security, and performance.

Tip: Be sure to keep a record of all names and passwords you specify, and all directories where the installation programs installation software.

Table 132. Key decisions for Sametime V8 installation

Procedure	Decision point	Recommendations
Sametime server software installation	**Setting up the Directory Type** dialog box You can choose Domino Directory (this selection is known as *native*) or an LDAP server (which can be either a separate Domino LDAP server or other non-Domino LDAP server) as the repository for user authentication and management.	The people awareness features and the authentication features behave differently, depending on the directory you choose. • If you select Domino Directory, people awareness can display names in both the common name format and hierarchical name format. Configuring Sametime to use the native Domino Directory allows the most flexibility for people awareness. By default, Sametime searches the native Domino Directory first for user names. • If you choose an LDAP server, Sametime installs a Directory Assistance database (`da.nsf`). If directory assistance is used, multiple LDAP directories can be searched after Sametime queries the native Domino Directory. In addition, because Sametime searches the native Domino Directory first and external LDAP servers second, the Domino Directory on the Sametime server should contain only users that are for administering Sametime, not WebSphere Portal Express users. The Directory Assistance feature is useful in environments where the same users are not listed in both the LDAP directory and Domino Directory.

Sametime 8.5 requires the use of an LDAP directory for user authentication.

Sametime Product Page

WebSphere Portal detailed system requirements

Installing a Sametime Proxy Server

Configuring Sametime Proxy

If IBM WebSphere Portal Express and IBM Sametime are both authenticating with the same LDAP server, SSO configuration is simple.

Before you begin

1. Install WebSphere Portal Express and configure it with an LDAP.
2. Install and configure the IBM Domino 8.5.2 server.
3. Install and configure the Lotus Notes Administrator client.
4. Install the IBM Sametime server with the IBM Domino 8.5.2 server and configure the same LDAP you used with WebSphere Portal Express.
5. Install the Sametime Proxy server with the Sametime server. Configure it to work with the WebSphere Portal Express server.
6. Reboot the Sametime Proxy sever and the WebSphere Portal Express server.

Note: Only users in the LDAP will have awareness functions.

About this task

Use the following steps to configure WebSphere Portal with the Sametime Proxy server.

Procedure

Configuring Sametime single sign on to work with WebSphere Portal Express.

1. Install WebSphere Portal Express Version 8.5.
2. Log in to the IBM WebSphere Application Server Integrated Solutions Console and click **Security** > **Global Security**.
3. Click **Web and SIP security** > **Single Sign-on SSO**.
4. Set the single sign-on domain and save it to Master Configuration.
5. From the main Global Security page, click **LTPA**.
6. Enter a password for the token, then enter a path for the token.
7. Click **Export Keys** and then **OK**.
8. Save to Master Configuration.
9. Copy the key to the Sametime Proxy server machine.
10. Open the **Address Book** for the domain.
11. Open the **Web** > **Web Configuration** section. Open the **Web SSO Configuration** twistie and delete the existing token.
12. Click the **Configuration** tab. Click **Server** > **All Server documents**.
13. Open **Web** > **Web SSO Configuration**. The Web SSO Configuration for: page opens.
14. Open **Keys** > **Import WebSphere LTPA Key**.
15. Enter the path and password for the key you created. The key imports.
16. Set the domain starting with a period. For example, `.rtp.yourco.com`.

    Note: There must be a period at the beginning of the domain.

17. Choose the Domino server name from the twistie. Choose the **Domino Address Book** as the source.
18. Set the token format to `LtpaToken` and `LtpaToken 2`.
19. Click **Save and Close** to save the token.

Creating the Resource Environment Providers

20. Log in to the IBM WebSphere Application Server Integrated Solutions Console.
21. Click **Resources** > **Resource Environment Providers**.
22. Open the **WP CommonComponentConfigService** provider.
23. Create the following custom properties if the are not already created:

    cc.sametime.proxy.enabled
    Set the value to `true`.

    cc.sametime.proxy.scheme
    Set the value to `http` or `https`. It must match the way your Sametime Proxy Server is accessed.

    cc.sametime.proxy.host
    Set the value to the name of your server. For example, `hostname.domainname.com`.

    cc.sametime.proxy.port
    Set the value to the port of your server.

    cc.sametime.connect.client
    Set the value to `false`. If you set the value to true Sametime Proxy uses the Sametime connect client which is installed on Sametime Proxy server machine.

    cc.sametime.proxy.version
    Set the value to `9.0`.

    cc.sametime.proxy.includedock
    Set the value to `true` to show the Sametime web client dock.
24. Save to Master Configuration.
25. Log in to WebSphere Portal Express as a Sametime user.
26. Navigate to the page with the Sametime Web 2.0 Contact List portlet.
27. Edit the page properties and set the profile to the custom profile you created.
28. Log in as a user in the LDAP and open the page with the Sametime Web 2.0 Contact List portlet. Click **Applications** > **Collaboration** > **IBM Sametime**. The portlet shows that the user is online and you can use other Sametime Web 2.0 Contact List functions to see other online users.

Related tasks:

"Serving HTTP OPTIONS requests to the server context root by WebDAV clients" on page 1358
Some WebDAV clients send an HTTP OPTIONS request to the server context root (/) to check whether the server supports WebDAV. To support these clients, the portal provides a web application called `wp.webdav.options.war` that you can enable. This application responds to such requests with a confirmation that the portal supports WebDAV.

Related information:

Exporting Lightweight Third Party Authentication keys

People awareness

People awareness makes people's names appear as hyperlinks that users can click to display information about the individual and gain access to actions for contacting and working with him or her. If the administrator has configured an IBM Sametime server to work with WebSphere Portal Express, users can see each other's online presence in their person links according to the status options they have set in their Sametime client (for example, whether the person is active, away, offline, or does not want to be disturbed). The person's online status appears only if Sametime is enabled.

Note: Users who are not in an LDAP user registry do not have awareness and cannot see if other users are online. This can happen if you install your portal and then enable a Federated LDAP or Federated DB repository that does not contain that user. Also, users who sign up using the Self Care portlet do not have awareness.

User impersonation and people awareness: When a user who is enabled for impersonation impersonates other users, the people awareness feature is disabled for the entire session for which that user is authenticated.

Person card

Move the cursor over an active (underlined) name to see the **Click here for Person Card** option. The Person card displays business card details such as the email address, job title, and so on. Available actions display following the business card section.

Click **Profile** to display full information about the person including (by default) business card information, contact information, current job, and background. The information in the business card section is distinct from the set of information you can configure to appear from a person link, so you may choose to display different information about people in each of these contexts.

You can also customize how much information is displayed. For example, you can show just the business card fields by default and let users choose whether to expand the information shown to include contact information, job, and background fields. You can also configure how long the Person card displays.

Additional actions that are available on the Person card depend on whether Domino and collaboration products, the Lotus Collaborative Services, or both, are configured to work with WebSphere Portal Express. These actions can include:

- **Send Mail**

  Opens a new message in the preferred email client as specified in browser and operating system. This option appears only if the user has an email address.
- **Chat**

  Appears only if Sametime is enabled. This action is not available if the person is offline or has set status to "Do not disturb me."
- **Add as Sametime Contact**

  Appears only if Sametime is enabled. Action displays a window where a user can add the person to the contact list, as a member of a new or existing personal group. For more information about Sametime client features, see the Sametime documentation.

If you are using a screen reader, you can press Shift + Enter to see the Person card, and then press Tab to navigate through the available actions.

People awareness and the Person tag

People awareness in the form of online presence (names displayed as hyperlinks) is supported by Collaborative Services. In contexts where the Person card is available, the Person JSP tag provides contextual collaboration functionality that is related to a named person. The tag generates the HTML that renders both the actions to display on the Person card and the online presence state to display for that person, taking into account the Domino and collaboration product servers that are installed and enabled in the portal environment.

For more information on configuring a collaborative portal, see the topic on integrating Domino and the Extended Product Portlets into WebSphere Portal Express. When configuring collaboration, pay special attention to the Collaborative Services environment properties file, `CSEnvironment.properties`, which supports people awareness.

For details on the implementation of the Person tag, and instructions on customizing the tag for WebSphere Portal Express applications that you develop, see the Collaborative Services API topic.

"Configuring contact information on person links"
When users click a person link, the Person card displays contact information for the selected person. You configure this information by modifying custom properties in the WebSphere Integrated Solutions Console, specifying the Member Manager attributes that correspond to the fields you want to display in the contact information and the order in which you want the information to appear.

Related tasks:

"Setting display duration for the Person card" on page 3107
You can configure the Person card to display longer than the default number of milliseconds by modifying the `personTagTimeout` custom property in the WebSphere Integrated Solutions Console.

Related reference:

"People Finder" on page 928
The **People Finder** portlet provides both quick search and advanced search options for locating people and information about people. Once found, a person is visible to other users as a person link that indicates online presence and displays a menu of instant messaging and other options.

Related information:

Sametime documentation

Configuring contact information on person links:

When users click a person link, the Person card displays contact information for the selected person. You configure this information by modifying custom properties in the WebSphere Integrated Solutions Console, specifying the Member Manager attributes that correspond to the fields you want to display in the contact information and the order in which you want the information to appear.

Procedure

1. Select the appropriate console, depending on your environment:

- If you are running stand-alone, use the local WebSphere Integrated Solutions Console.
- If you are running in a cluster, use the console of the Deployment Manager.

2. Start the WebSphere Integrated Solutions Console by entering the URL in the location field of a web browser:

   `http://example.com:admin_port/ibm/console`

   where *example.com* is the name of your server and *admin_port* is the port that is assigned to the WebSphere Integrated Solutions Console.
3. In the navigation, click **Resources** > **Resource Environment** > **Resource Environment Providers**.
4. Locate and click the resource **WP PeopleService**.
5. Under Additional Properties, click **Custom Properties**.
6. Locate the custom properties **collapsedBCardItems** and **expandedBCardItems** and set each property's value to the Member Manager attributes that you want to display. The order in which you specify the attributes determines the order in which the corresponding information displays.

   collapsedBCardItems
   Identifies the items that the Person card displays when business card details are hidden from view. For example: `ibm-jobTitle`, `telephoneNumber`

   expandedBCardItems
   Identifies the items that the Person card displays when business card details are visible. For example: `ibm-primaryEmail`, `homePostalAddress`, `stateOrProvinceName`, `postalCode`, `countryName`

   The following Member Manager attributes are valid for specifying person link contact information:
   - businessCategory
   - carLicense
   - cn
   - countryName
   - departmentNumber
   - description
   - displayName
   - employeeNumber
   - employeeType
   - facsimileTelephoneNumber
   - givenName
   - homePostalAddress
   - ibm-gender
   - ibm-hobby
   - ibm-jobTitle
   - ibm-otherEmail
   - ibm-personalTitle
   - ibm-primaryEmail
   - ibm-regionalLocale
   - ibm-timeZone
   - Initials

- localityName
- manager
- mobile
- pager
- postalAddress
- postalCode
- preferredLanguage
- roomNumber
- secretary
- seeAlso
- sn
- stateOrProvinceName
- street
- telephoneNumber
- uid

7. Click **Apply** and then save the settings.
8. Restart the portal server.

Collaborative Services environment properties

If your collaborative site requires optional configuration that is not accomplished by the tasks that you run on the IBM WebSphere Portal Express server to integrate IBM Domino and the collaboration products, you can modify the operation of the collaborative servers and portlets in various ways by manually editing the Lotus Collaborative Services environment properties file (`CSEnvironment.properties`) on the WebSphere Portal Express server.

The file is installed in the following directory:

Windows
wp_profile_root`\PortalServer\config\config`

Linux *wp_profile_root*`/PortalServer/config/config`

IBM i *wp_profile_root*`/PortalServer/config/config`

This file contains the following information about the portal environment:

- A flag to indicate whether the Collaborative Services are being used within the portal context
- Location, protocol, port, and version of Domino Directory server
- Location, protocol, port, and version of IBM Sametime server for Sametime 8.5.1 or earlier
- Configuration and performance tuning settings specific to Collaborative Services
- A flag to indicate the type of token that is being used: **`lpta token`** or **`ltpa token2`**

"Editing the CSEnvironment.properties file" on page 963
To modify any Lotus Collaborative Services environment properties, you must stop the portal server, locate the file in a location specific to your platform, back up the file before editing it, use a text editor to open and modify it, and then restart the server.

"Auto-detecting user mail information from a secondary LDAP server" on page 964

You can set the Lotus Collaborative Services in the portal to detect users' mail file information from an additional (secondary) non-Domino LDAP user directory. For example, you may need to configure two directories if your organization has one for customers and one for employees.

"Customizing Collaborative Services user credentials for eTrust SiteMinder" on page 964
If you protect the portal and any of the Domino and Extended Products Portlets or Common Mail portlet with Computer Associates eTrust SiteMinder, you must set the Lotus Collaborative Services to use the eTrust SiteMinder token instead of the default LTPA token.

"Supporting automatic mail detection with an LDAP directory other than Domino" on page 965
If the LDAP directory configured for the portal and for Lotus Collaborative Services is not IBM Domino, and you want the automatic mail detection feature in Domino messaging portlets, you can modify the `CSenvironment.properties` file to support the feature.

"Tuning performance of the Domino Directory" on page 967
If you are using Domino Directory as the primary (and only) LDAP server for WebSphere Portal Express, you can set the following property in the `CSEnvironment.properties` file to false to improve the performance of Domino Directory.

"Using LtpaToken2 for user login" on page 967
By default, the credential settings in the `CSEnvironment.properties` file are set to use an LTPA token for user login. If your environment is configured with LtpaToken2 only, you must modify the `CSEnvironment.properties` file to use LtpaToken2 instead of LtpaToken.

Editing the CSEnvironment.properties file

To modify any Lotus Collaborative Services environment properties, you must stop the portal server, locate the file in a location specific to your platform, back up the file before editing it, use a text editor to open and modify it, and then restart the server.

Before you begin

About this task

Procedure

1. Stop the WebSphere_Portal server.
2. Open the `CSEnvironment.properties` file in a text editor. The file is located in the following directory:

   Windows: *wp_profile_root*`\PortalServer\config\config`

   Linux: *wp_profile_root*`/PortalServer/config/config`

   IBM i: *wp_profile_root*`/PortalServer/config/config`
3. Before making any changes, make a back up copy of the `CSEnvironment.properties` file.
4. Edit the `CSEnvironment.properties` file to include the appropriate values.
5. Remove the comment tag (#) from the beginning of each edited line.
6. Save the changes.
7. Start the WebSphere_Portal server.

Auto-detecting user mail information from a secondary LDAP server

You can set the Lotus Collaborative Services in the portal to detect users' mail file information from an additional (secondary) non-Domino LDAP user directory. For example, you may need to configure two directories if your organization has one for customers and one for employees.

Before you begin

The secondary LDAP directory server is specified for the property `CS_SERVER_DOMINO_DIRECTORY_1.custom_ldap_host`.

About this task

Modify the `CSEnvironment.properties` file.

The following example shows the syntax with comments.

```
# Optional advanced settings
# The following fields are disabled, by default.
# If it is enabled (determined by custom_ldap_host)
and a different server is specified,
# The following user information will be retrieved
from this secondary server.
# Mail Server,  Mail file and Email address
#
#CS_SERVER_DOMINO_DIRECTORY_1.custom_ldap_host=my.server.com
#CS_SERVER_DOMINO_DIRECTORY_1.custom_ldap_port=389
#CS_SERVER_DOMINO_DIRECTORY_1.custom_ldap_ssl=true
#CS_SERVER_DOMINO_DIRECTORY_1.custom_ldap_searchBase=base
```

Customizing Collaborative Services user credentials for eTrust SiteMinder

If you protect the portal and any of the Domino and Extended Products Portlets or Common Mail portlet with Computer Associates eTrust SiteMinder, you must set the Lotus Collaborative Services to use the eTrust SiteMinder token instead of the default LTPA token.

Before you begin

The following are custom credential settings with the possible values shown as variables:

```
CS_SERVER_CUSTOM_CRED.enabled=true/false
CS_SERVER_CUSTOM_CRED.useridAttribSource=header/cookie
CS_SERVER_CUSTOM_CRED.useridAttrib=useridAttribName
CS_SERVER_CUSTOM_CRED.ssoTokenAttribSource=header/cookie
CS_SERVER_CUSTOM_CRED.ssoTokenAttrib=tokenAttribName
```

About this task

The custom settings that you use for this task accomplish two goals:

- They override the logged in user's credentials through a custom user name, allowing mapping of principal user identities (fully qualified user names or DNs) between two LDAP directories. In this case, the *useridAttrib* setting is retrieved from the header.
- They override the logged in user's credentials with a custom SSO token that is generated from eTrust SiteMinder. In this case, the *tokenAttribName* setting is retrieved from the cookie.

Procedure

1. Make sure that WebSphere Portal Express, Domino, and Sametime are all configured properly so that eTrust SiteMinder can authenticate.
2. Modify the `CSEnvironment.properties` file.
3. In the **Collaborative services Credential Overrides** section, modify settings to match the following example, where *SMSESSION* is the name of the token that is generated by eTrust SiteMinder, and *SM_USERDN* is the same as the attribute passed by eTrust SiteMinder to Domino and Sametime.

   Tip: The attribute is usually *SM_USERDN*. Other common variations are *SM_NOTESDN*, *SM_USER*, or *SM_USERUID*. If the Domino servers in your site are already protected by eTrust SiteMinder, examine the eTrust SiteMinder WebAgent Configuration file (`WebAgent.conf`) on the Domino server and use the attribute that is specified in the field *dominoheaderforlogin*.

   ```
   CS_SERVER_CUSTOM_CRED.enabled=true
   # Valid values are header/cookie
   CS_SERVER_CUSTOM_CRED.useridAttribSource=header
   CS_SERVER_CUSTOM_CRED.useridAttrib=SM_USERDN
   # Valid values are header/cookie
   CS_SERVER_CUSTOM_CRED.ssoTokenAttribSource=cookie
   CS_SERVER_CUSTOM_CRED.ssoTokenAttrib=SMSESSION
   ```
4. Create new parameters for each instance of the Common Mail and Lotus Notes View portlets in your site. For more information, see the section on the **`AuthTokenName`** parameter for Lotus Notes View, and the section on the **`CPP_PassHttpCookies`** parameter for the Common Mail portlet.

Related tasks:

"Configuring eTrust SiteMinder to perform authentication" on page 1661
IBM WebSphere Portal Express includes a configuration task called `enable-sm-tai`. This task interacts with IBM WebSphere Application Server security configuration to enable the eTrust SiteMinder TAI and to create it as one of the interceptors. You can configure eTrust SiteMinder to provide authentication independently from configuring it to provide authorization. Using it to perform authorization only is not supported at this time.

Supporting automatic mail detection with an LDAP directory other than Domino

If the LDAP directory configured for the portal and for Lotus Collaborative Services is not IBM Domino, and you want the automatic mail detection feature in Domino messaging portlets, you can modify the `CSenvironment.properties` file to support the feature.

Procedure

1. Modify the `CSEnvironment.properties` file.
2. Enable the lines under the Mail server and Mail File Queries section. The following example shows the syntax with comments.

   ```
   # Mail server and Mail File Queries:
   #CS_SERVER_DOMINO_DIRECTORY_1.
   mailfileserver_objectclass=person
   #CS_SERVER_DOMINO_DIRECTORY_1.
   mailserver_attrib=mailserver
   #CS_SERVER_DOMINO_DIRECTORY_1.
   mailfile_attrib=mailfile
   # Email Address query
   CS_SERVER_DOMINO_DIRECTORY_1.
   email_objectclass=person
   CS_SERVER_DOMINO_DIRECTORY_1.
   email_attrib=internetaddress
   ```

Note: If adding the mailserver attribute to a non-Domino LDAP server and Lotus Collaborative Services is configured with this server, make sure that this attribute is in the fully qualified distinguished name `my.server.com` format.

3. To enable the `CS_SERVER_DOMINO_DIRECTORY_1.mailserver_attrib` and `CS_SERVER_DOMINO_DIRECTORY_1.mailfile_attrib` attributes for the primary non-Domino LDAP directory that is configured for your portal site, add the following entry:

   ```
   CS_SERVER_DOMINO_DIRECTORY_1.primary_ldap_custom_attribute_enabled=true
   ```

   Note: By default, these attributes are used only if your portal configuration uses a custom LDAP directory, but adding the previous command line allows them to be used for a non-Domino LDAP.

4. Enable the following section in the file, specify your Domino LDAP for `CS_SERVER_DOMINO_DIRECTORY_1.hostname`, and make sure that there is no return character after the equal sign on that line:

   ```
   ############################################################
   #
   # DOMINO DIRECTORY properties
   # (LDAP server)
   # Important:
   # Should always point to a Domino Server.
   # Leave enabled flag as true.
   # Use the custom_ldap_* settings to point
    to any LDAP Server to
   # get user information.
   ############################################################

   CS_SERVER_DOMINO_DIRECTORY.enabled=true
   CS_SERVER_DOMINO_DIRECTORY_1.hostname=
   yourserver.yourdomain.com
   CS_SERVER_DOMINO_DIRECTORY_1.port=389
   CS_SERVER_DOMINO_DIRECTORY_1.ssl=false
   CS_SERVER_DOMINO_DIRECTORY_1.anonymous=true
   ```

5. Copy and paste the following section into the file directly following the section in the previous step, and enable it. If there are return characters that follow the equal signs or anywhere else in the middle of each statement, remove them.

   ```
   ########################################################
   # dual directory settings
   ########################################################

   CS_SERVER_DOMINO_DIRECTORY_1.searchBase=O=DominoPortal

   # In the following queries
   #   %c = common name
   #   %d = ldap dn
   #  %n = fq notes name
   #  %v = the first item in the id like "cn=jane doe" or "uid=jdoe"

   #CS_SERVER_DOMINO_DIRECTORY_1.query_base_search=(objectclass=*)

   #CS_SERVER_DOMINO_DIRECTORY_1.query_distinguished_name=
   (& (objectclass=person) (|(uid=%c)(cn=%c)))
   #CS_SERVER_DOMINO_DIRECTORY_1.query_distinguished_name_attrib=cn

   #CS_SERVER_DOMINO_DIRECTORY_1.query_domino_servers=
   (&(objectclass=dominoServer)(http-hostname=*))
   #CS_SERVER_DOMINO_DIRECTORY_1.query_domino_servers_attrib=
   http-hostname

   #CS_SERVER_DOMINO_DIRECTORY_1.query_http_host_name=
   (| (& (objectclass=server)(%v) ) (& (objectclass=dominoServer)(%v) ) )
   #CS_SERVER_DOMINO_DIRECTORY_1.query_http_host_name_attrib=
   http-hostname

   #CS_SERVER_DOMINO_DIRECTORY_1.query_last_resort=
   (| (& (objectclass=person)(%v) ) (& (objectclass=groupOfNames)(%v) )
   ```

```
(& (objectclass=server)(%v) )(& (objectclass=dominoServer)(%v) ))

CS_SERVER_DOMINO_DIRECTORY_1.query_user_emailaddr=
(&(objectclass=person)(cn=%c))
#CS_SERVER_DOMINO_DIRECTORY_1.query_user_emailaddr_attrib=
internetaddress

CS_SERVER_DOMINO_DIRECTORY_1.query_user_mailserverfile=
(&(objectclass=person)(cn=%c))
#CS_SERVER_DOMINO_DIRECTORY_1.query_user_mailserverfile_attrib=
mailserver,mailfile

#  %l = login name
#  %a = wmm attribute use with CS_SERVER_DOMINO_DIRECTORY_1.other_lookup_attribute

CS_SERVER_DOMINO_DIRECTORY_1.allow_dn_search=false
CS_SERVER_DOMINO_DIRECTORY_1.other_lookup_attribute=ibm-primaryEmail
CS_SERVER_DOMINO_DIRECTORY_1.query_user=(&(objectclass=person)(mail=%a))
```

6. Save the properties file.

Tuning performance of the Domino Directory

If you are using Domino Directory as the primary (and only) LDAP server for WebSphere Portal Express, you can set the following property in the `CSEnvironment.properties` file to false to improve the performance of Domino Directory.

About this task

Modify the `CSEnvironment.properties` file to change the following setting:

```
CS_PERF_PROP_USEWMM.enabled=true
```

Using LtpaToken2 for user login

By default, the credential settings in the `CSEnvironment.properties` file are set to use an LTPA token for user login. If your environment is configured with LtpaToken2 only, you must modify the `CSEnvironment.properties` file to use LtpaToken2 instead of LtpaToken.

About this task

Note: If your environment uses both tokens (LtpaToken and LtpaToken2), you do not need to change this setting in `CSEnvironment.properties`

Procedure

1. Modify the `CSEnvironment.properties` file.
2. To override the default LtpaToken setting and use LtpaToken2 instead, change the following setting to the value shown:

   ```
   CS_SERVER_WEBSPHERE_PORTAL_EXTEND.credential_type=LtpaToken2
   ```

Integrating business processes

Access relevant tasks and activities for multiple business process management solutions from a single user interface. The Unified Task List portlet provides a single point of integration between multiple systems and displays tasks that WebSphere Portal Express users must complete to advance workflows. The topics in this section provide information and instructions for developing and customizing the Unified Task List.

Unified Task List Portlet features a service provider layer that accesses, retrieves, and formats workflow events from a back-end system. The service provider layer

is coupled with a presentation layer that renders the data in a visually appealing user interface. The separation of the service layer and the presentation layer lets you develop, test, and deploy your own customized Unified Task List in a way that conforms with service-oriented architecture.

The Unified Task List portlet can be found on the Collaborations page of WebSphere Portal Express.

Note: If Unified Task List is deployed in clustered environment, there is no need to repeat any configuration steps on the secondary nodes.

"Overview of the Unified Task List portlet"
Review concepts about the Unified Task List portlet to understand the different elements.

"Configuring the Unified Task List portlet" on page 969
You can configure the Unified Task List portlet to retrieve tasks from IBM Forms Experience Builder, WebSphere Lombardi Edition, andIBM Business Process Manager.

"Configuring Unified Task List portlet with process servers" on page 976
You can configure specific process servers to run tasks in the Unified Task List portlet.

"Configuring the Unified Task List portlet with IBM Forms Experience Builder" on page 977
This task provider retrieves tasks from IBM Forms Experience Builder and surfaces them in the Unified Task List portlet.

Overview of the Unified Task List portlet

Review concepts about the Unified Task List portlet to understand the different elements.

"Task providers" on page 969
Task providers are services that access back-end systems to retrieve tasks. The task providers also use a Web Experience Factory Transform builder to provide a uniform data set that displays in the Unified Task List user interface.

"Task provider instance" on page 969
Task provider instances are services that access back-end systems to retrieve tasks. Task provider instances reside in the Task Provider Instance Registry (TPIR) and contain the parameters that you specify in task providers.

"Task Provider Instance Registry" on page 969
The Task Provider Instance Registry (TPIR) contains task provider instance configurations. A task provider instance configuration contains a set of parameters that are required to connect to a back-end system. It also contains a unique ID to map the parameters to the appropriate task provider. The Task Provider Instance Registry service is in IBM WebSphere Application Server and stores the task provider configurations in an XML variable. The Task Provider Instance Registry service also provides a service to get and modify task provider instances.

"Task dispatcher" on page 969
The task dispatcher acts as a link between the Unified Task List portlet and the task providers. When an action occurs in the portlet, the task dispatcher retrieves task provider instance configurations from the task provider instance registry service and calls a `getTaskList` service operation on each task provider instance configuration.

"Task handler" on page 969
Task handlers define what the Unified Task List portlet does when users select

a task to advance a workflow. The task handlers determine how the Unified Task List portlet connects to the tasks that the users must complete.

Task providers

Task providers are services that access back-end systems to retrieve tasks. The task providers also use a Web Experience Factory Transform builder to provide a uniform data set that displays in the Unified Task List user interface.

You can create multiple task providers to aggregate tasks from several back-end systems. For example, you can create a task provider to access, retrieve, and format tasks from a particular back-end system. You can then create another task provider to access, retrieve, and format tasks from a different back-end system. The result of these two task providers is that a single set of tasks displays in the user interface, but originate from two different back-end systems.

Task provider instance

Task provider instances are services that access back-end systems to retrieve tasks. Task provider instances reside in the Task Provider Instance Registry (TPIR) and contain the parameters that you specify in task providers.

Task Provider Instance Registry

The Task Provider Instance Registry (TPIR) contains task provider instance configurations. A task provider instance configuration contains a set of parameters that are required to connect to a back-end system. It also contains a unique ID to map the parameters to the appropriate task provider. The Task Provider Instance Registry service is in IBM WebSphere Application Server and stores the task provider configurations in an XML variable. The Task Provider Instance Registry service also provides a service to get and modify task provider instances.

Task dispatcher

The task dispatcher acts as a link between the Unified Task List portlet and the task providers. When an action occurs in the portlet, the task dispatcher retrieves task provider instance configurations from the task provider instance registry service and calls a `getTaskList` service operation on each task provider instance configuration.

You can configure the Unified Task List portlet to use a cached task dispatcher if you do not want to access the back-end systems each time an action occurs in the user interface. The cached task dispatcher uses dynamic caching in WebSphere Application Server to store and retrieve tasks.

Task handler

Task handlers define what the Unified Task List portlet does when users select a task to advance a workflow. The task handlers determine how the Unified Task List portlet connects to the tasks that the users must complete.

Front-end developers can customize the Unified Task List portlet in Web Experience Factory if you want to provide functions for completing tasks. For example, if there is a task to approve or deny a request in a Human Resources workflow, you can use Web Experience Factory builders to provide a simple menu with approve and deny actions.

Configuring the Unified Task List portlet

You can configure the Unified Task List portlet to retrieve tasks from IBM Forms Experience Builder, WebSphere Lombardi Edition, andIBM Business Process Manager.

"Configuring Unified Task List portlet for single sign-on"
Set up a single sign-on between IBM Process Server, IBM Forms Experience Builder, WebSphere Lombardi Edition, IBM Business Process Manager and WebSphere Portal Express. Single sign-on (SSO) provides a secure method of authenticating a user within an environment and applies that authentication to access other applications, systems, and networks for the duration of the session.

"Configuring Unified Task List portlet at run time"
You can customize the Unified Task List portlet at run time as a WebSphere Portal Express administrator. Customizing at run time involves accessing the deployed Unified Task List to configure the portlet settings.

Configuring Unified Task List portlet for single sign-on

Set up a single sign-on between IBM Process Server, IBM Forms Experience Builder, WebSphere Lombardi Edition, IBM Business Process Manager and WebSphere Portal Express. Single sign-on (SSO) provides a secure method of authenticating a user within an environment and applies that authentication to access other applications, systems, and networks for the duration of the session.

About this task

In the context of the Unified Task List portlet single sign-on enables communication between WebSphere Portal Express, Process Server, IBM Forms Experience Builder, WebSphere Lombardi Edition Server and IBM Business Process Manager . Because the single sign-on and LTPA configuration settings are WebSphere Application Server security settings, it can be applied to any server that runs on WebSphere Application Server .

Visit the WebSphere Application Server documentation for details on how to configure single sign-on and LTPA between two WebSphere Application Server.

Configuring Unified Task List portlet at run time

You can customize the Unified Task List portlet at run time as a WebSphere Portal Express administrator. Customizing at run time involves accessing the deployed Unified Task List to configure the portlet settings.

"Accessing the configuration view" on page 971
Customize the Unified Task List portlet by accessing the configuration view. The configuration view contains several windows that let you perform tasks such as editing settings, configuring task provider instances and task handlers, or adding and removing filters.

"Editing common settings" on page 971
Edit common settings from the Unified Task List portlet.

"Adding and removing filters" on page 972
Filters provide specialized views for tasks. Filters let you separate tasks according to the back-end systems where the tasks originate or by a particular context. When you add filters, the Unified Task List portlet displays tasks separated according to the task provider instance. For example, you can add a filter for tasks that come from IBM Process Server portlet so that these tasks are not displayed with all other tasks in the Unified Task List portlet.

"Localizing the task list filters" on page 973
When creating new filters, it is recommended that you know before hand which filters you need to create and then create filters all at once. Creating all filters at once minimizes the times you must restart the server. The restart is required to update the filter resource bundles on the file system with the new

filters and include them on the class loader. A WebSphere Application Server variable must also be created to define the name of the resource bundle to use for the localized filters.

"Exposing the Business Processes to enable Task Handling Configuration" on page 974
To enable task handling configuration data to be retrieved for the Unified Task List BPM task provider you must first expose your Business Process and Human Service data to all users. This section is only applicable if you are working with the IBM Business Process Manager task provider in the Unified Task List.

"Showing and hiding table columns" on page 974
The Unified Task List portlet shows tasks in a table. The task information presented in this table includes priority, description, owner, among others. You can show or hide these table columns.

"Editing shared settings" on page 974
The Unified Task List portlet has shared settings that are common to all users, such as the filters that display in the user interface. You can edit these settings by accessing the portlet menu.

"Changing the number of rows in the task list table" on page 975
The task list table contains rows of tasks that users can select. You can edit the task list table to display a specific number of rows per page in the Unified Task List portlet. You can specify any number of rows per page, however, if there are fewer tasks than the number of rows available, the Unified Task List portlet displays only the rows that contain tasks. If there are more tasks than the number of rows available, the Unified Task List portlet displays a link to another page for those tasks.

"Configuring dynamic user interface" on page 975
Create a dynamic page and register it using the ConfigEngine.

Accessing the configuration view:

Customize the Unified Task List portlet by accessing the configuration view. The configuration view contains several windows that let you perform tasks such as editing settings, configuring task provider instances and task handlers, or adding and removing filters.

About this task

Accessing the configuration view involves clicking the portlet menu icon from the Unified Task List portlet.

Procedure

1. Log in to WebSphere Portal Express with either as an administrator or a user assigned to the Manager role for the Unified Task List portlet.
2. Navigate to the Unified Task List portlet.
3. Hover the cursor over the Unified Task List portlet title bar to access the portlet menu and select Configure.

Editing common settings:

Edit common settings from the Unified Task List portlet.

Procedure

1. Log in to WebSphere Portal Express with administrative access to the Unified Task List portlet.
2. Access the Unified Task List configuration view and select Common Settings, which is in the navigation pane. The Common Settings window opens.
3. Provide values for the following fields to configure the common settings:

   Show Menu
   Select this check box to display the filter menu in the Unified Task List. The filter menu displays a list of filters that segregate tasks from multiple back-end systems.

   Enable Claim-Release of Tasks
   Select this check box to let users perform claim and release operations on tasks. Users perform claim and release operations in the Unified Task List through the use of the Claim and Release buttons in the user interface. When users select a task and click **Claim**, they take ownership of the task and remove the task from the list of shared tasks. When users select a task and click **Release**, they no longer claim ownership of the task. The task then returns to the list of shared tasks. Users can also perform claim and release operations through the drag-and-drop menu that is displayed in the user interface.

   Enable Business Card Integration
   Select this check box to show user details when hovering over the owner or originator in a task list. The Unified Task List uses the people-awareness features in WebSphere Portal Express to retrieve the user details from the corresponding profile pages. To show user awareness of the owner or originator in a task list, you must configure a IBM Sametime server to interact with the WebSphere Portal Express Server.

   Use Dynamic Cache
   Select this check box to store and retrieve tasks in the WebSphere Application Server dynamic cache service. When using the WebSphere Application Server dynamic cache service, the task dispatcher stores and retrieves tasks in the cache for faster task loading.

   Dynamic Page Extension Node UID
   This field is required if you have task handlers that use dynamic pages for task completion. Specify the ID for the dynamic page extension node in WebSphere Portal Express. Leave the default value in this field if you do not have task handlers that use dynamic pages.
4. Click **Save** and **Back** to return to the main portlet page.

Adding and removing filters:

Filters provide specialized views for tasks. Filters let you separate tasks according to the back-end systems where the tasks originate or by a particular context. When you add filters, the Unified Task List portlet displays tasks separated according to the task provider instance. For example, you can add a filter for tasks that come from IBM Process Server portlet so that these tasks are not displayed with all other tasks in the Unified Task List portlet.

Adding filters:

Procedure

1. Log in to WebSphere Portal Express with administrative access to the Unified Task List portlet.
2. Access the Unified Task List portlet configuration view and select **Filters** from the navigation menu. The **Filters** window opens.
3. Select **Add**.
4. Enter a name for the filter in the **Name** field.
5. In the **Resource Key** field enter a resource key.
6. From the list select the task provider instances to include in the filter.

   Note: You can apply the filter to multiple task provider instances. Select the add icon to add additional task provider instances.
7. Select **Submit**.
8. Select **Save**.

Removing filters:
Procedure

1. Log in to WebSphere Portal Express with administrative access to the Unified Task List portlet.
2. Access the Unified Task List portlet configuration view and select **Filters** from the navigation menu. The **Filters** window opens.
3. Select the filter that you want to remove then select **Remove**.
4. Select **Save**.

Localizing the task list filters:

When creating new filters, it is recommended that you know before hand which filters you need to create and then create filters all at once. Creating all filters at once minimizes the times you must restart the server. The restart is required to update the filter resource bundles on the file system with the new filters and include them on the class loader. A WebSphere Application Server variable must also be created to define the name of the resource bundle to use for the localized filters.

Procedure

1. Access the WebSphere Integrated Solutions Console.
2. Navigate through **Resources** > **Resource Environment** > **Resource environment providers** > **WP ConfigService** > **Custom properties**.
3. Click **New**.
4. Enter `processintegration.filtersetresourcebundle` in the **Name** field.
5. Enter the name of your resource bundle in the **Value** field including the complete package name. For example: If your file is stored under `shared/app/`*`your_company`*`/filterlocales_en.properties` you would enter *`your_company`*`.filterlocales`.
6. Click **Apply**.
7. Click **OK** and then **Save to the master configuration**.
8. Place your resource bundles in the `shared/app/`*`your_company`* directory.
9. Restart the portal server.
10. Open the filter configuration page of the Unified Task List portlet and add the new filters as they were entered in the English version of the resource bundle.

The **Name** field must match the value of the resource key and the **Resource key** field must match the key used for the property in the resource bundle.

Exposing the Business Processes to enable Task Handling Configuration:

To enable task handling configuration data to be retrieved for the Unified Task List BPM task provider you must first expose your Business Process and Human Service data to all users. This section is only applicable if you are working with the IBM Business Process Manager task provider in the Unified Task List.

Procedure

1. Access the Business Process Designer for BPM and open a Business Process.
2. Select the **Overview** tab.
3. Under the section title **Exposing** click the **Select** button for the **Expose to start** field.
4. From the list of **Participant Groups** select the entry which is most appropriate for this Business Process. Either select **All Users** or the group where the Unified Task List administrative user is a member.
5. Repeat steps 3 and 4 for the **Expose business data** and **Expose performance metrics** fields.
6. Click **Save**.
7. Open the first **Human Service in the Business Process**.
8. Open the **Overview** tab.
9. Under the **Exposing** section click the **Select** button for the **Expose to start** field.
10. Select the appropriate group from the list of **Participant Groups**.
11. Click **Save**.
12. Repeat steps 8-11 for each Human Service in the Business Process.
13. Repeat steps 2-12 for each Business Process in the Designer.

Showing and hiding table columns:

The Unified Task List portlet shows tasks in a table. The task information presented in this table includes priority, description, owner, among others. You can show or hide these table columns.

Procedure

1. Log in to WebSphere Portal Express with administrative access to the Unified Task List portlet.
2. Access the Unified Task List portlet configuration view and select **Table Customizer**from the navigation pane. The **Table Customizer** window opens and a list of all the available columns.
3. Select either **Show** or **Hide** for the appropriate columns.
4. Select **Save**.

Editing shared settings:

The Unified Task List portlet has shared settings that are common to all users, such as the filters that display in the user interface. You can edit these settings by accessing the portlet menu.

Procedure

1. Log in to WebSphere Portal Express with administrative access to the Unified Task List portlet.
2. From the main page of the Unified Task List portlet, hover the cursor over the title bar to access the portlet menu and select **Edit Shared Settings**. The **Configure List of Visible Filters** window opens.
3. Select a filter from the list to add to the shared settings and click **Save**. It is possible to add multiple filters to the shared settings by selecting the **add icon**, which is parallel to the list.
4. Select the **remove icon**, which is parallel to the filter name in the **Available Filters** list to remove filters from the shared settings and click **Save**.

Changing the number of rows in the task list table:

The task list table contains rows of tasks that users can select. You can edit the task list table to display a specific number of rows per page in the Unified Task List portlet. You can specify any number of rows per page, however, if there are fewer tasks than the number of rows available, the Unified Task List portlet displays only the rows that contain tasks. If there are more tasks than the number of rows available, the Unified Task List portlet displays a link to another page for those tasks.

Procedure

1. Log in to WebSphere Portal Express with administrative access to the Unified Task List portlet.
2. From the main page of the Unified Task List portlet, hover the cursor over the title bar to access the portlet menu and select **Personalize**. The **User Interface Settings** window opens.
3. In the **Paging Size** field, enter the number of rows that you want to display per page in the task list table.
4. Select **Save**.

Configuring dynamic user interface:

Create a dynamic page and register it using the ConfigEngine.

Procedure

1. Create a page, give it a unique ID, such as `wps.utl`, and place the Unified Task List portlet on the new page.
2. Create the dynamic page template and give it a unique ID. Make sure that the page is set to inherit parent theme in the page options.
3. Open a command prompt.
4. Change to the `IBM\WebSphere\wp_profile\ConfigEngine` directory.
5. Enable the Unified Task List portlet page to start dynamic pages by running the following command:
   - Linux: `./ConfigEngine.sh action-enable-page-as-extension-node-wp.dynamicui.config -DPageUniqueName=wps.utl`
   - Windows: `ConfigEngine.bat action-enable-page-as-extension-node-wp.dynamicui.config -DPageUniqueName=wps.utl`
   - IBM i: `ConfigEngine.sh action-enable-page-as-extension-node-wp.dynamicui.config -DPageUniqueName=wps.utl`

Where **-DPageUniqueName** is the value of the unique ID you previously specified.

Configuring Unified Task List portlet with process servers

You can configure specific process servers to run tasks in the Unified Task List portlet.

The following process servers can be configured with the Unified Task List portlet:

- WebSphere Lombardi Edition.
- IBM Business Process Manager.

"Configuring a WebSphere Lombardi Edition process server"
This specific provider surfaces tasks for WebSphere Lombardi Edition in the Unified Task List portlet.

"Configuring an IBM Business Process Manager process server"
This task provider retrieves tasks from IBM Business Process Manager and surfaces them in the Unified Task List portlet.

Configuring a WebSphere Lombardi Edition process server

This specific provider surfaces tasks for WebSphere Lombardi Edition in the Unified Task List portlet.

Procedure

1. Open the applications menu and go to **Collaboration** > **Unified Task List**.
2. Open the page with the Unified Task List portlet on it.
3. Configure the Unified Task List portlet to add task provider instances for WebSphere Lombardi Edition. For more information, see *Configuring a WebSphere Lombardi Edition task provider instance* in the related links.
4. Create a task handler for the process instances of IBM Business Process Manager. For more information, see *Adding and removing task handlers* in the related links.
5. Open the applications menu and go to **Collaboration** > **Unified Task List**.
6. Add the Coach portlet to the Unified Task List page.
7. Configure the Coach portlet with host name and port number of the Lombardi server. For more information, see *Configuring the Coach portlets* in the related links.
8. Add wires to link the Coach portlet and theUnified Task List portlet. For more information on adding wires, see *Adding a wire* in the related links.
9. Claim a Lombardi task and then select it to start the process instance in the Coach portlet.

Configuring an IBM Business Process Manager process server

This task provider retrieves tasks from IBM Business Process Manager and surfaces them in the Unified Task List portlet.

Procedure

1. Open the applications menu and go to **Collaboration** > **Unified Task List**.
2. Open the page with the Unified Task List portlet on it.
3. Configure the Unified Task List portlet to add task provider instances for Business Process Manager. For more information, see *Configuring an IBM Business Process Manager task provider instance* in the related links.

4. Create a task handler for the process instances of Business Process Manager. For more information, see *Adding and removing task handlers* in the related links.
5. Open the applications menu and go to **Collaboration** > **Unified Task List**.
6. Add the Coach portlet to the Unified Task List page.
7. Configure the Coach portlet with host name and port number of the Business Process Manager server. For more information, see *Configuring the Coach portlets* in the related links.
8. Add wires to link the Coach portlet and theUnified Task List portlet. For more information on adding wires, see *Adding a wire* in the related links.
9. Claim a Business Process Manager task and then select it to start the process instance in the Coach portlet.

Configuring the Unified Task List portlet with IBM Forms Experience Builder

This task provider retrieves tasks from IBM Forms Experience Builder and surfaces them in the Unified Task List portlet.

Procedure

1. Open the page with the Unified Task List portlet on it.
2. Configure a Forms Experience Builder task provider instance. For more information, see *Configuring an IBM Forms Experience Builder task provider instance* in the related links.
3. Configure a Forms Experience Builder task handler. For more information, see *Adding and removing task handlers* in the related links.
4. Add theForms Experience Builder portlet to the Unified Task List page.
5. Configure theForms Experience Builder portlet.
6. Add a wire to link the Forms Experience Builder portlet and the Unified Task List portlet. For more information on adding wires, see *Adding a wire* in the related links.

Integrating with web applications

The web application bridge uses reverse proxy technology to integrate web-based content providers, such as the Microsoft SharePoint server, with IBM WebSphere Portal Express. Administrators must first define the virtual web applications or content providers. A lightweight iFrame portlet renders the content from the backend applications. Users can then access the iFrame on a page without requiring direct network access to the backend application. A special engine maps Uniform Resource Identifier (URIs) on the iFrame portlet to real URIs from the content providers.

The intention of the Web Applications Bridge is to support the complex and heterogeneous web applications. Ensure that the web applications are constructed with common practices and function according to industry accepted standards. Since there are no rigorous industry standards, it is impossible to verify that the Web Application Bridge can work with any arbitrary web application. You might need to customize the Web Application Bridge or change the web application to ensure success. The Web Applications Bridge was designed to integrate Microsoft Sharepoint into your website. However, you can integrate with other products. The Web Application Bridge is routinely enhanced to support integration with other products and systems per demand.

For those web applications that do not comply or are unable to work correctly, modify the application to support the integration through the Web Application Bridge. In cases where the application cannot be modified to comply with the Web Application Bridge, add custom filters to the Web Application Bridge to process the markup. Take care when you implement these filters for performance and reliability. The customer makes the customization themselves. When you use the Web Application Bridge, access WebSphere Portal Express with the fully qualified host name.

Integrating the web applications with WebSphere Portal Express is a multistep process. To learn more about the web application bridge, go to Web application bridge.

CF03 Mobile support is provided for web applications that were developed and tested for rendering inside mobile device browsers. If the web application was originally built and tested for desktops, they will not work properly on a mobile device. Instead, they display the same way that they would on the desktop. If the web application provides navigation, content, and features for a mobile device, it is available when rendered through the Web Dock portlet.

CF03 Configure the Web Dock portlet to always allow dynamic size. This setting allows the screen to respond to the different sizes of the applications. If you do not have Dynamic Size set to always, the Web Dock portlet shows the desktop version of the content.

Note: CF03 Mobile devices might not show scroll bars for any overflow content. Instead, the swipe feature of the mobile is enabled.

"Configuring the web application bridge for anonymous login"
You can map your web application bridge to allow anonymous users to log on and access information.

"Configuring multiple web dock applications on a page" on page 980
You can have multiple web dock applications that point to different hosts on the same portal page. You can also allow users to open two different portal pages that contain web dock applications in a new browser window or tab.

"Troubleshooting the web application bridge" on page 981
The troubleshooting information is useful for planning and implementing your web application bridge integration (WAB).

Related tasks:

"Providing short vanity URLs" on page 2101
You might want to make your vanity URLs as short and simple as possible for your customers. You can create vanity URLs that contain only the vanity segment by omitting the string `/wps/vanityurl`. In this case, you must use a web server and define a rewrite rule. If you also use IBM Web Application Bridge, or if you have static files in the root of the HTTP server document directory, adapt the rewrite rule.

Related information:

OpenAjax.hub.publish(name, publisherData)

Configuring the web application bridge for anonymous login

You can map your web application bridge to allow anonymous users to log on and access information.

Procedure

1. Complete the following steps to set the IBM WebSphere Portal Express security:
   a. Log in to the WebSphere Integrated Solutions Console.
   b. Go to **Applications** > **Application Types** > **WebSphere enterprise applications**.
   c. Select **wp.vwat.servlet.ear**.
   d. Select **Security role to user/group mapping**.
   e. Select **All Role** check box.
   f. Select **Everyone** from the **Map Special Subjects** menu.
   g. Click **OK**.
   h. Save your changes.
   i. Go to **Security** > **Global Security** > **Web and SIP Security**.
   j. Click **General Settings**.
   k. Select the **Use available authentication data when an unprotected URI is accessed** check box.
   l. Click **OK**.
   m. Save your changes.
   n. Log out of the WebSphere Integrated Solutions Console.
   o. Restart WebSphere Portal Express.
2. Log on to WebSphere Portal Express.
3. To open the **Manage Pages** portlet, click the **Administration menu** icon. Then, click **Portal User Interface** > **Manage Pages**.
4. Click **Content Root** > **Home**.
5. Click **New page** and create a page for your web application. For this example, the new page is called TestPage.
6. Complete the following steps to give the page anonymous user access:
   a. Click the **Administration menu** icon. Then, click **Access** > **Resource Permissions**.
   b. Select **Pages** as the resource type.
   c. Locate the page that you created. For example, go to **Resource Type** > **Pages** > **Content Root** > **Home** > **TestPage**.
   d. Select **Assign access**.
   e. Click **Edit Role** corresponding to the user.
   f. Click **Add**.
   g. Select **Anonymous Portal User**.
   h. Click **Apply**.
7. Complete the following steps to give the web dock application anonymous user access:

   Note: Configure anonymous user access for each web dock application that you create.
   a. Click the **Administration menu** icon. Then, click **Access** > **Resource Permissions**.
   b. Select **Portlets** as the resource type.
   c. Locate the web dock application.
   d. Select **Assign access**.
   e. Click **Edit Role** corresponding to the user.

f. Click **Add**.
g. Select **Anonymous Portal User**.
h. Click **Apply**.

8. Add the web dock application to the page.

   Tip: To get the web dock application to render on a page, the page must either have the **Web Dock** profile or a profile that includes the wp_webdock module. Edit the page properties and change the profile or add the wp_webdock module to the profile applied to the page:

   CF03 Starting with CF03, the Web Dock profile no longer exists. If you are using the Resource Aggregator for Portlets, no additional steps are necessary. If you are not using the Resource Aggregator for Portlets, add the **wp_webdock** module to an existing profile on your page.

   a. Connect to the theme repository with the fs-type1 connection.
   b. Go to your theme.
   c. Open the profile file in the `/profiles` directory.
   d. Make a copy of the profile file and give it a unique name.
   e. Edit the `.json` file and add the **wp_webdock** module ID.
   f. Copy the profile that you created to the `/profiles` directory.
   g. Invalidate the resource aggregator cache to integrate your changes. Click the **Administration menu** icon in the toolbar. Then click **Theme Analyzer** > **Utilities** > **Control Center** > **Invalidate cache**. CF06 Auto invalidation recognizes your changes automatically for WebDAV based themes. No further action is required. For more information, see Utilities.

Configuring multiple web dock applications on a page

You can have multiple web dock applications that point to different hosts on the same portal page. You can also allow users to open two different portal pages that contain web dock applications in a new browser window or tab.

About this task

Restriction: If you complete these steps, the inter-portlet communication feature is disabled.

Important: This alias is prefixed to the server name used to access the portal. It is then used to access the portal internally. If the server name is `servername.domain.ibm.com`, then make sure that the server is accessible through `myhost1.servername.domain.ibm.com` and `myhost2.servername.domain.ibm.com`.

Procedure

1. Log in to the WebSphere Integrated Solutions Console.
2. Go to **Resources** > **Resource Environment** > **Resource Environment Providers**.
3. Click **WP Virtual Web Application Manager Config**.
4. Click **Custom properties** in the **Additional Properties** heading.
5. Click **host_alias_mapping**.
6. Enter the aliases for the hosts in **Values**. For example, enter `myhost1 = http://remotesite1.example.ibm.com, myhost2 = http://remotesite2.example.ibm.com`.

Important: The aliases for the hosts must all be lowercase.

7. Click **OK**.
8. Complete the following steps to enable single sign-on:
   a. Go to **Security** > **Global Security** > **Web and SIP security** > **Single sign-on (SSO)**.
   b. Set the **Domain name** field. For example, enter `domain.ibm.com`.
9. Restart the WebSphere_Portal server.
10. Go to your domain name server (DNS) and enter the host aliases for each of the host aliases that you plan to use. For example, enter the following information:

    portal_serverIP `myhost1.servername.domain.ibm.com`

    portal_serverIP `myhost2.servername.domain.ibm.com`

    Where *portal_serverIP* is something like *9.27.27.155*.

What to do next

Complete the following steps to remove this enhancement:

1. Log in to the WebSphere Integrated Solutions Console.
2. Go to **Resources** > **Resource Environment** > **Resource Environment Providers**.
3. Click **WP Virtual Web Application Manager Config**.
4. Click **Custom properties** in the **Additional Properties** heading.
5. Click **host_alias_mapping**.
6. Remove the aliases for the hosts in the **Values** field.
7. Click **OK**.
8. Restart the WebSphere_Portal server.

Troubleshooting the web application bridge

The troubleshooting information is useful for planning and implementing your web application bridge integration (WAB).

About this task

The following items are known limitations:

Known issue with Microsoft Silver light plug-in
Disable the Microsoft Silver light plug-in in browsers when you use the Sharepoint features with the Web Application Bridge.

Known issue when you edit the host or port information for a content provider profile
If the system administrator changes the host or port information in the content provider profile, you must edit the web dock application and reselect the profile. Otherwise, the web dock application does not pick up the changes.

Known security issue
Do not enter < or > into any of the text boxes.

Known issue with turning on information mode
If you turn on information mode while you create a content provider, the dialog closes. You return to the summary table with no additional information shown. Turn on information mode and then create your content provider.

Web applications that contain navigation to multiple hosts
A web page that is served by an application that contains URLs that point to a host that is not the registered host for the web application does not work.

Web applications with URL redirection
Any web application that uses URL redirection for serving content is not supported. For example, `<meta http-equiv="refresh" content="2;url=http://someotherserver.com/">` does not work.

Web applications that serve content with incorrect mime-types
Any web application that serves web resources with an incorrect mime-type does not work. For example, a jpg image that is served as text/html instead of the correct image/jpeg mime-type does not work.

Web applications that server an iFrame that overlays the complete page
Any web application that serves content inside an iFrame that overlays the complete page is not supported.

Web applications that prevent their content to be loaded inside an iFrame
Any web application that contains a script to check whether the page document window is the main window or not before it displays the contents does not work.

Web applications with non-standard browser features
Any web application that depends specifically on a non-standard feature that is provided by a specific vendor's web browser does not work.

Web applications with vendor-specific client-side capabilities
Any web application that uses vendor-specific offline caching APIs, for example: Google and Gears, does not work.

Web dock applications and Mobile devices

CF03 Starting with CF03, mobile support is provided for web applications that were developed and tested for rendering inside mobile device browsers. If the web application was originally built and tested for desktops, it does not work properly on mobile devices.

Note: Mobile devices might not show scroll bars for any overflow content. Instead, the swipe feature of the mobile is enabled.

If you have CF02 or earlier, web dock applications are not supported on mobile devices. You might see an error message; for example: "Error 500: Internal Server Error: Some unexpected error". The administrator can configure their web server to redirect these errors to a friendlier error message. Refer to your web server documentation for information on how to redirect Error 500 messages.

Tip: You can also write a visibility rule to hide the portlet from mobile devices:

- Log in to WebSphere Portal Express.
- Go to **Personalization**.
- Create the following rule to hide your portlet:

```
Hide page or portlet when
    current Device.Device Class  includes  smartphone  or
    current Device.Device Class  includes  tablet
  Otherwise show
```

- To open the **Manage Pages** portlet, click the **Administration menu** icon. Then, click **Portal User Interface** > **Manage Pages**.
- Find your page and click **Edit layout**.
- Go to the web dock application that you want to apply the rule to.

  Note: If necessary, you need to apply this rule to every web dock application that you created.
- Select **Show Portlet Rule Mapping**.
- Select the rule that you created.
- Save your changes.

Edit Shared Settings does not work on mobile devices
The web application bridge does not support the **Edit Shared Settings** mode when accessed through a mobile device.

Reverse Proxy servlet
- No Persistent Cookie handling (all cookies are treated as sessions)
- No special HTTP 1.0 support
- Caching that is based on HTTP headers not yet implemented

The Portal search does not work for WAB - iFrame content
If the search crawler indexes a page, the page might not be available for search in a later session. Therefore, make sure that the Search crawler user ID does not have access to the web application bridge.

Sharepoint integration
The **View RSS feed** option is not supported.

Review the following questions to help you integrate and troubleshoot your web application bridge integration:

Can I use the localhost or IP address of an application to integrating it with the web application bridge?
Always specify fully qualified host name of your application. Do not use the localhost or IP address. You must also use the fully qualified host name when you access WebSphere Portal Express.

What request headers are always propagated?
- Date
- Pragma
- Via
- Accept
- Accept-Charset
- Accept-Encoding
- Accept-Language
- From
- Referrer
- Allow
- Content-Encoding
- Content-Language
- Content-Length
- Content-Location
- Content-MD5

- Content-Type
- User-Agent

What request headers are always blocked?

- Host
- Authorization
- Range
- Connection
- Keep-Alive
- Proxy-Authorization
- TE
- Trailers
- Transfer-Encoding
- Upgrade

What response headers are always propagated?

- Date
- Pragma
- Via
- Server
- Allow
- Content-Encoding
- Content-Language
- Content-Length
- Content-Location
- Content-MD5
- Content-Type

What response headers are always blocked?

- Location
- WWW-Authenticate
- Proxy-Authenticate
- Accept-Ranges
- Content-Range
- Connection
- Trailers
- Transfer-Encoding
- Upgrade

What do I do if I consistently see an error page in the view mode?

Log out of WebSphere Portal Express. Clear all cookies and log back in to WebSphere Portal Express. Use the fully qualified host name.

How do I remove the Sharepoint navigation that shows in the Web Dock portlet?

Review your Sharepoint documentation about hiding the navigation pane without changing the master page. You can also add filters to your application to parse the content that is not required.

What sites create integration problems?

The following types of sites can cause integration problems:

- Sites that have absolute URLs in the content or JavaScript
- Sites that use JavaScript, META refresh, absolute URLs for redirection
- Sites that use JavaScript to ensure that a web application is within the top frame and not an embedded frame, for example:

  ```
  if(top.location.href!=self.location.href){top.location.href=self.location.href
  ```

What is the unit for specifying height and width in the Web Dock portlet?
Height and width are specified in pixels. The page theme might restrict the width to maximum limit allowed by the theme.

How can I enable tracing for the web application bridge?
Add the following string to the Enable Tracing portlet in WebSphere Portal Express:

```
com.ibm.wps.vwat.*=all:com.ibm.wps.wab.*=all
```

Why can I not access my internet mail application?
If you are using an internet application that has complex security features, the web application bridge might not be able to access the application. One example of an internet application with complex security features is Yahoo. If you are unable to access your internet application and you verified that your settings in the application component are correct, contact Support.

Browse page never loads and keeps cycling
If your web browser never loads and keeps cycling, your server times might not match. If you are using Firefox, you see a message that your portal session timed out and to log in. To fix this issue, match your server time to the application you are bridging and restart portal.

Public URLs with multiple host do not display properly
If the public site fetches content from multiple hosts, then such sites do not render properly on the Web Dock portlet. For example, Wikipedia loads content from the following different hosts:

- `en.wikipedia.org`
- `bits.wikimedia.org`
- `upload.wikimedia.org`
- `meta.wikimedia.org`

Cookies that are exchanged between the web server and the application server
Setting the cookies that are exchanged between the web server and the application server to **HTTP only** disables the web application bridge.

Does WAB support SAML (Security Assertion Markup Language)?
If you have CF05 or earlier, WAB does not support SAML, unless the SAML token is inside of a cookie and the Portal server and the target server are in the same domain. The client-side cookie forwarding feature can be used in such a scenario. For example, the name of the cookie needs to be specified in the **Policy** > **Request** > **HTTP Cookies** section of the VWA Manager portlet.

Note: CF06 Starting with CF06, WAB does support SAML for single sign-on authentication.

What if the context root for the application that needs to be integrated matches the context root of another application that is already installed on the portal server?
You want to integrate an application whose URI starts with `/abc`. A second application exists on the Portal server with the same context root: `/abc`. If

the first application needs to be integrated into portal through the web application bridge, then the second application needs to be stopped or removed from the portal server.

I see too many pollings requests when I integrate with Netweaver
This issue might be because some headers are not being forwarded to the Netweaver server. These headers are **is_icm_polling_user**, **userId**, and **Content-Type**. Open the Virtual Web Application Manager portlet and add these headers to the list of allowed headers in the policy for Netweaver.

Using Simple and Protected GSS-API Negotiation (SPNEGO) on Windows
With SPNEGO-based single-sign on, the credentials are always automatically picked. Therefore, the user does not need to provide the credentials in the **Personalize** mode. They are always the user who is logged in to Windows.

Single sign-on
It is expected that the login buttons or similar things like "Switch user" buttons of the backend application are not available. They are either removed with the filters or the backend applications are directly configured. In other words, the content author can provide the credentials only through the **Personalize** mode of the web dock application portlet.

Single sign-on settings
The Web Application Bridge stores the authentication cookies that are received from the backend application in session. Perform authentication with the backend server only once per session. You do not need to authenticate for every request. After the user logs in to the backend server with single sign-on through WAB, the authentication remains active for the entire session. Even if the single sign-on settings in the policy change for the backend application, the user is still authenticated until the user logs out of portal. Therefore, if you change the policy, make sure that you log out of portal and then log back on to completely change the policy settings.

Integrating with SAP NetWeaver Portal

You can use IBM WebSphere Portal Express Integrator for SAP to integrate content from an SAP NetWeaver Portal into your IBM WebSphere Portal Express. You can integrate navigational structures and single content pieces.

About this task

Integrator for SAP integrates the SAP NetWeaver Portal navigation into WebSphere Portal Express. The navigation is retrieved new from the SAP NetWeaver Portal for each WebSphere Portal Express session and used for the duration of that session.

By default, the installation names the SAP NetWeaver Portal integration page **SAP**. WebSphere Portal Express users can navigate to this page by selecting **Applications** > **IBM WebSphere Portal Express Integrator for SAP** > **SAP**.

The following topics describe the prerequisites and procedure for setting up Integrator for SAP.

"Prerequisites and support for Integrator for SAP" on page 987
Integrator for SAP works with the prerequisites and under the conditions and limitations listed here.

Prerequisites and support for Integrator for SAP

Integrator for SAP works with the prerequisites and under the conditions and limitations listed here.

1. For the integration, use Integrator for SAP only with SAP NetWeaver Portal Version 7.3 SP2 with note 1638641 *Interoperability fix for SAML1.1 assertions in web services*. For more information about this note see the web link section. Note that you need a user ID and password from SAP to access this information.
2. Make sure that both WebSphere Portal Express and SAP NetWeaver Portal are installed in the same domain, for example *example*.com and have direct access to each other.
3. For virtual portals, WebSphere Portal Express supports only one integration point per virtual portal.
4. Use only the browsers and browser versions that are supported by both WebSphere Portal Express and SAP NetWeaver Portal. For details about browser support, read the appropriate documentation:
   - For WebSphere Portal Express, read *System requirements*.
   - For SAP NetWeaver Portal, read the product documentation for that product.
5. To configure single sign-on (SSO) between WebSphere Portal Express and SAP NetWeaver Portal, you can use either of the following options:
   - HTTP Basic Authentication for single sign-on (SSO) to SAP NetWeaver Portal. To configure HTTP Basic Authentication for single sign-on, configure Basic Authentication for SSO for the SAP navigation integration. For details, read *Configuring Integrator for SAP*.
   - A Security Assertion Markup Language (SAML) environment using IBM Tivoli Federated Identity Manager. For the installation and setup instructions, read the product documentation for IBM Tivoli Federated Identity Manager.

The navigation integration is temporary for each session and not imported or persisted in WebSphere Portal Express. Therefore the following limitations apply:

- Users cannot bookmark integrated pages, or tag or rate integrated content.
- If a search crawler indexes a page, the page might not be available for search by users in a later WebSphere Portal Express session. Therefore make sure that the WebSphere Portal Express Search crawler user ID does not have access to the SAP integration content.

Related tasks:

"Preparing your system environment and the prerequisites for Integrator for SAP"
To prepare your WebSphere Portal Express and the prerequisites for installing Integrator for SAP, make sure that you have all the required files and configure your outbound HTTP connections.

"Configuring Integrator for SAP" on page 991
Before you can use the SAP navigation, you need to perform the configuration.

"System requirements" on page 103
Before you install IBM WebSphere Portal Express, review the hardware and software requirements to ensure that you have the supported versions of prerequisite and corequisite software and the required hardware.

Preparing your system environment and the prerequisites for Integrator for SAP

To prepare your WebSphere Portal Express and the prerequisites for installing Integrator for SAP, make sure that you have all the required files and configure your outbound HTTP connections.

Procedure

1. Configure your outbound HTTP connections:
   a. Copy the following sample code and save it in a file named `proxy-config.xml` in a temporary directory on your WebSphere Portal Express server:

```
<?xml version="1.0" encoding="UTF-8"?>
<proxy:proxy-rules
     xmlns:proxy="http://www.ibm.com/xmlns/prod/sw/ajax/proxy-config/1.0"
     xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
    <proxy:mapping url="*" contextpath="/proxy"/>
    <proxy:mapping url="*" contextpath="/myproxy"/>
    <proxy:mapping url="*" contextpath="/common_proxy"/>
    <proxy:policy  url="xample_sap_portal.company.com:50000/*"
                   basic-authsupport="true" acf="none">
        <proxy:actions>
            <proxy:method>GET</proxy:method>
            <proxy:method>HEAD</proxy:method>
        </proxy:actions>
        <proxy:cookies>
            <proxy:cookie>MYSAPSSO2</proxy:cookie>
        </proxy:cookies>
        <proxy:headers>
            <proxy:header>User-Agent</proxy:header>
            <proxy:header>Accept*</proxy:header>
            <proxy:header>Content*</proxy:header>
            <proxy:header>Authorization*</proxy:header>
            <proxy:header>set-cookie</proxy:header>
        </proxy:headers>
    </proxy:policy>
    <proxy:meta-data>
        <proxy:name>socket-timeout</proxy:name>
        <proxy:value>10000</proxy:value>
```

```
    </proxy:meta-data>
    <proxy:meta-data>
        <proxy:name>retries</proxy:name>
        <proxy:value>2</proxy:value>
    </proxy:meta-data>
    <proxy:meta-data>
        <proxy:name>max-connections-per-host</proxy:name>
        <proxy:value>5</proxy:value>
    </proxy:meta-data>
    <proxy:meta-data>
        <proxy:name>max-total-connections</proxy:name>
        <proxy:value>100</proxy:value>
    </proxy:meta-data>
    <proxy:meta-data>
        <proxy:name>forward-credentials-from-vault</proxy:name>
        <proxy:value>true</proxy:value>
    </proxy:meta-data>
</proxy:proxy-rules>
```

For more information about configuring your outbound HTTP connection services, read *Configuring outbound HTTP connections*.

b. If you do not use Basic Authentication for single sign-on, remove the references to Basic Authentication from the file `proxy-config.xml` .

c. In the file `proxy-config.xml`, set the values for the parameters **`socket-timeout`** and **`retries`** according to your environment. If your SAP NetWeaver Portal is not available for some reason, these parameters determine the amount of time that the task spends on the inaccessible connection. WebSphere Portal Express tries a connection once for each user who logs in to the WebSphere Portal Express and who has access rights to the SAP navigation.

   Note: If the connection fails for many users, the failures can affect the performance of WebSphere Portal Express.

d. In the file `proxy-config.xml`, replace the proxy URL with your SAP NetWeaver Portal host and port. Example: `http://example_sap_portal.company.com:50000` .

e. In the file `proxy-config.xml`, make sure to add your SSO token name to the cookie section of the SAP NetWeaver Portal host. For example, the token name can be `MYSAPSSO2` .

f. If you want to run the configuration task in the following step without specifying passwords, add the user IDs and passwords for WebSphere Application Server and WebSphere Portal Express to the file `wp_profile/ConfigEngine/properties/wkplc.properties` .

g. Run the WebSphere Portal Express configuration task `checkin-wp-proxy-config` as follows:

   - If you added user IDs and passwords to the file `wp_profile/ConfigEngine/properties/wkplc.properties` , enter the task as follows:

     ```
     ConfigEngine.bat|sh create-outbound-http-connection-config
                         -DConfigFileName=/proxy-config.xml
                         -DOutboundProfileType=global
     ```

   - If you want to specify the user IDs and passwords when you run the configuration task, enter the task as follows:

     ```
     ConfigEngine.bat|sh create-outbound-http-connection-config
                         -DConfigFileName=/proxy-config.xml
                         -DOutboundProfileType=global
                         -DWasPassword=password
                         -DPortalAdminPwd=password
     ```

For more information, read *Configuring outbound HTTP connections by using configuration tasks*.

2. Optional: If you do not have a page with the unique name `ibm.portal.page.Applications` in your WebSphere Portal Express, create it before you install Integrator for SAP. The installation process expects to find a page with the unique name `ibm.portal.page.Applications` in WebSphere Portal Express. It adds integration artifacts to this page as child pages. If you do not have this page in your WebSphere Portal Express and run the Solution Installer install task, an XMLAccess exception occurs.

Results

You have completed the preparation for Integrator for SAP.

Related tasks:

"Installing Integrator for SAP"
Integrator for SAP is delivered as a portal application archive (PAA) file. You find it under the following location: *PortalServer_root*/base/wp.integration/sap.package/installableApps/sap_integration.paa . You install and deploy the application by using WebSphere Portal Express Solution Installer.

"Configuring outbound HTTP connections" on page 2992
In WebSphere Portal Express Version 8.0 and earlier versions, outbound HTTP connections were accessible through the Ajax Proxy service. The Ajax Proxy service was configured by a configuration document named `proxy-config.xml`. You find this document in the `/WEB-INF` directory of the web module that uses the Ajax Proxy service. Starting with WebSphere Portal Express Version 8.5 and the new outbound connection service, the configuration of outbound HTTP connections is now part of the standard datastore-based portal configuration.

"Configuring outbound HTTP connections by using configuration tasks" on page 3013
Programmers can create, read, update, or delete settings of the outbound HTTP connection by using the appropriate portal configuration engine tasks.

Installing Integrator for SAP

Integrator for SAP is delivered as a portal application archive (PAA) file. You find it under the following location: *PortalServer_root*/base/wp.integration/sap.package/installableApps/sap_integration.paa . You install and deploy the application by using WebSphere Portal Express Solution Installer.

About this task

For details about the Solution Installer, read the section about *Installing add-ons*.

Note: The installation and deployment process expects to find a page with the unique name `ibm.portal.page.Applications` in WebSphere Portal Express. It adds integration artifacts to that applications page as child pages. If you do not have this applications page in your WebSphere Portal Express and run the Solution Installer install task, an XMLAccess exception occurs. In this case create a page with the unique name `ibm.portal.page.Applications` and rerun the task that failed.

Procedure

1. Install the Integrator for SAP PAA file by using the portal Solution Installer. For this installation step, run the installation configuration task as follows:

Linux `./ConfigEngine.sh install-paa -DPAALocation=/sap_integration.paa`

IBM i `ConfigEngine.sh install-paa -DPAALocation=/sap_integration.paa`

Windows
`ConfigEngine.bat install-paa -DPAALocation=/sap_integration.paa`

2. Deploy the Integrator for SAP PAA file by using the portal Solution Installer. For this deploy step, run the deployment configuration task, and specify the value `sap_integration` for the parameter `appName` as follows:

   Linux `./ConfigEngine.sh deploy-paa -DappName=sap_integration`

   IBM i `ConfigEngine.sh deploy-paa -DappName=sap_integration`

   Windows
   `ConfigEngine.bat deploy-paa -DappName=sap_integration`

3. Restart your WebSphere Portal Express for the installation to become active. You must restart your portal before you configure Integrator for SAP.

Related tasks:

"Configuring Integrator for SAP"
Before you can use the SAP navigation, you need to perform the configuration.

"Installing add-ons" on page 210
You can use the Solution Installer through the Configuration Wizard to install and uninstall add-ons to an IBM WebSphere Portal Express server instance. The Solution Installer uses the Portal Application Archive (PAA) format as the standard format for application distribution. Portal Application Archive (PAA) updates are not supported in the configuration wizard currently. For more information about updating add-ons using a command prompt, see the Managing your existing PAA file section.

Configuring Integrator for SAP

Before you can use the SAP navigation, you need to perform the configuration.

About this task

The SAP navigation integration uses a set of configuration parameters, but you must configure these parameters separately:

Procedure

Configuring the SAP navigation page: By default, the WebSphere Portal Express installation names the SAP integration page **SAP** and places it as a subpage of **Applications** > **IBM WebSphere Portal Express Integrator for SAP**.
If you want to change the title of the SAP navigation page or move the page to another location in your WebSphere Portal Express, use the standard tools of WebSphere Portal Express. For example, you can use **Manage Pages** in the WebSphere Portal Express administration.
All required page properties for configuring the SAP navigation page are stored in the page properties of the SAP navigation page. For a list of configuration parameters see the topic about *Configuration parameters for the SAP navigation integration*. You must check and verify these settings and change them as appropriate for your environment, if required. To perform this task, proceed as follows:

1. To open the **Manage Pages** portlet, click the **Administration menu** icon. Then, click **Portal User Interface** > **Manage Pages**.

2. Click **Content root** > **Applications** > **IBM WebSphere Portal Integrator for SAP**.
3. Click **Edit page properties** for the page that is named **SAP**, or however you might have renamed it.
4. Select **Advanced options** > **I want to set parameters**.
5. Change the page properties as required. For a list of configuration parameters, read the topic about *Configuration properties for the SAP navigation integration*. If your values for the page properties remain within a length limit of 255 characters, you can set them directly in the page properties as described here. If the values for any of the properties exceed 255 characters, you must set that property in the WP Configuration Service, reference it in the page properties, and prefix its value in the page properties with `ConfigService:` . For example, the most likely parameter to have a value that exceeds 255 characters is `sap.SSOTokenUrl` . In this case you configure the following settings:
   - In the WP Configuration Service: *`actual.SSO.tokenUrl = "your_URL"`*
   - In the page properties: `sap.SSOTokenUrl = "ConfigService:`*`actual.SSO.tokenUrl`*`"`

   For details about how portal service configuration properties and how to set them, read *Configuration Service* and *Setting service configuration properties*. For the parameter `sap.SSOTokenUrl`, you can specify a page URL of the SAP portal of your choice, except the `sap.BaseUri`.
6. Restrict the access to the SAP navigation page to the correct audience, for example to all or selected SAP users. To perform this task, use the WebSphere Portal Express Access Control.
7. Optional: Like portal pages, you can configure the navigational integration label to use a theme template. Within the navigational integration, integrated SAP NetWeaver portal pages inherit that configuration from the label. To perform this configuration, add the page parameter `com.ibm.portal.theme.template.file.name.htm` to the label by using the XMLAccess configuration interface. After you install Integrator for SAP, all integration pages are already configured to use a side navigation theme template. You can remove the side navigation by removing the parameter for the side navigation theme template from the label.

What to do next

After you have completed the configuration, restart your WebSphere Portal Express server for your changes to take effect.

For more information about how to configure Integrator for SAP see these topics:

"Configuring Basic Authentication for SSO for the SAP navigation integration" on page 993
For single sign-on between WebSphere Portal Express and SAP NetWeaver Portal, you can configure HTTP Basic Authentication using the Credential Vault.

To configure the SAP navigation integration of Integrator for SAP, you can set the following page configuration properties.

"Configuration Service" on page 297
The portal Configuration Service is responsible for collecting the most essential configuration data of the IBM WebSphere Portal Express engine.

Configuring Basic Authentication for SSO for the SAP navigation integration

For single sign-on between WebSphere Portal Express and SAP NetWeaver Portal, you can configure HTTP Basic Authentication using the Credential Vault.

About this task

For you to be able to perform this configuration, the SAP Navigation WS must be running and accessible. This should be given by default in a SAP NetWeaver portal installation.

To configure HTTP Basic Authentication for SSO, proceed as follows:

Procedure

1. Access the portal with an administrative user ID.
2. Create a Credential Vault slot that can later store a user's credentials by using the WebSphere Portal Express administration. For more information, read *Credential Vault*.
3. Configure HTTP Basic Authentication for SSO for Integrator for SAP:
   a. Set the page parameter for the SAP integration page `sap.CredentialSlotId` to the name of the Credential Slot that you created in the previous step.
   b. Set the parameter `sap.SSOTokenUrl` to a URL in your SAP NetWeaver Portal.

   For details see the topics *Configuring Integrator for SAP* and *Configuration parameters for the SAP navigation integration*.

4. Users must add their credentials to the slot in the Credential Vault Dialog. They can access the Credential Vault Dialog by typing the web address of the Credential Vault Dialog into a web browser. For example, `http://<host>:<port>/wps/mypoc?uri=cvfiller:<credentialVaultSlotName>`.
5. Optional: If you do not want users to be able to edit the user ID and password credentials that the integrator portlet uses with Basic Authentication, then you can revoke the Privileged User role at the portlet for these users. You do this by using the WebSphere Portal Express Access Control. This can be useful if you use a shared Credential Vault slot and a group of users share the same user ID and password for accessing the SAP NetWeaver Portal.
6. Optional: Configure single sign-on with the SAP navigation integration for browsers. If you configure HTTP Basic Authentication for single sign-on, Integrator for SAP provides single sign-on between WebSphere Portal Express and the SAP NetWeaver Portal navigation only. This means that users can see the integrated navigation, but when they access an integrated page, SAP NetWeaver Portal prompts them for authentication, if SSO is not implemented by other means. You can include browsers in the configuration of this single sign-on. If you want WebSphere Portal Express to pass the SAP NetWeaver Portal authentication token to the user's browser, you must perform both of the following tasks:
   a. Set the page parameter `sap.SSOTOkenDomain` to the domain for which you want to set the token. For details, read the topic about *Configuration properties for the SAP navigation integration*.
   b. Configure the following login and logout filters in the Resource Environment Provider WP Authentication Service:

```
login.explicit.filterchain    com.ibm.wps.integration.sap.login.LoginFilter
login.implicit.filterchain    com.ibm.wps.integration.sap.login.LoginFilter
logout.explicit.filterchain   com.ibm.wps.integration.sap.logout.LogoutFilter
logout.implicit.filterchain   com.ibm.wps.integration.sap.logout.LogoutFilter
```

      For details, read the topic *Configuring authentication filters*.

What to do next

Note that configuring single sign-on with the SAP navigation integration for browsers is supported only for HTTP Basic Authentication.

Related concepts:

"Credential Vault" on page 1523
The Credential Vault is a service that stores credentials that allow portlets to log in to applications outside the realm on behalf of the user. It manages multiple identities for portlets and users.

"Page properties for configuring the SAP navigation integration" on page 997
To configure the SAP navigation integration of Integrator for SAP, you can set the following page configuration properties.

Configuring Tivoli Federated Identity Manager with SAML for single sign-on to SAP NetWeaver Portal

You can also use Tivoli Federated Identity Manager with Security Assertion Markup Language (SAML) for single sign-on to SAP NetWeaver Portal.

About this task

In such a scenario, Tivoli Federated Identity Manager with SAML is responsible for handling the authentication flow by using Security Assertion Markup Language. For the SAP integration into WebSphere Portal Express, the supported SAML scenario is named *Service Provider initiated single sign-on*. To use such a scenario, you need technical expertise for all three participating systems: IBM WebSphere Portal, IBM Tivoli Federated Identity Manager, and SAP NetWeaver Portal.

To use Tivoli Federated Identity Manager (Tivoli Federated Identity Manager) for single sign-on to SAP NetWeaver Portal with Integrator for SAP, follow these instructions:

Procedure

- Make sure that your Tivoli Federated Identity Manager is configured correctly for authentication of the participating service providers and the users in a service-provider initiated single sign-on scenario. The service providers are the SAP NetWeaver Portal instance and the WebSphere Portal Express instance.
  - For the navigation integration, you must set up a Web Service Single Sign On for the Web Service Client **NavigationWS**. This Web Service Client is hosted in the enterprise application **IntegrationSAP** in the WebSphere Integrated Solutions Console.
  - For the SAP navigation integration, you must set up Web Single Sign On to the SAP NetWeaver Portal.
- To make the Integrator for SAP, use Tivoli Federated Identity Manager do not set any other authentication configuration:
  - For the SAP navigation integration, do not set the parameters `sap.CredentialSlotId` and `sap.SSOTokenUrl`. Also, do not configure single sign-on for browsers as described under the topic about *Configuring basic authentication for single sign-on to SAP NetWeaver Portal*.
  - Do not add the login or logout filter of the SAP integration to the filter chains.
- To test and verify your environment use the SAP navigation integration. This test requires that the web service single sign-on is configured.

Related tasks:

"Configuring logout handling"

"Configuration Service" on page 297
The portal Configuration Service is responsible for collecting the most essential configuration data of the IBM WebSphere Portal Express engine.

Configuring logout handling

When a user logs out of WebSphere Portal Express, a log out from SAP NetWeaver Portal needs to be performed as well. Otherwise, the user session on the SAP NetWeaver Portal remains open until it times out.

About this task

You can configure automatic log out from SAP NetWeaver Portal when a user logs out of WebSphere Portal Express. To perform this configuration, insert the following JavaScript function into your theme and call it on click of the logout link. Replace *your_sap_portal_host* and *port* with the values for your SAP NetWeaver Portal host and port.

```
function logoffFinalCall() {

   if (document.cookie.length>0) {
      isCookieExisting=document.cookie.indexOf("MYSAPSSO2")
      if (isCookieExisting != -1) {
         var lnDotPos = document.domain.indexOf( "." );
         if(lnDotPos>=0)document.domain = document.domain.substr(lnDotPos+1);

         var logoffForm = document.createElement("form");

         var logoffParam = document.createElement("input");
         logoffParam.name = "Command";
         logoffParam.value = "LOGOFF";
         logoffForm.appendChild(logoffParam);

         var logoffParam2 = document.createElement("input");
         logoffParam2.name = "Autoclose";
         logoffParam2.value = "1000";
         logoffForm.appendChild(logoffParam2);

   //This component logs the user out of SAP NetWeaver portal.
      logoffForm.action =
      "http://your_sap_portal_host:port/irj/servlet/prt/portal/prtroot/com.sap.portal.dsm.Terminator";

         logoffForm.method = "post";
         logoffForm.target = "_blank";
         document.body.appendChild(logoffForm);

         logoffForm.submit();
      }
   }
}
```

Replace the variables as follows:

MYSAPSSO2
: Replace this variable with the name of the SSO cookie for your SAP NetWeaver Portal.

your_sap_portal_host
: Replace this variable with the fully qualified URL to your SAP NetWeaver Portal.

port
: Replace this variable with the port of your SAP NetWeaver Portal.

"Page properties for configuring the SAP navigation integration" on page 997
To configure the SAP navigation integration of Integrator for SAP, you can set the following page configuration properties.

Page properties for configuring the SAP navigation integration

To configure the SAP navigation integration of Integrator for SAP, you can set the following page configuration properties.

For details about where and how to set these properties, read the topic about *Configuring your Integrator for SAP*.

sap.BaseUri

This property is mandatory. Use this property to specify the base URI to the SAP NetWeaver Portal. Example: `http://sapportal.company.com:50000` . This property has no default.

sap.CredentialSlotId

This property is mandatory only if you use Basic Authentication for SSO. Use this property to specify the name of the Credential Vault slot that you want to use for authentication to the SAP NetWeaver Portal.

sap.SSOTokenUrl

This property is mandatory only if you use Basic Authentication for SSO and if you have created a Credential Vault slot for this authentication method. In this case use this property to specify the absolute URL to a protected resource of your choice in your SAP NetWeaver Portal, for example a specific page or iView. This URL is used for login to retrieve the SSO token. During retrieval of the SSO token, WebSphere Portal Express follows all HTTP redirects. If you use a SAML scenario, you do not need to set this property.

sap.SSOTokenDomain

This property is mandatory only if you use Basic Authentication for SSO. Add this property if you want to pass also the SSO token defined by the property `sap.SSOTokenName` from WebSphere Portal Express to the client browser. If you do so, the integration also authenticates the clients that use the configured SSO scenario between WebSphere Portal Express and SAP NetWeaver Portal. To enable this authentication by token, specify the domain for which you want to set the token, starting with a dot, for example `.ibm.com` . This property has no default. If you set this property, you also must do the following:

- Add the login filter implementation `com.ibm.wps.integration.sap.login.LoginFilter` to both the explicit **and** implicit login filter chains.
- Add the logout filter implementation `com.ibm.wps.integration.sap.logout.LogoutFilter` to both the explicit **and** implicit logout filter chains.

For details see the topic about *Configuring authentication filters*.

sap.SSOTokenName = (MYSAPSSO2)

This property is optional. Use it only if you use Basic Authentication for SSO. Use this property to specify the SSO token name of your SAP NetWeaver Portal. If you use the Credential Vault, use this property for authentication of the web service call. The default value is `MYSAPSSO2` .

sap.NavUri = (/NavigationWS/NavigationWSConfig?style=document)

This property is optional. Use this property to specify the relative URI of the SAP NetWeaver Portal navigation web service. The default value is `/NavigationWS/NavigationWSConfig?style=document` .

sap.InteropUri = (/irj/portal/interop)
This property is optional. Use this property to specify the relative URI of the SAP Interop service. The default value is `/irj/portal/interop` .

sap.NavUriTimeout
This property is optional. Use this property to specify a timeout in seconds for the web service call. The default value is `5` .

sap.ClientSideLogging = (false)
This property is optional. Use this property to determine whether WebSphere Portal Express gives out client-side JavaScript debugging messages to the JavaScript console. This is helpful if problems with the automatic resizing of the iframe occur. If you want the portal to give out client-side JavaScript debugging messages to the JavaScript console, set this property to `true` . Restart the WebSphere Portal Express server for the change to become active.

Related concepts:

"Configuring authentication filters" on page 265
The portal authentication filters are a set of plug-in points. You can use them to intercept or extend the portal login, logout, session timeout, and request processing by custom code, for example to redirect users to a specific URL.

Performance tuning for Integrator for SAP

See the following hints and tips that might help improve performance of your Integrator for SAP.

General considerations

- Cache sizes have a direct impact on the memory requirements of WebSphere Portal Express, specifically the demands on the Java heap. To determine if your portal has enough memory resources available to handle an additional increase, monitor the usage of caches and the portal memory usage under a heavy workload, before you increase the cache sizes.
- If you do not use the portlet menu for IBM API portlets, disable it. To do this, proceed as follows:
  1. Access the WebSphere Integrated Solutions Console.
  2. Navigate to **Resources** > **Resource Environment** > **Resource Environment Providers**.
  3. Select **WP ConfigService**.
  4. Add the following custom property:
     - Property name: `navigation.portletmenu.mode`
     - Value: `0`

Limiting availability of the SAP navigation page for users

Each time a user accesses the SAP navigation page for the first time during a WebSphere Portal Express session, WebSphere Portal Express sends a request to the SAP NetWeaver Portal. Therefore limit the access to the SAP navigation page to the correct audience, for example, to all or selected SAP users. To perform this task, use the WebSphere Portal Express Access Control. This measure limits request volume to the appropriate requests only. For more information about Portal Access

Control refer to the topic *Controlling access*.

Caches for performance and memory consumption

For tuning purposes, Integrator for SAP provides two portal caches with entries for each integrated SAP portal page and for each logged in user. Set their size and lifetime according to your environment.

com.ibm.wps.integration.sap.NodeCache
Content: This cache holds one entry for each integrated page per locale, independent of the user. For example, if your SAP NetWeaver Portal contains a maximum of 500 pages and all your users use one and the same locale, this cache can never exceed 500 entries.

com.ibm.wps.integration.sap.NodeCache.size = (1000)
Default size: 1000 entries

com.ibm.wps.integration.sap.NodeCache.lifetime = (-1)
Default lifetime: This cache never expires.

com.ibm.wps.integration.sap.ModelCache
Content: This cache holds one entry for each logged in user who has access to the SAP navigation. This cache entry is removed on logout by the user.

If you have only limited memory available, you can use this cache to limit the memory consumption of the SAP navigation integration. However, limiting memory consumption this way might in turn affect performance. Note that if you add pages to SAP NetWeaver Portal, the memory consumption grows accordingly, even if you do not increase this cache size. If you set this cache size too small, performance might decrease.

com.ibm.wps.integration.sap.ModelCache.size = (1000)
Default size: 1000 entries

com.ibm.wps.integration.sap.ModelCache.lifetime = (-1)
Default lifetime: This cache never expires.

For more information about how to configure WebSphere Portal Express caches, read *Cache Manager Service* and *Setting service configuration properties*.

Ajax Proxy configuration

Set appropriate values in the file `proxy-config.xml` according to your environment for the maximum number of connections and the number of connections per host. Otherwise, a limitation of available connections can occur.

Set appropriate values for the parameters `socket-timeout` and `retries` . If SAP NetWeaver Portal is not available for some reason, these two parameters limit the length of time that the task spends on the inaccessible connection. For details about the two parameters read*Preparing your system environment and the prerequisites*. For each user who logs in to WebSphere Portal Express and who has access rights to the SAP NetWeaver Portal navigation page, WebSphere Portal Express tries a connection at least once, depending on the cache settings described in the previous section. If these attempts fail for many users, it can affect the performance of WebSphere Portal Express.

For more information about configuring your Ajax Proxy, read *Configuring Outbound HTTP Connections*.

Related tasks:

"Preparing your system environment and the prerequisites for Integrator for SAP" on page 988
To prepare your WebSphere Portal Express and the prerequisites for installing Integrator for SAP, make sure that you have all the required files and configure your outbound HTTP connections.

"Setting service configuration properties" on page 283
IBM WebSphere Portal Express comprises a framework of services to accommodate the different scenarios that portals need to address. Services are available for both WebSphere Portal Express and IBM Web Content Manager. You can configure some of these services.

"Configuring outbound HTTP connections" on page 2992
In WebSphere Portal Express Version 8.0 and earlier versions, outbound HTTP connections were accessible through the Ajax Proxy service. The Ajax Proxy service was configured by a configuration document named `proxy-config.xml`. You find this document in the `/WEB-INF` directory of the web module that uses the Ajax Proxy service. Starting with WebSphere Portal Express Version 8.5 and the new outbound connection service, the configuration of outbound HTTP connections is now part of the standard datastore-based portal configuration.

Observe the following hints and tips in case of problems with Integrator for SAP.

"Configuration Service" on page 297
The portal Configuration Service is responsible for collecting the most essential configuration data of the IBM WebSphere Portal Express engine.

"Cache Manager Service" on page 292
The portal Cache Manager Service is responsible for managing the different caches used in WebSphere Portal Express.

Hints and tips for Integrator for SAP

Observe the following hints and tips in case of problems with Integrator for SAP.

Autosizing the SAP navigation page does not work for all themes in client-side mode

The automatic resize feature for the SAP navigation iframe does not work for static pages in client-side rendering mode. Under these conditions a height of 600 pixels applies to the SAP navigation page. Autosizing the SAP navigation page works for pages with all themes rendered in server-side mode.

This limitation does not apply to the integrator portlet IBM WebSphere Portal Express Integrator for SAP.

Replacement page in case of errors

If the SAP navigation retrieves an exception, it shows a replacement page as a child page to the navigation page. It shows a message such as the ones given in the following list. In this case check the system logs for the root cause of the exception. The following examples give some typical issues and their resolution.

EJQIA0017E: The Ajax Proxy returned HTTP: [403 Forbidden] when trying to get the SSO Token from URL

Reason: The Ajax Proxy blocked the request.

Action: Configure the Ajax Proxy. Verify the Ajax Proxy configuration by calling the Ajax Proxy directly: `http://`

your_IBM_WebSphere_Portal.domain.com:*port*/wps/*your_proxy*/http/
sap.ssoTokenURL-Value?hpaa.slotid=*your_Credential_Vault_Slot_ID*

EJQIA0017E: The Ajax Proxy returned HTTP: [502 Bad Gateway] when trying to get the SSO Token from URL

Reason: SAP NetWeaver Portal is not available.

Action: Make sure that SAP NetWeaver Portal is available.

EJQIA0017E: The Ajax Proxy returned HTTP: [504 Gateway Timeout] when trying to get the SSO Token from URL

Reason: SAP NetWeaver Portal is not available.

Action: Make sure that SAP NetWeaver Portal is available.

"Using Web Application Bridge"
If you plan to use IBM Web Application Bridge, you need to configure all remote context roots.

Using Web Application Bridge

If you plan to use IBM Web Application Bridge, you need to configure all remote context roots.

For the detailed steps see the documentation for Web Application Bridge.

Note: Web Application Bridge does not support SAML (Security Assertion Markup Language) unless the SAML token is inside a cookie, and the Portal server and the target server (SAP Netweaver portal in this case) are in the same domain. The client-side cookie forwarding feature can be used in such a scenario. For example, the name of the cookie must be specified in the **Policy** > **HTTP Cookies** section of the VWA Manager portlet.
To identify the context root on SAP NetWeaver Portal, consult your SAP NetWeaver Portal administrator. Note that the context roots depend on your environment and usage scenario. You can use the following list as a starting point in a review meeting with your SAP administrator.

Integrating with IBM MobileFirst

You can integrate WebSphere Portal Express with MobileFirst to provide multi-channel support to your web communities. You can create a hybrid application that adds native device functions and a unified web experience on mobile device browsers and in mobile device native applications. You can use MobileFirst to create a hybrid application that adds native device functions to your portal.

There are three types of applications you can create for your cross-platform environments with WebSphere Portal Express and MobileFirst.

Native applications
Native applications for enterprise mobile apps have the highest UI fidelity and range of function of the types of web applications included here, but have the highest cost to develop and maintain. Cross-platform issues can increase costs, and mobile operating system updates can require frequent updates to be submitted in application stores. MobileFirst provides tools to reduce costs.

Pure web applications
Pure web applications that are based on HTML5, CSS3, and JavaScript, or that use client-side frameworks like Dojo and jQuery, provide a simple way to make mobile-friendly websites. Development and maintenance costs are less expensive. You can work more easily across multiple devices and are not typically impacted by mobile operating system updates. WebSphere Portal Express provides a platform for pure web applications and websites. With a pure web application, you only have access to the native device features that the browser provides to you, and you are more limited in the user interface fidelity.

Hybrid applications
Hybrid applications combine the characteristics of pure and native applications. You can build an application with the simplicity of developing with HTML/CSS/JavaScript. But you can augment that with a wide range of native services and produce an application for application stores. With technology like Apache Cordova, which MobileFirst includes, you can call native features with JavaScript from your web markup. For example, you can call the camera with a simple JavaScript line, such as: `navigator.camera.getPicture`. MobileFirst provides tools for creating these hybrid applications. Hybrid applications are native applications that wrap the WebSphere Portal Express web application. The two are tightly integrated to use each other's capabilities to make the development experience as quick and easy as possible.

As a WebSphere Portal Express customer, you can use the MobileFirst tools for free and create two free applications. But the applications must be hybrid applications that use WebSphere Portal Express.

Planning to install IBM MobileFirst

Determine the services and function of your hybrid application before you install MobileFirst. You must install a MobileFirst server in some instances.

Running a hybrid application in a portal page

When your hybrid application runs with your WebSphere Portal Express pages rendered in a native application, WebSphere Portal Express loads the appropriate native resources for the device. These resources are loaded automatically through modules that are provided in WebSphere Portal Express. It starts with the `wp_worklight_ext` module, which is listed in some of the default profiles, including `profile_deferred.json`, `profile_dojo_deferred.json`, and `profile_basic_content.json`.

If you want access to the appropriate native resources for the device on a particular page of your WebSphere Portal Express, use a profile that includes the `wp_worklight_ext` module. The default profile, `profile_deferred.json`, includes `wp_worklight_ext`, so the appropriate native resources are available to your WebSphere Portal Express pages by default.

`wp_worklight` is a version-independent meta-module that is defined by the `mobilefirst70.json` file in your theme's contributions folder. This module is a prerequisite of the default MobileFirst resources that enable access to native features. It also includes the overrides that enhance performance and allow the API libraries to work within the module framework.

The version-dependent platform modules that are included by the module framework are `mf_ios_70` and `mf_android_70`. These platform modules are defined by the `plugin.xml` file in your theme's *PortalServer_root*`\theme\wp.theme.worklight.ext\installedApps\wp.theme.worklight.ext.ear\`

wp.theme.worklight.ext.war\WEB-INF folder. These platform modules load the appropriate native resources for the device, giving access to the full MobileFirst and Cordova APIs. For example, it gives access to the following resources on the device:

- Camera
- Geolocation
- Contacts
- Local storage
- Media
- Push notifications
- User information

These platform modules are loaded or not based on device class conditions, as you can see in the following plugin.xml code snippet for the mf_android_70 module:

```
<module id="mf_android_70">
         <runtimeActivation>
    <condition deviceClass="worklight+android"/>
   </runtimeActivation>
```

The mf_android_70 module loads if the device class is both MobileFirst and Android. The device class is determined by the WebSphere Portal Express server that is based on the user agent string of the client device. For example, a user agent string for an Android phone looks like this example:

```
Mozilla/5.0 (Linux; U; Android 4.0.4; en-gb; GT-I9300 Build/IMM76D) AppleWebKit/534.30 (KHTML, like
```

A MobileFirst hybrid application automatically appends "/Worklight/*version*" to the end of the user agent string, such as:

```
Mozilla/5.0 (Linux; U; Android 4.0.4; en-gb; GT-I9300 Build/IMM76D) AppleWebKit/534.30 (KHTML, like
```

Windows Phone MobileFirst applications cannot modify the user agent. Instead, WebSphere Portal Express sets a session cookie that is called wp.agent.ext to "/Worklight" whenever it detects a uri=wl:id request parameter, and appends that cookie's value to the agent before it evaluates device classes. This parameter must be present on the initial request from the hybrid application or MobileFirst is not available on Windows Phone devices.

Appropriate matching is used to determine the device classes from the user agent string. The device classes in turn determine the appropriate platform modules to load. For example, the mf_android_70 native resources are loaded for a portal that runs in a MobileFirst hybrid application on an Android device. But it does not load in many other cases. For example, if it is on an iOS device, or if it is a portal that is not wrapped in a MobileFirst hybrid application, these resources do not load.

The same portal pages adapt their capability that is automatically based on the context in which they are running. For example, a page can provide access to the device's camera if it runs in the context of a MobileFirst hybrid application. The same page cannot get access while it is running outside the context of a MobileFirst hybrid application.

The Cordova and MobileFirst API have overrides to improve performance and allow integration with WebSphere Portal Express. The overrides allow the MobileFirst Client API to find the resources in the deployed web application. The overrides also allow the Cordova plug-ins to be packaged into a module and allow

the multiple JavaScript resources to be fetched in one request by the resource aggregation framework.

Shell application

If your application is a shell that uses a web view to render all markup from the WebSphere Portal Express site, then you do not need a MobileFirst server.

If your application is using a mixed model approach where some of the application markup is coming from your WebSphere Portal Express and other markup of the application is coming from native resources that might be fetching Web Content Manager resources, then you must install a MobileFirst server to provide these resources.

Direct update service

If you plan to use the direct update service feature to update the embedded markup for changes, you require a MobileFirst server.

Native notifications

If your application uses native notifications, MobileFirst is required to generate the iOS and Android notification service.

Authentication services

If you use the MobileFirst authentication or access control service for single sign-on (SSO) between MobileFirst and WebSphere Portal Express, you must install a MobileFirst server. If you plan to use anonymous access or access all resources of the application through WebSphere Portal Express or IBM Web Content Manager, then you do not need a MobileFirst server.

Tracking usage

If your application uses MobileFirst to track usage, you must install a MobileFirst server. The server that you install must also support the load from clients who send usage data.

Device provisioning

If you are providing device provisioning, you must install a MobileFirst server to provide the certificate for the device and data.

Application Center EAR

The Application Center Ear is an optional application that provides an application store environment. If you are using it to manage applications on devices as an MDM solution, you need a MobileFirst server to run the MobileFirst EAR and the Application Center EAR.

Default component overview

When you integrate MobileFirst and WebSphere Portal Express, you can create a MobileFirst hybrid application that includes a WebSphere Portal Express web application. This hybrid application can run in a mobile browser and as a native mobile application.

Modules

- wp_worklight_ext
- `wp_worklight`
- wp_worklight_css

The `wp_worklight_ext` module is included in the default deferred profile and is active by default. This module automatically loads the MobileFirst Client and Cordova APIs for you so you can add native device capabilities in your hybrid applications. The APIs are JavaScript resources and are optimized for each device. For example, the iOS resources are loaded in a MobileFirst hybrid application on an iOS device. But they are not loaded in other circumstances such as in a web application, on an android device, or on a desktop.

Device classes

- `worklight`
- `ios`
- `android`
- `iemobile`
- `blackberry`
- `smartphone`
- `tablet`

With these device classes, you can target the appropriate environment to expose your native capabilities within WebSphere Portal Express. The default MobileFirst modules use these devices classes to determine which resources to load. If you are adding to the default capabilities, you can also use these device classes to optimally load your own device-specific resources.

Device class equations

- `android+smartphone`
- `worklight+(ios/android)`
- `(android/ios)+worklight+!tablet`

With device class equations, you can create a specific device class that includes or excludes some of the device classes. You can use parenthesis to group the device classes. To use the operation AND, use the plus sign, `+`. To use the operation OR use the forward slash, `/`. To use the operation NOT, use the exclamation point, `!`.

APIs & Samples

- Worklight Client
  - `WL.Client.getUserInfo`
  - `WL.Client.Push.subscribe`
  - And others
- Cordova
  - `navigator.camera.getPicture`
  - `navigator.geolocation.getCurrentPosition`
  - And others
- Authentication
  - `WL.Client.createChallengeHandler`
  - And others

The new MobileFirst resources allow access to native device capabilities by using the high-level JavaScript without having to know or use the native device programming language. The JavaScript APIs call the native device APIs for you. Sample apps are provided on the catalog for each of the APIs to show example usage syntax. You can copy, paste, and modify these samples to fit your needs.

To get started, create a MobileFirst hybrid application that points to and renders your WebSphere Portal Express URL. Modify your WebSphere Portal Express code to call the JavaScript APIs to access the native device capabilities. For example, your application could have a feature for taking and uploading a picture that is available on devices that have cameras and unavailable otherwise. Or a feature that is tailored to the user's geolocation on devices that have GPS and not otherwise. Or a feature that sends and receives push notifications on devices that support push notifications and not otherwise.

Apache Cordova

MobileFirst API

Creating a MobileFirst hybrid application for your portal

You can create a hybrid application to add native device capabilities to your portal with IBM MobileFirst.

Before you begin

To test an iPhone and iPad hybrid application, you must use a Mac with Xcode installed. To test an Android hybrid application, you must have an Android Virtual Device created. To test a Windows Phone hybrid application, you must have Windows 8 and the Windows Phone SDK installed.

Procedure

1. Create your MobileFirst Hybrid Application in the MobileFirst Eclipse development environment by selecting **New** > **MobileFirst Project**.
2. In the **Name** field, name your project. In this example, name your project `MFPortal`. In the **Project Templates** field, select **Hybrid Application**, which is the default, and click **Next**.
3. In the **Application Name** field, name your application. In this example, name your application `MFPortalApp`. Check the JavaScript libraries that you want your application to use if any and click **Finish**. The project and application artifacts are created. You can see your *project_name*\apps*app_name* folder in the Project Explorer. Your application descriptor, `application-descriptor.xml`, is in the Application Descriptor Editor.
4. In `application-descriptor.xml`, you can change the basic settings of your application, such as your `application id`, `displayName`, `description`, and `author` details.
5. In `application-descriptor.xml`, change `mainFile` to your WebSphere Portal Express URL with the **`uri=wl:id`** parameter appended to the end. For example, enter `http://localhost:port/wps/portal?uri=wl:id:MFPortalApp`. Replace **localhost** with your host name and `MFPortalApp` with your application name.
6. In the `common/images` folder, replace the `icon.png` and `thumbnail.png` files with the custom images that you want for your application. The `thumbnailImage` shows that the icons used for your application are in the `common/images` folder.

7. Save your changes.
8. Create a MobileFirst environment to build the native part of the hybrid application. Right-click your *project_name*\apps*app_name* folder and then select **New** > **MobileFirst Environment**.
9. In the New MobileFirst Environment dialog, select any native environments that you want your application to support, such as iPhone, iPad, Windows Phone, and Android phones and tablets. Click **Finish**. Your Project Explorer window is updated with a native application in a folder named *project_name**app_name**platform*. In this example, the folder for Android is MFPortal\MFPortalApp\Android. For iOS, it is MFPortal\MFPortalApp\iphone or MFPortal\MFPortalApp\ipad for iOS. For Windows Phone, it is MFPortal\MFPortalApp\windowsphone8. For Windows Phone applications, set the URI entered for the **mainFile** value of the application-descriptor.xml as the **StartPageUri** value in MainPage.xaml. MobileFirst manages the lifecycle of these folders. When the web application you initially created in the project is built and deployed, the native applications are overwritten with any application changes.
10. To test your application, right-click the *project_name*\apps*app_name* folder and select **Run As** > **Build All Environments**.
    a. To test an Android hybrid application, you must have an Android Virtual Device created. Then, right-click on your native Android application folder, and select **Run As** > **Android Application**. The native Android application is a peer to your project. In this example, a project that is named MFPortalMFPortalAppAndroid is in your MobileFirst project.
    b. To test an iPhone and iPad hybrid application, you must use a Mac with Xcode installed. Right-click on your native iPhone or iPad application folder, which is *project_name*\apps*app_name*\iphoneor *project_name*\apps*app_name*\ipad, and select **Run As** > **Xcode project**. Then, in Xcode, select your emulator and run the application.
    c. To test a Windows Phone hybrid application, you must have Windows 8 with Windows Phone 8 SDK installed. Right-click your native Windows Phone application folder, which is project_name\apps\app_name\ windowsphone8, and select **Run As** > **Visual Studio Project**. Then, in Visual Studio, select your emulator and run the application.

Module framework for IBM MobileFirst

The module framework allows extensions to contribute to different areas of a page to provide flexibility, enhance the user experience, and maximize performance.

IBM WebSphere Portal Express provides the MobileFirst 7.0 resources by default through modules that are defined in the default profiles. These modules use prerequisites to ensure that all necessary resources are aggregated and device classes to ensure that they are only provided for a particular environment. For more information, see *The module framework*.

"Configuring the MobileFirst properties" on page 1009
Configure the MobileFirst properties to add your preferences to the portal page.

CF07 "Setting up single sign-on with MobileFirst 7.0" on page 1010
You can set up single sign-on with MobileFirst so users can share a session between a WebSphere Portal Express and MobileFirst server.

"Meta-Modules for IBM MobileFirst integration" on page 1022
MobileFirst provides a set of ready-to-use modules.

Related concepts:

"The module framework" on page 2526
The module framework allows extensions to contribute to different areas of a page to provide flexibility, enhance the user experience, and maximize performance.

Configuring the MobileFirst properties

Configure the MobileFirst properties to add your preferences to the portal page.

Before you begin

The wp_worklight module requires a wl_config module that is defined in *PortalServer_root*\theme\wp.theme.worklight.ext\installedApps\wp.theme.worklight.ext.ear\wp.theme.worklight.ext.war\WEB-INF\plugin.xml file.

Procedure

1. Use the wl_config module to load the MobileFirst configuration properties.

```
<extension point="com.ibm.portal.resourceaggregator.module" id="wl_portal_config" >
    <module id="wl_config">
     <runtimeActivation>
   <condition deviceClass="worklight"/>
  </runtimeActivation>

          <contribution type="config">
              <sub-contribution type="config_dynamic">
                  <uri value="wl:id" />
              </sub-contribution>
          </contribution>
      </module>
  </extension>
```

2. To activate the MobileFirst configuration properties, add the **"?uri=wl:id:appid"** parameter to the URL from the hybrid application, where the **appid** is replaced with the actual application ID in MobileFirst. After it is activated, the MobileFirst configuration properties are dynamically injected from the application HTML file to the portal page. For example:

```
<script>
  // Define WL namespace.
  var WL = WL ? WL : {};
  /**  * WLClient configuration variables.  * Values are injected by the deployer that packs t
  WL.StaticAppProps = {    "APP_DISPLAY_NAME": "DemoApp",
         "APP_SERVICES_URL": "\/apps\/services\/",
         "ENVIRONMENT": "iphone",
         "LOGIN_DISPLAY_TYPE": "embedded",
         "POSTFIX_APP_SERVICES_URL": "\/apps\/services\/",
         "POSTFIX_WORKLIGHT_ROOT_URL": "\/apps\/services\/api\/DemoApp\/iphone\/",
         "WORKLIGHT_ROOT_URL": "\/apps\/services\/api\/DemoApp\/iphone\/"
       };
</script>
```

3. Configure the MobileFirst configuration properties through JavaScript. For example, use this code:

```
WL.StaticAppProps.ENVIRONMENT
```

4. If your application needs configuration properties in addition to the base ones provided, you can easily mix them into this WL.StaticAppProps object with JavaScript. For example:

```
<script type="text/javascript">
i$.bindDomEvt(window, "onload", function(evt) {
 if (window.WL && window.WL.StaticAppProps) {
  window.WL.StaticAppProps.APP_VERSION = "1.0";
```

```
 window.WL.StaticAppProps.WORKLIGHT_PLATFORM_VERSION = "7.0.0";
 }
});
</script>
```

5. Inject the JavaScript code that you created onto your page from your theme. You can add the code that you just created to one of your existing dynamic content spot `.jsps` or create a new dynamic content spot. Or, you can add the JavaScript to an HTML file in an existing or new module.

Setting up single sign-on with MobileFirst 7.0

You can set up single sign-on with MobileFirst so users can share a session between a WebSphere Portal Express and MobileFirst server.

Before you begin

Both WebSphere Portal Express and MobileFirst servers must be configured to use the same user registry, LTPA keys, and be set with a specified domain for SSO. If you are using the WebSphere Application Server, see the WebSphere Application Server documentation.

For more information about system support requirements, see System requirements.

Procedure

1. Run the following **configEngine** tasks. These **configEngine** tasks are available only on the WebSphere Portal Express server. If the MobileFirst server is on WebSphere Application Server, run the following commands from the WebSphere Integrated Solutions Console. You can use steps B and C if MobileFirst is on the same instance as WebSphere Portal Express.
   a. **ConfigEngine.bat configure-single-signon -Ddomain=<domain name> -DWasRemoteHostName=<hostname> -DWasSoapPort=<port> -DWasPassword=<password> -Dinteroperable=true -DattributePropagation=true -DrequiresSSL=false**
   b. Optional: **ConfigEngine.bat export-ltpakeys-single-signon -DkeyFile=c:\ltpa.txt -DkeyPass=<testpass> -DdmgrFlag=false -DWasRemoteHostName=<hostname> -DWasSoapPort=<port> -DWasPassword=<password>**
   c. Optional: **ConfigEngine.bat import-ltpakeys-single-signon -DkeyFile=c:\ltpa_demo.txt -DkeyPass=<somepassword> -DdmgrFlag=false -DWasRemoteHostName=<hostname> -DWasSoapPort=<port> -DWasPassword=<password>**
2. To prepare the MobileFirst server, you must update the MobileFirst WAR to enable applications to authenticate with the user registry. Update `authenticationConfig.xml` in your MobileFirst project. IT is in *MobileFirst Project*`/server/conf/authenticationConfig.xml`. Find the `<securityTests>` element and add the mobile and web security tests.
   a. Find the `<securityTests>` element and add the mobile and web security tests from the following example.

```
<mobileSecurityTest name="mobileTests">
    <testDeviceId provisioningType="none" />
    <testUser realm="WASLTPARealm" />
</mobileSecurityTest>
<webSecurityTest name="WASLTPARealmTests">
    <testUser realm="WASLTPARealm"/>
</webSecurityTest>
```

b. Uncomment the security realm.

```
<!-- For websphere -->
<realm name="WASLTPARealm" loginModule="WASLTPAModule">
   <className>com.worklight.core.auth.ext.WebSphereFormBasedAuthenticator
       </className>
   <parameter name="login-page" value="/login.html"/>
   <parameter name="error-page" value="/loginError.html"/>
</realm>
```

c. Uncomment the login module for WebSphere.

```
<!-- For websphere -->
<loginModule name="WASLTPAModule">
    <className>com.worklight.core.auth.ext.WebSphereLoginModule</className>
</loginModule>
```

3. Modify the MobileFirst project WAR by adding two new HTML files to the WAR. The project WAR is in */MobileFirst Project*/bin. Copy this WAR to another location for editing.

a. Create an login.html file with the following contents.

```
<html>
    <head>
        <title>Login</title>
    </head>
    <body>
        <form method="post" action="j_security_check">
            <label for="j_username">User name:</label>
            <input type="text" id="j_username" name="j_username" />
            <br />
            <label for="j_password">Password:</label>
            <input type="password" id="j_password" name="j_password" />
            <br />
            <input type="submit" id="login" name="login" value="Log In" />
        </form>
    </body>
</html>
```

b. Create a loginError.html file with the following contents.

```
<html>
    <head></head>
    <body>
        Login Error
    </body>
</html>
```

c. Add the login.html and loginError.html files to the highest level directory of the WAR.

4. Modify the MobileFirst project WAR that was updated in the previous step by editing the web.xml file in the WEB-INF directory.

```
<login-config>
    <auth-method>FORM</auth-method>
    <form-login-config>
        <form-login-page>/login.html</form-login-page>
        <form-error-page>/loginError.html</form-error-page>
    </form-login-config>
</login-config>
```

5. Optional: Add a security constraint to protect the web resource by modifying web.xml in the updated MobileFirst project WAR

```
<security-constraint id="SecurityConstraint_1">
 <web-resource-collection id="WebResourceCollection_1">
  <web-resource-name>mobilefirst</web-resource-name>
  <description>Protecting mobilefirst application</description>
  <url-pattern>/*</url-pattern>
  <http-method>GET</http-method>
  <http-method>POST</http-method>
```

```
 </web-resource-collection>
 <auth-constraint id="AuthConstraint_1">
  <description>MobileFirst applications</description>
  <role-name>Administrator</role-name>
 </auth-constraint>
 <user-data-constraint id="UserDataConstraint_1">
  <transport-guarantee>NONE</transport-guarantee>
 </user-data-constraint>
</security-constraint>

<security-role id="SecurityRole_1">
 <description>Only specific users</description>
 <role-name>Administrator</role-name>
</security-role>
```

6. When the MobileFirst project WAR is updated, deploy it to the MobileFirst server.
7. Restart the server where MobileFirst is installed. If you added the security constraint, map the group or user to the EAR file.
8. Update the `application-descriptor.xml` file to add the security tests you configured. Open *MobileFirst Project*`/apps/`*mobilefirst app*`/application-descriptor.xml` in the design view and update it to have the correct realms and security tests.
9. In the main application, add a security test that is called **WASLTPARealmTests** in the Common (optional) section.
10. In **Android phones and tablets** > **Details**, add the Security test called **mobileTests**.
11. After you create the server-side WAR, change the client side to allow authentication between the two servers. In a demonstration application, modify the HTML of *MobileFirst Project*`/apps/mobilefirst app/common/index.html` to include a login form and JavaScript to handle the response. In a demonstration, `index.html` includes the code in the following example.

```
<!DOCTYPE HTML>
<html>
     <head>
      <meta charset="UTF-8">
      <title>index</title>
      <meta name="viewport" content="width=device-width, initial-scale=1.0, maximum-scale=1.0, m
      <link rel="shortcut icon" href="images/favicon.png">
      <link rel="apple-touch-icon" href="images/apple-touch-icon.png">
      <link rel="stylesheet" href="css/main.css">
      <script>window.$ = window.jQuery = WLJQ;</script>
     </head>
     <body id="content" style="display: none">
      <div id="AppBody">
          <div class="wrapper">
          </div>
      </div>
      <div id="AuthBody" style="display: none">
          <div id="loginForm">
              Username:<br/>
              <input type="text" id="usernameInputField" autocorrect="off" autocapitalize="off"
              Password:<br/>
              <input type="password" id="passwordInputField" autocorrect="off" autocapitalize="o
              <input type="button" id="loginButton" value="Login" />
              <input type="button" id="cancelButton" value="Cancel" />
          </div>
      </div>
      <!--application UI goes here-->
      Hello Worklight
      <script src="js/initOptions.js"></script>
      <script src="js/main.js"></script>
```

```
      <script src="js/messages.js"></script>
      <script src="js/challengeResponse.js"></script>
     </body>
</html>
```

12. Update the initialization options for MobileFirst to force the application to connect to the MobileFirst server on start by adding `WL.Client.connect();` in *MobileFirst Project*/apps/*mobilefirst app*/common/js/main.js.
13. Add JavaScript to handle the response from the MobileFirst and WebSphere Portal Express servers. In this SSO demonstration application, create a file that is called challengeResponse.js, in *MobileFirst Project*/apps/*mobilefirst app*/common/js. Add the following example to the contents of the file. Update the line `goToPortalServer("http://server:port/wps/myportal");` to point to your WebSphere Portal Express server.

```
/*
*  Licensed Materials - Property of IBM
*  5725-G92 (C) Copyright IBM Corp. 2006, 2012. All Rights Reserved.
*  US Government Users Restricted Rights - Use, duplication or
*  disclosure restricted by GSA ADP Schedule Contract with IBM Corp.
*/

var sampleAppRealmChallengeHandler = WL.Client.createChallengeHandler("WASLTPARealm");
var busyIndicator = new WL.BusyIndicator('content', {text: "Loading..."});

sampleAppRealmChallengeHandler.isCustomResponse = function(response) {
    if (!response || response.responseText === null) {
        return false;
    }
    var indicatorIdx = response.responseText.search('j_security_check');

    if (indicatorIdx >= 0){
  return true;
 }
 return false;
};

sampleAppRealmChallengeHandler.handleChallenge = function(response) {
 busyIndicator.show();
 $('#AppBody').hide();
 WL.EncryptedCache.open("wpsadmin", true, onReadOpen, onOpenError);
};

sampleAppRealmChallengeHandler.submitLoginFormCallback = function(response) {
    var isLoginFormResponse = sampleAppRealmChallengeHandler.isCustomResponse(response);
    if (isLoginFormResponse){
     sampleAppRealmChallengeHandler.handleChallenge(response);
    } else {
     $('#AppBody').show();
     $('#AuthBody').hide();
     sampleAppRealmChallengeHandler.submitSuccess();
     WL.Client.getCookies().then(function (cookies) {
      busyIndicator.hide();
      goToPortalServer("http://server:port/wps/myportal");
     });
    }
};

$('#loginButton').bind('click', function () {
 busyIndicator.show();
 WL.EncryptedCache.write("username", $('#usernameInputField').val(), onWriteSuccess, onWriteF
 function onWriteSuccess(status){
  WL.EncryptedCache.write("password", $('#passwordInputField').val(), onWriteSuccess2, onWrit
  function onWriteSuccess2(status2){
   WL.EncryptedCache.close(onCloseCompleteHandler, onCloseFailureHandler);
```

```
  }
 }
 function onWriteFailure(status){
  alert("Encrypted cache closed, writing failed");
 }
});

function onCloseCompleteHandler(status){
 var reqURL = '/j_security_check';
    var options = {};
    options.parameters = {
        j_username : $('#usernameInputField').val(),
        j_password : $('#passwordInputField').val()
    };
    options.headers = {};
    sampleAppRealmChallengeHandler.submitLoginForm(reqURL, options, sampleAppRealmChallengeHandl
}

function onCloseFailureHandler(status){
 alert("close faiure");
}

$('#cancelButton').bind('click', function () {
 sampleAppRealmChallengeHandler.submitFailure();
 $('#AppBody').show();
 $('#AuthBody').hide();
});

function onReadOpen(status){
 WL.EncryptedCache.read("username", onDecryptReadSuccess, onDecryptReadFailure);
 function onDecryptReadSuccess(value){
  WL.EncryptedCache.read("password", onDecryptReadSuccess2, onDecryptReadFailure);
  function onDecryptReadSuccess2(value2){
   if (value && value2){
    // submit 1 & 2
    var reqURL = '/j_security_check';
       var options = {};
       options.parameters = {
           j_username : value,
           j_password : value2
       };
       options.headers = {};
       sampleAppRealmChallengeHandler.submitLoginForm(reqURL, options, sampleAppRealmChallengeHa
   } else {
    // Didn't find any cached info, ask for login.
    busyIndicator.hide();
    $('#AuthBody').show();
    $('#passwordInputField').val('');
   }
  }
 }
 function onDecryptReadFailure(status){
  alert("Encrypted cache closed, reading failed");
 }
}

 function onOpenError(status){
 switch(status){
  case WL.EncryptedCache.ERROR_KEY_CREATION_IN_PROGRESS:
   alert("ERROR: KEY CREATION IN PROGRESS");
   break;
  case WL.EncryptedCache.ERROR_LOCAL_STORAGE_NOT_SUPPORTED:
   alert("ERROR: LOCAL STORAGE NOT SUPPORTED");
```

```
   break;
  case WL.EncryptedCache.ERROR_NO_EOC:
   alert("ERROR: NO EOC");
   break;

   break;
  default:
   alert("AN ERROR HAS OCCURED. STATUS :: " + status);
 }
}
```

yes

14. Create a Cordova Plugin that adds the token the the WebView's cookie store so WebSphere Portal Express can recieve the LtpaToken from an Android application.
    a. Create a Java file called `CookieInjector.java` in *`MobileFirst Project`*`/apps/`*`mobilefirst app`*`/android/native/src/com/`*`mobilefirst app`*. Add the following code to it. Replace *mobilefirst app* with your app name.

```
package com.mobilefirst_app;

import java.util.List;

import org.apache.cordova.CallbackContext;
import org.apache.cordova.CordovaArgs;
import org.apache.cordova.CordovaPlugin;
import org.apache.http.client.CookieStore;
import org.apache.http.cookie.Cookie;
import org.json.JSONException;

import android.webkit.CookieManager;

import com.worklight.common.Logger;
import com.worklight.wlclient.HttpClientManager;

public class CookieInjector extends CordovaPlugin {
 Logger l = Logger.getInstance(CookieInjector.class.getName());

 @Override
 public boolean execute(String action, CordovaArgs args, CallbackContext callbackContext)
  if ("INJECT-COOKIES-TO-WEBVIEW".equals(action)){
   l.debug("Started injecting cookies");

   CookieStore cookieStore = HttpClientManager.getInstance().getHttpClient().getCookieSto
   List<Cookie> list = cookieStore.getCookies();
   for (Cookie cookie : list){
    String cookieName = cookie.getName();
    l.debug("Found cookie :: " + cookieName);
    if ("LtpaToken".equals(cookieName)){
     l.debug("Found LtpaToken cookie");
     CookieManager cookieManager = CookieManager.getInstance();
     String cookieValue = cookie.getName() + "=" + cookie.getValue();
     cookieManager.setCookie(cookie.getDomain(), cookieValue);
     break;
    }
    l.debug("LtpaToken cookie not found");
   }
   l.debug("Done injecting cookies");
   callbackContext.success();
   return true;
```

```
        }
        return false;
      }
    }
```

b. Add the following code to *MobileFirst Project*/apps/*mobilefirst app*/android/native/res/xml/config.xml before the closing </widget> tag. Replace *mobilefirst app* with your app name.

```
<feature name="CookieInjector">
    <param name="android-package" value="com.mobilefirst_app.CookieInjector" />
</feature>
```

15. Add the following function to *MobileFirst Project*/apps/*mobilefirst app*/android/apps/mobilefirst app/android/js/main.js.

```
function goToPortalServer(url) {
 cordova.exec(function () {
  location.href = url;
 }, function () {
  alert('failure injecting cookies');
 }, "CookieInjector", "INJECT-COOKIES-TO-WEBVIEW",[]);
}
```

16. Build your MobileFirst application for your MobileFirst server by right-clicking the MobileFirst application and selecting **Run As** > **Build Settings and Deploy Target**.
17. Select **Build the application to work with a different MobileFirst server**.
18. Add the information for your MobileFirst server to the **Server** and **Context path** fields.
19. Build your application by right-clicking the MobileFirst application and selecting **Run As** > **Build All Environments**.
20. Install the MobileFirst application to your MobileFirst server. Open the MobileFirst console at http://server:port/worklightconsole and upload the MobileFirst application by adding it to the **Deploy application or adapter** field. Your MobileFirst application file can be found in your Eclipse workspace in the bin folder. The MobileFirst application file has the .wlapp extension.

CF07 "Setting up single sign-on with MobileFirst"
You can set up single sign-on with MobileFirst so users can share a session between a WebSphere Portal Express and MobileFirst server.

Setting up single sign-on with MobileFirst:

You can set up single sign-on with MobileFirst so users can share a session between a WebSphere Portal Express and MobileFirst server.

Before you begin

SSO is no longer supported on Android with Worklight 6.2.

Both WebSphere Portal Express and MobileFirst servers must be configured to use the same user registry, LTPA keys, and be set with a specified domain for SSO. For more information, see *Configuring Portal to use a user registry* and *Managing your user registry*. Or, if you are using the WebSphere Application Server, see the WebSphere Application Server documentation.

For more information about system support requirements, see System requirements.

Procedure

1. Run the following **configEngine** tasks. These **configEngine** tasks are available only on the WebSphere Portal Express server. If the MobileFirst server is on WebSphere Application Server, run the following commands from the WebSphere Integrated Solutions Console. You can use steps B and C if MobileFirst is on the same instance as WebSphere Portal Express.
   a. **ConfigEngine.bat configure-single-signon -Ddomain=<domain name> -DWasRemoteHostName=<hostname> -DWasSoapPort=<port> -DWasPassword=<password> -Dinteroperable=true -DattributePropagation=true -DrequiresSSL=false**
   b. Optional: **ConfigEngine.bat export-ltpakeys-single-signon -DkeyFile=c:\ltpa.txt -DkeyPass=<testpass> -DdmgrFlag=false -DWasRemoteHostName=<hostname> -DWasSoapPort=<port> -DWasPassword=<password>**
   c. Optional: **ConfigEngine.bat import-ltpakeys-single-signon -DkeyFile=c:\ltpa_demo.txt -DkeyPass=<somepassword> -DdmgrFlag=false -DWasRemoteHostName=<hostname> -DWasSoapPort=<port> -DWasPassword=<password>**
2. To prepare the MobileFirst server, you must update the MobileFirst WAR to enable applications to authenticate with the user registry. Update `authenticationConfig.xml` in your MobileFirst project. IT is in *MobileFirst Project*`/server/conf/authenticationConfig.xml`. Find the `<securityTests>` element and add the mobile and web security tests.
   a. Find the `<securityTests>` element and add the mobile and web security tests from the following example.

```
<mobileSecurityTest name="mobileTests">
    <testDeviceId provisioningType="none" />
    <testUser realm="WASLTPARealm" />
</mobileSecurityTest>
<webSecurityTest name="WASLTPARealmTests">
    <testUser realm="WASLTPARealm"/>
</webSecurityTest>
```

   b. Uncomment the security realm.

```
<!-- For websphere -->
<realm name="WASLTPARealm" loginModule="WASLTPAModule">
   <className>com.worklight.core.auth.ext.WebSphereFormBasedAuthenticator
       </className>
   <parameter name="login-page" value="/login.html"/>
   <parameter name="error-page" value="/loginError.html"/>
</realm>
```

   c. Uncomment the login module for WebSphere.

```
<!-- For websphere -->
<loginModule name="WASLTPAModule">
    <className>com.worklight.core.auth.ext.WebSphereLoginModule</className>
</loginModule>
```

3. Modify the MobileFirst project WAR by adding two new HTML files to the WAR. The project WAR is in */MobileFirst Project*`/bin`. Copy this WAR to another location for editing.
   a. Create an `login.html` file with the following contents.

```
<html>
    <head>
        <title>Login</title>
    </head>
    <body>
        <form method="post" action="j_security_check">
            <label for="j_username">User name:</label>
```

```
                <input type="text" id="j_username" name="j_username" />
                <br />
                <label for="j_password">Password:</label>
                <input type="password" id="j_password" name="j_password" />
                <br />
                <input type="submit" id="login" name="login" value="Log In" />
            </form>
        </body>
    </html>
```

b. Create a `loginError.html` file with the following contents.

```
<html>
    <head></head>
    <body>
        Login Error
    </body>
</html>
```

c. Add the `login.html` and `loginError.html` files to the highest level directory of the WAR.

4. Modify the MobileFirst project WAR that was updated in the previous step by editing the `web.xml` file in the `WEB-INF` directory.

```
<login-config>
    <auth-method>FORM</auth-method>
    <form-login-config>
        <form-login-page>/login.html</form-login-page>
        <form-error-page>/loginError.html</form-error-page>
    </form-login-config>
</login-config>
```

5. Optional: Add a security constraint to protect the web resource by modifying `web.xml` in the updated MobileFirst project WAR

```
<security-constraint id="SecurityConstraint_1">
 <web-resource-collection id="WebResourceCollection_1">
  <web-resource-name>mobilefirst</web-resource-name>
  <description>Protecting mobilefirst application</description>
  <url-pattern>/*</url-pattern>
  <http-method>GET</http-method>
  <http-method>POST</http-method>
 </web-resource-collection>
 <auth-constraint id="AuthConstraint_1">
  <description>MobileFirst applications</description>
  <role-name>Administrator</role-name>
 </auth-constraint>
 <user-data-constraint id="UserDataConstraint_1">
  <transport-guarantee>NONE</transport-guarantee>
 </user-data-constraint>
</security-constraint>

<security-role id="SecurityRole_1">
 <description>Only specific users</description>
 <role-name>Administrator</role-name>
</security-role>
```

6. When the MobileFirst project WAR is updated, deploy it to the MobileFirst server.
7. Restart the server where MobileFirst is installed. If you added the security constraint, map the group or user to the EAR file.
8. Update the `application-descriptor.xml` file to add the security tests you configured. Open *MobileFirst Project*`/apps/`*mobilefirst app*`/application-descriptor.xml` in the design view and update it to have the correct realms and security tests.
9. In the main application, add a security test that is called **WASLTPARealmTests** in the Common (optional) section.

10. In **Android phones and tablets** > **Details**, add the Security test called **mobileTests**.
11. Open *MobileFirst Project*/apps/*mobilefirst app*/application-descriptor.xml and add the <securityTests> element.

```
<securityTests>
    <mobileSecurityTest name="mobileTests">
        <testDeviceId provisioningType="none" />
        <testUser realm="WASLTPARealm" />
    </mobileSecurityTest>
    <customSecurityTest name="WASLTPARealmTests">
        <test realm="WASLTPARealm" isInternalUserID="true"/>
    </customSecurityTest>
</securityTests>
```

12. Add the example <realm> for WASLTPARealm.

```
<realm loginModule="WASLTPAModule" name="WASLTPARealm">
      <className>com.worklight.core.auth.ext.FormBasedAuthenticator</className>
  </realm>
 </realms>
```

13. Add the example <loginModule> for WASLTPAModule.

```
<loginModule name="WASLTPAModule">
 <className>com.worklight.core.auth.ext.NonValidatingLoginModule</className>
</loginModule>
```

14. After you create the server-side WAR, change the client side to allow authentication between the two servers. In an SSO demonstration application, modify the HTML of *MobileFirst Project*/apps/mobilefirst app/common/index.html to include a login form and JavaScript to handle the response. In a demonstration, index.html includes the code in the following example.

```
<!DOCTYPE HTML>
<html>
     <head>
      <meta charset="UTF-8">
      <title>index</title>
      <meta name="viewport" content="width=device-width, initial-scale=1.0, maximum-scale=1.0
      <link rel="shortcut icon" href="images/favicon.png">
      <link rel="apple-touch-icon" href="images/apple-touch-icon.png">
      <link rel="stylesheet" href="css/main.css">
      <script>window.$ = window.jQuery = WLJQ;</script>
     </head>
     <body id="content" style="display: none">
      <div id="AppBody">
          <div class="wrapper">
          </div>
      </div>
      <div id="AuthBody" style="display: none">
          <div id="loginForm">
              Username:<br/>
              <input type="text" id="usernameInputField" autocorrect="off" autocapitalize="of
              Password:<br/>
              <input type="password" id="passwordInputField" autocorrect="off" autocapitalize
              <input type="button" id="loginButton" value="Login" />
              <input type="button" id="cancelButton" value="Cancel" />
          </div>
      </div>
      <!--application UI goes here-->
      Hello Worklight
      <script src="js/initOptions.js"></script>
      <script src="js/main.js"></script>
      <script src="js/messages.js"></script>
      <script src="js/challengeResponse.js"></script>
     </body>
</html>
```

15. Update the initialization options for MobileFirst to force the application to connect to the MobileFirst server on start by changing `connectOnStartup` from **`false`** to **`true`** in *`MobileFirst Project`*`/apps/`*`mobilefirst app`*`/common/js/initOptions.js`.
16. Add JavaScript to handle the response from the MobileFirst and WebSphere Portal Express servers. In this SSO demonstration application, create a file that is called `challengeResponse.js`, in *`MobileFirst Project`*`/apps/`*`mobilefirst app`*`/common/js`. Add the following example to the contents of the file. Update the line <code>location.href= "http://server:port/wps/myportal"</code> to point to your WebSphere Portal Express server.

```
/*
*  Licensed Materials - Property of IBM
*  5725-G92 (C) Copyright IBM Corp. 2006, 2012. All Rights Reserved.
*  US Government Users Restricted Rights - Use, duplication or
*  disclosure restricted by GSA ADP Schedule Contract with IBM Corp.
*/

var sampleAppRealmChallengeHandler = WL.Client.createChallengeHandler("WASLTPARealm");
var busyIndicator = new WL.BusyIndicator('content', {text: "Loading..."});

sampleAppRealmChallengeHandler.isCustomResponse = function(response) {
    if (!response || response.responseText === null) {
        return false;
    }
    var indicatorIdx = response.responseText.search('j_security_check');

    if (indicatorIdx >= 0){
  return true;
 }
 return false;
};

sampleAppRealmChallengeHandler.handleChallenge = function(response) {
 busyIndicator.show();
 $('#AppBody').hide();
 WL.EncryptedCache.open("wpsadmin", true, onReadOpen, onOpenError);
};

sampleAppRealmChallengeHandler.submitLoginFormCallback = function(response) {
    var isLoginFormResponse = sampleAppRealmChallengeHandler.isCustomResponse(response);
    if (isLoginFormResponse){
     sampleAppRealmChallengeHandler.handleChallenge(response);
    } else {
  $('#AppBody').show();
  $('#AuthBody').hide();
  sampleAppRealmChallengeHandler.submitSuccess();
  setTimeout(function(){
      busyIndicator.hide();
   location.href= "http://server:port/wps/myportal";
  }, 1000);
    }
};

$('#loginButton').bind('click', function () {

    alert("ERROR: CREDENTIALS MISMATCH");
    break;
   default:
    alert("AN ERROR HAS OCCURED. STATUS :: " + status);
  }
 }
```

yes

17. Build your MobileFirst application for your MobileFirst server by right-clicking the MobileFirst application and selecting **Run As** > **Build Settings and Deploy Target**.
18. Select **Build the application to work with a different MobileFirst server**.
19. Add the information for your MobileFirst server to the **Server** and **Context path** fields.
20. Build your application by right-clicking the MobileFirst application and selecting **Run As** > **Build All Environments**.
21. Install the MobileFirst application to your MobileFirst server. Open the MobileFirst console at `http://server:port/worklight/console` and upload the MobileFirst application by adding it to the **Deploy application or adapter** field. Your MobileFirst application file can be found in your Eclipse workspace in the `bin` folder. The MobileFirst application file has the `.wlapp` extension.

Meta-Modules for IBM MobileFirst integration

MobileFirst provides a set of ready-to-use modules.

These MobileFirst integration modules are not associated with a specific release. You can define which version of MobileFirst or Worklight to use.

The Meta-Module definitions are stored in the following files: CF07

- `mobilefirst70.json`
- `dav:fs-type1/themes/Portal8.5/contributions/mobilefirst70.json`
- If you want to use a previous version of MobileFirst, other versions are available at `PortalServer/theme/wp.theme.worklight.ext/installedApps/wp.theme.worklight.ext.ear/wp.theme.worklight.ext.war/`*`worklight version`*`/`

You can have only one file in the folder at one time because the contribution files are not supported at the same time. Specific MobileFirst Integration modules are listed in the MobileFirst 6.1 Integration sections.

MobileFirst Meta-Modules

- wp_worklight_ext
- wp_worklight
- wp_worklight_css
- wp_worklight_css_android
- wp_worklight_css_ios
- wp_worklight_jsonstore

CF07

MobileFirst 7.0 Integration

These modules initialize the MobileFirst Client and Cordova API to enable support for native device capabilities and other functions of the MobileFirst server. The modules are only aggregated when accessed through the MobileFirst hybrid shell.

The `plugin.xml` file location is *PortalServer_root*`/theme/wp.theme.worklight.ext/installableApps/wp.theme.worklight.ext.ear/wp.theme.worklight.ext.war/WEB-INF/plugin.xml`

For more information about these modules, their prerequisites or runtime activation, use the Theme Analyzer Portlet.

Table 133. List of MobileFirst 7.0 integration modules

Module	Description
mf_overrides_70	Provides overrides to the MobileFirst Client API to allow integration with WebSphere Portal Express
mf_android_70	Provides MobileFirst Client and Cordova JavaScript resources for Android devices
mf_ios_70	Provides MobileFirst Client and Cordova JavaScript resources for iOS devices
mf_winphone_70	Provides MobileFirst Client and Cordova JavaScript resources for Windows Phone devices.
mf_plugins_reg_android_70	Provides the Cordova plug-in definition list
mf_plugins_android_70	Provides the Cordova plug-ins JavaScript resources that enable native feature access for Android devices
mf_plugins_ios_70	Provides the Cordova plug-ins JavaScript resources that enable native feature access for iOS devices
mf_plugins_windphone_70	Provides the Cordova plug-ins JavaScript resources that enable native feature access for Windows Phone devices.
mf_client_css_android_70	Provides MobileFirst client CSS for Android devices, specifically for the diagnostic window, and modal dialog
mf_client_css_ios_70	Provides MobileFirst client CSS for iOS devices, specifically for the diagnostic window, and modal dialog
mf_client_css_winphone_70	Provides MobileFirst client CSS for Windows Phone devices, specifically for the diagnostic window, and modal dialog.
mf_client_jsonstore_android_70	Provides the JSON store feature for Android devices
mf_client_jsonstore_ios_70	Provides the JSON store feature for iOS devices
mf_client_jsonstore_winphone_70	Provides the JSON store feature for Windows Phone devices.

CF03

MobileFirst 6.2 Integration

These modules initialize the MobileFirst Client and Cordova API to enable support for native device capabilities and other functions of the MobileFirst server. The modules are only aggregated when accessed through the MobileFirst hybrid shell.

The `plugin.xml` file location is *PortalServer_root*`/theme/wp.theme.worklight.ext/installableApps/wp.theme.worklight.ext.ear/wp.theme.worklight.ext.war/WEB-INF/plugin.xml`

For more information about these modules, their prerequisites or runtime activation, use the Theme Analyzer Portlet.

Table 134. List of MobileFirst 6.2 integration modules

Module	Description
wl_overrides_62	Provides overrides to the MobileFirst Client API to allow integration with WebSphere Portal Express
wl_android_62	Provides MobileFirst Client and Cordova JavaScript resources for Android devices
wl_ios_62	Provides MobileFirst Client and Cordova JavaScript resources for iOS devices
wl_winphone_62	Provides MobileFirst Client and Cordova JavaScript resources for Windows Phone devices.
wl_plugins_reg_android_62	Provides the Cordova plug-in definition list
wl_plugins_android_62	Provides the Cordova plug-ins JavaScript resources that enable native feature access for Android devices
wl_plugins_ios_62	Provides the Cordova plug-ins JavaScript resources that enable native feature access for iOS devices
wl_plugins_windphone_62	Provides the Cordova plug-ins JavaScript resources that enable native feature access for Windows Phone devices.
wl_client_css_android_62	Provides MobileFirst client CSS for Android devices, specifically for the diagnostic window, and modal dialog
wl_client_css_ios_62	Provides MobileFirst client CSS for iOS devices, specifically for the diagnostic window, and modal dialog
wl_client_css_winphone_62	Provides MobileFirst client CSS for Windows Phone devices, specifically for the diagnostic window, and modal dialog.
wl_client_jsonstore_android_62	Provides the JSON store feature for Android devices
wl_client_jsonstore_ios_62	Provides the JSON store feature for iOS devices
wl_client_jsonstore_winphone_62	Provides the JSON store feature for Windows Phone devices.

MobileFirst 6.1 Integration

These modules initialize the MobileFirst Client and Cordova API to enable support for native device capabilities and other functions of the MobileFirst server. The modules are only aggregated when accessed through the MobileFirst hybrid shell.

The `plugin.xml` file location is *PortalServer_root*`/theme/wp.theme.worklight.ext/installableApps/wp.theme.worklight.ext.ear/wp.theme.worklight.ext.war/WEB-INF/plugin.xml`

For more information about these modules, their prerequisites or runtime activation, use the Theme Analyzer Portlet.

Table 135. List of MobileFirst 6.1 integration modules

Module	Description
wl_overrides_61	Provides overrides to the MobileFirst Client API to allow integration with WebSphere Portal Express
wl_android_61	Provides MobileFirst Client and Cordova JavaScript resources for Android devices
wl_ios_61	Provides MobileFirst Client and Cordova JavaScript resources for iOS devices
wl_plugins_reg_android_61	Provides the Cordova plug-in definition list
wl_plugins_android_61	Provides the Cordova plug-ins JavaScript resources that enable native feature access for Android devices
wl_plugins_ios_61	Provides the Cordova plug-ins JavaScript resources that enable native feature access for iOS devices
wl_client_css_android_61	Provides MobileFirst client CSS for Android devices, specifically for the diagnostic window, and modal dialog
wl_client_css_ios_61	Provides MobileFirst client CSS for iOS devices, specifically for the diagnostic window, and modal dialog
wl_cordova_css_61	Provides Cordova client CSS, specifically for the tab bar component
wl_client_jsonstore_android_61	Provides the JSON store feature for Android devices
wl_client_jsonstore_ios_61	Provides the JSON store feature for iOS devices

"Enabling JSON store module"
JSONStore features add the ability to store JSON documents in IBM MobileFirst applications.

Enabling JSON store module:

JSONStore features add the ability to store JSON documents in IBM MobileFirst applications.

About this task

JSONStore is a lightweight, document-oriented storage system that is included as a feature of MobileFirst, and enables persistent storage of JSON documents by using JavaScript API. Documents in an application are available in JSONStore even when the device that runs the application is offline. This persistent, always-available storage gives customers, employees, or users access to documents when for example there is no network connection to the device.

Procedure

1. Create page.
2. Place your custom portlet with the JSON store feature on the page that you created.
3. Edit the page profile and add the module `wp_mobilefirst_jsonstore` to the profile and save it.

Target MobileFirst resources

You can change the way that a web page looks for any device with responsive web design. Device classes are generic groupings of form factors so client devices can view web pages for every form factor without designing the page for each device.

When a client communicates with the server, it can be profiled into one or more of the generic device classes. Then, the client can be sent only the resources it needs for rendering its form factor. If you are using device classes, often you can also use device class logic equations, which are Boolean equation of device classes. Device class logic equations help narrow down the exact situation you want resources to be loaded.

With the default theme, responsive design and device classes and logic minimize resources that are downloaded by devices. For example, when you use navigation across devices, the theme modules provide a different navigation JSP for rendering and separate style sheets for different device types. The desktop gets the normal default experience. When a tablet or smartphone is detected, it switches over to the mobile navigation JSP page. With a `tablet` device class, the mobile navigation JSP turns into a side navigation. If any smartphone is detected and given the `smartphone` device class, the mobile navigation is rendered in a list. The device classes also change the containers to allow the content to fit on the smaller screen. Some features, such as edit mode, can be disabled.

The main use of device classes is by modules, which can use them to specify when a subcontribution resource is used. Dynamic content spots can also target a device class with a multiview choice (MVC) URL. For more information, see *mvc:URI scheme*. The device class is available as an attribute on the Composite Capabilities/Preference Profiles and can be retrieved within a JSP. You can also use device equations, which are device classes with Boolean logic for further control of what devices receive which set of resources. For more information, see *Device class equations*. There is a global variable available on the configuration object that can help targeting code in the JavaScript editor. For more information, see *Additional information about device classes for developers*.

There are some cases where you cannot use device classes with the device class logic equations. They cannot be used to determine layout templates, page filtering with the `supported-deviceclass` tag, and personalization. Personalization cannot

use device equation logic directly as defined by the Boolean logic. But it can create its own targeting rules of Boolean logic with the visibility rules editor. For more information, see *Device classes*.

A global JavaScript variable is provided for further customizing the user experience. The global variable `com_ibm_device_class` provides an array list of all currently set devices classes. If none are set, it is an empty array. For example, if you have JavaScript specific for processing smartphones, you can include the following code.

```
if (com_ibm_device_class.indexOf("smartphone") !== -1) {
//process smartphone
}
```

If you wanted to be more specific and target an iOS device that runs in a MobileFirst container, you can include the following code.

```
if (com_ibm_device_class.indexOf("ios") !== -1 && com_ibm_device_class.indexOf("worklight") !== -1
//process ios worklight
}
```

Related concepts:

"mvc:URI scheme" on page 2823
The `mvc:URI` scheme is a special URI format that accesses different resources, depending on the device class. This scheme is used by the Portal 8001 theme in the definition of several dynamic content spots.

"Device class equations" on page 2825
Device class equations are expressions that involve a mixture of device class operands and boolean logic operators.

"Device classes" on page 2821
Device classes are used in IBM WebSphere Portal Express as an abstraction for common properties for the device of a client. For instance, tablet computers can be grouped into a device class `tablets`, since they share a form factor and possibly other traits such as touch interface, or additional hardware sensors.

"Additional information about device classes for developers" on page 2822
The `DeviceClass` profile attribute contains only the highest priority device class on the client. Highest priority is determined as the first device class listed for the client. `DeviceClassList` provides access to all device classes on a client, as a string of comma-separated values.

Upgrading MobileFirst

You can create an EAR file, and copy MobileFirst resources into that EAR to keep up to date with the newest MobileFirst release.

About this task

The existing MobileFirst extension EAR is installed under the `\PortalServer\theme` location. You cannot modify this location directly since any changes can be overridden by a fix pack. You must create your own custom MobileFirst extension EAR and install it in `\wp_profile`. When you create your own EAR, start with a copy of the existing EAR and modify it. During this process, you replace occurrences of `wp` and `wps` with `custom` and occurrences of the current MobileFirst version number with your MobileFirst version number.

Procedure

1. Export the `worklight_extension.ear` from the WebSphere Integrated Solutions Console.

a. Click **Applications** > **Application Types** > **WebSphere enterprise applications**.
b. Click **Next** until you find the **worklight_extension** application.
c. Select **worklight_extension** and click **Export** on the toolbar.
d. Click the `worklight_extension.ear` link to download and save the EAR file to your file system.

2. Import the `worklight_extension.ear` into Eclipse or Rational Application Developer with Java EE Developer tools plug-in.
   a. Click **File** > **Import**.
   b. Select **Java EE** > **EAR file**. Then, click **Next**.
   c. Click **Browse**. Find and select `worklight_extension.ear` you exported to your file system.
   d. Rename the EAR project from **worklight_extension** to `custom_mobilefirst_extension` and then click **Next** twice.
   e. In the **Project Name** field, change the name from **wp.theme.worklight.ext** to `custom.theme.mobilefirst.ext` and then click **Finish**.
3. Customize the ear in Eclipse or Rational Application Developer for the new version of MobileFirst.
   a. In the custom_mobilefirst_extension EAR project, delete the `EarContent\META-INF\ibmconfig` folder and its contents.
   b. Right-click on the custom_mobilefirst_extension EAR project and select **Properties**. Select **Deployment Assembly**.
   c. Select the **wp.theme.worklight.ext.war Deploy Path** and rename it to `custom.theme.mobilefirst.ext.war`.
   d. Click **Apply** and **OK**.
   e. In the custom_mobilefirst_extension EAR project, delete the `EarContent\wp.theme.worklight.ext.war` file.
4. In the `custom_mobilefirst_extension` EAR project, modify the `EarContent\META-INF\application.xml` file. Change the display-name from MobileFirst Extension to `Custom Mobilefirst Extension`.
   a. Change the module ID from `wp.theme.worklight.ext` to `custom.theme.mobilefirst.ext`.
   b. Change the `web-uri` from `wp.theme.worklight.ext.war` to `custom.theme.mobilefirst.ext.war`.
   c. Change the `context-root` from `/wps/worklightExt` to `/custom/mobilefirstExt`.
5. In the `custom.theme.mobilefirst.ext` war project, modify the `WebContent\WEB-INF\web.xml` file.
   a. Change the web-app ID from wp_theme_worklight_ext_webapp_1 to `custom_theme_mobilefirst_ext_webapp_1`.
   b. Change the display-name from `Worklight_Extensions` to `Custom MobileFirst Extensions`.
6. In the `custom.theme.mobilefirst.ext` war project, in WebContent, create your new version folder and its contents. First, examine the existing version folder and its contents because that shows the folder structure that you create.
   a. Right-click on **WebContent** and select **New** > **Folder**.
   b. Enter the MobileFirst version number that you are working with as the folder name. For example, use v*your_new_mobilefirst_version*, where *your_new_mobilefirst_version* is your current version number.

c. Right-click on the folder you created and create child folders that are called `android` and `ios`.

d. Locate the Android-specific folders in your MobileFirst project. In previous versions, they were in `\YourMFProject\apps\YourApp\android\native\assets\www\default\js` and `\YourMFProject\apps\YourApp\android\native\assets\www\default\worklight` folders in your Eclipse MobileFirst project. Copy and paste them into the `v*your_new_mobilefirst_version*\android` folder.

e. Locate the iOS specific folders in your MobileFirst project. In previous versions, they were in `\YourMFProject\apps\YourApp\iphone\native\assets\www\default\js` and `\YourMFProject\apps\YourApp\iphone\native\assets\www\default\worklight` folders in your Eclipse MobileFirst project. Copy and paste them into the `v*your_new_mobilefirst_version*\ios` folder.

f. Locate the Windows Phone specific folders in your Worklight project. In previous versions, they were in `\YourMFProject\apps\YourApp\windowsphone8\native\assets\www\default\js` and `\YourMFProject\apps\YourApp\windowsphone8\native\assets\www\default\worklight` folders in your Eclipse MobileFirst project. Copy and paste them into the `v*your_new_mobilefirst_version*\winphone` folder.

g. Locate the `init.js` file in `WebContent\v*previousversion*\android\js` folder and copy it to the `WebContent\v*new_version*\android\js` folder.

h. Locate the `init.js` file in `WebContent\v*previousversion*\ios\js` folder and copy it to the `WebContent\v*new_version*\ios\js` folder.

i. Locate the `init.js` file in `WebContent\v*previousversion*\winphone\js` folder and copy it to the `WebContent\v*new_version*\winphone\js` folder.

j. Locate the `mobilefirst*previous_version*.json` file in the current version folder, where *previous_version* is the current MobileFirst version number. Copy it and paste it in your new version folder. Rename the file `mobilefirst*new_version*.json`, where *new_version* is your new MobileFirst version number.

k. Edit the newly copied file, find, and replace all occurrences of the current MobileFirst version number with your MobileFirst version number and save the file. This file defines the version-independent meta modules that `prereq` the version-dependent modules that are defined in the `plugin.xml` file in the next step.

7. Determine whether overrides for Cordova and MobileFirst APIs are required. WebSphere Portal Express defines overrides for Cordova and MobileFirst APIs to improve performance and integrate with WebSphere Portal Express.

   a. To prevent an error when MobileFirst resources load, the `WL.Utils.loadWLClientMessages` and `WL.Utils.setLocalization` functions are overridden. If these are still needed, locate and copy the portal directory from each of the Android and iOS directories in `WebContent\v*previous_version*\` and copy them to their respective directories in `WebContent\v*new_version*\`. Verify that the content of these functions accurately reflects the content from your new version of MobileFirst.

   b. If the Cordova APIs did not change, either copy the changes in the `WebContent\v*previousversion*\android\worklight\cordova.js` file and `WebContent\v*previousversion*\ios\worklight\cordova.js` to the new version of the MobileFirst folder. This method reduces the number of requests to WebSphere Portal Express. Or, Leave the Cordova API, and add a `<script>` element to all the pages that require MobileFirst resources. The `<script>` element must reference the `cordova.js` file directory. To

improve performance for MobileFirst applications in WebSphere Portal Express, two Cordova APIs were changed. Originally, the Cordova APIs attempt to load all of the Cordova plug-ins individually by dynamically determining their location. However, it is not possible with WebSphere Portal Express resource aggregation. The `injectScript` and `findCordovaPath` functions are rewritten to use the `ibmCfg.portalConfig.worklightResourcesPath[version_number]` JavaScript variable to determine the location of the Cordova resources. This value of this variable comes from the Resource Environment Provider property that you create in a following step. The `version_number` used in the variable must be updated to reflect the new version number, which is reflected in the following changes to the resource environment provider property.

c. Copy the changes that are in `WebContent\vprevious_version\android\worklight\cordova.js` and `WebContent\vprevious_version\ios\worklight\cordova.js` and copy them into the new version of MobileFirst that you are upgrading to. This offers a performance improvement, because it reduces the number of requests that are made to the WebSphere Portal Express server for the MobileFirst resources.

d. Leave the Cordova API as it is and add a `<script>` element to all pages that require MobileFirst resources. The `<script>` element must reference the `cordova.js` file directly.

8. In the `custom.theme.mobilefirst.ext` war project, edit the `WebContent\WEB-INF\plugin.xml` file.

   a. Change the plug-in ID from `wp.theme.worklight.ext` to `custom.theme.mobilefirst.ext`.

   b. Change the plug-in name from MobileFirst plug-ins to `Custom MobileFirst plugins`.

   c. Change the plug-in provider-name from IBM to your company's name.

   d. Find and replace all occurrences of the current MobileFirst version number with your MobileFirst version number. Find and replace version numbers in both the formats 000 and 0.0.0. These changes must correspond with the changes made previously to `mobilefirstprevious_version.json`. This `plugin.xml` file defines the version-dependent modules that are `prereqed` by the version-independent meta modules that are defined in `mobilefirstprevious_version.json` in the previous step.

   e. Locate the `mf_android_new_version` and `mf_ios_new_version` modules, where *new_version* is the new MobileFirst version number, and verify all of their subcontributions. Review the resources for the new version of MobileFirst, and if there are any differences, modify the subcontributions so that each resource file has a subcontribution. In these modules, each resource is explicitly listed when debug mode is enabled. When it is not enabled, WebSphere Portal Express provides a single JavaScript layer for the MobileFirst resources. Create a similar layer for the resources of the new version of MobileFirst. This layer must be defined as a subcontribution here. If you choose not to create a JavaScript layer for the MobileFirst resources, add and verify that required resources are listed as subcontributions.

   f. Locate the `mf_plugins_android_new_version` and `mf_plugins_ios_new_version` modules, where *new_version* is the new MobileFirst version number, and verify all of their subcontributions. Review the resources for the new version of MobileFirst, and if there are any differences, modify the subcontributions so that each resource file has a subcontribution. In these modules, each resource is explicitly listed when debug mode is enabled. When it is not enabled, WebSphere Portal Express

provides a single JavaScript layer for the MobileFirst resources. Create a similar layer for the resources of the new version of MobileFirst. This layer must be defined as a subcontribution here. If you choose not to create a JavaScript layer for the MobileFirst resources, add and verify that required resources are listed as subcontributions.

g. In the `custom.theme.mobilefirst.ext` war project, delete the `WebContent\previous_version` folder, where *previous_version* is the current MobileFirst version number, and all of its contents.

9. Export your customized ear as `custom_mobilefirst_extension.ear` from Eclipse or Rational Application Developer.
   a. Right-click **custom_mobilefirst_extension ear project** and select **Export** > **EAR** file.
   b. Click **Browse** and choose a destination folder and name of `custom_mobilefirst_extension.ear`.
   c. Click **Finish** to save the EAR file to your file system.
10. Add a `resources.mobilefirst.extensions.`*new_version* resource environment provider property in the WebSphere Integrated Solutions Console.
   a. Click **Resources** > **Resource Environment** > **Resource Environment Providers**.
   b. Click **Next** until you find the **WP ConfigService** resource environment provider and then select it.
   c. Click the **Custom properties** link.
   d. Click **New** from the toolbar.
   e. Enter `resources.mobilefirst.extensions.`*new_version* for the name, where *new_version* is replaced by your new MobileFirst version number.
   f. Enter `/custom/mobilefirstExt/`*new_version* for the value where *new_version* is replaced by your new MobileFirst version number.
   g. Enter the path to the MobileFirst v*new_version_number* extensions for the description where *new_version_number* is replaced by your new MobileFirst version number in the `v0.0.0` format.
   h. Click **OK**.
   i. Click **Save** to save directly to the master configuration.
11. Deploy the `custom_mobilefirst_extension.ear` in the WebSphere Integrated Solutions Console.
   a. Click **Applications** > **Application Types** > **WebSphere enterprise applications**.
   b. Click **Install** in the toolbar.
   c. Click **Browse** in the local file system, find, and select your `custom_mobilefirst_extension.ear` file and click **Next**.
   d. Take the defaults and click **Next**.
   e. Take the defaults and click **Next**.
   f. Verify that the Directory to install application field is blank so that it installs to the default location. Delete anything in the field if it is not.
   g. Take the defaults and click **Next**.
   h. Click **Finish**.
   i. When the EAR is done installing without error, click **Save** to save to the master configuration.

j. Find and check your new Custom MobileFirst Extension enterprise application and click **Start** from the toolbar. Your EAR is now installed at \wp_profile\installedApps*cell*\Custom Mobilefirst Extension.ear.

12. Modify your theme contributions to load your new version of the MobileFirst extensions. You continue to use the same meta module names in your theme profiles, such as wp_worklight_android and wp_worklight_ios. You must change the JSON file in the theme contributions folder to change which version-specific modules the meta modules load.
    a. Use WebDAV to connect to fs-type1:themes*yourtheme*\contributions.
    b. Delete the mobilefirst*previous_version*.json file, where *previous_version* is the previous MobileFirst version number. If you back up the file, move it to a different location. Do not rename the file .jsonbak, for example, because every file in the contributions folder is loaded by the system. You must remove the file completely.
    c. Copy your mobilefirst*new_version*.json file into the contributions folder. The file can be copied from \wp_profile\installedApps*cell*\Custom Mobilefirst Extension.ear\custom.theme.mobilefirst.ext.war\v*new_version*\mobilefirst*new_version*.json, where *new_version* is replaced by your MobileFirst version number. If you must revert to the previous version of MobileFirst, you can get the mobilefirst*previous_version*.json file back from \PortalServer\theme\wp.theme.worklight.ext\installedApps\wp.theme.worklight.ext.ear\wp.theme.worklight.ext.war\v*previous_version*\mobilefirst*previous_version*.json, where *previous_version* is the original MobileFirst version number.
13. Restart the WebSphere Portal Express server.

Results

The MobileFirst meta modules, such as wp_worklight_ext, now load and use the resources for your new version of MobileFirst.

Integrating with Brightcove

If you are using videos as part of your website, integrate your portal with the Brightcove video streaming server.

Brightcove is a video hosting and streaming service in the cloud that is designed to host large video files and serve simultaneous requests. Web Content Manager content repository and the Rich Media Edition Asset Management system are not designed for video. Brightcove also transcodes the video into different formats and bit rates for mobile users. Web Content Manager provides default integration with Brightcove. Users can seamlessly select video for the content author and a rendering of the video with the Brightcove cloud.

Security

Brightcove uses a model that is based on tokens and not user IDs and passwords or certificates. These tokens are stored as part of the portlet preferences and exported with xmlaccess exports of the portal configuration.

"Configuring WebSphere Portal Express to use Brightcove" on page 1033
Before you can integrate with Brightcove, you must configure WebSphere Portal Express.

Configuring WebSphere Portal Express to use Brightcove

Before you can integrate with Brightcove, you must configure WebSphere Portal Express.

Before you begin

You must have a Brightcove account to integrate it with WebSphere Portal Express.

Procedure

1. Log in to Brightcove.
2. Click **Account Settings** > **API Management**.
3. Select **Read Token** and **Upload Token**.
4. Run the ConfigEngine task to set up Brightcove. In the following command, replace *readToken* and *uploadToken* with the read and upload tokens you selected from Brightcove. Upload tokens are called Write tokens in Brightcove. Replace *wasPassword* and *wpsPassword* with the WebSphere Application Server and WebSphere Portal Express passwords.

   ```
   ConfigEngine.sh setup-brightcove-plugins -DBrightcove.ReadToken=readToken -DBrightcove.UploadT
   ```

   By default, this task is performed on the base portal. To run this task on a different virtual portal, identify the virtual portal by adding one of the following parameters to the command line. Each parameter requires the prefix **-D** on the command line.

   VirtualPortalHostName
   Specify the host name of the virtual portal. For example, vp.*your_host*.com.

VirtualPortalContext
Specify the virtual portal context that identifies the virtual portal. For example, `vp1`.

5. Restart WebSphere Portal Express.

   Note: For cluster installs, the ConfigEngine task must be performed the primary node only. The restart must be performed on all nodes in the cluster.

Results

The Brightcove setup task performs the following actions.

- Install the `dam.brightcove` WAR file that contains the integration plug-in and the Brightcove video management portlet with unique name `ibm.portal.Brightcove`.
- Sets the preferences `BC_READ_TOKEN` and `BC_UPLOAD_TOKEN` to the provided values.
- Creates a hidden page with unique name `ibm.portal.page.hidden.Brightcove` and puts the Brightcove video management portlet on that page.

Updating the Brightcove read or upload tokens

The read or upload Brightcove tokens can be updated with a ConfigEngine task.

Procedure

1. To update the Brightcove tokens in WebSphere Portal Express, run a ConfigEngine task to set your portlet preferences. Use the same *readToken* and *uploadToken* from Brightcove. If you do not set these values, the test tokens are installed. Your *readToken* must have URL access to enable the preview video on the video details page.

   `ConfigEngine.sh set-portlet-preferences.brightcove -DBrightcove.ReadToken=`*`readToken`* `-DBrightcove.`

   By default, this task is performed on the base portal. To run this task on a different virtual portal, identify the virtual portal by adding one of the following parameters to the command line. Each parameter requires the prefix **-D** on the command line.

   VirtualPortalHostName
   Specify the host name of the virtual portal. For example, `vp.`*`your_host`*`.com`.

   VirtualPortalContext
   Specify the virtual portal context that identifies the virtual portal. For example, `vp1`.

2. Restart WebSphere Portal Express.

   Note: For cluster installs, the ConfigEngine task must be performed the primary node only. The restart must be performed on all nodes in the cluster.

Brightcove video management portlet

The Brightcove video management portlet renders the selection user interface for selecting a video. It uses the public Brightcove REST API to connect to Brightcove and retrieve the data. It connects with the Outbound and Ajax proxy.

Portlet configuration settings

Access the Brightcove video management portlet. Click the **Administration menu** icon. Then, click **Portlet Management** > **Portlets**. Search for the Brightcove video management portlet. Click **Configure**.

BC_BASE_LIBRARY_URL
Default: `http://api.brightcove.com/services/library` Brightcove URL used for the REST read calls.

BC_BASE_URL
Default: `https://videocloud.brightcove.com/`. Brightcove URL started for the **Launch Video Manager** button.

BC_DEFAULT_SORT_TYPE
Default: `Publish Date`. Default sort criteria for the videos list. Valid values: `Publish date, Creation date, Last modified date, Total plays, Plays this week`.

BC_META_DATA
Default:
`id,name,shortDescription,linkURL,linkText,tags,thumbnailURL,referenceId,FLVURL,ec`
Metadata that is retrieved from Brightcove from the REST call.

BC_READ_TOKEN
Default: `none`. Brightcove Read REST token, specific to the Brightcove account, see Update tokens section.

BC_UPLOAD_TOKEN
Brightcove Write REST token, specific to the Brightcove account, For more information, see *Update the Brightcove read or upload tokens*.

BC_UPLOAD_URL
Default: `http://api.brightcove.com/services/post`. Brightcove URL for uploading videos.

BC_USE_AJAX_PROXY
Enables or disables the Ajax proxy. If you disable the Ajax proxy, upload no longer works because of browser security restrictions.

Configuring the Outbound/AJAX proxy

The default configuration is stored in the `proxy-config.xml` of the Brightcove WAR file. For more information, see *Set up Ajax proxy*.

Related tasks:

"Set up Ajax proxy" on page 748
The support for community pages uses the Ajax proxy to access the remote server. The Ajax proxy is updated for the base Connections URLS during the Connections Portlets installation. If FileNet is used, you must still configure the Ajax proxy manually to update for FileNet. Configure the Ajax proxy so that direct requests that the CCM portlet makes to the FileNet server are allowed to pass through the proxy Server.

"Updating the Brightcove read or upload tokens" on page 1034
The read or upload Brightcove tokens can be updated with a ConfigEngine task.

Overriding default configurations

The Brightcove portlet stores some default values, such as the Brightcove REST read and upload token or the default view to render. You can override the read REST token, the upload REST token, and the view configuration settings with the content template.

About this task

When you override the default configuration settings, you can make specific content templates for playlists. Or you can create content templates for a new account.

Procedure

1. In the Brightcove portlet preferences, configure the content template elements `BC_OVERRIDE_READ_TOKEN`, `BC_OVERRIDE_UPLOAD_TOKEN`, and `BC_OVERRIDE_VIEW`. For example, set `BC_OVERRIDE_READ_TOKEN` to read, `BC_OVERRIDE_UPLOAD_TOKEN` to upload and `BC_OVERRIDE_VIEW` to view.
2. Define the corresponding elements in then default content. The elements must be of type text or OptionSelection. The values defined in the content template and default content are active. The elements can be hidden from the content authors creating content items based on the these templates.

Brightcove selection user interface overview

Brightcove is integrated with the Web Content Manager user interface.

Selecting a video or playlist

After you install Brightcove, the authoring form of the File Resource Component or a File Resource element in a content items authoring template provides an option to choose from in the Brightcove Video Manager. If a user clicks **Select**, the Brightcove video management portlet starts in a new window that displays the videos from the Brightcove account that matches the read token. The user can select a video or playlist, or read the details of the selection. To preview a video, the browser must be able to display the uploaded file format.

Uploading a video

You can upload a new video. Click **Upload**. The video is not immediately available for playback on the website while Brightcove transcodes the video.

Starting the video management user interface

With **Launch Video Manager**, the full Brightcove user interface can be started in a new browser tab to work with videos. You must log in with the Brightcove user ID and password.

Search

You can search videos with the search box by the video name, description and tags. You can also click a tag on the detail page of a video to search for other videos with that tag.

To search for terms that start with a letter sequence, you can use the `*` as wildcard, such as `sam*` to find `sample`.

Related tasks:

Searching for Videos with the Media API

Integrate the Brightcove video player

The video that you select in your file element or file component does not render without a Brightcove video player. Brightcove provides a customizable player that you can copy and paste into a Web Content Manager presentation template or HTML component.

In this example, the video ID can be accessed with the format parameter **videoID** in component or element tags.

```
[Element context="current" type="content" key="Video" format="videoID"]
Accesses the video ID of a file element named "Video".
```

The following example replaces the hardcoded video player ID with the element tag. Replace the value *YOUR PLAYER TOKEN* and *YOUR PLAYER KEY* in the **playerID** and **playerKey** parameters.

```
<style type="text/css">
  .outer-container {
           position: relative;
           height: 0;
           padding-bottom: 56.25%;
         }
         .BrightcoveExperience {
           position: absolute;
           top: 0;
           left: 0;
           width: 100%;
           height: 100%;
         }
     </style>

<div id="container1" class="outer-container">
<!-- Start of Brightcove Player -->
<div style="display:none">

</div>

<!--
By use of this code snippet, I agree to the Brightcove Publisher T and C
found at https://accounts.brightcove.com/en/terms-and-conditions/.
-->

<script language="JavaScript" type="text/javascript" src="http://admin.brightcove.com/js/Brightcov

<object id="myExperience_[Property context="current" type="content" field="id"]" class="Brightcove
  <param name="wmode" value="transparent" />

  <param name="bgcolor" value="#FFFFFF" />
  <param name="playerID" value="YOUR PLAYER TOKEN" />
  <param name="playerKey" value="YOUR PLAYER KEY" />
  <param name="isVid" value="true" />
  <param name="isUI" value="true" />
  <param name="dynamicStreaming" value="true" />

  <param name="@videoPlayer" value="[Element context="current" type="content" key="Video" format="
</object>

<!--
This script tag will cause the Brightcove Players defined above it to be created as soon
as the line is read by the browser. If you wish to have the player instantiated only after
the rest of the HTML is processed and the page load is complete, remove the line.
-->
```

```
<script type="text/javascript">brightcove.createExperiences();</script>

<!-- End of Brightcove Player -->
</div>
```

If the following message displays for every video, `The video you are trying to watch is currently unavailable. Please check back soon.`, verify the player token and key are correct.

For a playlist player, the **playlistTabs** parameter must point to the ID of the currently selected playlist.

```
<param name="@playlistTabs" value="[Element context="current" type="content" key="Video" format="vide
```

You can store these markup templates as an HTML component and have different components for each player. Then, you can combine the file and player in one authoring template. For example, you can add a `File Element` called `Video` and a `Component Reference` called `Video Player`.

Then, display the player in the presentation template. In this example, you can change the selected video with inline editing.

```
[EditableElement context="current" type="content" key="Video" format="div"]
   [Element context="current" type="content" key="Video player"]
 [/EditableElement]
```

Note: The Brightcove video player is not supported in Opera.

Related tasks:

Creating an editable element tag

Uninstalling Brightcove

Uninstalling Brightcove removes the integration WAR file and the hidden portal page.

Procedure

1. Run the **remove-brightcove-plugins** ConfigEngine task. `ConfigEngine.sh remove-brightcove-plugins [-DWasPassword=`*wasPassword*`] [-DPortalAdminPwd=<`*wpsPassword*`]`. This task is performed on the base portal. But since it removes the WAR file, you must also remove the hidden pages from all virtual portals that have the Brightcove hidden page deployed.
2. To remove the hidden pages, run the **action-remove-pages-portlet.brightcove** ConfigEngine task. `ConfigEngine.sh action-remove-pages-portlet.brightcove [-DWasPassword=<`*wasPassword*`>] [-DPortalAdminPwd=<`*wpsPassword*`>`

   By default, this task is performed on the base portal. To run this task on a different virtual portal, identify the virtual portal by adding one of the following parameters to the command line. Each parameter requires the prefix **-D** on the command line.

   VirtualPortalHostName
   Specify the host name of the virtual portal. For example, `vp.`*`your_host`*`.com`.

   VirtualPortalContext
   Specify the virtual portal context that identifies the virtual portal. For example, `vp1`.
3. Restart WebSphere Portal Express.

Note: For cluster installs, the ConfigEngine task must be performed the primary node only. The restart must be performed on all nodes in the cluster.

Troubleshooting the Brightcove player

If you are having trouble with your videos, check this troubleshooting section to see if there are workarounds.

Brightcove video does not render on the screen

Check to see whether the video player markup has the correct player ID and key. Compare it to the markup from the Brightcove video cloud user interface. If that doesn't work, check to see whether the Brightcove cloud is experiencing any issues with the Brightcove Status page.

Brightcove video cannot be edited

Check to see whether the Brightcove plug-in was successfully deployed and if the read and upload tokens are correct. For more information, see *Brightcove video management portlet*.

Video on subscriber portals do not play

Without the plug-in and proper tokens, Web Content Manager cannot play the video on a subscriber portal. Syndicate a virtual portal instead. The Brightcove plug-in is global and available to base and virtual portals.

Limitations and known issues

- The Video details view contains a preview of the video. This preview renders the originally uploaded video, and creates an error if the current browser does not support the video format.
- The **Upload** and **Delete** buttons do not display in Internet Explorer. Internet Explorer does not support JSON return messages.
- Brightcove searches use word stemming by default. For more information, see *Searching for videos in the media module*.
- Playlists are not searchable.
- Tags in Brightcove do not synchronize with WebSphere Portal Express and do not show up as tags in your portal.
- Page numbers do not immediately reflect additional video uploads.
- Internet Explorer 10 or older does not support media fragments in an HTML5 video player. The preview and setting starting and ending points with the slider function are not functional.
- For any playback issues on different devices and browsers, see the Brightcove support site for more information.

Chapter 11. Administering

Use the administration tools that are provided with the portal to do various day-to-day administration tasks. There are two methods for editing portal setup: using the administration portlets or the XML configuration interface. The administration portlets are a convenient way to make real-time updates to the portal's configuration. While the XML configuration interface is suited to more advanced administration, including batch processing of updates.

"Managing your site" on page 1296
Earlier versions of WebSphere Portal Express provided the Resource Manager portlet for performing site management. With Version 8.0 of WebSphere Portal Express and Web Content Manager, this site management functionality has been replaced by the new functionality for managing pages.

"Tagging and rating" on page 1297
Get an overview of the administrative tasks related to tagging and rating.

"Using WebDAV with WebSphere Portal Express" on page 1351
WebSphere Portal Express provides a Web-based Distributed Authoring and Versioning (WebDAV) implementation that individual services can use by plugging into. WebDAV is a set of extensions to the HTTP protocol that allows you to collaborate on editing and managing files on remote Web servers. Caching Proxy supports WebDAV methods used by Microsoft Exchange Server, and user-defined (customized) methods. These methods are hard coded and managed by the Enable and Disable directives. Administrators can also use the corresponding method-mask defined in the PROTECT directive to authorize the use of these methods.

"Virtual portals" on page 1361
View information on how you can scope your WebSphere Portal Express to have multiple virtual portals.

"Language support" on page 1419
To reach as many users as possible, WebSphere Portal Express supports different languages for different locations. For instance, a large, international corporation might address users in different countries or regions through multilingual Web sites. In this context the portal can concurrently serve portal views to large numbers of users, each in the user's preferred language.

"WSRP services" on page 1433
IBM WebSphere Portal Express supports the Web Services for Remote Portlets (WSRP) standard. By using this standard, portals can provide portlets, applications, and content as WSRP services. Other portals can then integrate the WSRP services as remote portlets for their users.

"Browser behavior and scenarios" on page 1506
Browser behavior for the back button, bookmarks and history affect user interaction and cause unexpected results.

Portal administration tools

Learn about the different tools that you can use to administer your portal.

You can administer and configure portal resources by using one of the following tools:

- The portal administration portlets.
- The portal XML configuration interface.
- The Portal Scripting Interface.
- The portal ReleaseBuilder.
- The configuration wizard.

The portal provides several administration tools for limited purposes. These tools are documented in the context where they can be used. An example is the SLCheckerTool, which you can use to delete orphaned data.

Security considerations

IBM WebSphere Portal Express provides a flexible delegation model for administering portal resources. This means that a master administrator can delegate administration and configuration work to subadministrators or other users as required in a highly detailed manner. For example, the master administrator can delegate the responsibility and rights for different administrative tasks to different departments in the same business. These departments can be for developing, deploying, and operating software solutions that are based on WebSphere Portal Express.

The delegation model is implemented by access control, which works by access control decisions, which guard the execution of administrative tasks that manipulate portal resources. Users can complete a task only if they have the access permissions that are required for that task. Access permissions are implemented as user rights on actions that are related to portal resources, not on the resources themselves. For more information, refer to the documentation about access control.

The extent to which the portal delegation model and access control is tied in varies between the portal administration tools. Security might therefore influence which tool you use for a certain purpose.

Overview of administration portlets

Portal administrative users can use the administration portlets for the following tasks:

- Completing administrative tasks and actions on portal resources, depending on the access rights that the administrative user has on those resources. These tasks include:
  - Configuring individual portal resources.
  - Configuring individual portal resources, together with their dependent resources. For example, this configuration can be pages and the pages that are derived from them.
- Giving other users, for example subadministrators, limited access rights on selected portal resources. These subadministrators can then complete administrative tasks that their access rights allow. As the master administrator, you can widen or limit that extent by modifying the access rights for these users on the portal resources. This way, you can delegate administrative tasks as required.
- Deploying your own custom developed artifacts, such as portlets, themes, or skins.

You cannot use the administration portlets to complete scripted or automated administration or configuration tasks.

For more information, refer to the documentation about the administration portlets that are supplied with WebSphere Portal Express.

Overview of the XML configuration interface

The XML configuration interface works as follows:

- The XML configuration interface provides a batch processing interface for portal configuration updates. It allows you to export an entire portal configuration or

parts of a configuration, for example-specific pages, to an XML file. You can then re-create the exported configuration from such a file on another portal.

- You access the XML configuration interface by using a command-line tool. This command-line client is a small separate program that connects to the server by using an HTTP connection. You can therefore use it remotely.
- You can use the XML configuration interface to process portal resources, but not portal actions or tasks.
- You can use the XML configuration interface to process the configuration of portal resources that exist, for example pages. In this context, the XML configuration interface processes derived resources, but it does not automatically create them.
- The XML configuration interface does not reflect the access control authorization model with delegated administration. You need only the access permission to use the XML configuration interface. An administrator who works with the XML configuration interface does not need access permission for the portal resources that are processed by the XML request. (The reason for this is that access control gives users access permissions on actions and not on resources.)

You can use the XML configuration interface for the following tasks:

- Exporting, importing, and updating complete or partial portal installations. These tasks can be for the following purposes:
  - Transfer or migration between workstations
  - Back up of the portal configuration
  - Overview of the portal configuration.
  - Cloning of a portal. To complete this step, you use the object ID generation mode of the XML configuration interface.
- Copying parts of a configuration, such as specific pages, from one portal to another.
- Transferring portal configurations from one installation to another. You do this transfer by exporting and importing the portal configuration. This usage scenario includes the case where you try out a new portal configuration on a test portal for evaluation, and then transfer it to a production portal in a separate step by using the portal configuration interface.
- Creating a portal configuration file by XML export. You complete this step by an XML export.
- Installing extra resources on a portal.
- Completing recurring administration tasks in an automated and reproducible manner.
- Completing these administrative tasks remotely, that is, from another server through an HTTP connection.

Security: A user who uses the XML configuration interface to complete administrative tasks needs only the access permission on the virtual resource XML_ACCESS. The user does not need access rights on the portal resources that are updated by the XML configuration interface.

Use of the XML configuration interface for the following tasks is limited:

- Delegating administrative tasks, that is, having other administrative users with specific access permissions complete these tasks.
- Limiting administrative tasks to a particular user or to particular portal resources.

For more information, refer to the documentation about the XML configuration interface.

The XML configuration interface is also used for release staging, that is, for staging a portal from development through test to production. For more information about staging your portal to production, refer to the topics about staging to production and ReleaseBuilder.

Overview of the Portal Scripting Interface

The Portal Scripting Interface works as follows:

- The Portal Scripting Interface is a command-line tool.
- The Portal Scripting Interface behaves just like the portal administration portlets. It provides delegated administration in the same manner as the portal administration portlets and access control. To work with Portal Scripting Interface, a user needs access permission on the WebSphere Portal Express and on the portal resources that the user administers.
- It allows implicit derivation during administrative work. This means when you modify a portal resource, the Portal Scripting Interface creates the derivations of that resource in the same process, depending on your access rights.

You can use the Portal Scripting Interface for the following tasks:

- Making fine-tuned changes to a portal configuration.
- Transferring configuration updates in a safe and controlled manner, and without disturbing the production portal. For example, this process can happen by the following steps:
  1. On a development system, a development team develops configuration updates for the portal, and the script for running these updates.
  2. After the script is completed, a test team tests both the script and the new configuration.
  3. After the script and the new configuration are tested and approved, they can be applied to the production portal.
  4. An operator team processes the scripts that update the production portal.

The Portal Scripting Interface has the following advantages:

- Security: The user IDs and access roles of the involved teams provide separation between the responsibilities for the subtasks:
  - The development and test team do not have access rights on the production portal.
  - The operator who runs the script must have access rights on the resources that are created and updated by the script. Therefore, if you limit the access rights for that user as required, the script cannot affect other resources unintentionally.
- Safety and availability of the production portal:
  - The scripts can be tested and verified before it is put into production.
  - After the scripts are tested and verified, they perform the update in a reliable way. Human errors that might happen when you are working with the administration portlets are not possible.
  - The production portal does not even require an Administration page for performing the update.
  - The update can be performed over night without disturbing production.

Use of the Portal Scripting Interface is limited in the following way:

- The Portal Scripting Interface offers only a subset of the functionality of the portal administration portlets. For details, refer to the Portal Scripting Interface command reference.

Overview of ReleaseBuilder

To generate or stage follow-on releases of IBM WebSphere Portal Express portals, configurations, and artifacts need to be moved between systems. ReleaseBuilder enables management of release configurations independent of user configurations.

Release configuration data are exported to XML files that can be imported using the XML configuration interface (XmlAccess). Using ReleaseBuilder it is possible to stage release configurations between two portals. This allows you to track which configuration entities were removed, added, or changed compared to the previous release generated from a given portal and to apply these differential updates to another portal. Detecting the differences between one configuration and another of the same portal server creates differential updates. A third configuration or "diff", generated by ReleaseBuilder, represents the changes made between the two configurations. The third configuration can be used to apply not only addition and update modifications but also deletions to the target server. This allows two portal servers, for example, a staging server and a production server, to remain in synch. ReleaseBuilder is designed to eliminate the need to generate complete XmlAccess exports to move a partial configuration or to manually create XML response files to export a partial configuration. ReleaseBuilder also helps to prevent the problem of configuration bloat on the target server.

Overview of Configuration Wizard

Use the Configuration Wizard to set up stand-alone servers and new deployments, create clusters, migrate and update to new versions, and add new capabilities to existing deployments.

In the Configuration Wizard, you answer questions about the environment that you are configuring. Based on your answers, the wizard prompts you for custom values that are needed to configure your environment. Finally, the wizard generates custom steps and scripts to set up your environment.

"Portal administration portlets" on page 1047

Portal administration portlets

Administration portlets are supplied with IBM WebSphere Portal Express. Use them to perform administration tasks and actions on portal resources, give other users limited access rights on selected resources, and deploy custom portlets, themes, or skins.

"Administration portlets overview"
WebSphere Portal Express has administration portlets that assist you with managing resources. Get an overview of the administration portlets and the tasks you can complete with each portlet.

"Working with administration portlets" on page 1052
Working with the portal administration portlets allows you to customize the administration portlet and its features, such as, defining the number of rows to display in a table.

Related information:

Technotes for administration portlets

Administration portlets overview

WebSphere Portal Express has administration portlets that assist you with managing resources. Get an overview of the administration portlets and the tasks you can complete with each portlet.

Note: Subadministrators of virtual portals might not have access to all administration portlets listed here. For information, refer to the topics about multiple virtual portals.

Portal User Interface

The following sections describe the portlets that are provided for customizing the user interface for WebSphere Portal Express.

Manage Pages
Use the **Manage Pages** portlet to export page configurations in XML, create, edit, activate, order, and delete pages and external web pages and labels. Available tasks depend on which item is selected.

Themes and Skins
Use the **Themes and Skins** portlet to install, edit, and delete themes and skins. You can also select a default theme and skin with this portlet. See the Themes and Skins portlet help for specific instructions on these tasks.

Page Templates
Page Templates are not accessed by a portlet, but they provide a means for managing portal pages. Page templates include common page elements and make page creation easy. To work with page templates, users can, but

do not have to configure pages and their properties, such as theme or page layout. For example, web site designers can create and manage page templates that match your web site design. Content authors can then use the page templates to create content ready pages for different content types. Working with page templates is not limited to administrators. Users need only limited access permissions to work with page templates.

Portlet Management

The following sections describe the portlets that are provided for working with portlets, web modules, and applications.

Web Modules
Use the **Manage Web Modules** portlet to install new portlets from either a web service or a WAR file. You can also use the portlet to manage existing portlets or view a list of portlet applications for a web module. A web module is a WAR file that contains portlet applications.

Applications
Use the **Manage Applications** portlet to enable a portlet application as a web service or to manage existing portlet applications. It displays a list of all web modules and associated portlet applications that are installed on WebSphere Portal Express. You can view and change portlet application settings from this portlet. Tasks include renaming and deleting portlet applications, and modifying configuration parameters. See the Manage Applications portlet help for steps on completing these and related tasks.

Portlets
Use the **Manage Portlets** portlet to view or manage existing portlets, or enable portlets as web services. It displays a list of all installed portlets. Use the **Manage Portlets** to view and change portlet settings. Tasks include renaming and deleting portlets, and adding, modifying, or deleting portlet configuration parameters. See the Manage Portlets help for steps on completing these and related tasks.

Web Services
Use the **Web Service Configuration** portlet to set up your portal for consuming web services for Remote Portlets (WSRP) by configuring WSRP Producers on the Consumer side. For more details, refer to the topics about Using WSRP services.

You cannot use the **Web Service Configuration** portlet for the following actions:

- Provide web services that make your portlets available to other systems such as remote web services. To provide web services as a Producer, use the **Manage Portlets** portlet.
- Consume web services that integrate web services that are provided by a Producer as remote portlets. To consume web services as a Consumer, use the **Manage Web Modules** portlet.

Virtual Web Application Manager
Use the **Virtual Web Application Manager** portlet to create content provider profiles in your portal site. These profiles are required to integrate web-based content from different providers, such as Microsoft SharePoint. You can then create Web Dock applications based on the content provider application details that are rendered on a portal page in an iFrame.

Portal Access

Users and Groups

Use the **Users and Groups** portlet to search for, edit, and delete existing users and groups. You can also create new users and groups and modify group membership.

Resource Permissions

Use the **Resource Permissions** portlet to set access roles. You can assign access roles to associate users and groups with resources to determine the level of interaction a user can have with a resource.

User and Group Permissions

Use the **User and Group Permissions** portlet to easily assign, view, and modify the roles and permissions that users and groups have on various resources. Refer to the **User and Group Permissions** portlet help.

Credential Vault

Use the **Credential Vault** portlet to complete tasks that are specific to vault management. You can add or manage vault segments and vault slots.

Portal Settings

Global Settings

You can use the **Global Settings** portlet to define what the user sees, including the default language and the **Find** link. The default language that is specified in Global Settings applies to all users when the language preference specified in their browser is not supported. For example, the portal is configured to support English, German, and Spanish, with English as the default language in **Global Settings**. A user, whose browser language preference is set to Italian, would see English because Italian is not supported in this case. A user can also select a preferred language when they register.

The **Global Settings** portlet also determines what users see when they return to the portal. For example, you can choose to display the most recently viewed page rather than a default page. You can allow users themselves to choose what they see when they log on, or if they see the default page or the most recently viewed page. You can also determine a URL for the **Find** link. For more information about the **Find** link, refer to the topic about setting the search engine that opens when users select **Find**.

Note: The **Global Settings** portlet does not work in portal cluster configurations.

Custom Unique Names

WebSphere Portal Express uses object IDs to identify resources unambiguously even between different portals. They consist of an extended alphanumeric string that might be difficult to remember. Use the **Custom Unique Names** portlet to assign unique names to resources. You can select names that are easy to read and remember. These custom unique names make identification of resources easier than the object IDs assigned by WebSphere Portal Express, for example when porting resources from one portal to another.

Supported Markups

Use the **Supported Markups** portlet to determine which markups are

recognized. You can add, edit, activate or deactivate, and delete a markup. The installation default is HTML. See the **Supported Markups** portlet help for detailed instructions.

Note: Leave the default HTML markup enabled. Removing or changing the HTML markup causes access problems. If the default HTML markup is disabled, use the XML configuration interface to re-enable the HTML markup.

Supported Clients
With the **Supported Clients** portlet, you can determine what types of devices and web browsers can access the portal. You can add, edit, order, or delete clients. If you need to test a portlet with a device simulator, you might need to add the user agent string of the device simulator to the portal client list. Consult the documentation included with the device simulator to determine the user agent strings the simulator supports and add them with the **Supported Clients** portlet. Read the **Supported Clients** portlet help for detailed steps on working with clients.

Import XML
Use the **Import XML** portlet to import an XML file. For example, from a staging server you can export pages and portlets into XML with **XML export** on **Manage Pages** and then use the **Import XML** portlet to import the configuration to a production server.

Portal Content

Web Content Libraries
Add, edit, copy, and delete web content libraries to better manage your web content. You can also specify access control settings for the library itself and the types of content it contains.

Syndicators
Create, edit, and delete syndicators that are used to replicate content between Web Content Manager environments. Syndicators identify the libraries that are available for replication by subscribers. You can define which libraries are available for syndication and change the order that libraries are syndicated.

Subscribers
Create, edit, and delete subscribers that are used to replicate content between Web Content Manager environments. Subscribers are associated with a syndicator and receive updates from all libraries that are specified by the syndicator.

Feed Configuration
The Feed Configuration portlet helps you create and manage RSS feed consumers for creating and updating web content.

Feed Jobs
The Feed Jobs portlet helps you create and manage schedules for the web content RSS feed consumers.

Search Administration

Manage Search
Use the **Manage Search** portlet to create and manage search services, search collections, and search scopes. Searchable resources include various document types, for example HTML and text documents. WebSphere

Portal Express sites can also be indexed and searched. Refer to the Manage Search portlet help for detailed instructions about working with search.

Portal Analysis

Theme Analyzer
Use the Theme Analyzer to view, but not edit, all parts of the theme optimization framework of WebSphere Portal Express. With this portlet, you can view which pages have specific profiles that are set or inherited. You can also see which profiles are available and belong to which theme.

Additionally, you can browse and explore all aspects of the available modules: You can see which modules are loaded for a specific profile or all modules of the whole system. You can drill down into the dependency hierarchy to understand interdependencies and get different views on it, such as a parent view. The module explorer also features a rich search set so that you can easily find modules that contribute certain resources or capabilities, or browse all exposed data.

This portlet also provides a number of utilities to help you debug theme issues such as client-side tracing, export module languages, and other debugging tools. In case of problems, you can also export your set of data as a compressed file and share it with others. They can then import your data set and examine your profiles and modules.

Frequent Users
The **Frequent Users** portlet shows how many users are logged in for the past 90 days.

Enable Tracing
Use the **Enable Tracing** portlet to enable or disable the tracing logs. See the Enable Tracing portlet help for detailed instructions on working with logs.

Use the **Enable Tracing** portlet to dynamically enable or disable trace-logging for individual classes and entire packages without restarting WebSphere Portal. In a WebSphere Portal cluster, the portlet lists and changes the currently running trace loggers on only one individual server (not the entire cluster). To dynamically change the trace specification for the entire cluster, you must use the Enable Tracing portlet on each individual server (horizontal or vertical cluster member).

About WebSphere Portal Express
This portlet shows the version and fix level of your WebSphere Portal Express. It also shows the product numbers and the Copyright years.

Manage Virtual Portals

Manage Virtual Portals
Use the **Virtual Portal Manager** portlet to create, list, modify, and delete virtual portals. When you create a virtual portal, it is filled with the initial default content for virtual portals. For more information about the **Virtual Portal Manager**, refer to the portlet help.

Other portlets that are useful for administration

There are other portlets not accessible from Administration that is also useful in administering WebSphere Portal Express.

Site Map

WebSphere Portal Express provides the **Site Map** portlet. It serves two purposes:

- You can use the Site Map portlet to browse the site. It displays a list of the pages and portlets. You can access this portlet by logging in to the portal, clicking **Search Center**, then clicking the **Site Map** tab
- The Site Map portlet enables external search crawlers to collect pages more efficiently.

Properties

Use the **Properties** portlet to modify properties on pages and portlets. You can access this portlet when you create a new page, editing an existing page, or from the **Manage pages** administration portlet.

Note: The current limitations for the **Properties** portlet are:

- The list of shareable pages that are displayed by the **Properties** portlet is limited to those pages that the user can go to. As a result, a user might not be able to create explicitly derived pages from some shareable pages.
- A user must have at least Editor privileges on a page to be able to edit the properties on that page. Privileged users are not able to edit a page's properties or edit personalization rules because Personalization rules are part of a page's properties.

Working with administration portlets

Working with the portal administration portlets allows you to customize the administration portlet and its features, such as, defining the number of rows to display in a table.

To work with the portal administration portlets, click the **Administration menu** icon to open the administration menu. The portal displays the navigation for the administration portlets.

Before you use the portal administration portlets, read the concept and background information for administrative tasks. Refer to the appropriate topics in the *Administering* section of this portal information center. For detailed steps for performing portal administrative tasks, refer to the help of each portlet.

You can customize the administration portlets by using the configure mode of the portlet. For example, you can configure features such as the layout of the portlet and the number of rows to display.

Searching for portal resources in administration portlets

Portal administration portlets that list portal resources, such as pages, portlets, users, or virtual portals, provide a search feature. You can search for resources available in the portlet. You can use an asterisk (*) as a wildcard character for your search. Following is a list of some search types. Their availability differs between portlets. It depends on the portal resource type that the portlet administers.

- **Title starts with:** Select this option to search on the beginning of a string in the title. This setting is the default setting, and the input is expected in string format.
- **Title contains:** Select this option to search on a string in the title. The input is expected in string format.

- **Name starts with:** Select this option to search on the beginning of a string in the name. The input is expected in string format.
- **Name contains:** Select this option to search on a string in the name. The input is expected in string format.
- **Keyword starts with:** Select this option to search on the beginning of a keyword. The input is expected in string format.
- **Keyword contains:** Select this option to search on a keyword. The input is expected in string format.
- **Description starts with:** Select this option to search on the beginning of a string in the description. The input is expected in string format.
- **Description contains:** Select this option to search on a string in description. The input is expected in string format.
- **Unique Name start with:** Select this option to search the beginning of a string in the unique name. The input is expected in string format.
- **Unique Name contains:** Select this option to search on a string in the unique name. The input is expected in string format.
- **Markup starts with:** Select this option to search the beginning of a string in the markup type. This search returns a list of pages that support that markup. The input is expected in string format.
- **Markup contains:** Select this option to search on a string in the markup type. This search returns a list of pages that support that markup. The input is expected in string format.
- **Label:** Select this option to search on a URL context label. The input is expected in string format.
- **Attributes:** Select this option to search on a user or group attribute. The input is expected in string format.
- **Last modified:** Select this option to search by items that were modified on or since a specific date. The input is expected in the format `YYYY MM DD`.
- **All available:** Select this option to return a listing of all items. No input is required.

Notes:

For title search:

By default, searches for **Title starts with** and **Title contains** return only portal resources with titles in the locale of the current portal session. You can configure portal administration portlets to return search results across all supported locales, regardless of the locale of the current portal session or the locale set in the browser. To do this configuration, proceed as follows:

1. Access the **Manage Portlets portlet**.
2. Locate the administration portlet for which you want to configure search of resources across all locales. To locate, use the search feature that is described earlier.
3. Click the **Configure portlet** icon for the portlet.
4. Add the parameter `searchByTitle.all.locales` with the value `true`.
5. Click **Add** and **OK**.

The default value of the parameter `searchByTitle.all.locales` is `false`. Searches for portal resources return results only in the locale of the current portal session or the locale set in the browser.

Note: Configuring search across all locales can have an impact on the search performance.

.

For the Users and Groups portlet:

Searching with wild characters, such as the asterisk (*), is only supported for the User and Groups and User and Groups Permissions portlets. Wildcard character searches for the User and Groups and User and Groups Permissions portlets must have the asterisk (*) at the end or beginning of the search parameter. For example, the following searches are supported for the User and Groups and User and Groups Permissions portlets:

- *user
- user*
- *user*

The following searches are not supported for the User and Groups and User and Groups Permissions portlets:

- us*r

The XML configuration interface

Use the XML configuration interface (XML Access) for exchanging portal configurations.

"About the XML configuration interface" on page 1055
The XML configuration interface provides a batch processing interface for portal configuration updates. It allows you to export an entire portal configuration or parts of a configuration, for example specific pages, to an XML file. You can then re-create the exported configuration from such a file on another portal.

"Changes to the XML configuration interface for this version of WebSphere Portal Express" on page 1059
Learn about the changes that were made to the XML configuration interface from earlier versions to current versions of IBM WebSphere Portal Express. This information can be useful to you if you migrate your WebSphere Portal Express from one version to a later version.

"Working with the XML configuration interface" on page 1061
You can use the XML configuration interface to export and import IBM WebSphere Portal Express configurations. This way you can configure selected features or areas of your portal. You can also transfer a complete configuration from one portal to another.

"XML configuration reference" on page 1082
Learn more about XML input structure, XML tags for portal resources, attributes for special purposes such as locale data, object IDs, and more. Also find information about action attributes that determine the type of processing that the XML configuration reference applies to the portal resource. There are syntax restrictions that you need to consider as well as information about how to determine the object IDs for portal resources.

Related tasks:

"Using the XML configuration interface to work with Producer definitions" on page 1477
You can use the XML configuration interface to work with Producer definitions in different ways.

"Using the XML configuration interface to consume portlets from a Producer portal" on page 1484
You can use the XML configuration interface (XMLAccess) to consume portlets from a Producer portal.

"Creating a web content page with the XML configuration interface" on page 2074
As with other portal pages, you can create a web content page with the XML configuration interface (**xmlaccess** command). Page definition is similar to a standard portal page. However, there is an additional page parameter that specifies the site area that is associated with the web content page.

Related reference:

"XML configuration interface parameters for the Web Content Viewer" on page 415
As with other portlets in your portal, you can use the XML configuration interface (**xmlaccess** command) to deploy and configure the Web Content Viewer. To simplify the configuration of the portlet with the XML configuration interface, the portlet parameters you can specify accept path values in addition to the standard IDs.

"XML configuration interface and content associations" on page 2076
With the XML configuration interface (**xmlaccess** command), you can perform batch updates of content associations or export associations to import into another portal. Content association information is represented in the XML configuration schema by content-mapping-info elements.

 Technotes for XML Access and Release Builder

About the XML configuration interface

The XML configuration interface provides a batch processing interface for portal configuration updates. It allows you to export an entire portal configuration or parts of a configuration, for example specific pages, to an XML file. You can then re-create the exported configuration from such a file on another portal.

How do I access the XML configuration interface?

You access the XML configuration interface using a command line tool. This command line client is a small separate program that connects to the server using an HTTP connection or a secure HTTPS connection with SSL. It is therefore possible to configure the portal remotely.

Tasks that you can perform with the XML configuration interface

These are typical tasks for which you use the XML configuration interface:

- Copy parts of a configuration, such as specific pages, from one portal to another. This usage scenario includes the case where you try out a new portal configuration on a test portal for evaluation, and then transfer it to a production portal in a separate step using the portal configuration interface.
- Install additional resources on a portal.
- Perform recurring administration tasks in an automated and reproducible manner.

Use of the XML configuration interface for backing up or restoring complete portal configurations is restricted by the following limitations:

1. A complete XML export of a portal configuration is not sufficient to re-create the portal. You also need the WAR files for your portlets and possibly additional file resources, such as theme files if they are not part of the standard portal installation.
2. The XML configuration interface is not designed to deal efficiently with large volumes of data. For a backup and restore solution on a production server, you should rely on low-level database and file system backups.

Access and security considerations

To be able to use the XML configuration interface, you need to have the manager role on the virtual resource `XML_ACCESS` and the security administrator role on the virtual resource PORTAL. This implies that you must be a super administrator of the portal, who can perform any action. Consequently, there are no further access control checks that could restrict your actions when you use the XML configuration interface; you may view all resources in the portal and you may update and delete all resources.

When you run the XML command line tool, you must authenticate yourself by specifying your portal user ID and password. When you use an HTTP connection, the user and password are sent to the server unencrypted, therefore you should only connect to the XML configuration interface from inside a protected intranet where you can be sure that the HTTP connection is not compromised. In all other networks configure SSL and use a secure HTTP**S** connection to connect to the XML configuration interface.

Overall structure of the XML input and output

There are two main types of requests that can be sent to the XML configuration interface:

Export requests
: An export request triggers the export of complete or partial portal configurations into XML. It does not modify the configuration of the portal. It results in a response file.

Update requests
: An update request modifies the configuration of the portal according to the values found in the XML script.

A third request type is available for preparing the deletion of orphaned data:

Export-orphaned-data requests
: An export-orphaned-data request exports the complete portal configuration into XML, including orphaned data. It results in a response file.

Requests to and responses from the XML configuration interface use the same XML format. An export request generates an XML response that contains all the configuration data required to re-create the exported configuration part. This means that you can export a portal configuration, save the XML output file and, without modification, send it to another portal to re-create the same configuration there.

Use the XML schema for the XML format that WebSphere Portal Express provides for reference. You will find it in the JAR file `wp.xml.jar` in the WebSphere Portal Express installation directory:

- Linux: *PortalServer_root*`/base/wp.xml/shared/app`
- IBM i: *PortalServer_root*`/base/wp.xml/shared/app`
- Windows: *PortalServer_root*`\base\wp.xml\shared\app`

Unpack the JAR file and you will find the file with the XML schema under the path `com/ibm/wps/command/xml/PortalConfig_8.5.0.xsd`. An XML request contains the following:

- A mandatory `portal` section; it describes the parts of the portal configuration that should be exported or updated

- An optional status section. In an XML response it indicates the success or failure of the requested operation. During the import of configuration data the XML processing ignores this section of the XML input file.

Representation of a portal configuration in XML

The XML hierarchy that is found under the `portal` section in the XML request file represents the structure of a portal as an XML tree. This tree contains resources in the portal, such as portlets or pages, and their configuration data. The XML hierarchy of all supported portal resources is shown in the following table:

Table 136. Tree hierarchy of portal resources in the portal section of an XML request

XML element	Description
`portal`	Main element of every XML request
`global-settings`	Global portal settings
`services-settings`	Global portal settings for portal services
`language`	Languages that are defined in portal
`task`	Tasks that can be used to schedule programs
`action`	Actions that can be used to create action sets
`action-set`	Action sets that can be used to create roles. They are also known as Role Types.
`virtual-resource`	Virtual resources that have associated access control settings
`resource-type`	Resource types that you can use to create custom resources.
`protected-resource`	A resource instance that is protected by Portal Access Control (PAC).
`user`	Users defined in the portal user management system
`group`	Groups defined in the portal user management system
`markup`	Markups that can be supported by portal pages
`client`	Client devices (browsers) that the portal knows about
`device-class`	Device class information
`skin`	Visual appearance settings that can be applied to user interface elements
`theme`	General visual settings that can be applied to the user interface
`wsrp-producer`	Producer of web services as defined in the consumer portal
`wsdl-url`	The URL to the Producer's WSDL document
`porttype`	The URL to the service description, markup, registration, or portlet management of the Producer
`web-app`	Web modules containing portlets
`url`	The WAR file that contains the web application
`context-root`	The context root that is assigned to the web application of the portlet application in the predeployed EAR file (reference: application.xml)
`display-name`	The name that is assigned to the application in the predeployed EAR file (reference: application.xml)

Table 136. Tree hierarchy of portal resources in the portal section of an XML request (continued)

XML element	Description
servlet	Servlets that are defined in the web module
portlet-app	Portlet applications that are defined in the web module
portlet	Portlets that are defined in the portlet application
federation-server	The federation server definition. This server is used to retrieve content nodes.
content-node	Elements of the portal content tree (pages or labels)
supported-markup	The markups that are supported by this content node
allowed-portlet	The portlets that are allowed on this page
component	Layout components of pages
component	Subcomponents in the structure of the page
portletinstance	Occurrences of a portlet on a page with customized settings
cross-page-wire	Property broker wiring between two portlet instances. **Note:** The `wire` tag has been deprecated with WebSphere Portal Express Version 7, as it supports property broker wiring between two portlets *on the same page* only. Use the `cross-page-wire` tag as it supports property broker wiring between portlets on the same page and on different pages.
credential-segment	Segments for storing credentials in the credential vault
credential-slot	Slots in a credential segment that hold a credential
url-mapping-context	User defined URLs that map to pages in the portal
user-resource	Allows exporting and deletion of a specific user resources.
policy-node	Policies that are defined in the portal
application-role	A named set of authorization roles that can be assigned to users or groups.
wsrp-customized-portletinstance	A customized occurrence of a portlet provided by WSRP on a Producer portal
custom-resource	A custom resource that can be tagged or rated by users
category-instance	A category assigned to a custom resource
tag	A tag applied to a resource by a user
rating	A rating applied to a resource by a user
filter-instance	A filter for preprocessing data before the data is finally stored.

Depending on the content of an XML request, these resources can be created, modified, deleted or exported. An XML request can contain any number of such resource definitions. It can therefore create hundreds of new resources in one step or modify only a single configuration setting of one existing resource.

Related tasks:

"Setting up SSL" on page 1596
Get an overview of the tasks that are required to configure SSL for IBM WebSphere Portal Express. Some of these tasks are completed on the IBM WebSphere Application Server and the web server. The steps that refer to the WebSphere Application Server and the web server are summarized here; refer to the WebSphere Application Server and the web server documentation for detailed information. Steps that are unique to WebSphere Portal Express are described in detail here.

"Deleting orphaned data" on page 280
You use the SLCheckerTool to delete orphaned data in the database.

Changes to the XML configuration interface for this version of WebSphere Portal Express

Learn about the changes that were made to the XML configuration interface from earlier versions to current versions of IBM WebSphere Portal Express. This information can be useful to you if you migrate your WebSphere Portal Express from one version to a later version.

Changed XML schema

The XML schema is updated for new versions of WebSphere Portal Express as required. Make sure that your XML scripts specify the correct version of the XML schema according to the version of your portal installation. For example, for portal Version 8.5 specify the current version of the XML schema as follows:

```
<?xml version="1.0" encoding="UTF-8"?>
<request
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd"
 type="export | update">
  . . . configuration . . .
</request>
```

The different versions of WebSphere Portal Express use the following syntax definitions for the XML configuration interface:

Table 137. XML syntax definitions for different WebSphere Portal Express versions

WebSphere Portal Express Version	XML schema
Version 7.0.0	7.0.0
Version 7.0.0.2	7.0.0_2
Version 8.0.0	8.0.0
Version 8.5	8.5.0

Notes:

1. **Backward compatibility:** The later XML schemas are backward compatible with earlier supported versions of WebSphere Portal Express. This means that you can run XML scripts from earlier portal versions that IBM supports under a later version of the portal. For example, you can run an XML script that is based on the `PortalConfig_7.0.0.xsd` under portal Version 8.5. In such cases a warning message is written to the output script, which informs that a previous version of the XML schema was used.
2. **Schema file naming convention:** If the XML schema is enhanced by updates, a new version of the xsd file with a new file name is created according to the following naming convention:

- Starting with portal V 6.0.1 the schema file name includes the portal version number as follows: `PortalConfig_portal_version_number.xsd`. Example: `PortalConfig_7.0.0.xsd`.
- If the schema is enhanced during a portal version, the name includes additional ID information to ensure unique schema file names: `PortalConfig_portal_version_number_id.xsd`. Example: `PortalConfig_7.0.0_2.xsd`.

New XML resources in WebSphere Portal Express Version 8.5

In WebSphere Portal Express Version 8.5 the following new resource tags have been introduced:

Table 138. New resource tags

New XML configuration interface tags in portal Version 8.5	Tag specifies the following type of portal resource
`device-class`	a device class
`global-target-settings`	a section containing the cross-page wire settings that are set as global targets
`target`	a global target

For more details about this tag refer to the XML configuration interface reference.

New XML attributes in WebSphere Portal Express Version 8.5

This section lists the attributes that have been added to WebSphere Portal Express for Version 8.5.

- A new boolean flag `system` has been introduced for content-mapping tags.
- You can now set `parameter` sections for task nodes.
- A new attribute `target-portletdefinitionref` has been introduced on cross-page-wire items,

Removed XML resources in WebSphere Portal Express Version 8.5

The following XML resource is no longer supported in portal Version 8.5:

- `event-handler`

Setting the project scope in WebSphere Portal Express Version 8.5

The managed pages feature enables you to edit portal resources, such as pages, in the scope of a project. By working in a project, you can create, update, and approve pages in a draft state, without affecting the live server. You can specify a project scope for actions performed with the XML configuration interface command by including the object ID of the project in the URL. See *XML configuration interface and managed pages* for details.

Related reference:

"XML configuration interface and managed pages" on page 1271
You can use the XML configuration interface (XML Access) to manipulate managed pages just as you can for other portal resources.

Working with the XML configuration interface

You can use the XML configuration interface to export and import IBM WebSphere Portal Express configurations. This way you can configure selected features or areas of your portal. You can also transfer a complete configuration from one portal to another.

Using the XML configuration interface

IBM WebSphere Portal Express provides a highly configurable framework of services to accommodate the different scenarios that portals of today need to address. The framework allows convenient replacement of service implementations as well as modification of the configuration of each service. When you work with the XML configuration interface, the results, especially of configuration imports or updates, are influenced by the property settings in these configuration services. This includes changes that you have made to these settings. For more detail about the configuration services, refer to the topics about the portal service configuration.

There are two ways to use the XML configuration interface to work with portal configuration data:

- By using the XML configuration command line client. The XML configuration command line client provides all the XML configuration interface functions.
- By using administration portlets you can export and import XML configurations.

Both options are described in the following sections.

Terminology

These topics use the following terminology in the context of the XML configuration interface:

export This term can have either of the following meanings, depending on the context:

- In the administrative context: a human administrative task, for example exporting a portal configuration or a part of it
- In the context of the XML configuration interface: an XML request and action, for example to export the data of a portal configuration or a part of it.

import

This term represents only the human task in the administrative context, for example importing a portal configuration or a part of it. It has no corresponding XML request type. In the context of the XML configuration interface, an import is performed by specifying the `update` request type, together with the `create` or `update` action for the resources that are to be imported.

The topics in the documentation describe the portal XML configuration interface. Internally within the portal, this tool is named XMLAccess.

Sample XML scripts

The following topics mention several sample files suitable for different purposes of portal configuration using XML. Before you use them, read the other topics about the XML configuration interface carefully. These sample files are documented here for reference purposes only. If you want to use the XML samples for work on your portal configuration, use the files provided in your portal installation, as they

might be more up to date than this documentation. The XML sample files are located in the following directory of your WebSphere Portal Express installation:

- Linux: *PortalServer_root*/doc/xml-samples
- IBM i: *PortalServer_root*/doc/xml-samples
- Windows: *PortalServer_root*\doc\xml-samples

"Using administrative portlets for XML configuration"
XML configuration through administrative portlets allows you to export and import configurations. You can export a page or an entire page hierarchy by clicking the **Export** icon in the Manage pages administration portlet. You can also import an XML configuration file by using the Import XML portlet.

"Using the XML configuration command line client" on page 1064
You access the XML configuration interface using a command line tool. This command line client is a separate program that connects to the server. Connecting to a **remote** server makes it possible to configure the portal remotely. You use the command line syntax of the XML configuration interface.

"Generating a complete XMLAccess export of a Portal configuration" on page 1081
To help troubleshooting a WebSphere Portal issue, you might be asked by IBM Support to generate or collect a full or complete export of your Portal configuration. The complete export can be generated by using the XML Configuration Interface, commonly known as XMLAccess.

IBM WebSphere Portal Express comprises a framework of configuration services to accommodate the different scenarios that portals of today need to address. You can configure some of these services.

Using administrative portlets for XML configuration:

XML configuration through administrative portlets allows you to export and import configurations. You can export a page or an entire page hierarchy by clicking the **Export** icon in the Manage pages administration portlet. You can also import an XML configuration file by using the Import XML portlet.

About this task

Notes:

- You must enable support for JavaScript and disable pop-up blocking in your browser settings.
- Do not use the administration portlets to export or import complete portal configurations. For details about how to transfer a complete configuration see the related reference information.

  "Exporting pages or page hierarchies by using the Manage Pages portlet"
  You can do an XML export of a page or an entire page hierarchy by using the Manage Pages portlet.

  "Importing pages or page hierarchies by using the XML Import portlet"
  You can import an XML configuration file by using the XML Import portlet.

Related tasks:

"Transferring a complete configuration" on page 1074
For transferring complete portal configurations, WebSphere Portal Express provides a Release Builder tool.

Exporting pages or page hierarchies by using the Manage Pages portlet:

You can do an XML export of a page or an entire page hierarchy by using the Manage Pages portlet.

Procedure

1. To open the **Manage Pages** portlet, click the **Administration menu** icon. Then, click **Portal User Interface** > **Manage Pages**.
2. Locate the portal page that you want to export.
3. Click the **Export** button for that page.
4. The portlet prompts you to indicate whether you want to export the entire page hierarchy or only the selected page. Select one of the following options:
   - Click **Yes** to export the entire page hierarchy.
   - Click **No** to export only the selected page.
   - Click **Cancel** to stop the page export.
5. If you selected Yes or No in the previous step. The portlet prompts you to save the XML configuration file. Type a file name and select the location where you want the file to be saved.
6. When the export is complete, the portlet shows a success message.
7. On the Download complete screen, click **Open** to view the newly saved XML configuration file. Check the content of the file and make sure that it does not contain a `<failure>` tag. If you do not want to view the XML file, close the extra window that is open for viewing the file.

Importing pages or page hierarchies by using the XML Import portlet:

You can import an XML configuration file by using the XML Import portlet.

About this task

To import an XML configuration file by using the Import XML portlet, proceed as follows:

Procedure

1. Click the **Administration menu** icon. Then, click **Portal Settings** > **Import XML**.
2. Locate the XML configuration file that you want to import. Use the **Browse** button to help locate the file.
3. Click **Import** to import the configuration file.
4. When the import is complete, the portlet shows a success message.

Using the XML configuration command line client:

You access the XML configuration interface using a command line tool. This command line client is a separate program that connects to the server. Connecting to a **remote** server makes it possible to configure the portal remotely. You use the command line syntax of the XML configuration interface.

About this task

The remote connection can be either an HTTP connection, which is not secure, or a secure HTTPS connection. Apply care and use the appropriate type of connection that is required for your environment. Use an HTTP connection to connect to the XML configuration interface only from inside a protected intranet where you can be sure that the HTTP connection is not compromised. In all other networks use a secure HTTP**S** connection to connect to the XML configuration interface. For details about how to use an HTTPS connection refer to XML Syntax for using a secure connection with SSL.

You invoke the command line client by using the following shell scripts in the directory *wp_profile_root*/PortalServer/bin :

- Linux: ./xmlaccess.sh
- IBM i: xmlaccess.sh
- Windows: xmlaccess.bat

You can also use the XML configuration interface remotely from a machine that does not have portal installed. In this case copy the required files to the remote machine and configure the portal from there. All you need is a Java run time. However, you have to adapt the path settings in the shell scripts accordingly. These are the required files:

- *PortalServer_root*/base/wp.xml.client/bin/wp.xml.client.jar
- *PortalServer_root*/base/wp.base/shared/app/wp.base.jar
- *PortalServer_root*/base/wp.base/shared/app/wp.engine.impl.jar
- *PortalServer_root*/base/wp.base/shared/app/wp.utilities.streams.jar
- *AppServer_root*/lib/j2ee.jar
- *AppServer_root*/lib/bootstrap.jar
- *AppServer_root*/lib/com.ibm.ws.runtime.jar
- *AppServer_root*/plugins/j2ee.jar
- *AppServer_root*/plugins/com.ibm.wps.emf.jar
- *AppServer_root*/plugins/org.eclipse.emf.ecore.jar
- *AppServer_root*/plugins/org.eclipse.emf.common.jar
- *PortalServer_root*/bin/xmlaccess.sh or *PortalServer_root*\bin\xmlaccess.bat , depending on your operating system.

Note: When you update your portal by installing fix packs, these files might be updated. In such cases make sure that you always use the most recent versions of these files.

"Command line syntax of the XML configuration interface"
The command line syntax for working with the XML configuration interface can vary, depending on your portal installation environment and configuration.

"Transferring portal configuration data by using the XML configuration interface" on page 1072
When you use the XML configuration interface to transfer WebSphere Portal Express configuration data, you export or import an XML script file. In most cases, you can use the result file from an XML export for an XML import. Sometimes you can use the export result file directly, sometimes you must modify it.

"Creating and modifying resources" on page 1077
In addition to copying and restoring configurations of existing portal resources, you can use the XML configuration interface to install new resources in the portal. You can also use the XML configuration interface as an alternative to the portal administrative user interface for running some administration tasks.

"Activating and deactivating portlets, portlet applications, and web applications" on page 1079
You can change the states of portlets, portlet applications, and web applications between active and inactive by using the portal XML configuration interface.

"Scheduling the delayed cleanup of portal pages" on page 1079
You can use the example XML script `Task.xml` to schedule the cleanup of pages that have been marked for deletion.

"Registering predeployed portlets" on page 1079
You can manually predeploy portlet application WAR files using the WebSphere Integrated Solutions Console. You can later register and configure the predeployed portlet applications into WebSphere Portal Express, together with other J2EE resources and artifacts, by using the XML configuration interface.

"Removing users and groups" on page 1080
Depending on circumstances, you might want to remove users or groups from your WebSphere Portal Express that are no longer used or required. You can use the XML configuration interface (XML Access) to list such users and groups. You can also remove only some selected users and groups, and keep others for further use.

"Preparing the deletion of orphaned resources" on page 1081
You can use the XML configuration interface to delete orphaned data from your WebSphere Portal Express.

Related reference:

"XML Syntax for using a secure connection with SSL" on page 1068
You can also use the XML command line client with SSL over a secure HTTPS connection.

Command line syntax of the XML configuration interface:

The command line syntax for working with the XML configuration interface can vary, depending on your portal installation environment and configuration.

"Basic XML command line syntax" on page 1066
The basic command line syntax for the XML configuration interface is as follows.

"XML Syntax for using a secure connection with SSL" on page 1068
You can also use the XML command line client with SSL over a secure HTTPS connection.

"XML Syntax for exporting and importing credential vault data" on page 1070
When you use the XML command line for credential export or import, the command syntax is slightly different than for normal command-line use.

Basic XML command line syntax:

The basic command line syntax for the XML configuration interface is as follows.

```
xmlaccess -user user_ID -password password
          -url myhost:10039/wps/config
          -in input_file.xml -out result_file.xml
```

Note: All data, including the user ID and password, are sent to the server unencrypted. Therefore you should only connect to the XML configuration interface from inside a protected intranet where you can be sure that the HTTP connection is not compromised. In all other networks use a secure HTTPS connection to connect to the XML configuration interface.

Prompting for credentials: You can use the parameter `askForCredential` and leave out the parameters `user` and `password`. The XML configuration interface will then prompt you for the user ID and password. This can be useful in security sensitive environments, as the user credentials are not visible on the console or in the process view. The parameter `askForCredential` requires no value to be specified. Example:

```
xmlaccess -askForCredential -url myhost:10039/wps/config
          -in input_file.xml -out result_file.xml
```

Placing the credentials in a properties file: You can also place the credentials in a properties file and use the option `useEncryptedCredentials`. This option reads the encrypted or unencrypted credentials from the properties file, and then saves the file back using the encrypted password. If you do not want to write the properties file back with the encrypted credentials, use the **additional** flag `noUpdateProperties`. In this case you can use the `PropFilePasswordEncoder` utility to encrypt the password in the properties file. This option reads the following properties out of the file:

- For the user ID: `com.ibm.SOAP.loginUserid = userID`
- for the password: `com.ibm.SOAP.loginPassword = password`

An example of a command line is as follows

```
xmlaccess -in Export.xml -useEncryptedCredentials myProperties.properties
                         -url portal.example.com:10039/wps/config
```

Virtual portals: If you have virtual portals in your configuration, you can access a virtual portal by its host name or its URL mapping context. Example for accessing a virtual portal by its URL mapping context:

```
xmlaccess -user user_ID -password password
          -url myhost:10039/wps/config/URL_mapping_context_of_the_VP
          -in input_file.xml -out result_file.xml
```

Example for accessing a virtual portal by its host name:

```
xmlaccess -user user_ID -password password
          -url my_VP_host:10039/wps/config
          -in input_file.xml -out result_file.xml
```

"Syntax elements for the XML configuration interface command line"
This topic lists the syntax elements for using the XML configuration interface command line client over an HTTP connection.

Syntax elements for the XML configuration interface command line:

This topic lists the syntax elements for using the XML configuration interface command line client over an HTTP connection.

For information about the XML syntax elements for a secure HTTPS connection see the topic about *XML Syntax elements for using a secure connection with SSL*.

Table 139. Descriptions for the Syntax elements

Syntax element	Description
`xmlaccess`	This is the shell script. It is located in directory *`wp_profile_root`*`/PortalServer/bin` . Use one of the following scripts: • Linux: `./xmlaccess.sh` • IBM i: `xmlaccess.sh` • Windows: `xmlaccess.bat`
`-in`	Use this element to specify the name of a file containing the XML request (configuration export or update) that should be processed.
`-user` and `-password`	Use these elements to specify the user identification and password describing the authority under which the request should be processed. For the value for `user` you must specify the short user name as specified during login; full distinguished names (DN) are not supported. The XML configuration interface is only accessible to users that have the manager role on the virtual resource XML_ACCESS and the administrator role on the virtual resource PORTAL.
`-askForCredential`	You can use the parameter `askForCredential` and leave out the parameters `user` and `password`. The XML configuration interface will then prompt you for the user ID and password. The parameter `askForCredential` requires no value to be specified.
`-useEncryptedCredentials`	Use this option if you want to provide the user credentials in a properties file rather than with the XML command.
`-noUpdateProperties`	Use this option additionally with the option `useEncryptedCredentials`, if you do not want to have the encrypted credentials written back to the properties file.
`-url`	Use this element to specify the URL to access the configuration servlet. This URL consists of the host name, the base URI as specified during installation (for example `/wps`), and the servlet extension `/config`.
`-out`	The name of the result file that contains the XML output. This file gives a result status and thereby indicates whether the XML request was performed successfully, or what errors might have occurred. In the case of an XML export, this file contains the exported configuration. You can later use this file to re-import the exported configuration.

XML Syntax for using a secure connection with SSL:

You can also use the XML command line client with SSL over a secure HTTPS connection.

In this case the command syntax is as follows:

```
xmlaccess -user user_ID -password password
          -url https://myhost:10035/wps/config/
          -in input_file.xml -out result_file.xml
          -truststore trustStore -trustpwd trustPassword
          -trusttype trustType [ -keystore keyStore
          -keypwd keyPassword -keytype keyType ]
```

The following rules apply:

1. The `https://` prefix in the URL is required to allow the XML client to detect whether a secure HTTPS connection is required. The appropriate HTTPS port must be provided instead of the HTTP port.
2. The options starting with the string `trust` are mandatory in all configurations where a custom certificate store is used for storing certificates required for secure connections. For configurations that use the Java standard `cacerts` certificate store, the parameters starting with `trust` are optional.
3. The options starting with the string `key` are optional. They are only required when client certificate authentication is used for establishing the SSL connection.
4. The default value for `-keytype` and `-trusttype` is `jks`. Therefore the `-keytype` and `-trusttype` options are optional unless the used keystore or truststore uses a different format.

Note: When your WebSphere Portal Express runs on the Oracle Solaris platform, the default protocol handler for the hybrid IBM JDK is the Sun handler. Therefore, in order to successfully connect by using the XML configuration interface and the IBM JSSE2 provider, you need to add an additional parameter to the file *wp_profile_root*`/PortalServer/bin/xmlaccess.xml` . Edit that file and add the parameter `-Djava.protocol.handler.pkgs=com.ibm.net.ssl.www2.protocol` as follows:

```
   . . . . .
${JAVA}
-Djava.protocol.handler.pkgs=com.ibm.net.ssl.www2.protocol
-classpath ${WPS_HOME}/. . . . .
   . . . . .
```

"XML syntax elements for using a secure connection with SSL"
This topic lists the syntax elements for using the XML command line client with SSL over a secure HTTPS connection.

XML syntax elements for using a secure connection with SSL:

This topic lists the syntax elements for using the XML command line client with SSL over a secure HTTPS connection.

Table 140. Description of the Syntax elements used for a secure connection with SSL

Syntax element	Description
`-truststore`	Use this element to specify the name of the truststore file that contains the server certificates that are required for accepting SSL connections with trusted servers. If no truststore is provided, the XML client will use the default Java `cacerts` truststore.
`-trustpwd`	Use this element to specify the password that is required for accessing the truststore. If the default Java `cacerts` truststore is used, no trust password needs to be provided.
`-trusttype`	Use this element to specify the type of the truststore that is used. The default type is `jks`. As long as the used truststore is of type `jks`, you do not have to provide this parameter.
`-keystore`	Use this element to specify the name of the keystore file that contains client certificates that are required for establishing an SSL connection with a server that requires client certificate authentication. If no keystore is provided, the XML client will use the default Java `cacerts` keystore.
`-keypwd`	Use this element to specify the password that is required for accessing the keystore. If the default Java `cacerts` keystore is used, no key password needs to be provided.
`-keytype`	Use this element to specify the type of the used keystore. The default type is `jks`. If the used keystore is of type `jks`, you do not have to provide this parameter.
`-protocol`	Use this element to specify the protocol, for example `SSL`, `SSLv1`, `SSLv3`, or `TLS` . Note that you can select only protocols that WebSphere Application Server supports and has enabled. The parameter is evaluated only if the URL of the XMLAccess servlet selects a secure connection with HTTP**s**. Otherwise, the parameter is ignored.

See the following examples.

Example 1

The following is an example of how to use the XML configuration interface to establish an SSL connection with a WebSphere Portal Express server, using the default certificate stores that are provided by WebSphere Application Server:

```
xmlaccess.sh -user wpsadmin -password your_password -url https://portalhost:10035/wps/config/
             -in $PortalHome/doc/xml-samples/ExportAllUsers.xml -out result.xml
             -truststore $WASHome/profiles/wp_profile/etc/trust.p12
             -trustpwd WebAS -trusttype PKCS12
```

For this example to run, use the `trusttype` parameter with a value of `PKCS12` to avoid an `invalid file format` error.

Example 2

The following is an example of how to use the XML configuration interface to establish an SSL connection with a WebSphere Portal Express server, using the dummy certificate stores that are provided by WebSphere Application Server:

```
xmlaccess.sh -user wpsadmin -password your_password -url https://portalhost:10035/wps/config/
             -in $PortalHome/doc/xml-samples/ExportAllUsers.xml -out result.xml
             -truststore $WASHome/profiles/wp_profile/etc/DummyClientTrustFile.jks -trustpwd WebAS
```

For this example to be able to run, you need to configure the SSL configuration in WebSphere Application Server using the `DummyServerKeyFile.jks` and the `DummyServerTrustFile.jks` for secure connections. The option **require client authentication** must not be active.

Example 3

If the option **require client authentication** is active, you need to provide a keyfile when establishing the SSL connection with the XML configuration interface:

```
xmlaccess.sh -user wpsadmin -password yourpassword -url https://portalhost:10035/wps/config/
             -in $PortalHome/doc/xml-samples/ExportAllUsers.xml -out result.xml
             -truststore $WASHome/profiles/wp_profile/etc/DummyClientTrustFile.jks -trustpwd WebAS
             -keystore $WASHome/profiles/wp_profile/etc/DummyClientKeyFile.jks -keypwd WebAS
```

This example allows the XML configuration interface to send a client certificate to the server, if the server requests one. Using client certificate authentication is required wherever the number of clients that can administer WebSphere Portal Express needs to be controlled. Only clients with the correct client certificate will be able establish a connection with WebSphere Portal Express.

XML Syntax for exporting and importing credential vault data:

When you use the XML command line for credential export or import, the command syntax is slightly different than for normal command-line use.

Prerequisite configuration: Before you run the `xmlaccess` command to export or import credential vault data, make sure that you added the two properties `export.userDN` and `export.enforceSSL` to the WebSphere Application Server configuration.

When you use the XML command line for credential export or import, you need to add two more parameters: `-credentialexport` and `-passphrase` to the XML command. See the following example:

```
xmlaccess -user user_ID -password password
   -url https://myhost:10035/wps/config/
   -truststore
    wp_profile_root/config/cells/cellname/nodes/nodename/trust.p12
   -trusttype PKCS12    -trustpwd WebAS
   -in input_file.xml -out result_file.xml
   -credentialexport -passphrase encryptionPassphrase
```

Table 141. Additional XML Syntax elements for credential secret migration

Syntax element	Description
`-credentialexport`	This parameter, without a value, indicates that the export of credentials must be enabled.

Table 141. Additional XML Syntax elements for credential secret migration (continued)

Syntax element	Description
`-passphrase`	Use this element to specify the `encryptionPassPhrase` for the encryption. The minimum length of this string is the number of bits set as the export `keylength` in the WP Vault Service Custom properties, which are divided by 8. The `-passphrase` value is used to create a key of the specified length for the encryption. For details about the WP Credential Vault Service, see the topic about the Credential Vault Service. For details about how to configure or determine service configuration properties see the topic about Setting service configuration properties.

Usage notes:

- The following rules apply to these parameters:
  - For export or import of encrypted credential secrets, the options `credentialexport` and `passphrase` are mandatory. For example, during migration you need to specify these options.
  - For all XML Configuration actions that do not export or import encrypted credential secrets during migration, the options `credentialexport` and `passphrase` are optional.
- Use the same `passphrase` for both the export and the import.
- The import might fail if the user DN schema was changed between the previous and the current system or when credentials for users are contained in the XML import file that is not present in the current system. In this case, manually remove the obsolete credential entries from the XML file, then complete the import.
- For security reasons, use an HTTPS connection when you import credentials; however, if you choose not to, set the `export.enforceSSL` configuration property to `false`.

Example

Following is an example of how to use the XML configuration interface to export/import credential secrets by using HTTPS:

```
xmlaccess.sh -user wpsadmin -password your_password -url https://portalhost:10035/wps/config/
     -in ExportedCredentialSecrets.xml -out result.xml
     -credentialexport -passphrase JGD786JHgasdf8a67kjhUIT7sdj7nsh776jasdf786regUFZT756675zufurz
     -truststore $WASHome/profiles/wp_profile/etc/DummyClientTrustFile.jks -trustpwd WebAS
```

"Adding `export.userDN` and `export.enforceSSL` to the WebSphere Application Server configuration" on page 1072
Before running the `xmlaccess` command to export or import credential vault data, you need to add two properties to the WebSphere Application Server configuration.

Related tasks:

"Setting service configuration properties" on page 283
IBM WebSphere Portal Express comprises a framework of services to accommodate the different scenarios that portals need to address. Services are available for both WebSphere Portal Express and IBM Web Content Manager. You can configure some of these services.

"Adding export.userDN and export.enforceSSL to the WebSphere Application Server configuration"
Before running the xmlaccess command to export or import credential vault data, you need to add two properties to the WebSphere Application Server configuration.

Related reference:

"Credential Vault Service" on page 332
You can use the portal Credential Vault Service to configure Vault Adapter implementations that are used by the Credential Vault Service to store credential secrets.

Adding export.userDN and export.enforceSSL to the WebSphere Application Server configuration:

Before running the xmlaccess command to export or import credential vault data, you need to add two properties to the WebSphere Application Server configuration.

About this task

Proceed as follows:

Procedure

1. Log in to the WebSphere Integrated Solutions Console.
2. Click **Resources** > **Resource Environment** > **Resource Environment** > **Providers** > **WP_VaultService** > **Custom properties**.
3. Add the property export.userDN :
   Name: export.userDN
   Value: *administrator_DN*. For example: cn=wpsadmin,o=ibm
   Type: java.lang.String
4. Add the property export.enforceSSL :
   Name: export.enforceSSL
   Value: true
   Type: java.lang.Boolean
5. Save your configuration changes.
6. Restart the portal server.

Transferring portal configuration data by using the XML configuration interface:

When you use the XML configuration interface to transfer WebSphere Portal Express configuration data, you export or import an XML script file. In most cases, you can use the result file from an XML export for an XML import. Sometimes you can use the export result file directly, sometimes you must modify it.

Before you begin

An XML file that you process must always be in UTF-8 encoding. It must specify the root element and schema that is given in the following example code snippet.

```
<?xml version="1.0" encoding="UTF-8"?>
<request xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
         xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd"
```

```
        type="export|update">
      . . . configuration  . . .
    </portal>
  </request>
```

For an XML export, specify `export` for the request type. For an XML import, specify a request type of `update`. The line where you specify either of these request types is highlighted in the example. For more information about the structure of an XML input script file, see the reference topics about the *XML input script file structure*.

Procedure

1. Run the XML command-line interface with a file that has a request type of `export` in it. For example, you can use one of the XML sample files with request type `export` provided with WebSphere Portal Express. The XML command-line interface returns a result file that contains the resources that are specified in the XML file that you used for the export. This file can be, for example a resource and all dependent resources. The file that XML command-line interface returns specifies `update` for the request type and `locate` or `update` for the individual resources actions. This file is ready to be used for an XML import.
2. Optional: Modify the XML result file from the export as required. For example, to create extra resources, use the actions `create` or `update`.
3. Run the XML command-line interface, and specify the XML file that resulted from the XML export and that you might have modified in the previous steps. You can also use one of the XML sample files with request type `update` in it. The XML command-line interface returns a result file that indicates whether the specified resources were imported successfully, or what errors might have occurred.

What to do next

Usage notes:

Using the XML output result file for further processing:
When the XML request finishes processing on the server, the resulting XML output is sent back to the client and written to the standard output. You can write the output to an XML file by using the `-out` command-line option. Using this option always writes the output in UTF-8 encoding, so you can usually use that file for further XML processing. If you do not use this option, the output is written in a console encoding that depends on your operating system and active locale. It might therefore be invalid XML. For more information, see the topics about using the XML command-line client.

Usage notes on the difference between XML exports and imports:

- The command-line syntax and XML processing is the same for both exports and imports. You specify an XML input file to the XML configuration interface, and the XML configuration interface returns a resulting XML export file.
- The difference between export and import is determined by whether you set the request type to `export` or `update` in the XML input file that you specify in the command-line request. When you run an XML import, the resources `action` attribute can have the following values: `locate`, `create`

or `update`. For more information about XML resources, elements, and attributes, see the topics about the *XML configuration reference* and *Types of portal resources*.

For more information about XML exports and imports and transfers of portal configuration, see the following topics. For more information about the structure of an XML input script file, see the reference topics about the XML configuration interface.

"Transferring a complete configuration"
For transferring complete portal configurations, WebSphere Portal Express provides a Release Builder tool.

"Exporting and transferring parts of a portal configuration" on page 1075
You can also export partial configurations.

Related tasks:

"Using the XML configuration command line client" on page 1064
You access the XML configuration interface using a command line tool. This command line client is a separate program that connects to the server. Connecting to a **remote** server makes it possible to configure the portal remotely. You use the command line syntax of the XML configuration interface.

Related reference:

"XML input script file structure" on page 1084
When you use the XML configuration interface command line client, the XML script you use specifies the root element, the XML schema, the portal resources, and actions to be performed.

"Types of portal resources" on page 1085
The portal resources are represented by the following XML tags.

"Sample XML configuration files" on page 1111
Sample files are provided for your reference to help illustrate how to use XML configuration for different portal configuration purposes. Before you use them, read the other topics about the XML configuration interface carefully. Many of the samples need to be modified with valid page or user name before they can be used.

Transferring a complete configuration:

For transferring complete portal configurations, WebSphere Portal Express provides a Release Builder tool.

About this task

To transfer a complete portal configuration, use the WebSphere Portal Express ReleaseBuilder. For information about how to use it see the topics about ReleaseBuilder.

If you want to move a complete configuration from a test to a production server by using the portal ReleaseBuilder tool, use the XML sample file `ExportRelease.xml` provided with the portal . The attribute `domain="rel"` indicates that only shared and no private resources are exported. This sample file exports the complete portal configuration without private resources as required by the portal ReleaseBuilder tool.

Related concepts:

"ReleaseBuilder" on page 3624
To generate or stage follow-on releases of IBM WebSphere Portal Express portals, configurations, and artifacts need to be moved between systems. ReleaseBuilder

enables management of release configurations independent of user configurations.

Related reference:

"Sample XML configuration files" on page 1111
Sample files are provided for your reference to help illustrate how to use XML configuration for different portal configuration purposes. Before you use them, read the other topics about the XML configuration interface carefully. Many of the samples need to be modified with valid page or user name before they can be used.

Exporting and transferring parts of a portal configuration:

You can also export partial configurations.

About this task

To complete this step, you specify the XML hierarchy down to the specific portal resource that you want to export. For the portal resource element itself, you specify an `export` action; for its parents, you specify a `locate` action.

The sample XML request file `ExportPage.xml` provided with the portal exports a page with the unique name `ibm.portal.ssa.SamplePage`. This exported page does not exist in a newly installed portal. You can create it by running the `DeployPortlet.xml` sample file, which is covered in the next section.

Normally, you specify the resources that you want to export by their object ID or by their unique name. You can use the Custom Unique Names administration portlet to look up object IDs and unique names of portal resources. Some resources also support lookup by other attributes; see the XML reference documentation for detailed information.

Running the `ExportPage.xml` example request file that is mentioned earlier results in an XML file similar to `ExportPageResult.xml`. You can use this file to update the page to the exported state, if it still exists in the portal. You can also use this file to re-create the page, in case you delete it later.

When you look at the file, you notice that it includes not only the page itself but also other configuration elements that are referred to by the page, for example the portlet that is placed on the page. These other elements have a `locate` action. The export does not include their full configuration data, but enough information to look them up in the portal, assuming they exist. Note how the configuration of the page makes references to the `objectid` attributes of other resources, for example in the `portletref` attribute of the `portletinstance` elements.

All those references are described by object IDs. Therefore, if the object IDs are correct, the referenced resources can be looked up in the portal even if they were not included in the export. Locating resources before they are referenced is only necessary if you do not know their actual object IDs so that you must find the resources by some other identifying attribute. For more information, see the XML reference documentation. That way, for example a portlet can be identified by its name and by the `uid` attributes of its parents, and the referencing still works, even if the object ID is not available for looking up the portlet.

Exporting resource configurations normally creates `update` actions for all exported elements. This means that if the portal resource exists on the importing system, the

settings are modified, and if it does not yet exist, it is created. This in turn means that if you reimport the page into the portal that you exported it from, nothing changes.

You can import the XML file into another portal to create a copy of the page, this importation requires that the referenced resources (such as the portlet and the content parents) also exist on the target portal and can be found by an identifying attribute. In that case, the page and all contained resources take their object IDs with them so that they have the same object IDs on the source and target system - the resources retain their identity. You can avoid that by using the ID generating mode. For more information, see the XML reference documentation. When you use the ID generating mode, the object IDs in the input are not taken literally, but during the import process the resources obtain new object IDs when they are created on the target system. You apply ID generating mode by adding the following attribute to the main request tag:

```
<request . . . create-oids="true" . . . >
```

You can create a duplicate of the page in the portal from where you exported it by using the ID generating mode and changing the unique name of the page in the XML script. This way, the page, and its changed name, cannot be found for updating by either its object ID or its unique name, therefore a new page with the same settings is created. Change the page title so that you can distinguish between the two pages. The `CopyPage.xml` sample shows how this script would look.

When you are exporting resources to XML scripts, it is possible and often useful to export several resources by using one request. The `ExportPortletAndPage.xml` example extends the `ExportPage.xml` example by including also the portlet that is contained on the page. The resulting XML file contains the complete configuration data of the portlet and the page.

The `ExportSubTree.xml` example shows how you export subtrees of the portal content hierarchy. It exports part of the predefined administration page hierarchy that was created during the portal installation.

Using wildcard characters:

When you export portal resources, you can specify the asterisk (*) as a wildcard character for tag attributes. Be aware of the following limitations:

1. The asterisk wildcard character is supported for attributes of top-level tags only, that is, subtags of the `portal` tag.
2. Specify the asterisk wild character for the object ID attribute of tags as follows: `objectid='*'`, except for `policy-node` tags, where you can specify it for the `path` attribute.
3. Specify only the asterisk alone: **"*"**. The asterisk does not work in combination with partial strings that precede or follow it. For example, you cannot specify `"abc*"` or `"*xyz"`.
4. If you specify the asterisk as a wildcard character, all other attributes of that tag are ignored, except for the following tags, where the listed attributes are interpreted as filters:
   - The tag `content-node`, attribute `create-type`
   - The tag `tag`, attribute `locale`.

The `ExportAllPortlets.xml` example shows the use of the asterisk character (*) as a wildcard to export all resources of a given type. This example exports all the web modules that were installed in the portal and their contained portlets.

Also find information about action attributes that determine the type of processing that the XML configuration reference applies to the portal resource. There are syntax restrictions that you need to consider as well as information about how to determine the object IDs for portal resources.

"Sample XML configuration files" on page 1111
Sample files are provided for your reference to help illustrate how to use XML configuration for different portal configuration purposes. Before you use them, read the other topics about the XML configuration interface carefully. Many of the samples need to be modified with valid page or user name before they can be used.

Creating and modifying resources:

In addition to copying and restoring configurations of existing portal resources, you can use the XML configuration interface to install new resources in the portal. You can also use the XML configuration interface as an alternative to the portal administrative user interface for running some administration tasks.

About this task

In these cases, you cannot export and reimport XML scripts, but you must edit them. In most cases, it is still useful to start with an XML export and only partially modify it, rather than writing complete new XML scripts. The following scripts show examples for modifying different resources in the portal configuration by using XML scripts.

All the examples use the ID generating mode and do not specify literal object IDs. Therefore, you can run them on any portal installation, as they do not depend on hardcoded object ID values. As noted earlier, using literal object IDs makes sense only if you really want to create two instances of the *same* resource, and if you have a controlled environment where you can guarantee that all object IDs that your resources depend on have exactly the required values. As object IDs are difficult to use for identifying the resources, the examples assign unique names to most top-level resources. This way you can reference them later, and the resources are not duplicated if you run the scripts twice.

The first example file `DeployPortlet.xml` shows how you deploy a portlet and create a simple test page to display the portlet. Some of the attributes in the XML must match the corresponding settings that were defined in the `portlet.xml` deployment descriptor in the portlet WAR file. This is necessary so that the XML processing can properly identify the contents of the WAR file. When you want to deploy a different portlet, you must not only specify a different WAR file but also adapt those attributes. Also, the configuration that is specified for the portlet is less than what you see in an XML export result for the portlet. For example, the localized titles are not included in the XML script. This is because those settings are specified in the `portlet.xml` deployment descriptor; you do not have to override them with the XML configuration interface.

Note: As Windows limits the maximum path length to 260 characters, the name of the WAR file must be 25 characters or less. Deploying a WAR file with a name that is more than 25 characters results in an error.

The CreatePage.xml sample shows the following extra possibilities:

1. It assumes that the portlet is already installed. Therefore, it uses only a locate action for the web module, not an update action.
2. It sets a specific skin for displaying the portlet on the page.
3. It shows how you can specify localized titles in properties files rather than include them in the XML script: the titles and descriptions for the page are now loaded from two properties files for two different languages.

Both examples use a simple page layout with just one row and one column. If you want to generate more complex page layouts, you can use the administration portlets to create them. You can export the result to generate a template for your XML scripts.

When you create new resources, you might want to define specific access control settings for them, for example to make them visible to all portal users. The UpdateAccesscontrol.xml example shows the syntax for specifying different access control settings. This sample updates existing resources, but you can use the same syntax to define access control settings for new resources while you are creating them in an XML script. This sample also shows how you can specify access control user roles on virtual resources. This allows you to give a user access to all resources of a specific type that exist in the portal.

The CreateURL.xml sample defines a URL mapping for the sample page that was created with the DeployPortlet.xml example mentioned earlier. After you create the URL mapping, you can access the page directly by entering that URL in the browser.

The DeployTheme.xml example shows how you can use XML scripts to install new themes and skins into your portal. The XML scripts create these resources only in the portal database, so that they can be used in the portal. In addition, you must write the JSPs that run the actual visualization and copy them to the resource directory specified in the XML before you can use the theme in the portal.

The ModifyPortlet.xml example changes settings of a portlet instance that is shown on a page. Such settings are normally set in the edit mode of the portlet. It depends on the code of the portlet which settings are stored and how they are used.

The CreateUser.xml example imports a new user into the portal. It also creates a group that contains only that one user.

To add a language to the portal, use the CreateLanguage.xml example.

Note: To prepare for running this XML script, you must insert resource bundles and, where applicable, JSPs for the new language. For details about how to do this, refer to the topic about how to support new languages in the WebSphere Portal Express information center.

The UpdateVault.xml example demonstrates how to create new resources in the portal credential vault with an XML script.

The ClonePortlet.xml example shows how you can use the XML configuration interface to add new portlets with different settings to existing applications.

The `Transaction.xml` example demonstrates the effect of using different transaction levels for the execution of an XML import.

The `MovePage.xml` example shows you how to move a page to another node.

Note: The actual move of the page is done by the last two lines in the sample file.

Related tasks:

"Supporting a new language" on page 1421
To support a new language to IBM WebSphere Portal Express you add resource bundles and, where applicable, JSPs for the new language.

Activating and deactivating portlets, portlet applications, and web applications:

You can change the states of portlets, portlet applications, and web applications between active and inactive by using the portal XML configuration interface.

About this task

The `ActivatePortlet.xml` example shows you how to complete this step.

Scheduling the delayed cleanup of portal pages:

You can use the example XML script `Task.xml` to schedule the cleanup of pages that have been marked for deletion.

About this task

Notes:

1. If you delete a page with an object ID and then use the XML configuration interface to re-create the same page with the same object ID, you might receive an error message indicating the operation was canceled because it would have caused a duplicate key value.
2. When you run the cleanup task, the XML configuration interface only schedules the task to be run in WebSphere Application Server and returns. This does not necessarily mean that WebSphere Application Server runs the task immediately. To determine when a task started and ended, check the portal log `SystemOut.log` for the EJPDE0005I and JPDE0006I messages. These messages confirm that the cleanup task has successfully completed. After you have confirmed this, you can run the XML script for re-creating a page with the same object ID as it had before the deletion.

Registering predeployed portlets:

You can manually predeploy portlet application WAR files using the WebSphere Integrated Solutions Console. You can later register and configure the predeployed portlet applications into WebSphere Portal Express, together with other J2EE resources and artifacts, by using the XML configuration interface.

About this task

To install a predeployed portlet, use the sample file `RegisterPreDeployedEAR.xml`. You might have to change this sample for your requirements. For more information about how to predeploy portlets refer to the topic about *Deploying J2EE resources*.

Removing users and groups:

Depending on circumstances, you might want to remove users or groups from your WebSphere Portal Express that are no longer used or required. You can use the XML configuration interface (XML Access) to list such users and groups. You can also remove only some selected users and groups, and keep others for further use.

About this task

IBM WebSphere Portal Express stores users and groups that exist in the user registry as entries in the database. When you use the XML configuration interface or the **Manage User and Groups** portlet to delete users and groups, they are deleted from both the user registry and from the database. Deleting a user or group directly from the configured user registry does not remove the database entry. Also, WebSphere Portal Express does not remove entries from its database when users or groups are muted in the user registry, for example, users with too many wrong password attempts. You can manually remove the users and groups from the database.

Examples for removing users or groups can be the following cases:

- Portal users or groups were removed from the user registry, but not from the portal database.
- User IDs were deactivated, for example after too many wrong password attempts.

Note: After you delete these entries by using the modified XML script, all customization is lost for the deleted users and groups.
To remove users and groups from your portal, proceed as follows:

Procedure

1. Make a backup copy of your portal database.
2. To identify and list these users and groups, run an XML export and use the `cleanup-users` attribute.

   Specify the `cleanup-users` attribute with the `request` tag of type `export`, and set its value to `true`. You also need to set the `export-users` attribute to `true`.

   The resulting output file lists the affected users and groups with their action set to `delete`.

   The XML sample file `CleanupUsers.xml` shows an example of how you can export such users and groups. For information about the sample XML configuration files and their location, read *Sample XML configuration files*.

   Note: CF03 If the number of invalid users is very high, the XML export step can fail with an out-of-memory exception. For such cases, APAR PI23109 introduces a new XML element `threshold`. In case of such out-of-memory exceptions, add `threshold="10000"` to the `<request ... >` element in the `CleanupUsers.xml` script. This option limits the number of exported users to 10,000. When you use this approach, repeat the export step and all following steps until the exported file contains no entries any more. You need to have APAR PI23109 or fix pack CF03 installed to use this XML element.
3. Check the output file from the previous step and **remove** all users and groups that you want to **keep** in the portal database. For example, you might want to keep the muted users and re-enable their passwords. All users and groups that remain in the file are removed from the database in the following import step.

4. Import the modified XML file into your portal. The portal removes all users and groups that you retained in the XML file during the previous step from the portal database.

Results

After you delete these entries by using the modified XML script, all customization is lost for the deleted users and groups.

Related reference:

"Sample XML configuration files" on page 1111
Sample files are provided for your reference to help illustrate how to use XML configuration for different portal configuration purposes. Before you use them, read the other topics about the XML configuration interface carefully. Many of the samples need to be modified with valid page or user name before they can be used.

Preparing the deletion of orphaned resources:

You can use the XML configuration interface to delete orphaned data from your WebSphere Portal Express.

Procedure

1. To prepare for deleting orphaned data, use the example XML script `ExportIncludingOrphanedData.xml`. This script runs an export that includes all orphaned data. The resulting XML output file lists the affected portal resources with their action set to `delete`.
2. Check the output file from the previous step and remove all resources that you want to keep in the portal.
3. Import the modified XML file into your portal. The portal removes all resources that you retained in the XML file during the previous step.

Related tasks:

"Deleting orphaned data" on page 280
You use the SLCheckerTool to delete orphaned data in the database.

Generating a complete XMLAccess export of a Portal configuration:

To help troubleshooting a WebSphere Portal issue, you might be asked by IBM Support to generate or collect a full or complete export of your Portal configuration. The complete export can be generated by using the XML Configuration Interface, commonly known as XMLAccess.

To generate a full export of your Portal's configuration, do the following steps:

1. Open a terminal or command window. Change directory (cd) to `<WP_Profile_root>/PortalServer/bin`
2. Run the following command all on one line:

   ```
   xmlaccess -user Portal_admin_user -password Portal_admin_password -url
   http://<myhost>:<port>/wps/config -in <Portal home>/doc/xml
   -samples/Export.xml -out result.xml
   ```

   - Substitute `Portal_admin_user`, `Portal_admin_password`, `myhost`, and `port` with the correct values for your environment. It is recommended to use the direct URL and port so the request can bypass any webserver or load balancer that might be present.

- The file name that is specified after the `-out` parameter contains the Portal configuration as XML. The output file can have any name.
- The protocol can be omitted after the -url in the value for the parameter except in the case of SSL.

If you receive an error that any one of the variables JAVA, WPS_HOME or WAS_HOME are not defined run the script `<Appserver_home>/bin/setupCmdLine` in the current window.

You might also start XMLAccess without any parameters on the command line to test it in your environment.

If the file `Export.xml` is missing from your installation, contact IBM Support or take a copy from another Portal host.

Note: The file `Export.xml` is used as the input file in these examples to generate an export for diagnostic purposes. However, when Portal artifacts are to be imported to or updated in a Portal configuration, or for use by ReleaseBuilder the export file is generated by using `ExportRelease.xml` as the input file rather than `Export.xml`.

Virtual Portals

XMLAccess exports the base or default Portal for the specified host by using the `/config` URI. If virtual portals are defined, each must be exported separately. The virtual portal URL mapping context must be specified in the URL.

For example, given a Portal 7.0 virtual portal VP1 an example XMLAccess command to export the content of VP1 is:

```
xmlaccess -user Portal_admin_user -password Portal_admin_password -url
http;//host.raleigh.ibm.com:10039/wps0config/VP1 -in Export.xml -out
result_VP1.xml
```

If your Virtual Portal is defined by using an optional host name, specify the host name and `/config` URI to export the Virtual Portal content:

```
xmlaccess -user Portal_admin_user -password Portal_admin_password -url
http://MyVirtualPortalHost.com:10039/wps/config -in Export.xml -out
result_MyHost.xml
```

XML configuration reference

Learn more about XML input structure, XML tags for portal resources, attributes for special purposes such as locale data, object IDs, and more. Also find information about action attributes that determine the type of processing that the XML configuration reference applies to the portal resource. There are syntax restrictions that you need to consider as well as information about how to determine the object IDs for portal resources.

"XML input script file structure" on page 1084
When you use the XML configuration interface command line client, the XML script you use specifies the root element, the XML schema, the portal resources, and actions to be performed.

"Types of portal resources" on page 1085
The portal resources are represented by the following XML tags.

"Syntactic restrictions on the input syntax" on page 1099
There are certain restrictions on the allowed values for the `action` attribute.

"Hints and tips for using the portal XML configuration interface" on page 1110
In an example configuration, you might have two WebSphere Portal Express environments that are both configured for security with an LDAP server. However, the two LDAP servers have different directory structures.

"Sample XML configuration files" on page 1111
Sample files are provided for your reference to help illustrate how to use XML configuration for different portal configuration purposes. Before you use them, read the other topics about the XML configuration interface carefully. Many of the samples need to be modified with valid page or user name before they can be used.

XML input script file structure:

When you use the XML configuration interface command line client, the XML script you use specifies the root element, the XML schema, the portal resources, and actions to be performed.

The main level structure of an XML request or response is always as follows:

```
<?xml version="1.0" encoding="UTF-8"?>
   <request
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd"
    type="export|update">
      <portal . . . >
      definition of configuration parts to be exported or updated
      </portal>
      <status . . . >
      success or failure indication for the processing
      </status>
   </request>
```

The main request element specifies the XML schema used by the XML configuration interface. You must always use the schema reference that is shown in the example, that is a reference with no namespace to the schema `PortalConfig_8.5.0.xsd`. All XML requests must conform to this schema. For your reference, you can find the schema declaration in the JAR file `wp.xml.jar` under the location `com/ibm/wps/command/xml/PortalConfig_8.5.0.xsd`. The JAR file `wp.xml.jar` is located under the following directory:

- **For Linux:** *PortalServer_root*`/base/wp.xml/shared/app`
- **For IBM i:** *PortalServer_root*`/base/wp.xml/shared/app`
- **For Windows:** *PortalServer_root*`\base\wp.xml\shared\app`

All other XML sample files are located in the following directory:

- **For Linux:** *PortalServer_root*`/doc/xml-samples`
- **For IBM i:** *PortalServer_root*`/doc/xml-samples`
- **For Windows:** *PortalServer_root*`\doc\xml-samples`

Before you send requests to the portal, you can verify them against this schema using a suitable editor or parser to ensure syntactic correctness. The schema also contains annotations that give detailed information on the meaning and possible values of all configuration entries.

The `type` attribute indicates whether the XML request contains specifications for exporting or for updating portal resources.

The `portal` section describes the parts of the portal configuration that should be exported or updated. The contents of the hierarchy used are described in more detail in the following sections.

The `status` section is optional; in an XML response it indicates success or failure of the requested operation. If a status element is present in a XML request, the server simply ignores it.

The simplest request that you can send to a server is the following:

```
<?xml version="1.0" encoding="UTF-8"?>
   <request xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
      xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd"
         type="export">
      <portal action="export"/>
   </request>
```

This request exports the entire configuration of the portal. You can look at the contents of the response to see how the configuration of individual portal resources, such as portlets or pages, is represented in XML elements and attributes.

Additional to the `export` and `update` request types, a third request type `export-orphaned-data` is available for the special scenario of preparing the deletion of orphaned data.

Types of portal resources:

The portal resources are represented by the following XML tags.

request
The main tag of every XML request. This element must always appear exactly once and must enclose the request. You can use this attribute to export release data from the portal database to later feed that data it into the staging process.

portal The main element of every XML request. This element must always appear exactly once and supports only `locate` and `export` actions.

global-settings, services-settings
Settings for global portlet configuration values and for specific portal services. These elements support only `locate` and `export` actions.

Note: Leave the XML scripts for exporting and updating these settings unchanged. Do not manually change the values in the XML scripts, as this action might result in invalid portal configurations. To modify these settings, use the appropriate administration portlets instead after the XML update of a configuration.

language
Use this tag to add languages to the list of supported languages that are defined in the portal or to delete languages from that list. Use the following attribute for bidirectional languages.

bidi For bidirectional languages, specify this attribute as `true`.

task Schedules the cleanup of portal resources and the administration of federated tags. *Cleanup* refers to the deletion of portal pages and all page-dependent resources that are marked for deletion. Specify one or more tasks to be run immediately or at specified intervals. The scheduling interval parameters **`dayOfMonth`** and **`dayOfWeek`** are optional and are

mutually exclusive. Each scheduling interval parameter requires a value for the parameter **startTime**. If you want to run a task daily, use only the parameter **startTime**.

name Specifies the scheduling task to be run:

com.ibm.portal.datastore.task.ResourceCleanup
This task cleans up portal resources. If you specify this task without a scheduling interval parameter, portal resource cleanup is done immediately when you run the XML script.

com.ibm.portal.cp.SynchronizationTask
This task synchronizes collaborative data, including tag categorization information that is provided by Web Content Manager tagging. If you specify this task without a scheduling interval parameter, the portal does a resource cleanup immediately when you run the XML script.

com.ibm.portal.services.RefreshIWidgetDefinitionsTask
This task refreshes iWidget definitions that are stored in WebSphere Portal Express. Refreshing iWidget definitions refers to reloading the iWidget definition XML files and updating the corresponding iWidget Wrapper portlet clones.

Tip: To call this task directly, run the following portal configuration task: `refresh-iwidget-definitions`. See the topic about the *Task refresh-iwidget-definitions* for instructions.

com.ibm.portal.cmis.TransientSlotCleanupTask
This task removes temporary credential vault slots that were created by the federated documents wizard and were not used for at least 3 hours.

com.ibm.wps.cp.tagging.federation.taskhandler.FederationTaskHandler
This task retrieves tags and related data from federated tagging providers. Connections is an example of a federated tagging provider.

com.ibm.wps.cp.tagging.federation.taskhandler.FederationDeleteTaskHandler
This task removes federated tags and related data from WebSphere Portal Express. It is recommended to start the task when federation of tasks is no longer required.

dayOfMonth
If you want the task to run monthly, specify a number from *1* to *31*. If the number you specify is higher than the last day of the month, the cleanup is done on the last day of the month. For example, specifying a value of *31* sets the task to run on January 31, the last day of February, March 31, April 30, and so on.

dayOfWeek
If you want the task to run weekly, specify a number from *1* to *7*, where *1* is equivalent to Monday and *7* is equivalent to Sunday.

startTime
If you specified a scheduling interval of **dayOfMonth** or **dayOfWeek**, you must specify the time of day at which you want the task to start. Use the format *HH:MM* to specify a value from *0:00* to *23:59*.

You do not need to include leading zeros, for example *4:45*. To run the task daily, use this parameter only; do not use the parameters **dayOfMonth** or **dayOfWeek**.

The `Task.xml` sample shows you how to schedule the cleanup of portal resources.

Notes:

1. When you delete a page with an object ID, and re-create the same page by using the XML configuration interface. If you use the same object ID, you might receive an error message. The error message indicates that the operation was canceled because these actions created a duplicate key value.
2. When you run a cleanup task, the XML configuration interface schedules only the task to be run in IBM WebSphere Application Server. This action does not necessarily mean that WebSphere Application Server runs the task immediately. To determine when a task started and ended, check the portal log `SystemOut.log` for the *EJPDE0005I* and *JPDE0006I* messages. These messages confirm that the task was successfully completed. After you confirmed the completion of the task, you can run the XML script for re-creating a page with the same object ID that it had before the deletion.

action Use this tag to define the required action. For more information about actions, see the topic about *Actions on portal resources*.

virtual-resource
Virtual resources in the access control subsystem. Virtual resources have access control definitions that are attached, but are not otherwise represented in the portal. The virtual resource PORTLET_APPLICATIONS, for example, allows you to give users access to all installed portlets, but does not correspond to an actual portlet. The `virtual resource` element supports only `update` and `export` actions.

user Users in the portal user repository. The definitions include their properties, for example the user's preferred language, and portal access control settings that apply to users, for example, who is allowed to administer them. The XML configuration interface allows setting the password for a user, but it does not export the password. The password attribute is required for creating new users. Therefore, you cannot directly use the response file from an XML export request to create new users; you need to add a password attribute to the XML first.

You can specify the name attribute of users and groups with a full DN (distinguished name) as in `uid=wpsadmin,cn=users,...`. Or you can specify the name attribute with a short ID as it is used for portal login, for example `wpsadmin`. An XML response file from a portal export request always contains full DNs.

With regards to the user tag, there are two special cases for which you must specify particular attributes, depending on the task you want to do:

- Exporting users and groups
- Deregistering users and groups from the portal.

Both cases are described in the following sections.

Exporting users and groups: A full portal export does not normally include user and group information, but only if you explicitly specify in your XML

request that the user is to be exported. If you want to export all user and group information, set the `export-users` flag on the main request tag to `true` as follows:

```
<request . . . export-users="true" . . .>
```

If you want to export groups without the members, set the `export-users` flag to `no-member`.

Notes:

1. Searching for users or groups is a time consuming task. A search might time out or return more results than the system can handle or the user might expect. To prevent this behavior, you can limit searches for users or groups by setting a timeout or a maximum number of search results.
2. The values of some attributes of the tag `user` correspond to settings in included `parameter` tags. If you include both in your export request, but specify different values for them, then the value set by the `parameter` tag overwrites the value set by the attribute, and is exported as the attribute. The values of the attributes of the `user` tag correspond to the included `parameter` tags as follows:

Table 142. User tag: corresponding attributes and included parameter tags

Attribute	parameter tag with name=" "	Comments
firstname	givenName	
lastname	sn	
name	uid	
n/a	cn	This tag is a mandatory parameter tag for representing the LDAP attribute.

Example: You can define the first name of a user at creation by using either the attribute `firstname` or the `parameter` tag with the `givenName` attribute. If you use both and specify two different names, then the value that is specified by `givenName` is exported as the attribute `firstname`. Example XML export request:

```
<?xml version="1.0" encoding="UTF-8"?>
<!-- Description of this command file: Create 1 users -->
<request xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
         xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd"
         type="update" create-oids="true">
     <portal action="locate">
         <user action="update" firstname="John_1" password="password"
               lastname="Miller" name="John's name">
             <description>John Miller</description>
             <parameter name="cn" type="string" update="set">John Miller</parameter>
             <parameter name="givenName" type="string" update="set">John_2</parameter>
         </user>
     </portal>
</request>
```

This request sets the value `John_2` for the `firstname` attribute.

On some LDAP servers, where the `cn` is part of the distinguished name, you might not be able to update the `cn`.

Deregistering users and groups from the portal: If portal users or groups are removed from the user registry, but not from the portal database, or if users are muted, for example after too many wrong password attempts, you can export these users and groups for later removal. They can be

removed later by using the `cleanup-users` attribute with the `request` tag. To export these users and groups, set the `cleanup-users` flag on the main request tag to `true` as follows:

```
<request . . . cleanup-users="true" . . .>
```

If you set this property to `true`, all users and groups that no longer exist in the configured user repository, such as LDAP, are exported with their action set to `delete`. You also need to set the `export-users` attribute to `true`.

Before you reimport the file, you need to review and edit the result file and remove all users and groups that you want to keep in the portal database. During XML import, all users and groups that remain listed in the file are removed from the portal database.

Note: After you delete these entries through the modified XML script, all customization is lost for the deleted users and groups.

The sample XML file `CleanupUsers.xml` is an example of exporting users and groups.

group Groups in the portal user database. The definitions include portal access control settings and membership information, for example, which users belong to the group. For more information about how to handle groups in XML, see the preceding tag user.

markup
Definition of markup types that the portal pages support.

client Definition of client devices, how they are detected, and which markups and features they support.

device-class
Definition of a device class.

skin Describes the visual appearance, for example, the border of individual user interface elements, for example, of portlets on a page. Skins can be assigned to content nodes and components.

theme Describes basic properties, for example, colors and font type, of the appearance of an entire group of pages. Themes might restrict the selection of possible skins on the associated pages. Themes can be assigned to content nodes.

wsrp-producer
The wsrp-producer is the Producer definition on the Consumer side for Web Services for Remote Portlets (WSRP). It allows an administrator to use and integrate remote portlets that are provided by the WSRP Producer.

After you integrate a WSRP service, the portal handles it like a regular local portlet. For example, you can add the portlet to pages.

web-app
Web modules, which correspond to a deployed WAR file. To use them in the portal, one or more (concrete) portlet applications must be defined that describe specific settings. In a `portlet.xml` deployment descriptor, this element corresponds to the `portlet-app` tag.

Web modules for standard API-compliant portlets can contain only one single portlet application, whereas web modules for IBM API-compliant

portlets can contain more than one portlet application. For IBM API portlets, the `uid` attribute must match the`uid` attribute that is defined in the deployment descriptor.

Note: IBM API portlets are deprecated since WebSphere Portal Express Version 7.0, but are still supported.

For standard portlets, the `uid` attribute must be constructed by the `id` attribute of the `portlet-app` subelement and a `.webmod` suffix. If the `id` attribute is not specified, then the `uid` attribute is constructed by the WAR file name and a `.webmod` suffix. Example:

```
<web-app action="update" active="true" removable="true" uid="jsr_bookmarks_id001a.webmod">
     . . . . .
<portlet-app action="update" active="true" uid="jsr_bookmarks_id001a">
```

Depending on the path location of your WAR files, previously exported WAR files might not be found during an XML import due to incorrect path information. For information about how to use the `<url>` subtag with the `<web-app>` tag see the topic about *Importing WAR files*.

servlet

Servlets that are defined in the web module. They are created as part of the WAR file deployment and cannot be created or deleted explicitly, therefore the `create` and `delete` actions are not supported. In a standard `portlet.xml` deployment descriptor, this element corresponds to the `portlet` tag. In an IBM `portlet.xml`, one servlet is created for each `concrete-portlet` tag.

portlet-app

Portlet applications that are contained in a web module and contain specific settings. Usually, applications and their contained portlets are defined in the WAR file of the web module and are created by the portal during deployment. For IBM API-compliant portlets, this element corresponds to the `concrete-portlet-app` tag of the portlet deployment descriptor.

For standard compliant portlets, the `uid` attribute must match the `id` attribute of the `portlet-app` element that is defined in the deployment descriptor. If the `id` attribute is not set in the deployment descriptor, specify the WAR file name.

When the application is used in a WSRP context, the portlets that are contained in the application are defined remotely and can be integrated by using the XML configuration interface. In this case, portlet applications need to define a `groupid` attribute.

After you deploy a WAR file locally or integrated a WAR file as a WSRP service, you can also create more portlet applications (and the contained portlets) with different settings. This action is also known as copying or cloning the portlet application.

portlet

Portlets that can be placed on a page and contain specific settings. Normally, portlets are defined in the WAR file of the web module and are created by the portal during deployment. When the portlets that are contained in the web module are used in a WSRP context, they are defined remotely and are integrated by the XML configuration interface. In this case, portlet applications need to define a `handle` attribute. A new flag, `provided`, is introduced for providing portlets for remote invocation and withdrawing them.

When you create a new portlet in an extra application, it must refer to one of the servlets that was defined in the web module. In a `portlet.xml` deployment descriptor, this element corresponds to the `concrete-portlet` tag.

Note: If you write standard API-compliant portlets, you must not use the `parameter` tag to add parameters; use the `preferences` tag instead.

content-node
An element in the content hierarchy of the portal. The portal supports several types of content nodes:

- A page is a content node that is made up of nested layout elements and displays portlets.
- A label is a content node that serves for organizing the content hierarchy but does not display portlets.
- A static page is a content node that contains a static HTML file or an HTML fragment.
- An internal URL is a content node that points to other portal content by referencing a URL.
- An external URL is a content node that points to a web page outside the portal.

All content nodes in the portal are organized in a hierarchy; at the root of this hierarchy is the special content node wps.content.root. A content node of the type `page` can be derived from another parent content node so that it partially overrides or extends the layout of its parent. The portal and the portlet for Working with pages always display an aggregation of a composition layer and all of its ancestors. But the XML configuration interface must manage every layer separately.

Note: It is recommended to always export and replace an entire stack of page layers and *not* to use XML requests to modify individual layout components or derived page layers. In particular, do not try to manually create XML scripts for the definition of derived pages, as the reference structure is complex. Instead, use the portlet for Working with pages to edit page layouts, and then export the result into an XML response file.

component
A layout component inside a page. The portal supports two types of components:

- A container is a row or column container that aggregates child containers.
- A control component contains a portlet instance.

If you update an existing page with an XML script and the script specifies components inside that page, the `layout-processing` attribute of that page defines how those new components interact with the existing layout of the page.

portletinstance
An individual occurrence of a portlet on a page. The portlet instance includes the user-defined portlet data that was set by using the edit mode of the portlet.

Note:

1. A portlet instance is always contained in a component of type `control`; deleting a portlet instance automatically deletes the component in which the portlet was contained.
2. Instances of standard portlet API-compliant portlets must not use the `parameter` tag to add parameters; they must use the `preferences` tag instead.

For personalized content, where only portlet parameters but no page structure is changed, use the following attributes with the `portletinstance` tag:

owner Use this attribute to define the owner of the portletinstance.

parentref
Use this attribute to define the parent of the portletinstance.

cross-page-wire
Represents a property broker wiring between two portlet instances on either the same page or on different pages. A wire connects a source and a target portlet instance so that values that change in the source are propagated to the target. This tag has the `source-pageref` and `target-pageref` as the only extra attributes to the wire tag. When you export a page with cross-page wires that are connected, then the `cross-page-wire` tag is exported, even if there is no direct reference to or from the page or the wire.

Note: A wire can be created only if the wiring endpoints of the corresponding portlets exist. Legacy portlets that are not compliant with JSR 168 or 286 might create those endpoints programmatically on their first rendering. Therefore, the XML configuration interface cannot create a new wire for those portlets unless they are rendered the first time. To create this wire, first view the page that contains the portlet with a web browser and then create the wire by using the XML configuration interface.

wire Represents a property broker wiring between two portlet instances on a page. A wire connects a source and a target portlet instance so that values, which change in the source are propagated to the target.

Notes:

1. The `wire` tag is deprecated with WebSphere Portal Express Version 7.0, as it supports property broker wiring between two portlets on the same page only. Use the `cross-page-wire` tag as it supports property broker wiring between portlets on the same page and on different pages.
2. A wire can be created only if the wiring endpoints of the corresponding portlets exist. Legacy portlets that are not compliant with JSR 168 or 286 might create those endpoints programmatically on their first rendering. Therefore, the XML configuration interface cannot create a new wire for those portlets unless they are rendered the first time. To create this wire, first view the page that contains the portlet with a web browser and then create the wire by using the XML configuration interface.

credential-segment
Groups a collection of credential entries for a specific back-end credential store (vault). The configuration of credential segments cannot be modified after they are created.

credential-slot
A single credential entry that describes information that is required to

connect to a protected resource outside the portal. The XML configuration interface covers only the definition of the credential slot. The actual credential, for example the password for an application, is stored in the back-end credential store. It can be set or updated, but not exported by using the XML configuration interface.

For more information about setting user credentials by using the XML configuration interface, see the XML sample file `UpdateVault.xml` provided with the portal.

url-mapping-context
Use this tag to define arbitrary URL spaces that map to portal content.

user-resources
Use this tag to do export or delete actions for specific users.

policy-node
Use this tag to define arbitrary URL spaces that map to portal content. When you use the XML configuration interface to work with policies, some limitations apply.

application-role
Use this tag to define a compound role that combines multiple authorization roles and is specific for a set of users.

The following tags and attributes are for portal internal use only. If you encounter these tags or attributes in an XML export script that you want to use for later update, do not change these tags or their content in any way.

action-set
This tag is for portal internal use only.

category
This tag is for portal internal use only.

federation-server
This tag is for portal internal use only.

protected-resource
This tag is for portal internal use only.

resource-type
This tag is for portal internal use only.

transformation
This tag is for portal internal use only.

transformation-app
This tag is for portal internal use only.

transformationinstance
This tag is for portal internal use only.

serverref
The serverref is an attribute for the `content-node` tag; it is for portal internal use only.

content
This tag is for portal internal use only.

supported-processing-event
This tag is for portal internal use only.

supported-publishing-event
This tag is for portal internal use only.

qname
This tag is for portal internal use only.

alias This tag is for portal internal use only.

class-name
This tag is for portal internal use only.

The following tags are available for portal resources for tagging and rating: `tag`, `rating`, `custom-resource`, and `category-instance`. For more information about these tags, see the topic about *Using the XML configuration interface to administer tags and ratings*.

The XML configuration interface manages only resources of the portal core and not the resources of extra components, such as Portal Personalization.

"Special configuration data entries" on page 1095
Additional to the tags that represent portal resources as listed in the preceding section, XML provides the following tags or attributes for special purposes.

"Actions on portal resources" on page 1098
All XML elements that represent portal resources have a required `action` attribute. The `action` attribute of XML elements determines what type of processing is applied to the portal resources.

Related reference:

"Task refresh-iwidget-definitions" on page 1252
Use this configuration task to refresh iWidget definitions in the portal. This task affects all iWidget definitions that are referenced through absolute HTTP or HTTPS URLs in addition to iWidget definitions that are referenced through WebDAV URIs.

"Actions on portal resources" on page 1098
All XML elements that represent portal resources have a required `action` attribute. The `action` attribute of XML elements determines what type of processing is applied to the portal resources.

"Importing WAR files" on page 1107
To create new portlet applications, you need additional resources, the WAR files.

"Sample XML configuration files" on page 1111
Sample files are provided for your reference to help illustrate how to use XML configuration for different portal configuration purposes. Before you use them, read the other topics about the XML configuration interface carefully. Many of the samples need to be modified with valid page or user name before they can be used.

"Using the XML configuration interface to administer tags and ratings" on page 1343
You can use the XML configuration interface to manage tagging and rating in the portal. For example, you can move tagspaces and ratings between portal versions or for staging purposes.

"Using the XML configuration interface to administer analytics tags" on page 1729
You can use the XML configuration interface to manage analytics tags and site promotions in the portal.

Special configuration data entries:

Additional to the tags that represent portal resources as listed in the preceding section, XML provides the following tags or attributes for special purposes.

localedata
Describes locale specific data associated with portal resources. The `localedata` element allows a number of child elements (title, description and keywords), but not all of them are supported for all portal resources. Unsupported child elements are ignored. The `charset` attribute is only used in `markup` elements.

When you create XML files that contain lots of translated texts in different languages, it is sometimes more convenient to specify those texts in properties files instead of including them in the XML script. Therefore you can alternatively use a URL to specify a properties file. XML will then read the title, description, and keyword texts from that file.

parameter
Describes name-value pairs associated with portal resources. The `parameter` element supports a `type` attribute, but for all elements except portlet instances, the type must be `string`. Portlet instances additionally support the `binary` type which treats the parameter contents as Base 64 encoded binary data. User definitions support setting multiple values for the same parameter name. With all other resources, setting a parameter overwrites any previous value stored under the same parameter name.

If the WSRP Producer requires a registration of the WSRP Consumer with certain registration properties, you must specify these properties as parameters.

preferences
This is a derivation from the `name/value` pair. It relates to the `parameter` element. It describes name/multivalue combinations, that is, combinations of a `name` and one or more `value` child elements that are associated with the portal resources `wsrp-producer`, `portlet`, and `portlet-instance`.

Note:

1. The `value` elements support only string type attributes, no binary type attributes.
2. Setting a `preferences` value overwrites all values that were previously stored under the same `preferences` name.
3. `portlet` and `portlet-instance` can only have the `preferences` element if they comply with the standard portlet API. For all other portlets, use the `parameter` element.
4. If the WSRP Producer requires a registration of the WSRP Consumer with certain registration properties, you must specify these properties with the `parameter` tag.

Optionally, you can use the `preferences` element to define which user attributes you want to have transferred in the WSRP communication with the Producer. These user attributes are the user attributes that are defined in LDAP.

access-control
Describes the access permissions associated with portal resources. By specifying access-control subsections for resources in the XML, you can, for

example, define which users or groups are allowed to manage a resource. The access control definition for a resource includes all of the following information:

- The owner of the resource
- The roles defined on that resource
- The mapping of users or groups to a role
- Whether inheritance of a role or from the parent resource or to child resources is blocked.

Alternatively, a resource can be a private resource of a specific owner, or it can be managed externally.

When you specify users or groups in the access-control section of a resource, you can either use the full DN as in `uid=wpsadmin,cn=users,...` , or the short ID as it is used for portal login, for example `wpsadmin`. An XML response file from a portal export request always contains full DNs.

Note: When you change the access control state of a resource from public to private or vice versa, this also affects all the resources that inherit access control from this resource. You can never have a public resource that inherits access control from a private resource.

objectid

Almost all resources in the portal have an object ID, which identifies the resource. The object ID allows addressing the resource unambiguously. It is also used to express references from one resource to another. For example, when a theme is assigned to a page, the configuration of the page includes the object ID of the theme. For more information about object ID handling in XML scripts see the topic about *Object IDs in XML scripts*.

uniquename

A resource that has an object ID can optionally also have a unique name. The unique name can then also be used to identify the resource unambiguously, because a unique name can be used only once in a portal installation.

If you run an XML update that assigns a unique name which is already used on the system, the execution will fail. You can delete the unique name for a resource by setting it to the value `undefined`. When you create unique names in XML scripts that you run on many different portal installations, for example to install add-on portlets and pages, you should use a specific prefix for any unique names that you assign, to minimize the chances that they clash with existing unique names on the system. For example, the prefix `wps.` is used for all unique names that are created as part of the portal installation.

Note: When you create a nested element, for example a component, with a `uniquename` attribute, the whole hierarchy upward from that element must also have `uniquename` attributes. Example XML export request snippet:

```
<content-node ...
     <component uniquename="component_1"...
          <component uniquename"component_2"...
               <component uniquename"component_3"...
                    . . . . .
               </component>
          </component>
     </component>
</content-node>
```

Failing to do so might result in the following error message:

```
XMLC0142E: Unique name unique_name is already used in the portal.
```

ordinal

The client and component resources take an `ordinal` attribute which represents the sorting order. (In the case of client resources, if more than one client entry matches a connecting device, the entry with the higher ordinal takes precedence.)

When ordinals for resources are set in an XML script, you have the following options for specifying them:

- As a plain integer value. In this case, the value is written to the database. The resource is sorted into the position that this ordinal value has relative to the ordinals of existing siblings. For example, if you create a new page with `ordinal="350"` under an existing label, and there are already other pages under that label with the ordinals 100, 300 and 500, the new created page will appear in the third position. If you specify an ordinal which has already been assigned to an existing resource, the order of the two resources cannot be predicted.
- As a position indicator. Specify with a hash mark (**#**), followed by an integer value. In this case the resource is inserted in the sequence of resources at the position indicated by the specified value. For example, when you create a new page with `ordinal="#2"`, it appears in the second position in its content parent.
- The special values `first` and `last`. In this case, a value is chosen so that the resource is sorted at the first or last position in its content parent.

An XML export response file always contains the literal ordinal values as they are stored in the portal database. Note that specifying a position indicator or special value will not necessarily produce the required effect if you are working with derived pages, because in these cases the order of elements depends on the individual user viewing the portal.

domain

Use this attribute to specify in which database domain a specific resource should be stored. You can also use the `domain` attribute to export release data from the portal database by specifying `domain="rel"` to later feed that data it into the staging process. Use one of the following values with the `domain` attribute:

rel This value exports only the release data.

cust This value exports the release data with the customization data. This includes all referenced release data as `locate` statements.

export-release

This attribute is for use with the `request` tag. Do not use this attribute any more. Instead, use the preceding attribute `domain` by specifying `domain="rel"`.

The following two attributes have been added for the `portletinstance` tag. Use them for personalized content, where only portlet parameters are changed, but not the page structure.

owner Use this attribute to define the owner of the portlet instance.

parentref

Use this attribute to define the parent of the portlet instance.

global-target-settings

Contains those property broker actions that are defined as global targets. By using this tag, portlet instances can make Communication Targets available to Click-To-Action menus or for cross-page wiring. A `portletinstance` tag section can contain `target` elements that define a Communication Target that has been defined as global. The `target` definition specifies the communication target that is to be exported. Example:

```
<portletinstance ...>
   <global-target-settings>
      <target actionref="orderDetails" update="set"/>
   </global-target-settings>
</portletinstance>
```

You can find additional information on the meaning and possible values for configuration elements and attributes in the schema annotations.

Related reference:

"Object IDs in XML scripts" on page 1100
All resources in WebSphere Portal Express, except for the resources `portal` and the `settings`, have an object ID that uniquely identifies them in the portal. That ID is generated by the portal when the resource is created. These object IDs are represented by the `objectid` attributes in an XML export.

Actions on portal resources:

All XML elements that represent portal resources have a required `action` attribute. The `action` attribute of XML elements determines what type of processing is applied to the portal resources.

You can specify the following actions:

Table 143. Actions allowed to be set for the Action attribute of XML elements

Action	Resulting processing
`locate`	Identify the portal resource corresponding to this XML element (usually required as a context for other actions).
`create`	Create a new portal resource with the given attributes. A new resource is always created, even if another resource with the given name already exists.
`update`	Update the configuration of the corresponding portal resource with the given configuration data (attributes and dependent configuration data elements); if no corresponding portal resource can be found, it is created.
`delete`	Delete the portal resource corresponding to this XML element.
`export`	Include an XML representation of the portal resource corresponding to this element in the output of the XML command.

Example: the following XML snippet sets the portlet named "MySpecialPortlet" to inactive status:

```
<portlet name='MySpecialPortlet' action='update' active='false'/>
```

Syntactic restrictions on the input syntax:

There are certain restrictions on the allowed values for the `action` attribute.

They are listed here:

- If the request type was specified as `update`, only the actions `locate`, `create`, `update` and `delete` are permitted.
- If the request type has been specified as `export`, only the actions `locate` and `export` are permitted.
- `Create` actions (and `update` actions for non-existing elements) might require that certain attributes of the element are defined that are not required for other `update` or `delete` actions.
- Actions of nested elements must not be contradictory. If you choose to `delete` a resource, you cannot `create` any other resources inside it. The following table lists all commands, together with the allowed commands for subelements:

Table 144. Actions, together with the allowed actions for subelements

Action	Allowed actions in subelements
`locate`	`locate, create, update, delete, export`
`create`	`locate, create, update`
`update`	`locate, create`
`delete`	`no subelements allowed`
`export`	`no subelements allowed`

You can specify two or more XML elements that refer to the same portal resource. For example, you can have one element that creates a portal resource and another that updates the same resource with new configuration data.

Configuration data elements do not have an associated action, but most of them have an `update` attribute that determines the type of update that is applied. The following values are possible:

Table 145. Values for the Update attribute of configuration data elements

update	Resulting processing
`set`	The corresponding configuration data (for example, parameter) is set, or, if it does not yet exist, it is created.
`remove`	The corresponding configuration data (for example, parameter) is removed

Note that configuration data elements are processed only if their parent has an `update` action. For example, the following fragment will *not* update the capability information for the given page:

```
<client uniquename="smart.browser" action= "locate">
     <client-capability update="set">HTML_JAVASCRIPT</client-capability>
</client>
```

All specified actions are processed in the textual order in which they are specified in the XML input (document order). If there are any interdependencies between the actions, the user or program providing the XML input is responsible for ordering the elements correctly.

Object IDs in XML scripts:

All resources in WebSphere Portal Express, except for the resources `portal` and the `settings`, have an object ID that uniquely identifies them in the portal. That ID is generated by the portal when the resource is created. These object IDs are represented by the `objectid` attributes in an XML export.

References between resources are represented by these object IDs: One resource has a reference attribute that contains the object ID of another resource. For example, a portlet instance that is to be displayed on a page must reference a portlet. Therefore the `portletinstance` tag has a `portletref` attribute that corresponds to the `objectid` attribute of the portlet. Consequently, you see the following snippets in an XML export:

```
<portlet action="update" . . . objectid="Z3_G0Q03FH200A5202QRHAG4320G0" . . . >
    . . .
<portletinstance action="update" . . . portletref="Z3_G0Q03FH200A5202QRHAG4320G0" . . . >
```

All resources get an object ID assigned in the portal when they are created. That object ID can not be altered later. When you create new resources in the portal administrative user interface, they automatically get a new object ID generated by the portal. When you create a new resource with XML, it also always gets a new object ID, if you do not specify one in the XML. Note that you can not simply "invent" object IDs for new resources, because they must conform to a correct internal representation. The only way to get valid object IDs is from an XML export.

In XML scripts the `objectid` attribute of a resource is used for the following purposes:

- To look up the resource, if the action is `locate`, `export`, `update` or `delete`.
- To set the object ID for a new resource, if the action is `create`.
- To set the object ID for a new resource, if the action is `update` and no resource with that object ID exists.
- To describe links from one resource to another.

You can use object IDs to uniquely specify resources that you want to administer. For example, the following snippet deletes a specific known page. (You would normally get the object ID of the page from an XML export.)

```
<content-node action="delete" objectid="Z6_G0Q03FH200A5202QRHAG4320O0"/>
```

The following snippet looks up a page with a specific object ID. If it cannot find the object ID, it creates it. If it already exists, it updates it.

```
<content-node action="update" objectid="Z6_G0Q03FH200A5202QRHAG4320O0" type="page" . . . >
```

The next snippet creates or updates a theme with a specific object ID and then assigns that theme to a label:

```
<theme action="update" objectid="ZJ_G0Q03FH200A5202QRHAG4320S1" . . .>
    . . .
<content-node action="update" objectid="Z6_G0Q03FH200A5202QRHAG4320O0"
            type="label" themeref="ZJ_G0Q03FH200A5202QRHAG4320S1" . . . >
```

If the theme already exists with the specified object ID, you can directly use that object ID in references without having to include the theme in the XML script. The next snippet assumes that the theme has already been created. For example, it might have been copied from another server in a previous step. Therefore the snippet only assigns the theme to the label:

```
<content-node action="update" objectid="Z6_G0Q03FH200A5202QRHAG4320O0"
     type="label" themeref="ZJ_G0Q03FH200A5202QRHAG4320S1" . . . >
```

In this case, the theme is looked up in the portal data store using its object ID `ZJ_G0Q03FH200A5202QRHAG4320S1`. If no theme with that object ID is defined in the portal, you get an error during the XML validation.

An object ID is globally unique. Two object IDs that were automatically generated by different portal installations can never be the same. Therefore you can exchange resources between different portal installations using XML export and update requests without having to worry about possible object ID conflicts. The only way that you can ever duplicate an object ID is by transferring a resource (including the object ID) to another portal with an XML export and update.

In many cases, this is the required behavior. However, if you do not want to copy the same resource to another portal, but you want to create a new resource instead, regardless of existing OIDs and without any chance of causing conflicts, you must either use symbolic object IDs or delete the `objectid` attribute from the XML script. In the latter case the portal creates a new object ID.

"Symbolic object IDs and ID generating mode"
In some cases, you might need to use object ID attributes to express references between resources in your XML script, but you do not want these to be read from or written to the portal database. In this case, the object ID would be only a symbolic reference inside the XML script.

"Lookup of portal resources" on page 1103
XML elements with `locate`, `export`, `update` and `delete` actions need to refer to existing resources in the portal. Those resources must be identified by specific attributes.

Symbolic object IDs and ID generating mode:

In some cases, you might need to use object ID attributes to express references between resources in your XML script, but you do not want these to be read from or written to the portal database. In this case, the object ID would be only a symbolic reference inside the XML script.

For example, you might want to create a new theme and page, and reference the theme in the page. Nevertheless you want to let the portal chose an object ID for it because you do not want to accidentally overwrite an existing resource.

There are two ways to achieve this:

- You can switch the XML processing to **ID generating mode** by setting the `create-oids` flag on the main request tag:

  ```
  <request . . . create-oids="true" . . . >
  ```

  In this mode, all object IDs are not written to or read from the portal database. Instead, their only purpose is to express the linking between resources in the XML. When the XML processing creates new resources, they are created with a new system generated object ID, not with the object ID specified in the XML.
- When you use a value for an `objectid` attribute that cannot be decoded as an object ID, such as a simple string name, the XML processing treats it as symbolic and does not try to use it for looking up the object or write it to the database. This makes it possible to selectively treat individual object IDs as symbolic.

Note that even in symbolic object IDs, anything after the first space is not significant for processing. For example, you could use the following snippet to create a portlet and put it on a page using a symbolic object ID:

```
<portlet action="update" . . . objectid="Welcome_Portlet" . . . >
    . . .
<portletinstance action="update" . . . portletref="Welcome_Portlet" . . . >
```

As the object ID values are purely symbolic, you cannot use them in a reference without first "defining" them in the same XML script. Before you can use the `portletref="Welcome_Portlet"` attribute specification in an XML update, you must also have a portlet with `objectid="Welcome_Portlet"` defined in the same XML; otherwise a syntax error is reported.

Of course, the object IDs in the XML are also not used for looking up a resource. If you want to refer to an existing resource, you need to use a unique name instead. For details see the information later in this section and in the topic about *Lookup of portal resources*. In ID generating mode, the following snippet locates an existing portlet by its name, "defines" a symbolic object ID for it and places the portlet on a page:

```
<portlet action="locate" name="Welcome Portlet" objectid="Welcome_Portlet">
     . . .
<portletinstance action="update" . . . portletref="Welcome_Portlet" . . . >
```

As object IDs are not used to identify existing resources in ID generating mode, it is good practice to define unique names for all resources that are created in such scripts. That way, if the script is executed twice, the second execution can find and update the resource by its unique name, instead of creating two identical resources.

When you create resources using symbolic object IDs, it can sometimes be useful to know the actual object IDs of the new resources. You can set the export-mapping flag on the main request attribute to obtain this information:

```
<request . . .export-mapping="true" . . . >
```

When you set this flag, a mapping section is appended to the XML response. For every symbolic object ID given in the input, this mapping shows the actual object ID in the portal data store.

The ID generating mode is useful if you want to create an XML script that installs a group of new resources and is executed on many different portal installations. This can be, for example, a part of the installation procedure of a portal add-on that you give out to other parties. In this case, you have no control over the systems on which the XML script is executed, and it is of no interest to you which object IDs the resources actually get.

Note: Use the ID generating mode for all the examples under Working with the XML configuration interface, because they should work on any portal installation.

The identity of the objects that are configured in the XML script is expressed by their object ID. Therefore you should use "real" object IDs in your scripts, when you want the objects in your XML to retain their identity. For example, when you use an XML export request and the resulting response file to copy a resource from a staging to a production system, the resource is created on the production system with the same object ID as on the staging system. This way you can establish a correspondence between the two resources. When you later transfer the same

resource again, the XML processing looks up the resource by its object ID, finds that it already exists, and updates the existing resource instead of creating a new one.

When setting up the target system in such scenarios, you should use only the XML configuration interface to copy resources from the source system. If you deploy portlets on the target system during the portal installation or if you deploy them using the administration portlets, they will not have the same object IDs as on the source system, so you can run into problems when you later copy other resources that reference them.

Lookup of portal resources:

XML elements with `locate`, `export`, `update` and `delete` actions need to refer to existing resources in the portal. Those resources must be identified by specific attributes.

The relevant attribute to identify a resource in the portal is its object ID. Every resource must have an object ID and it must always be unique. Therefore, if you specify an `objectid` attribute for a resource, and you do not use symbolic object IDs as described earlier, the resource is looked up by that object ID.

Of course, there are cases where you do not have literal object ID values available when you write your scripts, especially if you are writing scripts that are executed on installations that you are not administering yourself. Therefore you can also specify other identifying attributes to look up resources. If the lookup by object ID fails, the XML processing also attempts to find the resource using other attributes.

An alternative method for looking up portal resources is to use a unique name. Every resource that has an object ID can also have an optional unique name, and the unique name must unambiguously identify the resource. Unique names are useful if you need a symbolic way to identify certain resources. They allow easy porting of configurations between portal installations. In contrast to object IDs, it is possible to modify unique names of resources, which can be an advantage in certain situations. To set a unique name for a resource, use the Custom Unique Names portlet under Administration, Portal Settings.

If a unique name is not given or cannot be found, some resources can also be searched using other attributes. Some resources can be looked up without any attribute information, because they exist only once in their context.

The following table shows the relationship between resources and the attributes you can use for locating them:

Table 146. Resources and attributes for locating them

Resource key	**Attributes used for locating the resources**
`portal, global-settings, services-settings`	None; these items always exist only once.
`markup, virtual-resource, user, group, credential-segment, credential-slot, portlet`	`name`
`web-app, portlet-app`	`uid`
`servlet`	`name` **Note:** The `refid` is used as fallback for XML imports from earlier portal versions that do not contain the `name` attribute.

Table 146. Resources and attributes for locating them (continued)

Resource key	Attributes used for locating the resources
portletinstance	None; there is at most one portletinstance per component.
url-mapping-context	label

In any case the lookup process first tries to find the resource by its object ID, if specified, and then by its unique name, if that is specified. Only when those attempts fail, other attributes are used for locating the resource.

Note: If an objectid attribute is specified in the XML input, but the corresponding resource cannot be found by that object ID but only by another attribute, and if that object ID is used in other parts of the XML script as a reference, those references are mapped to the actual object ID for the resource that was found. In this case the objectid attribute behaves like a symbolic object ID as described earlier.

Replacement variables in XML configuration interface script files:

XML script files that were created by an XML configuration interface export or that can be imported by the XML configuration interface can contain URLs to portal files. These URLs reference files that are in WebSphere Portal Express server directories. Depending on the installation directory of your WebSphere Portal Express installation, these file locations can differ. You can avoid the dependency on the file location by using variables.

For example, the web application of the portal login module contains the following XML element:

```
<url>file://localhost/$archive_root$/login.war.webmod/login.war</url>
```

On a Linux installation of WebSphere Portal Express, this URL might be interpreted as follows:

```
<url>file://localhost//opt/WebSphere/PortalServer/login.war.webmod/login.war</url>
```

On other WebSphere Portal Express installations, the login.war file can be in a different directory.

As the XML configuration interface uses different values for the variable replacement, the XML input file is independent of the specific WebSphere Portal Express installation directories.

The following table shows the available variables and provides examples of the replacement values they might have on a Linux installation of WebSphere Portal Express:

Table 147. Replacement variables in XML configuration interface script files

Variable for WebSphere Portal Express installation directory	Example replacement value
$app_install_root$	/opt/WebSphere/wp_profile/installedApps
$archive_root$	/opt/WebSphere/wp_profile/PortalServer/deployed/archive
$predeployed_root$	/opt/WebSphere/wp_profile/installedApps/wpsbvt

Table 147. Replacement variables in XML configuration interface script files (continued)

Variable for WebSphere Portal Express installation directory	Example replacement value
$profile_install_root$	/opt/WebSphere/wp_profile/installedApps
$server_root$	/opt/WebSphere/PortalServer
$user_install_root$	/opt/WebSphere/wp_profile
$wp_profile_root$	/opt/WebSphere/wp_profile

Exporting sets of resources:

You can specify more than one resource with an export action in the same request and thus generate an export response file that contains a selected group of resources, for example several portlets and pages.

The XML configuration interface provides two additional features that allow you to export selected subsets of the portal resources:

- When you export a content node, you can specify the `export-descendants` attribute for that resource. If you set this attribute to `true`, the export response file also includes the entire subtree in the content hierarchy that is located under that node. In addition, all derived pages that override the layout of pages in that subtree, are also exported. In other words, this exports all content nodes that can be reached via a chain of `content-parentref` or `derivation-parentref` attributes.

  Example: the following fragment exports a subtree of the content hierarchy that starts with the label as specified:

  ```
  <content-node uniquename="MyPages" action="export"
          export-descendants="true" />
  ```

- All first level resources that can take an `objectid` attribute, such as `markup`, `virtual-resource`, `user`, `group`, `client`, `event-handler`, `web-app`, `theme`, `skin`, `content-node`, `credential-segment` and `url-mapping-context` support the asterisk (*) as a wild card symbol that you can use as a value for the object ID. The asterisk can be used as a wild card symbol only with the export and delete actions. Depending on the action with which it is specified, it exports or deletes all resources of the respective type. For example: the following fragment exports the complete client configuration of the portal:

  ```
  <client objectid="*" action="export"/>
  ```

Note: A combination of a partial search string and the asterisk is not valid. The asterisk also has no special meaning if it is used as a value for any other attribute.

The XML configuration interface offers no other "query" features, that allow you to export resources based on specific criteria. The only other possibility to export a selected subset of resources is to specify all the resources individually with their object IDs or other identifying attributes in your XML input.

Mandatory and optional attributes:

Depending on the action that you perform by using the XML configuration interface, some attributes can be mandatory or optional.

Normally, you to specify only that part of the configuration data for an XML element that is necessary for the required operation. For example, when you delete

a portlet, it is sufficient to specify its reference ID to identify it; it makes no sense for this operation (although it is not forbidden), to specify a new active state, since the portlet is removed anyway.

When creating a new portal resource, some required attributes (depending on the type of resource) must be specified. Others can be omitted. They are then set to a default value.

When you update an existing portal resource, all attributes are optional, except those required to locate the element. The omitted attributes remain unchanged. In a few cases of page layout attributes, there is the possibility of explicitly specifying an "undefined" value. This means that the attribute is not defined at the respective level, but inherited. For example, if the skin for a component is undefined, it will be inherited from the setting of its page.

Note that there is a semantic difference between the following XML fragments:

```
<content-node uniquename="MyPages" action="update" active ="true"/
```

and

```
<content-node uniquename="MyPages" action="update" active ="true" skinref="undefined"/>
```

The first fragment only modifies the active attribute of the page and leaves its skin setting unchanged; the second fragment additionally resets the skin to the `undefined` value (whatever the previous skin setting was), so that the page will always display in the portal default skin.

Page layout modifications:

When you use an XML script to update an existing page with a new layout, you create or update child elements of type `component` for the `content-node` element of the page. Normally you use the XML script to define a complete new layout of the page rather than combine the existing layout with your new definitions. In such cases the XML configuration interface applies special processing.

It proceeds as follows: After it has updated the page layout, it deletes all components in the page that existed before but were not updated by the script. As a result, the page contains only those layout components that are specified in the XML script and no remainders of its previous layout. Otherwise you could easily end up with an invalid component structures.

In particular, this means that if you update a page layout in ID generating mode, all existing components of the page are deleted, and a new layout is created instead, even if the new layout is identical to the old one. This happens because components can only be looked up by their object IDs, and lookup by object ID is not possible in ID generating mode. Therefore all the components specified in the XML script are created, because they cannot be found for updating, and all existing components are deleted because they were not updated.

In the rare case that you actually want to update specific components in the page but do not want to delete the existing page layout, you can turn off this special processing by specifying the attribute `preserve-old-layout="true"` for the content node.

Marking pages as hidden under the content root:

By default, pages that you create under the content root display in the main menu. If you do not want a page that you create to appear in the main menu, you can hide the page.

You do this by setting the `hidden` flag for the page parameter for the `content-node` tag in XML. Use the following XML snippet:

Note: You can still view and work with pages that are marked as hidden in Administration portlets. You can also create a direct URL to the hidden page so that the page can be accessed from other areas of the site, such as the page menu.

```
<content-node action="update" ...>
  ....
<parameter name="com.ibm.portal.Hidden" type="string" update="set"><![CDATA[true]]></parameter>
 ...
</content-node>
```

Importing WAR files:

To create new portlet applications, you need additional resources, the WAR files.

You cannot include those WAR files in the XML input. Instead, you can add references to external URL locations to the XML input. See the following example:

```
<web-app uid="MySpecialPortlet" action="create">
        <url>file://localhost/C:/myportlets/Special.war</url>
</web-app>
```

The WAR files are not used in the running portal. However, when you process the XML request, the WAR files referenced in the XML script must be accessible to the portal. When you update a package and specify a `<url>` subelement, the WAR file is re-deployed, just as if you had selected the update of a portlet application in the browser. If you intend to deploy the same configuration into several new portals, you can set the URL to `http://deploymentserver/path/filename.war` . This way there is no need to copy all WAR files to each server machine. The `deploymentserver` machine needs to be set up properly so that the WAR files can be accessed by http.

An XML export request does not create any archive files that might be required. Instead, it only creates pseudo-references in the form of file URLs that rely on the assumption that the file resides in the `/installableApps/` subdirectory of the portal installation. If these assumptions are not met, an exported portal configuration cannot be successfully re-created without editing the generated URLs manually. A back up of a portal configuration requires that the WAR files required for redeployment are saved in addition to the XML export.

Importing static page content from archive or compressed files:

You can import the content of static pages from an external archive or compressed file by using the XML configuration interface.

The following example imports static page content from the file `index1.zip` :

```
<content-node action="update" active="true" allportletsallowed="true"
              content-parentref="homepage" create-type="explicit"
              domain="rel" ordinal="1500" themeref="ibm.theme"
              type="staticpage" uniquename="samplestaticpage1">
          ...
          <pagecontents markup="html" display-option="inline">
```

```
            <url>file:///$server_root$/doc/xml-samples/index1.zip</url>
        </pagecontents>
        ?
</content-node>
```

The referenced archive or compressed files must be accessible to the portal when the XML request is processed. For details about the administration of static pages with the XML configuration interface refer to the topics about *Using the XML configuration interface to work with static pages*.

Related reference:

"Exporting and importing static pages" on page 1872
You can work with static portal pages by using the portal XML configuration interface. Learn about the tasks that you can perform and the XML elements for working with static pages.

Viewing updates and changes made with the XML configuration interface:

For your users to be able to view updates that you made by using the XML configuration interface, they might have to log out and log back in again, or you might have to restart the portal. This depends on the type of update that you made.

Most portal data is cached on a per-user basis, therefore many modifications become visible to users only after a new logout and login. For example, a page that is created on behalf of users does not immediately become visible to those users if they are currently logged in. Other modifications only become visible after some timeout when internal caches are refreshed with current data. For some settings the portal needs to be restarted to activate the updates. Therefore, if an update you made does not become visible, restart the portal.

In general, the effect of an XML update is the same as if the update was made using administration portlets using a new browser and login session.

Transactionality:

When you use XML scripts to create, update or delete resources, the changes in the portal database are grouped into transactions. All changes that are part of one transaction are either executed completely or not at all. The XML configuration has two different levels of grouping database updates into transactions.

The grouping is defined by the `transaction-level` attribute of the main request element, which can have the following values:

resource
: Every top-level resource in the XML script is processed in one separate transaction. For example, this can be a content node with its complete layout. If an error occurs, all resources up to the one where the error was encountered have been fully processed; the resource where the error was encountered is not created, or, if it already existed, it remains unchanged.

request
: The entire XML script is executed in one transaction. If an error occurs, all database changes caused by the script are made undone, and the original state is restored. Note that using this level of transactionality might cause large and long-running database transactions if used in large XML scripts. As a result, you might encounter database errors caused by exceeding

database limits on transaction duration or transaction log size, depending on the configuration of your database.

none No explicit transactions will be opened for the processing. This is the default value.

Transactionality applies only to changes in the portal database. The following aspects of resources are not stored in the portal database and therefore not included in transactions:

- Enterprise applications for portlets that are deployed into WebSphere Application Server
- User and group information
- Role assignments in an external access control system.

An example of what this means is as follows: When you deploy a WAR file in an XML script that uses `transaction-level="request"` and an error occurs later in the execution of the XML script, the transaction is canceled, so the entries for the portlet are removed from the portal database. However, the corresponding enterprise application has already been deployed into WebSphere Application Server and is not removed. This will not further affect the operation of the portal; you can simply deploy the portlet again later. You will just have an unused enterprise application in WebSphere Application Server. Remove it manually.

Error recovery:

If errors occur during the processing of an XML script, the XML result file contains an error message. After fixing the cause of the error, you have two options to continue.

Perform one of the following two options:

1. Run the entire XML script once again.
2. Remove all resources before the point where the error occurred from the XML script and run only the rest of the XML script.

If the error occurs during the validation of the XML script, and no resources have actually been processed so far, you can simply run the entire script again. You can verify this by reviewing the progress reporting comments in the XML response.

If the error occurs after some resources have actually been processed, the best option depends on several circumstances:

- If you used the `request` transaction level, you must run the entire script once more, because all changes have been undone.
- If you used the `resource` transaction level, the preferable option is to run only the rest of the XML script, and not to repeat changes that have already been made; otherwise you might duplicate resources that were already created. You can only use this option if the rest of the XML script does not contain references to the resources that you are removing, that is, if you do not refer to symbolic object IDs of these resources. See Symbolic object IDs and ID generating mode for more information. You can always remove resources that have already been processed from the XML script, if your script uses only hard-coded object IDs for references, because in this case all references can be resolved by looking up the object IDs in the portal database.

To make error recovery easier, use scripts that can be run again partially or completely without the possibility of duplicating resources. To do that, specify an

object ID or another identifying attribute on every resource in the script and use only `update` actions. This way resources are simply overwritten with the same configuration if they have already been created. For more information about how to specify attributes, see the topic about *Mandatory and optional attributes*.

Related reference:

"Symbolic object IDs and ID generating mode" on page 1101
In some cases, you might need to use object ID attributes to express references between resources in your XML script, but you do not want these to be read from or written to the portal database. In this case, the object ID would be only a symbolic reference inside the XML script.

"Mandatory and optional attributes" on page 1105
Depending on the action that you perform by using the XML configuration interface, some attributes can be mandatory or optional.

Hints and tips for using the portal XML configuration interface:

In an example configuration, you might have two WebSphere Portal Express environments that are both configured for security with an LDAP server. However, the two LDAP servers have different directory structures.

For example, this can be different LDAP suffixes for the users or groups. To transfer such a portal configuration from one portal to the other, you can use the following XML script:

```
<?xml version="1.0" encoding="UTF-8"?>
<request
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd"
    type="export"
    export-users="false">
    <portal action="export"/>
</request>
```

When you use this XML script to transfer the configuration data between these two environments, be aware of the following:

1. By setting the tag `export-users` to `false` you only prevent the export of the LDAP hierarchy. Ownership and access control rules are still exported.
2. During the transfer all user-related information is lost, as the target portal does not know the user information from the source portal. For example, this affects access rights or ownership of private pages. You might see a warning about missing user or group information, but it should not prevent a successful import.
3. If you use this script for your export, you might find that your XML import fails with an exception and references one of the following two items:
   - Credential slots and segments. To avoid exceptions centering around the credential slots and segments, remove the references to these elements from your XML prior to running your XML import.
   - Private pages. The destination server cannot use information about private pages. To address exceptions centering around the private pages, use the following script for the XML export:

```
<?xml version="1.0" encoding="UTF-8"?>
<request type="update"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd">
```

```
    <portal action="locate">
    <content-node action="export" name="*" create-type="explicit"/>
</portal>
</request>
```

This procedure exports all pages which are not private, along with the information that is required to put the portlets on the pages. However, you must either deploy the portlet applications on the target portal prior to running the XML import, or you must modify the XML script to deploy the portlets in the same run.

Sample XML configuration files:

Sample files are provided for your reference to help illustrate how to use XML configuration for different portal configuration purposes. Before you use them, read the other topics about the XML configuration interface carefully. Many of the samples need to be modified with valid page or user name before they can be used.

Sample file location

The sample XML configuration files provided with the portal are located in the following directory: *PortalServer_root*/doc/xml-samples.

Sample file list

Some of the XML samples are listed in the following. This list is not complete. All samples are located under the directory given in the previous section.

- Export.xml
- ExportRelease.xml
- ExportPage.xml
- ExportPageResult.xml
- CreatePage.xml

  Note: If you do not want to set the page title for all portal supported locales, you need to set it at least for the default system locale of your portal.
- CreateCsaPage.xml
- CreateLegacyPage.xml
- CreatePageFromZip.xml
- CreatePageFromTemplate.xml
- DeployPortlet.xml
- ClonePortlet.xml
- ModifyPortlet.xml
- ExportPortletAndPage.xml
- ExportSubTree.xml
- UpdateAccesscontrol.xml
- UpdateVault.xml
- CopyPage.xml
- CreateURL.xml
- CreateUser.xml
- CreateLanguage.xml:

This XML sample adds a new language for the portal or removes an existing language from the portal.

Note: To define a new language for your portal, set the title for the new language in all locales that are supported for your portal in the XML file. If you do not want to set the title for all portal supported locales, you need set the title at least for the default system locale of your portal.

- DeployTheme.xml
- ExportAllPortlets.xml
- Transaction.xml
- MovePage.xml

  Note: The actual move of the page is done by the last two lines.
- ActivatePortlet.xml

  Use this sample to change the states of portlets, portlet applications, or Web applications between active and inactive by setting the attribute `active` of the appropriate tag to `true` (for active) or `false` (for inactive). The sample activates the respective resources.
- Task.xml

  This sample creates a scheduler task for cleaning up portal resources, com.ibm.portal.datastore.task.ResourceCleanup.
- RegisterPreDeployedEAR.xml

  Use this sample to install a predeployed portlet. You might have to change this sample for your requirements.

  Notes: For the *`deploy_target_directory`* in the `url` tag specify the directory to which you deployed the EAR file on the WebSphere Application Server. The default target directory is `AppServer`, but when deploying portlets for your portal it is a good option to specify `PortalServer` as the target directory.

  An Enterprise Application Archive (EAR) can hold more than one Web Application Archive (WAR) files. To configure the pre-deployed portlet resources into portal you need to reference each Web Application resource separately in the XML configuration script. Provide a dedicated `<web-app>` statement with the corresponding data in the XML script for every WAR file that contains a portlet application in that EAR file.
- CleanupUsers.xml

  You can use this sample to identify users and groups in your portal database who have been removed from the user registry, but not from the portal database. In order for the file to work properly, you must set both attributes `cleanup-users` and `export-users` to `true` . Running this sample file results in a file that lists those users and groups and marks them for deletion. The result file also lists all users who have been muted, for example after too many wrong password attempts. Before you re-import the file, check the file and remove all users and groups that you want to keep in the portal database. During XML import all users and groups that remain listed in the file will be removed from the portal database.

  Note: After deleting these entries via the modified XML script, all customizations are lost for the deleted users and groups.
- ExportIncludingOrphanedData.xml

You can use this sample file to perform an export that includes all orphaned data. You do this to prepare for deleting the orphaned data. Note that this sample uses the request type `export-orphaned-data`.

Portal Scripting Interface

You can use the Portal Scripting Interface to configure your portal by running scripts from a command line.

"About the Portal Scripting Interface"
IBM WebSphere Portal Express provides a scripting interface that enhances the possibilities for automated solution deployment and administration of the portal. The Portal Scripting Interface allows you to create scripts that portal administrators can use to perform administrative tasks from a command line.

"Getting started with the Portal Scripting Interface" on page 1115
With the Portal Scripting Interface, you can administer your portal installation by executing commands. You can do that either interactively by typing the commands into a console window with interactive scripting and pressing the Enter key, or you can write the commands into a file and run that file. Here are some hints and examples for using the Portal Scripting Interface.

"Working with the Portal Scripting Interface" on page 1120
Learn more about the different modes that you can use with the Portal Scripting Interface.

"Command reference for the Portal Scripting Interface" on page 1126
The IBM WebSphere Portal Express Scripting Interface component provides a scripting interface for the administration functions.

Related reference:

"Portal Scripting Interface and content associations" on page 2078
With the Portal Scripting Interface, you can create scripts to automate the management of content associations. Using the ContentMapping bean with the Portal Scripting Interface, you can add, modify, and remove content associations.

About the Portal Scripting Interface

IBM WebSphere Portal Express provides a scripting interface that enhances the possibilities for automated solution deployment and administration of the portal. The Portal Scripting Interface allows you to create scripts that portal administrators can use to perform administrative tasks from a command line.

The Portal Scripting Interface allows portal solution development teams to write scripts that are later executed by operation teams for solution deployment. These scripts have the same functionality as the portal administration user interface. This allows you to implement automated configuration management for various kinds of configuration changes.

Scripts can help you split the administrative workload between solution development and solution operation teams. Even if the solution development teams cannot work interactively with the productions system, they can apply the same administrative actions through the use of scripts. At the same time, the use of scripts enhances availability and quality of the solution as developers can write and test the scripts without interfering with the production system. Scripts provide repeatability and avoid user errors that are likely in manual administration procedures.

In addition to these benefits, portal scripts provide the following advantages:

- The Portal Scripting Interface provides delegated administration in the same manner as the portal administrative user interface. This allows distributed portal administration as follows:
  - Different development teams can work on related portal updates without interfering with each other's work.
  - Different administrative teams can perform the tasks of developing a solution, and deploying and operating that solution for production. These teams can be within the same organization (for example in the same enterprise), or in independent companies, such as independent solution centers for the operation. In a typical scenario, the solution development team may have in-depth knowledge about the software solution internals, the operation is focused on the external characteristics of the solution. The operation solution team can receive the solution from the development team as a black box that can be operated without much knowledge of the solution internals. This allows enterprises to use automated solution deployment and distributed staging processes.

  In this regard the portal scripting interface goes beyond the XML configuration interface that has been provided by WebSphere Portal Express for several releases now. The XML configuration interface does not allow for easy separation of distributed portal administration.
- You can use the portal scripting interface for staging and integration of new releases A new release can be developed and tested on a test system and can then be integrated into the production system while the system is running.
- You can use the scripting interface for all of the following:
  - Release staging and integration
  - Updates of portal content, portal configuration, releases. This includes, for example, adding, replacing, or removing components.
- Interactive portal administrative tasks do not require a Web browser.
- Operators can enhance productivity and quality by scripting repeated administrative tasks for automated administration and maintenance.
- You can apply portal configuration updates in real time.
- The scripting interface is an extension of the WebSphere Application Server scripting interface. This means that if you are already familiar with the interface, you should easily learn how to use Portal Scripting Interface.
- You use the scripting interface through the use of a user ID, similar to the portal UI.

- They are easy to use:
  - You can use any text editor to develop scripts.
  - It provides its own online help as part of the scripting environment. You do not need to leave the script window for command syntax descriptions.

Change from JACL to Jython syntax

In previous versions of WebSphere Portal Express the Portal Scripting Interface was based on JACL syntax. Starting with WebSphere Portal Express Version 6.1 the Portal Scripting Interface is based on Jython syntax. The JACL Version 7.0 syntax is still available and supported.

The Jython syntax can be derived from the JACL syntax in a generic way as follows:

JACL: `$Object method arg1 arg2` Example: `$Portal login myuserid mypassword`

Jython: `Object.method(arg1, arg2)` Example: `Portal.login('myuserid', 'mypassword')`

Getting started with the Portal Scripting Interface

With the Portal Scripting Interface, you can administer your portal installation by executing commands. You can do that either interactively by typing the commands into a console window with interactive scripting and pressing the Enter key, or you can write the commands into a file and run that file. Here are some hints and examples for using the Portal Scripting Interface.

About this task

Note: To simplify things, the following examples are based on a Linux portal installation in the directory `/opt/WebSphere`. If you use a different system or a different installation path, adopt the examples so.

"Opening a console window for interactive scripting" on page 1116
To start the Portal Scripting Interface from a console window, use the procedure described here.

"Logging in to the portal" on page 1116
Before you can work with portal scripting commands, you need to log in to the portal server instance where you want to work with the Portal Scripting Interface.

"Working with portal pages and other resources " on page 1116
The following exercise shows you some steps how to work with portal resources, such as pages and portlets, search for resources and information about them, and add a portlet to a page.

"Getting help for a command" on page 1118
The Portal Scripting Interface provides more commands and variants of commands than shown in the previous topics. To learn more about these commands and their syntax and function, and beans and parameters, refer to the integrated help of the Portal Scripting Interface.

"Logging out of the portal" on page 1120
After you complete working with the Portal Scripting Interface, you log out and exit the interactive scripting console.

Opening a console window for interactive scripting:

To start the Portal Scripting Interface from a console window, use the procedure described here.

Procedure

1. Change into the directory where your Portal Scripting Interface is installed: `cd /opt/WebSphere/PortalServer/bin`
2. Call the Portal Scripting Interface startup command file: `wpscript.sh|bat`.

   Note: You must indicate that you want to enter the commands in Jython as follows: `-lang jython`. If you prefer to use the JACL Syntax, you can type `-lang jacl`.

   a. Type the command as follows: `./wpscript.sh -lang jython`. This command starts the interactive scripting console. The Portal Scripting Interface prompts you for a user ID and password. The Portal Scripting Interface is an extension to the WebSphere Application Server `wsadmin` tool.

   b. Use a valid WebSphere Application Server administrator user ID. The Portal Scripting Interface returns the following response:

   ```
   WASX7209I: Connected to process "WebSphere_Portal" on node wpsbvt using SOAP connector;
              The type of process is: UnManagedProcess
   WASX7031I: For help, enter: "print Help.help()"
   ```

3. You can now enter Portal Scripting commands as required. You can also use all the available WebSphere Application Server `wsadmin` commands.

Logging in to the portal:

Before you can work with portal scripting commands, you need to log in to the portal server instance where you want to work with the Portal Scripting Interface.

About this task

At the command prompt `wsadmin>` use the following command: `Portal.login("your_userid", "your_password")`:

```
wsadmin> Portal.login(your_userid, your_password)
```

If you logged in successfully, the Portal Scripting Interface returns a message that starts with `logged in as . . .`. The console now shows the following lines:

```
wsadmin> Portal.login(your_userid, your_password)wsadmin>
logged in as "uid=your_userid,o=defaultWIMFileBasedRealm"
```

You can now administer the portal instance in a similar way as by using the Portal Administration user interface. The following examples show how you can work with pages.

Working with portal pages and other resources :

The following exercise shows you some steps how to work with portal resources, such as pages and portlets, search for resources and information about them, and add a portlet to a page.

About this task

Searching for a portal page:

Search for the **Getting Started** page. Enter the following command and specify the page by its unique name:

```
wsadmin>Content.find("page", "un", "ibm.portal.Home.Getting Started")
```

If a page with the specified unique name exists, the Portal Scripting Interface returns the object ID of the page as follows:

```
wsadmin>Content.find("page", "un", "ibm.portal.Home.Getting Started")
   'Z6_CGAH47L00OJCC0I6U1NESJ2GK0'
```

If you are not sure whether the resource is a page or a label you can specify the type `any` instead of `page`. In this case, you get the following response:

```
wsadmin>Content.find("any", "un", "ibm.portal.Home.Getting Started")
   'Z6_CGAH47L00OJCC0I6U1NESJ2GK0'
```

To find out more about the different ways of searching for portal resources, use the command `help()` that the Portal Scripting Interface provides for each command. For an example, see the section about Getting help for a command.

Finding out information about a portal page:

To display some standard information about a portal resource, use the `details()` command. You need to specify for which resource you want more detailed information. The following example can be the portal page Getting Started:

```
wsadmin>Content.find("page", "un", "ibm.portal.Home.Getting Started", "select")
'Z6_CGAH47L00OJCC0I6U1NESJ2GK0'
wsadmin>Content.details()
```

This returns the following response:

```
wsadmin>Content.find("page", "un", "ibm.portal.Home.Getting Started", "select")
'Z6_CGAH47L00OJCC0I6U1NESJ2GK0'
wsadmin>Content.details()
name: ibm.portal.Home.Getting_Started
id  :Z6_CGAH47L00OJCC0I6U1NESJ2GK0
type: staticpage
      no children
```

To find information about a portal resource, you need to specify the resource. If you do not specify the resource, for example, by entering only `wsadmin>Content.details()`, you get a response such as the following one:

```
WASX7015E: Exception running command: "Content.details()"; exception information:
   com.ibm.bsf.BSFException: exception from Jython:
Traceback (innermost last):
   File "<input>", line 1, in ?
EJPXD0020W: No object has been selected.
```

Here are some more examples for requesting information about a portal page:

```
wsadmin>Content.get("type")
   'staticpage'
wsadmin>Content.get("uniquename")
   'ibm.portal.Home.Getting Started'
wsadmin>Content.get("allportlets")
   'true'
```

```
wsadmin>Content.nlsget("title", "en")
   'Getting Started'
wsadmin>Content.parmget("com.ibm.portal.bookmarkable")
   'Yes'
```

The following example shows the hierarchy of a page:

```
wsadmin>Content.path()'Z6_00000000000000000000000A0 Z6_CGAH47L00GS790I6U1M1F020A3 Z6_CGAH47L00OJCC0I6U1NESJ2GK0'
```

This command returns a 'list' of object IDs of the nodes from the root node to your currently selected node. As you can see, it is not a 'true' list in the Jython sense, it is rather a string with entries separated by blanks. To get a list that is better readable, the command `split()` as shown in the following example:

```
wsadmin>for id in Content.path().split():
wsadmin>  Content.get(id, "un")
wsadmin>
'wps.content.root'
'ibm.portal.Home'
'ibm.portal.Home.Getting Started'
```

With this simple loop you can print out the whole hierarchy of nodes up to our currently selected 'Getting Started' page.

Creating a page:

To create a page as a child page to the currently selected page, use the following command:

```
wsadmin>Content.create("page", "Title of my first page", "html", "select")'
Z6_CGAH47L0082M00I6T9E0NL3001'
```

This command creates a page for HTML markup and returns its portal object ID. You can now start adding attributes or metadata to the page.

Adding a portlet to a page:

To add a portlet to the page that you created previously, use a the following command, for example:

```
wsadmin> myportlet = Portlet.find("portlet", "un", "wps.p.Information")
wsadmin> Layout.create("container", "horizontal", "select")'
Z7_CGAH47L008C970I6NA7U4300G2'
wsadmin> Layout.create("portlet", myportlet)'
Z7_CGAH47L008C970I6NA7U4300G1'
```

This adds the Information portlet to the page and places it in a horizontal container.

Getting help for a command:

The Portal Scripting Interface provides more commands and variants of commands than shown in the previous topics. To learn more about these commands and their syntax and function, and beans and parameters, refer to the integrated help of the Portal Scripting Interface.

About this task

Use the command `help()` and specify the command for which you want to get help. Start by entering the following command:

```
wsadmin>print Content.help("find")
```

This returns the following help output about how to use the help command:

```
> find <what> [<by> <value>] [select]
Finds a particular content node. The search scope is the subtree starting
at the current selection, or the whole tree if nothing is selected. Unlike
the 'search' command, this operation expects a single matching node as the
result of the search. An error is generated if there are multiple matches,
or if there is no match at all. If the keyword "select" is specified as the
last argument, the found node will be selected.
All other arguments are the same as for the 'search' command. See help on
'search-types' for the first argument. See help on 'search-criteria' for
the optional second and third arguments.
Example:> find page uniquename "My page"
Returns the id of a portal page node with the given unique name. If the page
with the given unique name does not exist, or if the node with the specified
unique name is not a page node, the command throws an exception.
```

To find out more detail about the search types, enter the following command:

```
wsadmin>print Content.help("search-types")
```

This returns the following help information about the search criteria:

```
> search <what>
> find <what>
The following is a list of supported keywords for content node types.
These keywords can be used as the first argument in 'search' and 'find'
operations.
- any, all
Any type of content node.
- label, labels
Only labels.
- page, pages, composition, compositions, comp
Only compositions, also called pages.
- url, urls, anyurl, allurls
Any type of URL node.
- iurl, iurls, internalurl, internalurls
Only internal URL nodes.
- xurl, xurls, externalurl, externalurls, eurl, eurls
Only external URL nodes.
```

To find out about the search criteria, use the following command:

```
wsadmin>print Content.help("search-criteria")
```

To find out which command the `Content` bean supports, enter the following command:

```
wsadmin>print Content.help()
```

This returns the following help output:

```
This bean provides access to the content hierarchy of the portal. The
content hierarchy consists of labels, pages, and links. Pages are also
called "compositions". Links can be internal or external URLs. Content
nodes can be accessed, created, and deleted with this bean. URLs of a
link can be modified with this bean.
The layout of a page is a component hierarchy of containers and controls.
That hierarchy must be accessed through the Layout bean rather than this
Content bean. When a page (composition) is selected in the Content bean,
the Layout bean can be used to access the component hierarchy of that page.
See the help for the Portal bean to learn about other available beans.
Invoke help with one of these methods as argument for further help:
help, resync, select, deselect, current, csn, root, parent, children, path,
index, details, get, set, nlsget, nlsset, nlsimport, urlget, urlset,
list, add, drop, empty, search, find, move, create, derive, delete,
pageget, pageset, parmget, parmset, transfer, deletecustomization
Other available help topics:
attribute-names, nls-files, list-names,
search-types, search-criteria, create-types
```

Logging out of the portal:

After you complete working with the Portal Scripting Interface, you log out and exit the interactive scripting console.

About this task

Enter the following commands:

```
wsadmin> Portal.logout()
wsadmin> exit
```

To find out more about the Portal Scripting Interface commands and usage refer to the other topics about the Portal Scripting Interface.

Working with the Portal Scripting Interface

Learn more about the different modes that you can use with the Portal Scripting Interface.

Prerequisite information

The Portal Scripting Interface provided by IBM WebSphere Portal Express is based on the wsadmin scripting tool that is provided by IBM WebSphere Application Server. Therefore, before you use the Portal Scripting Interface, familiarize yourself with how to use the WebSphere Application Server wsadmin tool.

Interactive mode

Use the interactive mode if you want to interact directly and dynamically with the portal to perform simple administrative tasks that should only be executed once. For example, the administrator wants to modify the permissions of a page for a certain principal, or the administrator wants to add a portlet to a page. Use the interactive mode if you do not intend to repeat the operation.

Before initiating a session in interactive mode, make sure that WebSphere Portal Express is running. The portal script client is located in the WebSphere Portal Express installation directory:

- Linux: *wp_profile_root*/PortalServer/bin
- IBM i: *wp_profile_root*/PortalServer/bin
- Windows: *wp_profile_root*\PortalServer\bin

Log in using the administrative user ID, and invoke the portal script client using the following commands:

- Linux: ./wpscript.sh
- IBM i: wpscript.sh
- Windows: wpscript.bat

The following procedures provide examples:

1. If WebSphere Application Server security is enabled, specify a user ID and password during login as shown in the following example:
   - Linux: ./wpscript.sh -port *port_number* -user *user_id* -password *password*
   - IBM i: wpscript.sh -port *port_number* -user *user_id* -password *password*
   - Windows: wpscript.bat -port *port_number* -user *user_id* -password *password*

The most basic parameters are explained briefly in the following table.

Table 148. Description of the basic parameters used with the `wpscript.bat|sh` task

Parameter	Description
`-lang`	Specifies the language of the script file, command, or an interactive shell. Specify one of the following values for the `-lang` parameter: • jacl • jython This parameter is optional and has no default value. This option overrides language determinations that are based on script file names, profile script file names, or the **`com.ibm.ws.scripting.defaultLang`** property. **Important:** If you do not specify the script language in the command line or as a parameter, and the wsadmin tool cannot determine the script language, an error occurs. If you do not specify the script language as the value for `-lang`, the wsadmin tool determines the script language as follows: • If you specify the `-f` *`script_file_name`* argument, the wsadmin tool determines the language from the name of the target script file. • If you specify the `-profile` *`profile_script_name`* argument, the wsadmin tool determines the language from the name of the profile script.
`-conntype`	The type of connection that should be established between scripting. Valid connection types include: • SOAP • RMI • NONE The default value is SOAP. This parameter is optional. Use the `-conntype NONE` option to run in local mode. The result is that the scripting client is not connected to a running server. If the connection type NONE is selected, the scripting beans are inactive and cannot be used for administration, with the exception of the help command.
`-port`	The connection port number. This parameter is optional. The port number depends on values chosen during installation. You can verify the value that is set for the **`WasSoapPort`** property in the `wkplc.properties` file found in the appropriate directory given here: • Linux: *wp_profile_root*`/ConfigEngine` • IBM i: *wp_profile_root*`/ConfigEngine` • Windows: *wp_profile_root*`\ConfigEngine` If you are running **`wpscript`** on a server that is part of a cell managed by a deployment manager, the *port_number* can vary depending on what ports are in use on the system when the deployment manager is created. To verify the value, check the setting for `SOAP_CONNECTOR_ADDRESS` in `serverindex.xml` located in the appropriate directory given here: • Linux: `dmgr_profile_root/config/cells/`*`cell_name`*`/nodes/`*`node_name`* • IBM i: `dmgr_profile_root/config/cells/`*`cell_name`*`/nodes/`*`node_name`* • Windows: `dmgr_profile_root\config\cells\`*`cell_name`*`\nodes\`*`node_name`*
`-user`	The user ID under which you establish the connection. This parameter can be mandatory, depending on your security configuration.
`-password`	The password for the user ID under which you establish the connection.

2. Log on to the portal using one of the following script commands:
   Jython: `Portal.login("`*`user_ID`*`", "`*`password`*`")`
   JACL: `$Portal login `*`user_ID password`*

3. Issue portal script commands as required.
4. After you have completed all tasks by the portal scripting interface, close and exit the script processor. All changes that you committed are applied to the portal configuration.

Script mode

Use the script mode to apply predefined changes to the configuration of a portal.

The wpscript tool executes a Jython or JACL script that contains the administrative operations. The scripting client inherits the script processor from wsadmin, so an administrator can exploit the Jython or JACL scripting language, in order to write re-usable, extendable administration scripts. This mode is typically preferred if reproducible administration tasks are created: For example, the administrator can write a script that produces a complete page subtree, and adds individual page layouts and portlets on each page.

Users who have access permission to perform XML configuration interface requests can change configurations of all resources. The Portal Scripting Interface is mostly consistent with the administration model that is exposed by the Portal user interface.

Before using script mode, make sure that WebSphere Portal Express is running and a portal script file is available. You must be logged in using the WebSphere administrative user ID. Use the following procedure:

1. Update the script file with the appropriate credentials, if required.
2. Use one of the following commands to launch the script processor tool:

   Jython: `wpscript.sh -port` *`port_number`* `-f` *`script_file_name.py`*

   JACL: `wpscript.sh -port` *`port_number`* `-f` *`script_file_name.jacl`*This initializes the interactive script environment of the portal JACL or Jython script processor.
3. Check the output from the script processor to ensure that no errors occurred during the execution of the script.

All changes committed by the script are immediately applied to the portal configuration.

The following script example creates a new page with the title **A page**. This page resides beneath the **Home** label. The page contains two portlets that are arranged horizontally.

Portal Jython script example

The following example is a Jython script file named `testme.py`:

```
# Scripting bean example: create a simple page (multi-column Layout)
#

# Procedure: create a multi-column page under the page that is currently
# selected, and place the given portlets into the layout.
#
# parameters:
#   name The name of the page
#   portlet_names A list of portlet names.
# returns:
#   oid The id of the page that has been created
def create_multi_col_page(name, portlet_names):
    thePage = Content.create("page", name, "html")
    Content.select(thePage)
```

```
    lyt0 = Layout.create("container", "horizontal", "select")
    for pn in portlet_names:
        pid = Portlet.find("portlet", "cn", pn)
        Layout.create("control", pid)

    return thePage

# main code starts here

# set User ID/ pwd for portal Login command
# Hint: User ID and passwords should normally not be placed inside a
# configuration script; better use property files or command line arguments
user = "user_ID"
pwd = "password"
Portal.login(user, pwd)

# determine and select the parent of the page to be created.
# In this example, This is the "Home" label.
Content.select(Content.find("all", "uniquename", "ibm.portal.Home")
# Invoke the page creation procedure. The label of the page is "My test page",
# portlets to be added are the reminder portlet and the welcome portlet.
newbie = create_multi_col_page("A Page", ["Reminder", "Welcome_to_WebSphere_Portal"])

print "ok, we are done."
```

Portal JACL script example

The following example is a JACL script file named `testme.jacl`:

```
# Scripting bean example: create a simple page (multi-column Layout)
#

# Procedure: create a multi-column page under the page that is currently
# selected, and place the given portlets into the layout.
#
# parameters:
#   name              The name of the page
#   portlet_names     A list of portlet names.
# returns:
#   oid               The id of the page that has been created
proc create_multi_col_page { name portlet_names } {
  global Content Layout Portlet
    set thePage [$Content create page $name html]
    $Content select $thePage
    set lyt0 [$Layout create container horizontal select]
    foreach pn $portlet_names {
      set pid [$Portlet find portlet cn $pn]
      $Layout create control $pid
    }
  return $thePage
}

# main code starts here

# set User ID/ pwd for portal Login command
# Hint: User ID and passwords should normally not be placed inside a
# configuration script; better use property files or command line arguments
set user user_ID
set pwd  password
$Portal login $user $pwd

# determine and select the parent of the page to be created.
# In this example, This is the "Home" label.
$Content select [$Content find all uniquename "ibm.portal.Home"]

# Invoke the page creation procedure. The label of the page is "My test page",
```

```
# portlets to be added are the reminder portlet, and the welcome portlet.
set newbie [create_multi_col_page "A Page" { "Reminder" "Welcome_to_WebSphere_Portal" } ]

puts "ok, we are done."
```

The scripts can receive parametric information externally, by using one of the following features:

- Profiles.
- Command line arguments.

Scripts can access command line arguments with the following variables:

argc Use this variable in JACL scripts to specify the number of command line arguments.

argv Use this variable in Jython and JACL scripts to specify the command line arguments.

Jython: In the preceding example script, `testme.py`, delete the following statements:

```
user = "portaladmin"
pwd = "adminpwd"
```

and replace them with the following statements:

```
if len(sys.argv) != 2:
   print "invocation syntax: wpscript testme.py <user> <pwd>"
   sys.exit(1)

user = argv[0]
pwd = argv[1]
```

JACL: In the preceding example script, `testme.jacl`, delete the following statements:

```
set user portaladmin
set pwd  adminpwd
```

and replace them with the following statements:

```
if { $argc != 2 }  {
    puts "invocation syntax: wpscript testme.jacl <user> <pwd>"
   exit
  }
  set user [lindex $argv 0]
  set pwd [lindex $argv 1]
```

The security-sensitive username and password are removed from the script. The modified code expects the user ID and password to be specified as command line arguments, for example:

Jython: `wpscript.sh -port` *port_number* `-f testme.py` *user_IDpassword*
JACL: `wpscript.sh -port` *port_number* `-f testme.jacl` *user_ID password*

Run scripting commands in a profile

A profile is a script that runs before the main script, or before entering interactive mode. Profiles can be used to set up environment specific behavior or user specific data. Profiles are specified when invoking wpscript, using the `-profile` parameter. For example, the `login` command can be placed in a profile.

Jython profile script example

The following example is a Jython profile script named mylogin.py:

```
# scripting profile
# contains log-in procedure on portal with disabled security
if len(sys.argv) != 2:
   print "invocation syntax: wpscript -f testme.jacl -profile
mylogin.py user_ID password"
   sys.exit(1)

user = argv[0]
pwd = argv[1]
Portal.login(user, pwd)
```

Remove or comment out the following statements in the testme.py script file:

```
if len(sys.argv) != 2:
   print "invocation syntax: wpscript testme.py user_ID password"
   sys.exit(1)

user = argv[0]
pwd = argv[1]
Portal.login(user, pwd)
```

To invoke mylogin.py, enter the following command: wpscript.sh -port *port_number* -profile mylogin.py -f testme.py *user_ID password*

JACL profile script example

The following example is a JACL profile script named mylogin.jacl:

```
# scripting profile
  # contains log-in procedure on portal with disabled security
  if { $argc != 2 }  {
    puts "invocation syntax: wpscript -f testme.jacl -profile mylogin.jacl user_ID password"
   exit
  }
  set user [lindex $argv 0]
  set pwd [lindex $argv 1]
  $Portal login $user $pwd
```

Remove or comment out the following statements in the testme.jacl script file:

```
  if { $argc != 2 }  {
    puts "invocation syntax: wpscript testme.jacl user_ID password"
    exit
  }
  set user [lindex $argv 0]
  set pwd [lindex $argv 1]
  $Portal login $user $pwd
```

To invoke mylogin.jacl, enter the following command: wpscript.sh -port *port_number* -profile mylogin.jacl -f testme.jacl *user_ID password*

The benefit of this change is that the environment-specific login procedure is removed from the administration script. For systems with enabled WebSphere Application Server security, the login procedure is:

Jython scripts

```
# scripting profile
# contains log-in procedure on portal with enabled security
Portal.login()
```

JACL scripts

```
# scripting profile
# contains log-in procedure on portal with enabled security
$Portal login
```

Command reference for the Portal Scripting Interface

The IBM WebSphere Portal Express Scripting Interface component provides a scripting interface for the administration functions.

With the Portal Scripting Interface, you can access the portal with any portal user ID and work within the access rights of that user ID.

Jython or Jacl are the two scripting languages that you can use for the scripting syntax and that are supported by the wsadmin tool of the WebSphere Application Server.

Jython

Jython is a general-purpose high-level programming language. It uses code indentation as block delimiters.

- The hash character (#) starts a comment that extends to the end of the line.
- By default, each line is interpreted as one statement.
- You can write multiple statements on one line by separating the statements with semicolons.
- Jython is case-sensitive.

Example:

```
# here is a comment
single_statement(with_arguments)
first_statement_in_line() ; second_statement()
outer statement [first inner] [second inner statement]
```

A variable can contain an object. In a statement, an object method starts with the object followed by a dot (.), the method name, and arguments that are passed to the method in parentheses ().

Example:

```
# variable 'Object' holds the object to invoke
# invoke the double argument version of the method
Object.method(arg1, arg2)

# and now the single argument version
Object.method(arg)

# there may be a version with three arguments
Object.method(arg1, arg2, arg3)

# invoke the single argument version
# the single argument is provided as a nested statement
# the nested statement invokes the double argument version
Object.method(Object.method(argInner1, argInner2)
```

Jacl

Jacl is an interpreted language without strong typing. It is a procedural language with some object-oriented concepts that are used by the scripting component.

- The number sign character (#) starts a comment that extends to the end of the line.
- By default, each line is interpreted as one statement.
- You can write multiple statements on one line by separating the statements with semicolons.
- You can nest statements by using brackets [] . The brackets are interpreted like back quotation marks in most AIX HP-UX Linux Solaris shells. The statement within the brackets is run, and its result is substituted in place of the bracketed statement before the surrounding statement is interpreted.
- Jacl is case-sensitive.

Example:

```
# here is a comment
single statement with arguments
first statement in line ; second statement
outer statement [first inner] [second inner statement]
```

The value of a Jacl variable is accessed by placing a $ in front of the variable name. A variable can contain an object. An object method is started by using the object as the first part of a statement, followed by the method name, and any arguments that are passed to the method. Since there is no strong typing, a method can be overloaded only by varying the number of arguments.

Example:

```
# variable 'Object' holds the object to invoke
# invoke the double argument version of the method
$Object method arg1 arg2

# and now the single argument version
$Object method arg

# there may be a version with three arguments
$Object method arg1 arg2 arg3

# invoke the single argument version
# the single argument is provided as a nested statement
# the nested statement invokes the double argument version
$Object method [$Object method argInner1 argInner2]
```

"Examples" on page 1173
The following are examples for deleting portlets and adding portlets.

"Troubleshooting" on page 1174
The following solutions help solve the troubleshooting issues.

"Property file format" on page 1174
You can provide locale-specific attributes for a set of locales in a Java property file. The generic format of Java property files is described in the Java API documentation for method load in class `java.util.Properties`. The description here covers the particular properties that are interpreted when locale-specific attributes are loaded from a portal script.

"Index paths" on page 1175
Index paths are used to refer to components in the component hierarchy. They are based on the index or position of a component in the surrounding container. An index path is a multi-dimensional index of a component, where the number of dimensions is equal to the depth of the component in the tree. Index paths are absolute or relative, depending on whether there is a leading slash. Absolute paths start with a leading slash and are resolved from the root component. Relative paths start with a number and are resolved from the selected component. Trailing slashes are irrelevant.

"Portal Scripting Interface and project support" on page 1260
With the Portal Scripting Interface, you can create Jacl or Jython scripts to automate the management of projects.

"Portal Scripting Interface and web content libraries" on page 1270
With the Portal Scripting Interface, you can create Jacl or Jython scripts to automate the management of web content libraries. Using the DocumentLibrary bean with the Portal Scripting Interface, you can create and delete libraries, retrieve a list of libraries, and retrieve library attributes.

Script beans:

The portal scripting component adds Script beans to the wsadmin tool. These Script beans are objects with methods that work on the portal data.

Portal objects are not represented by Jython or Jacl objects. Jython or Jacl object that represents a particular page or an individual portlet is not present. Rather, a fixed number of script beans provide access to specific areas of the portal data.

The available beans are

- Portal
- Content
- Layout
- Portlet
- Look
- Access
- PacList
- Application
- ArchivedApplication
- ApplicationCategory
- TemplateCategory
- Publish

Most method names are single English words, such as `get` or `search` or `parent`. All method names must be written in lowercase. Each bean has a help method. If started with a method name, it prints help for that method in the bean. If started without an argument, it prints general help for that bean, including a list of method names and other help topics. The general help message of the Portal bean includes an overview of the available beans and their responsibilities.

Jython example:

```
# get help - for the completely lost
Portal.help()

# get help on a particular bean
Portlet.help()
Access.help()

# get help on a method of a bean
Portal.help("login")
Layout.help("select")

# get help on an extended help topic of a bean
Content.help("search-criteria")
```

Jacl example:

```
# get help - for the completely lost
$Portal help

# get help on a particular bean
$Portlet help
$Access help

# get help on a method of a bean
$Portal help login
$Layout help select

# get help on an extended help topic of a bean
$Content help search-criteria
```

Portal objects:

Most portal objects are represented in the script by an object identifier string, which is based on the object ID in the portal. For example: `_6_00KJL57F9D02H456_A`.

These IDs are expected by methods as arguments and returned as results. Since an ID never contains white spaces or characters that would be misinterpreted by Jacl, it is a convenient handle for a portal object. If a method returns several objects, the IDs are separated by white spaces. The results are then used directly as a Jacl list.

Note: In Jython, you use the method split() on the result string to create a list.

Unlike with the GUI, where geometric arrangement and a locale-specific title provide information about an object, the IDs used in the script are unintelligible to the user. Most of the Script beans therefore provide a `details` method that prints information about an object. The `details` method of a bean works only for the objects that are handled by that bean. For example, the content bean cannot provide details about IDs returned by the layout bean.

Jython example:

```
# 'search' returns a list of objects
for child in Content.search("all").split():
  # details get printed, they are not returned as a result
  Content.details(child)
}
```

Jacl example:

```
# 'search' returns a list of objects
foreach child [$Content search all] {
  # details get printed, they are not returned as a result
  $Content details $child
}
```

The scripting component tries to generate a common name for the portal objects. The common name is based on a global unique name, an object name, or a title that is assigned to the object. The common name never contains white space, special characters, or characters outside of the US-ASCII range. Hence, even a terminal window that does not support national character sets can display the common name. If suitable input data is available, the generated common name might provide an indication of what an object represents.

Tree navigation:

The Content, Layout, and Portlet beans each represent a tree hierarchy. The basic navigation methods are the same for all three. A tree bean provides methods to access the root node to look up the parent and children of a node, and to maintain a cursor that points to a selected node in the tree.

The code examples use the Content bean, but you can do the same operations on the other tree beans as well. The command root returns the ID of the root node, as a fixed starting point for navigation.

Jython: `Content.root()`

Jacl: `$Content root`

You can select a node by its ID by using the `select` command. You can clear the current selection by using `deselect` or by using `select` without an argument. You can return the ID of the selected node by using the `current` command. For interactive use, `csn` is an alias for `current`.

Jython example:

```
Content.select ID
Content.deselect
Content.current
Content.csn

# example: select the root node
Content.select(Content.root())
```

Jacl example:

```
$Content select ID
$Content deselect
$Content current
$Content csn

# example: select the root node
$Content select [$Content root]
```

The `path` command returns a list of all IDs from the root to the currently selected node. In a similar way, the `children` command returns the children of the selected node. You can obtain the ID of the parent of the selected node by using `parent`.

Jython example:

```
Content.path
Content.parent
Content.children

# example: select a node and print its children
Content.select(node_ID)
for child in Content.children().split():
    print child
```

Jacl example:

```
$Content path
$Content parent
$Content children

# example: select a node and print its children
$Content select node_ID
foreach child [$Content children] { puts "$child" }
```

You can also use the commands `path`, `parent`, and `children` with an explicit ID instead of implicitly referring to the currently selected node.

Jython example:

```
Content.path(ID)
Content.parent(ID)
Content.children(ID)
```

Jacl example:

```
$Content path ID
$Content parent ID
$Content children ID
```

For simplicity, there are dedicated select commands for the root node and for the parent of the currently selected node. In the following example, the first argument is a dummy that is used to distinguish the method from the select with an ID argument. The dummy argument is not interpreted. The second argument is a keyword, which is not case-sensitive. Alternative, shorter keywords are documented in the bean help.

Jython example:

```
Content.select("the", "root")
Content.select("the", "parent")
```

Jacl example:

```
$Content select the root
$Content select the parent
```

Search:

All beans with tree navigation support identical commands for searching, but the available search criteria are different for each bean.

The generic examples use the Content bean. Searches in trees are scoped. The search scope is the subtree under the selected node, including the selected node itself. If nothing is selected, the search scope is the full tree that starts at the root.

There are two different commands for searching:`search` and `find.search` returns a list of matches, whereas `find` succeeds only if there is a single, unique match for the search. It fails if there is more than one match, or no match at all. `find` is used in cases where a script must end if the search result is not a unique match. If the keyword `select` is passed to `find`, the search result becomes the selected node.

Jython example:

```
Content.search(type)
Content.search(type), "by", (value)

Content.find(type)
Content.find(type), "by", (value)

Content.find(type, "select")
Content.find(type, "by", (value, "select")
```

Jacl example:

```
$Content search type
$Content search type by value

$Content find type
$Content find type by value

$Content find type select
$Content find type by value select
```

The first argument for all searches is the type of the nodes to look for. The type is specified by a keyword, which is not case-sensitive. The available types and corresponding keywords depend on the bean. In all beans, the keywords `all` and `any` are used to search regardless of the type. There is a dedicated help topic for the search types.

Jython example:

```
# example: return all nodes in the search scope
Content.search all

# example: get help on the available type keywords
Content.help search-types
```

Jacl example:

```
# example: return all nodes in the search scope
$Content search all

# example: get help on the available type keywords
$Content help search-types
```

You can combine the type selection with an extra search criteria, which is specified by a keyword (`by`) and a value to match against (*value*). The available search criteria and corresponding keywords depend on the bean. There is a dedicated help topic for the search criteria.

Jython example:

```
# example: get help on the available by keywords
Content.help("search-criteria")
```

Jacl example:

```
# example: get help on the available by keywords
$Content help search-criteria
```

The following are common search criteria. Alternative, shorter keywords are described in the help text on search criteria of the respective bean.

Table 149. A description of the common search criteria

Value	Description
id	The value is an ID. The search is for the object with that ID.
uniquename	The value is a string. The search is for the object with the string as its unique name.
commonnamehas	The value is a string. The search is for objects with the string as a substring in their common name. Comparison is not case-sensitive.
commonnameis	The value is a string. The search is for objects with the string as their common name. Comparison is case-sensitive.

Jython example:

```
# example: find and select by unique name
Content.find("any", "uniquename", "ibm.portal.Portlets", "select")
```

Jacl example:

```
# example: find and select by unique name
$Content find any uniquename "ibm.portal.Portlets" select
```

Attributes:

All beans use similar commands to query and modify attributes. Attributes are identified by a name, such as uniquename, title, or markup.

There are different commands for the different types of attributes. Similar to the `details` command in Portal objects, the commands must start on the bean responsible for the object type. For example, attributes of content nodes are accessed only through the Content bean, not through the Layout or any other bean.

The set of attributes that is supported for an object depends on the type of the object. Many attributes are read-only. Attribute values are always represented as strings in the scripting language. They are mapped from and to portal data types by the respective script bean. Exceptions are triggered if the mapping fails.

"Plain attributes" on page 1135
Plain attributes have a single value that is queried by using the `get` command. The object for which to query the attribute is specified by an ID, and the attribute is specified by name.

"List valued attributes" on page 1136
List valued attributes can have multiple values. They are queried by using the `list` command, which returns all values, which are separated by white space.

"Locale-specific attributes" on page 1137
Locale-specific attributes have different values for different languages and countries. They can be queried by using the `nlsget` command, where nls stands for National Language Support.

Plain attributes:

Plain attributes have a single value that is queried by using the `get` command. The object for which to query the attribute is specified by an ID, and the attribute is specified by name.

If the attribute is not read-only, the value is set by using the `set` command, which expects the new value as the last argument. If the bean supports a current selection, the ID is omitted for both commands to refer to the selected object.

Jython example:

```
Content.get(ID, attribute)
Content.set(ID attribute value)

# only for beans with a current selection
Content.get(attribute)
Content.set(attribute value)

# example: get unique name of a content node
Content.get(ID, "uniquename")

# example: get type of the selected content node
Content.get("type")

# example: set theme of a content node
themeid = Look.find("theme", "commonnameis", "Science")
Content.set(ID, "theme", themeid)
```

Jacl example:

```
$Content get ID attribute
$Content set ID attribute value

# only for beans with a current selection
$Content get attribute
$Content set attribute value

# example: get unique name of a content node
$Content get ID uniquename

# example: get type of the selected content node
$Content get type

# example: set theme of a content node
set themeid [$Look find theme commonnameis "Science"]
$Content set ID theme $themeid
```

The following are standard attribute names available for all objects. Names for more attributes of individual portal object types are documented with the respective bean. Alternative or shorter names are documented in the bean help.

Table 150. A description of the standard attributes names available for all objects

Value	Description
id	The identifier of the object.
type	The type of the object.
uniquename	The unique name of the object if it is assigned.
commonname	The common name of the object, if it is generated.

List valued attributes:

List valued attributes can have multiple values. They are queried by using the `list` command, which returns all values, which are separated by white space.

The object is specified by an ID and the attribute of the object, which is queried, is specified by name. If the bean supports a current selection, the ID is omitted to refer to the selected object.

You can modify list valued attributes by adding or removing a particular value, or by removing all values from the list. The respective commands are `add`, `drop`, and `empty`. With all commands, the object is specified by ID and the attribute by name. The `add` and `drop` commands also require the value to be added or removed.

These commands are appropriate if the values do not contain white space and the order of the elements is not important. Currently, all list valued attributes satisfy these restrictions.

You cannot modify all list valued attributes by all of these commands. For example, some lists might not be empty, in which case the `empty` command is not available. However, if an operation is supported for an attribute, the operation uses the command as described here. List valued attributes might also change as a side effect of other operations. For example, if a title is set for a previously undefined locale, the new locale shows up in the list of locales. For more information, see *Local specific attributes* for details on titles and locales.

Jython example:

```
Content.list(ID, attribute)
Content.add(ID, list, value)
Content.drop(ID, list, value)
Content.empty(ID, list)

# only for beans with a current selection
Content.list(attribute)
Content.add(list, value)
Content.drop(list, value)
Content.empty(list)

# example: add a new markup for the selected node
Content.add("markup", "wml")

# example: drop the american locale for the given node
Content.drop(node_ID, "locale", "en_US")

# example: drop all locales for the given node
Content.empty(node_ID, "locale")
```

Jacl example:

```
$Content list ID attribute
$Content add ID list value
$Content drop ID list value
$Content empty ID list

# only for beans with a current selection
$Content list attribute
$Content add list value
$Content drop list value
$Content empty list

# example: add a new markup for the selected node
$Content add markup wml
```

```
# example: drop the american locale for the given node
$Content drop node_ID locale en_US

# example: drop all locales for the given node
$Content empty node_ID locale
```

Related concepts:

"Locale-specific attributes"
Locale-specific attributes have different values for different languages and countries. They can be queried by using the `nlsget` command, where nls stands for National Language Support.

Locale-specific attributes:

Locale-specific attributes have different values for different languages and countries. They can be queried by using the `nlsget` command, where nls stands for National Language Support.

The object is specified by an ID and the object's attribute, which is queried is specified by name. If the bean supports a current selection, the ID is omitted to refer to the selected object. The following are the usual locale-specific attributes.

- `title`
- `description`
- `shorttitle`
- `keywords`

For the Content bean, only the locale-specific attributes `title` and `description` exist. For the Portlet bean, all four of the attributes exist.

The language and country are given as a locale, which consists of a language identifier, an optional country identifier, and an optional variant. Language and country are specified by standard two letter abbreviations, the language in lowercase and the country in uppercase letters. The components are separated by underscore characters. Here are some example locales:

Table 151. Example locales and their description

Locale	Description
en	General English
en_US	American English
de_CH	Swiss German
pt_BR	Brazilian Portuguese

The list valued attributes *locales* holds all locales for which a locale-specific attribute might be defined. However, all locale-specific attributes are optional for all locales. No fallback algorithm that would, for example, return the general Portuguese value if the Brazilian Portuguese value is not set is present. Such fallback algorithms are used when pages are assembled by the portal, but not for the administrative access that is provided by the portal scripting component.

Locale-specific attributes that are not read-only are set by using the `nlsset` command. Specify the new value of the attribute as the last argument in the arguments for the `nlsget` command. By setting an attribute for a locale that was not used before, the new locale is added to the list valued attribute *locales*.

Jython example:

```
Content.nlsget(ID, attribute, locale)
Content.nlsset(ID, attribute, locale, value)

Content.nlsget(attribute, locale)
Content.nlsset(attribute, locale, value)

# example: get american title of a specific content node
Content.nlsget(node_ID, "title", "en_US")

# example: set german description of current selection
Content.nlsset("description", "de_DE", "Kurze Beschreibung")

# example: set general english title of a specific node
Content.nlsset(node_ID, "title", "en", "English Title")
```

Jacl example:

```
$Content nlsget ID attribute locale
$Content nlsset ID attribute locale value

$Content nlsget attribute locale
$Content nlsset attribute locale value

# example: get american title of a specific content node
$Content nlsget node_ID title en_US

# example: set german description of current selection
$Content nlsset description de_DE "Kurze Beschreibung"

# example: set general english title of a specific node
$Content nlsset node_ID title en "English Title"
```

As locale-specific attributes are often translated independently from script development, the `nlsimport` command is used to read a separate property file that defines attribute values for a set of locales. By specifying an appropriate prefix, you can load values from the same property files that are used by the XML configuration interface (XMLAccess).

Jython example:

```
Content.nlsimport(ID, file_name)
Content.nlsimport(ID, file_name, prefix)
```

Jacl example:

```
$Content nlsimport ID file_name
$Content nlsimport ID file_name prefix
```

To delete all locale-specific attributes before a set of values is imported, empty the list valued attribute *locales* as described in *List valued attributes*.

Organization:

For some beans, in particular the Content and Layout beans, the order of nodes is significant. In tree beans, the parent relationship of the nodes defines the hierarchy. Only nodes with the same parent node are in a particular order in trees.

Sequence

The `move` command is used to reorder nodes. The order of nodes is tracked as a non-negative integer position assigned to each node, with the first node at position

0. For tree beans, the positions compare only among the children of a common parent node. You can query the position as a read-only plain attribute.

The order of nodes is changed by the `move` command. It is used on a single node to assign an absolute position or to displace by a distance. The positions of the other affected nodes are updated automatically. In both cases, the new position of the node always remains within bounds. The position or displacement argument is adjusted by the bean.

The `move` command expects the ID of the node to be moved, a keyword that indicates whether the change is absolute or relative, and the new position or distance. If the bean supports a current selection, the ID is omitted to move the selected object.

Jython example:

```
Layout.move(ID, "to", position)
Layout.move(ID, "by", distance)

# only for beans with a current selection
Layout.move("to", position)
Layout.move("by", distance)

# example: move selected node to the first position
Layout.move("to", 0)

# example: move given node one down in the list
# if it already is the last node, do nothing
Layout.move(node_ID, "by", 1)

# example: move selected node 4 up in the list
# if it is at position 0 to 4, it becomes the new head
Layout.move("by", -4)

# example: move given node to the last position
# negative absolute positions are interpreted as max int
Layout.move(node_ID, "to", -1)
```

Jacl example:

```
$Layout move ID to position
$Layout move ID by distance

# only for beans with a current selection
$Layout move to position
$Layout move by distance

# example: move selected node to the first position
$Layout move to 0

# example: move given node one down in the list
# if it already is the last node, do nothing
$Layout move node_ID by 1

# example: move selected node 4 up in the list
# if it is at position 0 to 4, it becomes the new head
$Layout move by -4

# example: move given node to the last position
# negative absolute positions are interpreted as max int
$Layout move node_ID to -1
```

Hierarchy

In some tree beans, you can change the parent of a node in the tree, moving the whole subtree under that node to another part of the tree.

This change of the parent of a node in the tree is achieved by the commands `transfer` or `adopt`. With `transfer`, the ID of the node and new parent are specified explicitly, whereas `adopt` uses the selected layout mode as the new parent. To improve readability and avoid confusion about the interpretation of the two IDs, the arguments of the transfer command are separated by the keyword `"to"`.

Jython example:

```
Content.transfer(child_ID, "to", parent_ID)
Layout.transfer(child_ID, "to", parent_ID)
Layout.adopt(child_ID)

# example: move a layout node under the root component of the page
Layout.select("the", "root")
Layout.adopt(node_id)
```

Jacl example:

```
$Content transfer child_ID to parent_ID
$Layout transfer child_ID to parent_ID
$Layout adopt child_ID

# example: move a layout node under the root component of the page
$Layout select the root
$Layout adopt node_ID
```

Content hierarchy accessed through Content bean:

The content hierarchy is a tree of content nodes. Content nodes can be labels, compositions, and links. Compositions are also called pages. Links can be internal or external. In the GUI, links represent the nodes in the Favorites list. Internal links point to a portal page, external links can point to any URL.

The content hierarchy is accessed and modified by using the Content bean, referenced as `$Content` in Jacl. The Content bean offers the following functions:

- Methods that allow to browse in the content tree hierarchy. The navigation method for the Content bean is a tree bean. For more information, see *Tree navigation*
- Methods that allow to locate a content node, or to search for particular content nodes. For more information, see *Search* .
- Methods for getting and setting attributes or metadata. The following attribute types are supported by the Content bean.
  - Plain attributes
  - List valued attributes
  - Locale-specific attributes
  - URL attributes
  - Metadata attributes
- Methods to create or delete pages, labels, or URL links, or to derive pages. For more information, see *Lifecycle* .
- Methods to move pages, labels, or URL links. The sequence of nodes can be modified as described in *Sequence*. For more information, see *Organization*. It is not possible to reorganize the content hierarchy..

"Search"
The generic search syntax is documented in Search. The Content bean supports the default search criteria, and the following keywords for node types in searches. Alternative, shorter keywords are documented in the bean help.

"Plain attributes" on page 1142
In addition to the default attributes, content nodes have the following attributes.

"List valued attributes" on page 1143
The content nodes have three list valued attributes, `locales`, `markups`, and `allowedportlets`. See the bean help for alternative, shorter names for these lists.

"Locale-specific attributes" on page 1144
The content nodes have two locale-specific attributes, `title` and `description`. See the bean help for alternative, shorter names for these attributes. The title must be defined for each locale, though you can set it to the empty string. A new locale is defined by setting the title for it.

"URL attributes" on page 1145
For a URL content node, the `urlget` command obtains the URLs. It requires the markup name as an argument. If an ID is given, the requested URL of that content URL node is returned. If the ID is omitted, the requested URL of the currently selected URL node is returned.

"Metadata attributes" on page 1145
Content nodes can own metadata, which are name-value pairs of data that is associated with the content node. Metadata are used by the portal, for example to set display attributes, or by the user. However, you must ensure that none of the metadata information that is set by the portal is overridden.

"Lifecycle" on page 1146
The `create` command creates a new content node. The `derive` command creates a new content node for a page that is derived from another page. The `delete` command removes a content node.

Related concepts:

"Tree navigation" on page 1131
The Content, Layout, and Portlet beans each represent a tree hierarchy. The basic navigation methods are the same for all three. A tree bean provides methods to access the root node to look up the parent and children of a node, and to maintain a cursor that points to a selected node in the tree.

"Organization" on page 1138
For some beans, in particular the Content and Layout beans, the order of nodes is significant. In tree beans, the parent relationship of the nodes defines the hierarchy. Only nodes with the same parent node are in a particular order in trees.

Search:

The generic search syntax is documented in Search. The Content bean supports the default search criteria, and the following keywords for node types in searches. Alternative, shorter keywords are documented in the bean help.

- `label`
- `composition or page`
- `internalurl`
- `externalurl`
- `url (either internal or external)`
- `all or any`

Jython example:

```
Content.help("search-types")

# example: search all content nodes
Content.search("all")

# example: find and select page by unique name
Content.find("page", "uniquename", "ibm.portal.Portlets", "select")

# example: find all pages under label "Administration"
Content.find("label", "uniquename", "ibm.portal.Administration", "select")
Content.search("composition")
```

Jacl example:

```
$Content help search-types

# example: search all content nodes
$Content search all

# example: find and select page by unique name
$Content find page uniquename "ibm.portal.Portlets" select

# example: find all pages under label "Administration"
$Content find label uniquename ibm.portal.Administration select
$Content search composition
```

Plain attributes:

In addition to the default attributes, content nodes have the following attributes.

Table 152. Description of content node attributes

Attribute	Description
`position`	The numeric position among the siblings, zero-based.
`themeid`	The identifier of the theme for the content node.
`themename`	The name of the theme for the content node.
`allportlets`	A flag that indicates whether all portlets are allowed for the page or not. If this flag is set true, the list of allowed portlets is ignored. Refer to *List valued attributes*.

The `themeid` attribute is writable. The `themename` attribute is not writable, but the value depends on the `themeid` attribute. The `position` attribute is not writable either, but the value depends on the organization of the content tree.

To get attributes of a static page content node, run the following command

Jython:

```
Content.get(oid, attribute, markup)
```

Jacl:

```
$Content get oid attribute markup
```

Valid attributes are as follows:

filename
Gets the file name of the static page layout file that is contained in the ZIP archive.

displayoption
Specifies markup languages such as HTML.

Jython example: `Content.get(6_CGAH47L00G2N802TJFV58Q3000, filename, html)`
Jacl example: `$Content get 6_CGAH47L00G2N802TJFV58Q3000 filename html`

The preceding example returns the file name of the entry point for the page display.

To set attributes for a static page, run the following command:

Jython example:
`Content.set(`*`oid`*`, `*`attribute`*`, `*`value`*`, `*`markup`*`)`

Jacl example:
`$Content set `*`oid attribute value markup`*

Valid attributes are **filename** and **displayoption**.

filename
Gets the file name of the static page layout file that is contained in the ZIP archive. For example, to set the entry point to display anotherindex.html for the specified markup run the following command:

Jython: `Content.set(6_CGAH47L00G2N802TJFV58Q3000, filename, anotherindex.html, htm`
Jacl: `$Content set 6_CGAH47L00G2N802TJFV58Q3000 filename anotherindex.html html`

displayoption
Specifies markup languages such as HTML. Valid options for **displayoption** are inline, iframe, and ajax. For example, to set the display option to iframe for the specified markup run the following command:

Jython: `Content.set(6_CGAH47L00G2N802TJFV58Q3000, displayoption, iframe, html)`
Jacl: `$Content set 6_CGAH47L00G2N802TJFV58Q3000 displayoption iframe html`

Related concepts:
"List valued attributes"
The content nodes have three list valued attributes, locales, markups, and allowedportlets. See the bean help for alternative, shorter names for these lists.

List valued attributes:

The content nodes have three list valued attributes, locales, markups, and allowedportlets. See the bean help for alternative, shorter names for these lists.

The locales list holds the locales for which locale-specific attributes are defined. For more information, see *Locale-specific attributes*. The commands list, drop, and empty are available for locales. New values can be added by setting a title for the respective locales.

The markups list holds the markups that are supported by the content node. The commands list, add, and drop are available for markups. At least one markup must be supported.

The allowedportlets list holds the portlets that are registered as allowed portlets for that page. The total list of portlets that can be used for the page is this allowedportlets list, plus the lists of allowed portlets of all parent pages.

Jython example:

```
# example for manipulating locales of a content node:
# select node, list locales, remove and re-create a locale
# "locale" is an alternative name for the "locales" list
Content.select(ID)
Content.list("locales")
Content.drop("locale", "en")
Content.nlsset("title", "en", "New English Title")

# example for manipulating markups of a content node:
# select node, list markups, replace wml by chtml
# "markup" is an alternative name for the "markups" list
Content.select(ID)
Content.list("markups")
Content.add("markup", "chtml")
Content.drop("markup", "wml")
Content.list("allowedportlets")
```

Jacl example:

```
# example for manipulating locales of a content node:
# select node, list locales, remove and re-create a locale
# "locale" is an alternative name for the "locales" list
$Content select ID
$Content list locales
$Content drop locale en
$Content nlsset title en "New English Title"

# example for manipulating markups of a content node:
# select node, list markups, replace wml by chtml
# "markup" is an alternative name for the "markups" list
$Content select ID
$Content list markups
$Content add markup chtml
$Content drop markup wml
$Content list allowedportlets
```

Related concepts:

"Locale-specific attributes"
The content nodes have two locale-specific attributes, title and description. See the bean help for alternative, shorter names for these attributes. The title must be defined for each locale, though you can set it to the empty string. A new locale is defined by setting the title for it.

Locale-specific attributes:

The content nodes have two locale-specific attributes, title and description. See the bean help for alternative, shorter names for these attributes. The title must be defined for each locale, though you can set it to the empty string. A new locale is defined by setting the title for it.

Jython example:

```
# example for manipulating locales of a content node:
# select node, remove all, import, add one manually
Content.select(ID)
Content.empty("locales")
Content.nlsimport("nls/content.nls", "page.visualization")
Content.nlsset("title", "en_GB", "Visualisation")
Content.nlsset("description", "en_GB", "A page for...")
```

Jacl example:

```
# example for manipulating locales of a content node:
# select node, remove all, import, add one manually
$Content select ID
$Content empty locales
$Content nlsimport nls/content.nls page.visualization
$Content nlsset title en_GB "Visualisation"
$Content nlsset description en_GB "A page for..."
```

URL attributes:

For a URL content node, the `urlget` command obtains the URLs. It requires the markup name as an argument. If an ID is given, the requested URL of that content URL node is returned. If the ID is omitted, the requested URL of the currently selected URL node is returned.

Jython example:

```
Content.urlget(markup)
Content.urlget(ID, markup)
# example: get WML URL of a specific content URL node
Content.urlget(node_ID, "wml")
```

Jacl example:

```
$Content urlget markup
$Content urlget ID markup

# example: get WML URL of a specific content URL node
$Content urlget node_ID wml
```

Metadata attributes:

Content nodes can own metadata, which are name-value pairs of data that is associated with the content node. Metadata are used by the portal, for example to set display attributes, or by the user. However, you must ensure that none of the metadata information that is set by the portal is overridden.

Jython example:

```
Content.parmget(ID, name)
Content.parmset(ID, name, value)
Content.drop(ID, "parm", name)
Content.list(ID, "parm")

# only for beans with a current selection
Content.parmget(name)
Content.parmset(name, value)
Content.drop("parm", name)
Content.list("parm")

# example: set the metadata for an instance property named #
"MyUserData" on the selected node
Content.parmset("MyUserData", "A_User_Value")

# example: get the metadata for an instance property named #
"MyUserData" (should return "A_User_Value")
print Content.parmget("MyUserData")

# example: list all metadata names
for pname in Content.list("parm").split():
    print pname
```

```
#example: Drop the metadata with the name "MyUserData"
Content.drop("parm", "MyUserData")
Organization
```

Jacl example:

```
$Content parmget ID name
$Content parmset ID name value
$Content drop ID parm name
$Content list ID parm

# only for beans with a current selection
$Content parmget name
$Content parmset name value
$Content drop parm name
$Content list parm

# example: set the metadata for an instance property named
# "MyUserData" on the selected node
$Content parmset MyUserData A_User_Value

# example: get the metadata for an instance property named
# "MyUserData" (should return "A_User_Value")
puts "[$Content parmget MyUserData]"

# example: list all metadata names
foreach pname [$Content list parm] {
  puts "$pname"
}

#example: Drop the metadata with the name "MyUserData"
$Content drop parm "MyUserData"
```

Lifecycle:

The `create` command creates a new content node. The `derive` command creates a new content node for a page that is derived from another page. The `delete` command removes a content node.

When you create a new content node, the parent for the new node must be selected. The first argument for creating is the type of the new node. Supported types are `label`, `page`, and `externalurl`. See the bean help for alternative and shorter names. It is not possible to create a node of type `internalurl` from a script.

The second argument is a name for the new node. It is set as the provisional English title, and the common name of the new node is computed from it. The last argument is one markup that is supported by these nodes. Extra markups can be enabled by manipulating the list of markups. For more information, see *List valued attributes*. The `create` command returns the ID of the newly created node. If the keyword `select` is appended to the command, the created node becomes the current selection.

Optionally, the script can specify a `shared-flag`, which indicates whether the new page is a shared page (`shared`) or a non-shared page (`nonshared`). The optional flag `private-flag` indicates whether the new page is private or public (possible values are `private` and `public`). This flag is only valid if the content node type is `page`.

When you derive a page, the parent for the new page in the content tree must be selected. Only pages that are flagged as shared and public can be used as base pages for derivation. The first argument is the name of the new page. The type of the node is implicit, since only pages can be derived.

The second argument is the keyword *from* and the third argument is the identifier of the page to derive `from`. The supported markups are the same as for the base page. The `derive` command returns the ID of the newly created node. If the keyword `select` is appended to the command, the created node becomes the current selection.

Do not rely on the name that is set as the English title, since this behavior might change in the future. Set the English title explicitly if you plan to support the *en*locale. However, the common name is computed from the name argument.

Jython example:

```
Content.create(type, name, markup)
Content.create(type, name, markup, "select")
Content.create(type, name, markup, [shared_flag,]
[private_flag,] "select")

Content.derive(name, "from", ID)
Content.derive(name, "from", ID, "select")

# example: create and select a label at the first level,
#          then create a derived page under the new label
Content.select("the", "root")
Content.create("label", "Leisure", "html", "select")
Content.derive("Movies", "from", node_ID)
```

Jacl example:

```
$Content create type name markup
$Content create type name markup select
$Content create type name markup [shared_flag] [private_flag]
select

$Content derive name from ID
$Content derive name from ID select

# example: create and select a label at the first level,
#          then create a derived page under the new label
$Content select the root
$Content create label "Leisure" html select
$Content derive "Movies" from node_ID
```

To create a static page, run the following command:

Jython:

```
Content.create(staticpage, title, markup, zip_file_name, filename, displayoption, "select")
```

For example, `Content.create(staticpage, MyStaticPageTitle, html, c:/tmp/StaticContentPage.zip, index.html, inline, "select")`

Jacl:

```
$Content create staticpage title markup zip_file_name filename [displayoption] [select]
```

For example, `$Content create staticpage MyStaticPageTitle html c:/tmp/StaticContentPage.zip index.html [inline] [select]`

The preceding example creates a static page beneath the currently selected content node for the HTML markup with the page title MyStaticPageTitle. The content of the page is read from `c:/tmp/StaticContentPage.zip`. The entry point for the page display is read from `index.html`, which must be contained in the `ZIP` archive. To specify the display method, you can use the optional parameter **`displayoption`**. This parameter takes one of the following values `inline`, `iframe`, or `ajax`. The

default value is `inline`. To make the newly created static page the currently selected content node, use the optional parameter **`select`**.

To get the static page content in the format of a `ZIP` archive, run the following command:

Jython:

```
Content.pageget(oid, markup, zip_file_name)
```

For example, `Content.pageget(6_CGAH47L00G2N802TJFV58Q3000, html, c:/tmp/MyStaticContentPage.zip)`

Jacl:

```
$Content pageget oid  markup  zip_file_name
```

For example, `$Content pageget 6_CGAH47L00G2N802TJFV58Q3000 html c:/tmp/MyStaticContentPage.zip`

The preceding example writes the content of the specified static page to `c:/tmp/MyStaticContentPage.zip`.

To set the static page content by specifying a `ZIP` file name, use the following command:

Jython:

```
Content.pageset(oid, markup, zip_file_name, filename)
```

For example, `Content.pageset(6_CGAH47L00G2N802TJFV58Q3000, html, c:/tmp/NewStaticContentPage.zip, index.html)`

Jacl:

```
$Content pageset oid markup zip_file_name filename
```

For example, `$Content pageset 6_CGAH47L00G2N802TJFV58Q3000 html c:/tmp/NewStaticContentPage.zip index.html`

The preceding example updates the specified static page content with the content of `c:/tmp/NewStaticContentPage.zip`. The entry point for the page display is read from `index.html`, which must be contained in the `ZIP` archive.

The command `delete` removes a content node that has no children. Nodes that have children cannot be deleted. To reduce the risk of accidental deletion, this command always requires the ID as an argument, even if the node to be deleted is selected.

When you delete a page, all pages that are derived from that page are also deleted. This action also affects other users that have pages that are derived from that base page. If the currently selected node is deleted, either directly or by deleting a base page, the bean clears.

Jython example:

```
Content.delete(ID)
```

Jacl example:

```
$Content delete ID
```

Related concepts:

"List valued attributes" on page 1143
The content nodes have three list valued attributes, `locales`, `markups`, and `allowedportlets`. See the bean help for alternative, shorter names for these lists.

Component hierarchy:

The component hierarchy is a tree of components on a page. Components can be containers and controls. A container holds other components, a control displays a portlet. The component hierarchy is accessed and modified by using the Layout bean, referenced as `$Layout` in Jacl.

Only pages have a component hierarchy. The Layout bean always refers to the page that is selected in the Content bean. For more information, see *Content hierarchy*. When the Content bean has no current selection, or the current selection is not a page, the Layout bean cannot be used. Whenever a node is selected in the Content bean it clears the current selection of the Layout bean.

In the GUI, the component hierarchy of a page is manipulated by the customizer. The operations of the Layout bean allow for the definition of component hierarchies that the customizer cannot handle. The script developer must take care if the customizer is to be used alongside scripting.

The Layout bean offers the following functions:

- Methods that allow to browse in the layout hierarchy. For more information, see *Navigation*.
- Methods that allow to locate a layout node, or to search for particular layout nodes. For more information, see *Search* .
- Methods for getting and setting attributes or flags. The following attribute types are supported by the Layout bean:
  - Plain attributes.
  - Global flags
- Methods to create or delete layout objects. For more information, see *Lifecycle*.
- Methods to move or transfer layout objects. You can modify the component hierarchy as described in *Sequence* and *Hierarchy*. For more information, see *Organization*.

  "Navigation" on page 1150
  The Layout bean is a tree bean. The layout bean provides the index command to obtain and resolve so-called index paths. For more information, see Index paths. When started with an ID as argument, the command returns the absolute index path for that component. When started without an argument, it returns the absolute index path for the currently selected component.

  "Search" on page 1151
  The generic search syntax is documented in Search. The Layout bean supports the following keywords for node types in searches. Alternative, shorter keywords are documented in the bean help.

  "Plain attributes" on page 1151
  In addition to the default attributes, components have the following attributes. Alternatively, shorter names are documented in the bean help.

  "Global flags" on page 1152
  A composition hierarchy has several global flags. The global flags are similar to attributes of the content page node, except that they are associated with the

composition hierarchy rather than the content node. Therefore, they are accessed through the Layout bean after the page in the Content bean is selected.

"Lifecycle" on page 1153
The `create` command creates a new component. You must select the parent container for the new component. The first argument is a keyword that indicates whether a `container` or `control` is created. Alternative, shorter keywords are documented in the bean help.

Related concepts:

"Content hierarchy accessed through Content bean" on page 1140
The content hierarchy is a tree of content nodes. Content nodes can be labels, compositions, and links. Compositions are also called pages. Links can be internal or external. In the GUI, links represent the nodes in the Favorites list. Internal links point to a portal page, external links can point to any URL.

"Organization" on page 1138
For some beans, in particular the Content and Layout beans, the order of nodes is significant. In tree beans, the parent relationship of the nodes defines the hierarchy. Only nodes with the same parent node are in a particular order in trees.

Navigation:

The Layout bean is a tree bean. The layout bean provides the index command to obtain and resolve so-called index paths. For more information, see Index paths. When started with an ID as argument, the command returns the absolute index path for that component. When started without an argument, it returns the absolute index path for the currently selected component.

When started with an index path and a keyword, the `index` command resolves the argument path. If the keyword is `find`, it returns the ID of the addressed component. If the keyword is `select`, it also selects it. The keyword is not case-sensitive. If the index path is not absolute, it is resolved relative to the selected component.

Jython example:

```
Layout.index()
Layout.index(ID)

Layout.index(ipath, "find")
Layout.index(ipath>, "select")

# example: resolve an absolute index path
Layout.index("/1/0/3", "find")

# example: select first child of current container
Layout.index("0", "select")
```

Jacl example:

```
$Layout index
$Layout index ID

$Layout index ipath find
$Layout index ipath select

# example: resolve an absolute index path
$Layout index /1/0/3 find

# example: select first child of current container
$Layout index 0 select
```

Related concepts:

"Index paths" on page 1175
Index paths are used to refer to components in the component hierarchy. They are based on the index or position of a component in the surrounding container. An index path is a multi-dimensional index of a component, where the number of dimensions is equal to the depth of the component in the tree. Index paths are absolute or relative, depending on whether there is a leading slash. Absolute paths start with a leading slash and are resolved from the root component. Relative paths start with a number and are resolved from the selected component. Trailing slashes are irrelevant.

Search:

The generic search syntax is documented in Search. The Layout bean supports the following keywords for node types in searches. Alternative, shorter keywords are documented in the bean help.

- `container`
- `control`
- `all or any`

Plain attributes:

In addition to the default attributes, components have the following attributes. Alternatively, shorter names are documented in the bean help.

Table 153. A description of the plain attributes

Attribute	Description
`position`	The numeric position among the siblings, zero-based.
`skinid`	The identifier of the skin for the component.
`skinname`	The name of the skin for the component.
`modifiable`	A flag indicates whether the component can be modified.
`deletable`	A flag indicates whether the component can be deleted.
`width`	The width of the component, in pixel or percent.

The `skinid`, `modifiable`, `deletable`, and `width` attributes are writable. The Boolean value of the flag attributes can be given as *true/false*, *t/f*, *1/0*, or *on/off*. It is returned as *true/false* by the `get` command. The flag values are local values of the component. On derived pages, a component is modifiable or deletable only if the flag is also set on all base pages where that component is defined. The value of the width attribute can be given as a number of pixels, or as a numeric percentage followed by the percent sign.

The `skinname` attribute is not writable, but the value depends on the `skinid` attribute. The `position` attribute is not writable either, but the value depends on the organization of the component tree. For more information, see *Organization*.

Jython example:

```
# examples for setting attributes of the selected node
Layout.set("modifiable", "true")
Layout.set("deletable", "0")
Layout.set("width", "350")
```

Jacl example:

```
# examples for setting attributes of the selected node
$Layout set modifiable true
$Layout set deletable 0
$Layout set width "350"
```

Containers have the following extra attributes:

Table 154. Description of the additional containers attribute

Attribute	Description
`orientation`	The orientation of the container.

The `orientation` attribute is writable. The value is returned as *horizontal* or *vertical*. It can be set as *horizontal/vertical* or as *row/column* or as *row/col*.

Controls have the following extra attributes:

Table 155. Description of the additional controls attributes

Attribute	Description
`portletdefinition`	The ID of the portlet that is shown in the control.
`portletentity`	The ID of the portlet entity that is shown in the control.

These attributes are not writable.

Related concepts:

"Organization" on page 1138
For some beans, in particular the Content and Layout beans, the order of nodes is significant. In tree beans, the parent relationship of the nodes defines the hierarchy. Only nodes with the same parent node are in a particular order in trees.

Global flags:

A composition hierarchy has several global flags. The global flags are similar to attributes of the content page node, except that they are associated with the composition hierarchy rather than the content node. Therefore, they are accessed through the Layout bean after the page in the Content bean is selected.

You can query the global flags with the `getflag` and modify them with the `setflag` command. The `getflag` command expects the name of the flag as the first argument. If the keyword `numeric` is added, it returns the value of the flag as a Boolean *1* or *0*. Without the keyword, it returns a string *true* or *false*. The `setflag` command expects the name of the flag as the first argument, the new value as the second. You can specify the new value as any Boolean value recognized by the BSF, like *1/0*, *true/false*, *t/f*, *on/off*.

Jython example:

```
Layout.getflag(flag)
Layout.getflag(flag, "numeric")

Layout.setflag(flag, value)

# query a flag in a condition
if Layout.getflag("active", "numeric"):
  ...
else:
  ...
```

Jacl example:

```
$Layout getflag flag
$Layout getflag flag numeric

$Layout setflag flag value

# query a flag in a condition
if [$Layout getflag active numeric] then {...} else {...}
```

The following global flags are supported. The bean help documents alternative and shorter names.

Table 156. Description of the global flags

Attribute	Description
`active, a`	Whether the page is active.
`bookmarkable, bookmark, b`	Whether an internal link to the page can be created.
`shareable, share, s`	Whether the page can be used as a base for derived pages.

A page is not shown in the navigation if the active flag is false. You can deactivate the pages while they are modified to prevent user from seeing an inconsistent view of the page. The `bookmarkable` flag is not writable.

Lifecycle:

The `create` command creates a new component. You must select the parent container for the new component. The first argument is a keyword that indicates whether a `container` or `control` is created. Alternative, shorter keywords are documented in the bean help.

The interpretation of the second argument depends on the type of object to create. When you create a container, it is the initial value for the `orientation` attribute. When you create a control, it is the value for the `portletdefinition` attribute. See *Plain attributes* for both attributes. If the keyword `select` is appended, the newly created node becomes the current selection.

A page that is created, or from which all components are deleted, does not have a root container. Only in that case, it is possible to create a container without selecting a parent. The new container becomes the root container for the page. It is not possible to create a page with a root control.

Jython example:

```
Layout.create("container", orientation)
Layout.create("container", orientation, "select")
```

```
Layout.create("control", portlet_ID)
Layout.create("control", portlet_ID, "select")

# example: append a column to the second row
Layout.index("/1", "select")
Layout.create("container", "column")

# example: create a new control in the first row or column
Layout.index("/0", "select")
Layout.create("control", portlet_ID)

# example: create a page with a control in a row
Content.create("page", "New Page", "html", "select")

# no deselect required, since nothing can be selected
Layout.create("container", "row", "select")
Layout.create("control", portlet_ID)
```

Jacl example:

```
$Layout create container orientation
$Layout create container orientation select

$Layout create control portlet_ID
$Layout create control portlet_ID select

# example: append a column to the second row
$Layout index /1 select
$Layout create container column

# example: create a new control in the first row or column
$Layout index /0 select
$Layout create control portlet_ID

# example: create a page with a control in a row
$Content create page "New Page" html select
# no deselect required, since nothing can be selected
$Layout create container row select
$Layout create control portlet_ID
```

The only argument that is required for the `delete` command is the ID of the node to delete. To prevent accidental deletion, you must explicitly specify the ID even if the node is selected. You can delete a container only if it is empty. If the selected node is deleted, the bean automatically clears.

Jython example:

```
Layout.delete ID
```

Jacl example:

```
$Layout delete ID
```

Related concepts:

"Plain attributes" on page 1151
In addition to the default attributes, components have the following attributes. Alternatively, shorter names are documented in the bean help.

Portlet repository:

The portlet repository provides access to portlets, portlet applications, and web modules. To provide easy access to the relations between the repository objects, the repository is modeled as a tree. Unlike with the content and component hierarchies, the repository tree is not arbitrarily nested.

At the root of the repository is a dummy node. Children of the root are the web modules. web modules are the deployment units of the portal. They correspond to WAR files. The children of a web module are portlet applications.

The portlet repository is accessed by using the Portlet bean, referenced as `$Portlet` in Jacl. Modification of the portlet repository from a script is not supported.

The Portlet bean provides the following functions:

- Methods to browse in the portlet repository tree. For more information, see *Navigation*.
- Methods to locate a portlet, application, or web module, or to search for particular repository objects. For more information, see *Search* .
- Methods for getting attributes, metadata, or portlet preferences. The following attribute types are supported by the Layout bean:
  - Plain attributes
  - List valued attributes
  - Locale-specific attributes
  - Portlet metadata
  - Portlet preferences

"Navigation" on page 1156
The Portlet bean is a tree bean. The navigation is documented in Tree navigation. For more information, see Tree navigation.

"Search" on page 1156
The generic search syntax is documented in Search. The Portlet bean supports the following keywords for node types in searches. Alternative, shorter keywords are documented in the bean help.

"Plain attributes" on page 1157
In addition to the default attributes, repository objects have some of the following attributes. Alternative, shorter names are documented in the bean help.

"List valued attributes" on page 1158
The portlet nodes have two list valued attributes, `locales` and `parameters`. See the bean help for alternative, shorter names for these lists. Only the `list` command is supported, you cannot modify the lists. The locales list is available for portlets and portlet applications. It holds the locales for which locale-specific attributes are defined in locale-specific attributes. The `parameters` list holds the setting names for the *init* parameter that are associated with the specified portlet.

"Locale-specific attributes in portlet bean" on page 1158
Portlets and portlet applications have the following locale-specific attributes. All attributes are optional. You can query the list of locales for which attributes are defined by using the `list` command (List valued attributes).

"Portlet metadata" on page 1158
Portlet nodes can own metadata, which are name-value pairs of data that is associated with the content node. Metadata are used by the portal, for example, to set display attributes, or by the user. The Portal bean allows read-only access on portlet metadata. Metadata can be assigned only with portlet-type or application-type repository objects.

"Portlet preferences in portlet bean" on page 1159
It is possible to get and set preferences to portlet instances. Because Portlet beans specify a static portlet only, and not a portlet instance that is found on a

page, portlet instances are identified by two ID values: The ID of the portlet that specifies the portlet, and the ID of the portlet entity `piid` that anchors an instance of the portlet in a page.

Navigation:

The Portlet bean is a tree bean. The navigation is documented in Tree navigation. For more information, see Tree navigation.

There is one dedicated `select` command to select the web module of the currently selected portlet application or portlet.

Jython example:

```
Portlet.select("the", "root")
Portlet.select("the", "parent")
Portlet.select("the", "webmodule")
```

Jacl example:

```
$Portlet select the root
$Portlet select the parent
$Portlet select the webmodule
```

Related concepts:

"Tree navigation" on page 1131
The Content, Layout, and Portlet beans each represent a tree hierarchy. The basic navigation methods are the same for all three. A tree bean provides methods to access the root node to look up the parent and children of a node, and to maintain a cursor that points to a selected node in the tree.

Search:

The generic search syntax is documented in Search. The Portlet bean supports the following keywords for node types in searches. Alternative, shorter keywords are documented in the bean help.

- `webmodule`, `webmodules`, `module`, `modules`, `wm`, `w`, `m`
- `application`, `applications`, `app`, `apps`, `a`
- `portlet`, `portlets`, `p`
- `concrete` (portlet or application)
- `abstract` (web module)
- `all or any`

In addition to the default search criteria, the Portlet bean supports two criteria that match on the name of the objects. The name is similar to a common name, except that there are no restrictions on the character set. The name is a real attribute of the repository objects, not a synthesized one like the common name.

Table 157. Descriptions of the 2 search criteria that match on the name of the objects

Attribute	Description
`namehas`	The value is a string. The search is for objects with the string as a substring in their name. Comparison is not case-sensitive.
`nameis`	The value is a string. The search is for objects with the string as their name. Comparison is case-sensitive.

Jython example:

```
# example: search all applications related to news
Portlet.deselect()
Portlet.search("application", "namehas", "News")

# example: find and select unique news portlet
#          will fail if none or several are found
Portlet.find("portlet", "nameis", "NewsPortlet", "select")
```

Jacl example:

```
# example: search all applications related to news
$Portlet deselect
$Portlet search application namehas "News"

# example: find and select unique news portlet
#          will fail if none or several are found
$Portlet find portlet nameis "NewsPortlet" select
```

Plain attributes:

In addition to the default attributes, repository objects have some of the following attributes. Alternative, shorter names are documented in the bean help.

Table 158. Description of the plain attributes for the repository objects

Attribute	Description
`name`	The name, for all object types.
`version`	The version number, for web modules only.
`contextroot`	The absolute path URI, for web modules only.
`resourceroot`	The relative directory, for web modules only.
`defaultlocale`	The default locale, for applications and portlets.

These attributes are also available:

Table 159. Description of the additional plain attributes for the repository objects

Attribute	Description
`id, oid, guid`	The identifier of the node. Suitable input for *select*.
`uniquename, uname, un`	The global unique name of the node.
`type`	The type of the node. Options: repository, web module, application, portlet
`name`	The name of the node.
`commonname, cname, cn`	The common name that is generated for the node.
`version`	The version number. Only for web modules.
`contextroot, context, uri`	The relative URI for addressing the web module. Only for web modules.
`resourceroot, resdir, dir, war`	The subdirectory where the web module resources can be found.
`defaultlocale, dlocale, defloc`	The default locale. Only for portlet applications and portlets.

Table 159. Description of the additional plain attributes for the repository objects (continued)

Attribute	Description
`servlet`	The ID of the associated servlet. Only for portlets.
`cachescope, cs`	The remote cache scope of this repository node. Only portlet nodes can have this read-only flag. The attribute value can be empty. Valid attribute values are *shared* or *s* for a shared remote cache scope, *nonshared*, or *ns* for a non-shared remote cache scope.
`cacheexpiration, cacheexp, cexp`	The expiration value of the remote cache, in seconds. Only portlet nodes can have this read-only flag. The attribute value must be a numeric expression, where *-1*means that the cache never expires, *0* means that the cache expires at each request.
`remotecachedynamic, rcd`	Indicates whether the remote cache is dynamic or static. Only portlet nodes can have this read-only flag. A value of true indicates that the remote cache is dynamic. false indicates that the remote cache is a static cache.

All attributes are read-only, there is no `set` command. The `resourceroot` attribute typically is the name of the WAR file of the web module.

List valued attributes:

The portlet nodes have two list valued attributes, `locales` and `parameters`. See the bean help for alternative, shorter names for these lists. Only the `list` command is supported, you cannot modify the lists. The locales list is available for portlets and portlet applications. It holds the locales for which locale-specific attributes are defined in locale-specific attributes. The `parameters` list holds the setting names for the *init* parameter that are associated with the specified portlet.

Locale-specific attributes in portlet bean:

Portlets and portlet applications have the following locale-specific attributes. All attributes are optional. You can query the list of locales for which attributes are defined by using the `list` command (List valued attributes).

- `title`
- `shorttitle`
- `keywords`
- `description`

Only the `nlsget` command is available for locale-specific attributes.

Portlet metadata:

Portlet nodes can own metadata, which are name-value pairs of data that is associated with the content node. Metadata are used by the portal, for example, to set display attributes, or by the user. The Portal bean allows read-only access on portlet metadata. Metadata can be assigned only with portlet-type or application-type repository objects.

Jython example:

```
Portlet.parmget(ID, name)
Portlet.list(ID, "parm")

# only for beans with a current selection
Portlet.parmget(name)
Portlet.list("parm")

# example: get the metadata for an instance property named #
"MyPortletConfig"
print Portlet.parmget("MyPortletConfig")

# example: list all metadata names for the selected portlet
for pname in Portlet.list("parm").split():
    print pname
```

Jacl example:

```
$Portlet parmget ID name
$Portlet list ID parm

# only for beans with a current selection
$Portlet parmget name
$Portlet list parm

# example: get the metadata for an instance property named # "MyPortletConfig"
puts "[$Portlet parmget MyPortletConfig]"

# example: list all metadata names for the selected portlet
foreach pname [$Portlet list parm] {
puts "$pname"
}
```

Portlet preferences in portlet bean:

It is possible to get and set preferences to portlet instances. Because Portlet beans specify a static portlet only, and not a portlet instance that is found on a page, portlet instances are identified by two ID values: The ID of the portlet that specifies the portlet, and the ID of the portlet entity `piid` that anchors an instance of the portlet in a page.

The command `prefnames` is used to obtain a list of available preference names. Portlet preferences might have multiple values. The command `getpref` therefore accepts a numeric `index` attribute. The numeric `index` attribute denotes the number of the value to be obtained. For example, *0* means to return the first preference value, *1* means to return the second value. The total number of available preference values for a specific preference name is returned by the `prefcount` command.

The `addpref` command is used to add a portlet preference value to the portlet preference list. You can set portlet preferences to read-only. You can control this setting with the commands `spprof` (Set Portlet Preference Read-only Flag) and `gpprof` (Get Portlet Preference Read-only Flag).

Jython example:

```
Portlet.prefnames(ID, piid)
Portlet.getpref(ID, piid, name, "at", index)
Portlet.addpref(ID, piid, name, value)
Portlet.gpprof(ID, piid, name, ["numeric"])
Portlet.spprof(ID, piid, name, readonly_flag)
```

Jacl example:

```
$Portlet prefnames ID piid
$Portlet getpref ID piid name at index
$Portlet addpref ID piid name value
$Portlet gpprof ID piid name [numeric]
$Portlet spprof ID piid name readonly_flag
```

The portlet is identified by two ID values: The ID of the portlet and the ID of the portlet entity. You can obtain the ID of the portlet entity by the command `$Layout get piid` or `Layout.get("piid")`.

Jython example:

```
# example: set a portlet preference
# 1. locate the control where the portlet resides
# 2. obtain its portlet instance ID
# 3. set the portlet preference accordingly
ctl = Layout.find("all", "pid", Portlet.csn(), "select")
piid = Layout.get(ctl, "piid")
Portlet.addpref(piid, "MYKEY", "Value")

# example: list portlet preference values for key "MYKEY"
# the control ID is stored in the variable ctrl
for ix in range($Portlet.prefcount(piid, "MYKEY")):
  print Portlet.getpref(piid, "MYKEY", "at", ix)

# example: drop all portlet preferences on a certain key
Portlet.droppref(piid, "MYKEY")
```

Jacl example:

```
# example: set a portlet preference
# 1. locate the control where the portlet resides
# 2. obtain its portlet instance ID
# 3. set the portlet preference accordingly
set ctl [$Layout find all pid [$Portlet csn] select]
set piid [$Layout get $ctl piid]
$Portlet addpref $piid MYKEY "SomeValue"

# example: list portlet preference values for key "MYKEY"
# the control ID is stored in the variable ctrl
for {set ix 0} {$ix < [$Portlet prefcount $piid MYKEY]} {incr ix} {
  puts "[$Portlet getpref $piid MYKEY at $ix]"
}

# example: drop all portlet preferences on a certain key
$Portlet droppref $piid  MYKEY
```

Dependent on the standard that the portlet complies with, there are differences in the handling of portlet preferences. You can set multiple preference values on a preference key with standard portlets, while IBM portlets support only single values on each portlet preference key.

Themes and Skins:

Themes and skins are two distinct sets of objects with a matrix relation, where each skin can be tied to any number of themes. The sets of themes and skins are accessible through the Look bean, which is referenced as `$Look` in Jacl.

The Look bean provides access to the portal theme and skin objects:

- Methods that allow to search on themes. For more information, see *Search* .
- Methods for getting attributes. Themes and Skins support the default attributes. Only the `get` command is available. Since there is no current selection, the ID of the node for which to obtain an attribute value must be given explicitly.

- Methods to retrieve theme and skin lists. For more information, see *Global lists*.

  "Navigation"
  The Look bean is a simple lookup mechanism to access the name and ID of the available themes and skins. It does not support a current selection, nor navigation of the matrix relation between both sets. Since that might change in the future, the `deselect` command is implemented. It can be used before searches to ensure that the search is global, even if a current selection is introduced in the future.

  "Search"
  The syntax for searching is similar to the generic tree search described in Search. Since the look bean does not support a current selection, the search is not scoped and the keyword `select` is not supported for the `find` command. The command `deselect` (Navigation) can be used to ensure that a search is global, even if a search scope is introduced in the future.

  "Global lists" on page 1162
  For ease of use, two global lists hold the common name of all themes and skins. You can access the global lists with the `listall` command, which expects the list name as an argument. The following list names are supported. See the bean help for alternative list names.

Navigation:

The Look bean is a simple lookup mechanism to access the name and ID of the available themes and skins. It does not support a current selection, nor navigation of the matrix relation between both sets. Since that might change in the future, the `deselect` command is implemented. It can be used before searches to ensure that the search is global, even if a current selection is introduced in the future.

Jython example:

```
Look.deselect()
```

Jacl example:

```
$Look deselect
```

Search:

The syntax for searching is similar to the generic tree search described in Search. Since the look bean does not support a current selection, the search is not scoped and the keyword `select` is not supported for the `find` command. The command `deselect` (Navigation) can be used to ensure that a search is global, even if a search scope is introduced in the future.

The look bean supports the default search criteria, and the following keywords for node types in searches. Alternative keywords are documented in the bean help.

- `theme`
- `skin`

Since the sets of themes and skins are distinct, there is no option to search for both type of nodes at the same time.

Global lists:

For ease of use, two global lists hold the common name of all themes and skins. You can access the global lists with the `listall` command, which expects the list name as an argument. The following list names are supported. See the bean help for alternative list names.

- `themes`
- `skins`

Jython example:

```
# example: list the names of all themes
Look.listall("themes")

# example output:
Admin WebSphere Engineering Science Finance Corporate
```

Jacl example:

```
# example: list the names of all themes
$Look listall themes

# example output:
Admin WebSphere Engineering Science Finance Corporate
```

Portal Access Control:

The scripting operations for access control differ fundamentally from content, layout, or the portlet repository. The reason is that access control data is not transparently cached on the client. To avoid many requests and slow response times for every simple lookup operation, a different programming model is adopted for access control data.

The collected access control data for a resource is represented on the client by an object. These objects are explicitly created, locally modified, and written back to the portal. All local modifications become effective when the object is written back.

Two script beans are provided for access control data. The Access bean, referenced as `$Access` in a script, is for reading and writing the access control objects. The PacList bean, referenced as `$PacList`, provides operations to view and edit access control objects.

The access bean and PacList bean provide the following functions:

- Methods to request or release access list objects, and to load the permission set for view, edit, or manage permissions. For more information, see *Lifecycle* .
- Methods to get a list of available action sets. For more information, see *Global lists*.
- Methods to grant or revoke access for principals on the portal resource, or to view the permissions that are defined for the portal resource. For more information, see *Principals*.
- Methods to set or clear permission blocks. For more information, see *Permission blocks*.

"Access control objects" on page 1163
The complete access control data for a resource is represented on the client by a PacList object. PAC stands for Portal Access Control. PacList objects are opaque, they cannot be manipulated directly. Instead, they are loaded into the PacList

bean, which provides the operations to view and edit the objects. PacList objects are obtained from and written back by using the Access bean.

"Lifecycle" on page 1164
PacList objects are read from and written back to the portal by using `getacl` and `setacl` in the Access bean. The command `getacl` returns the PacList object for a resource. It expects the category and identifier of the resource as arguments. The category identifies the Script bean that is responsible for the resource. It is given as a keyword, which can be the bean name or the type of the resource. The supported keywords are documented in the help for the Access bean. PacList objects are obtained only for resources that are handled by the Content and Portlet beans. For the root node of the portlet repository, there are no PacList objects.

"Global lists" on page 1166
A global list holds the names of the predefined action sets. The global list is accessed with the `listall` command in the Access bean. The command expects the list name as an argument. The only supported list name is `actionsets`. See the bean help for alternative list names.

"Principals" on page 1166
Use the `list` command to access the list of principals for an action set.

"Permission blocks" on page 1168
Use the `show` command to access the flags that control distribution of permissions. The first argument is the name of the action set, and the second is the name of the flag to obtain. The optional keyword numeric indicates whether the flag value must be returned as a human readable string, or as a numeric value suitable for programmatic evaluation. Since the string value is subject to translation into different locales, only the numeric value can reliably be used in conditional statements. The numeric value *0* indicates a block, while *1* stands for allowed distribution. The following names are supported for the two flags. Alternative names are documented in the help for the PacList bean.

Access control objects:

The complete access control data for a resource is represented on the client by a PacList object. PAC stands for Portal Access Control. PacList objects are opaque, they cannot be manipulated directly. Instead, they are loaded into the PacList bean, which provides the operations to view and edit the objects. PacList objects are obtained from and written back by using the Access bean.

The access control data for a resource is split in similar data groups for several action sets. It is also referred to as role types. The term action set is used here, as it has the smaller potential for misinterpretation. The portal uses predefined action sets, which combine the actions for the following types of portal users. One name for each action set is given in parentheses. Alternative names are documented in the help of the PacList bean.

- User (`User`)
- Privileged User (`PrivilegedUser`)
- Editor (`Editor`)
- Manager (`Manager`)
- Delegator (`Delegator`)
- Security Administrator (`SecurityAdmin`)
- Administrator (`Admin`)

For each action set, a list of principals are explicitly allowed to complete the corresponding actions. A principal is a group or user, which are specified by a name or distinguished name (DN). There are three special principals, which represent an anonymous user, all authenticated users, and all user groups.

In addition to the list of principals, two flags control the implicit distribution of permissions through resource hierarchies. The inheritance flag controls distribution of permissions from parent to child nodes. If inheritance is not blocked, a principal that has permission on the parent has permission on the child as well. This kind of permission is useful for administrative actions. The propagation flag controls the other direction. If propagation is not blocked, a principal that has permission on at least one child has permission on the parent as well. This kind of permission is useful for simple actions, such as viewing a page, which requires view access to all parents.

Although the flags can be manipulated for each action set, they are ignored for security administrators and administrators. For these two action sets, inheritance and propagation are never blocked.

Lifecycle:

PacList objects are read from and written back to the portal by using `getacl` and `setacl` in the Access bean. The command `getacl` returns the PacList object for a resource. It expects the category and identifier of the resource as arguments. The category identifies the Script bean that is responsible for the resource. It is given as a keyword, which can be the bean name or the type of the resource. The supported keywords are documented in the help for the Access bean. PacList objects are obtained only for resources that are handled by the Content and Portlet beans. For the root node of the portlet repository, there are no PacList objects.

The command `setacl` writes a PacList object back to the portal. That command is necessary only if the PacList object is modified. The PacList object is the only argument to the command. Each PacList object is tied to a particular resource and cannot be written for any other resource.

Jython example:

```
Access.getacl(category, ID)
Access.setacl(paclist)

# example: get PacList object for a particular page
#          the object is stored in variable "acl"
Content.find("label", "uniquename",
"ibm.portal.Administration", "select")
acl = Access.getacl("Content", Content.current())

# example: write back PacList object in variable "acl"
Access.setacl(acl)
```

Jacl example:

```
$Access getacl category ID
$Access setacl paclist

# example: get PacList object for a particular page
#          the object is stored in variable "acl"
$Content find label uniquename ibm.portal.Administration select
set acl [$Access getacl Content [$Content current]]

# example: write back PacList object in variable "acl"
$Access setacl $acl
```

To access or manipulate a PacList object, it must be loaded in the PacList bean. The operations of the PacList bean always refer to the PacList object currently loaded. An object can be loaded only for viewing by using `view`, or for manipulation by using `edit`. Both commands expect the PacList object as an argument. The PacList bean is loaded only if it is unloaded, or if it is loaded with an object that is not modified.

Jython example:

```
PacList.view(paclist)
PacList.edit(paclist)

# example: load PacList object for content root, view only
PacList.view(Access.getacl("Content", Content.root()))

# example: load PacList object for a particular page
Content.find("label", "uniquename",
"ibm.portal.Administration", "select")
acl = Access.getacl("Content", Content.current())
PacList.edit(acl)
```

Jacl example:

```
$PacList view paclist
$PacList edit paclist

# example: load PacList object for content root, view only
$PacList view [$Access getacl Content [$Content root]]

# example: load PacList object for a particular page
$Content find label uniquename ibm.portal.Administration select
set acl [$Access getacl Content [$Content current]]
$PacList edit $acl
```

The command `current` returns the name of the loaded object, which includes the identifier of the resource. The command `done` unloads the PacList bean and returns the object that was loaded. If the PacList bean is already unloaded, `done` still returns the PacList object that was loaded before, which is useful for dealing with errors.

If the currently loaded PacList object is modified since it was loaded, the command `modified` returns. If the keyword `numeric` is added, it returns the value of the flag as a Boolean *1* or *0*. Without the keyword, it returns a string *true* or *false*.

Jython example:

```
PacList.current()
PacList.done()

PacList.modified()
PacList.modified("numeric")

# example: write back and unload PacList object
#          only if it was modified
if PacList.modified("numeric"):
  Access.setacl(PacList.done()

# example: recover the last loaded PacList object
PacList.view(PacList.done())
```

Jacl example:

```
$PacList current
$PacList done
```

```
$PacList modified
$PacList modified numeric

# example: write back and unload PacList object
#          only if it was modified
if [$PacList modified numeric] {
  $Access setacl [$PacList done]
}

# example: recover the last loaded PacList object
$PacList view [$PacList done]
```

Global lists:

A global list holds the names of the predefined action sets. The global list is accessed with the `listall` command in the Access bean. The command expects the list name as an argument. The only supported list name is `actionsets`. See the bean help for alternative list names.

Jython example:

```
# example: list the names of all predefined action sets
Access.listall("actionsets")

# example output:
Admin SecurityAdmin Delegator Manager Editor PrivilegedUser User
```

Jacl example:

```
# example: list the names of all predefined action sets
$Access listall actionsets

# example output:
Admin SecurityAdmin Delegator Manager Editor PrivilegedUser User
```

Principals:

Use the `list` command to access the list of principals for an action set.

The first argument is the name of an action set. If the second argument is the keyword `all`, the command returns all principals in the list, which is separated by newlines. A regular principal is listed with its name. A special principal is listed with a dedicated name embraced by special characters, which makes the special principals easy to spot. Since principal names can include white space, the complete list cannot be parsed into items.

You can access the principals in the list individually. The keyword `at` as the second argument indicates that the third argument is an index. Alternative keywords are documented in the bean help. The command returns the principal at the given position in the list, where *0* is the index of the first position. If the index is out of range, the command returns empty. You can obtain the number of principals by using `count`, which expects the name of the action that is set as the only argument.

Jython example:

```
PacList.list(actionset, "all")
PacList.list(actionset, "at", index)
PacList.count(actionset)

# example: get first principal in list of administrators
PacList.list("Administrator", "at", 0)
```

```
# example: list all principals in all lists
for as in Access.listall("actionsets").split():
  print "Principals for " + as:" + PacList.list(as, "all")
```

Jacl example:

```
$PacList list actionset all
$PacList list actionset at index
$PacList count actionset

# example: get first principal in list of administrators
$PacList list Administrator at 0

# example: list all principals in all lists
foreach as [$Access listall actionsets] {
  puts "\nPrincipals for $as:"
  puts [$PacList list $as all]
}
```

The command `grant` adds a principal to a list of principals. The first argument is the name of the action that is set for which the principal is added. The second argument is a keyword that indicates whether a regular or special principal is to be added, as described later. The third argument specifies the principal to add. The PacList bean help documents alternative keywords for the second argument.

If the `keyword` name is given as the second argument, a regular principal is added. The third argument is the name of the principal, either as a fully qualified distinguished name, or as a short name. The name is resolved to a standard form when the PacList object writes back to the portal. Therefore, it is possible to have duplicates in the list, which is removed by the portal.

If the keyword `special` is given as the second argument, a special principal is added to the list. The third argument is a keyword that indicates which special principal can be added. The following special principals are supported. Alternative keywords are documented in the help for the PacList bean.

- `anonymous` - a user that is not logged in
- `authenticated` - any user that is logged in
- `allgroups` - any group of a user that is logged in. This virtual user group contains all non-virtual user groups.

The `grant` command returns a success message if a principal was added to the list. It returns empty if the principal to be added was spotted as a duplicate. As mentioned earlier, duplicates cannot be spotted by the PacList bean if names in non-canonical form are used.

Jython example:

```
PacList.grant(actionset, "name", name)
PacList.grant(actionset, "special", keyword)

# example: grant user access to anyone authenticated
PacList.grant("User", "special", "Authenticated")

# example: grant editor access to John Doe - twice
PacList.grant("Editor", "name", "johndoe")
PacList.grant("Editor", "name", "uid=johndoe,dc=example_1,dc=com")
```

Jacl example:

```
$PacList grant actionset name name
$PacList grant actionset special keyword
```

```
# example: grant user access to anyone authenticated
$PacList grant User special Authenticated

# example: grant editor access to John Doe - twice
$PacList grant Editor name "johndoe"
$PacList grant Editor name "uid=johndoe,dc=example_1,dc=com"
```

The command `revoke` deletes principals from the list for an action set. The first argument is the name of the action set. The second argument is a keyword that indicates how the principal to delete is specified, as described later. Alternative keywords are documented in the help for the PacList bean. In most cases, a third argument specifies the principal to be removed. The command returns a success message if a principal was removed from the list, or empty if the principal to be removed was not found.

If the second argument is the keyword `all`, the command deletes all principals from the list. This deletion of principals is the only case where more than one principal is removed. It is also the only case without a third argument.

If the second argument is the keyword `at`, the third argument is the index of the principal to be deleted. This addressing style is similar to the `list` command. It can be used to delete regular and special principals. The indexes of the succeeding principals are changed by this operation.

If the second argument is the keyword `name`, the third argument is the name of the regular principal to delete. This addressing style is similar to the `grant` command. Since the PacList bean cannot resolve names into canonical form, the name must be given in the exact same form in which it is present in the list. If the principal was read from the portal, that is the standard form. If the principal was added by a previous `grant` command, the name in the list is unchanged from the argument that is given to that command.

If the second argument is the keyword `special`, the third argument is a keyword for the special principal to delete. This addressing style is similar to the grant command and uses the same keywords for the special principals.

Jython example:

```
PacList.revoke(actionset, "all")
PacList.revoke(actionset, "at", index)
PacList.revoke(actionset, "name", name)
PacList.revoke8actionset, "special", keyword)
```

Jacl example:

```
$PacList revoke actionset all
$PacList revoke actionset at index
$PacList revoke actionset name name
$PacList revoke actionset special keyword
```

Permission blocks:

Use the `show` command to access the flags that control distribution of permissions. The first argument is the name of the action set, and the second is the name of the flag to obtain. The optional keyword numeric indicates whether the flag value must be returned as a human readable string, or as a numeric value suitable for programmatic evaluation. Since the string value is subject to translation into different locales, only the numeric value can reliably be used in conditional statements. The numeric value *0* indicates a block, while *1* stands for allowed

distribution. The following names are supported for the two flags. Alternative names are documented in the help for the PacList bean.

- `inheritance` - from the parent to this node
- `propagation` - from the children to this node

Jython example:

```
PacList.show(actionset, flag)
PacList.show(actionset, flag, "numeric")

# example: evaluate manager inheritance flag
if PacList.show("Manager", "inheritance", "numeric"):
  print "inheritance is permitted"
else:
  print "inheritance is blocked"
```

Jacl example:

```
$PacList show actionset flag
$PacList show actionset flag numeric

# example: evaluate manager inheritance flag
if [$PacList show Manager inheritance numeric] then {
  puts "inheritance is permitted"
} else {
  puts "inheritance is blocked"
}
```

The commands `block` and `unblock` are used to change the flags that control distribution of permissions. They expect the name of the action set and the name of the flag as the first and second argument. The `block` command prevents the corresponding distribution of permissions, and the `unblock` command allows it. The commands return a success message if the flag value changed, or empty if the flag already had the required value.

Jython example:

```
PacList.block(actionset, flag)
PacList.unblock(actionset, flag)

# example: prevent propagation of delegator permissions
PacList.block("Delegator", "propagation");

# example: allow inheritance of user permissions
PacList.unblock("User", "inheritance")
```

Jacl example:

```
$PacList block actionset flag
$PacList unblock actionset flag

# example: prevent propagation of delegator permissions
$PacList block Delegator propagation

# example: allow inheritance of user permissions
$PacList unblock User inheritance
```

Portal authentication:

The Portal bean handles functions that are outside of the responsibility of the other beans. This responsibility includes global data and technical aspects of scripting, such as the scripting session with the portal. The Portal bean is referenced as `$Portal` in Jacl.

The Portal bean provides the following functions:

- Methods to do a login and logout. For more information, see *Authentication*.
- Methods to set a virtual portal. For more information, see *Virtual Portal selection*.

"Authentication"
Before you can access any data from a script, you must establish the user identity for script execution.

"Virtual portal selection" on page 1172
You can set a virtual portal for a `login` or `Portal.login()` command with the `$Portal setvp` or `Portal.setvp()` command. It is possible to set the virtual portal during a session, but the session becomes effective only during the `$Portal login` command. The virtual portal is specified by the URL context. The URL context is the part of the home URL that identifies the virtual portal. If `$Portal setvp` or `Portal.setvp()` is started without a URL context, the default virtual portal is set.

Authentication:

Before you can access any data from a script, you must establish the user identity for script execution.

The `login` command authenticates the scripting engine against the portal and creates a user session for the subsequent commands. There are several different options for logging in, which can be distinguished by the number of arguments.

The `login` command with two arguments expects a user name and a password as the first and second argument. The user name identifies the portal user. It can be given as a fully qualified distinguished name, or as a login name. The portal looks up the user name and verify the password.

Jython example:

```
Portal.login(user_ID, password)

# example: login as Portal user
Portal.login(user_ID, password)
```

Jacl example:

```
$Portal login user_ID password

# example: login as Portal user
$Portal login user_ID password
```

The `login` command without arguments is used only if security is enabled in the portal. In that case, a user name and password had to be given to the application server to connect to the portal. The portal accepts the user identity from the connection without a second password check. This action requires that the application server user is also a portal user.

Jython example:

```
Portal.login()
```

Jacl example:

```
$Portal login
```

The `login` command with a single argument is used only if security is enabled in the portal. Like the version without argument, the user identity from the

connection is accepted by the portal. In addition, that user requires manage permission on the portal itself. That permission is the same permission that is required to use the XMLAccess tool.

If these preconditions are satisfied, the user name that is given as argument, is looked up and taken as the portal user identity. The user name that is given as argument is different from the user name of the connection. There is no second password check. This action is similar to the su command found in many operating systems, which allows the super user to act as any other user, without knowing the user password.

Jython example:

```
Portal.login(user_ID)

# example: login and change to Portal user
Portal.login("johndoe")
```

Jacl example:

```
$Portal login user_ID

# example: login and change to Portal user
$Portal login johndoe
```

The logout command ends the scripting session and allows the portal to free the resources that are allocated for that session. It must always be used before the scripting client exits. The logout command also invalidates the portal data that is cached in the client. It is therefore possible to reauthenticate as a different user without starting a new scripting client.

You must always logout and reauthenticate as the same user if the connection from the scripting client to the portal is re-established by using the AdminControl bean of the wsadmin tool. The portal might lose the user session in that case, which causes subsequent operations fail.

Jython example:

```
Portal.logout()
```

Jacl example:

```
$Portal logout
```

In a deployment scenario, the authentication must not be handled by the deployment script itself. Use a wrapper script for the authentication instead, so that you can run the deployment script under different user identities without changes. Here is an example for a wrapper script, which assumes that the deployment script defines a run_deployment procedure.

Jython example:

```
# keep the user identity of the connection
Portal.login()
# execute the deployment procedure
run_deployment()
# clean up before exit
Portal.logout()
```

Jacl example:

```
# keep the user identity of the connection
$Portal login
# execute the deployment procedure
run_deployment
# clean up before exit
$Portal logout
```

Alternatively, the deployment script can use procedures that are defined in a profile script for login and logout. Profile scripts are run on start of the scripting client.

Jython example:

```
# login function
def portal_login(user_ID, password):
  Portal.login(user_ID, password)
  # other startup operations, like logging the access
# logout function
def portal_logout():
  Portal.logout()
  # other shutdown operations
```

Jacl example:

```
# procedure for login
proc portal_login { } {
  $Portal login user_ID password
 # other startup operations, like logging the access
}

# procedure for logout
proc portal_logout { } {
  $Portal logout
  # other shutdown operations
}
```

Virtual portal selection:

You can set a virtual portal for a `login` or `Portal.login()` command with the `$Portal setvp` or `Portal.setvp()` command. It is possible to set the virtual portal during a session, but the session becomes effective only during the `$Portal login` command. The virtual portal is specified by the URL context. The URL context is the part of the home URL that identifies the virtual portal. If `$Portal setvp` or `Portal.setvp()` is started without a URL context, the default virtual portal is set.

Jython example:

```
# example: set the virtual portal and execute a portal login
# in the example, the virtual portal URL context is employees,
# which would correspond with a base URL of
'/wps/myportal/employees'

Portal.setvp("employees")

Portal.login()
```

Jacl example:

```
# example: set the virtual portal and execute a portal login
# in the example, the virtual portal URL context is employees,
# which would correspond with a base URL of '/wps/myportal/employees'

$Portal setvp employees

$Portal login
```

Examples:

The following are examples for deleting portlets and adding portlets.

Delete portlets

Jython example:

```
# delete all welcome-portlets from all pages of a user
# see the Authentication section for portal_login and
portal_logout
portal_login(user_ID, password)
for page in Content.search("pages").split():
  Content.select(page)
  for c in Layout.search("control", "commonnamehas",
"Welcome").split():
    Layout.delete(c)

portal_logout()
```

Jacl example:

```
# delete all welcome-portlets from all pages of a user
# see the Authentication section for portal_login and portal_logout
portal_login
foreach page [$Content search pages] {
  $Content select $page
  foreach c [$Layout search control commonnamehas Welcome] {
    $Layout delete $c
   }
 }
portal_logout
```

Add portlets

Jython example:

```
# add a FunPortlet next to each WeatherPortlet

# procedure: add a portlet next to a control
# this changes the current selection of the Layout bean
def add_portlet(control, portlet):
  Layout.select(control)
  pos = Layout.get("position")
  pos = pos + 1
  Layout.select("the", parent)
  Layout.create("control", portlet, "select")
  Layout.move("to", pos)

# main program
# see the Authentication section for portal_login and
portal_logout

portal_login(user_ID, password)
fun = Portlet.find("portlet", "nameis", "FunPortlet")

for page in Content.search("pages").split():
  Content.select(page)
  for c in Layout.search("control", "commonnamehas",
"Weather").split():
    add_portlet(c, fun)

portal_logout()
```

Jacl example:

```
# add a FunPortlet next to each WeatherPortlet

# procedure: add a portlet next to a control
# this changes the current selection of the Layout bean
proc add_portlet { control portlet } {
  global Layout
  $Layout select $control
  set pos [$Layout get position]
  set pos [expr $pos + 1]
  $Layout select the parent
  $Layout create control $portlet select
  $Layout move to $pos
}

# main program
# see the Authentication section for portal_login and portal_logout

portal_login
set fun [$Portlet find portlet nameis FunPortlet]

foreach page [$Content search pages] {
  $Content select $page
  foreach c [$Layout search control commonnamehas Weather] {
    add_portlet $c $fun
  }
}
portal_logout
```

Troubleshooting:

The following solutions help solve the troubleshooting issues.

- Connectivity problem / MBean not found - connected to wrong application server
- Bean is not enabled - not logged in
- Layout bean is not enabled - no page that is selected in Content bean
- PacList bean is not enabled - no PacList object loaded
- No method that is named "xxx" is found - typographical error or capitalization in method name, check bean help
- No method that is named "xxx" with y arguments is found - wrong syntax, check bean help

Property file format:

You can provide locale-specific attributes for a set of locales in a Java property file. The generic format of Java property files is described in the Java API documentation for method load in class `java.util.Properties`. The description here covers the particular properties that are interpreted when locale-specific attributes are loaded from a portal script.

The property files are loaded by the script interpreter. They must be on the client workstation where the script is run.

Note: A property file must be encoded in the ISO 8859-1 character encoding format.

Here is an example of a property file with no prefix.

Jython example:

```
locales = en de

en.title = English Title
en.description = A description, in English.

de.title = Deutscher Titel
de.description = Eine Beschreibung auf Deutsch.
```

At the core of the file, is the property `locales`, which holds a white space separated list of the locales for which attributes are defined in the file. Only the locales that are listed here are interpreted when the property file is loaded.

The actual attribute values for each locale are defined as separate properties. The key for these properties is composed of the locale and the attribute name, which is separated by a dot. The attribute name is `title` or `description`, the locale must match the string that is listed in the `locales` property. Case is significant for property keys.

There is no fallback algorithm when locale-specific attributes are loaded. If a property `title.en` is defined, it is not considered when the title for locale en_US is required.

To combine different sets of local data into a single property file, prefixes can be used. All properties of a set must use the same prefix, which is separated from the property name by a dot. Here is an example of a property file with two sets, by using the prefixes `leisure` and `finance`.

Jython example:

```
leisure.locales = en fr
leisure.en.title = Leisure Page
leisure.fr.title = Page de Loisir

finance.locales = en de
finance.en.title = Finance Page
finance.en.description = Holds financial info portlets.
finance.de.title = Finanzseite
```

You can also load property files in the scripting format by using the XML configuration interface. To complete this step, specify the locale as part of the prefix in a `localedata` tag.

Index paths:

Index paths are used to refer to components in the component hierarchy. They are based on the index or position of a component in the surrounding container. An index path is a multi-dimensional index of a component, where the number of dimensions is equal to the depth of the component in the tree. Index paths are absolute or relative, depending on whether there is a leading slash. Absolute paths start with a leading slash and are resolved from the root component. Relative paths start with a number and are resolved from the selected component. Trailing slashes are irrelevant.

/ The root component.

/0 The first child of the root component.

/1 The second child of the root component.

...

/0/0 The first child of the first child of the root component.

/0/1 The second child of the first child of the root component.

...

/5/1/3 The fourth child of the second child of the sixth child of the root component.

...

0 The first child of the current component.

1 The second child of the current component.

...

1/0 The first child of the second child of the current component.

...

Web content administration tools

IBM Web Content Manager includes tasks and tools to help maintain your content management system. For example, use the member fixer task to resolve renamed or deleted users and user groups. Use the workflow checker and updater tools to modify workflow security settings, reschedule pending actions, and add workflow to items. Web Content Manager also includes tools to assist with library and item management, and item and version history management.

"The web content member fixer task" on page 1177
Use the member fixer task to check whether any users or groups that are referenced in IBM Web Content Manager items have been renamed or deleted and fix these references.

"Update security task" on page 1187
Use the update security task to apply inherited access permissions and remove existing item access permissions for all items or all items of a specific type. This task is useful as a post-migration step, or if you are applying major changes to your inheritance settings.

"Managing workflows by using the workflow checker tool" on page 1189
Use the workflow checker tool to update workflow security settings, or reschedule pending workflow actions.

"Updating workflows by using the workflow update tool" on page 1191
Use the workflow update tool to add a workflow to existing items that aren't already workflow enabled.

"Clearing item history" on page 1192
You use the clear history tool to clear the history of an item.

"Clearing version history" on page 1194
You use the clear versions tool to clear the version history of an item.

"Resetting the web content event log" on page 1195
From time to time, you might need to reset the web content event log. The event log can be reset only on a syndicator server. Any changes that are made by resetting the event log are then syndicated to its corresponding subscribers. In most cases, you reset the event log on the server you imported or migrated data onto, or on a syndicator to troubleshoot syndication problems in a syndication relationship.

"The export cache settings task" on page 1197
Use the export cache settings task to display a summary of the current cache settings of your system.

CF03 CF03 "How to manage plug-in tag usage" on page 1197
Plug-in tags are used to reference rendering plug-ins in Web content. Use the `run-wcm-admin-task-tag-usage` task to find or update plug-in tags in your Web content.

"Exporting and importing web content libraries" on page 1200
IBM Web Content Manager provides two methods for exporting and importing web content libraries: an export or import that operates on one library, and an export or import that creates a separate copy of a library. With either method, you can export the contents of a web content library to disk and import this data into another web content server. If you're working with a copy of a library, you can also import that library into the same web content server multiple times, resulting in a new library after each import without affecting previous copies. Exporting and importing libraries can be used to make a backup copy of a web content library and can also be used to move data between servers. However, this function cannot be used to send updates, deletes, and moves. It is only suitable for populating new items.

"Deleting libraries by using the delete libraries tool" on page 1213
Use the delete libraries tool to delete multiple libraries, even where there are references between the selected libraries.

"How to clone a web content repository" on page 1214
Syndicating items from one server to another, either after migration or to roll out a new server, can take a long time. Your database backup and restore features can be used to clone data from one repository to another, making your system ready for syndication to be used from then on for incremental updates.

The web content member fixer task

Use the member fixer task to check whether any users or groups that are referenced in IBM Web Content Manager items have been renamed or deleted and fix these references.

Member fixer is used to:

- Fix references to users in library and item level access settings that refer to users and groups from a user repository where the structure of the user repository has been altered. For example, an LDAP transfer might have been run, or the LDAP schema might have changed, or users and groups might have been moved in the LDAP.
- Fix references to users in item level access settings that refer to users and groups who have been deleted from the user repository.

The member fixer task's function is to check all of the items in a specified library for references to users and groups that no longer exist in the current user repository. In report mode, it reports all the references to members. In fix mode, these references can be fixed, either by replacing them with references to members that exist, or by removing the references. The **`fix`** parameter determines whether the member fixer task runs in report or fix mode.

References to members in library items contain the distinguished name of the member or a unique ID for the member. This unique ID is an internal ID that is unique over time, and is different to the distinguished name. This means if a member is deleted and another member is created with the same distinguished name, the two members will have different unique IDs. The **`mismatchedId`** parameter can be used to update or remove references from web content items to users with these unique IDs.

When a member that has been given permissions on a library is deleted, the member permissions are entirely removed from the library, so that any inherited permissions for items in the library will also be removed. Therefore, the member fixer task cannot be used to update these permissions to a different member. However, when an LDAP transfer is carried out, the member permissions on the library are maintained. So, the member fixer task can be run after an LDAP transfer to update or remove these permissions

"How to use the member fixer task"
Enable the member fixer task, create custom mappings, and then run the task.

"Member fixer with syndication" on page 1183
You can configure your system to automatically run the member fixer tool when syndicating. The member fixer is run on the subscriber during syndication. It is run against items that have just been syndicated. Details of the member fixer operations are included in the syndication report.

"Member fixer task frequently asked questions" on page 1184
Some frequently asked question about how to use the web content member fixer task.

How to use the member fixer task

Enable the member fixer task, create custom mappings, and then run the task.

Enabling the member fixer tool

You must first enable the member fixer by adding the following parameters to the **WCM WCMConfigService** service using the WebSphere Integrated Solutions Console:

- **connect.businesslogic.module.memberfixer.class=**com.aptrix.pluto.security.MemberFixerModul
- **connect.businesslogic.module.memberfixer.remoteaccess=**true
- **connect.businesslogic.module.memberfixer.autoload=**false

Custom Mapping

To update a reference to a member that does not exist with a member that does exist, member mappings can be defined in a custom mapping file. Where the member fixer task does not find a mapping in this file for a member, it will search the user repository for members with the same ID as the member that no longer exists. If such a member is found, it will update the reference with this user or group, or remove the reference, as specified by the altDn parameter. If no such member is found, this member is classified as 'invalid' and will be updated or removed as specified by the `invalidDn` parameter.

If custom mapping is required you must perform the following steps to map the user and group domain names before running the member fixer task:

1. Update the following properties in the *wp_profile_root*/PortalServer/wcm/shared/app/config/wcmservices/MemberFixerModule.properties file:

   cn=contentAuthors,dc=lotus,o=ibm->cn=contentEditors,dc=rational,o=ibm
   This format is used to completely replace one distinguished name with another.

   cn=[ID],dc=websphere,o=ibm->cn=[ID],dc=tivoli,o=ibm
   This format is used to replace part of a distinguished name. This example will change all of the distinguished name except the common name.

Further examples are listed in the `MemberFixerModule.properties` file.

2. You then run the member fixer task using the **-DaltDn** option as details in the following section.

Running the Member Fixer task:

1. Open a command prompt.

   Library parameters in steps 2 and 3:

   - The library specified in the command is the library to be scanned by the member fixer task. If the query parameter "library" is omitted, the default library that has been configured with the `defaultLibrary` property in the `WCM WCMConfigService` service is used.

2. To create a report of users or groups referenced in Web Content Manager items that need fixing, run the following command from the *wp_profile_root*`/ConfigEngine` directory:

   Windows

   ```
   ConfigEngine.bat run-wcm-admin-task-member-fixer
   -DPortalAdminId=username -DPortalAdminPwd=password
   -DWasUserId=username -DWasPassword=password -Dlibrary="MyLibrary"
   ```

   Linux

   ```
   ./ConfigEngine.sh run-wcm-admin-task-member-fixer
   -DPortalAdminId=username -DPortalAdminPwd=password
   -DWasUserId=username -DWasPassword=password -Dlibrary="MyLibrary"
   ```

   IBM i

   ```
   ConfigEngine.sh run-wcm-admin-task-member-fixer
   -DPortalAdminId=username -DPortalAdminPwd=password
   -DWasUserId=username -DWasPassword=password -Dlibrary="MyLibrary"
   ```

   Note: An administrator user name and password is not required if you have already specified the portal administrator username and password using the **PortalAdminId** and **PortalAdminPwd** settings in the `wkplc.properties` file.

   Note: Before you progress to the next step and run the member fixer task in fix mode, ensure that the report mode indicates that the updates will happen as you require. A summary of the updates will be shown by the command.

   A detailed report containing the updates that will be made for each item will be shown in the SystemOut.log file located in *wp_profile_root*`\logs\WebSphere_Portal`. If the report indicates that the update will not happen as required, change the member fixer task parameters and run the report mode again. Repeat this process until you are satisfied that the fixes will be applied correctly. This is important because the fixes made by the member fixer task when run in fix mode may not be easy to undo if incorrect fixes are applied.

3. If there have been changes to users and groups, update the items that reference them by running the run-wcm-admin-task-member-fixer task. If the member fixer task indicates that certain mismatched member conditions exist, append the specified parameters to the command.

Table 160. Member fixer conditions

Condition description	Command to correct condition
Nonexistent users or groups have alternate distinguished names (DNs) available.	• To update references to nonexistent users or groups with the DN values that are mapped in the `MemberFixerModule.properties` file, append **`-DaltDn=update`** to the command. • To remove references to nonexistent users or groups append `-DaltDn=remove` to the command.
If users or groups have invalid distinguished names (DNs) the report lists these as "invalid". This means the distinguished name doesn't exist and there is no alternate distinguished name available.	• To remove references to users and groups that have invalid distinguished names append **`-DinvalidDn=remove`** to the command. • To update references to users and groups that have invalid distinguished names with the portal administrator user distinguished name, append **`-DinvalidDn=update`** to the command.
Users or groups have been found with mismatched unique IDs.	• To fix the mismatched unique IDs append **`-DmismatchedId=update`** to the command. • To remove references to users and groups with mismatched unique IDs append **`-DmismatchedId=remove`** to the command.

Windows

```
ConfigEngine.bat run-wcm-admin-task-member-fixer
-DPortalAdminId=username -DPortalAdminPwd=password
-DWasUserId=username -DWasPassword=password -Dlibrary="MyLibrary"
-Dfix=true
```

Linux

```
./ConfigEngine.sh run-wcm-admin-task-member-fixer
-DPortalAdminId=username -DPortalAdminPwd=password
-DWasUserId=username -DWasPassword=password -Dlibrary="MyLibrary"
-Dfix=true
```

IBM i

```
ConfigEngine.sh run-wcm-admin-task-member-fixer
-DPortalAdminId=username -DPortalAdminPwd=password
-DWasUserId=username -DWasPassword=password -Dlibrary="MyLibrary"
-Dfix=true
```

Note: An administrator user name and password is not required if you have already specified the portal administrator username and password using the **`PortalAdminId`** and **`PortalAdminPwd`** settings in the `wkplc.properties` file.

4. After the member fixer task runs, review the log output to verify that the task ran correctly. The member fixer task may not be able to save items that fail validation, such as items that contain invalid fields. You must edit these items to make them valid and then run the member fixer task again.

Running the Member Fixer in a federated security environment

In a federated security environment with multiple realms, you can specify the realm to run the member fixer task on by adding `-Drealm=realmName` to the command. If this parameter is omitted the default realm will be used.

The member fixer task will check whether there are any members and groups referenced in items that contain any of the base distinguished names defined for the specified realm and fix these references. References to members can only be updated with references to members in the specified realm.

Additionally, the member fixer task can be used to check whether there are any members and groups referenced in items that are not under any of the base distinguished names defined for any of the realms in the environment and fix these references. To do this, follow the same steps described for a single realm environment and add `-DnoRealmDn=true` to the command.

In a federated security environment with multiple realms, the member fixer task should be run for each realm in turn to make sure that all of the references are fixed.

Preserving dates

You can preserve the last modified date of items updated by the member fixer task by adding **`-DpreserveDates=true`** to the command. Otherwise, the last modified date is updated when the member fixer task is run.

Restricting which items types to fix

You can restrict which objects types are processed by appending **`-DrestrictOn=ItemType`** to the command.

For example:

- *content*
- *folder*
- *project*
- *style* for presentation templates
- *template* for authoring templates
- *taxonomy*
- *category*
- *SiteArea*
- *Workflow*
- *WorkflowStage*
- *WorkflowAction*
- *Cmpnt* for components

You can restrict multiple object types by separating the types with a comma (**,**). For example, to restrict workflows and workflow stages, you can specify **`-DrestrictOn=Workflow,WorkflowStage`**.

If not specified, all object types will be updated.

Running the task for all libraries

You can run this task for all libraries by replacing the option `-Dlibrary=`*`libraryName`* with the option **`-DallLibraries=true`** in the command. If neither option is specified, this task will process the default library that has been configured in the **WCM WCMConfigService** service using the WebSphere Integrated Solutions Console.

Running the task on a virtual portal

When running this task on a virtual portal you must add either `-DVirtualPortalHostName=`*name* or `-DVirtualPortalContext=`*context* to the command.

Parameters to set for large repositories

To prevent your session timing out before the task has finished, you can append the option `-DsessionTimeOut=`*timeOut* to the command. This sets the number of seconds in which the task must complete before its session will timeout. The default session timeout is 14,440 seconds, which is 4 hours. For large repositories you should increase this setting. For example: `-DsessionTimeOut=36000`, which is 10 hours.

Examples

These options can be combined when the conditions occur at the same time. For example, if alternate DNs are available for nonexistent users and groups and there are mismatched unique IDs, you would use the following command:

Windows

```
ConfigEngine.bat run-wcm-admin-task-member-fixer
-DPortalAdminId=username -DPortalAdminPwd=password
-DWasUserId=username -DWasPassword=password -Dlibrary="MyLibrary"
-Dfix=true -DaltDn=update -DmismatchedId=update
```

Linux

```
./ConfigEngine.sh run-wcm-admin-task-member-fixer
-DPortalAdminId=username -DPortalAdminPwd=password
-DWasUserId=username -DWasPassword=password-Dlibrary="MyLibrary"
-Dfix=true -DaltDn=update -DmismatchedId=update
```

IBM i

```
ConfigEngine.sh run-wcm-admin-task-member-fixer
-DPortalAdminId=username -DPortalAdminPwd=password
-DWasUserId=username -DWasPassword=password -Dlibrary="MyLibrary"
-Dfix=true -DaltDn=update -DmismatchedId=update
```

If there have been changes to users and groups that are within the specified realm or that are not within any realm, update the items that reference them by entering the following command:

Windows

```
ConfigEngine.bat run-wcm-admin-task-member-fixer
-DPortalAdminId=username -DPortalAdminPwd=password
-DWasUserId=username -DWasPassword=password -Drealm=MyRealm
-Dlibrary="MyLibrary" -Dfix=true -DnoRealmDn=true
```

Linux

```
./ConfigEngine.sh run-wcm-admin-task-member-fixer
-DPortalAdminId=username -DPortalAdminPwd=password
-DWasUserId=username -DWasPassword=password -Drealm=MyRealm
-Dlibrary="MyLibrary" -Dfix=true -DnoRealmDn=true
```

IBM i

```
ConfigEngine.sh run-wcm-admin-task-member-fixer
-DPortalAdminId=username -DPortalAdminPwd=password
-DWasUserId=username -DWasPassword=password -Drealm=MyRealm
-Dlibrary="MyLibrary" -Dfix=true -DnoRealmDn=true
```

Member fixer with syndication

You can configure your system to automatically run the member fixer tool when syndicating. The member fixer is run on the subscriber during syndication. It is run against items that have just been syndicated. Details of the member fixer operations are included in the syndication report.

To run the member fixer during syndication add or update the following properties in the `WCM WCMConfigService` service using the WebSphere Integrated Solutions Console:

Table 161. Member fixer syndication parameters

Parameter	Details
deployment.fixMembers	To enable member fixer to be run during syndication, set this parameter to *true*.
syndication.memberfixer.altDn	To update references to nonexistent users or groups with the portal administrator user distinguished name, set this parameter to *update*. To remove references to nonexistent users or groups, set this parameter to *remove*.
syndication.memberfixer.invalidDn	To update references to users or groups that have invalid distinguished names with the portal administrator user distinguished name, set this parameter to *update*. To remove references to users or groups that have invalid distinguished names, set this parameter to *remove*.
syndication.memberfixer.mismatchid	To fix references to users and groups with mismatched unique IDs, set this parameter to *update*. To remove references to users and groups with mismatched unique IDs, set this parameter to *remove*.
syndication.memberfixer.fixCase	This parameter is used to define how to treat case differences when updating or fixing distinguished names. To leave the case unchanged, set this parameter to *update*. To convert the case to lowercase, set this parameter to *lower*.
syndication.memberfixer.realm	In a federated security environment with multiple realms, you must specify the name of the realm to run the member fixer against using this parameter.
syndication.memberfixer.norealmdn	In a federated security environment with multiple realms, the member fixer task can be used to check whether there are any users and groups that are referenced in items that are not under any of the base distinguished names that are defined for the realm and fix these references. To enable this, set this parameter to *true*.

Note: The Member fixer, when run automatically via Syndication, preserves the dates of the updated items.

Member fixer task frequently asked questions

Some frequently asked question about how to use the web content member fixer task.

How can users or groups in web content items be replaced if they still exist in the user repository or LDAP?

The member fixer task cannot replace any valid users that exist in the user repository or LDAP.

How can last modified dates be preserved when web content items are updated by the member fixer task?

Use the **-DpreserveDates=true** option. See "How to use the member fixer task" on page 1178 for details.

How do I avoid session time-outs before the member fixer task is finished?

The session timeout needs to be increased for long running member fixer tasks. The default is 14,440 seconds which is 4 hours. For example, to set the session timeout to 10 hours add **-DsessionTimeout=36000** to the task request. See "How to use the member fixer task" on page 1178 for details.

How do I restrict the member fixer task to only operate on certain web content item types?

Use the **-DrestrictOn=ItemType** option. See "How to use the member fixer task" on page 1178 for details.

How can users or groups be deleted from web content items when they have been removed from the user repository or LDAP?

For example:

1. A user has left the organization and has been removed from the user repository. This user needs to be removed from web content items they previously had access to.
2. A functional group that is no longer required has been deleted from the user repository. This group needs to be removed from web content items they previously had access to.

Use the **-DinvalidDn=remove** and **-Dfix=true** options.

For example:

Windows

```
ConfigEngine.bat run-wcm-admin-task-member-fixer
-DPortalAdminId=username -DPortalAdminPwd=password
-DWasUserId=username -DWasPassword=password
-Dlibrary="MyLibrary" -DinvalidDn=remove -Dfix=true
```

Linux

```
./ConfigEngine.sh run-wcm-admin-task-member-fixer
-DPortalAdminId=username -DPortalAdminPwd=password
-DWasUserId=username -DWasPassword=password
-Dlibrary="MyLibrary" -DinvalidDn=remove -Dfix=true
```

IBM i

```
ConfigEngine.sh run-wcm-admin-task-member-fixer
-DPortalAdminId=username -DPortalAdminPwd=password
-DWasUserId=username -DWasPassword=password
-Dlibrary="MyLibrary" -DinvalidDn=remove -Dfix=true
```

How can users or groups be replaced in web content items by a specific user or group when they have been removed from the user repository or LDAP?

For example, a user or group has been removed from the user repository. Another user or group is continuing the duties of the removed member and needs to have access to their documents.

To fix this, use the **-DaltDn=update** and **-Dfix=true** options.

For this option, it is necessary to add member mappings in the custom mapping file: *wp_profile_root*/PortalServer/wcm/shared/app/config/wcmservices/MemberFixerModule.properties

The member mappings for one user or group to be replaced with another user or group use this format: `Old DN -> New DN`

For example, to replace any instance of `cn=group1,dc=lotus,o=ibm` with `cn=group2,dc=rational,o=ibm`, use:

```
cn=group1,dc=lotus,o=ibm -> cn=group2,dc=rational,o=ibm
```

Each member mapping corresponds to one user or group to be replaced. Once all the member mappings have been made, restart the portal server and execute the member fixer task:

Windows

```
ConfigEngine.bat run-wcm-admin-task-member-fixer
-DPortalAdminId=username -DPortalAdminPwd=password
-DWasUserId=username -DWasPassword=password
-Dlibrary="MyLibrary" -DaltDn=update -Dfix=true
```

Linux

```
./ConfigEngine.sh run-wcm-admin-task-member-fixer
-DPortalAdminId=username -DPortalAdminPwd=password
-DWasUserId=username -DWasPassword=password
-Dlibrary="MyLibrary" -DaltDn=update -Dfix=true
```

IBM i

```
ConfigEngine.sh run-wcm-admin-task-member-fixer
-DPortalAdminId=username -DPortalAdminPwd=password
-DWasUserId=username -DWasPassword=password
-Dlibrary="MyLibrary" -DaltDn=update -Dfix=true
```

How can users or groups be replaced in web content items where user common names are unchanged but their distinguished names have been changed in the user repository or LDAP?

For example, an organization unit or organization name changes in the user repository, but the common name of users and groups remain the same. There could potentially be hundreds or thousands of users affected by this organization unit change and listing each member explicitly in a custom mapping entry in the mapping file is not feasible. Only one member mapping is required when common names remain unchanged.

To fix this, use the **-DaltDn=update** and **-Dfix=true** options.

For this option, it is necessary to add member mappings in the custom mapping file: *wp_profile_root*/PortalServer/wcm/shared/app/config/wcmservices/MemberFixerModule.properties

Create member mappings for changing multiple users or groups DN with the exception of the common name portion. Once all the member mappings have been made, restart the portal server and execute the member fixer task.

For example, To replace all DNs like `cn=[ID],dc=websphere,o=ibm` with `cn=[ID],dc=tivoli,o=ibm`, use:

```
cn=[ID],dc=websphere,o=ibm -> cn=[ID],dc=tivoli,o=ibm
```

Each member mapping corresponds to one user or group to be replaced. Once all the member mappings have been made, restart the portal server and execute the member fixer task:

Windows

```
ConfigEngine.bat run-wcm-admin-task-member-fixer
-DPortalAdminId=username -DPortalAdminPwd=password
-DWasUserId=username -DWasPassword=password
-Dlibrary="MyLibrary" -DaltDn=update -Dfix=true
```

Linux

```
./ConfigEngine.sh run-wcm-admin-task-member-fixer
-DPortalAdminId=username -DPortalAdminPwd=password
-DWasUserId=username -DWasPassword=password
-Dlibrary="MyLibrary" -DaltDn=update -Dfix=true
```

IBM i

```
ConfigEngine.sh run-wcm-admin-task-member-fixer
-DPortalAdminId=username -DPortalAdminPwd=password
-DWasUserId=username -DWasPassword=password
-Dlibrary="MyLibrary" -DaltDn=update -Dfix=true
```

How can users or groups be replaced in web content items by the administrator user when they have been removed from the user repository or LDAP?

For example:

1. A user has left the organization and has been removed from the user repository. The administrator user needs to replace the removed user in all the web content items that references that user.
2. A group has been deleted from the user repository. The administrator user needs to replace the removed group in all the web content items that references that group.

To fix this, use the **-DinvalidDn=update** and **-Dfix=true** options.

For example:

Windows

```
ConfigEngine.bat run-wcm-admin-task-member-fixer
-DPortalAdminId=username -DPortalAdminPwd=password
-DWasUserId=username -DWasPassword=password
-Dlibrary="MyLibrary" -DinvalidDn=update -Dfix=true
```

Linux

```
./ConfigEngine.sh run-wcm-admin-task-member-fixer
-DPortalAdminId=username -DPortalAdminPwd=password
-DWasUserId=username -DWasPassword=password
-Dlibrary="MyLibrary" -DinvalidDn=update -Dfix=true
```

IBM i

```
ConfigEngine.sh run-wcm-admin-task-member-fixer
-DPortalAdminId=username -DPortalAdminPwd=password
-DWasUserId=username -DWasPassword=password
-Dlibrary="MyLibrary" -DinvalidDn=update -Dfix=true
```

Distinguished names for users and groups remain unchanged in the user repository, but users or groups cannot access web content items.

For example, web content items store a member's DN as well as a unique identifier of the LDAP entry of the user. When a member in the LDAP is

deleted and then recreated with the same details, such as the same distinguished name, the identifier in the user repository is different to the one stored in the web content Item.

To fix this, use the **-DmismatchedId=update** and **-Dfix=true** options.

For example:

Windows

```
ConfigEngine.bat run-wcm-admin-task-member-fixer
-DPortalAdminId=username -DPortalAdminPwd=password
-DWasUserId=username -DWasPassword=password
-Dlibrary="MyLibrary" -DmismatchedId=update -Dfix=true
```

Linux

```
./ConfigEngine.sh run-wcm-admin-task-member-fixer
-DPortalAdminId=username -DPortalAdminPwd=password
-DWasUserId=username -DWasPassword=password
-Dlibrary="MyLibrary" -DmismatchedId=update -Dfix=true
```

IBM i

```
ConfigEngine.sh run-wcm-admin-task-member-fixer
-DPortalAdminId=username -DPortalAdminPwd=password
-DWasUserId=username -DWasPassword=password
-Dlibrary="MyLibrary" -DmismatchedId=update -Dfix=true
```

Update security task

Use the update security task to apply inherited access permissions and remove existing item access permissions for all items or all items of a specific type. This task is useful as a post-migration step, or if you are applying major changes to your inheritance settings.

Running the Update Security task

1. Open a command line.
2. To apply inherited access permissions to all items in a library named "MyLibrary" for all roles, run the following command from the *wp_profile_root*/ConfigEngine directory:
   - IBM i: `ConfigEngine.sh run-wcm-admin-task-update-security -DPortalAdminId=username -DPortalAdminPwd=password -DWasPassword=password -Dlibrary=MyLibrary -DinheritPerms=apply -DlibSecurity=true`
   - Linux: `./ConfigEngine.sh run-wcm-admin-task-update-security -DPortalAdminId=username -DPortalAdminPwd=password -DWasPassword=password -Dlibrary=MyLibrary -DinheritPerms=apply -DlibSecurity=true`
   - Windows: `ConfigEngine.bat run-wcm-admin-task-update-security -DPortalAdminId=username -DPortalAdminPwd=password -DWasPassword=password -Dlibrary=MyLibrary -DinheritPerms=apply -DlibSecurity=true`

   Note: An administrator user name and password is not required if you already specified the portal administrator user name and password with the **PortalAdminId** and **PortalAdminPwd** settings in the wkplc.properties file.
3. To remove inherited access permissions to all items in a library named "MyLibrary" for all roles, run the following command:
   - IBM i: `ConfigEngine.sh run-wcm-admin-task-update-security -DPortalAdminId=username -DPortalAdminPwd=password -DWasPassword=password -Dlibrary=MyLibrary -DinheritPerms=remove`

- Linux: `./ConfigEngine.sh run-wcm-admin-task-update-security -DPortalAdminId=username -DPortalAdminPwd=password -DWasPassword=password -Dlibrary=MyLibrary -DinheritPerms=remove`
- Windows: `ConfigEngine.bat run-wcm-admin-task-update-security -DPortalAdminId=username -DPortalAdminPwd=password -DWasPassword=password -Dlibrary=MyLibrary -DinheritPerms=remove`

4. To remove existing item access permissions for all items in a library named "MyLibrary" for all roles, run the following command:
   - IBM i: `ConfigEngine.sh run-wcm-admin-task-update-security -DPortalAdminId=username -DPortalAdminPwd=password -DWasPassword=password -Dlibrary=MyLibrary -DremoveExistingPerms=true`
   - Linux: `./ConfigEngine.sh run-wcm-admin-task-update-security -DPortalAdminId=username -DPortalAdminPwd=password -DWasPassword=password -Dlibrary=MyLibrary -DremoveExistingPerms=true`
   - Windows: `ConfigEngine.bat run-wcm-admin-task-update-security -DPortalAdminId=username -DPortalAdminPwd=password -DWasPassword=password -Dlibrary=MyLibrary -DremoveExistingPerms=true`

Running the Update Security task for all libraries

You can run the Update Security task for all libraries by replacing the option **-Dlibrary**=*libraryName* with the option **-DallLibraries=true** in the command. If neither option is specified, the Update Security task processes the default library.

Restricting the task to update only specified items types

You can restrict which objects types are processed by appending **-DrestrictOn=ItemType** to the command. For example:

- *content*
- *folder*
- *project*
- *style* for presentation templates
- *template* for authoring templates
- *taxonomy*
- *category*
- *SiteArea*
- *Workflow*
- *WorkflowStage*
- *WorkflowAction*
- *Cmpnt* for components

If not specified, the security of all object types is updated.

Running the task on a virtual portal

When you run this task on a virtual portal, you must add either **-DVirtualPortalHostName**=*name* or**-DVirtualPortalContext**=*virtual_portal_context* to the command.

Preserving dates

You can preserve the last modified date of items that are updated by the update security task by adding **-DpreserveDates=true** to the command. Otherwise, the last modified date is updated when the update security task is run.

Defining the session timeout

To prevent your session from timing out before the task finishes, you can append the option **-DsessionTimeOut**=*timeOut* to the command. This parameter sets the number of seconds in which the task must complete before its session will timeout. The default session timeout is 14,440 seconds, which is 4 hours. For large repositories, increase this setting. For example: **-DsessionTimeOut=36000**, which is 10 hours.

Examples

All of the options can be combined. For instance, run the following task to accomplish the following tasks:

- Remove existing item access permissions
- Apply inherited access permissions to content in the library called 'MyLibrary'
- Preserve the last modified dates of the items
- IBM i: `ConfigEngine.sh run-wcm-admin-task-update-security -DPortalAdminPwd=`*`password`* `-Dlibrary=`*`MyLibrary`* `-DremoveExistingPerms=true -DinheritPerms=apply -DrestrictOn=Content -DpreserveDates=true`
- Linux: `./ConfigEngine.sh run-wcm-admin-task-update-security -DPortalAdminPwd=`*`password`* `-Dlibrary=`*`MyLibrary`* `-DremoveExistingPerms=true -DinheritPerms=apply -DrestrictOn=Content -DpreserveDates=true`
- Windows: `ConfigEngine.bat run-wcm-admin-task-update-security -DPortalAdminPwd=`*`password`* `-Dlibrary=`*`MyLibrary`* `-DremoveExistingPerms=true -DinheritPerms=apply -DrestrictOn=Content -DpreserveDates=true`

Managing workflows by using the workflow checker tool

Use the workflow checker tool to update workflow security settings, or reschedule pending workflow actions.

Before you begin

You must first enable the workflow update tool by adding the following parameters to the **WCM WCMConfigService** service by using the WebSphere Integrated Solutions Console:

```
connect.businesslogic.module.workflowcontrolchecker.class=com.aptrix.pluto.workflow.WorkflowContro
connect.businesslogic.module.workflowcontrolchecker.remoteaccess=true
connect.businesslogic.module.workflowcontrolchecker.autoload=false
```

Procedure

1. Log in to the portal as an administrator.
2. Open one of the following URLs in the browser:

   ```
   http://[HOST]:[PORT]/wps/wcm/myconnect/?MOD=WorkflowControlChecker
   &library=libraryname
   &updateDocSecurity=true&fix=true
   ```

   ```
   http://[HOST]:[PORT]/wps/wcm/myconnect/?MOD=WorkflowControlChecker
   &library=libraryname
   &rescheduleActions=true&fix=true
   ```

Note: If the "`library`" parameter is omitted, the default library that is configured in the **WCM WCMConfigService** service is used.

Note: If the "`&fix=true`" parameter is omitted, the tool runs in read-only mode and generates a report.

Results

&library
Enter a library name. If the `library` parameter is omitted, the default library that is configured in the **WCM WCMConfigService** service by using the WebSphere Integrated Solutions Console.

To run this tool against all libraries, you instead use `&alllibraries=true`. If you have many libraries, this process can take a long time to run, so it might be better to run this tool against individual libraries instead of all libraries.

&updateDocSecurity
If set to true, the workflowed item is saved and the workflow stage security is reapplied. This parameter is set to false by default.

&rescheduleActions
When set to true, workflow actions are rescheduled to run again. This parameter is set to false by default.

&restrictOn
Enter the items types to run the workflow checker tool against. Valid parameters are:

- `Content`
- `Cmpnt`
- `Template`
- `Site`
- `SiteArea`
- `Style`
- `Taxonomy`
- `Category`
- `Workflow`
- `WorkflowStage`
- `WorkflowAction`

&numberOfJcrOperationsPerLogin
This parameter is used to define the number of operations for 1 JCR login. Used to help with memory consumption.

&preserve_dates
When set to true, the current last modified date of the item is preserved. This parameter is set to false by default.

Running the tool on a virtual portal

There are two methods available when the tool is run on a virtual portal:

Using the URL context of a virtual portal:

```
http://[HOST]:[PORT]/wps/wcm/myconnect/[url_context]?MOD=WorkflowControlChecker
&library=libraryname
&updateDocSecurity=true&fix=true
```

Using the host name of a virtual portal:

```
http://[Virtual_HOST]:[PORT]/wps/wcm/myconnect?MOD=WorkflowControlChecker
&library=libraryname
&updateDocSecurity=true&fix=true
```

Updating workflows by using the workflow update tool

Use the workflow update tool to add a workflow to existing items that aren't already workflow enabled.

Before you begin

You must first enable the workflow update tool by adding the following parameters to the WCM WCMConfigService service by using the WebSphere Integrated Solutions Console:

- connect.businesslogic.module.workflowenablement.class=com.aptrix.pluto.workflow.Workflo
- connect.businesslogic.module.workflowenablement.remoteaccess=true
- connect.businesslogic.module.workflowenablement.autoload=false

Procedure

1. Log in to the portal as an administrator.
2. Open the following URL in the browser and specify which workflow you want to apply and the library that contains the items you want to apply the workflow to:

   ```
   http://[HOST]:[PORT]/wps/wcm/myconnect/?MOD=workflowenablement
   &library=libraryname
   &workflow=workflowname&fix=true
   ```

   Note: If the "library" parameter is omitted, the default library that is configured in the **WCM WCMConfigService** service is used.

   Note: If the "&fix=true" parameter is omitted, the tool runs in read-only mode and generates a report.

Results

Specifying the workflow:

If the workflow is in a different library to the workflow content, you must also specify the library name. For example: workflow=libraryName/WorkflowName

Specifying a workflow stage:

You can specify the workflow stage to move the updated items to by adding &workflowstage=*workflowstagename* to the URL. The stage that is specified here must have a status of published. You cannot assign items to stages with a status of draft. If not specified, items are assigned to the first stage with a status of published.

If the workflow stage is in a different library to the workflow content, you must also specify the library name. For example: workflowstage=libraryName/WorkflowStageName

Preserving dates:

You can preserve the last modified date of items that are updated by the Workflow update tool by adding &preserve_dates=true to the URL used to run the Workflow update tool.

Restricting which items types to fix:
You can restrict which objects types are processed by adding `&restrictOn=itemtype` to the URL used to run the Workflow update tool. For example:

- *content*
- *style* for presentation templates
- *template* for authoring templates
- *taxonomy*
- *category*
- *SiteArea*
- *Cmpnt* for components

If not specified, all object types are fixed.

library
Enter a library name. If the `library` parameter is omitted, the default library that is configured in the **WCM WCMConfigService** service by using the WebSphere Integrated Solutions Console.

To run this tool against all libraries, you instead use `&alllibraries=true`. If you have many libraries, this process can take a long time to run, so it might be better to run this tool against individual libraries instead of all libraries.

Unlocking items:
To force locked items to be unlocked while the tool is running, add `&forceUnlock=true` to the query. This setting defaults to true.

Specify a timeout in seconds:
To prevent your server from timing out before the workflow update tool finishes, you can specify `&sessionTimeOut=` to the URL. This setting is defined as the number of seconds before a session will timeout. For example: `&sessionTimeOut=36000`. The default session timeout is 14440 seconds.

Running the tool on a virtual portal

There are two methods available when the tool is run on a virtual portal:

Using the URL context of a virtual portal:
```
http://[HOST]:[PORT]/wps/wcm/myconnect/[url_context]?MOD=workflowenablement
&fix=true
```

Using the host name of a virtual portal:
```
http://[Virtual_HOST]:[PORT]/wps/wcm/myconnect?MOD=workflowenablement&fix=true
```

Clearing item history

You use the clear history tool to clear the history of an item.

Before you begin

You must first enable the clear history tool by adding the following parameters to the `WCM WCMConfigService` service by using the WebSphere Integrated Solutions Console:

- `connect.businesslogic.module.clearhistory.class=com.aptrix.history.ClearHistoryModule`
- `connect.businesslogic.module.clearhistory.remoteaccess=true`

- `connect.businesslogic.module.clearhistory.autoload=false`

Procedure

1. Log in to the portal as an administrator.
2. Open the following URL in the browser and specify details of what history details to clear:

   `http://[HOST]:[PORT]/wps/wcm/myconnect?MOD=ClearHistory&day=`*`date`*`&month=`*`month`*
   `&year=`*`year`*`&keep=`*`number_of_entries`*`&restrictOn=`*`item_type`*
   `&library=`*`library_name`*`&fix=true`

   day, month, and year
   The history details are cleared before the date specified in the day, month, and year parameters. If no date is specified, then the date defaults to one year before the current date.

   keep Specify the minimum number of history entries to keep. For example, if an item has not been updated for over a year, and you specify to clear all history entries more than a year old, but choose to keep the last five entries, all the history will be cleared except for the last five entries even though they are over a year old. If a number is not specified, then the minimum number of history entries to keep defaults to 10.

   restrictOn
   Select the item types to run the clear history tool against. If no item types are specified, all item types are processed. Use the following parameters for each item-type:
   - *content*
   - *folder*
   - *project*
   - *style* for presentation templates
   - *template* for authoring templates
   - *taxonomy*
   - *category*
   - *SiteArea*
   - *Workflow*
   - *WorkflowStage*
   - *WorkflowAction*
   - *Cmpnt* for components

   library
   Enter a library name. If the "library" parameter is omitted, the default library that is configured in the `WCM WCMConfigService` service is used.

   To run this tool against all libraries, you instead use `&alllibraries=true`. If you have many libraries, this process can take a long time to run, so it might be better to run this tool against individual libraries instead of all libraries.

   fix If omitted or set to false, a report listing which history items were cleared is displayed. If set to true, history items are cleared as specified.

Results

Note: You cannot completely clear item history. One history item always remains in an item no matter what parameters you select when the item history is cleared.

Running the tool on a virtual portal

There are two methods available when the tool is run on a virtual portal:

Using the URL context of a virtual portal:

```
http://[HOST]:[PORT]/wps/wcm/myconnect/[url_context]?MOD=ClearHistory
&fix=true
```

Using the host name of a virtual portal:

```
http://[Virtual_HOST]:[PORT]/wps/wcm/myconnect?MOD=ClearHistory&fix=true
```

Clearing version history

You use the clear versions tool to clear the version history of an item.

Before you begin

You must first enable the clear versions tool by adding the following parameters to the `WCM` `WCMConfigService` service by using the WebSphere Integrated Solutions Console:

- `connect.businesslogic.module.clearversions.class=com.aptrix.versioncontrol.ClearVersionsM`
- `connect.businesslogic.module.clearversions.remoteaccess=true`
- `connect.businesslogic.module.clearversions.autoload=false`

Procedure

1. Log in to the portal as an administrator.
2. Open the following URL in the browser and specify details of what history details to clear:

   ```
   http://[HOST]:[PORT]/wps/wcm/myconnect?MOD=ClearVersions&day=date
   &month=month&year=year&keep=number_of_entries&restrictOn=item_type
   &library=library_name&fix=true&preserve_dates=true
   ```

   day, month, and year
   The version history is cleared before the date specified in the day, month, and year parameters. If no date is specified, then the date defaults to one year before the current date.

   keep Specify the minimum number of history versions to keep. For example, if a version has not been created for over a year, and you specify to clear all versions more than a year old, but choose to keep the last five versions, all versions are cleared except for the last five versions even though they are over a year old. If a number is not specified, then the minimum number of versions to keep defaults to 10.

   restrictOn
   Select the item types to run the clear versions tool against. If no item types are specified, all item types are processed. Use the following parameters for each item-type:

   - *content*
   - *style* for presentation templates
   - *template* for authoring templates
   - *taxonomy*
   - *category*
   - *SiteArea*
   - *Workflow*

- *WorkflowStage*
- *WorkflowAction*
- *Cmpnt* for components

library
Enter a library name. If the `library` parameter is omitted, the default library that is configured in the `WCM WCMConfigService` service by using the WebSphere Integrated Solutions Console.

To run this tool against all libraries, you instead use `&alllibraries=true`. If you have many libraries, this process can take a long time to run, so it might be better to run this tool against individual libraries instead of all libraries.

fix If omitted or set to false, a report listing which versions were cleared is displayed. If set to true, versions are cleared as specified.

preserve_dates
If set to true, the last modified date of items that are updated by the module is preserved. If omitted or set to false, the last modified date is not preserved.

Results

Note: You cannot completely clear all versions. One version of an item always remains no matter what parameters you select when the version history is cleared.

Running the tool on a virtual portal

There are two methods available when the tool is run on a virtual portal:

Using the URL context of a virtual portal:
`http://[HOST]:[PORT]/wps/wcm/myconnect/[url_context]?MOD=ClearVersions`

Using the host name of a virtual portal:
`http://[Virtual_HOST]:[PORT]/wps/wcm/myconnect?MOD=ClearVersions`

Resetting the web content event log

From time to time, you might need to reset the web content event log. The event log can be reset only on a syndicator server. Any changes that are made by resetting the event log are then syndicated to its corresponding subscribers. In most cases, you reset the event log on the server you imported or migrated data onto, or on a syndicator to troubleshoot syndication problems in a syndication relationship.

Before you begin

You must first enable the reset event log module by adding the following parameters to the **WCM WCMConfigService** service by using the WebSphere Integrated Solutions Console:

- `connect.businesslogic.module.reseteventlog.class=com.ibm.workplace.wcm.services.eventlo`
- `connect.businesslogic.module.reseteventlog.remoteaccess=true`
- `connect.businesslogic.module.reseteventlog.autoload=false`

About this task

You must reset the web content event log under these circumstances:

- The contents of the repository is modified through an external mechanism such as a JCR import or some other custom application.
- As a post migration step during migration before syndication.
- To troubleshoot syndication problems such as items on the syndicator not being sent.

Note:

- Before you reset the web content event log, you must edit the `wkplc_dbtype.properties` file and ensure the DbSafeMode property is set to false. This file is located in *wp_profile_root*`/ConfigEngine/properties`.
- In clustered environments, you must reset only the event log on the primary node.
- Any objects that were purged on the syndicator since the last syndication is not purged on the subscriber. Purged objects are lost since the event log does not maintain records of objects that were deleted. To clean up purged items on a subscriber, you need to go the subscriber and manually delete them.

To reset

Run the `run-wcm-admin-task-reset-event-log` task from the *wp_profile_root*`/ConfigEngine` directory.

IBM i
```
ConfigEngine.sh run-wcm-admin-task-reset-event-log
-Dlibrary="library_name" -Dfix=true
```

Linux
```
./ConfigEngine.sh run-wcm-admin-task-reset-event-log
-Dlibrary="library_name" -Dfix=true
```

Windows
```
ConfigEngine.bat run-wcm-admin-task-reset-event-log
-Dlibrary="library_name" -Dfix=true
```

Note: If **`-Dfix=true`** is omitted, then the task runs in report-mode only.

Note: The library that is specified in the command is the library to be scanned by the reset event log task. If the query parameter "library" is omitted, the default library that is configured with the defaultLibrary property in the **WCM WCMConfigService** service is used.

Note: When you run this task on a virtual portal, you must add either `-DVirtualPortalHostName=`*name* or `-DVirtualPortalContext=`*virtual_portal_context* to the command.

Related tasks:

"Exporting and importing web content libraries" on page 1200
IBM Web Content Manager provides two methods for exporting and importing web content libraries: an export or import that operates on one library, and an export or import that creates a separate copy of a library. With either method, you can export the contents of a web content library to disk and import this data into another web content server. If you're working with a copy of a library, you can also import that library into the same web content server multiple times, resulting in a new library after each import without affecting previous copies. Exporting and importing libraries can be used to make a backup copy of a web content library and can also be used to move data between servers. However, this function cannot be used to send updates, deletes, and moves. It is only suitable for populating new

items.

The export cache settings task

Use the export cache settings task to display a summary of the current cache settings of your system.

When you run the export cache settings task, a summary of your cache settings is generated and set to the `SystemOut.log`. This summary includes the type of cache that is being used and how it is being applied. For example, basic caching per session or data caching per site.

Running the export cache settings task

1. Open a command prompt.
2. Run the following command from the *wp_profile_root*`/ConfigEngine` directory:

   Windows

   ```
   ConfigEngine.bat run-wcm-admin-task-export-cache-settings
   -DWasPassword=password -DPortalAdminId=username
   -DPortalAdminPwd=password -Dlibrary=MyLibrary
   -DinheritPerms=apply -DlibSecurity=true
   ```

   Linux

   ```
   ./ConfigEngine.sh run-wcm-admin-task-export-cache-settings
   -DWasPassword=password -DPortalAdminId=username
   -DPortalAdminPwd=password -Dlibrary=MyLibrary
   -DinheritPerms=apply -DlibSecurity=true
   ```

   IBM i

   ```
   ConfigEngine.sh run-wcm-admin-task-export-cache-settings
   -DWasPassword=password -DPortalAdminId=username
   -DPortalAdminPwd=password -Dlibrary=MyLibrary
   -DinheritPerms=apply -DlibSecurity=true
   ```

   Note: An administrator user name and password is not required if the portal administrator user name and password are specified in the **PortalAdminId** and **PortalAdminPwd** settings in the `wkplc.properties` file.

Displaying cache settings in a browser

You can also display your cache settings in a browser by using the following URL:

```
http://hostname:port/wps/wcm/connect?MOD=ExportCacheSettings&processLibraries=false
```

Related concepts:

"Cache expire parameters" on page 1842
You use the "expires" parameter in IBM Web Content Manager tags and URLs to specify how long to maintain data in the cache before it is expired. When data expires from a cache, the next request for the data will be retrieved from the original server. The **expires** parameter is not mandatory.

How to manage plug-in tag usage

Plug-in tags are used to reference rendering plug-ins in Web content. Use the `run-wcm-admin-task-tag-usage` task to find or update plug-in tags in your Web content.

Finding plug-in tags

To create a report of plug-in tags that are referenced in Web Content Manager items, run the following command from the *wp_profile_root*/ConfigEngine directory:

Windows

```
ConfigEngine.bat run-wcm-admin-task-tag-usage
-DPortalAdminId=username -DPortalAdminPwd=password
-Dfind=Plugin:PluginName -Dlibrary="MyLibrary"
```

Linux

```
./ConfigEngine.sh run-wcm-admin-task-tag-usage
-DPortalAdminId=username -DPortalAdminPwd=password
-Dfind=Plugin:PluginName -Dlibrary="MyLibrary"
```

IBM i

```
ConfigEngine.sh run-wcm-admin-task-tag-usage
-DPortalAdminId=username -DPortalAdminPwd=password
-Dfind=Plugin:PluginName -Dlibrary="MyLibrary"
```

Note: The library that is specified in the command is the library to be scanned by the task. If the query parameter "library" is omitted, the default library that is configured with the `defaultLibrary` property in the `WCM WCMConfigService` service is used.

Note: An administrator user name and password is not required if you specify the portal administrator user name and password by using the **PortalAdminId** and **PortalAdminPwd** settings in the `wkplc.properties` file.

Note: Before you progress to the next step and run the task in fix mode, ensure that the report mode indicates that the updates will happen as you require. A summary of the updates are shown by the command.

A detailed report of the updates that are made for each item is shown in the SystemOut.log file in *wp_profile_root*\logs\WebSphere_Portal. If the report indicates that the update will not happen as required, change the task parameters and run the report mode again. Repeat this process until you are satisfied that the fixes are applied correctly. This is important because the fixes made by the task when run in fix mode might not be easy to undo if incorrect fixes are applied.

Replacing plug-in tags

To replace one plug-in tag type with another when referenced in web content items, run the following command from the *wp_profile_root*/ConfigEngine directory:

Windows

```
ConfigEngine.bat run-wcm-admin-task-tag-usage
-DPortalAdminId=username -DPortalAdminPwd=password
-Dfind=Plugin:OldPluginName -Dfix=true
-Dreplace=Plugin:NewPluginName -Dlibrary="MyLibrary"
```

Linux

```
./ConfigEngine.sh run-wcm-admin-task-tag-usage
-DPortalAdminId=username -DPortalAdminPwd=password
-Dfind=Plugin:OldPluginName -Dfix=true
-Dreplace=Plugin:NewPluginName -Dlibrary="MyLibrary"
```

IBM i

```
ConfigEngine.sh run-wcm-admin-task-tag-usage
-DPortalAdminId=username -DPortalAdminPwd=password
```

```
-Dfind=Plugin:OldPluginName -Dfix=true
-Dreplace=Plugin:NewPluginName -Dlibrary="MyLibrary"
```

Note: The library that is specified in the command is the library to be scanned by the task. If the query parameter "library" is omitted, the default library that has been configured with the `defaultLibrary` property in the `WCM WCMConfigService` service is used.

Note: An administrator user name and password is not required if you specify the portal administrator user name and password by using the **`PortalAdminId`** and **`PortalAdminPwd`** settings in the `wkplc.properties` file.

Extra parameter values

Use these additional task parameters to update the parameters in a plug-in tag:

Table 162. Extra parameter values

Parameter	Description
`-DaddParam=`*ParameterName*	The name of a tag parameter to add to the 'find' tag when in fix mode.
`-DaddParamValue=`*ParameterValue*	The value of the tag parameter to add to the 'find' tag when in fix mode.
`-DupdateParam=`*ParameterName*	The name of the tag parameter to update on the 'find' tag when in fix mode.
`-DupdateParamNewName=`*NewParameterName*	The new name of the tag parameter to update on the 'find' tag when in fix mode.
`-DupdateParamValue=`*OldParameterValue*	The old value of the 'updateParam' parameter to update on the 'find' tag when in fix mode.
`-DupdateParamNewValue=`*NewParameterValue*	The new value that replaces the old value in the 'updateParam' parameter on the 'find' tag when in fix mode.
`-DremoveParam=`*ParameterName*	The name of a tag parameter to remove from the 'find' tag when in fix mode.
`-DremoveParamValue=`*ParameterValue*	The values of the updateParam to remove from the 'find' tag when in fix mode.
`-DfixBehavior=`*Behavior Parameter*	Used to determine how a fix is implemented. Valid behavior parameters are: **`allowMultipleValues`** If specified, parameters are allowed to have multiple values when you add parameter values in fix mode. **`ifParamValue:`*ParameterValue*** The fix is applied only to tags that have a parameter that has this value **`ifParamNotExist:`*ParameterName*** The fix is applied only to tags where this parameter does not exist.

Preserving dates

You can preserve the last modified date of items that are updated by the task by adding **-DpreserveDates=true** to the command. Otherwise, the last modified date is updated when the task is run.

Running the task for all libraries

You can run this task for all libraries by replacing the option `-Dlibrary=`*`libraryName`* with the option **-DallLibraries=true** in the command. If neither option is specified, this task processes the default library that is configured in the **WCM WCMConfigService** service by using the WebSphere Integrated Solutions Console.

Running the task on a virtual portal

When this task is run on a virtual portal, you must add either `-DVirtualPortalHostName=`*name* or`-DVirtualPortalContext=`*`context`* to the command.

Parameters to set for large repositories

To prevent your session timing out before the task has finished, you can append the option `-DsessionTimeOut=`*`timeOut`* to the command. This sets the number of seconds in which the task must complete before its session will timeout. The default session timeout is 14,440 seconds, which is 4 hours. For large repositories, you should increase this setting. For example: `-DsessionTimeOut=36000`, which is 10 hours.

Examples

In this example, the plug-in tag `ifEqual` has been deprecated and replaced with the plug-in tag `Equals`. To up date all instances of the `ifEqual` tag in your site, run the following commands:

```
./ConfigEngine.sh/bat run-wcm-admin-task-tag-usage -Dfind=Plugin:ifEqual -DallLibraries=true -Dfix=t
./ConfigEngine.sh/bat run-wcm-admin-task-tag-usage -Dfind=Plugin:ifEqual -DallLibraries=true -Dfix=t
./ConfigEngine.sh/bat run-wcm-admin-task-tag-usage -Dfind=Plugin:ifEqual -DallLibraries=true -Dfix=t
```

These commands replace the 'value1' and 'value2' parameters with 'text1' and 'text2' parameters, and then change the tag name to `Equals`.

Exporting and importing web content libraries

IBM Web Content Manager provides two methods for exporting and importing web content libraries: an export or import that operates on one library, and an export or import that creates a separate copy of a library. With either method, you can export the contents of a web content library to disk and import this data into another web content server. If you're working with a copy of a library, you can also import that library into the same web content server multiple times, resulting in a new library after each import without affecting previous copies. Exporting and importing libraries can be used to make a backup copy of a web content library and can also be used to move data between servers. However, this function cannot be used to send updates, deletes, and moves. It is only suitable for populating new items.

About this task

Before you begin, create an empty shared directory to hold the exported web content library. If you move data between servers, both systems must have write access to this directory. In addition, review the following considerations before you export or import web content libraries:

Importing libraries into different versions

You can import libraries from a different version of Web Content Manager so long as the version you are importing the library into is later than the version you exported the library from. For example:

- you can import a library that is exported from version 6.1.0.1 into version 7.0
- you cannot import a library that is exported from version 7.0 into version 6.1.0.1

Upgrade to the most recent version of each release before you attempt to import libraries between versions. It is not possible to export libraries from releases before 6.0.

Exporting and importing a web content library versus syndication.

This feature does not replace the syndication feature. Although this feature can be used to transfer data between servers, it is a manual process and is not meant to be used for regular updates between servers. Syndication is instead used to automatically keep two or more servers synchronized. Also, whereas syndication can be used to send updates, deletes and moves, the import feature is only suitable for populating new items.

Limitations of exporting and importing a web content library.

- Saved versions of items are not exported. Only the current version of each item is exported.
- Children are only exported and imported when the parent is successfully exported and imported.
- If an item exists on the target server with the same path, name and ID, then the item is overwritten.
- Library and item level access controls remain unchanged when a library is exported and imported. You need to run the member fixer tool on the imported library to fix references to missing users and groups.
- You cannot import an item if an item on the target server has the same ID but a different parent than the item that is being imported.
- Projects are not exported.

Disabling JCR text search.

Disable JCR text search indexing on your WebSphere Portal Express server before you export or import large libraries to reduce the load on the database during export and import.

1. Log in to the WebSphere Integrated Solutions Console.
2. Click **Resources** > **Resource Environment** > **Resource Environment Providers** > **JCR ConfigService PortalContent** > **Custom properties**.

   Cluster note: If you are using this web content server as part of a cluster, ensure that you use the WebSphere Integrated Solutions Console for the deployment manager when you edit configuration properties.
3. Change **jcr.textsearch.enabled** to false.

Note: You must restart your server any time you change these settings. After you export and import your library, you must then enable JCR text search again. It can take some time to rebuild the indexes when you re-enable JCR text search indexing.

Exporting and importing large libraries

- When web content libraries are imported, a temporary directory is used to store the library files during the upload process. If the size of the uploaded files exceeds the available disk space for the temporary directory, the import operation fails. When large libraries are exported, ensure that there is sufficient disk space to accommodate the import.
  1. Log in to the WebSphere Integrated Solutions Console.
  2. Click **Resources** > **Resource Environment** > **Resource Environment Providers** > **JCR ConfigService PortalContent** > **Custom properties**.
  3. Make sure the location that is specified under **jcr.binaryValueFileDir** has sufficient disk space to accommodate the import.
- When you export or import large libraries, you might need to adjust the following settings:
  1. Log in to the WebSphere Integrated Solutions Console.
  2. Click **Servers** > **Server Types** > **WebSphere application servers** > *portal_server* > **Container Services** > **Transaction Service**.
  3. Change the **total transaction lifetime timeout** and the **maximum transaction timeout** settings to 360 seconds.

Personalization components.

Personalization rules that are created within a Personalization component are exported and imported along with your web content library.

If you are using Personalization rules that are created directly in the Personalization portlet, you need to export and import your rules to and from Personalization on the same servers as your web content by using the same process as moving WebSphere Portal content from a staging system to a production system. Personalization export and import must be run before you export and import web content.

JSP components

If you are using JSP components that you must manually copy any related JSP files to and from the same servers that you are exporting and importing to.

"Exporting and importing a web content library" on page 1203
You can export the contents of a web content library to disk and import this data into another web content server. Use this feature to make a backup copy of a web content library, and to move data between servers. This function cannot be used to send updates, deletes, and moves. It is only suitable for populating new items.

"Exporting and importing a web content library copy" on page 1207
You can export the contents of a web content library to disk by creating a copy of the web content library. By working with an exported copy, you can import the copied library into the same web content server multiple times, resulting in a new library after each import without affecting previous copies. This is a quick way of creating new libraries that are fully populated with web content that you can easily adapt for other purposes.

Related tasks:

"Resetting the web content event log" on page 1195
From time to time, you might need to reset the web content event log. The event log can be reset only on a syndicator server. Any changes that are made by resetting the event log are then syndicated to its corresponding subscribers. In most cases, you reset the event log on the server you imported or migrated data onto, or on a syndicator to troubleshoot syndication problems in a syndication relationship.

"Exporting and importing a web content library"
You can export the contents of a web content library to disk and import this data into another web content server. Exporting and importing a web content library

You can export the contents of a web content library to disk and import this data into another web content server. Use this feature to make a backup copy of a web content library, and to move data between servers. This function cannot be used to send updates, deletes, and moves. It is only suitable for populating new items.

About this task

Follow these steps to export and import a web content library. The server that the data is being exported from is called the source server, and the server that the data is being imported into is called the target server.

Procedure

1. **Exporting:**
   a. Log in to the WebSphere Integrated Solutions Console on the source server.
   b. Click **Resources** > **Resource Environment** > **Resource Environment Providers** > **WCM WCMConfigService** > **Custom properties**.

      Cluster note: If you are using this web content server as part of a cluster, ensure that you use the WebSphere Integrated Solutions Console for the deployment manager when you are manipulating configuration properties.
   c. Create or update the export properties.

      export.directory
      The directory on the source server where the exported data is written. The export task creates a subdirectory with the name corresponding to library name within this directory for each exported library. The default value is `${USER_INSTALL_ROOT}/PortalServer/wcm/ilwwcm/system/export`.

      export.libraryname
      The name of the web content library to transfer. If you are exporting multiple libraries enter each library name, separated by a semi-colon. For example: `Lib_1;Lib_2;Lib_3`

Note: The library names that are specified in this parameter must be the original name of the library, not the localized name. Click the **Administration menu** icon. Then, click **Portal Content** > **Web Content Libraries**. You can view the original name and view the edit settings of the library.

export.singledirectory
If set to `true`, multiple libraries are written into a single directory that is specified by the `export.directory` property. If set to `false`, the export task created subdirectories with the name corresponding to each exported library names. For example, if `export.directory` is specified as `C:\export` and the library name is `Web Library`, the export task saves the exported library under `C:\export\Web Library`. Set this property to `true` when you are exporting multiple libraries that contain references between each library.

Note: You must restart your server any time you change these settings.

d. Export the web content library from the source server:
   - Open a command prompt on the source server.
   - Run the `export-wcm-data` task from the *wp_profile_root*`/ConfigEngine` directory.

     IBM i
     ```
     ConfigEngine.sh export-wcm-data -DWasPassword=password
     -DPortalAdminPwd=password
     ```

     Linux
     ```
     ./ConfigEngine.sh export-wcm-data -DWasPassword=password
     -DPortalAdminPwd=password
     ```

     Windows
     ```
     ConfigEngine.bat export-wcm-data -DWasPassword=password
     -DPortalAdminPwd=password
     ```

     By default, this task is done on the base portal. To run this task on a different virtual portal, identify the virtual portal by adding one of the following parameters to the command line. Each parameter requires the prefix `-D` on the command line.

     `VirtualPortalHostName`
     Specify the host name of the virtual portal. For example, `vp.example.com`.

     `VirtualPortalContext`
     Specify the virtual portal context that identifies the virtual portal. For example, `vp1`.

     Note:
     - You can override the `export.directory` property that is defined in the `WCM WCMConfigService` service by using the `-Dexport.directory` parameter. For example: `export-wcm-data -Dexport.directory=c:\export`
     - You can override the `export.singledirectory` property that is defined in the `WCM WCMConfigService` service by using the `-Dexport.singledirectory` parameter. For example: `export-wcm-data -Dexport.singledirectory=false` saves the exported libraries under different directories.
     - You can override the `export.libraryname` property that is defined in the `WCM WCMConfigService` service by using the `-Dexport.libraryname` parameter. For example: `export-wcm-data -Dexport.libraryname=`*`libraryname`*

- You can override the `export.libraryname` property that is defined in the `WCM WCMConfigService` service by adding the option `-Dexport.allLibraries` parameter to export all libraries. If this option is used, the export might take a long time to finish.

Important: To ensure that your exported libraries can be successfully imported, do not change the names of any of the folders or files within the exported data.

e. Verify that this transfer step completed without errors. If any errors occurred, check the portal logs on the target server for extended diagnostic information.

f. Verify that the export directories were populated correctly, including any subdirectories for each exported library.

2. **Importing:**

a. Log in to the WebSphere Integrated Solutions Console on the target server.

b. Click **Resources** > **Resource Environment** > **Resource Environment Providers** > **WCM WCMConfigService** > **Custom properties**.

Cluster note: If you are using this web content server as part of a cluster, ensure that you use the WebSphere Integrated Solutions Console for the deployment manager when you are manipulating configuration properties.

c. Create or update the `import.directory` property. This directory is from where the exported data is read when you are importing the data to the target server. If you are exporting and importing across a network, this property can be the same directory as the one specified in `export.directory` property. Otherwise, you must copy the exported data from the location that is specified in the `export.directory` property to the location specified in the `import.directory` property before you run the import task in step 2.

- If you specified `true` for the `export.singledirectory` property when you exported your libraries, specify the parent directory where all the exported libraries are located.
- If you specified `false` for the `export.singledirectory` property when you exported your libraries, or if you want to import only specific libraries, then you must list the directory of each library, separated by semicolons. For example: `c:\import\Lib1;c:\import\Lib2;c:\import\Lib3`. If you are using Linux use `/;` to separate each library, such as `/opt/importdata/Lib1/;/opt/importdata/Lib2/;/opt/importdata/Lib3`.

Note: You must restart your server any time you change this setting.

d. Import the web content library to the target server.

- Open a command prompt on the target server.
- Run the `import-wcm-data` task from the *wp_profile_root*`/ConfigEngine` directory.

IBM i
```
ConfigEngine.sh import-wcm-data -DWasPassword=password
-DPortalAdminPwd=password
```

Linux
```
./ConfigEngine.sh import-wcm-data -DWasPassword=password
-DPortalAdminPwd=password
```

Windows
```
ConfigEngine.bat import-wcm-data -DWasPassword=password
-DPortalAdminPwd=password
```

By default, this task is done on the base portal. To run this task on a different virtual portal, identify the virtual portal by adding one of the following parameters to the command line. Each parameter requires the prefix `-D` on the command line.

`VirtualPortalHostName`
Specify the host name of the virtual portal. For example, `vp.example.com`.

`VirtualPortalContext`
Specify the virtual portal context that identifies the virtual portal. For example, `vp1`.

Note: You can override the `import.directory` property that is defined in the `WCM WCMConfigService` service by using the `-Dimport.directory` parameter. For example: `import-wcm-data -Dimport.directory=c:\import\Lib1;c:\import\Lib2;c:\import\Lib3`.

Differences in paths between versions:

When you are exporting from a version 6.1 system, you can specify a folder to export the library to:

```
/opt/61/folder/jcr_root
```

When you are importing into version 8.0 from version 6.1, the jcr_root is not required to be specified in the import path:

```
/opt/61/folder/
```

When you are exporting from versions 7.0 or higher, the following structure is used:

```
/opt/70/folder1/folder2
```

When exported, `folder2` is automatically generated.

When you are importing into version 8.0 from version 7.0 or higher, `folder2` is not required to be specified in the import path:

```
/opt/70/folder1/
```

e. Verify that the imported libraries are imported by reviewing the list of libraries that are listed in the web content libraries section of the administration portlet on the target server. If any errors occurred, check the portal logs on the target server for extended diagnostic information.
f. Reset the web content event log.
g. Restart the server.

What to do next

Troubleshooting:

- If items are exported and imported twice between the same servers, and items are moved or deleted between the first and second export and import, then you must manually delete these items from the target server before you transfer the items again. If this step is not done, an error like this example is generated:

  ```
  javax.jcr.ItemExistsException: A node already exists with uuid:
  376dba00408608aea231b2c714d0bda6 at path: /contentRoot/icm:libraries[10]/
  F1/F3/test1.ort
  ```

- If you receive 500 errors on ext2 and ext3 versions of Linux, you exceeded the number of children that a parent folder can hold. You cannot store more than 32768 children under one folder on ext2 and ext3 versions of Linux. Move some content items out of the affected site area to another site area so that none of your site areas contain more than 32768 children under one folder and then try exporting again. You can move the content items back to the correct site areas when you import the library.

Related tasks:

"Exporting and importing web content libraries" on page 1200
IBM Web Content Manager provides two methods for exporting and importing web content libraries: an export or import that operates on one library, and an export or import that creates a separate copy of a library. With either method, you can export the contents of a web content library to disk and import this data into another web content server. If you're working with a copy of a library, you can also import that library into the same web content server multiple times, resulting in a new library after each import without affecting previous copies. Exporting and importing libraries can be used to make a backup copy of a web content library and can also be used to move data between servers. However, this function cannot be used to send updates, deletes, and moves. It is only suitable for populating new items.

Exporting and importing a web content library copy

You can export the contents of a web content library to disk by creating a copy of the web content library. By working with an exported copy, you can import the copied library into the same web content server multiple times, resulting in a new library after each import without affecting previous copies. This is a quick way of creating new libraries that are fully populated with web content that you can easily adapt for other purposes.

About this task

Although many aspects are the same for the standard export and import and the copy export and import, there are some important differences:

- When you export a library as a copy, new IDs are generated for all items in the library. This ensures that there are no conflicts with existing libraries or items when you import the copy into a web content server that already contains the original library. In this way, you can run multiple imports to the same web content server, resulting in a new library for each import.
- The configuration tasks (`export-library-copy` and `import-library-copy`) that work on library copies, use properties that can either be added to the `wkplc.properties` file or manually appended to the command line, for easier scripting.

Follow these steps to export or import a copy of a web content library. The server that the data is being exported from is called the source server, and the server that the data is being imported into is called the target server.

Procedure

- **Exporting:**
  1. Open a command prompt on the source server.
  2. Run the `export-library-copy` task from the *`wp_profile_root`*`/ConfigEngine` directory.

     Windows

     ```
     ConfigEngine.bat export-library-copy
     ```

```
-DLibraryPath=path_to_export_file
-DLibraryName=library_name_to_export -DWasPassword=password
-DPortalAdminPwd=password
```

Linux
```
./ConfigEngine.sh export-library-copy
-DLibraryPath=path_to_export_file
-DLibraryName=library_name_to_export -DWasPassword=password
-DPortalAdminPwd=password
```

IBM i
```
ConfigEngine.sh export-library-copy
-DLibraryPath=path_to_export_file
-DLibraryName=library_name_to_export -DWasPassword=password
-DPortalAdminPwd=password
```

The following properties must be specified either on the command line or in the `wkplc.properties` file.

Note: If you are specifying properties in the `wkplc.properties` file, it is not necessary to put quotation marks (") around values that contain spaces. These quotation marks are only required when specifying property values on the command line.

LibraryPath
The directory path and file name that is used to store the exported library. The export process creates a compressed archive file, so it is recommended that you specify a file extension such as `.zip`. If you are exporting and importing across a network, this location can be a network drive accessible by both the source and target servers.

LibraryName
The name of the web content library to copy. If you are exporting multiple libraries, separate each library name by a semi-colon (`;`). For example, `LibraryName="Web Content;Samples"`.

WasUserid
The administrator ID for WebSphere Application Server.

WasPassword
The administrator password for WebSphere Application Server.

PortalAdminId
The administrator ID for WebSphere Portal Express.

PortalAdminPwd
The administrator password for WebSphere Portal Express.

By default, this task is performed on the default virtual portal. To run this task on a different virtual portal, identify the virtual portal by adding one of the following parameters to the command line. Each parameter requires the prefix `-D` on the command line.

VirtualPortalHost
Specify the host name of the virtual portal. For example, `vp.example.com`.

Important: If the host name of the virtual portal is the same as the host name of the default virtual portal, you must also specify the **`VirtualPortalContext`** property. You can specify the **`VirtualPortalHost`** property by itself only if the host name is unique.

VirtualPortalContext
Specify the virtual portal context that identifies the virtual portal. For example, `vp1`.

Example commands:

– Windows: `ConfigEngine.bat export-library-copy -DLibraryPath=C:\wcm_export\webcontent.zip -DLibraryName="Web Content" -DWasPassword=mypassword -DPortalAdminPwd=mypassword -DVirtualPortalHost=vp.example.com`

– Linux: `./ConfigEngine.sh export-library-copy -DLibraryPath=/opt/wcm_export/webcontent.zip -DLibraryName="Web Content" -DWasPassword=mypassword -DPortalAdminPwd=mypassword -DVirtualPortalHost=vp.example.com`

– IBM i: `ConfigEngine.sh export-library-copy -DLibraryPath=/opt/wcm_export/webcontent.zip -DLibraryName="Web Content" -DWasPassword=mypassword -DPortalAdminPwd=mypassword -DVirtualPortalHost=vp.example.com`

3. Verify that this transfer step completed without errors. If any errors occurred, check the portal logs on the source server for extended diagnostic information.

- **Importing:**
  1. Open a command prompt on the target server.
  2. Run the `import-library-copy` task from the *wp_profile_root*`/ConfigEngine` directory.

     Windows
     `ConfigEngine.bat import-library-copy -DLibraryPath=`*path_to_export_file* `-DLibraryName=`*library_name_to_import* `-DWasPassword=`*password* `-DPortalAdminPwd=`*password*

     Linux `./ConfigEngine.sh import-library-copy -DLibraryPath=`*path_to_export_file* `-DLibraryName=`*library_name_to_import* `-DWasPassword=`*password* `-DPortalAdminPwd=`*password*

     IBM i `ConfigEngine.sh import-library-copy -DLibraryPath=`*path_to_export_file* `-DLibraryName=`*library_name_to_import* `-DWasPassword=`*password* `-DPortalAdminPwd=`*password*

     The following properties must be specified either on the command line or in the `wkplc.properties` file.

     Note: If you are specifying properties in the `wkplc.properties` file, it is not necessary to put quotation marks (") around values that contain spaces. These quotation marks are only required when specifying property values on the command line.

     Differences in paths between versions:

     When exporting from a version 6.1 system, you can specify a folder to export the library to:

     `/opt/61/folder/jcr_root`

     When importing into version 8.0 from version 6.1, the jcr_root is not required to be specified in the import path:

`/opt/61/folder/`

When exporting from versions 7.0 or higher, the following structure is used:
`/opt/70/folder1/folder2`

When exported, `folder2` is automatically generated.

When importing into version 8.0 from version 7.0 or higher, `folder2` is not required to be specified in the import path:
`/opt/70/folder1/`

LibraryPath
The directory path and file name containing the library to be imported. If you are exporting and importing across a network, the value for this property can be the same file path that was used for the `LibraryPath` property during the export process. Otherwise, you must copy the exported data to a location accessible by the target server before attempting to import.

LibraryName
The name to use for the web content library copy that you are importing. If you are importing multiple libraries, separate each new library name by a semi-colon (`;`). For example, `LibraryName="Web Content Copy;Samples Copy"`.

LibraryExportName
The sequence of library names used during the original export, as defined by the `LibraryName` property specified for the export process. For example, `LibraryExportName="Web Content;Samples"`.

This property enables the import process to correctly set the new library names for the imported copies, in conjunction with the `LibraryName` property specified for the import process. The `LibraryExportName` property is only required if you are importing multiple libraries at one time.

WasUserid
The administrator ID for WebSphere Application Server.

WasPassword
The administrator password for WebSphere Application Server.

PortalAdminId
The administrator ID for WebSphere Portal Express.

PortalAdminPwd
The administrator password for WebSphere Portal Express.

By default, this task is performed on the default virtual portal. To run this task on a different virtual portal, identify the virtual portal by adding one of the following parameters to the command line. Each parameter requires the prefix `-D` on the command line.

VirtualPortalHost
Specify the host name of the virtual portal. For example, `vp.example.com`.

Important: If the host name of the virtual portal is the same as the host name of the default virtual portal, you must also specify the **`VirtualPortalContext`** property. You can specify the **`VirtualPortalHost`** property by itself only if the host name is unique.

VirtualPortalContext
Specify the virtual portal context that identifies the virtual portal. For example, `vp1`.

The following properties are optional and can be specified either on the command line or in the `wkplc.properties` file:

LibraryTitle
The title to use for the web content library copy that you are importing. If you are importing multiple libraries, separate each new library title by a semi-colon (`;`). For example, `LibraryTitle="Web Content Title;Samples Title"`.

LibraryDescription
The description to use for the web content library copy that you are importing. If you are importing multiple libraries, separate each new library description by a semi-colon (`;`). For example, `LibraryDescription="Copy of Web Content library;Copy of Samples library"`.

LibraryNameTextProvider
This property specifies the name of the text provider to use to locate the translated title of the library that you are importing. If you are importing multiple libraries with different text providers, separate each provider name by a semi-colon (`;`). For example, `LibraryNameTextProvider=provider1;provider2`.

LibraryNameTextProviderKey
This property specifies the key within the associated text provider that identifies the translated title of the library that you are importing. If you are importing multiple libraries with different translated titles, separate each key by a semi-colon (`;`). For example, `LibraryNameTextProviderKey=key1;key2`.

LibraryBaseLocale
The locale used when importing the web content library copy.

Example commands:

- Windows: `ConfigEngine.bat import-library-copy -DLibraryPath=C:\wcm_import\webcontent.zip -DLibraryName="Web Content Copy" -DLibraryTitle="Web Content Copy Title" -DLibraryDescription="Copy of Web Content library" -DLibraryNameTextProvider=provider -DLibraryNameTextProviderKey=key -DLibraryBaseLocale=en -DWasPassword=mypassword -DPortalAdminPwd=mypassword`
- Linux: `./ConfigEngine.sh import-library-copy -DLibraryPath=/opt/wcm_import/webcontent.zip -DLibraryName="Web Content Copy" -DLibraryTitle="Web Content Copy Title" -DLibraryDescription="Copy of Web Content library" -DLibraryNameTextProvider=provider -DLibraryNameTextProviderKey=key -DLibraryBaseLocale=en -DWasPassword=mypassword -DPortalAdminPwd=mypassword`
- IBM i: `ConfigEngine.sh import-library-copy -DLibraryPath=/opt/wcm_import/webcontent.zip -DLibraryName="Web Content Copy" -DLibraryTitle="Web Content Copy Title" -DLibraryDescription="Copy of Web Content library" -DLibraryNameTextProvider=provider -DLibraryNameTextProviderKey=key -DLibraryBaseLocale=en -DWasPassword=mypassword -DPortalAdminPwd=mypassword`

3. Verify that the imported libraries have been imported by reviewing the list of libraries that are listed in the web content libraries section of the

administration portlet on the target server. If any errors occurred, check the portal logs on the target server for extended diagnostic information.

4. Reset the web content event log.

Example commands for exporting and importing multiple libraries

When exporting and importing multiple web content libraries with a single command, the following considerations apply:

- For properties such as `LibraryName` that reference multiple libraries, separate the respective values for that property with a semi-colon (`;`).
- The value of the `LibraryExportName` property must match the value of the `LibraryName` property used during the export process to indicate the sequence of libraries.

Windows

- Export: `ConfigEngine.bat export-library-copy -DLibraryPath=C:\wcm_export\webcontent.zip -DLibraryName="Web Content;Samples" -DWasPassword=mypassword -DPortalAdminPwd=mypassword`
- Import: `ConfigEngine.bat import-library-copy -DLibraryPath=C:\wcm_import\webcontent.zip -DLibraryName="Web Content Copy;Samples Copy" -DLibraryExportName="Web Content;Samples" -DLibraryTitle="Web Content Copy Title;Samples Copy Title" -DLibraryBaseLocale=en -DWasPassword=mypassword -DPortalAdminPwd=mypassword`

Linux

- Export: `./ConfigEngine.sh export-library-copy -DLibraryPath=/opt/wcm_export/webcontent.zip -DLibraryName="Web Content;Samples" -DWasPassword=mypassword -DPortalAdminPwd=mypassword`
- Import: `./ConfigEngine.sh import-library-copy -DLibraryPath=/opt/wcm_import/webcontent.zip -DLibraryName="Web Content Copy;Samples Copy" -DLibraryExportName="Web Content;Samples" -DLibraryTitle="Web Content Copy Title;Samples Copy Title" -DLibraryBaseLocale=en -DWasPassword=mypassword -DPortalAdminPwd=mypassword`

IBM i

- Export: `ConfigEngine.sh export-library-copy -DLibraryPath=/opt/wcm_export/webcontent.zip -DLibraryName="Web Content;Samples" -DWasPassword=mypassword -DPortalAdminPwd=mypassword`
- Import: `ConfigEngine.sh import-library-copy -DLibraryPath=/opt/wcm_import/webcontent.zip -DLibraryName="Web Content Copy;Samples Copy" -DLibraryExportName="Web Content;Samples" -DLibraryTitle="Web Content Copy Title;Samples Copy Title" -DLibraryBaseLocale=en -DWasPassword=mypassword -DPortalAdminPwd=mypassword`

Related tasks:

"Exporting and importing web content libraries" on page 1200
IBM Web Content Manager provides two methods for exporting and importing web content libraries: an export or import that operates on one library, and an export or import that creates a separate copy of a library. With either method, you can export the contents of a web content library to disk and import this data into another web content server. If you're working with a copy of a library, you can also import that library into the same web content server multiple times, resulting in a new library after each import without affecting previous copies. Exporting and importing libraries can be used to make a backup copy of a web content library and can also be used to move data between servers. However, this function cannot be used to send updates, deletes, and moves. It is only suitable for populating new items.

Deleting libraries by using the delete libraries tool

Use the delete libraries tool to delete multiple libraries, even where there are references between the selected libraries.

Before you begin

- Back up your database before the module is run as a precaution.
- You must first enable the delete libraries tool by adding the following parameters to the **WCM WCMConfigService** service by using the WebSphere Integrated Solutions Console:
  –
  `connect.businesslogic.module.deletemultiplelibraries.class=com.aptrix.pluto.util.Dele`
  – `connect.businesslogic.module.deletemultiplelibraries.remoteaccess=true`
  – `connect.businesslogic.module.deletemultiplelibraries.autoload=false`

  You must also edit the **connect.businesslogic.module** property, and add *deletemultiplelibraries* to the end of the comma-separated list.

Procedure

1. Log in to the portal as an administrator.
2. Open the following URL in the browser and specify which libraries you want to delete:

   `http://[HOST]:[PORT]/wps/wcm/myconnect/?MOD=deletemultiplelibraries &libraries=`*`libraryname1`*`,`*`libraryname2`*

   There are two methods available when the tool is run on a virtual portal:

   Using the URL context of a virtual portal:

   `http://[HOST]:[PORT]/wps/wcm/myconnect/[url_context]?MOD=deletemultiplelibraries &libraries=`*`libraryname1`*`,`*`libraryname2`*

   Using the host name of a virtual portal:

   `http://[Virtual_HOST]:[PORT]/wps/wcm/myconnect?MOD=deletemultiplelibraries &libraries=`*`libraryname1`*`,`*`libraryname2`*

Running the tool using the configuration engine

Run the `run-wcm-admin-task-delete-libraries` task from the *`wp_profile_root`*`/ConfigEngine` directory.

IBM i
```
ConfigEngine.sh run-wcm-admin-task-delete-libraries
-Dlibraries="library1,library2" -DPortalAdminId=username
-DPortalAdminPwd=password
```

Linux
```
./ConfigEngine.sh run-wcm-admin-task-delete-libraries
-Dlibraries="library1,library2" -DPortalAdminId=username
-DPortalAdminPwd=password
```

Windows
```
ConfigEngine.bat run-wcm-admin-task-delete-libraries
-Dlibraries="library1,library2" -DPortalAdminId=username
-DPortalAdminPwd=password
```

Note: When you run this task on a virtual portal, you must add either `-DVirtualPortalHostName=`*name* or `-DVirtualPortalContext=`*context* to the command.

How to clone a web content repository

Syndicating items from one server to another, either after migration or to roll out a new server, can take a long time. Your database backup and restore features can be used to clone data from one repository to another, making your system ready for syndication to be used from then on for incremental updates.

There are two basic cloning scenarios:

- Cloning all items from one server to another. For example, cloning data from one authoring server to another authoring server.
- Cloning all items from one server to another, but then removing unrequired data from the cloned server. For example, cloning data from an authoring server to a delivery server where you would want to remove version history and draft items from the delivery server repository.

Note: These procedures describe how to clone a web content repository only. To clone a WebSphere Portal environment, XMLaccess export and import are used to transfer the WebSphere Portal data to the target environment

Note: Do not attempt to clone the JCR database if managed pages are enabled.

"Cloning preparation"
You must prepare your source and target systems before a web content repository is cloned.

"Cloning data" on page 1215
These procedures describe how to clone web content data from one system to another.

Cloning preparation

You must prepare your source and target systems before a web content repository is cloned.

- Managed pages must be disabled on both the source and target environments if virtual portals are in use before the cloning procedure is begun.
- The source and target environments must be on the same version and fix level
- Ideally the source and target environments use the same LDAP
- If the target server already contains data:
  - If you need to use this data later, ensure that you take a backup of the target environment before cloning.
  - Note down the syndicator and subscriber setups. The syndication setup on the target environment is lost during the cloning process, and needs to be re-created.

– Note down the library access control setup. Library access levels for target environment are lost during the cloning process, and need to be reapplied.

Oracle databases

When you set up an Oracle database for JCR, you must have a separate physical Oracle database for each JCR repository. This setup makes it easy to copy a JCR repository from one system to another. If you do choose to store all of your JCR repositories in a single database, then you must use different schema names for each system. WebSphere Portal does not support more than one instance of WebSphere Portal running against a single JCR database or schema.

Cloning data

These procedures describe how to clone web content data from one system to another.

Before you begin

Note: Managed pages must be disabled on both the source and target environments if virtual portals are in use before you begin the cloning procedure.

Procedure

1. On the source system:
   a. Disable all syndicators
   b. Stop the Portal server
   c. Back up the data of JCR database name that is specified by "`jcr.DbName`" parameter in the `wkplc_dbdomain.properties` file:

Table 163. `wkplc_dbdomain.properties`

System	Location
Windows	*wp_profile_root*`\ConfigEngine\properties` directory.
Linux	*wp_profile_root*`/ConfigEngine/properties` directory.
IBM i	*wp_profile_root*`/ConfigEngine/properties`

      Refer to the documentation for your database for specific backup instructions.
   d. Restart the Portal server.
   e. Re-enable any syndicators that do not syndicate to the target server.
2. On the target system:
   a. Stop the Portal server.
   b. Remove the existing JCR database by dropping the database. Refer to the documentation for your database for specific instructions.
   c. Create a new database, and restore the source system database backup. Refer to the documentation for your database for specific instructions.
   d. Restart the Portal server.
   e. Delete all syndicators and subscribers as they are not valid for the target system.
   f. If the target system is using a different LDAP run the member fixer tool to fix member information to match the new LDAP. First run the module in

report mode to see what member information requires fixing and then run the tool in fix mode to fix various potential member information mismatches.

g. If you are cloning from an authoring system to a delivery system, run the clear versions tool to remove any versions from the delivery system.

h. Set up syndication:
   - Create subscribers and syndicators for this system.
   - If the target system is a syndicator to the original source system, leave that syndicator disabled for now. All other Syndicators can be enabled

3. On source system:
   a. If the target system is a subscriber to the source system, update the syndicator with the new target subscriber ID and enable syndication.
   b. If the target system is a syndicator to the source system, update the subscriber with the new target syndicator ID
4. On target system:
   a. If the target system is a syndicator to the source system, enable syndication.

What to do next

When you finish cloning your web content data:

- Validate that the web content data on the target environment is rendering correctly.
- Validate access control settings for both rendering and authoring are set as expected, and working correctly for a selection of users.
- Validate updates are being syndication into and from the target environment as expected.

Related tasks:

"Clearing version history" on page 1194
You use the clear versions tool to clear the version history of an item.

Starting and stopping servers, deployment managers, and node agents

Various installation and configuration tasks require you to start and stop IBM WebSphere Application Server and the IBM WebSphere Portal Express application servers, deployment managers, and node agents.

Procedure

1. Open a command prompt and change to the following directory:

   Note: In a clustered environment, use the `dmgr_profile_root` directory and not the *wp_profile_root* directory.

   Windows: *wp_profile_root*`\bin`

   Linux : *wp_profile_root*`/bin`

   IBM i: *wp_profile_root*`/bin`
2. Complete the following steps to start the servers, deployment managers, and node agents

Table 164. Steps to start the servers, deployment managers, and node agents.

Server	Steps
Deployment manager	Enter the following command: • Linux : `./startManager.sh` • Windows: `startManager.bat` • IBM i: `startManager`
Node agent	Enter the following command: • Linux : `./startNode.sh` • Windows: `startNode.bat` • IBM i: `startNode`
WebSphere Portal Express server	Enter the following command: **Note:** If you have a clustered environment or you renamed your WebSphere Portal Express server, *WebSphere_Portal* is the name that you defined for your WebSphere Portal Express server. • Linux : `./startServer.sh` *`WebSphere_Portal`* • Windows: `startServer.bat` *`WebSphere_Portal`* • IBM i: `startServer` *`WebSphere_Portal`*

3. Complete the following steps to stop the servers, deployment managers, and node agents:

Table 165. Steps to stop the servers, deployment managers, and node agents

Server	Steps
WebSphere Portal Express server	Enter the following command: **Note:** If you have a clustered environment or you renamed your WebSphere Portal Express server, *WebSphere_Portal* is the name that you define for your WebSphere Portal Express server. • Linux : `./stopServer.sh` *`WebSphere_Portal`* • Windows: `stopServer.bat` *`WebSphere_Portal`* • IBM i: `stopServer` *`WebSphere_Portal`*
Node agent	Enter the following command: • Linux : `./stopNode.sh` • Windows: `stopNode.bat` • IBM i: `stopNode`
Deployment manager	Enter the following command: • Linux : `./stopManager.sh` • Windows: `stopManager.bat` • IBM i: `stopManager`

4. In a clustered environment, you can use the deployment manager WebSphere Integrated Solutions Console to stop and start the application servers that are managed by the deployment manager:

Table 166. Stopping and starting the application servers that are managed by the deployment managerWebSphere Integrated Solutions Console.

Option	Steps
Start a specific application server in a cell	Complete the following steps to start a specific application server in a cell: 1. Open the deployment manager WebSphere Integrated Solutions Console. 2. Click **Servers** > **Application Servers**. 3. Select the server and click **Start**.
Start the entire cluster	Complete the following steps to start the entire cluster: 1. Open the deployment manager WebSphere Integrated Solutions Console. 2. Click **Servers** > **Clusters**. 3. Select the cluster and click **Start** or **Ripple Start**.
Stop a specific server in a cell	Complete the following steps to stop a specific application server in a cell: 1. Open the deployment manager WebSphere Integrated Solutions Console. 2. Click **Servers** > **Application Servers**. 3. Select the server and click **Stop** or **Immediate Stop**.
Stop the entire cluster	Complete the following steps to stop the entire cluster: 1. Open the deployment manager WebSphere Integrated Solutions Console. 2. Click **Servers** > **Clusters**. 3. Select the cluster and click **Stop** or **Immediate Stop**.

"Accessing the Configuration Wizard" on page 235
The home page of the Configuration Wizard provides access to common configuration tasks. Supported tasks include setting up a stand-alone server, setting up a cluster, transferring from Apache Derby to another supported database, migrating your server, installing add-ons, and more.

Users and groups

IBM WebSphere Portal Express offers you centralized administration of users and user groups, allowing you to better define users and manage user access rights. Users can register and manage their own account information, or an administrator can provision and manage users. Group memberships can be used to give the required permissions to access an object or perform a request.

"Choose the type of group to use" on page 1220
IBM WebSphere Portal Express offers many types of groups and locations to store the groups. Choosing the type of group and the location the groups are stored is an important step in planning for using groups with WebSphere Portal Express.

"Deregistering users and groups" on page 1237
Depending on circumstances, you might want to remove users or groups from your WebSphere Portal Express that are no longer used or required. You can use the XML configuration interface (XML Access) to list such users and groups. You can also remove only some selected users and groups, and keep others for further use.

Related concepts:

"Working with the Portal Scripting Interface" on page 1120
Learn more about the different modes that you can use with the Portal Scripting Interface.

Choose the type of group to use

IBM WebSphere Portal Express offers many types of groups and locations to store the groups. Choosing the type of group and the location the groups are stored is an important step in planning for using groups with WebSphere Portal Express.

The following list provides a summary of available options for using groups in WebSphere Portal Express.

File Repository

Type of group: Static only

Advantage: Configured with your initial installation

Disadvantage: Not supported in production systems

LDAP Type of group: Static, Nested (optional), Dynamic (optional)

Advantage: LDAP is an established industry protocol, which can integrate with multiple applications. In most use cases, WebSphere Portal Express connects to and uses existing groups in an LDAP server.

Disadvantage: LDAPs are only required to support static groups. Individual LDAP vendors might optionally choose to support both nested and dynamic groups or to support either nested group or dynamic group. Check with your LDAP administrator to determine which type of groups your LDAP supports. If you have more requirements for using groups, consider to use an LDAP location and another location for the groups that are listed next.

Virtual Member Manager Federated database

Type of group: Static only

Advantage: Useful in situations where LDAP is read-only and needs more groups specific to Portal. Allows for cross-repository groups, that is, users from LDAP#1 and users from LDAP#2 may exist in the same database group.

Disadvantage: Groups are not accessible outside of the WebSphere Portal Express server.

Rule Based User Groups

Type of group: Dynamic only

Advantage: Provides dynamic group functions to WebSphere Portal Express in cases where an LDAP server does not support dynamic groups.

Disadvantage: Only supported by WebSphere Portal Express. Other WebSphere Application Server based products cannot use these groups. Groups are accessible outside of the WebSphere Portal Express server.

Related concepts:

"User registry considerations" on page 128
A user registry or repository authenticates a user and retrieves information about users and groups to do security-related functions, including authentication and authorization.

"Rule-based user groups"
Rule-based user groups for IBM WebSphere Portal Express allow you to define dynamic portal user groups.

Related information:

 Configuring dynamic member attributes in a federated repository configuration

Managing users and groups

The Manage Users and Groups portlet allows you to view, create, and delete users and user groups. You can also change group memberships.

Procedure

1. Log in to IBM WebSphere Portal Express as an administrator.
2. Click the **Administration menu** icon. Then, click **Access** > **Users and Groups**.

Rule-based user groups

Rule-based user groups for IBM WebSphere Portal Express allow you to define dynamic portal user groups.

Rule-based user groups are implemented as a custom repository adapter for Virtual Member Manager (VMM). Rule based user groups are represented by a unique group name, the Lightweight Directory Access Protocol (LDAP) search filter rule expression, and an optional description. The portal handles them as normal portal user groups. They are in a special base distinguished name in the user realm hierarchy. Administrators can create, define, update, or delete them by using the VMM API in WebSphere Application Server or the Portal User Management Architecture (PUMA) in WebSphere Portal Express like other groups. You can use these soft groups to assign security role mappings, portal access permissions, or visibility rules the same way as other portal user groups. The rule-based user groups feature handles the correct membership determination for the users during run time. Advantages:

- Rule-based user groups allow you to define and assemble dynamic portal user groups. They are based on LDAP search filter expressions applied to user attributes.
- These groups are persisted in the portal database, not in the main portal user repository. You do not need to enter them into the LDAP.

What you can do with rule-based user groups

- Define a rule-based user group including the syntax validation of the rule.
- Modify the rule or description of an existing rule-based user group including the syntax validation of the rule.
- Search for rule-based user groups based on the group name.
- Resolve the rule-based user group membership for particular users during run time.
- Display the members of a particular rule-based user group.

Note: This operation can have an impact on the performance of your portal. Perform it only to verify the resulting set of members after defining a rule base group.

- Delete an existing rule-based user group.

Notes:

1. Rule based user groups can contain only individual users, but not groups.
2. After defining a rule-based user group, you cannot change the unique group name.

"Configuring the rule-based user groups adapter"
To install rule-based user groups on your WebSphere Portal Express, you must set up a database, and configure VMM rule based groups.

Configuring the rule-based user groups adapter

To install rule-based user groups on your WebSphere Portal Express, you must set up a database, and configure VMM rule based groups.

"Database setup"
You must create the database table manually before you can use rule based user groups.

"Database source configuration" on page 1223
The rule-based user groups adapter uses a Java data source to communicate with the database that holds the table for the rule-based groups.

"Configuring the VMM rule-based groups repository" on page 1224
To enable the VMM rule-based groups repository adapter, modify several VMM configuration files.

Database setup:

You must create the database table manually before you can use rule based user groups.

The rule-based user groups feature stores the definitions of the rule-based user groups in a database table. This includes the name, rule, and description of the group. Use one of the following SQL statements to create the table, using a database and schema of your choice. Replace *schema_name* in the scripts with the schema name of your choice.

Syntax for DB2 and Derby databases:

```
CREATE TABLE schema_name.SOFTGROUPS
(ID INT NOT NULL GENERATED ALWAYS AS IDENTITY,
 GROUPNAME VARCHAR(128) NOT NULL,
 RULE VARCHAR(300) NOT NULL,
 DESCRIPTION VARCHAR(512),
 LASTMODIFIED TIMESTAMP,
 PRIMARY KEY (ID),
 UNIQUE (GROUPNAME));

CREATE INDEX schema_name.SOFTGROUPSIX1 ON
schema_name.SOFTGROUPS (LASTMODIFIED DESC);
```

Syntax for SQL databases:

```
CREATE TABLE schema_name.SOFTGROUPS
(ID INT NOT NULL IDENTITY PRIMARY KEY,
GROUPNAME VARCHAR(128) NOT NULL UNIQUE,
"RULE" VARCHAR(300) NOT NULL,
DESCRIPTION VARCHAR(512),
LASTMODIFIED DATETIME);
```

```
CREATE INDEX SOFTGROUPSIX1 ON
schema_name.SOFTGROUPS(LASTMODIFIED DESC);
sp_indexoption 'schema_name.SOFTGROUPS',
'disallowpagelocks', TRUE;
```

Syntax for Oracle databases:

```
CREATE TABLE schema_name.SOFTGROUPS
  (
     ID           INT,
     GROUPNAME    VARCHAR(128) NOT NULL,
     RULE         VARCHAR(300) NOT NULL,
     DESCRIPTION  VARCHAR(512),
     LASTMODIFIED TIMESTAMP,
     PRIMARY KEY  (ID),
     UNIQUE (GROUPNAME)
  );

CREATE INDEX schema_name.SOFTGROUPSIX1 ON
schema_name.SOFTGROUPS  (LASTMODIFIED DESC);

CREATE SEQUENCE softgroups_seq;

CREATE TRIGGER softgroups_seq_trigger
  before INSERT ON schema_name.SOFTGROUPS
  FOR each ROW
BEGIN
    IF ( :new.id IS NULL ) THEN
      SELECT softgroups_seq.nextval
      INTO   :new.id
      FROM   dual;
    END IF;
END;
/
```

Oracle does not support auto-increment or identity feature directly as part of the ID column definition. You must create a sequence and a trigger. For easy submission of the statement, make sure to add the final slash character (/). You can submit the statement by pressing the `Enter` key.

Database source configuration:

The rule-based user groups adapter uses a Java data source to communicate with the database that holds the table for the rule-based groups.

You must define a data source that references the required JDBC driver and points to the database that contains the groups table. For information about how to configure a data source, see the related links section.

Create the data source and, if you have a portal cluster environment, map it to the cluster scope.

Before you continue with the next configuration step, run the **Test connection** operation in the WebSphere Integrated Solutions Console and make sure that it runs successfully. Configure the rule-based user groups adapter later with the JNDI name of the data source. See the related links section for information.

Configuring a data source using the administrative console

Configuring the VMM rule-based groups repository:

To enable the VMM rule-based groups repository adapter, modify several VMM configuration files.

About this task

In a cluster, you can change the configuration files directly on the deployment manager and then synchronize the changes to all cluster nodes.

"Configuring the VMM repository and realm"
Run the **wp-create-cur**, **wp-create-cur-custom-property**, and **wp-update-group-repository-relationship** commands to configure the VMM repository and realm.

"Configuring the rule attribute for the Group" on page 1225
In addition to the repository configuration, you must define the rule attribute as a new attribute for the entity type `Group`.

Related information:

"Database source configuration" on page 1223
The rule-based user groups adapter uses a Java data source to communicate with the database that holds the table for the rule-based groups.

Configuring the VMM repository and realm:

Run the **wp-create-cur**, **wp-create-cur-custom-property**, and **wp-update-group-repository-relationship** commands to configure the VMM repository and realm.

Procedure

1. Open a command prompt and change to the *wp_profile_root*`/ConfigEngine` directory.
2. Run the following task to add the repository configuration to VMM. See the related links section for information about this task.
   - Linux : `./ConfigEngine.sh wp-create-cur -DWasPassword=yourpassword -Dfederated.cur.id=SoftGroups -Dfederated.cur.adapterClassName=com.ibm.wps.vmm.adapter.softgroups.SoftgroupsAdapter -Dfederated.cur.baseDN=o=softgroups`
   - IBM i: `ConfigEngine.sh wp-create-cur -DWasPassword=yourpassword -Dfederated.cur.id=SoftGroups -Dfederated.cur.adapterClassName=com.ibm.wps.vmm.adapter.softgroups.SoftgroupsAdapter -Dfederated.cur.baseDN=o=softgroups`
   - Windows: `ConfigEngine.bat wp-create-cur -DWasPassword=yourpassword -Dfederated.cur.id=SoftGroups -Dfederated.cur.adapterClassName=com.ibm.wps.vmm.adapter.softgroups.SoftgroupsAdapter -Dfederated.cur.baseDN=o=softgroups`
3. Run the following command to update the repository configuration with custom properties: Specify the following attributes on the command line:

   dataSource
   The attribute must point to the correct JNDI name of the previously configured data source for the rule-based groups database.

   dbSchema
   The attribute must declare the database schema that holds the rule-based groups table.

   dbType If your database server type is SQLServer, you must declare the

attribute dbType by specifying SQLServer as the value. For all other database server types, you can omit the value.

Base entry specification
You can set the base entry specification that defines the base distinguished name and suffix for rule based groups to a different value.

name The name and the nameInRepository must be the same.

- Linux :

```
./ConfigEngine.sh wp-create-cur-custom-property -DWasPassword=yourpassword -Dcur.id=SoftGrou
./ConfigEngine.sh wp-create-cur-custom-property -DWasPassword=yourpassword -Dcur.id=SoftGrou
./ConfigEngine.sh wp-create-cur-custom-property -DWasPassword=yourpassword -Dcur.id=SoftGrou
```

- IBM i:

```
ConfigEngine.sh wp-create-cur-custom-property -DWasPassword=yourpassword -Dcur.id=SoftGroups
ConfigEngine.sh wp-create-cur-custom-property -DWasPassword=yourpassword -Dcur.id=SoftGroups
ConfigEngine.sh wp-create-cur-custom-property -DWasPassword=yourpassword -Dcur.id=SoftGroups
```

- Windows:

```
ConfigEngine.bat wp-create-cur-custom-property -DWasPassword=yourpassword -Dcur.id=SoftGroup
ConfigEngine.bat wp-create-cur-custom-property -DWasPassword=yourpassword -Dcur.id=SoftGroup
ConfigEngine.bat wp-create-cur-custom-property -DWasPassword=yourpassword -Dcur.id=SoftGroup
```

4. You must enable the cross repository group lookup for the repositories you want to use. To find Groups Entities in the SoftGroups Repository, run the following task:
   - Linux : `./ConfigEngine.sh wp-update-group-repository-relationship -DWasPassword=password -Drepository.id=ldapid -Drepository.forgroups=SoftGroups`
   - IBM i: `ConfigEngine.sh wp-update-group-repository-relationship -DWasPassword=password -Drepository.id=ldapid -Drepository.forgroups=SoftGroups`
   - Windows: `ConfigEngine.bat wp-update-group-repository-relationship -DWasPassword=password -Drepository.id=ldapid -Drepository.forgroups=SoftGroups`

Related information:

"Database source configuration" on page 1223
The rule-based user groups adapter uses a Java data source to communicate with the database that holds the table for the rule-based groups.

Configuring a federated custom user registry

Configuring the rule attribute for the Group:

In addition to the repository configuration, you must define the rule attribute as a new attribute for the entity type Group.

Procedure

1. Edit the file wimxmlextension.xml in the directory *PortalServer_root*/config/*cell_name*/wim/model/. If the file does not exist yet, create it.
2. Add the following attribute definitions:

```
<?xml version="1.0" encoding="UTF-8"?>
<sdo:datagraph xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
               xmlns:sdo="commonj.sdo"
               xmlns:wim="http://www.ibm.com/websphere/wim">
  <wim:schema>
    ...
      <wim:propertySchema nsURI="http://www.ibm.com/websphere/wim" dataType="String"
```

```
            multiValued="false"
            propertyName="rule">
           <wim:applicableEntityTypeNames>Group</wim:applicableEntityTypeNames>
      </wim:propertySchema>
     ...
   </wim:schema>
</sdo:datagraph>
```

See the related links section for information about adding attributes.

3. Restart the portal server for the VMM configuration changes to become effective. In a portal cluster environment, synchronize the changes and restart the complete cluster, including deployment manager and node agents.

Related tasks:

"Adding attributes" on page 569
The VMM is configured with a default attribute schema that might not be compatible with your LDAP server. Add attributes to extend the VMM attribute schema and then map them between IBM WebSphere Portal Express and your user registry.

Creating new users and groups

Use this topic to create new users and groups by using the portlet and adding them to an existing group.

About this task

The objective of this task is to step you through the process of creating new users and groups.

To complete this task, you must have at least the Editor@USERS role to create users and the Editor@USER_GROUPS role to create user groups. USERS and USER_GROUPS are virtual resources.

The portlets that are used in this task are Users and Groups

Note: As you follow the instructions for this task, refer to the *user IDs and passwords* topic, for more information on the characters you can use in the user ID, password, first name, and last name fields.

Procedure

1. Log in to your portal as an administrator.
2. Click the **Administration menu** icon. Then, click **Access** > **Users and Groups**.
3. Select the user group for the user.
4. Click **New User** or **New Group**.

   Note: If the Editor role is not assigned to the following virtual resources: USER, USER GROUPS, and USER SELF ENROLLMENT, **New User** and **New Group** might not display in virtual portals .
5. If you are creating a new user group, enter a name for the user group.
6. If you are creating a new user, do the following tasks:
   a. Enter a user ID for the new user. The user ID must be 3 - 60 characters in length.
   b. Enter and confirm a password for the new user. The password must be unique and 5 - 60 characters in length.
   c. Enter a first name for the new user.

d. Enter a last name for the new user.
e. Optional: Enter an email address for the new user. This field is not needed for successful creation of a new user.

Note: If you use an LDAP server for your users and groups, your LDAP configuration might place additional restrictions on user and group names. For example, the LDAP configuration might require user names and passwords to be a minimum of 8 characters in length. For information about supported characters, see the related links.

7. Select **Preferred language** from the drop-down list. This field is not needed for successful creation of a new user. If you do not select a preferred language or if the language is not supported by the portal, the default language is the default WebSphere Portal Express language.
8. Click **OK**.

Related information:

"User IDs and passwords" on page 107
Understanding character limitations for user IDs and passwords is important because they are used throughout the system to provide access and secure content. The character limitations provided here apply to the IBM WebSphere Portal Express administrator, IBM WebSphere Application Server administrator, database administrator, LDAP server administrator, and user IDs. Database and LDAP servers can have more restrictive limitations than provided here. Therefore, check the database and LDAP server product documentation for restrictions. Failure to correctly define user IDs and passwords during the installation process can result in installation failure. In addition, your company might have more restrictive user ID and password requirements that you must also follow.

Viewing the members of a group

Display a list of all the group members for a particular user group.

About this task

Perform these steps to view the members of a user group:

Procedure

1. Search for the user group whose members you want to view.
2. Click the required user group in the search results. All members of the group are listed.

Editing user information

Edit user information such as password, User ID, first name, last name, email address, or preferred language.

Procedure

1. Search for the required user or click the **All Authenticated Portal Users** link to get a list of users.
2. Click the **Edit** icon for the required user.
3. Make the necessary changes to the user information.
4. Click **OK** to save your changes, or **Cancel** to exit without saving your changes.

Reusing group information

During the authentication of a user, IBM WebSphere Application Server stores information about which groups users belong to. This information is static for the authentication session of the user. In addition, it can be provided by an External Security Manager via a Trust Association Interceptor. In this case, IBM WebSphere Application Server does not load the information on its own. IBM WebSphere Portal Express can participate in this flow and reuse the information from the WebSphere Application Server security context instead of retrieving it from the LDAP server. This function is also referred to as group assertion or WebSphere Application Server group assertion.

About this task

To prevent modifying existing behavior of your environment or losing existing group information, WebSphere Portal Express does not reuse group information by default. For this reason, you must configure WebSphere Portal Express to reuse group information from the WebSphere Application Server security context. You can choose to reuse group information for user management or for access control.

- Reusing group information for user management results in all components of WebSphere Portal Express benefit from the faster group membership lookup. During the authentication session, the membership of the current user is based on the information that is provided by WebSphere Application Server. This reuse of information reduces load on your LDAP server, increases authentication performance, and results in the ability to define group membership at the authentication layer.
- Reusing group information for access control enables the system to react on possible per request changes of the WebSphere Security context. By default the Security context is not modifiable during an authentication session. However,WebSphere Application Server provides plug points, which allow the execution of a Trust Association Interceptor on every request, which could be used to establish a new security Subject on every request. In this case Portal Access Control would be able to work with the updated subject information and would build a dynamic environment. However, this option requires more system resources, custom extensions to WebSphere Application Server security and impacts performance.

Note: The recommended option is for user management, as this case provides the performance and functional enhancements. The second option for access control is used in specific scenarios, typically as directed by IBM Support or IBM technical documentation.

Note: Do not combine both options as this leads to high CPU load on your system.

Complete the following steps to reuse group information:

Procedure

1. Log on to the WebSphere Integrated Solutions Console (or deployment manager WebSphere Integrated Solutions Console in a cluster).
2. Go to **Resources** > **Resource Environment** > **Resource Environment Providers**.
3. Choose the appropriate options to reuse group information:
   - To reuse group information for user management, the first option that is used typically as an enhancement, complete the following steps:
     a. Select the **WP_PumaStoreService** resource environment provider.

b. Select **Custom properties**.
c. Click **New**.
d. Enter `store.puma_default.filter.assertionFilter.classname` in the **Name** field.
e. Enter `com.ibm.wps.um.AssertionFilter` in the **Value** field.
f. Click **Apply**.
g. Click **Save** to save the changes to the master configuration.

- To reuse group information for access control, complete the following steps:
  a. Select the **WP PACGroupManagementService** resource environment provider.
  b. Select **Custom properties**.
  c. Click **New**.
  d. Enter `accessControlGroupManagement.useWSSubject` in the **Name** field.
  e. Enter `true` in the **Value** field.
  f. Click **Apply**.
  g. Click **Save** to save the changes to the master configuration.

4. Log out of the WebSphere Integrated Solutions Console.
5. Restart the WebSphere_Portal server.

Related tasks:

"Starting and stopping servers, deployment managers, and node agents" on page 1216
Various installation and configuration tasks require you to start and stop IBM WebSphere Application Server and the IBM WebSphere Portal Express application servers, deployment managers, and node agents.

Deleting users and groups

You can delete a user or user group from WebSphere Portal Express.

Procedure

1. From the **Users and Groups** page, choose the link for deleting either a user or a user group:
   - To delete a user, click **All Authenticated Portal Users**.
   - To delete a user group, click **All Portal User Groups**.
2. Select the user or user group that you want to delete.
3. Click the **Delete** icon. A dialog box warns that the selected user or group information and all private data will be removed from the database.
4. Click **OK** to save your changes, or **Cancel** to exit without saving your changes.

   Note: Deleting a user group from the portal does not delete the members of the group.

Virtual Users and Groups

There are two predefined virtual user groups (All Authenticated Portal Users and All Portal User Groups) and one virtual user (Anonymous Portal User). These predefined virtual groups and user allow for access control configuration that applies to abstract sets of users. They are not stored in the user registry. They only exist within the access control context. You cannot change group membership or other attributes of these virtual usergroups and user.

This section describes the following virtual user and user groups:

- Anonymous Portal User
- All Authenticated Portal Users
- All Portal User Groups

Anonymous Portal User

This virtual user models a user who has not yet logged in. Assigning roles to this user on a resource allows access to this resource prior to authentication. This is useful for creating public welcome pages. The **Anonymous Portal User** is not considered to be a member of any group. On pages and their virtual resource parents **CONTENT_NODES** and **PORTAL**, you can only assign the **Anonymous Portal User** to the **User** role type. Delegated Administration on the **Anonymous Portal User** are derived from privileges on the virtual resource **Users**. In other words, the delegating user must have at least Delegator role on the virtual resource **Users** before being allowed to delegate role assignments to **Anonymous Portal Users**.

All Authenticated Portal Users

This virtual user group models the set of all known users. After successfully logging in, users lose the **Anonymous Portal User** identity and become authenticated members of the **All Authenticated Portal Users** virtual user group. Roles assigned to this user group allow establishment of permissions that will apply to all authenticated users and thus support setting up the default privileges for authenticated portal access.

All Portal User Groups

This virtual user group contains all non-virtual user groups.

Administering user impersonation

Use the impersonation feature to access another user's system as though you are that user. Use caution with this configuration. The user who is doing the impersonation might get more permissions than initially granted to them.

Client-side aggregation does not support user impersonation. Do not activate client-side aggregation on any portal pages where the impersonation portlet is deployed.

Use the impersonation feature to view new pages and portlets. Users such as support specialists can use the impersonation feature to find issues and errors. For example, a portal administrator encounters a problem that cannot be resolve. A support specialist can use the impersonation feature to access the system to determine a solution to the problem.

You can use the default Impersonation portlet to impersonate specific users. Alternatively, you can create a resource environment provider to enable impersonation and develop a custom portlet for impersonating users. Use Portal Access Control to assign impersonation roles to users. Assign the **Can Run As User** role to the user you plan to impersonate after you enable the impersonation feature.

User impersonation and people awareness: When a user who is enabled for impersonation impersonates other users, the people awareness feature is disabled for the entire session for which that user is authenticated.

Restriction: A user cannot impersonate himself or herself.

"Enabling and disabling impersonation"
By default, user impersonation is enabled, but you can manually disable or enable the impersonation feature as needed.

"Developing a custom portlet" on page 1232
You can use the default Impersonation portlet to impersonate specific users. Alternatively, you can create a resource environment provider to enable impersonation and develop a custom portlet for impersonating users.

"Assigning the **Can Run As User** role" on page 1233
Users with administrator access in WebSphere Portal Express can assign the **Can Run As User** role to designated users. Use Portal Access Control to assign the role. You can use the Virtual Resources option to grant permission for all users or groups in the system.

"Impersonating an unauthenticated user" on page 1234
Users with administrator access in WebSphere Portal Express can impersonate an unauthenticated user.

Related concepts:

"Controlling access" on page 1524
After creating users and groups, you can assign them different levels of access to specific resources, roles, and policies. This access controls what actions they can perform on various pages, portlets, and applications.

"Auditing" on page 1731
IBM WebSphere Portal Express includes an auditing function that allows users to log certain events and their originators in to a separate log file. This file can then be used to track administrative activities.

"User and group management" on page 2902
The Portal User Management Architecture (PUMA) System programming interface (SPI) provides interfaces for accessing the profiles of a portal User or Group.

Related tasks:

"Installing a portlet" on page 1240
Installing a portlet makes it available to portal users. Adding a portlet to a page makes the portlet accessible to users with the appropriate rights.

Related information:

"Users and groups" on page 1218
IBM WebSphere Portal Express offers you centralized administration of users and user groups, allowing you to better define users and manage user access rights. Users can register and manage their own account information, or an administrator can provision and manage users. Group memberships can be used to give the required permissions to access an object or perform a request.

Enabling and disabling impersonation

By default, user impersonation is enabled, but you can manually disable or enable the impersonation feature as needed.

Procedure

1. Complete the following steps to disable or enable the impersonation feature:
   - To disable the impersonation feature, run the `disable-impersonation` task from the *wp_profile_root*`/ConfigEngine` directory.

Windows

```
ConfigEngine.bat disable-impersonation -DWasPassword=password
-DPortalAdminPwd=password -DCategoriesList=wp.auth.base
```

Linux

```
./ConfigEngine.sh disable-impersonation -DWasPassword=password
-DPortalAdminPwd=password -DCategoriesList=wp.auth.base
```

IBM i

```
ConfigEngine.sh disable-impersonation -DWasPassword=password
-DPortalAdminPwd=password -DCategoriesList=wp.auth.base
```

- To enable the impersonation feature, run the `enable-impersonation` task from the *wp_profile_root*`/ConfigEngine` directory.

  Windows

  ```
  ConfigEngine.bat enable-impersonation -DWasPassword=password
  -DPortalAdminPwd=password -DCategoriesList=wp.auth.base
  ```

  Linux

  ```
  ./ConfigEngine.sh enable-impersonation -DWasPassword=password
  -DPortalAdminPwd=password -DCategoriesList=wp.auth.base
  ```

  IBM i

  ```
  ConfigEngine.sh enable-impersonation -DWasPassword=password
  -DPortalAdminPwd=password -DCategoriesList=wp.auth.base
  ```

2. Stop and restart the *WebSphere_Portal* server.

Related tasks:

"Starting and stopping servers, deployment managers, and node agents" on page 1216
Various installation and configuration tasks require you to start and stop IBM WebSphere Application Server and the IBM WebSphere Portal Express application servers, deployment managers, and node agents.

Developing a custom portlet

You can use the default Impersonation portlet to impersonate specific users. Alternatively, you can create a resource environment provider to enable impersonation and develop a custom portlet for impersonating users.

Sample code

If you do not want to use the WebSphere Portal Express **Impersonation** portlet, use the following sample to develop a portlet to impersonate users:

```
import com.ibm.portal.portlet.service.impersonation.ImpersonationService;
import com.ibm.portal.portlet.service.PortletServiceHome;

public class MyImpersonationPortlet extends GenericPortlet
{
    private PortletServiceHome psh;

    @Override
    public void init() throws PortletException
    {
        try
        {
            javax.naming.Context ctx = new javax.naming.InitialContext();
            psh = (PortletServiceHome) ctx.lookup(ImpersonationService.
JNDI_NAME);
        } catch (Exception ex)
        {
            // error handling
        }
    }

    @Override
    public void processAction(ActionRequest request, ActionResponse
response) throws PortletException, IOException
    {
        // obtain the service object and use the service
        ImpersonationService impersonationService = (ImpersonationService)
```

```
psh.getPortletService(ImpersonationService.class);
        try
        {
            impersonationService.doImpersonate(request, response,
stringuserDN);
        } catch (Exception e)
        {
            // error handling
        }
    }
}
```

You can enter the information for the user you want to impersonate in the `stringuserDN`. Alternatively, you can use the PUMA SPI User object.

Note: The impersonation feature becomes active with the next request.

Assigning the Can Run As User role

Users with administrator access in WebSphere Portal Express can assign the **Can Run As User** role to designated users. Use Portal Access Control to assign the role. You can use the Virtual Resources option to grant permission for all users or groups in the system.

About this task

Important: If you use virtual resources to assign the **Can Run As User** role, the user can also impersonate the administrator.

Procedure

1. Log on to WebSphere Portal Express as an administrator.
2. Click the **Administration menu** icon in the toolbar.
3. Choose one of the following options to assign **Can Run As User** access:
   - Complete the following steps to assign **Can Run As User** access to a user:
     a. Click **Access** > **User and Group Permissions**.
     b. Click **Users**.
     c. Search for the user that you want to assign the **Can Run As User** role.
     d. Click the **Select Resource Type** icon for the appropriate user.
     e. Go to the page that contains the **Virtual Resources** option. Use the **Page Next** button and click the link.
     f. Go to the page that contains the **USERS** option and click the **Assign Access** icon.
     g. Select the **Explicitly Assign** check box for the **Can Run As User** role.
     h. Click **OK**.
   - Complete the following steps to assign **Can Run As User** access for a user group:
     a. Click **Access** > **Resource Permissions**.
     b. Click **User Groups**.
     c. Search for the user group that you want to assign the **Can Run As User** role.
     d. Click **Assign Access**.
     e. Select the **Explicitly Assign** check box for the **Can Run As User** role.
     f. Add the user that you want to impersonate the users of this user group.
     g. Click in the breadcrumb to return to the user group page.
     h. Click **Apply** and accept the changes.

i. Click **OK**.

4. Verify that the user now has **User** and **Can Run As User** access.

Impersonating an unauthenticated user

Users with administrator access in WebSphere Portal Express can impersonate an unauthenticated user.

Procedure

1. Log on to WebSphere Portal Express as the administrator.
2. Click the **Administration menu** icon. Then, click **Access** > **Resource Permissions**.
3. Click **Virtual Resources**.
4. Locate the **WCM REST SERVICES** resource type and then click the **Assign Access** icon.
5. Locate the **User** resource permission and then click the **Edit Role** icon.
6. Click **Add**.
7. Check the **Anonymous Portal User** check box.
8. Click **OK**.
9. Verify that you can now impersonate an unauthenticated user.

Results

The users with the **`Can Run As User`** role can now impersonate another user.

Customize common name generation

By default, IBM WebSphere Portal Express generates common names that consists of the user's first name followed by the last name. You can change the order that common names are generated.

To change the order of common names modify the following three configuration properties, located in the Puma Store Service. See the related links section for information:

- **`puma.commonname`**: This property defines how the common name is generated. You can define dynamic and static parts. Dynamic parts are added using *X*, where *X* stands as a reference number. Dynamic parts can only be available and valid user attributes. By default {0} {1} is used.
- **`puma.commonname.parts`**: This property defines the amount of dynamic parts in the common name.
- **`puma.commonname.X`**: This property defines the user attribute for dynamic part *X*. *X* must be between 0 and **`puma.commonname.parts-1`**.

Related tasks:

"Setting service configuration properties" on page 283
IBM WebSphere Portal Express comprises a framework of services to accommodate the different scenarios that portals need to address. Services are available for both WebSphere Portal Express and IBM Web Content Manager. You can configure some of these services.

Nested groups

Two groups are nested if one of the groups contains the other group as a member. The access control system treats this as though all members of the contained group are also members of the containing group. In other words, permissions for nested groups are treated as cumulative.

One group, GlobalMarketing, could for example contain another group, USMarketing, resulting in all members of USMarketing being treated as members of GlobalMarketing. This means that members of USMarketing inherit the access rights granted to GlobalMarketing members. So, if GlobalMarketing has view access to the **File Server** portlet, and USMarketing has view access to the **Reminder** portlet, USMarketing has view access to both the **File Server** and **Reminder** portlets. For example, Joe, as a member of the GlobalMarketing group, can only access the **File Server** portlet, but Susan, as a member of the USMarketing group, can access both portlets.

Note: If you do not plan to use nested groups for access control inheritance, set **accessControlDataManagement.enableNestedGroups** to `false` in the **Access Control Data Management** service, **nestedGroupLookup.disabled** to true in the **WCM WCMConfigService** service, and **rulesEngine.user.nestedGroupLookup** to false in **WCM PersonalizationService** to improve performance. This will limit the membership lookup that Portal Access Control performs to one group level in the hierarchy. This means that a user is granted access rights only by explicit role mappings or role mappings to the groups of which that user is a direct member. See Setting service configuration properties for information.

Related tasks:

"Setting service configuration properties" on page 283
IBM WebSphere Portal Express comprises a framework of services to accommodate the different scenarios that portals need to address. Services are available for both WebSphere Portal Express and IBM Web Content Manager. You can configure some of these services.

Registration/Edit My Profile and Login portlets

The Registration/Edit My Profile and Login portlet resides on special pages where the anonymous user has access rights based on the User role. The unique name **wps.Login** is assigned to the page holding the login portlet, and the unique name **wps.Selfcare** is assigned to the page holding the Registration/Edit My Profile portlet.

The Registration/Edit My Profile portlet is for subscriber management. Registration allows users to register for access and information entered during Registration can be updated in Edit My Profile. Registration is also referred to as "Sign up".

This topic is divided into the following subtopics:

Registration/Edit My Profile

During registration, the user enters mandatory data, such as the user ID and first and last names. The user has the option to select the preferred language from a list

of available languages. The portal uses this language in all interactions and makes this information available to all portlets so that they can adapt to the user preference. If a language is not selected, the portal determines which language to use from the users' browser settings.

Table 167. Registration/Edit My Profile portlet configuration parameters

Parameter Name	Registration/Edit My Profile portlet configuration parameters
HomePageUniqueName	Use this property to identify the page that is selected when users click **Cancel**. Update this parameter to match your environment. Default: `ibm.portal.Home`
GenerateCN	Use this property to specify whether WebSphere Portal Express should generate the value of the `cn` attribute from the supplied user attributes. Default: `true`
attr_XXX	This portlet applies special handling to a subset of user attributes. You can use the **attr_XXX** parameters to match the actual attribute name to the logical name used in the portlet. Attributes that receive special handling: **alternativeCalendar** **cn** **email** **firstDayOfWeek** **firstName** **firstWorkDayOfWeek** **lastName** **password** **preferredCalendar** **preferredLanguage** **timeZone,uid**

Creating new attributes for the Registration/Edit My Profile portlet

You can change information entered at registration. Administrators can determine what information appears in the profile. LDAP or member management fields determine what fields appear as potential fields for the user profile. Some fields are disabled because they are required fields in PUMA (user management), and cannot be removed. Optional attributes of data type **string** can be added using the configuration mode of the portlet. If you do not see the required attribute displayed in the configuration mode, review the information under Adapting the attribute configuration to ensure that the attribute was properly added, mapped, or both.

By default, the same portlet instance is used for Registration and for Edit My Profile. In this design, changes made with the configure link apply to both cases.

Since a separate instance of the Registration/Edit My Profile portlet exists for each virtual portal, it is possible to have different customized portlets for each virtual portal.

Login

To access the Login portlet, click **Log In** in the banner. The Login portlet can also be placed on any page.

Since a separate instance of the Login portlet exists for each virtual portal, it is possible to have different customized portlets for each virtual portal.

Related concepts:

"Authentication" on page 1520
Authentication requires users to identify themselves to gain access to a system or resources. The combination of a user ID and a password is the most common method of authentication. Users can identify themselves immediately upon entry to the system or the system can prompt users to identify themselves before accessing protected resources. After users successfully authenticate, the system identifies which resources-specific users have sufficient authorization to access.

Using step-up authentication and/or the Remember me cookie lets you fine-tune user authentication to pages and portlets.

Deregistering users and groups

Depending on circumstances, you might want to remove users or groups from your WebSphere Portal Express that are no longer used or required. You can use the XML configuration interface (XML Access) to list such users and groups. You can also remove only some selected users and groups, and keep others for further use.

About this task

IBM WebSphere Portal Express stores users and groups that exist in the user registry as entries in the database. When you use the XML configuration interface or the **Manage User and Groups** portlet to delete users and groups, they are deleted from both the user registry and from the database. Deleting a user or group directly from the configured user registry does not remove the database entry. Also, WebSphere Portal Express does not remove entries from its database when users or groups are muted in the user registry, for example, users with too many wrong password attempts. You can manually remove the users and groups from the database.

Examples for removing users or groups can be the following cases:

- Portal users or groups were removed from the user registry, but not from the portal database.

- User IDs were deactivated, for example after too many wrong password attempts.

Note: After you delete these entries by using the modified XML script, all customization is lost for the deleted users and groups.
To remove users and groups from your portal, proceed as follows:

Procedure

1. Make a backup copy of your portal database.
2. To identify and list these users and groups, run an XML export and use the `cleanup-users` attribute.

   Specify the `cleanup-users` attribute with the `request` tag of type `export`, and set its value to `true`. You also need to set the `export-users` attribute to `true`.

   The resulting output file lists the affected users and groups with their action set to `delete`.

   The XML sample file `CleanupUsers.xml` shows an example of how you can export such users and groups. For information about the sample XML configuration files and their location, read *Sample XML configuration files*.

   Note: CF03 If the number of invalid users is very high, the XML export step can fail with an out-of-memory exception. For such cases, APAR PI23109 introduces a new XML element `threshold`. In case of such out-of-memory exceptions, add `threshold="10000"` to the `<request ... >` element in the `CleanupUsers.xml` script. This option limits the number of exported users to 10,000. When you use this approach, repeat the export step and all following steps until the exported file contains no entries any more. You need to have APAR PI23109 or fix pack CF03 installed to use this XML element.
3. Check the output file from the previous step and **remove** all users and groups that you want to **keep** in the portal database. For example, you might want to keep the muted users and re-enable their passwords. All users and groups that remain in the file are removed from the database in the following import step.
4. Import the modified XML file into your portal. The portal removes all users and groups that you retained in the XML file during the previous step from the portal database.

Results

After you delete these entries by using the modified XML script, all customization is lost for the deleted users and groups.

Sample files are provided for your reference to help illustrate how to use XML configuration for different portal configuration purposes. Before you use them, read the other topics about the XML configuration interface carefully. Many of the samples need to be modified with valid page or user name before they can be used.

Managing portlets, portlet applications, and iWidgets

You must do some preparatory tasks before you make your portlets, portlet applications, or iWidgets available to your users by putting them on portal pages. This preparatory task includes installing, deploying, and configuring portlets, applications, and iWidgets.

You can further work with portlets by using the administration portlets that are available under the portal **Administration menu** > **Portlet Management**. Refer to the portlet helps for details. After you complete preparing your portlets or iWidgets, you can make them available for your users.

start of the page that is displayed, even if the link that was clicked points to a portlet, which is placed further down on the page. To achieve this, you can disable the anchors.

"Managing iWidgets in your portal" on page 1247
You can add iWidgets to your IBM WebSphere Portal Express.

Web modules, portlet applications, and portlets

A web module represents a web application. It is used to assemble servlets and JSP files as well as static content, such as HTML pages, into a single deployable unit.

Web modules are stored in web archive (WAR) files, which are standard Java archive files. The standard file extension for WAR files is `.war`. A Web module can contain one or more portlet applications, servlets, JavaServer Pages (JSP) files, and other files. A deployment descriptor, stored in an Extensible Markup Language (XML) file, declares the contents of the modules, information about the structure and external dependencies, and a description of how the components are to be used at run time.

Portlet applications are created implicitly when a WAR file is deployed. The portlet application holds one or more related portlets that come packaged in the same installation file. These portlets can share resources and send messages among themselves to communicate events. A portlet application may consist of a single portlet or multiple portlets. An example of a single portlet application is the Reminder portlet application, which contains a single portlet named Reminder Portlet. An example of a portlet application with multiple portlets is Portlet Manager Application, which contains Manage Web Modules, Manage Applications, and Manage Portlets.

You can add portlets to a running system at any time. After installation, the new portlets are immediately available to administrative users. They can assign the appropriate user roles to the appropriate groups and users so that they can access and use the portlets. Once available, the portlets can be selected for display on the portal pages of users and can be edited as appropriate. Identification information of WAR files is stored in a database for easy deployment in complex server environments with multiple portal servers. By allowing all files associated with a portlet to be packed into a single file, distribution and deployment of new portlets is made easier. Portlets can be distributed in WAR file format through websites and other means.

Installing a portlet

Installing a portlet makes it available to portal users. Adding a portlet to a page makes the portlet accessible to users with the appropriate rights.

Before you begin

Before you install a portlet, you must be aware of the following requirements:

- An administrator must have the Manager role on the portal to install portlets. Therefore, you must log in with a user ID with the Manager role access rights.
- Windows limits the maximum path length to 260 characters, the name of the WAR file must be 25 characters or less. Installing a WAR file with a name that is more than 25 characters results in an error.
- You cannot install a portlet more than once. If you want two instances of a portlet application or portlet, use the copy command to create a second instance.

About this task

Each WAR file includes descriptive information about the portlet, which is placed in a database that can be queried by other portal components. During installation, Application Server unpacks the WAR file and places the portlet classes and resources in a file system.

During the installation, the portlet state is set to active, and a new rule is automatically added to Access Control that defines the user who installed the portlet as the owner, granting management access for that portlet. The user must assign the appropriate user roles to the appropriate users and groups so that they can access and use that portlet.

Procedure

1. Click the **Administration menu** icon. Then, click **Portlet Management** > **Web Modules**.
2. Click **Install**.
3. Enter the location of the WAR file or click **Browse** to find the location of the file to install.
4. Click **Next**.
5. Verify WAR file information and click **Finish** to install the WAR file.

Results

By default, portlet applications and portlets are set to an active state after installation. After you install a portlet, you can add the portlet to a page with the Portlet Palette. Add the installed portlet to a category in the Portlet Palette and then drag the portlet to the page. If you do not plan to frequently add this portlet to other pages, you can still add the portlet to a page without adding the portlet to a category. To add a portlet to the page without adding it a category, search for the installed portlet in the Portlet Palette and drag the portlet to the page.

What to do next

After the installation is complete, a message appears at the start of the page that indicates a successful installation. If there are any problems during the process, an error message appears in the Manage Web Modules page. Click the **View Details** link to examine the error log.

Deploying Java Platform, Enterprise Edition resources

You can manually pre-deploy portlet application WAR files by using the WebSphere Integrated Solutions Console and later register them into WebSphere Portal Express, together with other Java Platform, Enterprise Edition resources and artifacts.

About this task

Portlet applications are usually packaged into single WAR files. These WAR files can be directly deployed into the portal by using portal administration means. For example, the Manage Web Modules portlet or the XML configuration interface. The portal administration functions manage the correct deployment and configuration into both WebSphere Application Server and WebSphere Portal Express.

You might want to deploy portlet applications together with EJBs, or bundle several WAR files into the same EAR file, or work with similar scenarios. For this type of requirement WebSphere Portal Express provides the predeployed mode with the XML configuration interface. It allows you to configure portlet applications into the portal that you predeployed into the application server as part of a larger EAR file.

You deploy the EAR file into the application server by using the application server administration interfaces, such as the WebSphere Integrated Solutions Console or the `wsadmin` command-line tool. When you deploy the EAR file into the application server, you can use the portal XML configuration interface to run the portal specific configuration steps that are required to configure the available portlet applications.

Procedure

1. Bundle the portlet applications that you want to register together with other Java Platform, Enterprise Edition resources as an Enterprise Application Archive (EAR file). For details about how to do this procedure refer to the correct version of the WebSphere Application Server product documentation: http://www.ibm.com/software/webservers/appserv/was/library/.
2. Deploy this EAR file into WebSphere Application Server. To do this step, use the `wsadmin` command-line tool or the WebSphere Integrated Solutions Console. Consult the WebSphere Application Server product documentation for details about how to do this step. Take a note of the target directory to which you deploy the EAR file; this step is needed for creating the XML file in the next step. Also, make sure that the web modules in the EAR file are deployed with the same server and virtual host mappings as the portal.
3. Create a portal XML script file that deploys and configures the portlet applications that are deployed with the EAR file. For a sample XML file for deploying and configuring a predeployed portlet, refer to RegisterPreDeployedEAR.xml.
4. Run the XML script by using the portal XML configuration interface.

Results

After you complete these steps, the portlet is ready for use.

Note:

1. You can register predeployed applications into the portal only by using the XML configuration interface. When you register a predeployed application, the Manage Web Modules portlet shows this application.
2. You can later use the portal administration portlets to remove the portlet definitions from the portal database. However, this process does not remove the EAR file from WebSphere Application Server.
3. You can update a predeployed portlet application only by using the XML configuration interface.
4. You cannot update a deployed portlet application WAR file with a predeployed EAR file and vice versa. If you want to change between the two types of files, you must delete the existing portlet application and deploy the new one. However, deleting the existing portlet application also deletes all configuration data of that application. A predeployed application can be updated only by updating the EAR file in WebSphere Application Server and subsequent update

of the contained WAR file in portal by using the XML configuration interface. Cross updates of a predeployed EAR file with a real WAR and vice versa are not possible.

5. The WebSphere Application Server administrator must take care of correctly configuring the dispatch mechanisms for these applications.

For more information about the XML configuration interface and how to use it, refer to XML configuration interface. The sample XML file RegisterPreDeployedEAR.xml shows you an example for deploying and configuring a predeployed portlet.

The following table shows the differences between WAR and EAR deployment:

Table 168. Differences between WAR files and predeployed EAR files and the affected portal area

Affected portal area	WAR file	Predeployed EAR file
Portlet application	The portlet application is provided as WAR file. The portal configuration is read directly from the file stream. The WAR file is deployed into the application server by the portal.	The portlet application is already extracted and deployed into the application server as part of the EAR file. The portal server reads the available portal configuration information (`portlet.xml`, and so on) from the location where the contained WAR file was extracted to.
Context Root	The context root is assigned by the portal during WAR deployment.	The context root is assigned by the EAR developer and stored in the file `application.xml`. You must ensure that the context root that you specify when you register the portlet matches the one specified in the EAR `application.xml`. (refer to the sample XML file RegisterPreDeployedEAR.xml.
Display name	The display name is assigned by Portal during WAR deployment.	The display name is assigned by the EAR developer and stored in the file `application.xml`.
WebSphere Application Server policy for portlet applications	The policy is stored in the WAR file and promoted to the EAR file by the portal during WAR deployment.	The policy is stored in the EAR file.
Portlet administration	You administer WAR files by using the XML configuration interface and the administration portlets.	You can register EAR files only by using an XML script with `predeployed` mode. You can remove EAR files by using either the administration portlet or an XML script.

"Sample XML configuration files" on page 1111
Sample files are provided for your reference to help illustrate how to use XML configuration for different portal configuration purposes. Before you use them, read the other topics about the XML configuration interface carefully. Many of the samples need to be modified with valid page or user name before they can be used.

Activating and deactivating portlet applications or portlets

By default, portlet applications and portlets are set to an active state after installation. You can deactivate a resource to prevent users from accessing it without changing their user roles. When a portlet application or portlet is in the active state, portal users with appropriate access can include it on their personal pages and customize it. Users that have active references to those inactive portlets on a portal page will see a message stating that the portlet is temporarily disabled.

Before you begin

About this task

You can toggle portlet application or portlet states to active or inactive by using the portal XML configuration interface.

Related concepts:

"The XML configuration interface" on page 1054
Use the XML configuration interface (XML Access) for exchanging portal configurations.

Related reference:

"Sample XML configuration files" on page 1111
Sample files are provided for your reference to help illustrate how to use XML configuration for different portal configuration purposes. Before you use them, read the other topics about the XML configuration interface carefully. Many of the samples need to be modified with valid page or user name before they can be used.

Related information:

"Working with the XML configuration interface" on page 1061
You can use the XML configuration interface to export and import IBM WebSphere Portal Express configurations. This way you can configure selected features or areas of your portal. You can also transfer a complete configuration from one portal to another.

Modifying portlet applications and portlets

You must perform some preparatory tasks before you make your portlets and portlet applications available to your users by putting them on portal pages. This includes installing, deploying, and configuring portlets and applications.

A portlet is initially displayed in the **View** mode. A user can apply customizations to individual, selected, or all instances of the portlet by leaving the View mode and entering into the Personalize, Edit Shared Settings, or Configure mode as appropriate. To access these other modes, hover over the portlet title bar, click ▼ to display the portlet menu, and select the appropriate mode. Refer to the following descriptions for more information about the Personalize, Edit Shared Settings, and Configure modes.

Note: Once you leave the View mode by selecting another portlet mode, you must click **Back** from the portlet menu to return to the View mode. You must return to the View mode before changing to another mode.

- **Personalize:** Updates change the look of the portlet only for the user who makes the updates. In order for a user to have access to personalize settings, they must be granted at least Privileged User role on the page and Privileged User role on the corresponding Portlet Definition. This is available for standard portlets and IBM portlets.

- **Edit Shared Settings:** Updates change the default look of the portlet on a specific page. All users see the change when they access that page. In other words, all (the particular) portlet instances on a page are modified, but not all instances of that portlet on every page. If you want the changes to appear on every page that portlet appears, you must modify the settings on each page. In order for a user to have access to edit shared settings they must be granted at least Editor role on the page and Editor role on the corresponding Portlet definition. This is available for standard portlets and IBM portlets.
- **Configure:** Updates change the default look of a portlet for all portlet instances. All users see the portlet changes on all pages that portlet is available. A user needs to have at least Manager role on portlet definition to have access to configure a portlet.

It depends on the portlet which selection options are available in the portlet menu.

"Configuring portlet applications or portlet parameters"
Many portlet applications and portlets have associated configuration parameters that must be changed after deployment. Manage Applications and Manage Portlets allow you to modify configuration parameters.

Configuring portlet applications or portlet parameters

Many portlet applications and portlets have associated configuration parameters that must be changed after deployment. Manage Applications and Manage Portlets allow you to modify configuration parameters.

About this task

The original configuration is determined by settings in the `portlet.xml` deployment descriptor file. Configuration changes apply to each specific instance of the portlet. WebSphere Portal Express does not validate configuration modification to portlet applications. Some of the portlet parameters can be configured in the portlets themselves by using the portlet modes.

For instructions about the tasks and detailed steps for changing configuration values refer to the **Manage Applications** or **Manage Portlets** helps.

Copying portlet applications

Using the Manage Portlet Application, you can copy a portlet application, which includes some or all of the portlets from the original portlet application. If you want additional instances of a portlet application, use the Manage Portlet Application to make copies.

About this task

Copying can be useful when different portlet configuration parameters are required for different instances of a portlet. A copy of the portlet application can be used to configure the portlet instance for each portlet application. For example, the administrator might want to have multiple Welcome applications. Each copied application would have a different URL, accessing a different content channel, configured for its WelcomePortlet.

When you copy a portlet application, give the copy a new name. The portlet data and the portlet application data are copied, but the copied portlet application uses the same resources as the original portlet application. The new portlet application also uses the same resources as the original portlet application. An example of portlet data is the portlet configuration parameters needed for a particular instance

of a portlet. An example of a portlet resource is an image that the portlet displays in the user interface. While the portlet configuration parameter is associated with each instance of the portlet, all instances of the portlet use the same image.

Results

Only portlets in the copied portlet application are in the new portlet application. For instance, if the copied portlet application contains four portlets and the original contains five portlets, only the four portlets are copied to the new portlet application.

Copying portlets

Use Manage Portlets to copy a portlet. If a portlet is copied or a remote portlet is integrated, a new portlet application is created by the portal that holds the new portlet.

About this task

When you copy a portlet, give the copy a new name. When you copy the portlet, the portlet data is copied, but the copied portlet uses the same resources as the original portlet. When a copied portlet is copied, the new portlet also uses the same resources as the original portlet. An example of portlet data is the portlet configuration parameters needed for a particular instance of a portlet An example of a portlet resource is an image that the portlet displays in the user interface. While the portlet configuration parameter is associated with each individual instance of the portlet, all instances of the portlet use the same image.

Updating Web modules, portlet applications, and portlets

Update a portlet application by updating the WAR file in Manage Web Modules. The newer version of the resource in the WAR file updates the existing portlet application, without breaking the links between user data and the resource. User-specific settings for portlets within the updated resource remain unchanged.

About this task

Before a selected Web module is updated, WebSphere Portal Express checks for an identical resource name in the selected WAR file. If the name of the selected object and the object name in the deployment descriptor of the WAR file do not match, the update is not performed, and a message is displayed.

When a Web module is updated, WebSphere Application Server removes the existing files and installs the updated application in the same directory.

New parameters that are introduced by the updated Web module are always added to the Web module.

Deleting Web modules, portlet applications, or portlets

Web modules can be deleting or uninstalled in Manage Web Modules and portlet applications can be deleted using Manage Applications. Portlets can be deleted using Manage Portlets.

Before you begin

About this task

After selecting an object for deletion, the system waits until all outstanding requests for the portlet application or portlet have been completed and then removes all related files and resources from the portal server. Before removing a portlet application, you must first delete all of its copied portlet applications. If you have the portlet WAR file, you may reinstall the portlet components after deleting it from the system by updating the WAR file in Manage Web Modules. You can reinstall the deleted portlet after ensuring all portlet applications installed in the portlet WAR file have been removed and that the WAR file has been uninstalled.

Important: Do not delete any of the portal administration portlets.

For instructions about the tasks and detailed steps for deleting Web modules, portlet applications, or portlets refer to the **Manage Applications** or **Manage Portlets** helps.

Disabling anchors in portlet URLs

When you access a portlet in IBM WebSphere Portal Express, the portal appends an anchor to the portlet URL. If several portlets are arranged vertically on a page, this appended anchor forces the browser to scroll down to the portlet rather than display the start of the page. You might prefer to have the start of the page that is displayed, even if the link that was clicked points to a portlet, which is placed further down on the page. To achieve this, you can disable the anchors.

About this task

The use of the anchors depends on the configuration of your device, for example your desktop browser. It is controlled by a client device capability called `FRAGMENT_IDENTIFIER`. When the used device, for example the browser, has this capability enabled, the portal adds an anchor to the portlet URL. You can disable the addition of the anchors by deleting the capability `FRAGMENT_IDENTIFIER` from the appropriate clients. Click the **Administration menu** icon. Then, click **Portal Settings** > **Supported Clients**.

If you want to enable the anchors again, restore the `FRAGMENT_IDENTIFIER` capability. Use the same portlet to add it back to the appropriate clients.

Managing iWidgets in your portal

You can add iWidgets to your IBM WebSphere Portal Express.

About this task

Proceed as follows:

Procedure

1. Register the iWidget in the portal. You do this by running the portal configuration task `register-iwidget-definition`. This procedure places the iWidget in a clone of the wrapper portlet. After this the iWidget behaves like a portlet. For information about using the task see *Task register-iwidget-definition*.

2. Place the iWidget on a page by using the portal administration tools for adding portlet to pages. For example, you can use the Manage Pages portlet, the portal administration tools embedded in the theme, or the XML configuration interface (XML Access) (XMLAccess).

   "Task register-iwidget-definition"
   Run the portal configuration task `register-iwidget-definition` to register individual iWidget definitions on WebSphere Portal Express.

   "Task refresh-iwidget-definitions" on page 1252
   Use this configuration task to refresh iWidget definitions in the portal. This task affects all iWidget definitions that are referenced through absolute HTTP or HTTPS URLs in addition to iWidget definitions that are referenced through WebDAV URIs.

Related concepts:

"The XML configuration interface" on page 1054
Use the XML configuration interface (XML Access) for exchanging portal configurations.

Related tasks:

"Manage pages portlets" on page 1273
Use Manage Pages to create, edit, activate, order, and delete pages and external web pages and labels. Available tasks depend on which item is selected. Each page can contain multiple pages. All pages on which you have the User or greater role are displayed in a navigation menu. You must expand pages to access nested pages. The options that you see are dependent upon your access level.

Related reference:

"Putting a portlet on a page" on page 2882
Portal Model REST services allow you to put portlets on pages.

"Task register-iwidget-definition"
Run the portal configuration task `register-iwidget-definition` to register individual iWidget definitions on WebSphere Portal Express.

Related information:

"Customizing pages" on page 1285
The page customizer contains portlets for editing the layout, content, and appearance of pages. It also provides the Wires portlet, which allows users to set up connections between cooperative portlets on a page, and the Locks portlet, which allows users to lock and unlock containers and container content. You can configure the settings for these portlets to show a certain set of functions, restricting basic users from performing more advanced tasks.

Task register-iwidget-definition

Run the portal configuration task `register-iwidget-definition` to register individual iWidget definitions on WebSphere Portal Express.

Identify the iWidget definition by an absolute URL that points to the iWidget definition XML file. Executing this task downloads the iWidget definition XML file from the specified location and creates a corresponding iWidget Wrapper portlet clone. If an iWidget Wrapper portlet clone for the given iWidget URL exists already, no new portlet clone is created, but the existing portlet is updated with the information loaded from the specified iWidget definition XML file.

Syntax: Invoke this task as part of the ConfigEngine script file as follows:

- Linux: `./ConfigEngine.sh register-iwidget-definition -DIWidgetDefinition=`*`IWidget Definition URL`* `-DIWidgetCatalog=dav:fs-type1/iwidgets/`*`IWidget_name`*`/catalog.xml -DPortalAdminPwd=`*`wpsadmin`* `-DWasPassword=`*`wpsadmin`*
- IBM i:
  - **From the UserData directory:** `ConfigEngine.sh register-iwidget-definition -DIWidgetDefinition=`*`IWidget Definition URL`* `-DIWidgetCatalog=dav:fs-type1/iwidgets/`*`IWidget_name`*`/catalog.xml -DPortalAdminPwd=`*`wpsadmin`* `-DWasPassword=`*`wpsadmin`*
- Windows: `ConfigEngine.bat register-iwidget-definition -DIWidgetDefinition=`*`iwidget_Definition_URL`* `-DIWidgetCatalog=dav:fs-type1/iwidgets/`*`IWidget_name`*`/catalog.xml -DPortalAdminPwd=`*`wpsadmin`* `-DWasPassword=`*`wpsadmin`*

Mandatory parameters that you can specify through the command line or in `wkplc.properties`:

`WasUserid`
User ID for WebSphere Application Server

`WasPassword`
Password that corresponds to the user ID for WebSphere Application Server

`PortalAdminId`
Administrator ID for WebSphere Portal Express

`PortalAdminPwd`
Password that corresponds to the administrator ID for WebSphere Portal Express

`WPS_SOAP_PORT`
SOAP port that connects the portal server to remote connections

Mandatory parameters that you can specify only through the command line:

`IWidgetDefinition`
URL of the iWidget definition XML file

Optional parameters that you can specify only through the command line:

`IWidgetCatalog`
URL of an IBM Mashup Center catalog XML file. If you specify this parameter, the task `register-iwidget-definition` parses the referenced catalog XML file to register IWidget definitions or to refresh existing IWidget Wrapper portlet clones. If the parsed catalog XML file contains an entry with a definition element that points to the same iWidget definition file as the parameter `IWidgetDefinition` or the IWidget Wrapper portlet clone that is identified by the parameter `PortletDefinition` , the titles and descriptions from the matching catalog entry are considered for creating or updating the IWidget Wrapper portlet clone. More precisely, the titles and descriptions from the catalog entry are only set on the IWidget Wrapper portlet clone if the corresponding iWidget definition does not define the titles or descriptions in its `idescriptor` item set. When you run the task `register-iwidiget-definition` and provide the IWidgetCatalog parameter but omit `IWidgetDefinition` and `PortletDefinition`, IWidget Wrapper portlet clones for all iWidget definitions referenced in the given catalog XML file are created or updated.

PortletDefinition

Unique name or serialized ObjectID of an iWidget Wrapper portlet clone to refresh. If you specify this parameter, the task `register-iwidgetdefinition` performs a refresh of the referenced iWidget Wrapper portlet clone. This means that the iWidget definition referenced by the existing iWidget Wrapper portlet clone is parsed again to update the portlet.

PortletUniqueName

If this parameter is specified, a new iWidget Wrapper portlet will be created with a unique name as specified by this parameter. If this parameter is specified, the task always creates a new iWidget Wrapper portlet clone independent of the given **IWIdgetDefinition** URL that is already being registered at portal.

Note: If the given unique name is already assigned to some other resource, the task fails and no IWidget Wrapper portlet is created.

Assumptions/Prerequisites: WebSphere Portal Express is running. If WebSphere Portal Express is not running, the task will start it.

Error Conditions: None

Task dependencies: None

Tasks invoked: None

Examples: You can register the iWidget definition XML file located at `http://server_name:port_number/someWidget/someWidget/someWidget.xml` as follows:

```
./ConfigEngine.sh register-iwidget-definition
   -DPortletUniqueName="someWidget"
   -DIWidgetDefinition=http://server_name:port_number/someWidget/someWidget/someWidget.xml
   -DPortalAdminPwd=wpsadmin -DWasPassword=wpsadmin
```

You can refresh the IWidget Wrapper portlet clone with the unique name *someWidget*:

```
./ConfigEngine.sh register-iwidget-definition -DPortletDefinition="someWidget"
   -DPortalAdminPwd=wpsadmin -DWasPassword=wpsadmin
```

You can register the iWidget definition XML file located at `http://server_name:port_number/someWidget/someWidget/someWidget.xml` considering titles and descriptions from the Mashup Center catalog XML file located at `http://server_name:port_number/someWidget/someWidget/catalog.xml`:

```
./ConfigEngine.sh register-iwidget-definition
   -DIWidgetDefinition=http://server_name:port_number/someWidget/someWidget/someWidget.xml
   -DIWidgetCatalog=http://server_name:port_number/someWidget/someWidget/catalog.xml
   -DPortalAdminPwd=wpsadmin -DWasPassword=wpsadmin
```

You can refresh the IWidget Wrapper portlet clone with the unique name *someWidget*, considering titles and descriptions from the Mashup Center catalog XML file located at `http://server_name:port_number/someWidget/someWidget/catalog.xml`:

```
./ConfigEngine.sh register-iwidget-definition
   -DPortletDefinition="someWidget"
   -DIWidgetCatalog=http://server_name:port_number/someWidget/someWidget/catalog.xml
   -DPortalAdminPwd=wpsadmin -DWasPassword=wpsadmin
```

You can perform a bulk registration of iWidget definition XML files or a refresh of IWidget Wrapper portlet clones by using an Mashup Center catalog XML file:

```
./ConfigEngine.sh register-iwidget-definition
   -DIWidgetCatalog=http://server_name:port_number/catalog.xml
   -DPortalAdminPwd=wpsadmin -DWasPassword=wpsadmin
```

Notes:

1. The URL can point to the portal server itself or to an external server. Configure the portal AJAX proxy to allow access to that server. For details refer to the following section.
2. If the definition element of an entry in the Mashup Center catalog XML file contains a relative URL, the URL is resolved into an absolute form using the URL from the **IWidgetCatalog** parameter as a base URL. Only that absolute URL is used for further processing such as accessing the iWidget definition XML file. The absolute URL is also compared with the **IWidgetDefinition** parameter value or the iWidget definition URL of the IWidget Wrapper portlet clone identified by the **PortletDefinition** parameter in order to determine whether or not to consider titles and descriptions from the catalog XML file entry when parsing creating or updating the IWidget Wrapper portlet clone.
3. The **register-iwidget-definition** task only updates titles and descriptions of an IWidget Wrapper portlet clone when you set the following portlet preferences to `true`: `com.ibm.portal.replace.titles` and `com.ibm.portal.replace.descriptions`.
4. When the titles and the descriptions of an IWidgetWrapper portlet clone are set using values from an IBM Mashup Center catalog XML file, the portlet preferences `com.ibm.portal.replace.titles` (default: true) and `com.ibm.portal.replace.descriptions` are set to `false` on the IWidget Wrapper portlet clone. Those portlet preferences prevent the titles and the descriptions of the IWidget Wrapper portlet clone from being overwritten when performing subsequent updates. This is particularly useful when running the **register-iwidget-definition** task to update all IWidget definitions registered in WebSphere Portal Express. The task only considers iWidget definitions that comply with the iWidget specification and does not process IBM Mashup Center catalog XML files.
5. When you refresh IWidget Wrapper portlet clones, values of iWidget attributes (items of the iWidget attributes item set) are not updated unless the attributes are flagged as read only in the iWidget definition XML file. As a result, values of iWidget attributes customized after registering the iWidget in WebSphere Portal Express are prevented from getting lost during a refresh operation.

Registering an iWidget hosted on a Portal server

If you want to register iWidgets deployed as WAR or EAR files directly on your portal server, you can use server relative URLs pointing to the corresponding iWidget definition XML files; for example:

```
./ConfigEngine.sh register-iwidget-definition
     -DIWidgetDefinition=/someWidget/someWidget/someWidget.xml
     -DPortalAdminPwd=wpsadmin -DWasPassword=wpsadmin
```

Remember: Do not forget the leading slash "/" in your iWidget definition URL.

Registering an iWidget hosted on an external server

If you use an iWidget definition URL that points to a server different from your portal server, you need to make sure that your current AJAX proxy configuration

allows accessing this server. For details about this refer to the topics about AJAX proxy Configuration. One way of configuring this is to make sure that the URL to the iWidget definition XML file is mapped to the default_policy dynamic policy in the global AJAX proxy configuration file. You can map a given URL, for example `http://server_name:port_number/someWidget/someWidget/someWidget.xml`, to that policy by adding a custom property such as the following to the WP ConfigService Resource Environment Provider in the WebSphere Application Server administrative console:

```
wp.proxy.config.urlreplacement.default_policy.someID=http://some.server.com:10039/*
```

Notes:

1. The updated policy will not be effective until you restart either the portal server or the AJAX proxy Configuration enterprise application running on the portal server.
2. If you use a URL prefix, do not omit the trailing asterisk (*).

Registering light weight iWidgets stored in the WebDAV file store

Additional to HTTP or HTTPs based iWidget definition URLs, you can also use WebDAV file store URIs pointing to iWidget definition XML files located in the WebDAV file store. Such URIs have the following format:

```
dav:fs-type1/path_to_your_IWidget_definition_XML_file
```

For example, you might have an archive or compressed file with a light weight iWidget that contains an iWidget definition XML file called `someWidget.xml` in the file root folder of the archive or compressed file. In this case you typically first copy the archive or compressed file to the WebDAV file store by using a generic WebDAV client or by using the configuration task `webdav-deploy-zip-file` as follows:

```
./ConfigEngine.sh webdav-deploy-zip-file
     -DZipFilePath=/tmp/SomeWidgetPackage.zip
     -DTargetURI=dav:fs-type1/iwidgets/SomeWidget/
     -DPortalAdminPwd=wpsadmin -DWasPassword=wpsadmin
```

This extracts your light weight iWidget package represented by the file `/tmp/SomeWidgetPackage.zip` into the folder `/iwidgets/SomeWidget` of the WebDAV file store. Make sure to add the trailing slash (`/`) in the parameter `TargetURI`. After the extraction you can register the iWidget definition XML file `someWidget.xml` as follows:

```
./ConfigEngine.sh register-iwidget-definition
     -DIWidgetDefinition=dav:fs-type1/iwidgets/SomeWidget/someWidget.xml
     -DPortalAdminPwd=wpsadmin -DWasPassword=wpsadmin
```

Task refresh-iwidget-definitions

Use this configuration task to refresh iWidget definitions in the portal. This task affects all iWidget definitions that are referenced through absolute HTTP or HTTPS URLs in addition to iWidget definitions that are referenced through WebDAV URIs.

Refreshing an iWidget definition in this context means, reloading the iWidget definition XML files and updating the corresponding iWidget Wrapper portlet clone accordingly. You can run the task in a synchronous or asynchronous manner. If you run this task asynchronously, the configuration task completes immediately after you start a corresponding asynchronous system task. You can use this mode to avoid timeout problems that might occur if there are a high number of iWidget definitions to be refreshed. The completion of the system task is indicated in `SystemOut.log`.

Notes about this task:

- `refresh-iwidget-definitions` updates the titles and the descriptions of an iWidget Wrapper portlet clone only if you set the following portlet preferences to `true`: **`com.ibm.portal.replace.titles`** and **`com.ibm.portal.replace.descriptions`**. If these parameters do not exist in the installed iWidget, you must add them and set their values to `true`.
- If the lines with the iWidget `item id="title"` and `item id="description"` in the iWidget XML file do not include the option `readOnly="true"` set, the default command does not work. To correct this issue, you can choose between the following options:
  - In the portlet XML file, add the `readOnly="true"` option to the lines with `item id="title"` and `item id="description"` as follows:

    ```
    <iw:item id="title" lang="en" value="iWidget Title" readOnly="true">
      ...
    <iw:item id="description" lang="en" value="iWidget Description" readOnly="true">
    ```

  - When you run the ConfigEngine task, include the option `-DForceRefresh=true` option as follows:

    ```
    ./ConfigEngine.sh refresh-iwidget-definitions
                      -DIWidgetDefinition=/iWidget/iWidget.xml
                      -DForceRefresh=true
    ```

  - Add the following portlet parameter to the installed iWidget: `com.ibm.portal.replace.attributes = true`.
- When you refresh an iWidget Wrapper portlet clone, values of iWidget attributes, or the items of the iWidget attributes item set, are not updated. The values are updated if the attributes are flagged as read-only in the iWidget definition XML file. As a result, values of iWidget attributes that are customized after you register the iWidget in WebSphere Portal Express are prevented from becoming lost during a refresh operation.

Syntax: Invoke this task as part of the ConfigEngine script as follows:

- Linux: `./ConfigEngine.sh refresh-iwidget-definitions`
- IBM i:
  - **From the `UserData` directory:** `ConfigEngine.sh refresh-iwidget-definitions`
- Windows: `ConfigEngine.bat refresh-iwidget-definitions`

Mandatory parameters that you can specify through the command line or in `wkplc.properties`:

`WasUserid`
User ID for WebSphere Application Server.

`WasPassword`
Corresponding password for WebSphere Application Server.

`PortalAdminId`
User ID for WebSphere Portal Express.

`PortalAdminPwd`
Corresponding password for WebSphere Portal Express.

Optional parameters that you can specify only through the command line:

`Synchronous`
Specify one of the following values:

The value `true` to run the task in synchronous mode. This value is the default setting.

The value `false` to run this task in asynchronous mode.

Scheduling the `refresh-iwidget-definitions` task

You can schedule the task `refresh-iwidget-definitions` by using the following task: `com.ibm.portal.services.RefreshIWidgetDefinitionsTask`. See *XML configuration reference* for instructions.

Administering managed pages

You can run advanced administration tasks for managed pages, such as generating URLs for projects or working with projects by using scripts, or working with vanity URLs.

"Project URL generation" on page 1255
You can redirect request processing to a specific project by generating URLs with the ProjectIdentificationService API, or the REST API. Request processing operates either completely within the scope of a project or completely outside the scope of a project. You cannot switch projects during request processing.

"Access control for managed pages" on page 1256
Access control for managed pages provides more capabilities than access control for standard portal pages. In addition to the access control features available for pages through portal administration, you can also apply IBM Web Content Manager features, like workflow and syndication, to access control.

"Portal Scripting Interface and project support" on page 1260
With the Portal Scripting Interface, you can create Jacl or Jython scripts to automate the management of projects.

"Portal Scripting Interface and web content libraries" on page 1270
With the Portal Scripting Interface, you can create Jacl or Jython scripts to automate the management of web content libraries. Using the DocumentLibrary bean with the Portal Scripting Interface, you can create and delete libraries, retrieve a list of libraries, and retrieve library attributes.

"XML configuration interface and managed pages" on page 1271
You can use the XML configuration interface (XML Access) to manipulate managed pages just as you can for other portal resources.

"Lost-found site area" on page 1273
When Web Content Manager cannot determine the proper location of a page item in the Portal Site library, the page item is stored in the **lost-found** site area. This site area ensures that you can recover pages and any content that is stored beneath the pages when a problem occurs.

Related concepts:

"Vanity URLs" on page 2094
You can associate vanity URLs with portal pages and labels. Vanity URLs are short URLs that people can easily remember. They are shorter than full WebSphere Portal Express URLs. They are sometimes also called marketing URLs. You can publish vanity URLs for marketing campaigns through different channels, such as email or print. This way, you can use vanity URLs to direct customers to a specific portal page or content item. Interested site visitors who want to view your campaign can then remember or copy the short vanity URL and type it into the browser address field.

Related reference:

"Staging to production list" on page 2487
The items in the production list can be included in the staging to production Portal Application Archive (PAA) file. However, if you are not using the staging to production PAA file, use this list to determine the tools that are required to move your artifacts from the staging server to the production server. You can also use this list to determine what tool to use for the items not included in the staging to production PAA file.

Project URL generation

You can redirect request processing to a specific project by generating URLs with the ProjectIdentificationService API, or the REST API. Request processing operates either completely within the scope of a project or completely outside the scope of a project. You cannot switch projects during request processing.

When a request originates from within a project, the request URL contains a project identifier for that project. The project information is included only in the URL and is not bound to the session. The project identifier can be an object ID (OID), as used by the portal, or a universally unique identifier (UUID), as used by Web Content Manager. To direct request processing to a specific project, you must generate a URL for the project and then render the URL.

Java API

To generate URLs that target a project by using the Java API in the portal, you can use the ProjectIdentificationService API with the StateManagerService API:

- The ProjectIdentificationService provides methods to create a `ServerContext` object, based on the identifier of the target project and the current `ServerContext` object.
- The project-specific `ServerContext` object can then be used to retrieve a `URLFactory` object from the state manager service. All URLs generated with this factory contain the project ID.

This example constructs a portal URL to the current navigational state for a new project:

```
// construct a server context for the project
final ServerContext projectCtx = projectService.createServerContext(
  projectID, stateService.getServerContext());

// access the URL factory to create a URL
final URLFactory urlFct = stateService.getURLFactory(projectCtx);

// construct a URL to the current state
final EngineURL url = urlFct.newURL(Constants.SMART_COPY);
url.writeDispose(out);

// done with URL generation
urlFct.dispose();
```

This example constructs a portal URL to a URI in a specific project:

```
// construct a server context for the project
final PocServerContext projectCtx = projectService.createServerContext(
  projectID, pocService.getServerContext());

// access the URL factory to create a URL
final DisposablePocURLFactory urlFct = pocService
  .getURLFactory(projectCtx);

// construct a URL to the current state
```

```
final PocURL url = urlFct.newURL(PocURLFactory.LATE_BINDING);
url.setMode(Constants.VALUE_DOWNLOAD);
url.setURI(new URI("test:abc"));

// serialize
url.writeDispose(out);

// done with URL generation
urlFct.dispose();
```

REST API

If your application uses the Representational State Transfer (REST) architecture, you can use the remote APIs provided with the portal to construct project-specific URLs.

Access control for managed pages

Access control for managed pages provides more capabilities than access control for standard portal pages. In addition to the access control features available for pages through portal administration, you can also apply IBM Web Content Manager features, like workflow and syndication, to access control.

When you create a managed page in the portal, a corresponding page item is created in a web content library. You can view and change access control settings for a managed page in two ways:

- By navigating to the page and using the site toolbar
- By opening the corresponding page item in the web content authoring portlet

Regardless of the method you use to change an access control setting, the corresponding element is automatically updated. This synchronization ensures that effective permissions are coordinated between the portal page and the web content page item.

Special considerations

As managed pages integrate features from portal pages and Web Content Manager, there are special considerations that apply with access control for managed pages.

Unified set of applicable roles with different effective capabilities

With managed pages, portal pages and Web Content Manager are aware of the same roles; however, some roles are effectively ignored in Web Content Manager. For example, the roles of Privileged User and Markup Editor are used with portal pages to support features such as personalizing a page. In Web Content Manager, these roles have no effect on access control.

When you perform a web content action on a managed page, like previewing, publishing, or syndicating the page, Web Content Manager accounts for the portal roles. This awareness ensures that pages retain their appropriate permissions from the roles. For details on the portal roles, see *Roles*.

Virtual groups in Web Content Manager (authors, owners, creators)

In Web Content Manager you can grant access to virtual groups (authors, owners, creators) through the web content authoring portlet or as part of a workflow stage. Portal pages do not provide an equivalent mechanism. When you grant permissions on a page item to users or groups with the virtual groups, direct role mappings are assigned on the portal page. These role mappings ensure that equal permissions are applied.

The owner virtual group, however, is limited to a single owner for page items in Web Content Manager. The owner of the portal page is automatically synchronized with the owner of the page item. This owner has the same set of allowed actions as the Manager role, as described in the *Ownership* section of *Roles.*

Important: If you are using author or creator groups for access control management in Web Content Manager, use only the authoring portlet to perform access control tasks. Do not use the site toolbar in the portal interface to revoke permissions, because doing so can lead to a potentially complex assignment of permissions.

Traversal support for portal pages

With portal pages, traversal support provides implicit permissions that enable users to navigate through a page hierarchy. For example, a user might have permission to access a child page but might not have permission to access the parent page. Because of traversal support, the user is permitted to navigate to the child page. See *Roles* for details on traversal support.

However, traversal support is not provided for web content items. Content authors that use the authoring portlet must be assigned the User role on all pages higher than the child page to navigate to editable content. Without this access permission, the editable content is not visible in the authoring portlet, even though the author can access the page. Typical page administration tasks can still be performed from the page.

Permissions granted through virtual resources

With traditional portal pages, you can grant permissions on the virtual resources PORTAL and CONTENT_NODES that inherit permissions to the complete page hierarchy. This inheritance is described in *Resources.* You can also specify a similar inheritance for web content libraries that inherit from the root node.

Because permissions for managed pages are synchronized between portal pages and page items in Web Content Manager, such inheritance is problematic. This inheritance can result in different effective permissions on portal pages and content items. Although you can manage permissions correctly either through the page or the authoring portlet, the preferred approach is through the page. If you grant permissions to the entire page hierarchy with inheritance, grant this permission on the root resource for the page hierarchy (`wps.content.root` page). As the permission on this page node is synchronized to the corresponding page item in Web Content Manager, the effective permissions are automatically synchronized throughout the hierarchy.

Access control permissions managed by workflows

When working with managed pages, you can apply access control to page items through workflow stages and actions, as described in *Workflow and change management* In addition to permissions from the workflow, you can also modify permissions on the page with the site toolbar. Changes that you make with the site toolbar override the access permissions in effect with the current workflow stage. When the next workflow stage is entered, changes from the site toolbar are reset and the permissions specified by the workflow stage take effect.

Access control permissions for site areas and pages work only under Web Content Manager, but not under WebSphere Portal Express

Set the access permissions for the portal site library. Click the

Administration menu icon. Then, click **Portal Content** > **Web Content Libraries**. These access permissions restrict what users can do with a portal page site area item only under Web Content Manager. For example, only a user with the appropriate access permission can add content under a page or add a workflow. However, a user without such access permission might still be able to create, update, or delete pages on the WebSphere Portal Express side, if the user has the appropriate access permission on the page.

External security support
You cannot use externalized roles or role mappings with managed pages. Pages cannot be externalized while being edited in a project. Similarly, externalized resources cannot be added to a project.

Required permissions

The following permissions are required for typical actions with managed pages.

Table 169. Required permissions for typical actions with managed pages

Action	Required permission
Access a project view in the site toolbar	User on the WCM_REST_SERVICE virtual resource
View a project in the site toolbar	• User on the WCM_REST_SERVICE virtual resource, in addition to the permissions that are required to view a specific project • User on the selected project
Create a project	• Contributor on the Portal Site library • User on the WCM_REST_SERVICE virtual resource
Create new items	You set the access permission for creating new items at the library level, not at the item level. To create a new item, a user must have at least the following access permissions: • Contributor access on a library • Editor access on an item-type If a user has access permission to create an item type, the user can also create folders and projects.
Create a draft of a published page by editing the page in a project	• Editor on the page • User on the selected project
Create a draft of a published page with the **Create Draft** action in the site toolbar.	• User on the page and Approver on the corresponding web content page item. For details, see “Approver role for creating draft pages” on page 1260. • User on the selected project
Create a draft child page under a parent page in a project	• Contributor or Editor on the parent page • User on the selected project

Table 169. Required permissions for typical actions with managed pages (continued)

Action	Required permission
Preview a project	• Can Run As User on the USERS virtual resource • The user that is impersonated requires at least User access to the current portal page. If an anonymous user does not have access to the page, the **As Unauthenticated User** preview option is not available in the site toolbar. In addition, if you select the **As User** preview option, you cannot select users that do not have access to the page. • User on the selected project By default only users and unauthenticated users that have explicit access to the project can preview the project. You can globally assign access for users or unauthenticated users to view all items in all libraries and projects in a specific virtual portal or the default virtual portal. To assign these rights, use the **Set root access** setting in the library administration portlet. Click the **Administration menu** icon. Then, click **Portal Content** > **Web Content Libraries**.
Create web content by adding web content viewer to a page. The viewer is configured to create and render content from a web content library.	• Editor on the page • User on the viewer portlet • No library permissions are enforced.
Perform inline editing of content on a page	• Editor on the page • Appropriate permissions on the library that contains the content

For the required permissions for portal pages and web content items, see *Access permissions* for portal pages and *User roles and access* for web content items.

The default set of access control permissions for anonymous users and for members of the All Authenticated Users group are described in *Initial Access Control Settings.* With managed pages, the following default permissions exist:

- Anonymous users can view projects and have User access to the Portal Site library.
- Members of the All Authenticated Users group can create new projects and have Editor access to the Portal Site library. This access ensures that users can perform inline editing tasks. You can restrict access as needed with the library administration portlet.

To modify a portal page or page item, you require only those permissions that are needed to perform the action from the user interface or programming API. You do not also require permissions for the underlying synchronization actions that take place automatically. These automatic updates are performed with system privileges.

For example, you might add a portlet to a page by using the site toolbar. In this case, you require sufficient permissions on the page that you are editing and on the portlet that you are adding. However, you do not need additional permissions for the internal updates to the corresponding items in the web content library.

Approver role for creating draft pages

With managed pages, you can use a workflow to enable business users to create draft versions of pages that they are normally not allowed to edit. By using a workflow in this way, you accomplish two things:

- You provide business users with the ability to modify pages.
- You can still ensure that the drafts are reviewed and approved by technical users before the changes are published to the external site.

Typically a user with User access to a page has permission only to view the page. But if the user also has Approver access to the corresponding page item in the Portal Site library, the user can create page drafts. When a user has this access, the user can navigate to the portal page and use the site toolbar to create a draft.

To enable business users to create draft pages, complete the following steps:

1. In the Portal Site library, assign a workflow to the page items that correspond to the portal pages that you want users to modify. By default, page items are not managed in a workflow.
2. Edit the publish stage of the workflow, and update the access control properties to add the users to the Approver role.
3. Edit the initial draft stage of the workflow, and update the access control properties. Add the users to the roles that correspond to the permissions that the users require on the draft pages that they create.

Contributor role for creating child pages

Users with Contributor access to the published version of a page can create child pages under that page. When in edit mode on the parent page, contributors can use the site toolbar to create a child page.

Portal Scripting Interface and project support

With the Portal Scripting Interface, you can create Jacl or Jython scripts to automate the management of projects.

Using the Project bean with the Portal Scripting Interface, you can perform the following actions on projects:

- List all available projects
- Create and delete projects
- Set an active project
- Retrieve information about a specific project
- Retrieve locale-specific attributes for projects
- Submit a project for review
- Withdraw a project from review.
- Approve projects
- Decline a project
- Approve all documents of a project, that is all Web Content Manager items that are parts of a workflow

- Decline all documents of a project, that is all Web Content Manager items that are parts of a workflow
- Publish projects

To run commands with the Project bean, you can use the Portal bean to set a project as the context for subsequent commands.

List projects

To retrieve a list of projects, use the `listall` method. This method returns the names of the projects.

- Jacl syntax: `$Project listall`
- Jython syntax: `Project.listall()`

Jacl example:

```
wsadmin>$Project listall
'"TestProject1" "TestProject2"'
```

Jython example:

```
wsadmin>Project.listall()
'"TestProject1" "TestProject2"'
```

Create projects

To create a project, use the `create` method.

- Jacl syntax: `$Project create "`*`project_name`*`"`
- Jython syntax: `Project.create("`*`project_name`*`")`

Jacl example:

```
wsadmin>$Project create "TestProject1"
TestProject1
```

Jython example:

```
Project.create("TestProject1")
'TestProject1'
```

Note: If you create a project with the Portal Scripting Interface, the project is not listed with the recent projects in the project menu.

Delete projects

To delete a project, use the `delete` method.

- Jacl syntax: `$Project delete "`*`project_name`*`"`
- Jython syntax: `Project.delete("`*`project_name`*`")`

Jacl example:

```
wsadmin>$Project delete "TestProject1"
```

Jython example:

```
wsadmin>Project.delete("TestProject1")
```

Set active project

For commands that you want to run within a project, use the `setproject` method of the Portal bean to specify the project. When invoking the `setproject` method, you identify the active project with the name of the project. If you invoke the `setproject` method without specifying a project name, the active project is cleared. When you set the project during a session, the project is active immediately.

To set the active project, you must establish a user session with the portal by using the **login** command of the Portal bean.

- Jacl syntax: `$Project setproject "project_name"`
- Jython syntax: `Portal.setproject("project_name")`

Jacl example:

```
wsadmin>$Portal setproject "TestProject1"
```

Jython example:

```
wsadmin>Portal.setproject("TestProject1")
```

Retrieve project details

Retrieve project details with the `details` method. This method returns the following information about the project:

- Universally Unique Identifier (UUID)
- State
- Name
- Title
- Approvers
- Outstanding approvals
- Approval mode, that is whether all approvers need to approve or only one approver needs to approve
- History, that is which actions have been performed on the project before.

Syntax:

- Jacl syntax: `$Project details "project_name"`
- Jython syntax: `Project.details("project_name")`

Jacl example:

```
wsadmin>$Project details "TestProject2"
uuid                 : 47c7f3bd-b004-4b94-a6b5-397272d69eb7
state                : ACTIVE
name                 : TestProject2
title                : TestProject2
approvers            : wpsadmins

```

Retrieve translated attributes

If any project attributes are translated, such as the title or description, you can retrieve those attributes with the `nlsget` method. Specify the attribute with one of the following parameters:

- Title: **`title`** or **`t`**
- Description: **`description`**, **`descr`**, or **`d`**

Syntax:

- Jacl syntax: `$Project nlsget "`*`project_name`*`" `*`attribute_parameter`*` [`*`locale`*`]`
- Jython syntax:
  `Project.nlsget("`*`project_name`*`","`*`attribute_parameter`*`"[,"`*`locale`*`"])`

Jacl example:

```
wsadmin>$Project nlsget "TestProject1" descr en
This is the description for TestProject1.
```

Jython example:

```
wsadmin>print Project.nlsget("TestProject1", "descr", "en")
This is the description for TestProject1.
```

If you do not specify a value for the *`locale`* parameter, the currently selected locale is used.

Submit a project for review

To submit a project for review, use the `submitforreview` method. The project needs to be in active state, and all contained documents need to be in publish, pending, or deleted state. When you submit a project for review, the project moves into the review state.

- Jacl syntax: `$Project submitforreview "project_name"`
- Jython syntax: `Project.submitforreview("`*`project_name`*`")`

Jacl example:

```
wsadmin>$Project submitforreview TestProject

wsadmin>$Project details TestProject
uuid                 : 035c4488-973f-44a4-aa8e-92b9f36e2412
state                : REVIEW
name                 : TestProject
title                : TestProject
approvers            : wpsadmins
outstanding approvals: wpsadmins
approval mode        : single
```

```
history              : 10/16/13 6:23 PM: Document created by wpsadmin
                       10/16/13 6:26 PM: Submitted for review by wpsadmin
                       10/16/13 6:26 PM: Project state changed to Review
items:
  testpage (draft / new / publish pending)
```

Jython example:

```
wsadmin>Project.submitforreview("TestProject")

wsadmin>print Project.details("TestProject")
uuid                 : 035c4488-973f-44a4-aa8e-92b9f36e2412
state                : REVIEW
name                 : TestProject

                       10/16/13 6:26 PM: Project state changed to Review
items:
  testpage (draft / new / publish pending)
```

Withdraw a project from review

To withdraw a project from review, use the `withdrawfromreview` method. The project needs to be in review state. When you withdraw a project from review, the project moves into the active state.

- Jacl syntax: `$Project withdrawfromreview "project_name"`
- Jython syntax: `Project.withdrawfromreview("`*`project_name`*`")`

Jacl example:

```
wsadmin>$Project withdrawfromreview TestProject

wsadmin>$Project details TestProject
uuid                 : 035c4488-973f-44a4-aa8e-92b9f36e2412
state                : ACTIVE
name                 : TestProject
title                : TestProject
approvers            : wpsadmins
outstanding approvals: wpsadmins
approval mode        : single
history              : 10/16/13 6:23 PM: Document created by wpsadmin
                       10/16/13 6:26 PM: Submitted for review by wpsadmin
                       10/16/13 6:26 PM: Project state changed to Review
                       10/16/13 6:26 PM: Rejected by wpsadmin
                       10/16/13 6:26 PM: needs rework
                       10/16/13 6:26 PM: Project state changed to Rejected

                       10/16/13 6:28 PM: Project state changed to Active
items:
  testpage (draft / new / publish pending)
```

Approve projects

To approve the drafts in a project, use the `approve` method. Additional to the project, you can add a comment as a second parameter. If the project setup requires a comment, the comment is mandatory. If not, the comment is optional.

The command approves only the project. The drafts in the project need to be approved separately, for example by using the `approvedocuments` method. Before you can approve a project, all of its documents must be in publish, pending, or deleted state.

- Jacl syntax:

  ```
  $Project approve "project_name"
  $Project approve "project_name" "comment"
  ```

- Jython syntax:

  ```
  Project.approve("project_name")
  Project.approve("project_name", "comment")
  ```

Jacl example:

```
wsadmin>$Project approve TestProject "ok"

wsadmin>$Project details TestProject
uuid                 : 035c4488-973f-44a4-aa8e-92b9f36e2412
state                : PENDING
name                 : TestProject
title                : TestProject

```

Decline projects

To decline the drafts in a project, use the `decline` method. Additional to the project, you can add a comment as a second parameter. If the project setup requires a comment, the comment is mandatory. If not, the comment is optional. The command only declines the project. The drafts in the project remain in their current state. For a project to be declined, the project needs to be in review state.

- Jacl syntax:

  ```
  $Project decline "project_name"
  $Project decline "project_name" "comment"
  ```

- Jython syntax:

  ```
  Project.decline("project_name")
  Project.decline("project_name", "comment")
  ```

Jacl example:

```
wsadmin>$Project decline TestProject "needs rework"

wsadmin>$Project details TestProject
uuid                 : 035c4488-973f-44a4-aa8e-92b9f36e2412

items:
  testpage (draft / new / publish pending)
```

Approve all documents of a project

To approve all documents of a project, use the `approvedocuments` method. It approves all Web Content Manager items that are parts of a workflow.

- Jacl syntax: `$Project approvedocuments` *project_name*
- Jython syntax: `Project.approvedocuments("`*project_name*`")`

Jacl example:

```
wsadmin>$Project approvedocuments TestProject

wsadmin>$Project details TestProject
uuid                 : 5dffe3e4-59d1-4abf-8697-3e62a29a0cbf
state                : PENDING
name                 : TestProject
title                : TestProject
approvers            :
outstanding approvals:
approval mode        : single
history              : 10/16/13 6:14 PM: Document created by wpsadmin
                       10/16/13 6:16 PM: Project state changed to Pending
items:
  testpage (draft / new / publish pending)
```

Jython example:

```
wsadmin>Project.approvedocuments("TestProject")

wsadmin>Project.details("TestProject")
uuid                 : 5dffe3e4-59d1-4abf-8697-3e62a29a0cbf
state                : PENDING
name                 : TestProject
title                : TestProject
approvers            :
outstanding approvals:
approval mode        : single
history              : 10/16/13 6:14 PM: Document created by wpsadmin
                       10/16/13 6:16 PM: Project state changed to Pending
items:
  testpage (draft / new / publish pending)
```

Decline all documents of a project

To decline all documents of a project, use the `declinedocuments` method. This method declines all Web Content Manager items that are parts of a workflow.

- Jacl syntax: `$Project declinedocuments` *project_name*

- Jython syntax: `Project.declinedocuments("project_name")`

Jacl example:

```
wsadmin>$Project declinedocuments TestProject
wsadmin>$Project details TestProject
uuid                : 5dffe3e4-59d1-4abf-8697-3e62a29a0cbf
state               : ACTIVE
name                : TestProject
title               : TestProject
approvers           :
outstanding approvals:
approval mode       : single
history             : 10/16/13 6:14 PM: Document created by wpsadmin
                      10/16/13 6:16 PM: Project state changed to Pending
                      10/16/13 6:18 PM: Project state changed to Active
items:
  testpage (draft / new)
```

Jython example:

```
wsadmin>$Project.declinedocuments("TestProject")
wsadmin>$Project.details("TestProject")
uuid                : 5dffe3e4-59d1-4abf-8697-3e62a29a0cbf
state               : ACTIVE
name                : TestProject
title               : TestProject
approvers           :
outstanding approvals:
approval mode       : single
history             : 10/16/13 6:14 PM: Document created by wpsadmin
                      10/16/13 6:16 PM: Project state changed to Pending
                      10/16/13 6:18 PM: Project state changed to Active
items:
  testpage (draft / new)
```

Publish projects

To publish a project, use the `publish` method. Before you can publish a project, all items in the project must be approved and the project needs to be in publish pending state.

- Jacl syntax: `$Project publish "project_name"`
- Jython syntax: `Project.publish("project_name")`

Jacl example:

```
wsadmin>$Project publish TestProject

wsadmin>$Project details TestProject
uuid                : 035c4488-973f-44a4-aa8e-92b9f36e2412
state               : PUBLISHED
name                : TestProject
title               : TestProject
approvers           : wpsadmins
outstanding approvals:
approval mode       : single
history             : 10/16/13 6:23 PM: Document created by wpsadmin
                      10/16/13 6:26 PM: Submitted for review by wpsadmin
                      10/16/13 6:26 PM: Project state changed to Review
                      10/16/13 6:26 PM: Rejected by wpsadmin

```

Examples

These examples demonstrate a typical command sequence to create a page within a specific project. Each example script performs the following operations:

- Establishes a user session.
- Creates a project (`myproject`).
- Retrieves the details for the `myproject` project.
- Sets the active project to the `myproject` project.
- Locates the `Home` page in the portal.
- Creates the `testpage1` page as a child page of the `Home` page. This operation takes place within the context of the active project.
- Clears the active project.
- Terminates the user session.

Jacl example:

```
        $Portal login
        set myproject [$Project create "My new project"
        $Project details $myproject
        $Portal setproject $myproject
```

```
$Content find any un ibm.portal.Home select
$Content create page testpage1 html shared public
$Portal setproject
$Portal logout
```

Jython example:

```
Portal.login()
myproject = Project.create("My new project")
Project.details(myproject)
Portal.setproject(myproject)
Content.find("any", "un", "ibm.portal.Home", "select")
Content.create("page","testpage1","html", "shared", "public")
Portal.setproject()
Portal.logout()
```

Portal Scripting Interface and web content libraries

With the Portal Scripting Interface, you can create Jacl or Jython scripts to automate the management of web content libraries. Using the DocumentLibrary bean with the Portal Scripting Interface, you can create and delete libraries, retrieve a list of libraries, and retrieve library attributes.

Create libraries

To create a library, use the create method.

- Jacl syntax: `$DocumentLibrary create "`*`library_name`*`"`
- Jython syntax: `DocumentLibrary.create("`*`library_name`*`")`

Jacl example:

```
wsadmin>$DocumentLibrary create "Library1"
"library1"
```

Jython example:

```
wsadmin>DocumentLibrary.create("Library1")
'"library1"'
```

Delete libraries

To delete a library, use the delete method.

- Jacl syntax: `$DocumentLibrary delete "`*`library_name`*`"`
- Jython syntax: `DocumentLibrary.delete("`*`library_name`*`")`

Jacl example:

```
wsadmin>$DocumentLibrary delete "Library1"
```

Jython example:

```
wsadmin>DocumentLibrary.delete("Library1")
```

List libraries

To retrieve a list of libraries, use the listall method.

- Jacl syntax: `$DocumentLibrary listall`
- Jython syntax: `DocumentLibrary.listall()`

Jacl example:

```
wsadmin>$DocumentLibrary listall
"template page content" "wiki template v70" "blog template v70" "web resources v70"
"portal site" "web content templates" "blog solo template v70" "web content"
"library1"
```

Jython example:

```
wsadmin>DocumentLibrary.listall()
'"template page content" "wiki template v70" "blog template v70" "web resources v70"
"portal site" "web content templates" "blog solo template v70" "web content"
"library1"'
```

Retrieve library details

Retrieve library details with the details method. This method returns the following information about the library: the Universally Unique Identifier (UUID), state, name, and title.

- Jacl syntax: `$DocumentLibrary details "library_name"`
- Jython syntax: `DocumentLibrary.details("library_name")`

Jacl example:

```
wsadmin>$DocumentLibrary details "Library1"
uuid       : 64fa541a-a189-4ed6-8a6f-4c3dcc148295
name       : library1
title      : Library1
description:
enabled            : true
deletion prohibited: false
```

Jython example:

```
wsadmin>print DocumentLibrary.details("Library1")
uuid       : 13b06eb0-52c7-415b-9a93-4195968aa2a3
name       : library1
title      : Library1
description:
enabled            : true
deletion prohibited: false
```

XML configuration interface and managed pages

You can use the XML configuration interface (XML Access) to manipulate managed pages just as you can for other portal resources.

Project scope

When you use the XML configuration interface with managed pages, processing occurs either completely within a project or completely outside a project.

When you import a published page and specify a project scope, the page is created as a draft page in the project.

Important: You cannot export a draft page and then import that page as a draft in another project.

Important: Web Content Manager items, such as workflow items, categories, or keywords, are not exported or imported by the XML configuration interface (XML Access). You need to use the XML configuration interface (XML Access) library export and import feature instead.

To run the **xmlaccess** command from within a project, specify the project either with the project name or with the object ID of the project. The command uses the following format, depending on how you identify the project:

```
xmlaccess -in input_file -url http://hostname:port_number/wps/config/$project/project_name
xmlaccess -in input_file -url http://hostname:port_number/wps/config/$project/project_object_id
```

For example:

- `xmlaccess -in Export.xml -url http://www.example.com:10039/wps/config/$project/myproject`
- The following command must be entered all in one line:

  ```
  xmlaccess -in Export.xml -url
  http://www.example.com:10039/wps/config/$project/
  Z6QReDeN9E86O46P9CGJMK633P8JMG6J1P8MM47MPD6MMCC63PI3IL6GPD63R46J1
  ```

Note: Linux: You might have to precede the dollar sign ($) with a backslash (\) to prevent `$project` from being interpreted as an environment variable. For example:

```
xmlaccess -in Export.xml -url http://www.example.com:10039/wps/config/\$project/myproject
```

Use transaction processing with the XML configuration interface

Because pages are stored in the Portal Site library in Web Content Manager, each page has corresponding objects in the JCR database. You must be aware of this relation when you create, update, or delete pages with the XML configuration interface. If **`xmlaccess`** processing is interrupted, it can result in a mismatch between the page state and database state.

WARNING: If you redeploy your site daily, your JCR size increases because of page versions. Periodically clean up your versions to reduce the JCR size. Go to "Clearing version history" on page 1194 for information.

To ensure that page and database information for a page remain synchronized, use the `transaction-level` attribute of the `request` element in the XML file. For more information about using the `transaction-level` attribute, go to *XML configuration reference.*

Example:

```
<request
    type="update"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd"
    transaction-level="resource">
```

Excluding pages from being managed in Web Content Manager

By default, you can manage all WebSphere Portal Express pages in Web Content Manager except for the portal administration pages. When an administrator creates or imports a page, the portal checks whether the parent page has a portal page site area in Web Content Manager. If it does, the portal creates a portal page site area for the new page in Web Content Manager as well.

You can exclude pages from being managed in Web Content Manager. You can prevent the creation of the corresponding page item in Web Content Manager. The page is then not available to be managed in managed pages. It is good practice to exclude only pages on first-level nodes, for example the Search or Applications pages. To do so, run an XML configuration interface script and use the `content-mapping-info` element with the attribute `has-system-mapping`:

has-system-mapping=true | false
Use this flag as follows:

true When the XML script creates or imports a page, the portal creates a page item in Web Content Manager as well.

false When the XML script creates or imports a page, the portal does not create a page item in Web Content Manager.

(not specified)

If you do not set a value for this flag in the XML script, it follows the portal where the page is imported:

- If managed pages are enabled, it creates a page item in Web Content Manager as well.
- If managed pages are disabled, it does not create a page item in Web Content Manager.

Note: There is no indication in the user interface whether a page is managed in Web Content Manager or not. Therefore, excluding parts of a site can lead to an inconsistent portal user experience for portal site visitors.

Lost-found site area

When Web Content Manager cannot determine the proper location of a page item in the Portal Site library, the page item is stored in the **lost-found** site area. This site area ensures that you can recover pages and any content that is stored beneath the pages when a problem occurs.

The following causes are typical reasons that a page might be stored in the lost-found site area:

- The synchronization process between the portal and Web Content Manager finds page items in the Portal Site library that do not have corresponding pages in the portal.
- You move a managed page beneath an unmanaged page in the portal page hierarchy. In this case, the page item for the managed page is stored in the lost-found site area.

The lost-found site area is a read-only location. Although you cannot edit items in the lost-found site area, you can view the items and copy content that you want to save.

Manage pages portlets

Use Manage Pages to create, edit, activate, order, and delete pages and external web pages and labels. Available tasks depend on which item is selected. Each page can contain multiple pages. All pages on which you have the User or greater role are displayed in a navigation menu. You must expand pages to access nested pages. The options that you see are dependent upon your access level.

About this task

Use the Manage Pages portlet to complete the following tasks:

- Create, reorder, delete, and edit the properties of pages, labels, and URLs
- Reorder pages, labels, and URLs
- Assign access to pages, labels, and URLs
- Move pages to a new location in the portal hierarchy

Both administrators and users with appropriate access can create and delete pages. Users can delete only the pages that they create or the pages for which they have at least Manager access. User can create pages from the site toolbar.

"Pages and page types: derived and hidden pages"
Understanding the behavior of derived pages, and hidden pages, and the differences between them can help you manage pages and create the correct type of page for your needs.

"Selecting pages" on page 1279
Pages that you can modify in Manage Pages appear as links in a table. By clicking a link to select a page, you can navigate to other nested pages to perform page tasks. You can also select labels and URLs in Manage Pages.

"Using friendly URLs" on page 1280
You can associate friendly URLs with portal pages and labels. You and your users can use these friendly URLs to access specific portal pages or labels by using a human readable path, which is easy to remember.

"Task refresh-page-layout" on page 1284
Use this configuration task to refresh the page layout for all pages assigned a given page layout template.

"Customizing pages" on page 1285
The page customizer contains portlets for editing the layout, content, and appearance of pages. It also provides the Wires portlet, which allows users to set up connections between cooperative portlets on a page, and the Locks portlet, which allows users to lock and unlock containers and container content. You can configure the settings for these portlets to show a certain set of functions, restricting basic users from performing more advanced tasks.

Tuning for many pages

Pages and page types: derived and hidden pages

Understanding the behavior of derived pages, and hidden pages, and the differences between them can help you manage pages and create the correct type of page for your needs.

A page is an organization element that defines how content is displayed. A page can contain portlets and other pages. Derived pages are children of the original pages and have specific behavior that you must be aware of.

Derived pages inherit the properties of the original page. Creating a derived page is equivalent to creating a new, specialized layer on the original page. The original page and the new layer are aggregated together at rendering time. The new layer is contained within and controlled by the original page. You can give administrative access to other users by referencing an existing page while you maintain the content and layout from the original page. The following implications apply to derived pages:

- If content is locked on the page that is referenced, content is locked on all derived pages that reference that page.
- If a portlet is deleted from the page that is referenced, the portlet is deleted from all pages that reference that page. All individual user settings for that portlet are also lost.
- The user must have User role access to the original page to access the derived page. Therefore, private pages cannot be shared in this manner.

Changes made to the original parent page might be reflected to the derived pages that reference it. Layers can be created on other layers to create a chain of cascading pages, referred to as delegated page specialization. This process means that a root page can be created, and the top-level administrator can decide the

initial layout and content of the page. The next level administrator can then control and modify a specialized layer of the root page, adding more content and layout. This process can continue down a chain of page managers and submanagers. Managers or submanagers in the chain see only their individual layer of the chain. However, they must have the User role for every layer higher than theirs to see the content of the previous layers. A user is only able to see a layer of the page if appropriate access is given. Here are some examples to illustrate this concept.

John, the superadministrator, creates a page Home and titles it Home. Brandy, a subadministrator, manages the next level of the home page, named Home_operations. Brandy determines what more content needs be added to the Home page for employees in the operations group. Nick, the next level administrator, manages the next level of the Home page, Home_operations_transportation. Nick determines the content that needs to be available on the Home page for employees in the transportation department. Nick, as the transportation page administrator, must have the Manager role for Home_operations_transportation to change the page. The changes that Nick makes affects all users, and the User role for Home_operations and the User role for Home. Nick must have the User role on every layer that combines to create the Home_operations_transportation level. Desi, a user of the Home_operations_transportation page, must have the User role for Home_operations_transportation, and she must also have the User role for Home_operations and the User role for Home. When Desi, the user logs on to the portal, she sees one Home page. This Homepage is an aggregation of all the layers that are associated with the root Home page.

Notes:

- If you delete a page that is referenced by another page, all pages that reference the deleted page are also deleted.
- The markup that is specified for the root page cannot be modified on derived pages. The whole derivation tree structure with all layers supports the markup that is specified on the root page.
- You can disable the ability to change the title and description of derived pages by setting the **allow.derived.titles** parameter in the portal WP Configuration Service in the WebSphere Integrated Solutions Console. For details, see the description for the **allow.derived.titles** parameter in the topic about the portal Configuration Service.

  "Behavior of derived pages in combination with locks and changing access permissions" on page 1276
  Using and altering locks in conjunction with access permissions on the parent pages may result in changes on derived pages depending on the complexity of the derivation structure. The following scenario describes the behavior of derived pages.

Related tasks:

"Hiding and displaying pages in the navigation" on page 1803
By default, pages that you create are displayed in the navigation of the portal site. If you do not want a page that you create to appear in the navigation, you can hide the page by setting the **com.ibm.portal.Hidden** page parameter to `true`. While this parameter does not affect your portal access control settings for the page, it is hidden from the navigation.

Hidden pages

Hidden pages do not show in the portal, but contain portlets that can be opened from other pages. The hidden pages do not appear in the site navigation, but are started from generated links in portlets or theme code. The feature to set a page

that you create as a hidden page is not available in the UI. Follow the steps in the topic *Hiding and displaying pages in the navigation* to set a page as hidden. For ease of administration and conserving system resources, you can place and manage hidden pages in one place. An example is the Edit Page Properties portlet: users can start it from a link in the theme, but the portlet instance itself is on a hidden page in the content model.

Some scenarios and use cases require such hidden pages. The easiest way to create a hidden page for such purposes is to create the page as a child of the **Hidden Pages** label, which is a child of the content root. This label is hidden from the navigation. It is a container for hidden pages in the portal, and it minimizes the cycles that are required to render the top-level navigation links while still providing support for hidden pages.

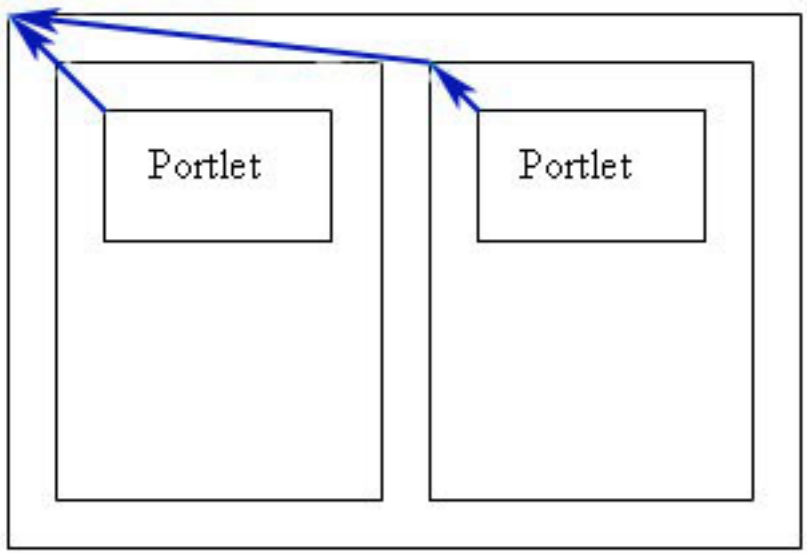
Set your custom theme when you create a hidden page, do not inherit the theme. If you use legacy themes, be aware that they render the top-level navigation that is based on the level that is specified in theme policy or page metadata to render the navigation at the appropriate level. If you use such a theme and you create a new hidden page under the Hidden Pages label, set the metadata value `com.ibm.portal.themepolicy.topNavigationStartLevel` for the page to 3.

Behavior of derived pages in combination with locks and changing access permissions

Using and altering locks in conjunction with access permissions on the parent pages may result in changes on derived pages depending on the complexity of the derivation structure. The following scenario describes the behavior of derived pages.

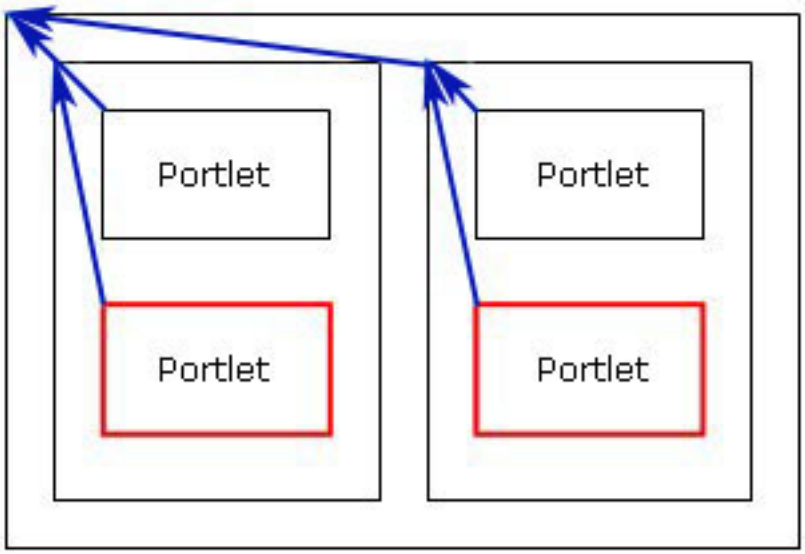
An administrator with the editor role creates a page with a two-column layout and places a portlet in each column. The blue arrows in the following figure indicate the child-to-parent relationship of the components of the page:

Two column layout:



Then a user with an editor role creates an explicit derivation from this page (under **Advanced Options**, selects **A page that uses content from a shared page**) and adds two portlets to the explicitly derived page, one portlet in each column as indicated in the following figure:

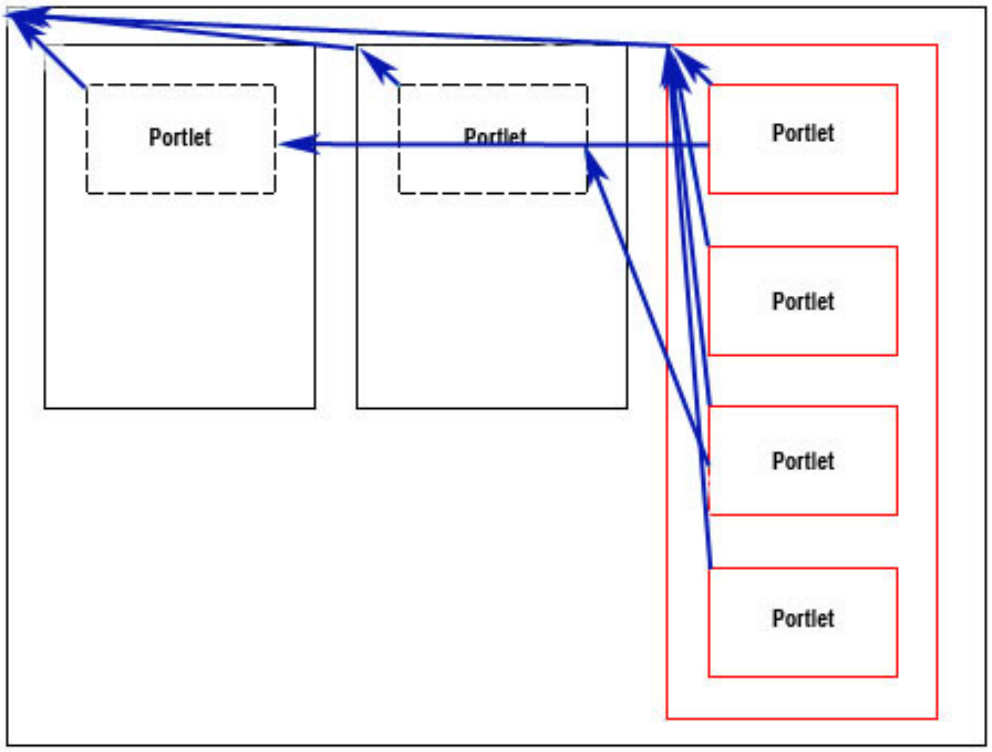
Two column four portlet layout:



The red boxes around the two new controls indicate that these controls are on a new *layer* of the page. The original page content and the new layer together comprise the complete page.

The user with an editor role creates a third column next to the two existing columns and moves all portlets to the new column. The new column exists on the layer of the derived page (red box); whereas, the original portlets are moved into the column through additional information (green arrows) as indicated in the following figure:

Three column layout:



Rendering the explicitly derived page shows all four portlets arranged vertically as shown in the previous picture.

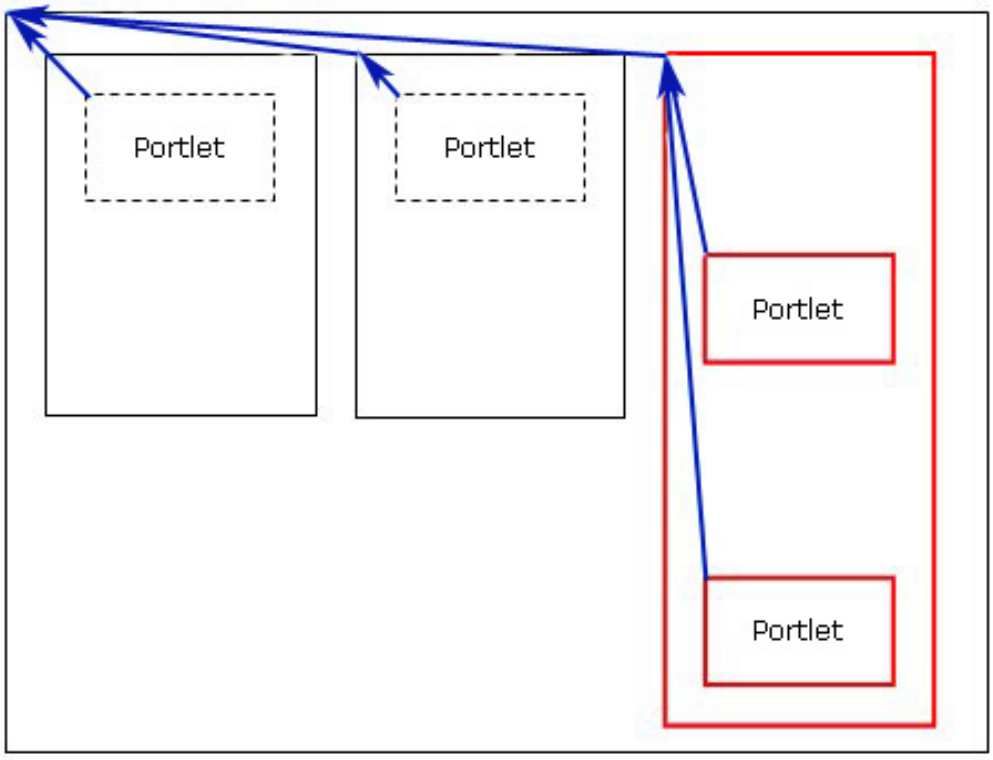
Next, the administrator locks all containers and portlets on the original page. This has no impact on the aggregated pages (original page and derived page). The administrator then removes the editor permission from the user who created the derived page and assigns only privileged user permissions to that user.

If this privileged user navigates to the derived page, the following issues occur:

- The administrator set the locks on the original page, which enforces the layout of the original page for the derived page. Therefore, the information that causes the original portlets to be moved into the new column (the green arrows in the three column layout figure) is deleted.
- Due to the locks, the additions on the extra layer of the derived page (red boxes) are suppressed. The privileged user sees the derived page exactly as the original page.

If the administrator reassigns editor permissions to the user for the derived page, the layout appears differently to the user from any of the stages of the derived page. The layer of additions to the derived page becomes visible again but the information about moving the original portlets has been deleted as indicated in the following figure:

Three column layout with missing information about moving the portlets:



The same principle applies to other layer scenarios in similar ways. Movement information of elements from the original page is deleted; whereas, actions on the layer of the derived page; for example adding portlets, rows, or columns; may persist after reassigning permissions as previously described.

IBM WebSphere Portal Page Derivation Concepts

Selecting pages

Pages that you can modify in Manage Pages appear as links in a table. By clicking a link to select a page, you can navigate to other nested pages to perform page tasks. You can also select labels and URLs in Manage Pages.

About this task

Manage Pages allows you to create, modify and delete pages, URLs, and labels. Any page that you are able to modify appears in a table, and the icons that display depend upon the tasks that you have permission to perform. If links exist in the **Page title** column, use those links to navigate to child pages of the selected page. As you perform page tasks, you will leave Manage Pages, but you will return to Manage Pages after completing each task.

For example, if you are able to modify the title of the page titled **My page**, clicking the Edit Page Properties icon takes you to Properties to change the page title and returns you to when you complete your changes.

- Displayed icons and links are dependent upon the tasks you have permission to perform.
- Upon completion of each task, you will be returned to Manage Pages.
- To access pages that are nested under others, click the Page title.

Using friendly URLs

You can associate friendly URLs with portal pages and labels. You and your users can use these friendly URLs to access specific portal pages or labels by using a human readable path, which is easy to remember.

Before you begin

For a friendly URL to work for a specific page, you must define a friendly URL name for every page or label in the path of the portal page hierarchy that leads to that page. You can do this in the page properties. Friendly URLs take the following general form:

`http://host_name:port_number/PortalServer_root/portal/page_id/[!ut/p/encoded_portal_suffix]`

The `page_id` portion of the friendly URL is made up of the friendly URL names of all pages in the path of the page hierarchy. This path begins at the content root and ends with the page for which you want to give your users a friendly URL.

Example: You have a portal page that is named **Products** in the user interface and has a friendly URL name `products`. Under this Products page you have another page, which is named **Appliances** and has a friendly URL name `appliances`. To access the **Appliances** page, users can type the following friendly URL into the browser address field:

`http://www.example.com:10039/wps/portal/products/appliances`

About this task

You can configure a friendly URL by using the portal toolbar or the Manage Pages administration portlet. To configure a friendly URL by using the Manage Pages portlet, proceed as follows:

Procedure

1. To open the **Manage Pages** portlet, click the **Administration menu** icon. Then, click **Portal User Interface** > **Manage Pages**.
2. Locate the page for which you want to configure a friendly URL.
3. Click the **Edit Page Properties** icon.
4. In the field **Friendly URL name**, type the friendly name for the page.
5. Click **OK** to save your changes.
6. Repeat this procedure for every page or label in the path of the portal page hierarchy that leads to the target page.

What to do next

To make up the full IBM WebSphere Portal Express URL, the portal appends a suffix to that friendly URL. This suffix represents the current state of the page and its components. Some scenarios require short and fully human readable URLs that omit the state information. For information about how to configure short stateless URLs see *Using friendly URLs without state information*.

"Using friendly URLs without state information" on page 1281
By default, WebSphere Portal Express URLs include navigational state information. If you configure pages for friendly URLs, the portal appends the state information to the friendly URLs. Some scenarios require short and fully

human readable URLs that omit the state information. For such scenarios, you can configure friendly URLs so that the portal does not show that state information.

Using friendly URLs without state information

By default, WebSphere Portal Express URLs include navigational state information. If you configure pages for friendly URLs, the portal appends the state information to the friendly URLs. Some scenarios require short and fully human readable URLs that omit the state information. For such scenarios, you can configure friendly URLs so that the portal does not show that state information.

Before you begin

If you are on combined cumulative fix 4 or earlier, go to "CF04 and earlier: Using friendly URLs without state information" on page 3631.

About this task

State information is an encoded aggregation of the navigational state of the portal and the portlet.

- The portal state includes page selection, expansions, label mapping, and action targets.
- The portlet state includes render parameters, window state, and portlet mode.

The presence of state information within the URL enables characteristics of dynamic websites, such as usage of bookmarks or the **Back** button. For example, when state information is included, users can bookmark a page and later return to the exact same state of that page.

Some scenarios require short and fully human readable URLs that omit the state information:

- You do not want the URL to make the impression that it references dynamic content.
- You want the URL to contain only information that a human person can read and interpret.
- You want the URL to easily fit into the address field of the web browser.
- Internet search engines expect static URLs that reference only one resource or web page for the time that the page exists.
- Internet search engines prefer short and friendly URLs.

For such scenarios, you can configure WebSphere Portal Express as follows:

- You configure themes to always display only short friendly URLs without state information.
- You configure pages that use that theme to display friendly URLs.

The configuration applies to all pages that use that theme and that are configured to display friendly URLs.

Notes:

- If you configure your portal to show stateless friendly URLs, you gain improved URL readability at the cost of losing the state functionality:
  - Portal URLs always point to the default state of a page because they do not contain the state information.
  - If a user clicks the **Back** button, or refreshes a page by clicking the **Refresh** button or the page title, the page moves back into the default View mode.

- If a user views a page and creates a bookmark, the bookmark later opens the page in the default View mode.
- Stateless friendly URLs do not contain information about the language of the page. The portal determines the language for the page by using the following steps:
  1. First, the portal looks for the user preference.
  2. If the user preference is not set, the portal looks for the preferred language that is set in the browser. If the page is a public page, the user is an anonymous user. In this case, the portal also looks for the preferred language that is set in the browser.
  3. If the portal cannot determine a preferred language setting for the portal or the browser, it applies the default language that is defined for the portal.

  You might want to present language-specific portal pages with stateless friendly URLs. For more information, see step 8 on page 1283 of the following procedure.

- Make sure that the JSPs of your theme provide a `<base>` tag in the header section of your markup. For example, you can use the portal tag `<portal-core:stateBase/>`. For more information, read *<portal-core/> tags*.

Procedure

1. Optional: Disable friendly URL redirects. If the incoming URL does not contain the friendly URL prefix of the addressed page, a URL redirect adds state information to the URL. To disable URL redirects, set the custom property `friendly.redirect.enabled` to the value `false` in the Resource Environment Provider (REP) WPConfigService in the WebSphere Integrated Solutions Console. If the property is not listed there, add it and set it to `false`. For information about this property and how to set it, see the topics *Configuration service* and *Setting service configuration properties*.
2. In the theme that you want to configure for stateless friendly URLs, set the parameter `com.ibm.portal.theme.hasBaseURL` to `true`. You can update the theme parameter by using the XML configuration interface. The following example shows a sample XML script:

```
<?xml version="1.0" encoding="UTF-8"?>

<request
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd"
 type="update">

 <!-- This sample sets the hasBaseURL Tag in the Portal 8.5 Theme. -->
 <portal action="locate">
 <theme action="update" uniquename="ibm.portal.85Theme" >
 <parameter name="com.ibm.portal.theme.hasBaseURL"
  type="string" update="set">true</parameter>
 </theme>
 </portal>
</request>
```

3. Make sure that no generated URLs in the theme include state information. In the default theme, you can complete this step by modifying the `navigation.jsp` and `sideNavigation.jsp` files. Use these steps to change the file `navigation.jsp`:

a. Change to the directory for the file navigation.jsp. You can find the file in the following location: *PortalServer_root*\theme\wp.theme.themes\default85\installedApps\DefaultTheme85.ear\DefaultTheme85.war\themes\html\dynamicSpots
b. Open the file navigation.jsp with an editor.
c. Search for the string node.urlGeneration and change it to one of the following stringa: CF05 node.urlGeneration.noNavigationalState

Use the following steps to change the file sideNavigation.jsp:

a. Change to the directory *PortalServer_root*\theme\wp.theme.themes\default85\installedApps\DefaultTheme85.ear\DefaultTheme85.war\themes\html\dynamicSpots.
b. Open the file sideNavigation.jsp with an editor.
c. Search for the string node.urlGeneration and change it to the following string: CF05 node.urlGeneration.noNavigationalState

4. Change the mobileNavigation.jsp file:
   a. Change to the directory *PortalServer_root*\theme\wp.theme.themes\default85\installedApps\DefaultTheme85.ear\DefaultTheme85.war\themes\html\dynamicSpots.
   b. Open the file mobileNavigation.jsp with an editor.
   c. Locate the string ?uri=nm:oid:${nodeID} and change it to the following string: CF05 ${node.urlGeneration.noNavigationalState}.
5. Change the mobileNavigationFeed.jsp file:
   a. Change to the directory *PortalServer_root*\theme\wp.theme.themes\default85\installedApps\DefaultTheme85.ear\DefaultTheme85.war\themes\html\dynamicSpots.
   b. Open the file mobileNavigationFeed.jsp with an editor.
   c. Search for the string node.url and change it to the following string: CF05 node.urlGeneration.noNavigationalState
6. Optional: If you are using IBM Web Content Manager, you might want the IBM Web Content Manager Rendering portlet to also display the friendly and stateless URLs. In this case, implement a plug-in that translates the IBM Web Content Manager URLs into the required custom format. For instructions and sample code for such a plug-in, see *Example 2, Generate a friendly URL for web content*.
7. Define friendly URL names for pages. For information about how to define friendly URLs, read *Using friendly URLs*.
8. Optional: You might want to present language-specific portal pages with stateless friendly URLs to your site visitors. In this case, structure your portal site to reflect which pages are targeted for specific countries or regions. You can create a node for a specific page, and then create language-specific child pages under that node. For example, in the node home, you create pages in English, French, and German. Your site visitors can then access the page in their preferred language by using one of the following friendly URLs:

   ```
   http://www.myco.com/wps/home/en/shop
   http://www.myco.com/wps/home/fr/shop
   http://www.myco.com/wps/home/de/shop
   ```

9. Restart the Portal server.

Results

The portal now no longer displays the navigational state information within the URLs.

"Example 2: Generate a friendly URL for web content" on page 3240
This example demonstrates a content URL generation filter that generates a friendly URL for web content.

"Configuration Service" on page 297
The portal Configuration Service is responsible for collecting the most essential configuration data of the IBM WebSphere Portal Express engine.

Related information:

"<portal-core/> tags" on page 2791
The <portal-core/> tags are used to provide portal core functionality such as entering the main render flow as well as URL-related aspects of the page.

Task refresh-page-layout

Use this configuration task to refresh the page layout for all pages assigned a given page layout template.

Description: You need to run this task if you have manually modified page layout template files stored in the folder `layout-templates` of the portal file store and you want those changes to be reflected on existing pages. The task reads the data of a specific page layout template from the portal file store and update all pages that are currently assigned that page template accordingly. Depending on the number of page affected, this task can run for a several minutes.

Assumptions/Prerequisites: WebSphere Portal Express is running. The execution of this task requires that the portal is running. If the portal is not running, the task starts the portal.

Usage: Reference the layout template by its file store URI, for example as follows:

```
/fs-type1/themes/Portal8.5/layout-templates/
```

Note: Make sure to provide the full URI here, especially if the URI has a trailing slash (/).
You can execute the task in synchronous or asynchronous manner. If you execute it asynchronously, the configuration task completes immediately after starting a corresponding asynchronous system task. You can use this mode to avoid timeout problems that might occur if a high number of pages are to be refreshed. The completion of the system task is indicated by a corresponding message in the file `SystemOut.log`.

Syntax: Start this task as part of the ConfigEngine script file as follows:

- For Linux: `./ConfigEngine.sh refresh-page-layout-template`
- For IBM i: From the UserData directory: `ConfigEngine.sh refresh-page-layout-template`
- For Windows: `ConfigEngine.bat refresh-page-layout-template`

Mandatory parameters to be specified on the command line or in the file `wkplc.properties` :

- **`WasUserid`** The WebSphere Application Server user ID
- **`WasPassword`** The WebSphere Application Server password

- **PortalAdminId** The portal administrator user ID
- **PortalAdminPwd** The portal administrator password

Mandatory parameter to be specified on the command line only:

- **PageLayoutTemplate** The file store URI of the page layout template

  Note: Make sure to provide the full URI here, especially if the URI has a trailing slash (/).

Optional parameters to be specified on the command line only:

- **VirtualPortalContext** or **VirtualPortalHost** Use this parameter to identify the virtual portal. Only pages contained in the specified virtual portal are refreshed. If you omit this parameter, by default no virtual portal page layout is refreshed.
- **Synchronous (=true)** Use this parameter to specify the execution mode. The default is synchronous. If you want to run this task in asynchronous manner, specify false .

Example:

```
./ConfigEngine.sh refresh-page-layout-template
     -DPageLayoutTemplate=dav:fs-type1/layout-templates/2Columnequal/
     -DVirtualPortalContext=virtual_portal_context_url
```

Customizing pages

The page customizer contains portlets for editing the layout, content, and appearance of pages. It also provides the Wires portlet, which allows users to set up connections between cooperative portlets on a page, and the Locks portlet, which allows users to lock and unlock containers and container content. You can configure the settings for these portlets to show a certain set of functions, restricting basic users from performing more advanced tasks.

Skins represent the border around a portlet, including its title bar. Users with appropriate access can select skins for individual portlets using the Appearance portlet of the page customizer. To set a skin for portlets, access the Page Customizer and select the Appearance portlet. See the portlet help for further information.

A page is deactivated when you start making changes to it. While editing the page, all changes are effective immediately and cannot be undone or cancelled. Other users will not be able to access the page and icons that launch the edit mode of portlets on the page are deactivated until you commit the changes by clicking **Done**.

Editing a shared page can have different results, depending on the role assigned to the user editing the page.

- Users with the Editor role for a page can make changes that affect all users of the page.
- Users with the Privileged User role for a page can only make changes to a private copy, or layer, of the page. The changes do not affect the other users of the page. The page must have an initial layout with at least one container before users with the Privileged User role can make any changes to the page.
- Users with the User role for a page cannot edit the page at all.

Log in to the portal and use one of the following methods to access the portlet:

- Navigate to the page you want to change and select **Edit Page Layout** from the drop-down menu. The drop-down menu for a page is located on the tab for that page. The Edit Layout portlet opens the current page for editing. Other portlets in the Page Customizer are available if you have appropriate access.
- After creating a new page, you are directed to the Edit Layout portlet to edit the layout and content of the new page. Other portlets in the Page Customizer are available if you have appropriate access. To create a new page, select **New Page** from the drop-down menu. The drop-down menu for a page is located on the tab for that page.
- Navigate to the Manage Pages portlet and click the **Edit Page Layout** icon in the appropriate row.

"Locking content on a page"
Use the Locks portlet to set permissions for moving containers or content, or for deleting portlets. This allows you to lock content to certain locations on a page. Any element on the page, such as a row container, a column container, or a portlet, can be locked or unlocked for many variations that give a user control of what can be modified. On a page where content and layout should be preserved, both can be locked, preventing other users from altering the arrangement of containers or portlets on the page.

"Connections between portlets"
The Portlet Wiring Tool allows you to configure connections, or *wires*, between *cooperative portlets*. Cooperative portlets can exchange information, or *properties*, with each other through the property broker. Properties are exchanged either by prompting the user with a Click-to-Action menu or automatically using preconfigured wires. As a result, portlets on the page can react in an integrated and unified manner to the user's actions.

"Themes and skins" on page 1287
A theme determines the global appearance of a page. The purpose of this is to ensure visual consistency. Themes affect the navigational structure, the banner, the colors and fonts, the available portlet skins, and other visual elements of a page. A skin determines the frame that is displayed around a portlet.

Locking content on a page

Use the Locks portlet to set permissions for moving containers or content, or for deleting portlets. This allows you to lock content to certain locations on a page. Any element on the page, such as a row container, a column container, or a portlet, can be locked or unlocked for many variations that give a user control of what can be modified. On a page where content and layout should be preserved, both can be locked, preventing other users from altering the arrangement of containers or portlets on the page.

Before you begin

In order to modify the locks for a certain page, a user must have Editor role on that page. If a user has appropriate access rights, the user can determine what other users are able to do with a page.

About this task

Be aware of the effect that locks and access permissions can have on pages that inherit content from a shared page. To lock or unlock content on a page:

Connections between portlets

The Portlet Wiring Tool allows you to configure connections, or *wires*, between *cooperative portlets*. Cooperative portlets can exchange information, or *properties*,

with each other through the property broker. Properties are exchanged either by prompting the user with a Click-to-Action menu or automatically using preconfigured wires. As a result, portlets on the page can react in an integrated and unified manner to the user's actions.

Setting up a wire between portlets allows the user's transfer selection choices to be saved. When specific interactions are performed, the wire can be used to automatically transfer properties to target portlets without displaying the pop-up menu prompting the user for more information. The Portlet Wiring Tool allows you to view the properties that portlets on the page can send or receive. If a match is available between two portlets, you can create a wire between the two portlets. Existing wires may also be deleted using the tool.

The Portlet Wiring Tool also provides the functionality to implement cross-page portlet communication. Cross-page wires allow portlets to exchange properties across pages. Before creating a cross-page wire, the target page must have receiving actions defined as global on its portlets. Setting an action as global will also make that action available to Click-to-Action menus. To set an action as global, navigate to the target page and select **Edit Page Layout** from the drop-down menu on the title bar. Then select the **Wires** tab and click **Manage Actions**. This will bring up a listing of the portlets on a page and their corresponding receiving actions.

As an alternative to the Portlet Wiring Tool, wires can also be created interactively in the portlet. Depending on the browser, users with sufficient permissions can create wires by holding either the **CTRL** or **ALT** keys and clicking an icon or hotspot in the portlet that is already associated with a Click-to-Action function. A dialog is displayed that allows the user to create a wire to other portlets on the page.

The wiring tool allows wires to be created in situations which are not handled by the interactive approach. For example, the tool does not require the existence of Click-to-Action menus to initiate wire creation It can be used to create multiple wires from a single source property (using the interactive approach, a single source can be wired to a single target or all targets, not an arbitrary subset). Wire creation or deletion is subject to the access control checks as described later.

In order to view the tool itself, users must possess at least "User" role permissions on the page and the portlet. Further access checks are performed before allowing the user to view, create, or delete wires between portlets. The user must possess at least "User" role permissions on a page and the wired portlets on it to be able to view wires for the page. Users may also be able to create or delete personal wires, which affect their view of the page, or create or delete public wires, which affect all users' view of the page. Users must possess at least "Privileged User" role permissions on the page and "User" permissions on the portlets to be able to create or delete personal wires, while at least "Editor" role permissions are required on the page and "User" permissions on the portlets to be able to create or delete public wires.

Themes and skins

A theme determines the global appearance of a page. The purpose of this is to ensure visual consistency. Themes affect the navigational structure, the banner, the colors and fonts, the available portlet skins, and other visual elements of a page. A skin determines the frame that is displayed around a portlet.

Use the Themes and Skins portlet to do the following:

- Set the portal default theme
- Set the portal default skin
- Associate skins with a theme
- Set the default skin for a theme
- Add new themes and skins to the portal
- Delete themes and skins from the portal.

Click the **Administration menu** icon. Then, click **Portal User Interface** > **Themes and Skins**. Refer to the respective portlet helps for more instructions.

Notes:

1. If you remove a theme, the references to that theme and the links between that theme and the related skins are also deleted. If you want to remove the skins that are related to the removed theme as well, apply special care to remove only skins that are related to no other theme than the deleted one. The skins are associated to the portlets. Therefore, if you have a skin that is related to several themes, and you delete one of those themes, then the skin still shows under the other themes.
2. Deleting a theme or skin does not remove the `/theme` or `/skin` directory from the server.
3. Some of the theme and skin titles might not appear correctly if your language preference uses DBCS characters. Correct the display of these titles, change the character set used by your language preference for HTML markup to `UTF-8`.

Related information:

"Changing the character set for a language" on page 1427
The character set is stored in the database. This is the character set used for the response to the user. You can change the character set for a language.

Managing theme capabilities

You can administer the theme module framework. This includes deploying resources that can be cached, configuring capability filters, and disabling the automatic prerequisite loading feature.

"Deploying themes with cacheable resources"
Data sources are used in a portal to serve content. Some resources are cached and other resources can define cache settings and pass them to a data source. In a production environment, use caching. When debugging themes, disable caching.

Deploying themes with cacheable resources

Data sources are used in a portal to serve content. Some resources are cached and other resources can define cache settings and pass them to a data source. In a production environment, use caching. When debugging themes, disable caching.

Caching information for combined requests is computed by the framework based on the individual data sources that are combined. However, in some cases the data sources do not provide caching information, such as in the case of static file inclusion. For example, with the resource data source, content is addressed with `res` in the `plugin.xml` file and the file serving servlet does not set the cache information.

To make resources cacheable, the resource aggregator provides a generic mechanism where it defines the cache settings for a single URI, URI patterns or

contribution types. These settings are then passed to the data source, which determines whether these settings are considered. The resource data source includes them, for example, where the dav data sources for the filestore provides their own settings. These settings are then considered for content in the `plugin.xml` file, which is addressed with `res`. Content addressed with `dav` in the `plugin.xml` file has its own settings and does not use the following parameters.

Caching information is set in the WP ConfigService resource environment provider. The available settings are:

com.ibm.wps.resourceaggregator.cache.info.<id>.type
The values can be set as `uri` or `contributiontype`.

com.ibm.wps.resourceaggregator.cache.info.<id>.re
The value is a regular expression that can be matched against a URI when `uri` is defined as the type, or a contribution type when `contributiontype` is set for the type.

com.ibm.wps.resourceaggregator.cache.info.<id>.max-age
The value is the maximum age of the resource in seconds.

com.ibm.wps.resourceaggregator.cache.info.<id>.cache-scope
The value is `public` when this resource can be cached in an external caching infrastructure or `private` if it cannot.

com.ibm.wps.resourceaggregator.cache.info.<id>.user-context
The value is `false` if this resource is shared between users, and `true` if the value is user specific.

Sample of entries in WP ConfigService:

- `com.ibm.wps.resourceaggregator.cache.info.0.type = "uri"`
- `com.ibm.wps.resourceaggregator.cache.info.0.re = ".*\.(js|css)"`
- `com.ibm.wps.resourceaggregator.cache.info.0.max-age = "86400"`
- `com.ibm.wps.resourceaggregator.cache.info.0.cache-scope = "public"`
- `com.ibm.wps.resourceaggregator.cache.info.0.user-context = "false"`
- `com.ibm.wps.resourceaggregator.cache.info.1.type = "contributiontype"`
- `com.ibm.wps.resourceaggregator.cache.info.1.re = "config_static"`
- `com.ibm.wps.resourceaggregator.cache.info.1.max-age = "100000"`
- `com.ibm.wps.resourceaggregator.cache.info.1.cache-scope = "public"`
- `com.ibm.wps.resourceaggregator.cache.info.1.user-context = "false"`

The following entries are set by default:

- Expiry is set to `1 day`.
- User context is set to `false`.
- Cache-scope is set to `public`.

There are configuration tasks that automatically add or remove these entries from the WP ConfigService resource environment provider. To add these entries, run the **`set-resourceaggregation-cache-info`** configuration task . If you want to remove entries from the WP ConfigService, then run the **`remove-resourceaggregation-cache-info`** configuration task .

Disabling caching on development systems

Usually, the profiles and contributions are determined once, when the portal server is started and then they are used unchanged. Updates to the portal are not included until a server restart occurs, for performance reasons.

To see the changes to profiles and contributions immediately, the `resourceaggregation.development.mode` property to `true` within the WP ConfigService resource environment provider.

Managing community pages

Community associations associate a portal page with a community in IBM Connections.

"Managing community associations"
You can create, view, modify, or delete community associations on a page with the Page Associations window, the XML configuration interface, and Portal Scripting Interface.

"Creating community associations during page template instantiation" on page 1293
When creating a page template, you can require that a community association is created when a page is created from the template.

"Community associations and APIs" on page 1295
Although community associations are typically managed through the portal user interface, you might want to access the associations programmatically.

Managing community associations

You can create, view, modify, or delete community associations on a page with the Page Associations window, the XML configuration interface, and Portal Scripting Interface.

Procedure

To create a community association, complete the following steps, according to the method you want to use.

- Create a community association in the user interface with the Manage Associated Communities window.
  - Open the Manage Associated Communities window from the site toolbar.
    1. In the site toolbar, click the **Page** > **General** > **Associated community**. If an association exists, it is displayed.
    2. Select **Associated community** to display the Manage Associated Communities window.

       Note: The **Community** section is displayed only if an IBM Connections server is configured for the portal.
  - Open the Associations window from the page properties portlet.
    1. To open the **Manage Pages** portlet, click the **Administration menu** icon. Then, click **Portal User Interface** > **Manage Pages**.
    2. Go to the page, and click the **Edit Page Properties** icon for the page.
    3. In the **Advanced options** section, click **I want to edit associations**.
    4. Click the **Community** tab. If an association exists, it is displayed.

Note: The **Community** tab is displayed only if an Connections server is configured.

1. Create the association. You can create an association with one of the following methods:
   - Click **Select Community**. The portal queries the Connections server and lists available communities. Select the community that you want to associate with the page.

     Depending on the number of available communities, only a subset of all communities might be listed. If the Connections server is not running, no communities are listed.

     You can filter the list of communities by entering text in the **Find community** field. The list of communities is narrowed to only those communities that contain the search text in the community title.
   - To associate the page with the same community that is associated with the parent page, click **Use default community from parent page**.
2. Optional: To automatically grant page access to members of the associated community, click **Limit access to this page to only community members**.

   Activating this feature results in the following changes:
   - The User role is assigned to the virtual user group that represents the community and the page. This access is in addition to any access that you explicitly grant to the page.
   - Role blocks are defined for the page for the User role and the Privileged User role. These role blocks prevent corresponding access privileges that are granted to the parent page from being propagated to this page.

   This setting is displayed only if you installed and enabled the IBM Connections adapter for VMM users and groups. For details, see *Automatically grant page access to community members*.

   Access control changes from this setting:

   When you select the **Limit access to this page to only community members** setting, the following changes are made:
   - The User role on the page is assigned to the virtual user group that represents the members of the associated community.
   - Role blocks are added on the page for the User role and the Privileged User role.

   When you clear the **Limit access to this page to only community members** setting, the following changes are made:
   - The User role on the page is removed for the virtual user group that represents the members of the associated community.
   - The role blocks on the page for the User role and Privileged User role are removed.

   If you change the community that is associated with the page, the following changes are made:
   - The User role on the page is removed for the virtual user group that represents the members of the previously associated community.
   - The User role on the page is assigned to the virtual user group that represents the members of the newly associated community.
   - If role blocks do not exist on the page for the User role and Privileged User role, the role blocks are created.

Activating this feature is restricted to users that are granted all roles that are required if the corresponding access control modifications are performed manually with the access control administration portlets. For more information about the roles that are required when you select **Limit access to this page to only community members**, see *Access permissions*.

3. Optional: If you want child pages of the page to be automatically associated with the same community as this page, select **Copy updated association to all *number* direct child pages**.

   This setting associates the community to all child pages where the user has sufficient access to update page associations. If the user does not have the required access for a page, it is not updated.

   Depending on the configuration of the server, the window displays the number of pages and nesting levels that are affected based on a threshold. If the number of affected pages exceeds the configured threshold value, this option is not displayed. For details on setting the page thresholds, see *Configuring support for community pages*.

   Note: When community associations for a page are copied to child pages, only the community associations are copied. The value of the **Limit access to this page to only community members** setting is not copied to child pages because of access control inheritance. This inheritance automatically enables members of the mapped community to view the child pages.

- Create a community association by using the XML configuration interface (**xmlaccess** command).

  When you are defining the association in the XML import file, use the <content-mapping-info> element, and specify a content mapping scope of `ibm.connections` for an individual nested <content-mapping> element.

  For additional information about the XML configuration interface and <content-mapping-info> elements, see *XML configuration interface and content associations*. This XML sample shows how to map a page to a community. In this example, the page has the unique name `unique-name-of-the-page-to-be-updated`, and the community is specified with the community UUID `some-ibm-connections-community-uuid` in Connections.

```
<request type="update" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
         xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd">
    <portal action="locate">
        <content-node action="update"  domain="rel" uniquename="unique-name-of-the-page-to-be-upda
            <content-mapping-info>
                <content-mapping content-id="some-ibm-connections-community-uuid"
                                 default="true" scope="ibm.connections"/>
            </content-mapping-info>
        </content-node>
    </portal>
</request>
```

"XML configuration interface and content associations" on page 2076
With the XML configuration interface (**xmlaccess** command), you can perform batch updates of content associations or export associations to import into another portal. Content association information is represented in the XML configuration schema by content-mapping-info elements.

Related information:

 REST API and content associations
If you are creating or extending an application and want to manage content associations with that application, you can use portal remote APIs. These APIs retrieve a list of content associations and then create, update, or delete associations.

Creating community associations during page template instantiation

When creating a page template, you can require that a community association is created when a page is created from the template.

About this task

When creating the community association, you have several options:

- You can associate the new page with a community that is automatically created during page template instantiation.
- You can associate the new page with a community that is associated with the parent page of the new page.
- You can associate the new page with a specific community that already exists.

Important: To create communities automatically when creating pages from a template, the user creating the page must be authorized on the Connections server to create communities.

"Creating communities during community page instantiation"
When you create a template for a community page, you can configure the template to create a community when you create a page from the template.

"Creating associations to existing communities during page instantiation" on page 1294
When you create a template for a community page, you can configure the template to associate the page created from the template with an existing community. In this case, the community is not modified in any way.

Related tasks:

"Managing community associations" on page 1290
You can create, view, modify, or delete community associations on a page with the Page Associations window, the XML configuration interface, and Portal Scripting Interface.

Creating communities during community page instantiation

When you create a template for a community page, you can configure the template to create a community when you create a page from the template.

About this task

In this case, when the page is created, a community is created in IBM Connections, and the new page is associated with the new community. The name of the new community is derived from the title of the new page.

Important: To create communities automatically when creating pages from a template, the user creating the page must be authorized on the Connections server to create communities.

Procedure

There are two ways to specify that a page template requires a community association.

- Add a community association to the page template by editing the page associations in the user interface or by using the XML configuration interface. See *Managing community associations* for details.

  The new community has the following characteristics:
  - The same title as the new page.
  - The same community description as the community that is associated with the page template.
  - The same **Access** setting as the community that is associated with the page template.
  - The user who creates the page is designated as the owner of the new community.
- Define parameters on the template page.
  1. Set the **ibm.portal.instantiation.community.create.new** parameter on the template page with a value of `true`.

     You can set this parameter by editing the page properties in the user interface or by using the XML configuration interface (**xmlaccess** command).

     The new community has the following characteristics:
     - The same title as the new page.
     - An empty community description.
     - An **Access** setting of `public`.
     - The user who creates the page is designated as the owner of the new community.
  2. Optionally, you can specify the **Access** setting for the community by specifying the **ibm.portal.instantiation.community.access.type** parameter on the template page.

     You can specify one of the following values: `public`, `restricted`, `moderated`.

Creating associations to existing communities during page instantiation

When you create a template for a community page, you can configure the template to associate the page created from the template with an existing community. In this case, the community is not modified in any way.

About this task

Procedure

Associate the new page with a specific community or with the community that is associated with the parent page of the new page.
Define the association on the template page by setting page parameters in one of the following ways:

- Edit the page properties in the user interface.
- Use the XML configuration interface (**xmlaccess** command).
- To associate page instances that are created from this template with a specific community, set the **ibm.portal.instantiation.community.ref** parameter.

  The value of the parameter is the universally unique ID (UUID) of the target community. The UUID of the community is identified by the **communityUuid** parameter in the URL for the community in IBM Connections.

  For example, in the following URL:

```
https://www.example.com:port_number/communities/service/html/communityview?communityUuid=e9f88a24-3dec-446a-91f3-90118d7e22c3
```

  The community UUID is `e9f88a24-3dec-446a-91f3-90118d7e22c3`.

  Note: You cannot use the **ibm.portal.instantiation.community.ref** parameter in combination with the **ibm.portal.instantiation.community.create.new** parameter. If both parameters are specified for a page template, the **ibm.portal.instantiation.community.ref** parameter takes precedence, and the **ibm.portal.instantiation.community.create.new** parameter is ignored.
- To associate page instances that are created from this template with the community that is associated with the parent page of the new page, set the **ibm.portal.instantiation.community.parent** parameter. Specify a value of `true` for the parameter.

  If there is no community association for the parent page, the new page is created without a community association.

  However, if you want to ensure that a community is created in this case, set the **ibm.portal.instantiation.community.create.new** parameter with a value of `true`. If the parent page has no community association, a new community is created with the same characteristics as described in *Creating communities during community page instantiation.*

When you create a template for a community page, you can configure the template to create a community when you create a page from the template.

Community associations and APIs

Although community associations are typically managed through the portal user interface, you might want to access the associations programmatically.

For example, a portlet on a specific page might need to communicate with a community in IBM Connections that is associated with the page. For this type of access, the content mapping service supports several APIs:

- Java API
- REST API
- Portal Scripting Interface
- XML configuration interface (**xmlaccess** command)

The content mapping service provides general access to associations of portal resources with other types of resources. Associations to resources of different types are grouped together and separated from one another by *scopes*. Community associations are managed in the `ibm.connections` scope.

Related reference:

"XML configuration interface and content associations" on page 2076
With the XML configuration interface (**`xmlaccess`** command), you can perform batch updates of content associations or export associations to import into another portal. Content association information is represented in the XML configuration schema by content-mapping-info elements.

Managing your site

Earlier versions of WebSphere Portal Express provided the Resource Manager portlet for performing site management. With Version 8.0 of WebSphere Portal Express and Web Content Manager, this site management functionality has been replaced by the new functionality for managing pages.

About this task

Managed pages are portal pages that are managed in Web Content Manager. You can manage your sites and move portal pages from one server to another by using the Web Content Manager syndication mechanism. This has the following advantages over the previous site management feature:

- You can create drafts of portal pages in the context of a project. You can preview these drafts, including possible updates by other coworkers on the same project.
- You can have staggered versions of pages.
- You can define a workflow for the pages. The workflow can include security settings for the pages. For example, you can remove edit rights from a page after the page is approved and published.
- You can submit draft pages for approval. You can also have the project approved for publication.
- You can preview the project as if it was published content.
- You can publish a project or individual pages to the subscriber server by one of the following mechanisms:
  - manually
  - based on date and time
  - automatically, when all items of a project have been approved and are pending for publication.

The only option to use the Resource Manager portlet and the site management functionality with WebSphere Portal Express Version 8.5 is to use a WebSphere Portal Express Version 7.0 and its Resource Manager portlet. For information about site management with the Resource Manager portlet, see the *WebSphere Portal Express Version 7 product documentation: Managing your site*.

Tagging and rating

Get an overview of the administrative tasks related to tagging and rating.

Attention: To use tagging and rating with your virtual portal, ensure that the **web resource v7.0** and **web content templates 3.0** libraries exist on the virtual portal.

Portal administrators can do the following tasks:

- Enable or disable tagging and rating for portal users. Tagging and rating are enabled in the IBM WebSphere Portal Express Portal 8.5 theme. You can disable and enable tagging and rating globally for the portal as a whole. To do so, use the following configuration properties:
  - To disable and enable tagging portal wide, use the property `com.ibm.wps.cp.tagging.isTaggingEnabled`.
  - To disable and enable rating portal wide, use the property `com.ibm.wps.cp.rating.isRatingEnabled`.

  these properties are available in the WP CP configuration service Resource Environment Provider in the WebSphere Integrated Solutions Console. For details about portal service configuration properties and how to set them refer to the topics about Portal configuration services and Setting service configuration properties.
- Add custom content that users can tag and rate, for example, pages, portlets, content that is managed by Web Content Manager, or custom content such as books in a bookstore.

  Note: If you want your users to tag and rate custom content, you must write code. The code must allow customers to find this content with the public APIs. You must also add the resources that you want your users to tag to the portal. Custom content is anything apart from portlets, portal pages, and Web Content Manager resources. For information, read *Enabling your own custom content to be tagged and rated*.
- Assign access rights to users for tagging and rating content. For details, read *Security for tagging and rating*.
- Administer the tag clouds. Administrators can set multiple parameters that affect the tag cloud. Two examples are described here in detail. For a list of the possible tag cloud parameters, read *The tagging and rating user interface* and the tagging and rating reference topics.
  - Scope tag clouds to the kind of resources for which you want tags to be displayed. A default tag cloud displays all tags that users applied in the portal. Administrators can change this behavior. For example, you can limit a tag cloud to display tags that were applied only to pages, portlets, or books. You scope tag clouds by setting either categories or type schemas for them. The tag cloud represents only portal content that matches the categories or type schemas that you specified. You can scope each single tag cloud instance differently. Scoping tag clouds also affects the result lists of resources that are shown when users click a tag. The result list shows only resources of the scoped type. For example, if a tag cloud is scoped to the type photo, the result list shows only photo images.
  - Configure the tag cloud behavior. Tag clouds can react differently to tag clicks:
    - Either the user is redirected to the portal Tag Center and a result list of resources is displayed to which this tag was applied is displayed.

- Or the tag cloud shows the clicked tags as shared render parameters, so that, for example, other portlets on the same page can display corresponding content.

- Stage a tagspace to a different portal system, for example, when you move your portal to a staging server or upgrading your portal to a new version. For details about how to do so, read *Using the XML configuration interface to administer tags and ratings*.
- Obtain statistics about the tagging and rating behavior of the portal users.
- Administrators can also do all tasks that portal users can do as described in the topics about portal user tasks.

Introduction to tagging and rating

Tagging and rating are features that support collaboration and interaction between users when using Web content.

Rather than relying on dedicated authors to be responsible for adding content, knowledge-sharing communities of users now collectively contribute to Web content. These systems grow quickly and are not as coordinated as they were when teams of dedicated authors were responsible for planning and creating content. For this reason, new methods of organizing and structuring content are required.

Tagging and rating are common and effective collaboration techniques that support the collective wisdom of communities:

Tagging

Tagging means assigning keywords as metadata to resources to describe or evaluate the content of these resources. These keywords are tags. For example, a user can apply the tag `websphere` to a page that provides information about IBM WebSphere products. Tagging content provides users the ability to describe, and better categorize, resources. By tagging content, users make it easier to find and highlight the importance or quality of content, which, in turn, benefits the other users in the knowledge-sharing community. Tagging provides better search results, as the search criteria is descriptive and users do not have to scan the content for the keywords.

A user typically assigns more than just one tag to a single resource. For example, a user can assign a book the tags `portal`, `web20`, and `computer_science` . This allows for multiple ways of finding the book, like putting multiple copies of the same book on different shelves.

Tagging has become one of the most popular techniques to allow users and entire user communities to classify, organize, and structure content autonomously. By tagging content users add valuable meta information and even lightweight semantics to Web content. Tagging allows non-expert users to develop folksonomies that categorize content available in the system.

Tag
A tag is a keyword that users apply to describe or evaluate the content of the resource that they tag. A user can apply the same private tag to multiple resources. This means that an individual user can use the same certain tag more than once, but only once per resource. By default users can only delete tags that they have applied themselves. Users with the MANAGER role have more rights.

Tag cloud
Tag clouds help users find and retrieve resources by showing aggregated views of tags that users have applied to specific resources. Tag clouds provide different visual representations of all the tags that users have applied. For example, depending on the configuration settings, tag clouds can display all available tags or how often specific tags occur. Tag clouds usually highlight the popularity or importance of specific tags by increasing the size of the tags or changing the color of the tags.

Tagspace
A tagspace represents the number of occurrences of a certain tag. It contains the name of the tag, the number of occurrences and the information whether the current user has applied this tag as a private tag. To represent the tag cloud, the portal loads the tagspaces rather than retrieving the single tag instances from the database and accumulating the numbers.

Rating
Rating is the evaluation or assessment of something, in terms of quality, for example, (as with a critic rating a novel), quantity (as with an athlete being rated by his or her statistics), or a combination of both. Examples of quality ratings are critics who rate books or customers who rate purchased products for quality. Examples of quantitative ratings can be the performance data of cars or computers. Users rate resources by assigning numeric or other values to resources to indicate how much they like the resource. Thus, a rating is a value associated to a resource. Ratings are selected from a range of possible values where one end of the range usually refers to "like" and the other end to "dislike".

Rating allows users and entire communities to express which content they like or dislike.

By default users can only delete ratings that they have applied themselves. Users with the MANAGER role have more rights.

Resource
A user can apply the same rating to multiple resources. A resource is

anything that can be uniquely identified and addressed in a portal. For example, this can be a portal page, or portlet, or an item for sale in an internet shop.

Public and private tagging and rating

Users can assign public or private tags and ratings:

Private tagging and rating
With private tagging and rating users can see only their own tags and ratings. This allows users to browse through their Web content and retrieve important resources fast. A user typically assigns more than just one tag to a single resource. For example, a user can assign a book the tags `portal`, `web20`, and `computer_science`. This allows for multiple ways of finding the book, like putting multiple copies of the same book on different shelves.

Public tagging and rating
In a collaborative context users can see tags and ratings given by their collaborative community. First, users assign tags to resources just like under private tagging, creating their own way to browse through system content. Public tagging becomes powerful when multiple users start to tag resources and tags become part of the community pool of tags. This way tagging creates a bridge between personal and community knowledge and enables collective intelligence. Everyone's tags together form a kind of community consensus about an resource. The tags that are used most often might be the ones describing an item best.

Community and personal tags and ratings

Tags can be personal tags or community tags. All statements made for tags in the following apply also to ratings.

Personal tags
Personal tags are applied by a specific user. When a user tags a resource, the user applies the tag to the resource as a personal tag. Public tags can be seen by everyone who belongs to the community. Private tags can only be seen by the user who created the tag.

Community tags
Community tags are assigned by the community, that is by all other users in the system. Every public tag that a user assigns turns into a community tag, because it is visible to the community.

What is new in tagging and rating

With IBM WebSphere Portal Express Version 8.5, the tag and rating widgets have been replaced by new enhanced versions of these widgets.

Before IBM WebSphere Portal Express Version 8.5, tagging and rating provided two user interfaces with two different types of widgets:

- The default portal tagging and rating user interface featured several elements: dialog widgets for tagging and rating, the tag cloud, the Tag Center, and a feature for browsing tags. The dialog tag and rating widgets opened in separate pop-up windows.
- The alternative user interface provided inline widgets for tagging and rating. If you added such an inline widget to a portal resource, this widget was integrated into the portal resource. The user viewed the user interface for tagging or rating as part of the portal resource.

With IBM WebSphere Portal Express Version 8.5, both the dialog and inline tag and rating widgets of previous portal versions are deprecated. They are replaced by a

single pair of new enhanced inline widgets. They provide the functionality of both types of the old widgets. Users view them as part of the portal resource.

The new inline widgets have the following advantages:

- The new widgets combine the functionality of the dialog widgets and the inline widgets of earlier portal versions.
- With the new widgets, users can create, modify, and delete tags and ratings that they have assigned themselves. With the earlier inline widgets, user could only view tags and ratings. s
- The widgets provided by WebSphere Portal Express Version 8.0 and earlier versions required Dojo support. The new widgets in WebSphere Portal Express Version 8.5 are light-weight, as they work without Dojo.
- The new widgets provide easy and convenient access to various actions, for example switching between different scopes and viewing rating distribution.

For more detailed information about the new tag and rating widgets, read *The tag and rating widgets*.

To use the new widgets after a portal upgrade to version 8.5, you need to enable the widgets by running a configuration task. For more information, read *Enabling the new tag and rating widgets after a portal upgrade*.

In a default WebSphere Portal Express Version 8.5 installation, the new tag and rating widgets are enabled for specific profiles. You can enable and disable the new widgets for additional profiles. For more detailed information, read *Enabling and disabling the tag and rating widgets for additional profiles*.

The Dojo tagging and rating menu options of the earlier default widgets are still available in WebSphere Portal Express Version 8.5. They are enabled for specific profiles. You can enable and disable them for additional profiles. For more detailed information, read *Enabling and disabling the Dojo tagging and rating options for additional profiles*.

Related tasks:

"Enabling and disabling the tag and rating widgets for additional profiles" on page 1340
In a portal installation, the tag and rating widgets are available for specific portal profiles. You can enable the widgets for more other profiles by adding them to the profile.

"Enabling and disabling the Dojo tagging and rating options for additional profiles" on page 1341
In a portal installation, the Dojo tagging and rating menu options for portal pages and portlets are available for a specific portal profile. You can enable these options for other profiles by adding them to the profile.

"Enabling the new tag and rating widgets after a portal upgrade" on page 917
If you upgrade your IBM WebSphere Portal Express from an earlier version to Version 8.5 and want to use the new tag and rating widgets, you must first enable blogs and wikis. Then, complete the following task to ensure that tag and rating widgets are enabled.

Related reference:

"The tag and rating widgets" on page 1310
The portal provides one widget each for tags and for ratings.

How tagging and rating works in the portal

Use these topics for general administrative information about tagging and rating in the portal.

"How public and private tags and ratings work in the portal"
Users can choose between applying a tag or rating as a private or public tag or rating.

"Tagging and rating with anonymous users" on page 1304
Anonymous users of the portal can tag and rate portal content, if an administrator adds the anonymous user to the appropriate roles on the virtual resources as described in the topic about Security for tagging and rating.

"Grouping tags and ratings via resource categorization" on page 1304
Users apply tags and ratings to resources. Users can tag and rate all resources that can be uniquely identified.

"Normalizing tags" on page 1305
The portal provides several options for normalizing tags. Normalization is a process of transforming a text fragment, such as a tag, into another, more generic representation. This bundles different spellings or grammatical versions of the same lexical word that users might use as tags, for example `color, Color, COLOR, colour, colors, colored`.

"Type-ahead feature for the deprecated tag widget" on page 1306
The tag widget from earlier IBM WebSphere Portal Express versions provided a type-ahead feature. With portal V 8.5, that tag widget is deprecated. The type-ahead feature makes it easier for users to find suitable tags. Type-ahead supports users when they work with tags. For example, when users apply tags using the tag widget, or when they search for tags, for example by using the open search functionality, type-ahead provides users suggestions for tags that other users have applied already before. Type-ahead can also help reduce the number of variants of tags.

"Filtering content for tagging" on page 1307
You can use filtering mechanisms to control which terms users can use and which terms they cannot use as tags. The portal provides both a blacklist and a whitelist filter.

How public and private tags and ratings work in the portal

Users can choose between applying a tag or rating as a private or public tag or rating.

The differences between private and public tags and ratings are described in the following. All statements made for tags in the following are also applicable to ratings.

Private tags

- A private tag can be seen only by the user who applied it
- A user can apply the same private tag only once to one specific resource.
- A user can apply the same private tag to multiple resources. This means that an individual user can use the same tag more than once, but only once per resource.
- Users can only delete private tags that they have applied themselves. Users with a Manager role have more rights. For more information see the topic about *Security for tagging and rating*.

Public tags

- All public tags and ratings are visible to all users who belong to the community and who have access to the resource itself, independent of who created the tag or rating.
- A user can apply the same public tag only once to one specific resource.
- A user can apply the same public tag to multiple resources. This means that an individual user can use the same tag more than once, but only once per resource.
- The same public tag can be applied to the same specific resource by multiple users. In other words, all users can apply the same tag or rating to a resource once; as a result, the resource can have the same tag applied to it multiple times.
- Users can only delete public tags that they have applied themselves. Users with a Manager role have more rights. For more information see the topic about *Security for tagging and rating*.
- Public tags are also community tags.

Related reference:

"Security for tagging and rating" on page 1342
For administering which users can tag and rate content, the portal provides virtual resources for tagging and rating and roles on these virtual resources.

Tagging and rating with anonymous users

Anonymous users of the portal can tag and rate portal content, if an administrator adds the anonymous user to the appropriate roles on the virtual resources as described in the topic about Security for tagging and rating.

As the portal cannot distinguish one anonymous user from another, there are some side effects that need to be understood:

- For tagging, the same user can normally not apply the same tag to the same resource more than once, but an anonymous user can apply the same tag more than once.
- For rating, the same user can normally rate a single resource only once, but an anonymous user can rate the same resource more than once.
- Anonymous users cannot view their personal tags, and they cannot delete tags or ratings.
- Anonymous users cannot tag or rate a page with the Search and Tag Center profile deployed on it.

Grouping tags and ratings via resource categorization

Users apply tags and ratings to resources. Users can tag and rate all resources that can be uniquely identified.

Examples:

- A URI that consists of a type schema and an SSP (scheme specific part), such as an article bar code: `item:item_bar_code_number`
- The ISBN number for a book: `book:isbn_number`.

These resources must be registered with the tagging and rating engine. The portal performs this registration whenever an existing resource is tagged or rated. To categorize tags and ratings, administrators can group resources. You can group resources by URI or by category specification:

Resource categorization per URI

When the portal registers resources, it assigns them a URI. The URI consists of a type schema and a scheme specific part (SSP). For example, users could register media as follows:

- some books under `content/books/action:/isbn`, where `content/books/action` is the type schema and `isbn` is the SSP.
- some other books under `content/books/thriller:/isbn`
- some DVDs under `content/dvds/action:/some_ID`
- some other DVDs under `content/dvds/romance:/some_ID`

Categorization of resources becomes important when tags or ratings are aggregated. For example, tags are aggregated in tag clouds. For details refer to the topic about Configuring the tag cloud. For example if a user wants to aggregate a tag cloud that shows all tags that are associated with the action books as previously mentioned, you could aggregate tags for resources that have been registered under the type schema `content/books/action`. For details about how to scope tag clouds for certain type schemas refer to the topic about Configuring the tag cloud.

Resource categorization per category specification

When resources are registered, they can be explicitly associated with one or more categories. A category is represented by a non-localized unique string based identifier. For example, users could register media as follows:

- some books under `content/books/action:/isbn` and the category `promotion`
- some other books under `content/books/thriller:/isbn` and the category `bestseller`
- some DVDs under `content/dvds/action:/some_ID` and the category `promotion`
- some other DVDs under `content/dvds/romance:/some_ID` and the category `bestseller`

For example, if you want to aggregate a tag cloud that shows all tags for promotion articles, you could aggregate tags for resources that have been associated with the category `promotion`, in the previous example action books and action DVDs. For details about how to scope tag clouds for certain type schemas refer to the topic about Configuring the tag cloud.

Normalizing tags

The portal provides several options for normalizing tags. Normalization is a process of transforming a text fragment, such as a tag, into another, more generic representation. This bundles different spellings or grammatical versions of the same lexical word that users might use as tags, for example `color`, `Color`, `COLOR`, `colour`, `colors`, `colored`.

The standard normalization algorithm provided by the portal removes all diacritical marks from all letters of words. This documentation refers to the diacritic free morphological variation of a word as the normalized form of the word.

This is important when you consider which tags you want to be aggregated together when they are displayed as part of a tag widget, or, even more important, part of a tag cloud.

You can control the normalization behavior by various configuration parameters. To configure normalization behavior, go to **Resources** > **Resource Environment** >

Resource Environment > **Providers** > **WP CPConfigurationService** > **Custom Properties**. You configure normalization by using the following parameter in the portal CP Configuration Service resource environment provider in the WebSphere Integrated Solutions Console:

normalization.displayNormalizedName = (false)
This parameter defines whether the normalized tag names are displayed (exposed) in the tag cloud. The default value for this parameter is `false`.

```
com.ibm.wps.cp.tagging.normalization.displayNormalizedNames = false
```

normalization.typeAhead = (normalized)
This parameter defines the tag names that the type ahead for tag creation mechanism displays to the user. Valid values are `normalized` and `unnormalized`. The default value for this parameter is `normalized`.

Note: The type-ahead feature works only with the dialog tag widget of the default tagging user interface of portal versions earlier than V 8.5. With WebSphere Portal Express V 8.5, the tag and rating widgets of earlier portal versions are deprecated.

Type-ahead feature for the deprecated tag widget

The tag widget from earlier IBM WebSphere Portal Express versions provided a type-ahead feature. With portal V 8.5, that tag widget is deprecated. The type-ahead feature makes it easier for users to find suitable tags. Type-ahead supports users when they work with tags. For example, when users apply tags using the tag widget, or when they search for tags, for example by using the open search functionality, type-ahead provides users suggestions for tags that other users have applied already before. Type-ahead can also help reduce the number of variants of tags.

Note: The type-ahead feature works only with the dialog tag widget of the default tagging user interface of portal versions earlier than V 8.5. With WebSphere Portal Express V 8.5, the tag and rating widgets of earlier portal versions are deprecated. As the user starts typing tag text, one or more possible matches for that text fragment are found and immediately shown to the user. This immediate feedback allows users to select one of the listed options rather having to type the entire word or phrase they were looking for. User can also choose a closely related option from the presented list. Thus, the type-ahead feature allows users to explore the tag space as they type. This can make it easier to find the correct term they want to use as the tag.

Another advantage of the type-ahead feature is that it reduces tag space littering; different users use different spellings for certain terms. An example is the term Web 2.0. Users might spell it as `Web 2.0`, `Web2.0`, `Web 20`, `Web20`, or `Web2` . Semantically all these morphological variations refer to the same term. Therefore it would be inconvenient to present all these variations separately in a tag cloud. If most users have already entered the term as Web 2.0 and new users want to tag

something with a variation of this term and start typing, the type-ahead feature would suggest `Web 2.0`, and most users would probably select this term form the list. This reduces the amount of variation.

The type-ahead feature starts suggesting tags after a user types three characters in a type-ahead enabled input field, for example in the tag widget.

Related concepts:

"Searching for tagged content" on page 610
Users can search the tag space by using the browser search box.

Related reference:

"Type-ahead with the deprecated tag widget" on page 3187
The tag widget from earlier IBM WebSphere Portal Express versions provided a query for the type-ahead feature. With portal V 8.5, that tag widget is deprecated. The type-ahead feature makes it easier for users to find suitable tags. Type-ahead supports users when they work with tags. For example, when users apply tags using the tag widget, or when they search for tags, for example by using the open search functionality, type-ahead provides users suggestions for tags that other users have applied already before. Type-ahead can also help reduce the number of variants of tags.

Filtering content for tagging

You can use filtering mechanisms to control which terms users can use and which terms they cannot use as tags. The portal provides both a blacklist and a whitelist filter.

You enable and disable both filters in the WebSphere Integrated Solutions Console under the **Resource Environment Provider** > **CPConfigService** for tagging and rating. For details see the topics about *Setting service configuration properties* and the *CP Configuration Service for tagging and rating*.

Blacklist filter

The blacklist filter allows you to block selected terms from being used as tags, for example terms that could be perceived as offensive. If you enable the blacklist filter, the portal checks every term that users type as a tag before it is eventually applied and stored. If a user types a term listed on the blacklist, the portal blocks this tag and responds with a message. You can determine the terms that you want to be on the blacklist by using the XML configuration interface.

To enable the blacklist filter, the following configuration property in the CP Configuration Service to true:

```
com.ibm.wps.cp.filter.tagging.blacklist = true
```

Whitelist filter

The whitelist filter allows you to limit the set of tags that users can apply. If you enable the whitelist filter, the portal checks every term that users type as a tag against the whitelist before it eventually applies and stores it. If a user types a term that is **not** listed on the whitelist, the portal blocks this tag and responds with a message. You can set the terms that you want to be on the whitelist by using the XML configuration interface.

To enable the whitelist filter, add at least one entry to the whitelist filter database and set the following configuration property in the CP Configuration Service to `true`:

```
com.ibm.wps.cp.filter.tagging.whitelist = true
```

Note: The portal applies the filter only if you activate it **and** add at least one entry to the whitelist filter database.

You can configure both filter lists by using the XML configuration interface. The following examples show how to add or remove terms to the blacklist. To work with the whitelist, adapt the examples by changing the ID of the filter from `DefaultBlacklistFilter` to `DefaultWhitelist Filter` . Sample scripts for the XML configuration interface are located under the directory *`PortalServer_root`*`/doc/xml-samples` .

Example: Creating new words to the blacklist filter:

```
<request
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd"
    type="update" create-oids="true">
    <!-- sample for creating a filter with some sample entries -->
    <portal action="locate">
        <filter-instance action="update" id="DefaultBlacklistFilter">
            <filter-data value="badword_1" action="update"/>
            <filter-data value="badword_2" action="update"/>
        </filter-instance>
    </portal>
</request>
```

This sample snippet registers the two words `badword_1` and `badword_2` with the blacklist filter for all locales. Note that you must specify `DefaultBlacklistFilter` for the attribute `id` of the tag filter. You can optionally specify the attribute `locale` for the tag filter data. After you run this XML script, users will not be able to use `badword_1` or `badword_2` as tags.

Example: Creating or deleting individual words:

```
<request
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd"
    type="update" create-oids="true">
    <!-- sample for creating a filter with some sample entries -->
    <portal action="locate">
        <filter-instance action="update" id="DefaultBlacklistFilter">
            <filter-data value="badword_1" update="delete"/>
            <filter-data value="badword_3" update="update"/>
        </filter-instance
    </portal>
</request>
```

This sample snippet removes the term `badword_1` and adds `badword_3` from the blacklist.

Example: Deleting all terms from the blacklist filter:

```
<request
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd"
    type="update" create-oids="true">
    <!-- sample for deleting a whole filter -->
    <portal action="locate">
        <filter-instance action="delete" id="DefaultBlacklistFilter">
        </filter-instance>
    </portal>
</request>
```

This sample snippet deletes all terms from the blacklist.

You can use the XML configuration interface to export and import IBM WebSphere Portal Express configurations. This way you can configure selected features or areas of your portal. You can also transfer a complete configuration from one portal to another.

The tagging and rating user interface

Learn about the user interface that IBM WebSphere Portal Express provides for users to work with tags and rating.

Portal tagging and rating offers the following user interface elements that users can use to work with tags and ratings:

- The tag and rating widgets:
  - The tag widget. This is an inline widget that you can add to your portal content and that users use to tag that portal content.
  - The rating widget. This is an inline widget that you can add to your portal content and that users use to rate that portal content.
- The tag cloud.
- The Tag Center.
- A feature for browsing tags.

Note: With IBM WebSphere Portal Express Version 8.5, both the dialog and inline tag and rating widgets of previous portal versions are deprecated. They are replaced by a single pair of new enhanced inline widgets. They provide the functionality of both types of the old widgets. Users view them as part of the portal resource.

You can configure the widgets by using a set of parameters. You can set these parameters globally for all tag or rating widgets in your portal in the WP CP configuration service. You can also set them for individual instances of the tag and rating widgets by using JavaScript parameters. All these parameters are listed and described in the topic about the WP CP configuration service and the parameter reference topics for tagging and rating.

"The tag and rating widgets" on page 1310
The portal provides one widget each for tags and for ratings.

"The portal Tag Center" on page 1320
The Tag Center is a separate portal page. It combines the tag cloud and the tags result list.

"The portal tag cloud" on page 1322
The portal provides a **tag cloud** for aggregating tags for multiple resources. Users can select tags from the tag cloud.

"Browsing tags" on page 1324
Besides tagging content and viewing tags users can browse tags. This can be useful for finding related or similar content.

 IBM WebSphere Portal V 8 Product Documentation

The tag widget:

Users can use the tag widget to view, apply, and update tags that were applied to a resource.

The tag widget displays tags for users to view directly in the page. When users use the tag widgets, they can perform the following tasks:

Switch between tag scopes:
Users can switch the tag scopes by using the drop-down menu in the widget.

Add new tags:
Users can add new tags by using the input field that shows when a user clicks the **Plus** icon. Users can click this icon if the tag scope is **My public tags** or **My private tags**. Users can add more than one tag by using commas or spaces as separators.

Go to the Tag Center
If the **tagClickActionMode** parameter is set to TAG_CENTER, users can click a tag to go to the portal Tag Center page.

View more tags
If the number of tags exceed the number of tags that is configured to be shown, the user can click **More tags**. The widget then shows the extra tags in a dialog.

Delete tags:
The user can delete tags that the user added. To do so, the user clicks the delete icon that is shown next to the tags. The delete option is available only if the tag scope is **My public tags** or **My private tags**. A user can delete only the tags that the user added.

Users cannot modify tags in the tag widget.

The tag widget has the following user interface controls:

Label Displays a title that represents the scope of the tags that are displayed.

Depending on the setting of the tag scope parameter for the widget instance, the tag widget shows one of the following tag sets.

The title indicates the scope of the tags that are shown:

Tags With this scope, the widget shows the community tags. Community tags are tags that other users applied to the resource as public tags.

My public tags
With this scope, the widget shows personal public tags. Personal public tags are tags that the user applied to this resource.

My private tags
With this scope, the widget shows personal private tags. Personal private tags are all private tags that the user applied to this resource. This scope is available only when the `privateTaggingEnabled` parameter is set to `true`.

The scope of the tags that the widget shows depends on the setting of the tag scope parameter. For more information about this parameter, read the *Tag widget parameter reference*. You can set this parameter to one of the following values:

`COMMUNITY_PERSONAL_PUBLIC`
This is the default setting. With this setting, the tag widget shows the community tags and the personal public tags of the user

`PERSONAL_PUBLIC`
With this setting, the tag widget shows the personal public tags of the user.

`PERSONAL_PRIVATE`
With this setting, the tag widget shows the personal private tags of the user.

Tags The available tags are displayed after the title. The tag list uses commas as separators. Users can click the tags. Clicking a tag redirects the user to the tag center with the tag cloud. The tag cloud view scope depends on the setting of the **`tagClickActionMode`** parameter and on the scope that the user selected, **All** or **My public tags**. For more information about this parameter, read the *Tag widget parameter reference*. You can set this parameter to one of the following values:

`TAG_CENTER`
With this setting, the tag cloud shows the **All** view.

More tags
Users can configure how many tags the widget shows at the same time. If there are more tags than the user configured for display, the user can click **More tags**. The widget then shows the extra tags in a dialog.

Arrow for drop-down menu
Users can use this menu to switch between the tag scopes. The options in the drop-down menu depend on the tag scope that is displayed. For example, if the widget is in the **Tags** scope and shows the community tags, then clicking the drop-down menu shows an option that is called **My public tags**.

Plus (+) icon
The widget shows this icon. When a user clicks this icon, the widget opens an input field where the user can type tags.

"Adding the tag widget to your portal content"
By default, the tag widget is available for Web Content Manager article template pages and blogs and wikis. You can also add tag widgets to your portal content as required.

"Customizing the tag widget" on page 1314
The user interface of the tag widget consists of Web Content Manager HTML components. You can customize the tag widgets by modifying one or more of these components. For example, you can change the order of the user interface elements, or you can remove a field that you do not want to show in the user interface. The components are listed here.

Adding the tag widget to your portal content:

By default, the tag widget is available for Web Content Manager article template pages and blogs and wikis. You can also add tag widgets to your portal content as required.

About this task

To include a tag widget in a portal page, a portlet or other portal content, insert the following HTML snippet into your JSP or other code:

```
<div id="tagginglight_${resource_ID}" class="wpTaggingLight">
    <div class="label">
        <label class="text" id="tagginglightlabeltext_${resource_ID}"></label>
    </div>
    <div class="menu" >
        <a id="tagginglightmenulink_${resource_ID}" role="link" tabIndex="0">
            <img src='img_Src' border="0"  title="" />
        </a>
    </div>
    <div class="divider1" id="tagginglightdivider1_${resource_ID}"></div>
    <span id="tagginglighttagslist_${resource_ID}" class="tags" resource_ID="my_ID"></span>
    <div class="divider2" id="tagginglightdivider2_${resource_ID}">
    </div>
    <div class="moretags" id="moretagslink_${resource_ID}">
        <a id="tagginglightmoretagslink_${resource_ID}" href="javascript:;"
           onclick='getMoreTags("${resource_ID}");'>
        </a>
    </div>
    <div class="divider3" id="tagginglightdivider3_${resource_ID}"></div>
    <div class="addtag">
        <a id="tagginglightAddTaglink_${resource_ID}">
            <img src='img_Src' border="" width="12" height="12"  title="" />
        </a>
    </div>
    <span id="tagginglightinput_${resource_ID}" class="addtag">
        <input id="tagginglightinputField_${resource_ID}" type="text" name="text">
    </span>
    <div id="tagginglighterrordivider_${resource_ID}"  class="errorMessagedivider"></div>
    <div class="errorMessageStyle" id="tagginglighterrorDiv_${resource_ID}">
        <img src="" border="" width="16" height="16"  title="" />
        <label id="tagginglighterrorlabel_${resource_ID}"  class="errorMessageText" ></label>
    </div>
</div>
```

resource_ID
For the resource ID, specify the identifier of the piece of content that shows the widget. This identifier needs to be unique. For example, for a portal page, specify the portal object ID of that page.

src

Specify the appropriate values for the src attribute for the images. To obtain these values, copy them from the src attributes for images from the Web Content Manager HTML - Tag Widget Light - Menu component. Proceed as follows:

1. In Web Content Manager, go to **Applications** > **Content** > **WCM Authoring** > **Libraries** > **Web Resources v70** > **Components**.
2. Select the check box for **HTML - Tag Widget Light - Menu**.
3. Click **Read** and copy the src attribute value that you found here.
4. Paste the value into your code for including the tag widget.

These parameters are mandatory. For information about the optional parameters, read the *Tag widget parameter reference*.

Related reference:

"Tag widget parameter reference" on page 1331
You configure specific tag widget instances by setting the JavaScript parameters that are listed here.

Customizing the tag widget:

The user interface of the tag widget consists of Web Content Manager HTML components. You can customize the tag widgets by modifying one or more of these components. For example, you can change the order of the user interface elements, or you can remove a field that you do not want to show in the user interface. The components are listed here.

About this task

Changes that you make here apply to all instances of the rating widget.

Some of the components are mandatory. Do not remove them.

To modify the components, navigate to **Applications** > **Content** > **WCM Authoring** > **Libraries** > **Web Resources v70** > **Components**.

HTML - Tagging Widget Light - Label:

This component is mandatory. It renders the default label for the tag widget. The tag widget shows one of the following tag sets. The shown tag set depends on the setting of the tag scope parameter for the widget instance. For more information about this parameter, read the *Tag widget parameter reference*.

Community tags

With the tag scope parameter set to this value, the tag widget shows tags that other users applied to the resource as public tags.

Personal public tags

With the tag scope parameter set to this value, the tag widget shows all public tags that the user applied to this resource.

Personal private tags

With the tag scope parameter set to this value, the tag widget shows all private tags that the user applied to this resource.

The following labels are shown for the corresponding tag scopes:

Tags This label indicates COMMUNITY_PERSONAL_PUBLIC tags.

My public tags
This label indicates PERSONAL_PUBLIC tags.

My private tags
This label indicates PERSONAL_PRIVATE tags.

HTML - Tagging Widget Light - Tags:
This component is mandatory. It renders the list of tags for the resource.

HTML - Tagging Widget Light - Menu:
This component is mandatory. It renders the drop-down menu that is used for switching between the different tag scopes.

HTML - Tagging Widget Light - More Tags:
This component is mandatory. It renders the **More tags** link that is used to show the extra tags that cannot be displayed by using the HTML - Tagging Widget Light - Tags component. When a user clicks **More tags**, the widget shows the extra tags.

HTML - Tagging Widget Light - Divider1:
This component renders the divider that separates the tags and the **More tags** link.

HTML - Tagging Widget Light - Divider2:
This component renders the divider that separates the **More tags** link and the drop-down menu.

HTML - Tagging Widget Light - Divider3:
This component renders the divider that separates the drop-down menu and the plus (**+**) icon.

HTML - Tagging Widget Light - ErrorMessageDivider:
If the widget shows an error message, this component renders the divider that separates the tags and the error message.

HTML - Tagging Widget Light - Add Tags - Image:
This component is mandatory. It renders the plus (**+**) icon for showing the input field for adding tags.

HTML - Tagging Widget Light - Add Tags - Input:
This component is mandatory. It renders the input field in which a users adds tags.

HTML - Tagging Widget Light - Messages:
This component is mandatory. If the widget shows an error message while a user is using the tag widget, this component renders the error message.

HTML - Tagging Widget Light:
This component contains all the components shown earlier in this list.

Related reference:

"Tag widget parameter reference" on page 1331
You configure specific tag widget instances by setting the JavaScript parameters that are listed here.

The rating widget:

Users can use the rating widget to view, apply, and update ratings that were applied to a resource.

The rating widget displays ratings for users to view directly in the page. The rating widget shows ratings for the resource that has the widget included. When users use the rating widget, they can perform the task given in the following list.

Note: For these tasks, a user needs the rights to edit the IBM Web Content Manager component library `Web Resources V70`.

Switch between rating scopes:
Users can view the rating value for other rating scopes. They can switch to another rating scope by clicking the rating menu.

Display Rating Description:
To display the rating description in the rating widget, users must do both of the following tasks:

- Add the Web Content Manager HTML component named `HTML - Rating Widget Light - Description` to the `HTML - Rating Widget Light`.
- Set the attribute `ratingDescription` to `ALL` in the `Web Resources v70\Components\HTML - Rating Widget Light - Description - Stars`.

The rating description is displayed only for community average ratings.

Add a rating:
Users can add personal public or personal private ratings. To do so, they switch to the **Personal public** or **Personal private** rating scope and then assign a rating by clicking the appropriate asterisk.

Change a rating:
User can change ratings that they assigned. To do so, they click the appropriate asterisk. Users can change a shown rating only if that rating is a personal public or personal private rating and the widget shows the **Personal public** or **Personal private** rating scope. The default rating view displays the community average rating. When a user clicks the asterisks, the scope changes to PERSONAL_PUBLIC and the rating value is updated.

Remove a Rating:
Users can remove a rating by using the **Delete** option in the **Action** menu. The Delete option is available only if a rating was assigned to the resource and the rating value is not zero (`0`).

Customize the Web Content Manager components in the rating widget:
Users can reorder, remove, and edit the properties of Web Content Manager components in the rating widget. The rating widget definition is available in the Web Content Manager component `Web Resources v70\Components\HTML - Rating Widget Light`. For example, to move the rating description before the rating stars, the user can move the rating description subcomponent before the rating asterisks in the component definition. Here is the list of all subcomponents:

- HTML - Rating Widget Light - Label
- HTML - Rating Widget Light - Stars
- HTML - Rating Widget Light - Menu
- HTML - Rating Widget Light - Description
- HTML - Rating Widget Light - Divider1
- HTML - Rating Widget Light - Divider2

The rating widget has the following user interface controls:

Label The label displays a title that represents the scope of the rating that is displayed. The rating widget shows the rating, depending on the setting of the rating scope parameter for the widget instance. For more information about this parameter, read the *Rating widget parameter reference*.

(The default scope has no label)
The default scope shows the average of all ratings that all users applied to the resource as public ratings.

My public rating
This scope shows all public ratings that the user applied to this resource.

My private rating
This scope shows all private ratings that the user applied to this resource.

The scope of the ratings that the widget shows depends on the setting of the rating scope parameter. For more information about this parameter, read the *Rating widget parameter reference*. You can set this parameter to one of the following values:

COMMUNITY_PERSONAL_PUBLIC
With this setting, the rating widget shows the community ratings, in other words the ratings that all users applied to this resource. This value is the default value.

PERSONAL_PUBLIC
With this setting, the rating widget shows the personal public ratings of the user.

PERSONAL_PRIVATE
With this setting, the rating widget shows the personal private ratings of the user.

Asterisks
The rating widget shows the rating by the number of asterisks. The more asterisks are highlighted, the better the rating is for the resource.

Drop-down menu
This menu can show the following options:

An option to switch between rating scopes
Users can select to a different rating scope. The options that the menu shows depend on the current rating scope. For example, if the current scope is Community personal public rating, the menu shows the option Personal public rating.

Rating distribution
Users can also view the distribution of ratings. To do so, the users select **Rating distribution** from the menu. This option is available only when the rating scope is Community personal public rating.

Rating description
The rating description shows the numerical rating value and the total number of ratings that users applied to this resource.

- By default the widget displays five asterisks (*****), where five stars are the highest rating and one star is the lowest rating that a resource can have.
- The rating widget shows a tooltip with a numeric representation of the rating value, for example `Rating: 3.4/5`.

Adding the rating widget to your portal content:

By default, the rating widget is available for Web Content Manager article template pages and blogs and wikis. You can also add rating widgets to your portal content as required.

About this task

To include a rating widget in a page or a portlet or other content, insert the following HTML snippet into your JSP or other code:

```
<div class="ratingLightWidget" resourceID= "${contentItem.URI}"
     id="ratingLightWidget_${contentItem.URI}">
    <div id="ratinglight_${contentItem.URI}" class="wpRatingLight">
        <div class="label">
            <div id="ratinglightlabeltext_${contentItem.URI}" class="text"></div>
        </div>
        <div class="menuShow" id="ratinglightmenuDIV_${contentItem.URI}" role="link">
            <a onkeypress="getRatingMenu('${contentItem.URI}')"
               onclick="getRatingMenu('${contentItem.URI}')"
               id="ratinglightmenulink_${contentItem.URI}" role="link" tabindex="0">
                <img alt="Rating Menu" src='img_Src' title="Rating Menu" border="0">
            </a>
        </div>
        <div id="ratinglightdivider2_${contentItem.URI}" class="divider2Show"></div>
        <div class="description">
            <div id="ratinglightdescriptionlabel_${contentItem.URI}"></div>
        </div>
        <div id="ratinglightdivider1_${contentItem.URI}" class="divider1Show"></div>
        <div class="stars" resourceid="${contentItem.URI}"
             id="ratinglightstars_${contentItem.URI}">
            <div style="width: 70px;" id="ratinglightstarsempty_${contentItem.URI}"
                 class="empty" tabindex="0">
                <div style="width: 0px;" id="ratinglightstarsfull_${contentItem.URI}"
                     class="full"></div>
            </div>
        </div>
        <div id="ratinglighterrordivider_${contentItem.URI}" class="errorMessagedivider"></div>
        <div class="errorMessageStyle" id="ratinglighterrorDiv_${contentItem.URI}">
            <img alt="Error - check console" src='errorimg_Src'
                 title="Error - check console" height="16" border="" width="16">
            <label id="ratinglighterrorlabel_${contentItem.URI}" class="errorMessageText"></label>
        </div>
    </div>
</div>
```

Specify the appropriate values for the parameters:

resource_ID
For the resource ID, specify the identifier of the piece of content that you want to show the widget. This identifier needs to be unique. For example, for a portal page, specify the portal object ID of that page.

***xxxxx*_src**

To obtain the values for the src attribute for the images, copy them from the src attributes for images from the Web Content Manager menu component. For each attribute, use the specific procedure:

img_Src

For the img_Src attribute, proceed as follows:

1. In Web Content Manager, go to **Applications** > **Content** > **WCM Authoring** > **Libraries** > **Web Resources v70** > **Components**.
2. Select the check box for **HTML - Rating Widget Light - Menu**.
3. Click **Read** and copy the src attribute value that you found here.
4. Paste the value into your code for including the rating widget.

errorimg_Src

For the errorimg_Src attribute, proceed as follows:

1. In Web Content Manager, go to **Applications** > **Content** > **WCM Authoring** > **Libraries** > **Web Resources v70** > **Components**.
2. Select the check box for **HTML - Rating Widget Light - Messages**.
3. Click **Read** and copy the src attribute value that you found here.
4. Paste the value into your code for including the rating widget.

These parameters are mandatory. For information about the optional parameters, read the *Rating widget parameter reference*.

Related reference:

"Rating widget parameter reference" on page 1334
You configure rating widget instances by setting the Javascript parameters listed here.

Customizing the rating widget:

The user interface of the rating widget consists of Web Content Manager HTML components. You can customize the rating widgets by modifying one or more of these components. For example, you can change the order of the user interface elements, or you can remove a field that you do not want to show in the user interface. The components are listed here.

About this task

Changes that you make here apply to all instances of the rating widget.

Some of the components are mandatory. Do not remove them.

HTML - Rating Widget Light - Label:

This component is mandatory. Do not remove it. This component renders the default label for the rating widget. The rating widget shows one of the following types of rating. The shown rating type depends on the setting of the rating scope parameter for the widget instance. For more information about this parameter, read the *Rating widget parameter reference*.

Personal public rating

With the rating scope parameter set to this value, the rating widget shows all public ratings that the user applied to this resource.

Personal private rating

With the rating scope parameter set to this value, the rating widget shows all private ratings that the user applied to this resource.

The following labels are shown for the corresponding rating scopes:

My public rating
This label indicates PERSONAL_PUBLIC rating.

My private ratings
This label indicates PERSONAL_PRIVATE rating.

HTML - Rating Widget Light - Menu:
This component is mandatory. Do not remove it. This component renders the drop-down menu that is used for switching between the different rating scopes.

HTML - Rating Widget Light - Divider1:
This component renders the divider that separates the menu and the rating asterisks.

HTML - Rating Widget Light - Stars:
This component is mandatory. Do not remove it. This component renders the asterisks that show the rating for the resource.

HTML - Rating Widget Light - Divider2:
This component renders the divider that separates the menu and the rating description.

HTML - Rating Widget Light - Divider3:
If the widget shows an error message, this component renders the divider that separates the rating description and the error message.

HTML - Rating Widget Light - ErrorMessageDivider:
If the widget shows an error message, this component renders the divider that separates the ratings and the error message.

HTML - Rating Widget Light - Messages:
This component is mandatory. Do not remove it. If the widget shows an error message while a user is using the rating widget, this component renders the error message.

HTML - Rating Widget Light:
This component contains all the components that are shown earlier in this list.

You configure rating widget instances by setting the Javascript parameters listed here.

The portal Tag Center

The Tag Center is a separate portal page. It combines the tag cloud and the tags result list.

Users can get to this page by one of the following ways:

- By clicking the **Tag Center** link from the portal menu bar.
- By selecting the option **Browse tags** from the page action menu or the portlet menu.
- By clicking a tag from a custom tag cloud that you placed on a page of your portal.
- By clicking a tag from an tag widget in a portal or custom resource, for example a portal page, a portlet, a wiki, or a blog.

By default the Tag Center page shows the following two portlets:

1. The **Tag Cloud** portlet. Refer to the topic about the tag cloud. Users can select different views in the Tag Cloud:
   - **All tags** view
   - **IBM Connections tags** view. The federation view can show Activities, Blogs, Bookmarks, Communities, Files, Forums, Profiles, or Wikis.
   - **Others tags** view
   - **My public tags** view
   - **Latest tags** view
   - **My private tags** view
2. The **Tag Results** portlet. It shows resources that have been tagged with the tags that the users selected from the tag cloud. For example, if a user selects the tag **IBM** from the tag cloud, the Tag Result List portlet shows resources that have been tagged with the tag IBM. The Tag Result List portlet displays for each resource its name, its optional description, the tags that have been assigned to it, and the average community rating. In the Tag Results portlet users can click icons to choose between a **Summary** view and a **Details** view. The Summary view is the default.

   Users can click the shown tags and resources:
   - If the user clicks a tag listed under a resource in the result list, both the tag cloud and the tag results list change to show the information for the newly selected tag just as if the user had selected the tag from the tag cloud:
     – The tag cloud highlights the tag that the user selected from the tag result list and changes to the view from which the user selected the tag in tag the result list.
     – The tag result list shows all resources that have been tagged with the newly selected tag.

     Example: Initially the user selects the tag TAG_1 from the **All tags** view of the tag cloud. The tag result list shows all resources that have TAG_1 applied. Then the user selects TAG_2 from the Your private tags under one of the resources in the tag result list. As a result, the tag cloud highlights TAG_2 and changes to the **My private tags** view, and the tag result list shows all resources that have been tagged with TAG_2.
   - If the users clicks a resource, the portal redirects the user to that resource.

The combination of view options selected in both the tag cloud and in the tag result list determine what the tag result list shows. Refer to the following table:

Table 170. How the selected view options of the Tag Cloud and Tag Results portlets determine what the Tag Results list shows

Tag cloud portlet view selected	**Tag result portlet**	**Tag result portlet**
	Summary view shows these tags:	**Details** view adds these tags to the view:
All tags view	Community tags personal public tags optional Connections tags	personal private tags
Connections tags view	Connections tags (federated tags)	description of the resource
Others' tags view	community tags	personal public tags
My public tags view	personal public tags	description of the resource

Table 170. How the selected view options of the Tag Cloud and Tag Results portlets determine what the Tag Results list shows (continued)

Tag cloud portlet view selected	Tag result portlet	Tag result portlet
Latest tags view	community tags personal public tags	personal private tags
My private tags view	personal private tags	description of the resource

Examples:

- User A views tags in the tag cloud by using the Community view. When user A clicks **TAG_3**, the Tag Results portlet lists the summary view of all resources that have been tagged with TAG_3. Each resource is listed with all community tags that users applied to it. When user A changes to the details view by clicking **Details view** icon, all personal public tags that user A has applied to the resource are displayed additionally.
- User B views tags in the tag cloud by using the Personal View. When user B clicks **TAG_4**, the Tag Results portlet lists the summary view of all resources that have been tagged with TAG_4. Each resource is listed with all personal public tags that user B has assigned to this resource. When user B changes to the detail view by clicking **Details view** icon, descriptions of the resources are displayed additionally.

Users can sort the results by resource type, date, resource title, and rating.

Note: Resources given in the Tag Result List portlet might not always show the tag that the user selected from the tag cloud to start the search. This depends on how the resource has been otherwise tagged by users. If other tags have been applied to the resource more often than the tag by which the user searched, then those tags will take precedence among the tags shown for that resource. By default the Tag Result List portlet shows the three most popular tags; you can configure this number for the portlet.

When users are on the Tag Center page, they can select additional tags from the cloud to narrow down their result list. Users can clear tags, either by clicking them in the cloud or by clearing them from the Tag Result List portlet.

The portal tag cloud

The portal provides a **tag cloud** for aggregating tags for multiple resources. Users can select tags from the tag cloud.

The tag cloud is available as a portlet and as a Dojo widget. You can add the tag cloud portlet to any page as required. You can also integrate the tag cloud widget into a theme or embed it into a portlet.

The tag cloud shows the tags in alphabetical order. The font size indicates how often the tag has been applied within a defined scope. The larger the font of a tag is, the more often it as been applied. Users can select from the following options:

- Users can view in a cloud view or in a list view:
  - In the cloud view users can determine whether they wan to view more or fewer tags by moving a slider.
  - The list view has a pagination bar.
- Users can select different tag cloud views to filter what is displayed in the tag cloud:

- The **All tags** view shows all tags that have been applied by users in the portal. This includes all community tags and all personal public and personal private tags of the user who is viewing the tags. You can also configure the **All tags** view to include tags from remote systems.
- The **IBM Connections tags** view shows all public tags from remote systems for the currently selected federation features. These tags can be embedded in the **All tags** view.
- The **Others** view shows all public portal tags applied by other users, except for the user's own personal public tags.
- The **My public tags** view shows only the public portal tags that the user who invoked the cloud has assigned.
- The **Latest tags** view shows only the portal tags that have been created most recently.
- The **My private tags** view shows only the private portal tags that the user who invoked the cloud has assigned.

Administrators can configure the following additional settings:

- Whether they want only related tags to be displayed when a users clicks a tag. For example, if a user clicks a tag TAG_1 Related means that the tag cloud then shows only the tag TAG_1 clicked by the user and all tags that have been applied to resources to which TAG_1 has also been applied. Tags that have been applied to resources without being in combination with TAG_1 are not shown.
- The minimum number of tags that they want to be displayed when the user moves the slider all the way to the minimum position
- The maximum number of tags that they want to be displayed, that is when the slider is moved all the way to the maximum position.
- The default number of tags that they want to be initially displayed and the corresponding position of the slider.

- Users can select between different scoping modes:
  - Users can change the scope for which they want to view tags, for example books or movies. Users or administrators can configure the available scopes, depending on their access rights. For details about this refer to the topic about Configuring the tag cloud.
  - Administrators can configure the available scopes by using the option **Edit shared settings** from the tag cloud menu. When a users selects a scope, only tags that have been assigned to resources in that scope are displayed. For more information and a scoping example see the topic about *Grouping tags and ratings via resource categorization*.
  - You can also scope the tag cloud in a way that it only shows tags that have been assigned to resources of a certain category or type schema. For details see *Configuring the tag cloud*.

For more details refer to the help topic about the *Tag cloud*.

The tag cloud portlet has several configuration options. You can configure each individual tag cloud portlet instance separately by using its **Edit shared settings** menu. For details see the topic about *Configuring the tag cloud*.

Related reference:

"Grouping tags and ratings via resource categorization" on page 1304
Users apply tags and ratings to resources. Users can tag and rate all resources that can be uniquely identified.

Browsing tags

Besides tagging content and viewing tags users can browse tags. This can be useful for finding related or similar content.

For example, when a user views a resource such as a weather portlet, the user might want to know if there are similar portlets available. In this case the user can select the **Browse tags** feature to search resources tagged with the same tags, and optionally additional ones.

For a page users select the **Browse Tags** option from the Actions menu link in the page header. For a portlet users select the **Browse Tags** option from the portlet menu.

Clicking **Browse Tags** redirects the user to the tag center. The tag cloud shows the **All** view. The user can now select tags and views as required.

Tagging and rating for static pages

Tagging or rating for static pages works only with the dialog widgets of earlier portal versions.

Starting with IBM WebSphere Portal Express Version 8.5, you can use tagging or rating for static pages only by using the dialog widgets of earlier portal versions. For information about how to do this, read the WebSphere Portal Express Version 8.0 documentation.

Note: Tagging or rating for static pages works only with the dialog widgets, but not with the inline widgets of earlier portal versions.

Related reference:

"The tagging and rating user interface" on page 1309
Learn about the user interface that IBM WebSphere Portal Express provides for users to work with tags and rating.

Enabling your own custom content for tagging and rating

Enabling your own custom content for tagging and rating works only with the dialog widgets of earlier portal versions.

Starting with IBM WebSphere Portal Express Version 8.5, you can enable your own custom content for tagging and rating only by using the dialog widgets of earlier portal versions. For information about how to do this, read the WebSphere Portal Express Version 8.0 documentation.

Note: Tagging or rating for your own custom content works only with the dialog widgets, but not with the inline widgets of earlier portal versions.

Federating tags

WebSphere Portal allows the federation of remote tagging systems, such as Connections.

Tags from remote tagging systems can be integrated in the WebSphere Portal Tag Cloud. When a tag from a remote system is selected in the Tag Cloud, the Tag Results portlet lists all federated resources to which users have applied the tag. The title of the remote resource, and the description if available, are displayed. The

title is preceded by an icon that symbolizes the resource type of the resource. For details about how you can specify an icon for a federated resource type see *Administration of tag federation*.

If a federated resource is selected two different kinds of behavior are supported:

1. Redirect to an external website where the resource is displayed. This external redirection is always possible.
2. Redirect to a page with a portlet that can display this resource. This internal redirection requires a portlet that can integrate a remote resource in WebSphere Portal.

For details about how you can define a portlet as a target of an internal redirection see *Administration of tag federation*.

Configuration settings for the WebSphere Portal tagging and rating features such as normalization, black- and white lists are also applied to the federated tags. That allows for example the scenario that remote tags are not visible in WebSphere Portal because they do not fit to the configured settings.

Federation of Connections tags

Connections comprises multiple features, such as Activities, Blogs, Bookmarks, Communities, Files, Forums, Profiles, and Wikis. Tags that belong to the resources of these features can be integrated in the Tag Cloud. When a Connections tag is selected, links with the titles of corresponding Connections resources are listed in the Tag Results portlet. When such a resource is selected, either a redirect to a Portal page with the corresponding Connections portlet is performed, or a redirect to the Connections website is made to display more detailed information about the resource.

For Blogs, Forums, Wikis and Profiles, the selected resource is rendered in a Connections portlet by default. For more information on how a target page for the redirect can be specified and how to deploy and configure the Connections POC Resolver see the Connections documentation. The Connections POC resolver is required to render tagged Connections resources within Connections Portlets.

If you do not want to have a connections resource rendered in a Connections portlet, you can set a Connections Site as target of a redirect for a particular Connections feature. For details see *Administration of tag federation*.

Note: The Connections portlets must be deployed into WebSphere Portal and configured accordingly .

The following specifics regarding Connections need to be mentioned:

Connections does not distinguish between private and public tags like WebSphere Portal does. Therefore, the Connections tags are available in the Connections tags view in the tag cloud for WebSphere Portal Express. The **All tags** view can be configured to include Connections tags. These tags are not integrated in the **Others' tags**, **My public tags**, or **My private tags** views.

The most frequently used tags are retrieved through the Connections feature. A limit of 100 tags is provided by Connections.

As Connections does not provide globalization information for tags nor for related resources, the same tag name, title and description of resources are displayed no matter which locale is selected by the user.

During configuration or administration of the Connections integration there are steps where the identifier of a Connections feature must be supplied. Use the following overview of all Connections features identifiers to select the correct feature identifier:

Table 171. Connections feature identifiers

Connections Feature	Feature identifier
Activities	activities
Blogs	blogs
Bookmarks	dogear
Communities	communities
Files	files
Forums	forums
Profiles	profiles
Wikis	wikis

"Administering tag federation"
When tags from remote systems, such as IBM Connections are integrated into your WebSphere Portal Express site, you need to schedule tasks to retrieve tags and related data from the remote system, and later to clean them up from the portal. You can also redirect the rendering of federated resources to IBM Connections and add icons to federated resources.

Administering tag federation

When tags from remote systems, such as IBM Connections are integrated into your WebSphere Portal Express site, you need to schedule tasks to retrieve tags and related data from the remote system, and later to clean them up from the portal. You can also redirect the rendering of federated resources to IBM Connections and add icons to federated resources.

"Importing federated tags and resources" on page 1327
When tags from remote systems, such as Connections are integrated into WebSphere Portal Express, you need to schedule a task to retrieve the tags and related data from the remote system.

"Cleaning up federated tags and resources" on page 1328
When federated tags are no longer integrated in WebSphere Portal Express, you invoke the task `com.ibm.wps.cp.tagging.federation.taskhandler.FederationDeletionTaskHandler` to remove unnecessary data.

"Redirecting to a Connections site" on page 1328
When a user clicks a Connections resource in the result list portlet, this resource is rendered within a Connections portlet, if that portlet exists and can handle this resource.

"Specifying an icon for a federated resource" on page 1329
When federated resources are displayed in the Tag Results portlet, you can have them preceded by a icon.

Related tasks:

"Configuring task to retrieve tags" on page 753
When you integrate Connections with your portal server, the portal uses a task to retrieve tags and related resources from the various Connections features (such as activities, blogs, bookmarks, communities, files, forums, profiles, and wikis). Then, the portal integrates the tags in the portal tag cloud. You can schedule the task to retrieve the tags to run periodically.

Importing federated tags and resources:

When tags from remote systems, such as Connections are integrated into WebSphere Portal Express, you need to schedule a task to retrieve the tags and related data from the remote system.

About this task

To retrieve tags and related resource for federation, schedule a task named `com.ibm.wps.cp.tagging.federation.taskhandler.FederationTaskHandler` WebSphere Portal Express by using the XML configuration interface (XMLAccess). In the following example, the XML task `triggerTask.xml` is scheduled to run the task `com.ibm.wps.cp.tagging.federation.taskhandler.FederationTaskHandler` once a day:

```
<?xml version="1.0" encoding="UTF-8"?>
   <request type="update" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
            xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd">
      <portal action="locate">
         <task action="create" name="com.ibm.wps.cp.tagging.federation.taskhandler.FederationTaskHandler">
            <startTime>22:00</startTime>
         </task>
      </portal>
   </request>
```

This tasks handles all Connections features.

You can also select and specify which Connections features you want a task to handle. For example, you can have data for Connections wikis and blogs collected on a different schedule than Connections files. Refer to the following example:

```
<?xml version="1.0" encoding="UTF-8"?>
<request type="update" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
          xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd">
     <portal action="locate">
          <task action="create" name="com.ibm.wps.cp.tagging.federation.taskhandler.FederationTaskHandler">
              <startTime>12:00</startTime>
              <parameter>wikis</parameter>
              <parameter>blogs</parameter>
        </task>
        <task action="create" name="com.ibm.wps.cp.tagging.federation.taskhandler.FederationTaskHandler">
              <startTime>07:00</startTime>
          <parameter>files</parameter>
        </task>
      </portal>
</request>
```

Notes:

- The `<parameter>` element contains the ID of the Connections feature. These IDs are listed on the page Federating Tags.
- Carefully consider which features you want to integrate into portal. With each Connections feature, there is potential for coupling large amounts of data.

To retrieve changes in the Connections tag cloud, you need to run the `FederationTaskHandler` script.

Related information:

"Working with the XML configuration interface" on page 1061
You can use the XML configuration interface to export and import IBM WebSphere Portal Express configurations. This way you can configure selected features or areas of your portal. You can also transfer a complete configuration from one portal to another.

Cleaning up federated tags and resources:

When federated tags are no longer integrated in WebSphere Portal Express, you invoke the task `com.ibm.wps.cp.tagging.federation.taskhandler.FederationDeletionTaskHandler` to remove unnecessary data.

About this task

The following example XML script `triggerDeleteTask.xml` shows how you schedule the task to cleanup federated tags:

```
<?xml version="1.0" encoding="UTF-8"?>
    <request type="update" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
             xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd">
        <portal action="locate">
        <task action="create"
              name="com.ibm.wps.cp.tagging.federation.taskhandler.FederationDeletionTaskHandler"/>
</portal></request>
```

Notes:

- As this example does not explicitly define a schedule, the task is performed immediately.
- You can also select and specify the Connections features for which you want the cleanup to be run. For details about selecting features see the topic about Importing federated tags and resources.

Related information:

"Working with the XML configuration interface" on page 1061
You can use the XML configuration interface to export and import IBM WebSphere Portal Express configurations. This way you can configure selected features or areas of your portal. You can also transfer a complete configuration from one portal to another.

Redirecting to a Connections site:

When a user clicks a Connections resource in the result list portlet, this resource is rendered within a Connections portlet, if that portlet exists and can handle this resource.

About this task

For more information about deployment and configuration of the portlets and the Connections POC Resolver, see the Connections documentation.

If you do not require this behavior, you can redirect to a Connections server website. You configure this redirection in the Resource Environment Provider for the WP CP Configuration Service for tagging and rating in the WebSphere Integrated Solutions Console. For each Connections feature, a custom property exists. The name of the property follows this pattern:

`com.ibm.wps.cp.tagging.federation.uri.scheme.`*`FederatorID`*

To redirect to the Connections server, use the following value pattern: `connections - FederatorID` .

This setting is used in the next run of the FederationTaskHandler that retrieves Connections tags and tagged resources. After that a redirect to the external Connections website is possible.

Related tasks:

"Setting service configuration properties" on page 283
IBM WebSphere Portal Express comprises a framework of services to accommodate the different scenarios that portals need to address. Services are available for both WebSphere Portal Express and IBM Web Content Manager. You can configure some of these services.

"CP Configuration Service for tagging and rating" on page 312
The CP Configuration Service provides the properties for tagging and rating.

Specifying an icon for a federated resource:

When federated resources are displayed in the Tag Results portlet, you can have them preceded by a icon.

About this task

To define an icon for a resource type, you specify a custom property with either a URI for the image or a relative path that is attached to the base URL of the Connections service of the resource type. The name of the custom property for the icon follows this pattern:

`com.ibm.wps.cp.tagging.federation.iconURL.FederatorID`

For more information about a Connections feature see the topic about Federating tags.

You configure the custom properties in the Resource Environment Provider for the WP CP Configuration Service for tagging and rating in the WebSphere Integrated Solutions Console.

Note: The icons are part of the portal installation. For theConnections features, the custom properties for the icons exist without a predefined path. Unless no icon URL is defined, the icons are loaded directly from WebSphere Portal Express.

In a portal installation, the tag and rating widgets are available for specific portal profiles. You can enable the widgets for more other profiles by adding them to the profile.

"Enabling and disabling the Dojo tagging and rating options for additional profiles" on page 1341
In a portal installation, the Dojo tagging and rating menu options for portal pages and portlets are available for a specific portal profile. You can enable these options for other profiles by adding them to the profile.

Parameter reference for the tag and rating widgets

You can configure each of the portal tagging and rating features to determine the look and functionality of these features. To do so, you configure the tag and rating widgets.

How to configure the tag and rating widgets

You can configure all tag and rating widgets globally by setting parameters in the portal CP configuration service in the WebSphere Integrated Solutions Console. You can also configure individual instances of the tag and rating widgets by using the JavaScript parameters in the following topics. These settings become effective for the affected individual widget instance and override the settings set in the CP configuration service. The parameter settings take override priority by the following hierarchy:

1. Settings that are specified for an individual tagging or rating widget instance take highest priority.
2. If a parameter is not set for the individual widget instance, the settings specified in the CP Configuration Service takes effect.
3. If a parameter is not set by either of the two previous options, the default value defined in the widget class itself takes effect.

Example: In the CP Configuration Service, the attribute for custom labels `com.ibm.wps.cp.tagging.inline.customLabel` has no default value. The tag widget ABC instance includes the attribute `customLabel=MyTags`. As a result, all tag widgets in the portal have the custom label set to an empty string, as no default value is set. The tag widget ABC is the exception, because it has the attribute `customLabel=MyTags` set.

Most of the parameters exist as corresponding sibling parameters that you can set both globally in the CP Configuration Service and for individual widget instances

and in your code. The parameter in the CP Configuration Service consists of the prefix `com.ibm.wps.cp.` and the related parameter for configuring widget instances. Example:

- Parameter in the CP Configuration Service: `com.ibm.wps.cp.tagging.inline.maxResults`
- Parameter for an individual tag widget instance: `maxResults`.

Some of the parameters have no corresponding siblings and exist only for one of the two ways of configuring them. The parameters that exist only for configuring widget instances are mandatory, as they identify the resource for which the widget is called.

For details about the parameters in the CP configuration service and how to set them, read the topics about the portal *CP Configuration Service for tagging and rating* and *Setting service configuration properties*.

Usage notes for the parameter lists in the following topics:

- The lists show the parameters with their default if they have one. In these cases the parameters are shown with an equal sign between the parameter and the value. This is how you specify the setting when you include the widget declaratively. If you include the widget programmatically, use a colon instead of the equal sign.
- The parameters listed here are specific to the inline tag and rating widgets that were introduced with IBM WebSphere Portal Express Version 8.5. The dialog and inline widgets of earlier portal versions were deprecated with portal V 8.5. For information about the earlier widgets and their parameters, read the appropriate topics in the WebSphere Portal Express Version 8.0 product documentation.

  "Tag widget parameter reference"

Tag widget parameter reference:

You configure specific tag widget instances by setting the JavaScript parameters that are listed here.

Note: The parameters listed here are specific to the inline tag widget that was introduced with IBM WebSphere Portal Express Version 8.5. For information about the earlier widgets and their parameters, read the appropriate topics in the WebSphere Portal Express Version 8.0 product documentation.

To set the parameters, proceed as follows:

1. In IBM Web Content Manager, go to **Applications** > **Content** > **WCM Authoring** > **Libraries** > **Web Resources v70** > **Components**.
2. Select the check box for **HTML - Tagging Widget Light - Menu**.
3. Click **Edit**.

The following parameters are optional for the tag widget. They correspond to similar parameters in the WP CP Configuration Service.

countsEnabled = false
Use this parameter to specify whether the count of each community tag is displayed. The count shows how often the tag was applied by users. The default value is `false`. To show the count of each community tag, specify `true`. The count is then displayed in parentheses.

customLabel
Use this parameter to specify a non-localized custom label to describe the displayed tags. If you do not want any further labeling or if you want to keep the label short, you can specify an empty string.

customLabelCommunityTags = = (false)
Use this parameter to specify the non-localized label that you want to be used to describe the meaning of the community tagging that is displayed. The default value is `false`.

customLabelPersonalPublicTags = (false)
Use this parameter to specify the non-localized label that you want to be used to describe the meaning of the personal public tagging that is displayed. The default value is `false`.

customLabelPersonalPrivateTags = (false)
Use this parameter to specify the non-localized label that you want to be used to describe the meaning of the personal private tagging that is displayed. The default value is `false`.

customMessageNoTags
Use this parameter to specify a non-localized custom label that you want to be displayed if no tags are available. This case can occur when users did not assign tags to the piece of content yet. Non-localized means that the label does not change with the browser language. This parameter has no default value.

maxResults = 5
Use this parameter to specify the number of tags that are shown per resource. The default value is `5`.

order = DESC|ASC
Use this parameter to specify the order direction for displaying the tags. This parameter is related to the parameter `orderMetric` . It can take the following values:

DESC This value is the default value. It specifies descending order. For example, if the default `TAG_SPACE_COUNT_REVERSE_NAME` is specified

for the orderMetric parameter that is listed later, tags with the highest count and the lowest character in the alphabet are listed first.

ASC This value specifies ascending order. For example, if the order metric parameter is specified as orderMetric = TAG_SPACE_COUNT, tags with the lowest count are listed first.

orderMetric = TAG_SPACE_COUNT_REVERSE_NAME

Use this parameter to specify the order metric for the order by which the tags are displayed. To determine the actual order, use the parameter order that was listed earlier. The default value is TAG_SPACE_COUNT_REVERSE_NAME. This default value means that tags are shown first by the tag count, with resources with more tags shown before resources with fewer tags, then, if resources have the same number of tags, alphabetically. This parameter can take the following values:

- TAG_SPACE_NAME
- TAG_SPACE_COUNT
- TAG_SPACE_COUNT_NAME
- TAG_SPACE_COUNT_REVERSE_NAME. This value is the default value.
- TAG_SPACE_CREATION_DATE
- TAG_SPACE_LAST_MODIFIED_DATE

For more information, see the class com.ibm.portal.cp.Constants.OrderMetric in the portal Javadoc.

privateTaggingEnabled = (false)

Use this parameter to specify the PERSONAL_PRIVATE scope for the tags that you want to show in this widget. The default value is false. By this default, users cannot add private tags. If you set this parameter to true, users can also add private tags.

resourceCategories = ["*resrc_category_1*", "*resrc_category_2*", . . . "*resrc_category_n*"]

Use this parameter to specify an array of categories that are assigned to the resource for which the widget was called. Represent each category by a string, for example Books or a Web Content Manager category. A typical value is ["books", "action"].

resourcePrivate = true | false

You can set this parameter to avoid access control issues with private resources. Users can add private tags only to private resources. The default value is false.

resourceType

Use this parameter to specify the portal resource type. Specify either CONTENT_NODE or NAVIGATION_NODE. Specifying a value for this parameter is mandatory for portal resources only.

tagClickActionMode = TAG_CENTER | PUBLIC_RENDER_PARAMETER

Use this parameter to determine what happens when a user clicks a tag. Specify one of the following values:

TAG_CENTER

With this value, the widget redirects the user to the tag center. This value is the default value.

PUBLIC_RENDER_PARAMETER
With this value, the widget exposes a public render parameter with the tag name.

tagClickTransmitScopes = (false)
Use this parameter to specify whether scopes to which a tag belongs, for example categories, are transmitted, when a user clicks a tag. Setting this parameter set to `true` makes sense only if you also set the parameter `com.ibm.wps.cp.tagging.inline.tagsClickable` to `true`.

tagsClickable = true | false
Use this parameter to determine whether the tags can be clicked for redirection or public render parameter exposure. The default is `true`.

tagScope = (COMMUNITY_PERSONAL_PUBLIC)
Use this parameter to specify the scope of tags that you want to show in this widget. Specify one of the following values:

```
PERSONAL_PUBLIC|PERSONAL_PRIVATE|COMMUNITY_PERSONAL_PUBLIC
```

If you do not specify a value, the parameter defaults to `COMMUNITY_PERSONAL_PUBLIC`.

Rating widget parameter reference:

You configure rating widget instances by setting the Javascript parameters listed here.

Note: The parameters listed here are specific to the inline rating widget that was introduced with IBM WebSphere Portal Express Version 8.5. For information about the earlier widgets and their parameters, read the appropriate topics in the WebSphere Portal Express Version 8.0 product documentation.

To set the parameters, proceed as follows:

1. In IBM Web Content Manager, go to **Applications** > **Content** > **WCM Authoring** > **Libraries** > **Web Resources v70** > **Components**.
2. Select the check box for **HTML - Rating Widget Light - Stars**.
3. Click **Edit**.

Mandatory parameters

The following parameters are mandatory for the rating widget.

id = unique_ID
Use this attribute to specify a unique ID for parsing all surrounding `<div>` tags to enable your widgets

resourceID
Use this parameter to specify the identifier of the piece of content that will show the widget. This needs to be unique. For example, for a portal page specify the portal object ID of that page.

Optional parameters

The following parameters are optional for the rating widget. They correspond to similar parameters in the WP CP Configuration Service.

customLabel
Use this parameter to specify a non-localized custom label to describe the displayed ratings.

customLabelCommunityRatings
Use this parameter to specify the non-localized label that you want to be used to describe the meaning of the community rating that is displayed.

customLabelPersonalPublicRatings
Use this parameter to specify the non-localized label that you want to be used to describe the meaning of the personal public rating that is displayed.

customLabelPersonalPrivateRatings
Use this parameter to specify the non-localized label that you want to be used to describe the meaning of the personal private rating that is displayed.

deletingEnabled = (true)
Use this parameter to control whether the Delete Rating option is enabled in the inline widget. The default value is `true`.

nonCSSuiEnabled
Set this parameter to the value `true` for to enable rendering on a user interface that is accessible for iOS devices used with a bluetooth keyboard. The default value is `false`.

numStars = 5
Use this parameter to specify the number of stars or asterisks of which a rating consists. Specify a positive numeric value. The default value is `5`. Do not specify a value larger than the value specified for the property `com.ibm.wps.cp.rating.maxratingvalue` in the WP CP configuration service for tagging and rating. For more information about this property, read *General properties for tagging and rating*.

privateRatingEnabled = (false)
The default value of this parameter is `false`. By this default, users cannot add private ratings. For users to be able to add private ratings, set this parameter to `true`.

ratingDescription=NONE
Use this parameter to specify the type of description for community average ratings in the rating widget. Specify one of the following values:

RATING_VALUE
With this value, the rating description includes only the numerical rating value.

TOTAL_NO_RATING
With this value, the rating description includes only the total number of ratings.

ALL With this value, the rating description includes the numerical rating value and the total number of ratings.

NONE
With this value, the rating description is not shown. This is the default value.

If you do not specify a value, the parameter defaults to `NONE`.

ratingScope = (COMMUNITY_PERSONAL_PUBLIC)
Use this parameter to specify the scope of ratings that you want to show in this widget. Specify one of the following values:

```
PERSONAL_PUBLIC|PERSONAL_PRIVATE|COMMUNITY_PERSONAL_PUBLIC
```

If you do not specify a value, the parameter defaults to `COMMUNITY_PERSONAL_PUBLIC`.

resourceCategories = ["*resrc_category_1*", "*resrc_category_2*", . . . "*resrc_category_n*"]
Use this parameter to specify an array of categories assigned to the resource for which the widget was called. Represent each category by a string, for example `Books` or a Web Content Manager category. A typical value is `["books", "action"]`.

resourcePrivate = true | false
You can set this parameter to avoid access control issues with private resources. Users can add private ratings only to private resources. The default value is `false`.

resourceType = NAVIGATION_NODE | CONTENT_NODE
Use this parameter to specify the type of the resource for which the rating widget is called. This parameter is mandatory only for portal resources such as pages or portlets. Valid values are `NAVIGATION_NODE` or `CONTENT_NODE`.

Related concepts:

CSS classes for tagging and rating

The portal tag and rating widgets allow for detailed look and feel customization by providing a customizable CSS class hierarchy.

Each widget has a set of tagging and rating specific CSS classes assigned to it. This allows administrators to customize either the complete set or a subset of the tag and rating widgets, or individual tag and rating widgets. To do this, the administrator modifies the CS class or classes for the widget that needs to be customized. For details refer to the information in the following tables.

Table 172. Available tag and rating widgets and CSS classes assigned to them

Widget name	Tagging and rating CSS class assigned to the widget
`TagCloud`	`trc trcTagCloud`
`AddTag dialog`	`trc trcTagging trcDialog trcDialogTagging`
`AddRating dialog`	`trc trcRating trcDialog trcDialogRating`
`InlineTag`	`trc trcTagging trcInline trcInlineTagging`
`InlineRating`	`trc trcRating trcInline trcInlineRating`

Table 173. Available CSS hierachy groups

Group name	CSS class that needs to be modified to customize the given group of widgets
All tag and rating widgets	`trc`
All tag widgets	`trcTagging`
All rating widgets	`trcRating`
All dialog based widgets	`trcDialog`
All inline widgets	`trcInline`

Table 174. Individual widgets CSS classes

Widget name	CSS class that needs to be modified to customize the given widget
TagCloud widget	`trcTagCloud`
AddTag dialog widget	`trcDialogTagging`
AddRating dialog widget	`trcDialogRating`
InlineTag widget	`trcInlineTagging`
InlineRating widget	`trcInlineRating`

Hierarchy of CSS classes

The following list shows all available tagging and rating CSS classes that can be used for customizing the appearance of tag and rating widgets in the order of

significance. The list shows the CSS classes in the order of their significance from low to high. More significant CSS classes shown further down in the list override definitions of the less significant CSS classes shown further up in the list.

1. `trc`
2. `trcTagging`
3. `trcRating`
4. `trcDialog`
5. `trcDialogTagging`
6. `trcDialogRating`
7. `trcInline`
8. `trcInlineTagging`
9. `trcInlineRating`

Administrators can override each CSS class that is used by the widget by adding customized CSS classes of the following format in file `widgets_combined.css` :

```
.trc <CSS classname to override> {
     // custom CSS definitions for tag and rating widgets in general
}

.trcTagging <CSS classname to override> {
    // custom CSS definitions for all tag widgets
}

.trcTagCloud <CSS classname to override> {
   // custom CSS definitions for the Tag Cloud widget only
}
```

Customizing tagging and rating specific CSS classes

The CSS classes used to customize the visual appearance of the tag and rating widgets are located in the following file: *PortalServer_root*`/theme/wp.theme.modules/webapp/installedApps/ThemeModules.ear/ThemeModules.war/modules/portalclient/css/trcWidgets.css` .

This file contains CSS classes specific to tagging and rating. They either start with the prefix `trc`, for example `trc Editable` or `trc Delete` or they are otherwise scoped to the tagging and rating context, for example `ul.trcEdit` . To customize the visual appearance of tag and rating widgets, you override these definitions in the CSS file. To do this, you add class definitions at the end of the file `trcWidgets.css` based on the CSS class hierarchy given by the Hierarchy of CSS classes list.

Examples: To change the link color for all tag and rating widgets to green, use the following CSS class declaration in the file `trcWidgets.css` :

```
.trc a {
    color: green;
}
```

If you do this, all tag and rating widgets show their links in a green color.

To change only the link color for the Tag Cloud to red, use the following CSS class declaration:

```
.trcTagCloud a {
    color: red;
}
```

A more specific declaration overrides a less specific declaration. Therefore you can have both declarations in the file `trcWidgets.css` at the same time. While the Tag Cloud shows its links in red, all other tag and rating widgets continue to show their links in green.

The following example shows how you can modify link appearance within all the available tag and rating widgets. It shows how to inherit from less significant CSS class definitions and how to overwrite inherited definitions to further customize a specific widget instance:

```
/* Give all links within tag and rating widgets a default background */
.trc a {
   background-color: #d0efff;
}

/* Make tagcloud links appear in a black color */
.trcTagCloud a {
  color: black;
}

/* Give all tag widgets a blue link color */
.trcTagging a {
  color: blue;
}

/* Give all rating widgets a green link color */
.trcRating a {
  color: green;
}

/* Links in all dialog widgets appear in italic,
   colors are inherited from trcRating/trcTagging */
.trcDialog a {
  font-style: italic;
}

/* Links in all inline widgets appear as underlined,
   colors are inherited from trcRating/trcTagging */
.trcInline a {
  font-style: underline;
}

/* links in Tag Widget Dialog inherit italic font-style from .trcDialog,
   but overwrite the color inherited from .trcTagging with another color */
.trcDialogTagging a {
  color: #770000;
}

/* links in Rating Widget Dialog keep the inherited link color defined by
   .trcRating, but change the inherited font-style, by setting it to none */
.trcDialogRating a {
  font-style: none;
}

/* modify the inherited color (from .trcTagging) and reset the font-style (from
   .trcDialog) to none. */
.trcInlineTagging a {
  color: green;
  font-style: none;
}

/* no changes for the inline rating widget. It simply uses the color and font-style
   from the super classes .trcRating and .trcInline instead */
.trcInlineRating a {
}
```

Enabling and disabling the tag and rating widgets for additional profiles

In a portal installation, the tag and rating widgets are available for specific portal profiles. You can enable the widgets for more other profiles by adding them to the profile.

About this task

In a default IBM WebSphere Portal Express V 8.5 installation, the tag and rating widgets are available with the following profiles:

- Basic Content profile: `profile_basic_content.json`
- Basic Content with Dojo profile: `profile_dojo_basic_content.json`
- Content Targeting Portlet profile: `profile_personalization.json`.

To enable the tag and rating widgets for other profiles, proceed as follows:

Procedure

1. Open the profile for which you want to enable the widgets.
2. Add the module `wp_tagging_rating_light` to the list of modules in the section `moduleIDs`.
3. Apply the modified profile. To do so, proceed as follows:
   a. Start a WebDAV client.
   b. Create a connection with the entry point to `/wps/mycontenthandler/dav/fs-type1` of WebSphere Portal Express Version 8.5.
   c. Go to **Themes** > **Portal 8.5** > **Profiles**.
   d. Upload the modified profile by using the **Upload** option in the WebDAV client.
   e. Log in to the portal server.
   f. Invalidate the cache with the Portal Theme Analyzer. Or, click **Administration** > **Utilities** > **Control Center** > **Invalidate cache**. CF06 Auto invalidation recognizes your changes automatically for WebDAV based themes. No further action is required. For more information, see Utilities.

   This step applies the changes that you made to the profile on the server.

Results

You can now use the tag and rating widgets with the modified profile.

Notes:

- The tag and rating widgets are available with the Basic Content profile. If you create a page by using the Article template, the portal applies the Basic Content profile by default. If you add a blog or a wiki to a page with a different profile and you want to have the tag and rating widgets that are shown, you must apply the Basic Content profile to the page.
- Enabling the widgets for a profile can influence performance.

To disable the widgets, remove the module `wp_tagging_rating_light` from the profile, and apply the modified profile on the server by the described procedure.

Enabling and disabling the Dojo tagging and rating options for additional profiles

In a portal installation, the Dojo tagging and rating menu options for portal pages and portlets are available for a specific portal profile. You can enable these options for other profiles by adding them to the profile.

About this task

In a IBM WebSphere Portal Express V 8.5 installation, the Dojo tagging and rating menu options for portal pages and portlets are available for the Search and Tag Center profile. This profile is named `profile_search_tag.json`. You can apply this profile to a page or portlet where Dojo tagging and rating options are required. After you apply this profile, the page action menu or portlet menu shows the tagging and rating options.

Notes:

- If you upgraded your WebSphere Portal Express from version 8.0 to 8.5, you also need to update the page to which you add the tagging and rating options with the new Portal V 8.5 theme. For more information, read *Post-migration steps for Tag and Search enter pages*.
- Enabling the Dojo tagging and rating menu options for a profile can influence performance.

To enable the Dojo tagging and rating options for other profiles, proceed as follows:

Procedure

1. Open the profile for which you want to enable the modules.
2. Add the module `wp_tagging_rating_menu` to the list of modules in the section `moduleIDs`.
3. Apply the modified profile. To do so, proceed as follows:
   a. Start a WebDAV client.
   b. Create a connection with the entry point to `/wps/mycontenthandler/dav/fs-type1` of WebSphere Portal Express V 8.5.
   c. Go to **Themes** > **Portal 8.5** > **Profiles**.
   d. Upload the modified profile by using the **Upload** option in the WebDAV client.
   e. Log in to the portal server.
   f. Invalidate the cache with the Portal Theme Analyzer. Or, click **Administration** > **Utilities** > **Control Center** > **Invalidate cache**. CF06 Auto invalidation recognizes your changes automatically for WebDAV based themes. No further action is required. For more information, see Utilities.

   This step applies the changes that you made to the profile on the server.

Results

You can now use the Dojo tagging and rating menu options with the modified profile. To disable the Dojo options for a profile, remove the module `wp_tagging_rating_menu` from the profile, and apply the modified profile on the server by the described procedure.

Related tasks:

"Tag and Search Center pages" on page 887
When you migrate to IBM WebSphere Portal Express Version 8.5, the migration process does not apply the Portal 8.5 theme to all portal pages. For example, this affects the Tag and Search Center pages. To continue to use your Tag Center and Search Center pages, you must update the theme for the pages to the Version 8.5 theme. You must also update the profile of the pages to the Search and Tag Center profile.

Security for tagging and rating

For administering which users can tag and rate content, the portal provides virtual resources for tagging and rating and roles on these virtual resources.

The portal provides the following virtual resources: `TAGS` and `RATINGS`. These resources allow you to determine user rights that related to tagging and rating. The following list explains which roles users require to perform tagging and rating operations. The user actions correspond to the normal portal roles. Privileges are inherited.

In a default portal installation, the group All Authenticated Portal Users has the CONTRIBUTOR role. There is no role assigned to the anonymous user. Please note that anonymous users need at least the CONTRIBUTOR role to be able to apply tags and ratings as they can only apply public tags or ratings, not private ones.

USER

Can view community tags and community ratings that other users have applied and all personal tags, both personal private and personal public.

PRIVILEGED USER

Includes USER actions.

Can view community tags and community ratings that other users have applied.

Can create and delete personal private tags and ratings.

CONTRIBUTOR

Includes USER actions.

Can view community tags and community ratings that other users have applied.

Can create and delete personal public tags and ratings, but cannot create or delete personal private tags and ratings.

MANAGER

Includes USER and CONTRIBUTOR actions.

Can view community tags and community ratings that other users have applied.

Can create and delete personal public tags and ratings.

Can delete community tags regardless of ownership.

Note:

- In a default portal installation, the group All authenticated users has CONTRIBUTOR and privileged USER access to tags and rating under virtual resources. If you want to test what an authenticated user with the default role assignments in the portal can do with tags and ratings, remove these permissions first.

- In a default portal installation, anonymous users have no role assigned. For anonymous users to create and delete personal public tags and ratings, assign them the CONTRIBUTOR role.

Related concepts:

"Access permissions" on page 1537
Learn about sensitive operations for resources and the roles that are required to perform those operations. Sensitive operations include common tasks such as viewing portlets on specific pages and complex, high-risk tasks like running XML configuration interface scripts.

Using the XML configuration interface to administer tags and ratings

You can use the XML configuration interface to manage tagging and rating in the portal. For example, you can move tagspaces and ratings between portal versions or for staging purposes.

The XML resources related to tagging and rating are `tag`, `rating`, and `custom-resource`. Portal resources and custom resources are tagged and rated by different ways:

- To tag or rate **portal resources**, you use their object IDs directly.
- To represent **custom resources**, for example books, you use the XML resource `custom-resource`. The object ID of the `custom-resource` resource is used as the `resourceref` attribute in the `tag` and `rating` tags.

The XML resource tags and their attributes are listed in the following.

Notes:

1. When you create tags, ratings, or custom resources, you need to specify all attributes except the ones marked as optional.
2. When you move tagspaces between portals, both the users who have applied the tags and the resources to which the tags have been applied must exist in the target portal.
3. You can update existing ratings, but not existing tags by using the XML configuration interface. The XML configuration interface `action="update"` works only for implicitly creating a new tag.

tag Use the following attributes with the XML resource tag `tag` :

resourceref = "*object_ID*"
This attribute specifies the reference to the resource that is being tagged.

domain = "comm | cust"
This attribute specifies the database domain for the tagged resource. Possible values are:

cust Specify this value for private tags.

comm Specify this value for public tags.

locale This attribute specifies the locale of the tag. This attribute is optional. The default is `null`.

owner = "*user*"
This attribute specifies the owner of the tag.

rating Use the following attributes with the XML resource tag `rating` :

resourceref = "*object_ID*"
This attribute specifies the reference to the resource that is being rated.

domain = "comm | cust"
This attribute specifies the database domain for the rated resource. Possible values are:

cust Specify this value for private ratings.

comm Specify this value for public ratings.

value = "*integer*"
This attribute specifies the rating value.

owner = "*user*"
This attribute specifies the owner of the rating.

custom-resource
Use this tag to represent custom resources, for example books. Use the following attribute with the XML resource tag `custom-resource` :

uri = "*string*"
This attribute specifies a URI that identifies the custom resource.

Use the following subtag with the XML resource tag `custom-resource` :

category-instance
Use the subtag `category-instance` to assign a category in the format of a string to a custom resource. You can assign several categories to a custom resource. Use the following attribute with the subtag `category-instance` :

name = "*category_instance_name*"
Use this attribute to specify a name for a category instance.

Refer to the following code samples.

Example: Exporting tags and ratings

```
<?xml version="1.0" encoding="UTF-8" ?>
<request
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd"
    type="export">

    <!-- This sample exports all custom resources, ratings, and tags.
         Related sample files:
             CreateTagsAndRatings.xml
             DeleteTagsAndRatings.xml
     -->
    <portal action="locate">

        <custom-resource action="export" objectid="*"/>
        <rating action="export" objectid="*"/>
        <tag action="export" objectid="*"/>

        <!-- Export all tags with a specific locale in the system -->
        <!-- <tag action="export" objectid="*" locale="SPECIFIC_LOCALE"/> -->

    </portal>
</request>
```

Example: Creating tags and ratings

```
<?xml version="1.0" encoding="UTF-8"?>
<request
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd"
    type="update">

    <!-- This sample creates ratings and tags.

         Related sample files:
             ExportTagsAndRatings.xml
             DeleteTagsAndRatings.xml

         NOTE: This sample file needs to be modified before execution.
               Update the value of the 'owner' attributes of the 'access-control',
               'rating', and 'tag' tags, and specify an existing user.
    -->

    <portal action="locate">

        <!-- Parent element under which a new page for this sample is inserted -->
        <content-node action="locate" objectid="parentPage" uniquename="ibm.portal.Home"/>

        <!-- A new empty page to which a tag and rating are assigned.-->
        <content-node action="update" objectid="samplePageOID"
                      uniquename="ibm.portal.SamplePage.TagsAndRatings"
                      ordinal="last" content-parentref="parentPage"
                      active="true" create-type="explicit" type="page">
            <supported-markup markup="html" update="set"/>
            <localedata locale="en">
                <title>Sample page for tag and rating creation</title>
            </localedata>
        </content-node>

        <!-- A custom resource can be used to assign tags and ratings to resources
             that are not managed by XMLAccess, but can be identified by an URI -->
        <custom-resource action="update" objectid="CH_B1L68B1A00DO80IG7PCV0I1000"
                         uri="book:mySampleBookURI">
            <category-instance action="update" name="cookbook"/>

Moving tags and ratings between portals by using the XML configuration interface

To move tags and ratings between portals, for example for staging purposes, proceed as follows:

1. Make sure that all users who have applied tags and ratings on the source portal also exist on the target portal.
2. Make sure that all tagged and rated resources on the source portal also exist on the target portal.
3. Use the provided XML sample script to export all tags and ratings from the source portal.
4. Import the result file from the previous export step to the target portal.

Related reference:

"Types of portal resources" on page 1085
The portal resources are represented by the following XML tags.

Related information:

"Working with the XML configuration interface" on page 1061
You can use the XML configuration interface to export and import IBM WebSphere Portal Express configurations. This way you can configure selected features or areas of your portal. You can also transfer a complete configuration from one portal to another.

Hints and tips for tagging and rating

Hints and tips for developers and portal administrators

Learn about some hints and tips for administrators who work with tagging and rating.

Using tagging and rating on a virtual portal

To use tagging and rating with your virtual portal, ensure that the **web resource v7.0** and **web content templates 3.0** libraries exist on the virtual portal.

Administrators can assign access roles to users for tagging and rating content.

The portal user roles give users the following rights:

USER The user can view tags and ratings that other users applied.

PRIVILEGED USER
The user can also apply private tags and ratings.

CONTRIBUTOR
The user can also apply public tags and ratings.

MANAGER
The user can also modify tags and ratings that other users applied.

Users can work only with tagging and rating according to their access rights on portal resources.

Examples:

- Users can tag and rate only portal resources that they can access.
- When users click a tag in the tag cloud, they can view only resources that they can access.

Limitation: There is not security handling for tag clouds. When a user clicks a tag, the resources are filtered by the user's access rights and then listed for the user to view. Users might see tags even if they have no access rights on the tagged resources. When they click the tag, the list is empty.

Tags in tag clouds do not reflect access rights.

The tags that are shown in tag clouds do not reflect the access rights that users have on the tagged resources. Resources are filtered by access rights only after the user clicks a tag. This action has the following consequences:

Users might see tags without underlying resources.
Users might see tags that are applied to resources to which the users have no access. If they click a tag that is applied only to resources to which they have no access, they view an empty resource list.

Tag size does not represent frequency of the tag on resources that a user can access.
When a user views a tag cloud, tag sizes in the tag cloud represent how often the tag is applied. It does not represent how often the tag is applied to resources that the user can access.

Only portal content can be pre-tagged.
You can pre-tag only portal resources, such as pages and portlets. You cannot pre-tag custom content or Web Content Manager content.

Tags in a virtual portal can be seen only in that virtual portal.
If your portal contains virtual portals, the tags and ratings are limited to the virtual portal in which they were created. It is not possible to share tags across several virtual portals. Tags that are created in a virtual portal cannot be seen anywhere else.

Tagspace cleanliness.
The portal implementation of tagging prevents tag space littering that is the inclusion of tags that do not contribute to categorizing content. It manifests mostly in the following two issues:

- Redundant tags that result from similar names or spelling variants, for example, `web20` and `Web 2.0`. The portal reduces such duplicate tags by a syntactical type-ahead feature. This feature helps reduce tag space littering by suggesting tag name variants that other users already use. For example, if a user types `web2` and other users already use `Web 2.0` to tag portal resources, the type-ahead feature suggests `Web 2.0`, although `web2` is not an exact partial string of the suggested tag name. It supports users to not use too many different variants of the same tag name when you tag portal resources.

  Note: The type-ahead feature works only with the dialog tag widget of the default tagging user interface of portal versions earlier than V 8.5. With WebSphere Portal Express V 8.5, the tag and rating widgets of earlier portal versions are deprecated.
- Tags pointing to resources that are deleted. You can use the portal administrative cleanup tool, SLChecker. Use it to check for invalid links that do not exist any more and for tags that someone applied who is no longer a portal user. The SLChecker tool can identify and delete tags for deleted resources and tags that are applied by deleted users. For information, read *Deleting orphaned data*.

Staging and migrating tagspaces.
You can transfer the tag space from one portal to another, for example for staging or for migrating from one portal version to another. To do so, use the XML configuration interface (XML Access). For more information, read *Using the XML configuration interface to administer tags and ratings*.

Note: Users can create private and public tags. Private tags are stored in the customization database, whereas public tags are stored in the community database. Only content of the community database is staged and migrated.

Tagging custom content requires UI development.
If you want your users to tag and rate custom content, you must write code. The code must allow customers to find this content with the public APIs. You must also add the resources that you want your users to tag to the portal. Custom content is anything apart from portlets, portal pages, and Web Content Manager resources. For information, read *Enabling your own custom content to be tagged and rated*.

Tag filtering.
You can apply tag filters to suppress words that you do not want to be used as tags in your portal. As you can have more multiple active filters, a tag must pass all filters to be applied. A simple filter is shipped with the portal. If you need more advanced filtering, you must provide your own filters. For more information about creating custom filters, read *Filtering content for tagging*.

SQL Server URI length limit for custom resources.
For SQL Server , tags for custom resources with URIs of which the scheme-specific part in UTF-8 is larger than 850 bytes cannot be stored. As a workaround you can either use URIs with shorter scheme-specific parts or drop the respective index in the database table. Because of this limitation, a warning about the index key length is written when you transfer the database for SQL Server .

Tag Cloud, Tag Center, and Results List portlets do not support WSRP.
The Tag Cloud and Tag Center portlets, including the Result List portlet, do not support WSRP. It is not possible for a Producer portal to provide these portlets as remote web services. It is not possible for a Consumer portal to consume them so that its users can use them.

Maximum number of available tags.
By default the tag widget can show up to 50 different tag names. This limit applies separately to each kind of tags, **community** tags, **personal public**, and **personal private** tags. You can configure these maximum values by using the following two properties:

- For community tags: `com.ibm.wps.cp.tagging.dialog.maxCommunityTags`
- For personal tags: `com.ibm.wps.cp.tagging.dialog.maxPersonalTags`.

Increasing the 50 maximum figures can lead to slower responses of the user interface of the tag widget. The number of tags per resource averages 5 - 8. Users tend to reuse tag names that other users already used and that the tag widget then suggests by the type-ahead feature.

You configure these two properties globally in the CP Configuration Service for tagging and rating or for individual widgets in the widget properties. For details, read *CP Configuration Service for tagging and rating* and *Setting service configuration properties*.

Note: The type-ahead feature works only with the dialog tag widget of the default tagging user interface of portal versions earlier than V 8.5. With WebSphere Portal Express V 8.5, the tag and rating widgets of earlier portal versions are deprecated.

Angled brackets are not allowed in tag names.
Angled brackets (< and >) are not allowed within tag names. Therefore, no matter how you customize the regular expression, angled brackets are not accepted.

You can use filtering mechanisms to control which terms users can use and which terms they cannot use as tags. The portal provides both a blacklist and a whitelist filter.

Hints and tips for portal users

Learn about some hints and tips for portal users who work with tagging and rating.

Tag names must contain at least one alphanumeric character.
Tag names that consist only of non-alphanumeric characters are not allowed. Example: `"!^#"` .

Tags in tag clouds do not reflect access rights.
The tags that are shown in tag clouds do not reflect the access rights that users have on the tagged resources. Resources are filtered by access rights only after the user clicks a tag. This action has the following consequences:

Users might see tags without underlying resources.
Users might see tags that are applied to resources to which the users have no access. If they click a tag that is applied only to resources to which they have no access, they view an empty resource list.

Tag size does not represent frequency of the tag on resources that a user can access.
When a user views a tag cloud, tag sizes in the tag cloud represent how often the tag is applied. It does not represent how often the tag is applied to resources that the user can access.

How can I avoid closing the widget when clicking on listed resource links?
Rightclick the link that you want to view and select **Open in New Tab**. The widget will remain open, and you can proceed with the other links in the same way.

Type-ahead support requires at least 3 characters
When a user types a tag, the user needs to type at least 3 characters for the type-ahead support feature to work.

Note: The type-ahead feature works only with the dialog tag widget of the default tagging user interface of portal versions earlier than V 8.5. With WebSphere Portal Express V 8.5, the tag and rating widgets of earlier portal versions are deprecated.

Using WebDAV with WebSphere Portal Express

WebSphere Portal Express provides a Web-based Distributed Authoring and Versioning (WebDAV) implementation that individual services can use by plugging into. WebDAV is a set of extensions to the HTTP protocol that allows you to collaborate on editing and managing files on remote Web servers. Caching Proxy supports WebDAV methods used by Microsoft Exchange Server, and user-defined (customized) methods. These methods are hard coded and managed by the Enable and Disable directives. Administrators can also use the corresponding method-mask defined in the PROTECT directive to authorize the use of these methods.

About this task

Examples of such services are:

- WebDAV for managing pages and static content.
- WebDAV filestore. For example, this is used by portal themes.
- WebDAV for Web Content Manager.

Note: WebDAV does not support secure connections, such as, HTTPS. For specific WebDAV client version compatability, refer to the detailed systems requirements documentation and the Tech Note about *WebDAV clients for accessing IBM WebSphere Portal Express*.

"Configuring the WebDAV file store" on page 1352
By default only administrative users can perform write operations on specific folders of the WebDAV file store. This affects public and user owned folders. You can enable write access for all authenticated users on WebDAV file stores folders.

"Using WebDAV file store" on page 1352
You can use WebDAV to work with the portal themes.

"Serving HTTP OPTIONS requests to the server context root by WebDAV clients" on page 1358
Some WebDAV clients send an HTTP OPTIONS request to the server context root (`/`) to check whether the server supports WebDAV. To support these clients, the portal provides a web application called `wp.webdav.options.war` that you can enable. This application responds to such requests with a confirmation that the portal supports WebDAV.

"Working with WebDAV clients" on page 1358
WebDAV is an HTTP extension framework with a plug point for the access and management of hierarchical data, for example, in content management systems. WebDAV stores the data in collections and allows you to work with the data in a user interface view that is similar to that of a file system. Various tools are available for integrating WebDAV resources into the client file system, known as WebDAV clients. To use WebDAV for WebSphere Portal Express, you must first set up your WebDAV clients.

"Task `webdav-deploy-zip-file`" on page 1359
Use this configuration task to manage theme artifacts and to deploy iWidgets. This task uploads archive or compressed files to portal WebDAV folders.

Detailed system requirements

WebDAV clients for accessing IBM WebSphere Portal

WebDAV with web content

Configuring the WebDAV file store

By default only administrative users can perform write operations on specific folders of the WebDAV file store. This affects public and user owned folders. You can enable write access for all authenticated users on WebDAV file stores folders.

Procedure

1. Add the following property to the WP ConfigService resource environment provider in the WebSphere Integrated Solutions Console: `filestore.writeaccess.allowed`.
2. Set the value for the property to `true` .
3. Restart the portal server for the new setting to take effect.

What to do next

Notes:

- There are several WebDAV entry points. However, the property **`filestore.writeaccess.allowed`** applies to the **`filestore`** entry points for home directories for each user located at: `http://server_name:WC_default_host/wps/mycontenthandler/dav/fs-type1/users/user_name`
- Users can modify only their own directories.

Using WebDAV file store

You can use WebDAV to work with the portal themes.

WebDAV overview and entry point URL

WebDAV is defined by RFC2518 as an HTTP extension framework with a plug point for the access and management of hierarchical data. For example, in content management systems. WebDAV stores the data in collections. You can work with the data in a user interface view that is similar to that of a file system. A folder

represents a WebDAV collection. Various tools are available for integrating WebDAV resources into the client file system. Users can use these tools to view and modify resources that they can access with WebDAV. For WebDAV specification information, see the RFC2518 document in the related links. For more information about WebDAV in the portal, see the topics about Using WebDAV with WebSphere Portal Express.

Note: The HTTP Basic Authentication Trust Association Interceptor (TAI) must be enabled to use WebDAV in WebSphere Portal Express. This TAI is enabled by default. See the related links for information.

You can obtain the entry point URL to the WebDAV file store from the service document under the URL `/wps/mycontenthandler/!ut/p/model/service-document`. The service document contains the top-level access point as follows:

```
<app:collection href="/webdav/!ut/p/dav/fs-type1/">
     <atom:title>fs-type1</atom:title>
     <app:categories fixed="yes">
          . . . . .
          <atom:category term="webdav"/>
          <atom:category term="filestore"/>
          . . . . .
     </app:categories>
</app:collection>
```

The entry point URL for themes is as follows:

`http://`*`server`*`:`*`port`*`/`*`PortalServer_root`*`/mycontenthandler/dav/fs-type1/`

Examples of URLs for themes are as follows:

`http://www.my_company.com:10027/wps/mycontenthandler/dav/fs-type1/`

- For theme-related resources:

  `http://my_company.com:10027/wps/mycontenthandler/dav/fs-type1/themes/`
- For skin-related resources:

  `http://my_company.com:10027/wps/mycontenthandler/dav/fs-type1/skins/`

If you want to authenticate against a specific virtual portal, you can identify the target virtual portal either by its host name or its URL context. Examples:

- To authenticate to the virtual portal identified by the host name `vp.mycompany.com` and then connect to the themes folder, use the following URL entry point:

  `http://vp.mycompany.com:10027/wps/mycontenthandler/dav/fs-type1/themes/`
- To authenticate to the virtual portal identified by the URL context `vp1` and then connect to the themes folder, use the following URL entry point:

  `http://localhost:10027/wps/mycontenthandler/vp1/!ut/p/dav/fs-type1/themes/`

For details about the WebDAV specification, see the RFC2518 document in the related links.

Folder structure and reserved folder names

The fs-type1 WebDAV entry points provide the following set of predefined root folders that are used by themes:

- `themes`
- `skins`
- `layout-templates`
- `common-resources`

- `iwidgets`

The fs-type1 WebDAV entry points also provide the following set of predefined root folders. You can access them by using the Remote Model function that is provided by the Enabler API:

- `public`
- `users`

The fs-type1 WebDAV entry points provide the following internal folder:

- `system`

None of the folders that are listed here can be deleted, not even by an administrator.

The two sets of folders differ in the access control policy that guards access to the resources contained in those folders. See the following sections for details.

Theme folders

The following list shows the folder structure for the themes. Each folder represents a WebDAV collection. You administer write access to the theme folders with the virtual resource THEME MANAGEMENT provided by portal access control.

/themes
: Use this folder to store resources that are associated to themes, such as theme templates. Typically, each subfolder represents one theme.

/skins
: Use this folder to store global skins. Typically, each subfolder of this folder represents one global skin.

/layout-templates
: Use this folder to store templates for layouts that can be used by individual themes. Typically, each subfolder represents one layout template.

/common-resources
: Use this folder to share common resources between different themes, so that they can be managed in a single place.

/iwidgets
: Use this folder to place widgets into it.

WebDAV prevents the deletion of these folders. Even users with administrator rights cannot delete these folders and the data in them.

Managing access control for Page Builder theme folders

- All users have view access to all resources in these folders. It includes both anonymous users and authenticated users.

  To give users write access to resources contained in these folders, assign the users MANAGER role on the virtual resource THEME MANAGEMENT in portal access control. Managers can create, modify, or delete such resources

Assigning access control to users and managers for theme resources in WebDAV

To allow non-administrator users to update or modify existing files do the following steps.

1. Open a command prompt and change to the *wp_profile_root*/ConfigEngine directory.
2. Run the following **ConfigEngine** task.
   - Linux :
   - IBM i: `ConfigEngine.sh export-nodes -DWasPassword=wpsadmin -DPortalAdminPwd=wpsadmin -Dquery="/filestore/fs-type1/themes" -Dwp.content.repository.output.dir="c:\temp\jcr"`
   - Windows: `ConfigEngine.bat export-nodes -DWasPassword=wpsadmin -DPortalAdminPwd=wpsadmin -Dquery="/filestore/fs-type1/themes" -Dwp.content.repository.output.dir="c:\temp\jcr"`
3. Edit the file that was exported in the `c:\temp\jcr` directory. Add the manager and user role by adding the following code.

   ```
   <icm:role icm:actions="actionset:Manager,actions:Traverse,View,Edit,Add_Child,Delete,Join,">
       <icm:principal icm:name="uid=testuser,o=defaultwimfilebasedrealm" icm:type="USER" />
     </icm:role>
   ```

   Add it after the `<icm:owner>` element. See the following complete code snippet for reference.

   ```
   <icm:node>
   <icm:access>
     <icm:wps>
      <icm:owner>
       <icm:principal icm:name="uid=wpsadmin,o=defaultwimfilebasedrealm" icm:type="USER" />
      </icm:owner>
      <icm:role icm:actions="actionset:Manager,actions:Traverse,View,Edit,Add_Child,Delete,Join,"
       <icm:principal icm:name="uid=testuser,o=defaultwimfilebasedrealm" icm:type="USER" />
      </icm:role>
     </icm:wps>
   </icm:access>
   </icm:node>
   ```

4. Import the file with the following **ConfigEngine** task.
   - Linux :
   - IBM i: `ConfigEngine.sh import-nodes -DWasPassword=wpsadmin -DPortalAdminPwd=wpsadmin -Dwp.content.repository.input.dir="c:\temp\jcr"`
   - Windows: `ConfigEngine.bat import-nodes -DWasPassword=wpsadmin -DPortalAdminPwd=wpsadmin -Dwp.content.repository.input.dir="c:\temp\jcr"`

Other folders

The following list shows extra folders. Each of these folders represents a WebDAV collection. The access control policy for them is hardcoded as described for each folder.

/public
: All authenticated users have read and write access to this folder.

  Anonymous users have read access only.

/users
: All authenticated users have read access only to this folder.

Anonymous users have read access only.

/users/*user_name*

Only the user *user_name* has access to these files. This folder is created for the individual user *user_name* when the user accesses the WebDAV file store for the first time.

Note: To have human readable folder names, the portal uses the user IDs of the individual users as the names for the users' folders *user_name*. Internally, the portal uses the VMM ID of the user, so data does not need to be moved when the user name is changed.
If you want to programmatically find the URL entry point to a folder for the current user, you can look into the services document. The access point for user-specific data is provided as follows:

```
<app:collection href="/webdav/!ut/p/dav/fs-type1/users/<username>">
     <atom:title>fs-type1-user</atom:title>
     <app:categories fixed="yes">
          . . . . .
          <atom:category term="webdav"/>
          <atom:category term="filestore"/>
          <atom:category term="user"/>
          . . . . .
     </app:categories>
</app:collection>
```

/users/*user_name*/public

The user *user_name* has read and write access to this folder. This folder contains content that the user *user_name* shared with other users. Portal access control mapping: inherited.

All authenticated users have read access to this folder.

Anonymous users have read access to this folder.

All other subfolders of `/users/`*user_name* can only the accessed by the user *user_name*.

/system

The `system` folder is reserved for system internal information. Administrators can view this folder in WebDAV. Other portal users cannot view this folder. Portal access control mapping: None.

File store cache control

The WebDAV file store supports serving timeout values for HTTP Cache Header entries.

You can use regular expressions to specify the timeout value for elements in the file store folder structure that match the regular expression. You need to add the following two custom properties to the WP Config Service resource environment provider with the following key = value properties:

```
filestore.cache.expiration.id.re=regular expression
filestore.cache.expiration.id.seconds=value
```

The id value can consist of an arbitrary string. It is used only to establish the mapping between a regular expression and its associated timeout value. If there are multiple regular expressions that match any file store resource, the maximum of the associated timeout values are used. Examples:

1. All items under the `/themes` folder have an expiration time of 1800 seconds:

```
filestore.cache.expiration.0.re=themes/.*
filestore.cache.expiration.0.seconds=1800
```

2. All items of a certain resource type, such as jpg or gif have an expiration time of 6000 seconds:

```
filestore.cache.expiration.1.re=.*\.jpg|.*\.gif
filestore.cache.expiration.1.seconds=6000
```

   All css files in the themes folder have an expiration time of 8000 seconds:

```
filestore.cache.expiration.2.re=themes/.*\.css
filestore.cache.expiration.2.seconds=8000
```

Supported HTTP methods

WebDAV file store supports the following HTTP methods:

PROPFIND
: This method allows portal users to find out details about the resource hierarchy, such as the WebDAV collection structure. Users can also find details about resources, such as their names, sizes, and dates of last modification.

MKCOL
: This method allows users to create new folders, that are WebDAV collections.

GET This method allows users to retrieve resources on which they have at least View role access rights.

HEAD
: This method allows users to retrieve HTTP headers of resources on which they have at least View role access rights.

POST
: This method allows users to upload new resources.

DELETE
: This method allows users to delete resources or folders, that is WebDAV collections.

PUT This method allows users to update resources, such as documents or images in a folder.

COPY
: This method allows users to copy resources or folders, that is WebDAV collections.

MOVE
: This method is used to move or rename resources or folders, that is WebDAV collections.

Related tasks:

"Enabling HTTP Basic Authentication for simple clients" on page 1610
IBM WebSphere Portal Express provides an HTTP Basic Authentication Trust Association Interceptor that can be enabled to allow specific clients to log into the portal by using HTTP Basic Authentication instead of HTTP Form Based Authentication.

Serving HTTP OPTIONS requests to the server context root by WebDAV clients

Some WebDAV clients send an HTTP OPTIONS request to the server context root (/) to check whether the server supports WebDAV. To support these clients, the portal provides a web application called wp.webdav.options.war that you can enable. This application responds to such requests with a confirmation that the portal supports WebDAV.

About this task

To enable this WAR file, adapt the application.xml files of the deployed Enterprise Application (EAR), wps.ear, so that wp.webdav.options.war is mapped to the context root (/). Proceed as follows:

Procedure

1. Export the EAR, wps.ear, through the WebSphere Integrated Solutions Console.
2. Open a command prompt.
3. Run the following command to expand the EAR:

   ```
   ./EARExpander.sh|bat -ear directory/WebDAV_for_WebSphere_Portal.ear
   -operationDir directory webdav_expanded -operation expand
   ```

4. Locate the file application.xml in the expanded EAR file directory.
5. Edit the file application.xml of the exported EAR, and uncomment or add the following section:

   ```
   <module>
        <web>
             <web-uri>wp.webdav.options.war</web-uri>
             <context-root>/</context-root>
        </web>
   </module>
   ```

6. Run the following command to collapse the EAR:

   ```
   EARExpander.sh|bat -ear directory/wps.ear
                      -operationDir directory/wps_expanded
                      -operation collapse
   ```

7. Update the enterprise application with these changes by using the WebSphere Integrated Solutions Console.
8. Save your changes.
9. Restart the portal for your changes to take effect.

What to do next

Note: Depending on how your web server is set up, this change might cause all requests to be routed to the web server plug-in. In this case refer to your web server documentation for information about how to route only OPTIONS requests to the plug-in.

Working with WebDAV clients

WebDAV is an HTTP extension framework with a plug point for the access and management of hierarchical data, for example, in content management systems. WebDAV stores the data in collections and allows you to work with the data in a user interface view that is similar to that of a file system. Various tools are available for integrating WebDAV resources into the client file system, known as WebDAV clients. To use WebDAV for WebSphere Portal Express, you must first set up your WebDAV clients.

About this task

For specific WebDAV client version compatability, refer to the detailed systems requirements documentation and the Tech Note about *WebDAV clients for accessing IBM WebSphere Portal*.

Notes:

- Numerous other WebDAV clients are available that you can use for WebDAV access. IBM supports the use of these WebDAV clients; however, IBM does not provide fixes or give support for issues found to be specific to a particular WebDAV client.
- Some WebDAV clients have specific restrictions, for example a limit to the size or number of files that you can handle when using WebDAV, or a read only restriction. These restrictions usually have security reasons. If you encounter issues when working with WebDAV, consult the documentation and forums for your WebDAV client.

When you use a Web server to work with WebDAV, complete the following steps:

Procedure

1. Access the WebSphere Integrated Solutions Console.
2. Select **Web servers** > **webserver name** > **Plug-in properties** > **Request and response**.
3. Set **Accept content for all requests** to `true` for the Web server plug-in.
4. Regenerate the web server plug-in.
5. Copy the file `plugin-cfg.xml` to the `Plugin` directory.
6. Open your `plugin-cfg.xml` file and set **`AcceptAllContent`** to `true`.
7. Restart the web server.

Detailed system requirements

WebDAV clients for accessing IBM WebSphere Portal

Task `webdav-deploy-zip-file`

Use this configuration task to manage theme artifacts and to deploy iWidgets. This task uploads archive or compressed files to portal WebDAV folders.

Address the target folder by using a corresponding DAV URI, for example `dav:fs-type1/iwidgets/myWidget/`.

Note:

- By default, this task replaces the referenced target folder by the extracted contents of the referenced archive or compressed file. As a result, files or folders that are contained in the referenced WebDAV folder are deleted before the new content is added. If you want to avoid this behavior and merge the contents, set

the optional `UpdateMode` parameter to the value `merge`. If you add this setting, the task merges the contents of the archive or compressed file into the content that exists at the target URI.

- If you have a portal cluster installation, start the task on the primary node only. Starting the task on a secondary node has no effect.

If the WebDAV folder referenced by the target URI does not exist yet, the task creates it. In this case, make sure to have a trailing slash (**/**) at the end of the target URI.

Description:
This task uploads archive or compressed files to portal WebDAV folders.

Mandatory parameters to be specified on the command line or in the file `wkplc.properties`:

`WasUserid`
The WebSphere Application Server user ID.

`WasPassword`
The WebSphere Application Server password.

`PortalAdminId`
The WebSphere Portal Express administrator user ID.

`PortalAdminPwd`
The WebSphere Portal Express administrator password.

Mandatory parameters to be specified on the command line only:

`TargetURI`
The URI of the WebDAV folder where you want the archive or compressed file to be extracted.

Path parameter:
use only one of the following two path parameters. They are mutually exclusive:

`ZipFilePath`
The file system path to the archive or compressed file. Do not use this parameter in combination with the parameter **`ZipFileClassPath`**.

`ZipFileClassPath`
The Java class path to the archive or compressed file. Do not use this parameter in combination with the parameter **`ZipFilePath`**.

Optional parameters to be specified on the command line only:

`UpdateMode (=replace)`
The default value for this parameter is **`replace`**. If you want to merge the content of the archive or compressed file with the content that exists at the target URI, set this parameter to the value **`merge`**. In this case files that do not yet exist are created, existing files are updated, and no files are deleted.

`VirtualPortalContext`
`VirtualPortalHost`
Use one of these two parameters to identify the virtual portal. Only pages that are contained in the specified virtual portal are refreshed. If you omit this parameter, by default no virtual portal page layout is refreshed.

Example:

You can upload the file `foo.zip` to the public folder of the file store by using either one of the following options:

- Copy the file `foo.zip` to the portal class path, for example `AppServer/lib/ext`.
- Copy the file `myWidget.zip` to the temporary directory `/tmp` on the portal server node.
- Run the configuration task `webdav-deploy-zip-file` as follows:

```
./ConfigEngine.sh webdav-deploy-zip-file
     -DTargetURI=dav:fs-type1/iwidgets/myWidget/
     -DZipFilePath=/tmp/myWidget.zip
```

Virtual portals

View information on how you can scope your WebSphere Portal Express to have multiple virtual portals.

Virtual portals can be of benefit if you want to serve multiple user groups by separate virtual portals for different purposes, but still want to keep your environment simple and limited to a single WebSphere Portal Express installation. Virtual portals allow a large extent of scoping and separating portal resources, user groups, and administration.

Scenarios with multiple portals for your business requirements

Before you decide on a portal installation with multiple virtual portals, you need to determine your specific business requirements and the purpose of your portal. This can help you decide whether virtual portals are a valid solution for your requirements, or whether it is better for you to use multiple real portals. Consider and answer the questions in the following sections.

Using virtual portals versus multiple real portals

The benefit of virtual portals consists of sharing several resources between the virtual portals. Rather than having one of these resources for each portal, all virtual portals use the same single instance of such a resource. This reduces the administrative cost and optimizes the resource usage. Typically, virtual portals share the following resources:

- The JVM
- Portlets and other code fragments
- The database

Additional to the benefit of sharing these resources, the virtual portals can be scaled to a large extent, and you can host many virtual portals on a single portal installation. For a complete list of the resources that virtual portals share, see *Separating and sharing resources between virtual portals*. Sharing resources, however, can create dependencies between virtual

portals. For example, if one of the virtual portals requires maintenance, all virtual portals are affected by the outage and undergo the same maintenance updates. If you can accept such dependencies in your business environment, virtual portals are a simple and cheap solution for you. Otherwise, you have the alternative of using multiple real portal installations. For more information, see *Alternative concepts for virtual portals on WebSphere Portal Express*.

Sharing or separating virtual portal administration

Do you plan to have each virtual portal administered by its own group of administrators, or will you have a central administration group for the entire portal installation and all virtual portals?

You can select a specific group of subadministrators who can manage the resources and users of a particular virtual portal. The master administrator of the portal installation can set up the privileges of the individual subadministrators for each virtual portal.
If you do not require a specific subadministrator group for each virtual portal, the portal administrators can share the administrative work for all virtual portals.

Sharing or separating user populations

Does each virtual portal need its own separate user population, or can all virtual portals share the single user population?

To ensure that only members of a dedicated user population can access a virtual portal, use the realm concept that is provided by the Virtual Member Manager (VMM). VMM is available as a built-in user registry in WebSphere Application Server. This security concept is known as federated security.
If all your virtual portals can use the same user population, you can configure federated security with a single realm. This realm can contain users and groups from one or more repositories.

Technotes for virtual portals

Alternative concepts for virtual portals on WebSphere Portal Express

Besides virtual portals, another possible configuration may be an alternative for you, depending on your business needs. This setup is referred to as true portals.

This setup allows the re-use of a single hardware, with multiple complete portal installations, that is, one dedicated software profile for each portal. Each portal installation requires its own complete WebSphere Application Server installation. These are the main advantages of true portals:

- The strong isolation of the configuration data due to separate configuration databases
- The full isolation of applications, due to a separate JVM for each true portal. This allows better quality of service.

If you want to implement this solution, be aware of the following limitations:

- You can run only a limited number of true portals on a single hardware machine. This is due to the memory volume required by the JVM.
- You cannot share applications or data between true portals.

Technotes for virtual portals

Usage scenarios for virtual portals

Learn about three typical usage scenarios for virtual portals.

Scenario 1: Multi-Portal Enterprise

In this scenario a single enterprise operates multiple different virtual portals on a single portal installation. The virtual portals are used for different parts of the organization, such as the following:

- Development, production, and marketing
- Organizations or branches in different locations and foreign countries
- Affiliate or franchise business models
- Different branding.

These are some of the typical business requirements:

- The portal installation as a whole is operated by the company, as the different parts of the organization are too small to have their own IT staff.
- A common group of administrators is responsible for the administration of all the virtual portals in the installation.
- Each part of the organization wants their own individually customized virtual portal.
- Many applications are commonly used by the different parts of the company, and they are shared between the virtual portals.
- All portal users are contained in the company user directory.
- The portal installation might typically have between ten and thirty virtual portals.

As many resources are commonly used by all sections of the company, sharing these resources has large benefits, and the resulting dependencies are acceptable for the enterprise. In this case, using virtual portals is the appropriate option, as it reduces the amount of resources required for the administration of the portal. For the requirements of this scenario, you can select one or both of the following options:

- As the sections of the company are too small to each have their own administrative staff, you can use a shared group of administrative users.
- To allow all members of the company to access all virtual portals, a shared user population is a suitable approach. Nevertheless, you can reduce the availability of specific resources to specific user groups by assigning access rights accordingly.

Scenario 2: Workgroup Service Provider

In this scenario one central organization provides virtual portals for a large number of small, decentralized, and independent teams. For example, this can be teamrooms for project management in small work units. This scenario supports virtual portals for different parts of the organization as follows:

- It supports a large number of individual virtual portals on a single portal installation. This can be more than a hundred virtual portals.
- The individual logical Portals are intended for small user groups, projects or departments.
- The owning enterprise operates this installation like an IT service provider.
- It is important that virtual portal administrators can create additional virtual portals with predefined default content fast, easily, and on demand. These can be based on a customized virtual portal template.
- Sharing content and applications is a very important aspect in this scenario.
- Administration of each virtual portal and its users and resources is independent and self-contained.

Scenario 3: Hosted Enterprises

In this scenario a service provider hosts and operates independent enterprises on the same portal installation. For example, this scenario can support virtual portals for different tenants or service customers, such as:

- A service provider who supports services for small businesses of the same type.
- A provider who offers services for medical doctor practices.
- A central banking service provider who offers services to different branches of banks.

The business requirements for this scenario include the following:

- Most applications are shared between the tenants.
- The tenants need to be able to administer their virtual portals themselves. If the critical business data of the tenant is stored in the back end of the tenant system, and not in the shared database of the virtual portals, sharing of other portal resources, such as JVM and database is acceptable for the tenants.
- The portal installation might typically have between ten and thirty virtual portals.
- Each tenant portal has its own user directory.
- The content shown to users in the portlets are maintained in the back ends of the tenant companies themselves. For example, this is the case in a service portal with separate virtual portals for individual banks.

Based on these business requirements, you can select one or more of the following options:

- Each virtual portal has its own groups of administrators. The administrators of one virtual portal manage the rights of the users in that virtual portal.
- As the tenants each have their own user repository, they can set up their virtual portal with their own realm. This provides strong separation between the users in the different virtual portals. If individual users need to access more than one of these virtual portals, they need a user ID for each virtual portal that they access.
- You can circumvent the dependency on a common maintenance window by setting up two sets of virtual portals: while one is used for production and carries the user load, the other one is free for maintenance. This also gives the required high availability.

You need to set up the configuration required for such a scenario carefully. As an alternative for this scenario, you can consider using separate portal installations rather than virtual portals. This can be the easier solution especially if you provide

service for a small number of large tenants.

Planning for virtual portals

Before you create your virtual portals, review this information for planning purposes. Determine how many virtual portals your business requires, and how and for which purposes you will use them. Based on your decision, plan how you implement and configure your virtual portals.

IBM has tested an installation with 300 virtual portals successfully. The limiting factor is not the absolute number of virtual portals, but the overall number of pages and URL mappings. For more details see the topic about *Known limitations for virtual portals*.

IBM WebSphere Portal Express provides two pre-configured virtual portals, one each for use as internet and intranet portals. For more information see the topic about *Scope of virtual portals*.

"Separating and sharing resources between virtual portals" on page 1367
Separation between virtual portals is achieved by **scoping** the portal resources of the virtual portals. Scoping means making portal resources available uniquely and separately to individual virtual portals and their users.

 Technotes for virtual portals

"Tasks for administering virtual portals" on page 1389
Administering virtual portals and their content comprises the tasks described in the following topics.

Separating and sharing resources between virtual portals

Separation between virtual portals is achieved by **scoping** the portal resources of the virtual portals. Scoping means making portal resources available uniquely and separately to individual virtual portals and their users.

Scoping of resources works as follows:

- A portal resource that is scoped for virtual portals exists individually for each virtual portal. It has an identification that is unique within the entire portal installation. The resource is available only in one particular virtual portal. Consequently, you can customize such resources for each virtual portal independently. Example: The resource `resource_A` is scoped for the virtual portals `VP_1`, `VP_2`, and `VP_3` as `resource_A_VP_1`, `resource_A_VP_2`, and `resource_A_VP_3`. Customizing `resource_A_VP_1` does not affect `resource_A_VP_2` or `resource_A_VP_3`.
- A portal resource that is not scoped for virtual portals is shared between all virtual portals. Consequently, if you customize this resource, this will affect that resource in all virtual portals equally.

Scoping works for some portal resources, but not for others:

- IBM WebSphere Portal Express scopes some portal resources for virtual portals. This means that these resources exist separately for each virtual portal.
- Other resources are common for all virtual portals in a portal installation. However, you can scope some of these resources:
  - You can scope some resources by using portal administration and Portal Access Control.
  - There are some portal resources that cannot be scoped at all.
- The user population can be scoped to one or more specific virtual portals.

The differences in scoping portal resources are described in the following sections.

Portal resources that are scoped for virtual portals

WebSphere Portal Express has the following portal resources scoped internally for virtual portals:

- Portal pages

- Portlet instances
- Portal Search Engine search services and search collections. This includes the search content sources.
- IBM Web Content Manager web content libraries. See the note later in this section.

Scoping of these resources is managed by internal portal mechanisms. Scoped resources are only available for the virtual portal for which they are defined. They are well isolated from other virtual portals. Scoped resources cannot be shared with other virtual portals. They are not visible or accessible outside of the virtual portal for which they have been created. This behavior cannot be changed by any portal access control settings.

The following rules apply:

- Within each virtual portal you or a sub-administrator can use Portal Access Control to grant individual users of that virtual portal specific access permissions to the scoped portal resources. This works just like under a single portal installation.
- An administrator can give access permissions to users who are members of the user population of a virtual portal only on the scoped resources of that same virtual portal. This implies that, vice versa, you can give access permissions on the resources of a virtual portal only to those users who are members of the user population of that virtual portal.
- Users can only use these access permissions when they access the specific virtual portal under which they have the access permissions on the scoped resources. The same users cannot access the resources when logging in to a different virtual portal.

Note for IBM Web Content Manager web content libraries: IBM Web Content Manager web content libraries are scoped to virtual portals if Managed Pages are enabled as by the default WebSphere Portal Express installation. If you want to make IBM Web Content Manager web content libraries available between your virtual portals, you can do so by disabling Managed Pages and restarting your portal. IBM Web Content Manager web content libraries of the base portal are then also available to the virtual portals.

Portal resources that you can separate for virtual portals by using Portal Access Control

There are some portal resources that are not scoped internally for a particular virtual portal. These resources are shared among all virtual portals of the entire installation. However, as a master administrator you can yourself separate such portal resources for the virtual portals. To do this, use Portal Access Control and the access permissions portlets to set up the appropriate access permissions for users on the resources of each virtual portal as required.

You can separate the following portal resources by using Portal Access Control to give users of an individual virtual portal access permission to the resources:

- Portlets
- Portlet applications
- Web modules
- URL mapping contexts
- Users and groups.

You can separate these resources for individual virtual portals by using Portal Access Control. When you do this, apply special care. It can be of benefit to document the relationships between the users and the virtual portals.

Portal resources that cannot be separated for virtual portals

There are some types of portal resources that are not scoped to a particular virtual portal, and you cannot separate them yourself by using Portal Access Control. The following list shows portal resources that you cannot separate for virtual portals:

Themes and skins
If you do not want sub-administrators to be able to manage themes and skins, restrict their access permissions on them.

Vault segments and vault slots
To avoid security problems, use private credentials only. They can be used by only one specific user.

Supported clients and markups
The settings for these are configured in the corresponding portlets; therefore they apply to the entire portal installation.

Policies
Policy resources are not scoped to virtual portals. Users see the policy resources to which they have access, regardless of the virtual portal assignments.

Personalization
Personalization is not aware of virtual portals. A document library that is available in the initial portal installation is also available in each virtual portal, if Personalization is available in that virtual portal and is configured to use that document library. Searching for a document in a document library will produce a document reference (URL) that is different in each virtual portal, but points to the same document in the document library. To provide separation of content within virtual portals, use separate document libraries for each virtual portal. To provide content collaboration between virtual portals, use the same document libraries between virtual portals.

Example: Themes and skins can be accessed by all sub-administrators who have the access permission to apply themes and skins to the pages that they can administer, regardless of which virtual portal the sub-administrators are responsible for.

Separating portlets, portlet applications, and portlet instances

Portlet applications are not scoped for virtual portals. Therefore, the configuration settings that you set for a portlet application by using the Manage Applications portlet apply to that portlet application in all virtual portals. If you need different configurations for a portlet application between virtual portals, create a copy of the portlet application, and configure the copied portlet application as required.

Portlets are separate portal resources, but they are not scoped for each separate virtual portal. However, each portlet in a virtual portal shares its portlet application on the initial portal installation with its siblings on the other virtual portals. Therefore the following configuration settings set for a portlet apply to that portlet in all virtual portals:

- The configuration settings that you set for a portlet by using the Manage Portlets portlet

- The configuration settings that you set for a portlet by using the **Configure** mode of the portlet.

Portlet instances are scoped to the virtual portals. If you need different configurations for a portlet between virtual portals, create a copy of the portlet, and configure the copied portlet as required. The configuration settings that you set for a portlet by using the **Personalize** or **Edit shared settings** mode of the portlet apply only to that individual portlet instance on that individual page.

Special case: Scoping unique names

Unique names that you apply to portal resources represent a special case with regards to scoping. Unique names are attributes to portal resources. Therefore, whether a unique name is scoped to a virtual portal or not is determined by whether the portal resource to which the unique name applies is scoped or not:

- Unique names for scoped portal resources are themselves also scoped.
- Unique names for resources that are not scoped are themselves not scoped.

Example for a scoped unique name: Each virtual portal has its own separate login page. Therefore you can assign the same identical unique name to all login pages for all virtual portals. The unique name that you give to the login page of a specific virtual portal applies only within that portal. It cannot be administered in a different virtual portal that has the same unique name for its login page.

Example for a unique name that is not scoped: Portlet applications are not scoped but shared between all virtual portals. You can assign a unique name to the portlet application. You can reference that portlet application by that unique name throughout the portal installation with all virtual portals.

Technotes for virtual portals

Managing the user population for virtual portals

You have two basic options for the management of user populations for your virtual portals: Virtual Member Manager (VMM) or Lightweight Directory Access Protocol (LDAP).

This depends on whether you want separate user populations for your virtual portals or a simple solution with one user population for all virtual portals:

- Using the **Virtual Member Manager** that is integrated with WebSphere Application Server; it is also known as the Federated Repository. You can use the Federated Repository to set up both types of configuration:
  - Configuring separate user populations for each of your virtual portals. This option offers a high flexibility for the user management of your virtual portals. With this configuration, you can define an individual user population for each virtual portal.
  - Using a common user population with the Virtual Member Manager for all your virtual portals. In this case, all users of that user population can access all virtual portals, unless their access permissions are explicitly restricted by portal access control settings. To achieve this restriction, you must define the access permissions manually by using the Portal Access Control portlets.

A user registry can be based on a Lightweight Directory Access Protocol (LDAP) or on a database. For more information about configuring your virtual portals with Virtual Member Manager and the different configuration options see the following sections.

- Using the **Lightweight Directory Access Protocol (LDAP)**. If a single common user repository is sufficient for all virtual portals within your installation, you can continue to use an LDAP in your virtual portal setup. This is the simpler one of the two options.

  With this configuration the entire portal installation and all virtual portals share a common user population, which is defined in a single user repository. In this case all users of that user population can access all virtual portals, unless their access permissions are explicitly restricted by portal access control settings. In order to achieve access restrictions for specific virtual portals, you can use the Portal Access Control portlets. You define user groups and assign to them the access permissions to the resources of each virtual portal.

For WebSphere Portal Express installations, the Federated Repository option offers you more flexibility for the user management of virtual portals. By using the Virtual Member Manager, you can limit the usage of a particular virtual portal to a specific user population. This is achieved by introducing the concept of **realms**.

The following sections give overview information of how to use the Virtual Member Manager and realms in the context of virtual portals. For a wider overview of portal security see the topics about *Securing* and *Configuring* the portal and about access permissions, users and groups. For more details about how to configure the Virtual Member Manager and realms see the topics about adding realm support for your environment.

A virtual portal can only be accessed by members of its associated user population. By using Portal Access Control that you can assign and restrict access permissions within the user population of a virtual portal to the resources of that virtual portal. However, Portal Access Control cannot overwrite the predefined assignment of a particular user population to their virtual portal. You cannot use Portal Access Control to assign access permissions that cross the separation between virtual portals. For example, you cannot use the Portal Access Control of a virtual portal VP_A to give a user User_A_1 of that portal access to resources of another virtual portal VP_B. The following conditions apply:

- A realm contains the entire user population of one virtual portal.
- Each virtual portal can have its own realm of users that are associated. However, it is also possible that multiple virtual portals can share their user population by using the same realm in parallel.
- To be able to log in to a particular virtual portal, a user must be a member of the realm that is associated with that virtual portal.

For more details about preparing the Virtual Member Manager and realms for your virtual portals, read the next section.

Preparing the user populations for your virtual portals

If you plan to use realms for your virtual portals, you need to configure Virtual Member Manager and the realms before creating your virtual portals. Each realm must specify the repository nodes (base entries) that belong to the user population represented by this realm.

In addition to the realms that you create to define the user populations of the individual virtual portals, you must create a super realm. This super realm spans all other realms and contains all the users of those other realms; it is also known as the default realm.

By default WebSphere Portal Express is configured with Federated Repositories as User Registry provider. By default only the super realm, or default realm, is configured. After you have configured your portal instance against your user backend repositories, you can use tasks that are provided by the portal to configure the realms that the Virtual Member Manager provides. For the task that describes how to add a realm and modify the base entries or nodes inside that realm, read the topics about adding realm support for your portal environment.

Using a non-default realm: If you assign a non-default realm to the default virtual portal, ensure that all administrative accounts are available within the non-default realm. If you have Web Content Manager, do not use a non-default realm, as Web Content Manager is not scoped to virtual portals.

The following sections give an overview of example configurations of the Virtual Member Manager for virtual portals. For more information about configuring realms for your virtual portals, read *Virtual Member Manager integration*.

Configuring a common user population for all virtual portals

In a simple setup, you can use the Virtual Member Manager together with a common user repository. This user repository is represented by a single realm, and used by all virtual portals. In this case, all virtual portals use a common realm and a common user repository. This configuration provides no separation between the users of the different virtual portals.

WebSphere Portal Express still supports the WebSphere Application Server Lightweight Directory Access Protocol (LDAP) custom user registry that previous versions of WebSphere Portal Express used. You can configure it as alternative. Again, this configuration uses a common user repository for all virtual portals without separation between the users of the different virtual portals.

Configuring separate user populations for the individual virtual portals

If you want to have the users of your virtual portals that are separated, you must apply the more advanced setup by using Federated Repositories. Then, configure separate realms for your virtual portals. When users access a virtual portal, the portal installation selects the appropriate realm that is based on the current virtual portal context. Within a virtual portal, only users of that corresponding realm are "visible". The administrator of a particular virtual portal can give access permissions only to users and groups in the population of that virtual portal. Therefore, when you create a virtual portal, the realm that represents the population of the new virtual portal must be a subset of the realm that is used by your portal installation.

Note: This separation of user populations between virtual portals works only with Federated Repositories. The portal supports separate realms and user repositories for virtual portals only when you use the Federated Repositories.

When you use the Federated Repositories, you can separate user groups and administrative users by configuring your virtual portals according to your business requirements. You do this based on the following relationships between user repositories, realms, and virtual portals:

- You can aggregate users and groups from one user registry in one realm, and expose them as one coherent user population to the portal installation. You can separate the user population of each virtual portal by assigning different LDAP suffixes to the different realms. The LDAP suffixes are called base entries. This way the concept of realms allows you various flexible configuration options.
- A realm can aggregate one or more base entries in a user registry.
- A realm can combine multiple base entries of one user repository. A suffix of a user repository can belong to one or more realms. The LDAP suffixes of the individual users must match the suffixes of the groups to which they belong.
- A virtual portal is associated with one realm. Each virtual portal uses exactly one realm, but a realm can be used by multiple virtual portals.
- A virtual portal can also be associated with no realm. If no realm is assigned for a virtual portal, the user population that was defined for the super realm can log on to the virtual portal.
- When you use Federated Repositories, the initial portal installation has no realm that is associated by default. The user population of the initial portal installation spans the entire user registry that you configured in the Virtual Member Manager.
- The individual user IDs must be unique across all realms.
- To log in to a virtual portal, the virtual portal administrator and all users must be a member of the realm for that virtual portal. To allow a user access to more than one virtual portal, that user (and the Virtual Member Manager node to which the user belongs in the hierarchy of the user directory) must be a member of all the realms that are associated with these virtual portals. For example, this information applies to a super administrator who is responsible for all virtual portals within an entire Portal installation.
- To administer a virtual portal, the base portal administrator must be a member of the realm that is associated with the virtual portal. The base portal administrator is required to be part of all realms.

  If the administrator is not a part of the virtual portal realm, then the administrator does not have access to that virtual portal. This also applies to the base portal administrator group. If the portal administrator is not part of all realms, then you might encounter issues or the inability to complete certain tasks. For example, a portal installation with virtual portals cannot be migrated, if the portal administrator cannot access the virtual portals for the migration.
- User populations of realms can overlap. In other words, users can be members of multiple realms. If realms overlap, then these users can work in all the virtual portals that are associated with these realms.

Important: The administrator unique ID for the Java Content Repository (JCR) must be a distinguished name (DN) for a super administrator. You specify the administrator unique ID as the value defined in the **jcr.admin.uniqueName** property. To view this property, log in to WebSphere Integrated Solutions Console. Go to **Resources** > **Resource Environment** > **Resource Environment Providers** > **JCR ConfigService PortalContent** > **Custom properties** > **jcr.admin.uniqueName**. For example, you can set up the following configurations:

You can configure one LDAP suffix with all administrative users, for example `dc=administrators,dc=ibm,dc=com` and a separate LDAP suffix with the users, for example `dc=users,dc=ibm,dc=com`.

You can configure separate LDAP suffixes that contain different user populations, for example `dc=bank1,dc=com` for Bank_1 and `dc=bank2,dc=com` for Bank_2.

Notes:

Considerations for deleting resources in virtual portals:
The Portal Access Control administration in the Resource Permissions portlet shows users from different realms who have role mappings on shared resources by their object IDs. Therefore, apply special care and consideration when you delete such portal resources: Do not delete resources on which users from other realms have role mappings, if they are required in other virtual portals. This information applies to members of roles on portal resources that cannot be scoped and are therefore shared between the virtual portals. Role members who belong to the realm of your local virtual portal are displayed as usual, but role members who belong to different realms are displayed in a different manner:

- Role members for shared resources who belong to the realm of the virtual portal where you are currently working are listed by their actual names.
- Role members for shared resources that do not belong to the realm of the current portal are listed by their portal object IDs. For example, a role member from a different realm might be represented as `8_0_B`.

Find the list of role members. Click the **Administration menu** icon. Then, click **Access** > **Resource Permissions**. From the list of Resource Types, select a Resource Type by clicking it. On the Resource Permissions page, click the **Assign Access** icon. The members are listed in the **Roles** column.

How to grant virtual portal administrators access to web content libraries:
Virtual portal administrators do not automatically have access to work with web content libraries when you use the administration portlet. To enable a virtual portal administrator to work with web content libraries, you need to assign them access to either the JCR content root node or individual web content libraries:

- You can assign virtual portal administrators access to the JCR content root node with `Set access on root` in the Web Content Library view of the Administration portlet. For more information, go to the portlet online help.
  - Assign virtual portal administrators administrator access to the JCR content root node to enable them to create new libraries and view, edit, and delete all existing libraries.
  - Assign virtual portal administrators contributor access to the JCR content root node to enable them to create new libraries and view, edit, and delete libraries that they created.
- You can also assign virtual portal administrators access to libraries they did not create by editing the access settings of individual libraries.

Chapter 12, “Securing,” on page 1517
Security tasks include setting up property extension databases and custom user repositories, configuring and activating SSL, and configuring authentication. In addition, tasks such as activating Federal Information Processing Standards (FIPS) and NIST SP800-131a security modules and configuring external security managers such as Security Access Manager might be required to secure your portal environment.

"Realm support" on page 134
A realm is a collection of users or groups from one or more branches of your repository tree. Those branches can be part of a single repository, for example an LDAP user registry, or it can be a combination of multiple user registries. A realm is then mapped to a Virtual Portal to allow the realm's user population to log in to the Virtual Portal. This functionality allows you to define areas within WebSphere Portal Express that only a limited set of users can access.

"Controlling access" on page 1524
After creating users and groups, you can assign them different levels of access to specific resources, roles, and policies. This access controls what actions they can perform on various pages, portlets, and applications.

"Virtual Member Manager integration" on page 132
IBM WebSphere Application Server includes the Virtual Member Manager (VMM), which IBM WebSphere Portal Express uses to access user and group information. VMM provides an interface that enables communication between WebSphere Portal Express and any repository, whether federated repositories or your own custom user registry.

Related tasks:

Chapter 5, "Configuring," on page 231
Run the following tasks after you install and deploy IBM WebSphere Portal Express. They address tasks that are typically run one time and have a global effect. Some configuration changes are made more frequently or do not have a global effect. These tasks are addressed in the Administering section.

"Adding realm support" on page 582
A realm is a group of users from one or more user registries that form a coherent group within IBM WebSphere Portal Express. Realms allow flexible user management with various configuration options. A realm must be mapped to a Virtual Portal to allow the defined users to log in to the Virtual Portal. When you configure realm support, complete these steps for each base entry that exists in your LDAP and database user registry to create multiple realm support.

"Managing the users of virtual portals" on page 1389
You manage the users of virtual portals by adding and configuring the user repository and later administering the users for virtual portals.

Virtual portal roles and their capabilities

A typical virtual portal scenario works with a master administrator and sub-administrators. Assigning access permissions to the users of virtual portals also requires special considerations.

"The master administrator" on page 1376
A key role for the administration of virtual portals is the master administrator. This user ID is created during the initial installation of WebSphere Portal Express with the role administrator on the portal (`admin@portal`). This administrator is also the master administrator of the initial portal installation and all virtual portals that are created. This master administrator is created with all necessary access permissions for administering tasks that are related to the initial portal and the virtual portals.

"Portal Access Control with virtual portals" on page 1378
You can scope some portal resources for your virtual portals by using portal administration and Portal Access Control. For example, you can scope portlet applications. These resources are available to all virtual portals. You can scope these resources to specific virtual portals by limiting their accessibility to the

user populations of the required virtual portals. To make this limit, you use Portal Access Control. Resources that you scoped this way for one virtual portal cannot be accessed from other virtual portals.

"Subadministrators of a virtual portal and their access roles and permissions" on page 1379
When you create a virtual portal by using the Virtual Portal Manager portlet, you select a user group of subadministrators who you want to be responsible for the administration of the new virtual portal.

"Users of a virtual portal and their access roles and permissions" on page 1382
When you create a virtual portal, you need to be aware of the implications listed here.

Technotes for virtual portals

The master administrator:

A key role for the administration of virtual portals is the master administrator. This user ID is created during the initial installation of WebSphere Portal Express with the role administrator on the portal (`admin@portal`). This administrator is also the master administrator of the initial portal installation and all virtual portals that are created. This master administrator is created with all necessary access permissions for administering tasks that are related to the initial portal and the virtual portals.

The master administrator has the necessary privileges to run the tasks that are related to managing virtual portals. Use either the **Virtual Portal Manager** portlet or the provided configuration tasks to complete these tasks. For information about these tools, go to *Administering virtual portals*.

The Virtual Portal Manager portlet is installed as part of the initial portal installation. You can use this portlet to create, modify, and delete virtual portals.

The master administrator defines the user population of each virtual portal. To separate the user populations of the virtual portals, the master administrator can either use the **User and Group Permissions** portlet or they can define realms in the Virtual Member Manager configuration files.

Before you create a virtual portal, you define a group of subadministrators. When you create the virtual portal, a default set of roles and access permissions is assigned to this group. As the master administrator, you can change these default assignments and delegate administration of individual virtual portals to subadministrators. Use the **Resource Permissions** portlet that is part of the Portal Access Control.

When you create a virtual portal, it is filled with a default set of portal pages and resources. You can further enhance the content of a virtual portal by either of the following ways:

- By the master administrator of the portal installation. For example, use the XML configuration interface.
- By the subadministrators or other users of the virtual portal. Use the **Manage Pages** portlet.

For information about the content of a virtual portal, go to *Content of a virtual portal*.

Typically, only the master administrator should have the access permissions for the following tasks:

- Using the Virtual Portal Manager portlet
- Using the XML configuration interface to run tasks that are related to one of the virtual portals
- Installing portlets, themes, and skins.

Note: Do not grant the subadministrators of virtual portals the access permissions to run any installation-related tasks, such as installation of portlets or themes. All virtual portals share a common Java virtual machine (JVM). Therefore, it is important to restrict the administration privileges of the virtual portal subadministrators and prevent them from installing their own code artifacts, such as themes or portlets. Unstable or malicious code that is introduced on one virtual portal can destabilize the entire portal installation and all other virtual portals. A flexible way to introduce virtual portal-specific portlets without impacting any other virtual portal is to use web services for remote portlets (WSRP). By using WSRP, you can provide portlets on a remote server and then have the virtual portals consume those portlets so that users can access them remotely. For more information about using WSRP with your portal, go to *Using WSRP services*.

For more information about Portal Access Control, go to *Controlling access*. For more information about virtual portal security, go to *Portal Access Control with virtual portals*.

View information to help you scope your WebSphere Portal Express to have multiple virtual portals.

Portal Access Control with virtual portals:

You can scope some portal resources for your virtual portals by using portal administration and Portal Access Control. For example, you can scope portlet applications. These resources are available to all virtual portals. You can scope these resources to specific virtual portals by limiting their accessibility to the user populations of the required virtual portals. To make this limit, you use Portal Access Control. Resources that you scoped this way for one virtual portal cannot be accessed from other virtual portals.

Portal Access Control provides a flexible concept to grant certain users or user groups access privileges to specific pages and other resources of a portal. A super administrator can delegate a subset of the administration privileges to other administrative users. You can use this flexibility to enable separation between different virtual portals in the following ways:

- Use the delegated administration model to set up individual partitions in your portal for the virtual portals.
- Define separate subadministrator users who administer the individual virtual portals and give each of the subadministrators the access permissions for their virtual portals.
- Define separate user populations who can access the individual virtual portals. For more detail about how this setting is supported see *Managing the user population for virtual portals*.

The inheritance concept of Portal Access Control allows this setup. The combination of access permissions that a subadministrator has on portal resources and on users and groups defines the scope of the virtual portal of that subadministrator:

- By inheritance, subadministrators of virtual portals implicitly have the administrative access permissions for all the child pages of their respective root content nodes, and of the content of their virtual portals. The subadministrator of a virtual portal cannot assign any access permission on resources that are scoped for other virtual portals.
- Depending on the access permissions to users and groups that the master administrator gives the subadministrators, they can grant access to users who belong to the user population of their virtual portals. The subadministrator of a virtual portal cannot assign any access permissions to users or groups of other virtual portals.

This way, each virtual portal represents a certain sub area of the main portal and can be managed individually.

Related concepts:

"Managing the user population for virtual portals" on page 1370
You have two basic options for the management of user populations for your virtual portals: Virtual Member Manager (VMM) or Lightweight Directory Access Protocol (LDAP).

Related information:

Technotes for virtual portals

Subadministrators of a virtual portal and their access roles and permissions:

When you create a virtual portal by using the Virtual Portal Manager portlet, you select a user group of subadministrators who you want to be responsible for the administration of the new virtual portal.

During the creation of the new virtual portal the Virtual Portal Manager portlet assigns the following default that is set of necessary access permissions on the virtual portal to the subadministrator group that you specified:

- Administrator role access permission on the root label of the virtual portal. You cannot change this access permission.
- Administrator role access permission on the virtual portal URL context. You cannot change this access permission.
- Editor role access permission on the administration portlets that are part of the virtual portal. You can change this access permission.

As the subadministrators have the Editor role access permissions on the administration portlets of their virtual portal, they can use these administration portlets to run administrative tasks on the virtual portal. For example, they can add portlets to pages. The default access permissions that are given to subadministrators of virtual portals are limited to managing the pages and documents in the virtual portal. Depending on your specific use case scenario, you might want to give the subadministrators extra permissions to manage more resources, or possibly users. Some of the permissions are not scoped to the virtual portal, but are global to the whole portal installation. This is particular critical for resources available in all virtual portals. For example, if you use a single realm for all virtual portals, the users are available in all virtual portals. A subadministrator who has the permissions to manage a user can manage that user in all virtual portals.

If you want to change the default access permissions for the subadministrators, use one of the following actions:

- If you want to change the default Editor access permission for the subadministrators on the administrative portlets or the list of portlets *globally* and *before* you create virtual portals, configure the Virtual Portal Manager portlet accordingly. For details about how to do this see *Pre-configuring the subadministrators for virtual portals*.
- If you want to assign extra access permissions to the subadministrators *specifically* and *after* creating a virtual portal, use the master administrator user ID of your initial portal installation and modify those access permissions for them manually in Portal Access Control. To do this, you can use the User and Group Permissions portlet, the Resource Permissions portlet, the XML configuration interface, or the Portal Scripting Interface. The consequences differ, depending on where you make the updates:
  - If you do this in the initial portal installation, you can change the access permissions for the subadministrators on the virtual portal as a whole.
  - If you do this in the virtual portal itself, you can change the access permissions for the subadministrators on the individual resources of the virtual portal.

The following list shows the tasks for which you can assign extra access permissions to subadministrators of virtual portals. It also specifies whether an access permission is scoped to the virtual portal or if it is global to the entire portal

installation, including all virtual portals. You can assign the permissions for these tasks to subadministrators only by using use the master administrator user ID of your initial portal installation.

Granting access permissions to users and groups of virtual portals
This task requires one of the following access permissions:

- Delegator on the group that defines the users of the virtual portal. This way is the preferred option, as the access permission is limited to the virtual portal.
- Delegator@Groups or Delegator@Users. Both of these access permissions apply globally to the entire portal installation, including all virtual portals.

Cloning portlet applications, for example, the web clipping portlet
This task requires Editor@Portlet Application. This access permission applies globally to the entire portal installation, including all virtual portals.

Access permissions for policies.
To manage policies, subadministrators need different access permissions, depending on the task that you want the subadministrative user to be able to complete. For example, to delete policies, a subadministrator needs Manager@Policy and User@Business Rules. This access permission is the highest permission. These access permissions apply globally to the entire portal installation, including all virtual portals.

Using the XML configuration interface
This task requires Security Administrator@Portal and Editor@XML access. These access permissions apply globally to the entire portal installation, including all virtual portals.

Managing portal search collections
This task requires Editor@Virtual Resource PSE_SOURCES. This access permission applies globally to the entire portal installation, including all virtual portals.

Managing URL mappings
This task requires Editor@parent context for parent mappings and Manager@context for URL mappings. These access permissions apply globally to the entire portal installation, including all virtual portals.

Managing tags and ratings
This task requires Manager@Tags and Manager@Ratings. These access permissions apply globally to the entire portal installation, including all virtual portals.

Managing personalization rules
This task requires the following access permissions:

- Privileged User on the following portlet applications:
  - Personalization Editors
  - Personalization Navigator
  - Personalization Picker
- Manager@the Personalization Rule

These access permissions apply globally to the entire portal installation, including all virtual portals.

Granting virtual portal administrators access to web content libraries
Virtual portal administrators do not automatically have access to work

with web content libraries when they are using the administration portlet. To enable a virtual portal administrator to work with web content libraries, you must assign them access to either the JCR content root node or individual web content libraries:

- You can assign virtual portal administrators access to the JCR content root node by using the `Set access on root` button in the Web Content Library view of the Administration portlet. For more information, see *Setting root access for all web content libraries* in the Portal Content help.
  - Assign virtual portal administrators administrator access to the JCR content root node to enable them to create new libraries and view, edit, and delete all existing libraries.
  - Assign virtual portal administrators contributor access to the JCR content root node to enable them to create new libraries and view, edit, and delete libraries that they created.
- You can also assign virtual portal administrators access to libraries they did not create by editing the access settings of individual libraries.

Templating sample content is provided by default with WebSphere Portal Express. This sample content is available from the Create Content tab of the site toolbar. If you want to use the sample content with a specific virtual portal, you must syndicate the following web content libraries to the virtual portal:

- `Template Page Content 3.0`
- `Web Content Templates 3.0`

If you fail to syndicate these libraries, the portal shows an error when you add the sample content to a page.

Technotes for virtual portals

Users of a virtual portal and their access roles and permissions:

When you create a virtual portal, you need to be aware of the implications listed here.

- The All Authenticated Users group is common across all virtual portals that share the same realm. When you create virtual portals, this group is given the Privileged User role on resources of all those virtual portals, independent of the role assignments that its users have on the initial portal installation. Restrict role assignments and thereby access permissions for the All Authenticated Users group, and assign access to user groups or users as required.

  Note that role assignments that you configured for users on the initial portal installation are not passed on to the virtual portal. For example, if you restricted access permissions to some virtual resources for users on the initial portal installation, these restrictions do not apply to the users in the context of the virtual portal.
- The All Authenticated Users group is valid over all virtual portals that share the same realm. This means that users who are in a realm that belongs to more than one virtual portal, these users have the assigned roles on all virtual portals to which they have access by membership to that realm.

If you want to change these default roles and the access permissions for the users, you can do this by one of the following ways:

- To configure the scope of access permissions for users *before* creating a virtual portal, configure your realms and user groups accordingly.
- To change the access permissions of users of a virtual portal *after* creating a virtual portal, use the Portal Access Control portlets in that virtual portal. You can have the sub-administrators of the virtual portal perform this task.

Technotes for virtual portals

Content of a virtual portal

The content of a newly created virtual portal can vary, depending on the method by which you create the virtual portal. You can change the pre-configured content for virtual portals.

When you create the virtual portal by using the Virtual Portal Manager portlet, the portlet starts an XML configuration interface script that creates the initial content of the new virtual portal. The content of a virtual portal is similar to that of a full portal installation, but some administration portlets that manage global portal settings are not included in the default content of virtual portals. For example, the administration portlet Virtual Portal Manager is installed as part of the initial portal installation only. It is not part of the default content of virtual portals that you create. You can use it only in the initial portal installation.

When the content is created, the Virtual Portal Manager portlet grants the following set of default roles and access permissions to the subadministrators of the virtual portal:

- Administrator to the content root (Administrator@content root) of the virtual portal
- Editor to portlet instances (Editor@portlet entities) that are created for the new virtual portal.

You can modify the roles and access permissions for the subadministrators of a virtual portal manually according to your business needs:

- To change the roles and access permissions for subadministrators on the portlets *globally* and *before* you create a virtual portal, configure the Virtual Portal Manager portlet accordingly. For details about how to do this see *Pre-configuring the subadministrators for virtual portals*.
- To change the roles and access permissions *specifically* and *after* creating a virtual portal, use the Portal Access Control portlets. If you do this change in the initial portal installation, you can change the access permissions on the virtual portal as a whole. If you do this change in the virtual portal itself, you can change the access permissions on the individual resources of the virtual portal.

If you want to change the content of virtual portals, it can be done by one of the following ways:

- To change the content *globally* and *before* creating a virtual portal, advanced master administrators can reconfigure the XML script that specifies the initial content for virtual portals. For details about how to do this see *Pre-configuring the default content for virtual portals.*

  Note: When you modify or replace this XML script, plan ahead and apply special care. You can add or remove some content to enhance or reduce the functionality of a virtual portal to a certain extent. The following portal resources are mandatory content of a virtual portal and must be included in a customized XML initialization script for virtual portals:
  - Content Root (`wps.content.root`)
  - Login (`wps.Login`)
  - Administration (`ibm.portal.Administration`).

  Depending on the functionality that you want to make available, more content is required. For example, to allow templating. Include Application Root (`wps.application.root`) and Templates (`ibm.portal.Templates`).
- To change the content *specifically* and *after* creating a virtual portal, use either of the following portal tools:
  - Use the Manage Pages portlet of the virtual portal. The subadministrator of the virtual portal can do this change.
  - Use the XML configuration interface to import content into the virtual portal. This procedure can be done only from the initial portal installation.

If you use the configuration task `create-virtual-portal` to create a virtual portal, the new virtual portal that you create is empty. You must create the content for the virtual portal. For example, you can do this by using the XML configuration interface. For more information, see *The XML configuration interface*.

Technotes for virtual portals

Shaping the user experience

You can improve the user experience that users have with your virtual portals by using human readable URLs, or by using custom themes and skins for your virtual portals.

"Human readable URL mappings for virtual portals"
You can provide human readable URLs for your users to access their virtual portals. For example, you can give each virtual portal a human readable URL, such as `http://www.ibm.com:10039/wps/portal/tivoli.` You can pass the human readable URL of a virtual portal to its users. They can then use it to access their virtual portal.

"Individual themes and skins for each virtual portal" on page 1385
If you expose multiple virtual portals on a single portal installation, you can give each virtual portal its own look and feel for the user experience.

Related information:

Technotes for virtual portals

Human readable URL mappings for virtual portals:

You can provide human readable URLs for your users to access their virtual portals. For example, you can give each virtual portal a human readable URL, such as `http://www.ibm.com:10039/wps/portal/tivoli.` You can pass the human readable URL of a virtual portal to its users. They can then use it to access their virtual portal.

When you create a virtual portal, you specify the human readable URL as required by your business environment. The URL mapping that you specify is assigned to the virtual portal during its initialization. The URL mapping points to the content root of the virtual portal.

Internally, this URL mapping corresponds to a unique name `wps.vp.`*`internal_ID_of_the_virtual_portal`*. The portal installation uses this unique name to identify and access the virtual portal unambiguously. The XML configuration interface and the Portal Scripting Interface also use this URL mapping to identify the virtual portal.

You can also specify extra URL mappings for a virtual portal, both for the content root or for other content of the virtual portal, for example, a page in the navigation of the virtual portal.

All URL mappings use the same context root and servlet name in the URL. This setting applies to both the initial URL mapping of a virtual portal and any additional URL mappings that you might create for it.

For more information, see *URL mappings*.

Notes:

1. There is a 1:1 relation between a virtual portal and its initial URL Mapping. Each mapped URL points to the root content node of one virtual portal. You cannot use the same URL Mapping for two different virtual portals.

2. You must not delete or modify the initial URL Mapping for a virtual portal or modify its unique name. Deleting this URL Mapping or modifying its unique name makes the virtual portal unusable. This setting is independent of whether you use the administration portlets URL Mapping or Custom Unique Names or the XML configuration interface to change the URL Mapping.
3. If you use an external security manager, such as Tivoli Access Manager, you can restrict the usage of virtual portals by using the URL Mappings. To restrict, you base the URL filtering rules of a security proxy on the URL Mappings that you defined. Block all URLs by default and explicitly enable the defined URL Mappings only.
4. A URL mapping that is defined for a resource in a particular virtual portal must use the same URL context as the human readable URL context for that virtual portal itself. Example: In a virtual portal that uses the human readable URL mapping `wps/portal/vp_1`, all URL mappings for portal resources must start with `wps/portal/vp_1`, for example `wps/portal/vp_1/url_1` and `wps/portal/vp_1/url_2`. Within this virtual portal, a URL mapping such as `wps/portal/url_1` is not valid, as the portion `vp_1` of the URL Context is missing.
5. There are some strings that you cannot use as URL mappings for virtual portals, for example `vp`. These strings are reserved names and correspond with URL codec names. They are listed in the following:

   ```
   a0,    a0_1,   a0_2,   a0_3,  a1,    a2, a3,
   base64xml
   b0,    b0_1,   b0_2,   b0_3,  b1,    b2, b3,
   c0,    c0_1,   c0_2,   c1,    c2,    c3, c4,  c4_1, c4_2, c4_3, c5, c6, c7,
   cxml,  cxml_1, cxml_2, cxmld, kcxml,
   d0,    d1,     d2,     d3,    d4,    d5, dl2, dl3,  dl4,  delta
   kcxml, nm1,    nm2,    nm3,   nm4,   p0, pw,
   resource,      sel,    s0,    t0,    vp, wml,
   z0,    z0_1,   z0_2,   z0_3,  z1,    z2, z3
   ```

   For more information see the topic about *Restrictions to names for URL mapping contexts*.

Technotes for virtual portals

Individual themes and skins for each virtual portal:

If you expose multiple virtual portals on a single portal installation, you can give each virtual portal its own look and feel for the user experience.

When you create virtual portals, the portal creates parallel root content nodes for each virtual portal. You can apply separate themes and skins for each content root and its child pages without impacting the representation of other content in the parallel trees for the other virtual portals. Each virtual portal will look like its own portal to its users. Users will not be aware that there are two or more different content nodes on the same physical portal installation.

You can apply the specific look and feel of each virtual portal to both the (unauthenticated) Welcome page and the authenticated pages of the virtual portal.

This means that each virtual portal can have its own look and feel even before the user logs in to the portal. Users can switch between the unauthenticated pages of different virtual portals by simply entering the different URL to get to the other portal. You can also provide specific login, and self-enrollment pages for each virtual portal. Once users log out, they are redirected to the specific unauthenticated page of the virtual portal that they had accessed.

Technotes for virtual portals

Virtual portals and managed pages

Virtual portals are created and managed through the portal administration interface with the Virtual Portal Manager portlet. When you create a virtual portal, a workspace is created that contains a new Portal Site web content library. Any managed pages that are created in the virtual portal are stored in the Portal Site library.

Because web content libraries are not shared across virtual portals, these pages are visible only within the virtual portal.

Syndication of the Portal Site library for a virtual portal is the same as syndication of any other web content library.

Administering virtual portals

View information to help you scope your WebSphere Portal Express to have multiple virtual portals.

Note: Before you start creating or administering virtual portals, read the information in *Planning for virtual portals*.

Administering virtual portals and their content comprises the following tasks:

- Administering the portal content and resources for virtual portals
- Administering the users for virtual portals
- Administering content and search with virtual portals

You can use the following tools to administer your virtual portals:

- The Virtual Portal Manager administration portlet
- Command line tools as follows:
  - You can use portal configuration tasks for administering virtual portals.
  - You can use the XML configuration interface to work with virtual portals.

The following table shows how you can use these portal tools to administer virtual portals:

Table 175. Administrative tasks and the portlets and other tools for these tasks

Administrative task	Portlet for this task	Configuration task	XML configuration interface
Configuring the sub-administrators for a virtual portal	Access control portlets	---	X
Creating a virtual portal	Virtual Portal Manager	X	---
Filling a virtual portal with initial content	Virtual Portal Manager	---	X
Listing all virtual portals	Virtual Portal Manager	X	---
Modifying a virtual portal	Virtual Portal Manager	X	---
Deleting a virtual portal	Virtual Portal Manager	X	---

Note: The following two administrative tasks are manual tasks:

- Adding and configuring the user repository for the virtual portal
- Pre-configuring virtual portals

The following sections provide more information about these administrative tasks and how you perform them. The portal configuration tasks for administering virtual portals are documented under *Portal configuration tasks for administering virtual portals*.

"Administering the portal content and resources for virtual portals"
When you create a virtual portal by using the Virtual Portal Manager portlet, the portlet also creates default portal content and resources for the virtual portal. This default content is determined by the default XML script file for initializing virtual portals. In general, you can administer portal resources for a virtual portal just like you do for a normal portal installation.

"Tasks for administering virtual portals" on page 1389
Administering virtual portals and their content comprises the tasks described in the following topics.

Technotes for virtual portals

"Working with the XML configuration interface" on page 1061
You can use the XML configuration interface to export and import IBM WebSphere Portal Express configurations. This way you can configure selected features or areas of your portal. You can also transfer a complete configuration from one portal to another.

Administering the portal content and resources for virtual portals

When you create a virtual portal by using the Virtual Portal Manager portlet, the portlet also creates default portal content and resources for the virtual portal. This

default content is determined by the default XML script file for initializing virtual portals. In general, you can administer portal resources for a virtual portal just like you do for a normal portal installation.

About this task

You must be aware that some resource types are scoped to a particular virtual portal and cannot be accessed from outside of that virtual portal. Such scoped portal resource types are assigned to only that one portal. Sharing of these resource types between virtual portals is not possible. This restriction is imposed by the portal system and provides a secure isolation between virtual portals. You cannot change this behavior.

Other resource types are not scoped. They are shared among all virtual portals of the same installation. If you want to restrict such resource types to particular virtual portals, you can define their visibility by using Portal Access Control. These access restrictions should usually be defined by the master administrator of the portal installation. For more information about scoping of portal resources for virtual portals, see *Planning for virtual portals* and *Separating and sharing resources between virtual portals*.

Procedure

- To change the content *globally* and *before* creating a virtual portal, modify the default XML script that specifies the initial content for virtual portals. For details about how to do this see *Pre-configuring the default content for virtual portals*.
- To change the content *specifically* and *after* creating a virtual portal, use either of the following portal tools:
  1. Use the Manage Pages portlet of the virtual portal. You can have the subadministrator of the virtual portal do this.
  2. Use the XML configuration interface to import content into the virtual portal. You can use this portal tool only from the initial portal installation.

  Note: When you create a virtual portal, the portlets that are associated with IBM Web Content Manager are not included in the virtual portal, even if you deployed these portlets as part of your original portal installation. To use any of these portlets in a virtual portal, you must manually create a page and add the portlets:
  - Authoring portlet: Select **Web Content Authoring** when you are adding the portlet.
  - Web Content Viewer portlet: Select **Web Content Viewer** when you are adding the portlet.

Managing the users of virtual portals:

You manage the users of virtual portals by adding and configuring the user repository and later administering the users for virtual portals.

"Adding and configuring the user repository for a virtual portal" on page 1390
For the user repository for your virtual portals, you have a choice of using either federated security or an LDAP.

"Administering the users for virtual portals" on page 1390
As the master administrator of the portal installation you assign administrative users for the virtual portals. These virtual portal sub-administrators can manage the access rights of the user population of the virtual portal for which they are responsible.

Related information:

Technotes for virtual portals

Adding and configuring the user repository for a virtual portal:

For the user repository for your virtual portals, you have a choice of using either federated security or an LDAP.

When you enable security on a portal installation, by default you have Federated Security as WebSphere Security provider. For details, review the section about Configuring the portal.

Related information:

Technotes for virtual portals

Administering the users for virtual portals:

As the master administrator of the portal installation you assign administrative users for the virtual portals. These virtual portal sub-administrators can manage the access rights of the user population of the virtual portal for which they are responsible.

When you use realms to separate the user populations of the virtual portals from each other, you need to configure the realms manually in a Virtual Member Manager configuration file. This is typically done by the master administrator of the portal installation.

When you create a virtual portal, be aware of the following implications:

- For scoped resources: Access rights that you configured for users on scoped resources of the initial portal installation are not passed on to similar resources of a virtual portal. This statement applies only to resources that are scoped for each virtual portal, such as pages or portlet instances, but not for shared resources. For example, if you restricted access rights to some pages or portlet instances for users on the initial portal installation, these restrictions do not apply for the users of the virtual portal. For more detailed information about scoped resources see *Planning for virtual portals* and *Separating and sharing resources between virtual portals*.
- The All Authenticated Portal Users group and the All Portal User Groups are valid over all portals that share the same realm. This means that users who are in a realm or user group that belongs to more than one virtual portal, these users have the assigned access rights on all virtual portals to which they have access.

If you want to change these default access rights for the users, you can do one of the following:

- To configure the scope of access rights for users *before* creating a virtual portal, configure your realms and user groups accordingly.
- To change the access rights of users of a virtual portal *after* creating a virtual portal, use the Portal Access Control portlets in that virtual portal. You can have the sub-administrators of the virtual portal perform this task.

Related concepts:

implement and configure your virtual portals.

"Separating and sharing resources between virtual portals" on page 1367
Separation between virtual portals is achieved by **scoping** the portal resources of the virtual portals. Scoping means making portal resources available uniquely and separately to individual virtual portals and their users.

Related information:

Technotes for virtual portals

Creating a virtual portal:

As a master administrator of the portal installation, you can create virtual portals by using the Virtual Portal Manager portlet.

When you create virtual portals, you specify the following attributes:

- The **title** of the virtual portal. This title is later displayed in the list of virtual portals in the Virtual Portal Manager portlet. The title is not visible for users of the virtual portal.
- A **description** for the virtual portal. This field is optional.
- Either a host name or a context for the virtual portal:
  - The portal **context** of the virtual portal. The context must be unique. The context is used to create the URL of the virtual portal. This URL is mapped to the actual internal URL of the virtual portal. You can give the friendly URL to the users of the virtual portal. They can use it to access the virtual portal without having to remember the internal URL.
  - A host name for the virtual portal. This attribute is optional. Use it to add a host name of your choice for the virtual portal. The portal uses that host name for the friendly URL of the virtual portal as follows: `http://your_host_name_example:port/wps/portal`. You can pass that friendly URL to your portal users for easier access to your portal.

    Notes:

    - This URL is used internally to access the virtual portal instance, even if you specify a context URL that is easy to use. Make sure that the host name that you specify here is accessible.
    - You cannot use the same virtual portal host name twice in the same portal installation.
    - After you create the virtual portal, you cannot change the host name that you specify for the virtual portal. If you must use a different host name for a virtual portal, see the topic about *Using a new host name for an existing virtual portal*.
    - If you use web content libraries, do not specify a context URL for the new virtual portal that matches the name of a library on your server. If the name of a library and the URL context of a virtual portal have the same value, incorrect rendering of web content can result.

  Notes:
  - You must specify either a host name or a context.
  - If you specify both a host name and a context, the host name takes precedence and the context is ignored.

  - There are some strings that you cannot use as URL mappings for virtual portals, for example `vp`. These strings are reserved names and correspond with URL codec names. For a list of these reserved strings, see *Shaping the user experience*.
  - Use only ASCII characters for the URL Context. For example, you cannot use a URL Context such as `språk`. If you use non-ASCII characters, the portal shows an error message such as the following `EJPAH2009E: Invalid characters were found in a context name or label`. Similarly, you cannot use escaped URL encoding either. For example, a URL Context such as `spr%E5k`.
- The **realm** that represents the user population for the virtual portal. This field is only shown if your portal configuration supports realms.

When you use the Virtual Portal Manager administration portlet to create the virtual portal, you can add the following additional parameters as well:

- The user group of **sub-administrators** who are able to administer the virtual portal.
- The **theme** of the virtual portal.

For details see, *Using the Virtual Portal Manager administration portlet*. As an alternative, you can also use the appropriate configuration task to create virtual portals. For details about the configuration tasks for administering virtual portals see, *Portal configuration tasks for administering virtual portals*. When you use the configuration task for creating a virtual portal, you need to deliver this information by using the XML configuration interface in a later step.

Notes:

1. Before you create a virtual portal, read the information in *Planning for virtual portals*.
2. If you use the configuration task `create-virtual-portal` to create a virtual portal, the virtual portal is created without content. For more information about filling a virtual portal with content, see *Filling a virtual portal with content*.
3. If you do not specify a virtual portal title in the language, which is either defined as the user-preferred language or defined in the user's browser, the display fallback uses the unique name if present, or a string version of the object ID. So, to display the virtual portal title and content root correctly, the administrator must select the preferred language for the portal user. Or the administrator must define the display language in the user's browser, according to the language in which the title is set. For information about the language search sequence, see *Selecting and changing the language*.
4. When you create a virtual portal, a workspace is created that contains a new portal site web content library. All managed pages that are created in the virtual portal are stored in the virtual portal site library. As web content libraries are not shared across virtual portals, such managed pages are visible only within the virtual portal. Syndication of the portal site library for a virtual portal is the same as syndication of any other web content library.

You can pre-configure the content and the sub-administrators for virtual portals. For details see, *Pre-configuring virtual portals*.

Technotes for virtual portals

Configuring the sub administrators for virtual portals:

You can administer the sub administrators of a virtual portal as required by using the Portal Access Control of your initial portal installation.

When you create a virtual portal by using the Virtual Portal Manager portlet, you select a user group of sub administrators. The sub administrators who you want to be responsible for the administration of the new virtual portal. During creation of the new virtual portal, the Virtual Portal Manager portlet creates a set of necessary access permissions on the virtual portal for the sub administrator group that you specified. This action includes EDITOR role access permissions on the administration portlets that are part of a virtual portal. As a result, the sub administrators of a virtual portal can do administrative tasks on the virtual portal with these administration portlets.

If you want to change the default access permissions for the subadministrators, use one of the following actions:

- If you want to change the default Editor access permission for the subadministrators on the administrative portlets or the list of portlets *globally* and *before* you create virtual portals, configure the Virtual Portal Manager portlet accordingly. For details about how to do this see *Pre-configuring the subadministrators for virtual portals*.
- If you want to assign extra access permissions to the subadministrators *specifically* and *after* creating a virtual portal, use the master administrator user ID of your initial portal installation and modify those access permissions for them manually in Portal Access Control. To do this, you can use the User and Group Permissions portlet, the Resource Permissions portlet, the XML configuration interface, or the Portal Scripting Interface. The consequences differ, depending on where you make the updates:
  - If you do this in the initial portal installation, you can change the access permissions for the subadministrators on the virtual portal as a whole.
  - If you do this in the virtual portal itself, you can change the access permissions for the subadministrators on the individual resources of the virtual portal.

Assigning additional access permissions to the sub administrators

Depending on the usage of your virtual portals, you might have to give the sub administrators extra access permissions on specific resources.

Note: Do not grant the sub administrators of virtual portals the access permissions to do any installation-related tasks, such as installation of portlets or themes. An unstable or malicious portlet that is installed in one virtual portal can destabilize the entire portal installation, as all virtual portals share Java virtual machine. Typically, only the master administrator of the portal installation can do installation-related tasks.

The following list shows the tasks for which you can assign extra access permissions to subadministrators of virtual portals. It also specifies whether an access permission is scoped to the virtual portal or if it is global to the entire portal installation, including all virtual portals. You can assign the permissions for these tasks to subadministrators only by using use the master administrator user ID of your initial portal installation.

Granting access permissions to users and groups of virtual portals
This task requires one of the following access permissions:

- Delegator on the group that defines the users of the virtual portal. This way is the preferred option, as the access permission is limited to the virtual portal.
- Delegator@Groups or Delegator@Users. Both of these access permissions apply globally to the entire portal installation, including all virtual portals.

Cloning portlet applications, for example, the web clipping portlet
This task requires Editor@Portlet Application. This access permission applies globally to the entire portal installation, including all virtual portals.

Access permissions for policies.
To manage policies, subadministrators need different access permissions, depending on the task that you want the subadministrative user to be able to complete. For example, to delete policies, a subadministrator needs Manager@Policy and User@Business Rules. This access permission is the highest permission. These access permissions apply globally to the entire portal installation, including all virtual portals.

Using the XML configuration interface
This task requires Security Administrator@Portal and Editor@XML access. These access permissions apply globally to the entire portal installation, including all virtual portals.

Managing portal search collections
This task requires Editor@Virtual Resource PSE_SOURCES. This access permission applies globally to the entire portal installation, including all virtual portals.

Managing URL mappings
This task requires Editor@parent context for parent mappings and Manager@context for URL mappings. These access permissions apply globally to the entire portal installation, including all virtual portals.

Managing tags and ratings
This task requires Manager@Tags and Manager@Ratings. These access permissions apply globally to the entire portal installation, including all virtual portals.

Managing personalization rules
This task requires the following access permissions:

- Privileged User on the following portlet applications:
  - Personalization Editors
  - Personalization Navigator
  - Personalization Picker
- Manager@the Personalization Rule

These access permissions apply globally to the entire portal installation, including all virtual portals.

Granting virtual portal administrators access to web content libraries
Virtual portal administrators do not automatically have access to work with web content libraries when they are using the administration portlet. To enable a virtual portal administrator to work with web content libraries, you must assign them access to either the JCR content root node or individual web content libraries:

- You can assign virtual portal administrators access to the JCR content root node by using the `Set access on root` button in the Web Content Library view of the Administration portlet. For more information, see *Setting root access for all web content libraries* in the Portal Content help.
  - Assign virtual portal administrators administrator access to the JCR content root node to enable them to create new libraries and view, edit, and delete all existing libraries.
  - Assign virtual portal administrators contributor access to the JCR content root node to enable them to create new libraries and view, edit, and delete libraries that they created.
- You can also assign virtual portal administrators access to libraries they did not create by editing the access settings of individual libraries.

Templating sample content is provided by default with WebSphere Portal Express. This sample content is available from the Create Content tab of the site toolbar. If you want to use the sample content with a specific virtual portal, you must syndicate the following web content libraries to the virtual portal:

- `Template Page Content 3.0`
- `Web Content Templates 3.0`

If you fail to syndicate these libraries, the portal shows an error when you add the sample content to a page.

The configuration task `create-virtual-portal` does not assign roles to the sub administrators of the virtual portal. In this case, you assign the required roles manually by using the portal access administration portlets or by using the portal XML configuration interface. For more information about the XML configuration interface and how to use it see, *The XML configuration interface*.

Technotes for virtual portals

Modifying a virtual portal:

You can modify a virtual portal by using either the Virtual Portal Manager portlet or the appropriate configuration task.

You can use the Virtual Portal Manager portlet to change the following settings of an existing virtual portal:

- The title of the virtual portal.
- The description of the virtual portal.
- The realm of the virtual portal.

  Note: Apply special care when you are changing the realm of a virtual portal. Changing the realm of a virtual portal might change the users and groups who have access to the virtual portal and to resources of that virtual portal. This includes the possibility that the sub-administrator of the virtual portal can lose the rights to administer the portal. If this happens, change the realm back to the original realm by using the **initial** portal installation as an administrative interface.
- The theme of the virtual portal.

Related reference:

"Task: modify-virtual-portal" on page 1411
Portal ConfigEngine task that modifies a virtual portal.

Related information:

Technotes for virtual portals

Deleting a virtual portal:

You can delete a virtual portal by using the Virtual Portal Manager portlet.

Note: You cannot delete the initial portal installation.
After the virtual portal resource is deleted, the scoped resources of that particular virtual portal are deleted later by a scheduled cleanup service. The URL mapping that was created when the virtual portal was created is also deleted. The following resources are not deleted:

- The unscoped resources that were available in the virtual portal; they belong to the initial portal installation and are therefore not deleted.
- Extra URL mappings which administrators might have created manually are not deleted.

Note: If you delete a virtual portal and you want to create a new virtual portal immediately after the deletion by using the same URL context, you do not have to wait for the scheduled cleanup service. Run the cleanup task for deleting resources by running the XML script `Task.xml` of the XML configuration interface. Then, you can create the new virtual portal. For details, see *Working with the XML configuration interface*.

Preparing the deletion of virtual portals

Virtual portals can be created in environments where multiple portal installations share database domains, such as Community or Customization. This environment can be in a staging environment or for different lines of production. In this case some portal resources, such as page customization within a virtual portal, can be visible in several of these installations. If you delete a virtual portal, then this portal installation cannot determine whether the corresponding resources can be deleted or if they are still valid in the context of other portal installations and must be preserved. It is the responsibility of the portal administrator to decide whether clean-up of related resources that are in shareable database domains is required before a virtual portal is deleted. The administrator must decide whether these resources are obsolete or still in use. You can complete the cleanup in two ways:

- Manual cleanup of virtual portal resources in shared database domains. To clean up manually, proceed as follows:
  1. Connect to the virtual portal that you want to delete.
  2. Clean up the two database domains Community and Customization. Run the XML configuration scripts `DeleteSharedCommunityContent.xml` and `DeleteSharedCustomizationContent.xml`.
  3. Delete the virtual portal.
- Automated cleanup of virtual portal resources in shared database domains. Run the configuration task `delete-virtual-portal` and specify either the URL context or the host name of the virtual portal that you want to delete. Example syntax for both options:
  - For IBM i:

```
- ConfigEngine.sh delete-virtual-portal
                  -DremoveResourcesInSharedDomains=true
                  -DVirtualPortalContext=URL_context_of_the_VP
- ConfigEngine.sh delete-virtual-portal
                 -DremoveResourcesInSharedDomains=true
                 -DVirtualPortalHostName=host_name_of_the_VP
```

  - For Linux:

```
- ConfigEngine.sh delete-virtual-portal
                  -DremoveResourcesInSharedDomains=true
                  -DVirtualPortalContext=URL_context_of_the_VP
- ConfigEngine.sh delete-virtual-portal
                 -DremoveResourcesInSharedDomains=true
                 -DVirtualPortalHostName=host_name_of_the_VP
```

  - For Windows:

```
- ConfigEngine.bat delete-virtual-portal
                   -DremoveResourcesInSharedDomains=true
                   -DVirtualPortalContext=URL_context_of_the_VP
```

```
- ConfigEngine.bat delete-virtual-portal
                  -DremoveResourcesInSharedDomains=true
                  -DVirtualPortalHostName=host_name_of_the_VP
```

For a list of database domains that can be shared, read the topic about Shared database domains and sharing database domains for your environment.

Cleaning up remaining resources if a virtual portal has been deleted already

If a virtual portal was deleted already without prior cleanup of resources in shareable database domains, and if these resources cannot be accessed by any other portal installation that shares the database domains, proceed by the following steps to remove the remaining resources:

1. Run the cleanup task for deleting resources by running the XML script `Task.xml` of the XML configuration interface.
2. Re-create the virtual portal that was deleted by using the identical URL mapping.
3. Follow the instructions to delete a virtual portal, including cleanup of resources in shareable database domains. This cleanup was described in the preceding section about Preparing for the deletion of virtual portals.

Pre-configuring virtual portals

When you use the Virtual Portal Manager portlet to create a virtual portal, the portlet creates the new virtual portal with default portal content and resources. It also creates default access rights for the virtual portal sub-administrators on those resources. You can modify both the default portal content and the default access rights for the sub-administrators *globally* and *before* creating a virtual portal.

"Pre-configuring the default content for virtual portals"
When you create the virtual portal by using the Virtual Portal Manager portlet, the virtual portal is pre-filled with default content. This default content is determined by the default XML script file for initializing virtual portals.

"Pre-configuring the subadministrators for virtual portals" on page 1402
You can configure the roles and access rights that are assigned to subadministrators on portlets of a virtual portal *globally* and *before* you create a virtual portal. The following steps must be completed on your initial portal installation.

Related information:

 Technotes for virtual portals

Pre-configuring the default content for virtual portals:

When you create the virtual portal by using the Virtual Portal Manager portlet, the virtual portal is pre-filled with default content. This default content is determined by the default XML script file for initializing virtual portals.

About this task

This file can have different names, for example, `InitVirtualPortal.xml`, or `InitVirtualContentPortal.xml`, or `InitAdminVirtualPortal.xml`, depending on your portal installation. It is in a WebSphere Application Server asset named `VirtualPortal.zip`. To get to this file, access the WebSphere Integrated Solutions Console, select **Applications** > **Application Types** > **Assets**, and locate the file in the list.

To find out which of these xml files is used for creating virtual portals in your installation, select **Manage Virtual Portals** to open **Virtual Portal Manager** portlet and select the option **Edit Shared Settings** from the portlet menu. This shows the WebSphere Application Server asset name and the XML file name inside that asset. To find out which content virtual portals have that you create, review the XML script file under the location that was given earlier.

Advanced master administrators can customize the default content for virtual portals as required by modifying or replacing the XML script that specifies the initial content for virtual portals.

Note: When you modify or replace this XML script, plan ahead and apply special care. You can add or remove some content to enhance or reduce the functionality of a virtual portal to a certain extent. The following portal resources are mandatory content of a virtual portal and must be included in a customized XML initialization script for virtual portals:

- Content Root (`wps.content.root`)
- Login (`wps.Login`)
- Administration (`ibm.portal.Administration`).

Depending on the functionality that you want to make available, more content is required. For example, to allow templating. Include Application Root (`wps.application.root`) and Templates (`ibm.portal.Templates`).

Procedure

1. Add your custom XML script to a WebSphere Application Server asset. To make this addition, proceed as follows:
   a. Export the file `VirtualPortal.zip` from your portal server.
   b. Log in to the WebSphere Integrated Solutions Console.
   c. Click **Applications** > **Application Types** > **Assets**.
   d. Select `VirtualPortal.zip`.
   e. Click **Export**.
   f. Make a copy of the exported `.zip` file, and name the copy `my_VirtualPortal.zip` or similar.
   g. Add your custom virtual portal script to your copy of the `.zip` file. For example, the script file can be `my_InitVirtualPortal.xml`. To add the script, use a utility program for `.zip` files.
   h. Log in to the WebSphere Integrated Solutions Console.
   i. Click **Applications** > **Application Types** > **Assets**.
   j. Click **Import**.
   k. Select your updated copy of the `.zip` file, for example `my_VirtualPortal.zip` .
   l. Click **Next** > **Next** > **Finish**.
   m. Save your changes to the master configuration.
2. Open the Manage Virtual Portals portlet by clicking the **Administration menu** icon. Then, click **Virtual Portals** > **Manage Virtual Portals**.
3. Open the **Manage Virtual Portals** portlet menu by clicking the dropdown arrow and select the option **Edit Shared Settings**.
4. Edit the SCRIPT_INIT_VP parameter of the portlet. Replace the current value with the name of your custom XML script and custom asset compressed (.zip) file. You can specify this attribute as a file inside a WebSphere Application Server asset by using a syntax such as this:

   `WebSphere:assetname=`*`my_VirtualPortal.zip`*`:`*`my_InitVirtualPortalScript.xml`*

   where `my_VirtualPortal.zip` is the name of your asset and `my_InitVirtualPortalScript.xml` is the name of a file inside the asset. Do not update the default asset `VirtualPortal.zip` installed with WebSphere Portal Express. Instead, create and maintain a separate second asset independent of the default asset `VirtualPortal.zip`.
5. Optional: If you want to create only an empty virtual portal with no content, you can specify the value for this parameter as follows: `WebSphere:assetname=VirtualPortal.zip:InitEmptyVirtualPortal.xml`.
6. Click **OK** twice to save your changes.

Related information:

Technotes for virtual portals

Pre-configuring the subadministrators for virtual portals:

You can configure the roles and access rights that are assigned to subadministrators on portlets of a virtual portal *globally* and *before* you create a virtual portal. The following steps must be completed on your initial portal installation.

Procedure

1. Click the **Administration menu** icon. Then, click **Portlet Management** > **Portlets**. Then, click **Manage Portlets** .
2. In the list of portlets, locate the Virtual Portal Manager portlet.
3. Click the **Configure Portlet** (wrench) icon of the Virtual Portal Manager portlet.
4. Perform the following steps, depending on the requirements for your virtual portals:
   a. If you want to change the list of portlets, to which the subadministrators have access:
      1) Edit the **portletListNeedAccess** parameter of the portlet. Remove those portlets for which you want the subadministrators of your virtual portals to have no access rights.
      2) Add portlets as required by adding the unique names of the portlets to the list. You might need to take a note of the list and remove the parameter, and then enter the parameter with your updated list.

      The default list contains all portlets that are listed under Content of a virtual portal.
   b. If you want to change the access rights that are granted to the subadministrators on the portlets of virtual portals, edit the **actionSetName** parameter of the portlet and change the role that you want to assign to the subadministrators to the role that fits your requirements. The default role is EDITOR. You might need to take a note of the parameter and remove it, and then reenter the parameter with the updated value. You can enter the following values: Administrator, Security Administrator, Delegator, Manager, Privileged User, User.

      Note: Subadministrators have the roles that you assign to them on *all* the portlets that are listed under the **portletListNeedAccess** parameter of the Virtual Portal Manager portlet (see the previous step).
5. Click **OK** to save your changes.
6. Assign the virtual portal subadministrators administrator rights on the JCR root as required.

Technotes for virtual portals

Using the Virtual Portal Manager administration portlet

After you complete a regular portal installation, the portal is ready and enabled for implementing virtual portals. For improved manageability of virtual portals, WebSphere Portal Express provides a portlet for administering virtual portals. It is named Virtual Portal Manager. It enables the creation of extra virtual portals as you need. You can also use it to list, modify, or delete virtual portals in your portal.

About this task

Creating a virtual portal

When you create a new virtual portal, you enter or select the following properties for the new virtual portal as required:

- The title for the new virtual portal. The title is later displayed in the list of virtual portals in the Virtual Portal Manager portlet. The title is not visible for users of the virtual portal. This field is limited to 255 characters.
- A description of the new virtual portal. This attribute is optional. This field is limited to 255 characters.
- Either a host name or a context for the virtual portal:
  - A human readable URL context that is used for accessing the virtual portal. You can set a URL that can be easily remembered and is therefore more easy to use than the actual full portal URL. The portal maps the friendly URL to the internal URL of the virtual portal. To do this mapping, it uses the portal URL Mapping feature. The string that you enter is used as the last part of the URL of the virtual portal and is appended to `http://www.example.com/wps/portal/`.

    Notes:

    - The URL context for each virtual portal must be unique.
    - All virtual portal URL contexts must be built from the root context for the portal server and must be unique. They cannot be subcontexts. For example, this URL is invalid:

      ```
      http://www.example.com/wps/portal/vp1/vp2
      ```

      This is the correct format:

      ```
      http://www.example.com/wps/portal/vp2
      ```
    - Use only ASCII characters for the URL Context of the virtual portal. Non-ASCII characters are not allowed for the URL Context. Examples: `språk` or **Düne**. Using non-ASCII characters results in an error message such as the following one:

      ```
      EJPAH2009E: Invalid characters were found in a context name or label
      ```

      Similarly, do not use escaped URL encoding either. For example, a URL Context of `spr%E5k` is not allowed.
  - A host name for the virtual portal. This attribute is optional. Use it to add a host name of your choice for the virtual portal. The portal uses that host name for the friendly URL of the virtual portal as follows: `http://`*`your_host_name_example`*`:`*`port`*`/wps/portal`. You can pass that friendly URL to your portal users for easier access to your portal.

    Notes:

    - This URL is used internally to access the virtual portal instance, even if you specify a context URL that is easy to use. Make sure that the host name that you specify here is accessible.
    - You cannot use the same virtual portal host name twice in the same portal installation.
    - After you create the virtual portal, you cannot change the host name that you specify for the virtual portal. If you must use a different host name for a virtual portal, see the topic about *Using a new host name for an existing virtual portal*.

- If you use web content libraries, do not specify a context URL for the new virtual portal that matches the name of a library on your server. If the name of a library and the URL context of a virtual portal have the same value, incorrect rendering of web content can result.

Notes:

– You must specify either a host name or a context.
– If you specify both a host name and a context, the host name takes precedence and the context is ignored.
– There are some strings that you cannot use as URL mappings for virtual portals, for example `vp`. These strings are reserved names and correspond with URL codec names. For a list of these reserved strings, see *Shaping the user experience*.
– Use only ASCII characters for the URL Context. For example, you cannot use a URL Context such as `språk`. If you use non-ASCII characters, the portal shows an error message such as the following `EJPAH2009E: Invalid characters were found in a context name or label`. Similarly, you cannot use escaped URL encoding either. For example, a URL Context such as `spr%E5k`.

- The Virtual Member Manager realm that contains the user population of the virtual portal. This entry field is only shown if your portal installation supports realms. If you leave the realm field blank, the user population is the same as for the default realm. If you use a single common user repository for all virtual portals, for example the WebSphere Application Server LDAP custom user registry, this entry field is not shown.
- The initial subadministrator user group for the virtual portal. The portal gives this group administrator access rights on the Content Root node of the new virtual portal and all its child pages. This group must be within the realm that is specified for the virtual portal.
- The Default theme that is applied to the pages of the virtual portal. You select the default theme from a pull-down list. By the default configuration for virtual portals a subadministrator cannot change that default theme, unless you change the roles and access rights give to the subadministrator.

After you enter this information, you create the new virtual portal. With that information the portlet triggers a sequence of processes to establish the new virtual portal. These processes include:

- Creating a new root content node for the virtual portal.
- Creating the new URL mapping to point to the new root content node.
- Assigning the selected theme to the new root content node.
- Granting the specified administrator group the action set for the Administrator role on the new root content node and on the new virtual portal.
- Calling the XML configuration interface script to create the initial content tree. This includes virtual portal specific instances of the following portal resources: Favorites, Administration, Home, Manage Portlets, and Page Customizer with the corresponding concrete portlets. To change the content *globally* and *before* creating a virtual portal, modify

the XML script that specifies the initial content for virtual portals. For details about how to do this see *Pre-configuring the default content for virtual portals*.

- Assigning default roles and access rights to subadministrators and users on the created resources.

Modifying or editing a virtual portal
You can modify the title and description of the virtual portal. You can also set locale-specific titles and descriptions.

Reinitializing a virtual portal
Applies the `InitVirtualPortal.xml` script again and re-creates the default content of a virtual portal. If you replaced the default XML script with your own and configured the Virtual Portal Manager portlet accordingly, your custom script is reapplied. Resources that you removed from the default content are re-created.

Note: Resources that you added to the default content remain in the virtual portal.

Deleting a virtual portal
Deletes the virtual portal, its initial URL mapping, and all the corresponding scoped resources.

Note: This does not delete the unscoped resources from the initial portal installation or extra URL mappings that administrators created.

Portal configuration tasks for administering virtual portals:

You can use configuration tasks for administering virtual portals.

WebSphere Portal Express provides the following configuration tasks that you can use to perform the following work with virtual portals:

- Create virtual portals
- List all virtual portals
- Modify a virtual portal
- Delete a virtual portal.

Before you use these configuration tasks, read the topics about *Planning for virtual portals* and *Administering virtual portals* carefully. For details about the configuration program and about how to use the configuration tasks see *Configuring*.

You pass the parameters in the parameter list for each configuration task as appropriate. You do this by either of the following methods:

- Specifying the parameter and value that is preceded by `-D` on the command line.
- Defining them in the file `wkplc.properties`.

Note: The property file must be encoded in the ISO 8859-1 character encoding format.

"Task: create-virtual-portal" on page 1407
Portal ConfigEngine task that creates a new virtual portal.

"Task: assign-virtual-portal-admin-group" on page 1409
Portal ConfigEngine task that assigns a group of administrators to a virtual portal.

"Task: list-all-virtual-portals" on page 1410

Chapter 5, "Configuring," on page 231
Run the following tasks after you install and deploy IBM WebSphere Portal Express. They address tasks that are typically run one time and have a global effect. Some configuration changes are made more frequently or do not have a global effect. These tasks are addressed in the Administering section.

Related information:

 Technotes for virtual portals

"Administering virtual portals" on page 1386
View information to help you scope your WebSphere Portal Express to have multiple virtual portals.

Task: create-virtual-portal:

Portal ConfigEngine task that creates a new virtual portal.

Use the **`create-virtual-portal`** task to create a new virtual portal. This task creates the virtual portal itself, but it does not create any default content for the virtual portal or grant any access permissions to the virtual portal administrators. You need to run these tasks separately after you create the virtual portal. For example, you can use the XML configuration interface create content and grant access permissions. For details, about the access permissions that are required for virtual portal administrators, see the section *Configuring the sub-administrators for virtual portals.*. For details about how to use the XML configuration interface see *The XML configuration interface*.

Parameters

`VirtualPortalTitle`
The title of the virtual portal.

This option is required.

`VirtualPortalRealm`
The realm of the virtual portal.

This input is required if you have realms that are enabled in your portal installation. If you do not have realms that are enabled, do not specify a value for the realm.

Virtual portal context or host name

You can address virtual portals by using either a portal context or a virtual host name. If you specify a host name, the context is ignored:

VirtualPortalContext

The portal context of the virtual portal. The context must be unique.

If you set the host name parameter that is described later, the `VirtualPortalContext` parameter is ignored.

Either the host name or the context option is required.

VirtualPortalHostName

The host name of the virtual portal.

If you specify the host name, the portal uses the host name, and the `VirtualPortalContext` parameter is ignored.

You cannot use the same virtual portal host name twice in the same portal installation.

After you create the virtual portal, you cannot change the host name that you specified for the virtual portal.

Either the host name or the context option is required.

VirtualPortalObjectId

The Object ID is used to reference the virtual portal. If VirtualPortalObjectId is not specified, a new VirtualPortalID is generated.

VirtualPortalNlsFile

The national language support (NLS) file for the virtual portal. Provide the path and file name of your national language support file. This input is optional.

You can create your own national language support file to specify more titles and descriptions in other languages for your virtual portal.

If you specify an NLS file, the value that is given for the virtual portal title in that NLS file overrides the title that you specify by the `VirtualPortalTitle` input parameter.

If you specify an NLS file, do not use prefixes in that NLS file.

If you do not specify an NLS file, the virtual portal is created with the title that you give as the value to the `VirtualPortalTitle` input parameter only. But the virtual portal is created without titles in other languages and without descriptions. If you specify no NLS file, the value that you specify by the `VirtualPortalTitle` input parameter shows to users as the title of the virtual portal in all language environments. This action is independent of the system and browser locale and the user preferences.

If you want to pass a description for the virtual portal to the configuration task, you must specify this action in the NLS file.

For more information about the NLS file and its format, see the *Command reference for the Portal Scripting Interface* and then under the section *Property File Format*.

For a list of the languages that are available with WebSphere Portal Express and their language codes refer to *Language support*.

Syntax

You pass the parameters in the parameter list for each configuration task as appropriate. You do this by either of the following methods:

- Specifying the parameter and value that is preceded by `-D` on the command line.
- Defining them in the file `wkplc.properties`.

Note: The property file must be encoded in the ISO 8859-1 character encoding format.

IBM i

```
ConfigEngine.sh create-virtual-portal -DWasPassword=password
-DPortalAdminPwd=password -DVirtualPortalTitle=MyVirtualPortalTitle
-DVirtualPortalContext=virtual_portal_context_url
```

Linux

```
./ConfigEngine.sh create-virtual-portal -DWasPassword=password
-DPortalAdminPwd=password -DVirtualPortalTitle=MyVirtualPortalTitle
-DVirtualPortalContext=virtual_portal_context_url
```

Windows

```
ConfigEngine.bat create-virtual-portal -DWasPassword=password
-DPortalAdminPwd=password -DVirtualPortalTitle=MyVirtualPortalTitle
-DVirtualPortalContext=virtual_portal_context_url
```

Technotes for virtual portals

Task: assign-virtual-portal-admin-group:

Portal ConfigEngine task that assigns a group of administrators to a virtual portal.

Use this task after the creation of a virtual portal to assign a subadministrator group to the virtual portal. This task gives this group permission on the root content node of the virtual portal and all its child pages. The task also gives Editor role access to the administration portlets of the virtual portal. This group must be within the realm that is specified for the virtual portal.

Parameters

VirtualPortalAdminGroup
The full DN (distinguished name) of the administrator group.

Virtual portal context or host name
You address the virtual portal by using either the portal context or the virtual host name, depending on what you specified when you created the virtual portal. If you specified both, specify the host name here.

VirtualPortalContext
The portal context of the virtual portal.

VirtualPortalHostName
The host name of the virtual portal.

Syntax

You pass the parameters in the parameter list for each configuration task as appropriate. You do this by either of the following methods:

- Specifying the parameter and value that is preceded by `-D` on the command line.
- Defining them in the file `wkplc.properties`.

Note: The property file must be encoded in the ISO 8859-1 character encoding format.

IBM i

```
ConfigEngine.sh assign-virtual-portal-admin-group
-DVirtualPortalAdminGroup=cn=vpadmins,o=defaultwimfilebasedrealm
-DVirtualPortalContext=mynewvp -DPortalAdminPwd=password
-DWasPassword=password
```

Linux

```
./ConfigEngine.sh assign-virtual-portal-admin-group
-DVirtualPortalAdminGroup=cn=vpadmins,o=defaultwimfilebasedrealm
-DVirtualPortalContext=mynewvp -DPortalAdminPwd=password
-DWasPassword=password
```

Windows

```
ConfigEngine.bat assign-virtual-portal-admin-group
-DVirtualPortalAdminGroup=cn=vpadmins,o=defaultwimfilebasedrealm
-DVirtualPortalContext=virtual_portal_context_url
-DPortalAdminPwd=password -DWasPassword=password
```

Note: You can create a virtual portal and assign the administrator group in the same command. For example, you can specify it as: `./ConfigEngine.sh create-virtual-portal assign-virtual-portal-admin-group -DVirtualPortalAdminGroup=cn=vpadmins,o=defaultwimfilebasedrealm -DVirtualPortalContext=virtual_portal_context_url -DVirtualPortalTitle=mynewvptitle -DPortalAdminPwd=password -DWasPassword=password`

Technotes for virtual portals

Task: list-all-virtual-portals:

Portal ConfigEngine task that lists all virtual portals.

Use this task to list all your virtual portals, together with the following information:

- The title of the virtual portal
- The description of the virtual portal
- The realm of the virtual portal
- The object ID of the virtual portal.

Parameters

This task does not take any parameters.

Syntax

IBM i

```
ConfigEngine.sh list-all-virtual-portals -DPortalAdminPwd=password
-DWasPassword=password
```

Linux

```
./ConfigEngine.sh list-all-virtual-portals -DPortalAdminPwd=password
-DWasPassword=password
```

Windows

```
ConfigEngine.bat list-all-virtual-portals -DPortalAdminPwd=password
-DWasPassword=password
```

Related information:

Technotes for virtual portals

Task: modify-virtual-portal:

Portal ConfigEngine task that modifies a virtual portal.

Parameters

Use this task to modify a virtual portal by using its object ID. To determine the correct object ID of the virtual portal, use the task `list-all-virtual-portals`.

VirtualPortalObjectId
The object ID of the virtual portal. This input is mandatory for identification of the virtual portal that you want to modify.

VirtualPortalRealm
The realm of the virtual portal. You can and must specify a realm only if you have realms that are enabled in your portal installation.

VirtualPortalNlsFile
The national language support (NLS) file for the virtual portal. Provide the path and file name of your national language support file. This input is optional.

You can create your own national language support file to specify more titles and descriptions in other languages for your virtual portal.

If you specify an NLS file, the value that is given for the virtual portal title in that NLS file overrides the title that you specify by the `VirtualPortalTitle` input parameter.

If you specify an NLS file, do not use prefixes in that NLS file.

If you do not specify an NLS file, the virtual portal is created with the title that you give as the value to the `VirtualPortalTitle` input parameter only. But the virtual portal is created without titles in other languages and without descriptions. If you specify no NLS file, the value that you specify by the `VirtualPortalTitle` input parameter shows to users as the title of the virtual portal in all language environments. This action is independent of the system and browser locale and the user preferences.

If you want to pass a description for the virtual portal to the configuration task, you must specify this action in the NLS file.

For more information about the NLS file and its format, see the *Command reference for the Portal Scripting Interface* and then under the section *Property File Format*.

For a list of the languages that are available with WebSphere Portal Express and their language codes refer to *Language support*.

Syntax

You pass the parameters in the parameter list for each configuration task as appropriate. You do this by either of the following methods:

- Specifying the parameter and value that is preceded by `-D` on the command line.
- Defining them in the file `wkplc.properties`.

Note: The property file must be encoded in the ISO 8859-1 character encoding format.

IBM i

```
ConfigEngine.sh modify-virtual-portal -DPortalAdminPwd=password
-DWasPassword=password
```

Linux

```
./ConfigEngine.sh modify-virtual-portal -DPortalAdminPwd=password
-DWasPassword=password
```

Windows

```
ConfigEngine.bat modify-virtual-portal -DPortalAdminPwd=password
-DWasPassword=password
```

Task: delete-virtual-portal:

Portal ConfigEngine task that deletes a virtual portal.

Parameters

Use this task to delete a virtual portal by using its object ID. To determine the correct object ID of the virtual portal, use the task `list-all-virtual-portals`.

`VirtualPortalObjectId`
The object ID of the virtual portal. This input is mandatory for identification of the virtual portal that you want to delete.

Syntax

You pass the parameters in the parameter list for each configuration task as appropriate. You do this by either of the following methods:

- Specifying the parameter and value that is preceded by `-D` on the command line.
- Defining them in the file `wkplc.properties`.

Note: The property file must be encoded in the ISO 8859-1 character encoding format.

IBM i

```
ConfigEngine.sh delete-virtual-portal -DPortalAdminPwd=password
-DWasPassword=password
-DVirtualPortalObjectId=objectID_of_virtual_portal_to_delete
```

Linux

```
./ConfigEngine.sh delete-virtual-portal -DPortalAdminPwd=password
-DWasPassword=password
-DVirtualPortalObjectId=objectID_of_virtual_portal_to_delete
```

Windows

```
ConfigEngine.bat delete-virtual-portal -DPortalAdminPwd=password
-DWasPassword=password
-DVirtualPortalObjectId=objectID_of_virtual_portal_to_delete
```

Technotes for virtual portals

Using a single configuration task to administer multiple virtual portals:

You can administer multiple virtual portals by running a single configuration command. The following configuration tasks support working with multiple virtual portals: `create-virtual-portal`, `delete-virtual-portal`, and `modify-virtual-portal`. Use the `-DvirtualPortalList` parameter with task to create, delete, or modify multiple virtual portals at the same time.

About this task

Specify the virtual portal property sets in the file `wkplc.properties` that is used with the configuration tasks. When you run the configuration task, you pass the list of virtual portals by using the parameter `-DvirtualPortalList`.

Here is an example for creating two virtual portals:

Procedure

1. Specify the two virtual portal property sets in the file `wkplc.properties` as follows:

```
vp1.VirtualPortalTitle=vp1
vp1.VirtualPortalRealm=
vp1.VirtualPortalHostName=
vp1.VirtualPortalContext=vp1
vp1.VirtualPortalNlsFile=

vp2.VirtualPortalTitle=vp2
vp2.VirtualPortalRealm=
vp2.VirtualPortalHostName=
vp2.VirtualPortalContext=vp2
vp2.VirtualPortalNlsFile=
```

Specify the realms and host names only if your portal has multiple realms.

2. To create both virtual portals by using a single configuration command, use the parameter `-DvirtualPortalList` to specify the two portals `vp1` and `vp2`:

   ```
   ConfigEngine create-virtual-portal -DvirtualPortalList=vp1,vp2
   ```

   - For IBM i: `ConfigEngine.sh create-virtual-portal -DvirtualPortalList=vp1,vp2`
   - For Linux: `ConfigEngine.sh create-virtual-portal -DvirtualPortalList=vp1,vp2`
   - For Windows: `ConfigEngine.bat create-virtual-portal -DvirtualPortalList=vp1,vp2`

Technotes for virtual portals

Using the XML configuration interface to work with virtual portals:

You can export and import the contents of individual virtual portals by using the XML configuration interface. For example, you can use the XML configuration interface to fill a newly created virtual portal with content. As each virtual portal has its own globally unique portal ID, you can determine all resources that are associated with that virtual portal clearly and individually.

About this task

Address the virtual portal by the URL context or the host name that you specified when you created the virtual portal. Specify the unique virtual portal URL or host name with your XML request by either of the following options:

Note: In the following examples, the commands are shown on three lines, but you must enter them as one line.

- If you created the virtual portal by specifying a URL context:

  ```
  xmlaccess -user user -password password -url
  my_host:port_number/wps/config/URL_Context_of _the_Virtual_Portal
  -in XML_file -out result.xml
  ```

  For the variable *URL_Context_of _the_Virtual_Portal* use the URL context that you specified when you created the virtual portal. For more information, see *Creating a virtual portal* and *Task create-virtual-portal*.

- If you created the virtual portal by specifying a host name:

  ```
  xmlaccess -user user -password password -url
  host_name:port_number/wps/config -in XML_file -out result.xml
  ```

For the variable *host_name* use the host name that you specified when you created the virtual portal. For more information, see *Creating a virtual portal* and *Task create-virtual-portal*.

Note: When you use the XML configuration interface to work with virtual portals, be aware of the following rules:

1. You cannot export or import a complete virtual portal by using the XML configuration interface. You can export or import only the contents of a virtual portal. If you want to transfer a virtual portal from a source server to a target server, proceed as follows:
   a. Create the virtual portal on the target server.
   b. Export the contents of the virtual portal from the source server. Specify the URL context or host name of the source virtual portal as described previously.
   c. Import the XML result script from the previous step to the target server. Specify the URL context or host name that you used to create the target virtual portal to which you want to import the content.

   For more information about how to export and import portal configurations by using the XML configuration interface, see *Working with the XML configuration interface*.
2. You can export and import the contents of a single individual virtual portal at a time by using the XML configuration interface. You cannot export or import multiple virtual portals at the same time or an entire portal installation with multiple virtual portals. You must specify a separate XML request for each virtual portal. You can also export content from one virtual portal and import it into a different virtual portal.
3. The access rights for the XML configuration interface are limited to the master administrator of the portal installation as a whole. Subadministrators for the virtual portals cannot use the XML configuration interface to export or import the virtual portal that they administer.
4. Apply special care when you configure unscoped resources by using the XML configuration interface. Unscoped resources are shared between all virtual portals across the entire portal installation. A change of unscoped resources by the XML configuration interface affects all other virtual portals. For example, this feature applies to the following tasks and types of XML processing:
   - Updating URL mappings by using the XML configuration interface: A URL mapping of a URL context in one virtual portal can be unintentionally updated by XML import into another virtual portal to point to a resource in that second virtual portal. Therefore, if you export the content of one virtual portal and import it into a different virtual portal, make sure that you do not include the URL mappings of virtual portal URL contexts in the XML script. Otherwise, you might make the virtual portal unusable in the following two circumstances:
     – If the source virtual portal and the target virtual portal are on the same portal server, the URL mappings of the source virtual portal are updated to point to resources in the target virtual portal into which you imported the content. You can no longer use such a URL context to access the resource in the source virtual portal.
     – If the source virtual portal and the target virtual portal are not on the same portal server, but there is another virtual portal on the target portal server that has the same URL context as the source virtual portal. The URL mappings of this virtual portal are updated to point to resources in

the target virtual portal into which you imported the content. And you can no longer use such a URL context to access the resource in this virtual portal.

Note: This step is critical for the URL mapping of a URL context that is created for a virtual portal during its creation. Updating this initial URL mapping of a virtual portal URL context makes that virtual portal unusable.

- Deploying portlet applications into a virtual portal by using the XML configuration interface: If you deploy a portlet, that portlet is available to all virtual portals in the portal installation, unless you restrict this deployment by using Portal Access Control. If that portlet was already deployed in other virtual portals, errors can occur during the execution of the XML request.

Hints and tips for working with virtual portals

View information about configuring virtual portals, hints and tips, and known limitations in WebSphere Portal Express Version 8.5:

- Do not grant the subadministrators of virtual portals the access permissions to run any installation-related tasks, such as installation of portlets or themes. The isolation between the different virtual portals as provided by WebSphere Portal Express Version 8.5 is limited to some extent. All virtual portals share a common Java virtual machine (JVM). Therefore, it is important to restrict the administration privileges of the virtual portal subadministrators and prevent them from installing their own code artifacts, such as themes or portlets. Unstable or malicious code that is introduced on one virtual portal can destabilize the entire portal installation and all other virtual portals. A flexible way to introduce virtual portal-specific portlets without impacting any other virtual portals is to use Web Services for Remote Portlets (WSRP). For more information about WSRP, go to *Using WSRP services*.
- Not all resources can be scoped to individual virtual portals. For example, all themes and skins are available to all virtual portals without restrictions. Credential vault, portlet services, and portal services are also common for an entire portal installation. They cannot be scoped to an individual virtual portal.

- The settings that are defined in the portal property files apply for the entire portal installation. You cannot specify separate settings for individual virtual portals.
- If you want to use the single signon feature that is provided by WebSphere Application Server, you must use the same common domain suffix for all virtual portals.
- Portal search, personalization, and templates, are not aware of virtual portals.
- There are no virtual portal-specific enhancements to the published portal commands and application programming interfaces.
- A URL mapping that is defined for a resource in a particular virtual portal must use the same URL context as the human readable URL context for that virtual portal itself. Example: In a virtual portal that uses the human readable URL mapping `wps/portal/vp_1`, all URL mappings for portal resources must start with `wps/portal/vp_1`, for example `wps/portal/vp_1/url_1` and `wps/portal/vp_1/url_2`. Within this virtual portal, a URL mapping such as `wps/portal/url_1` is not valid, as the portion `vp_1` of the URL Context is missing.
- The administration portlet Virtual Portal Manager cannot delete all resources that are associated with a virtual portal. For example, it does not delete extra URL mappings that administrators created for the virtual portal. You can use the XML configuration interface to delete the URL mappings.
- All virtual portals on a portal installation share a common logging and tracing.
- When you reinitialize a virtual portal by using the Virtual Portal Manager portlet, this applies the XML script for the default virtual portal content (or your custom script) again and re-creates the default content of the virtual portal. Resources that you removed from the default content are re-created. Resources that you added to the default content remain in the virtual portal.
- You must run the `wp-create-realm` task to create realms for your virtual portal. See the topics about *Realm support* and about adding realm support file for your operating system.
- The Portal Access Control administration in the Resource Permissions portlet shows users from different realms who have role mappings on shared resources by their object IDs. Therefore, apply special care and consideration when you are deleting such portal resources: Do not delete resources on which users from other realms have role mappings, if they are required in other virtual portals. This applies to members of roles on portal resources that cannot be scoped and are therefore shared between the virtual portals. Role members who belong to the realm of your local virtual portal are displayed as usual, but role members who belong to different realms are displayed in a different manner:
  - Role members for shared resources who belong to the virtual portal that you are currently working are listed by their actual names under which they were created.
  - Role members for shared resources that do not belong to the realm of the current portal are listed by their portal object IDs. For example, a role member from a different realm might be represented as `8_0_B`.

  Find the list of role members. Click the **Administration menu** icon. Then, click **Access** > **Resource Permissions**. .From the list of Resource Types, select a Resource Type by clicking it. On the Resource Permissions page, click on the **Assign Access** icon. The members are listed in the Roles column.
- You cannot create custom URLs in one virtual portal that address portal resource in another virtual portal. The reason is that both object IDs and unique names relate to resources of the local virtual portal.

Related concepts:

"WSRP services" on page 1433
IBM WebSphere Portal Express supports the Web Services for Remote Portlets (WSRP) standard. By using this standard, portals can provide portlets, applications, and content as WSRP services. Other portals can then integrate the WSRP services as remote portlets for their users.

"Realm support" on page 134
A realm is a collection of users or groups from one or more branches of your repository tree. Those branches can be part of a single repository, for example an LDAP user registry, or it can be a combination of multiple user registries. A realm is then mapped to a Virtual Portal to allow the realm's user population to log in to the Virtual Portal. This functionality allows you to define areas within WebSphere Portal Express that only a limited set of users can access.

Known limitations for virtual portals

The following sections describe known limitations of virtual portals.

"Scope of virtual portals"
IBM has tested an installation with 300 virtual portals and a total of more than 200,000 pages successfully. More detailed results of these tests are listed here.

"Using a new host name for an existing virtual portal" on page 1419
If you want to use a new host name for an existing virtual portal, you must delete the virtual portal. Then, re-create it with the new host name.

"Change of theme for virtual portal might not take effect" on page 1419
If you change the theme for a virtual portal by editing the virtual portal in the Virtual Portals portlet, this change affects only the root page of the virtual portal.

Related information:

Technotes for virtual portals

Scope of virtual portals:

IBM has tested an installation with 300 virtual portals and a total of more than 200,000 pages successfully. More detailed results of these tests are listed here.

- A IBM WebSphere Application Server 64-bit environment is suited best for a large number of virtual portals.
- For good results, you need to tune the portal caches and JVM.
- The limiting factor is not the absolute number of virtual portals, but the overall number of pages and URL mappings.
- In a limit and boundary test, the processor of the portal database machine was found to be the bottleneck.
- A large number of virtual portals can have an overall performance impact on administrative activities.
- Setting up and administering a large number of virtual portals by using the portal administration user interface can be time consuming.

Related information:

Technotes for virtual portals

Using a new host name for an existing virtual portal:

If you want to use a new host name for an existing virtual portal, you must delete the virtual portal. Then, re-create it with the new host name.

1. Export the contents of the virtual portal by using the XML configuration interface.
2. Delete the virtual portal.
3. Clean up references to the deleted virtual portal by using the `Task.xml` script of the XML configuration interface.
4. Create a new empty virtual portal by using the configuration task `create-virtual-portal`. Use the context of the deleted virtual portal, and specify the new host name as required.
5. Import the contents to the new virtual portal by using the XML configuration interface.

Related information:

Technotes for virtual portals

"Working with the XML configuration interface" on page 1061
You can use the XML configuration interface to export and import IBM WebSphere Portal Express configurations. This way you can configure selected features or areas of your portal. You can also transfer a complete configuration from one portal to another.

Change of theme for virtual portal might not take effect:

If you change the theme for a virtual portal by editing the virtual portal in the Virtual Portals portlet, this change affects only the root page of the virtual portal.

If pages in your virtual portal have explicitly assigned themes, updating the theme for the virtual portal by using the Virtual portals portlet does not alter these pages. To change the theme for such pages of a virtual portal, edit the pages by using the user interface, or use the XML configuration interface (XML Access).

Related information:

Technotes for virtual portals

Language support

To reach as many users as possible, WebSphere Portal Express supports different languages for different locations. For instance, a large, international corporation might address users in different countries or regions through multilingual Web sites. In this context the portal can concurrently serve portal views to large numbers of users, each in the user's preferred language.

If necessary, the portal can support portlets that are shown in different languages. If portlets do not support a requested language, the portal tries to match the user's language preference as well as possible. For example, if a page for a Japanese user shows several portlets in Japanese and a portlet is added that only supports English, then the page shows the new portlet in English but still shows the other portlets in Japanese.

Note: Some back-level versions of browsers and browsers that are not commonly used might have difficulty representing specific languages, depending on the

defined character set. In these cases, in order for the language to be rendered correctly, it might be necessary to define the same preferred language for the browser and the portal it accesses.

WebSphere Portal Express has already been translated into a number of languages. They are shown in the following list, together with the ISO 639 language codes. These codes are used for the languages in WebSphere Portal Express:

WebSphere Portal Express language codes:

- `ar` = Arabic
- `ca` = Catalan
- `cs` = Czech
- `da` = Danish
- `nl` = Dutch
- `en` = English
- `fi` = Finnish
- `fr` = French
- `de` = German
- `el` = Greek
- `iw` = Hebrew
- `hr` = Croatian
- `hu` = Hungarian
- `it` = Italian
- `ja` = Japanese
- `kk` = Kazakh
- `ko` = Korean
- `no` = Norwegian
- `pl` = Polish
- `pt` = Portuguese
- `pt_BR` = Brazilian Portuguese
- `ro` = Romanian
- `ru` = Russian
- `sk` = Slovak
- `sl` = Slovenian
- `es` = Spanish
- `zh` = Simplified Chinese
- `zh_TW` = Traditional Chinese
- `sv` = Swedish
- `th` = Thai
- `tr` = Turkish
- `uk` = Ukrainian

WebSphere Portal Express uses the *ISO 639 Codes for the Representation of Names of Languages* to represent localized resources. The names for directories containing language-dependent resources follow the ISO 639 naming convention (see "Directories for languages" on page 3621).

This section has the following topics:

"Supporting a new language"
To support a new language to IBM WebSphere Portal Express you add resource bundles and, where applicable, JSPs for the new language.

"Changing the character set for a language" on page 1427
The character set is stored in the database. This is the character set used for the response to the user. You can change the character set for a language.

"Dynamically changing the language during the user session" on page 1428
Allow users to change the language while they are logged in to the portal.

"Selecting and changing the language" on page 1429
You can control the multiple language-specific settings within the portal.

"How to control the behavior of the language fallback filter" on page 1431
You can manage the language fallback behavior of IBM WebSphere Portal Express by a built-in servlet filter. This way, you control the way by which the portal determines the language for rendering portlets.

Related reference:

"Directory structure" on page 3618
The topic shows the naming conventions that are used to denote the location of files on the servers and the types of resources you can find in those directories.

Supporting a new language

To support a new language to IBM WebSphere Portal Express you add resource bundles and, where applicable, JSPs for the new language.

About this task

Some JSPs use resource bundles; others, such as help JSPs, are translated directly. Then you update the list of available languages by adding the new language to the portal. You do this by using the XML configuration interface. Use the example XML script `CreateLanguage.xml` to add the new language for the portal. You can also use it to remove an existing language from the portal. The new language is then listed in the language selection menu boxes that are available in administration portlets, or for example, in **Edit My Profile**, **Preferred language**.

Note: The new language will be available only to portlets that you add to your portal, if these portlets support the newly added language and if you make the required language files available. None of the WebSphere Portal Express user interface or messages will be translated to the new language.

"Adding resource bundles for a new language" on page 1422
To allow your portal users to work in an extra language, you add resource bundles for that language. Resource bundles are used to store text that is displayed in JSPs or text that is used in Java code.

CF06 "Adding a new language to render localized content" on page 1425
You can add new languages to the portlet to render localized content in different languages and reach a larger audience.

"Adding JSPs for a new language" on page 1425
For the new language in your portal, you also need to add JSPs. Some JSPs that contain mostly text, such as help JSPs, are translated directly which means that the text is contained in the JSP and not in a resource bundle. For JSPs that do not use resource bundles, you need to copy and translate an existing JSP and store it in the appropriate location.

"Globalization for People Finder fields" on page 1426
All fields of the People Finder portlet must have associated language strings that are defined in each language property file,

PeopleFinderUI_*language_code*.properties. The field names are the names of the corresponding attributes in Member Manager.

"XML samples for creating or removing language definitions" on page 1427
You can modify these XML samples and use them to create or remove language definitions from your portal.

Adding resource bundles for a new language

To allow your portal users to work in an extra language, you add resource bundles for that language. Resource bundles are used to store text that is displayed in JSPs or text that is used in Java code.

About this task

In WebSphere Portal Express, resource bundles are in the JAR files wp.ui.jar and wp.theme.customizer.ext.jar in the nls directory inside the file.

The JAR file wp.ui.jar is in the following directory:

- IBM i: *PortalServer_root*/ui/wp.ui/shared/app
- Linux: *PortalServer_root*/ui/wp.ui/shared/app
- Windows: *PortalServer_root*\ui\wp.ui\shared\app

The JAR file wp.theme.customizer.ext.jar is in the following directory:

- IBM i: *PortalServer_root*/theme/wp.theme.customizer.ext/shared/app
- Linux: *PortalServer_root*/theme/wp.theme.customizer.ext/shared/app
- Windows: *PortalServer_root*\theme\wp.theme.customizer.ext\shared\app

If you want to add new resource bundles for extra languages, place them in the following directory:

- IBM i: *wp_profile_root*/PortalServer/config/nls
- Linux: *wp_profile_root*/PortalServer/config/nls
- Windows: *wp_profile_root*\PortalServer\config\nls

The naming convention for resource bundles is [bundle]_[language]_[country]_[variant].properties. The ISO standard ISO-639 is used for the language codes of most languages. For Hebrew, the old language code iw is used. The ISO standard ISO-3166 is used for the country/region codes. WebSphere Portal Express supports the use of [variant], although resource bundles supplied with the portal do not use it.

Note: If your portal configuration includes Lotus Collaborative Services, add a CSRes_language.properties file for each additional language to the following directory:

- IBM i: *wp_profile_root*/PortalServer/config/nls
- Linux: *wp_profile_root*/PortalServer/config/nls
- Windows: *wp_profile_root*\PortalServer\config\nls

WebSphere Portal Express uses properties files that are called by the Java class **java.util.ResourceBundle** to store text that is rendered in JSPs. The Java mechanism searches for the resource bundles in the following order:

1. [bundle]_[language]_[country]_[variant].properties
2. [bundle]_[language]_[country].properties
3. [bundle]_[language].properties

4. [bundle].properties

In WebSphere Portal Express, the default bundles [bundle].properties are in English.

All languages that are defined for WebSphere Portal Express need to have resource bundles that are defined as well for the themes to function correctly. After you install a new language, add and process the resource bundles located within wp.ui.jar and wp.theme.customizer.ext.jar by using the procedure that is outlined in the following.

Procedure

1. Copy all existing resource bundles into *wp_profile_root*/PortalServer/config/nls directory.
2. Name the resource bundles according to the naming convention for resource bundles with locale code for the languages installed.
3. Translate the resource bundle files.
4. Convert them into Unicode with the Native-to-ASCII converter native2ascii that comes as part of JDK. For more detail about native2ascii, go to the Java documentation *native2ascii - Native-to-ASCII Converter*.
5. Restart your WebSphere Portal Express so that it recognizes the new resource bundles.

"Resource bundles to support a Portal based custom theme"
You can add supported locale to the system. You must provide resource bundles for the new language to the Portal based custom theme to enable them.

Related information:

native2ascii - Native-to-ASCII Converter

Resource bundles to support a Portal based custom theme:

You can add supported locale to the system. You must provide resource bundles for the new language to the Portal based custom theme to enable them.

About this task

Vietnamese is used as an example language in the following steps.

Procedure

1. Run the following XML to create the "Vietnamese" language. Click the **Administration menu** icon. Then, click **Portal Settings** > **Import XML**.

```
<?xml version="1.0" encoding="UTF-8"?>
<request xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 type="update"
 xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd">
 <portal action="locate">
  <language action="update" bidi="false" domain="rel" locale="vi_vn">
   <localedata locale="en_us">
    <title>Vietnamese</title>
   </localedata>
  </language>
 </portal>
</request>
```

2. Copy the contents of the following files from your Portal server into a new file called language_vi_vn.js:

- *PortalServer_root*/theme/wp.theme.modules/webapp/installedApps/ThemeModules.ear/ThemeModules.war/modules/pagebuilder/js/nls/pb_ui_layer_en_us.js
- *PortalServer_root*/theme/wp.theme.modules/webapp/installedApps/ThemeModules.ear/ThemeModules.war/modules/portalclient/js/nls/rest_utils_en_us.js
- If you use Active Site Analytics *PortalServer_root*/theme/wp.theme.modules/webapp/installedApps/ThemeModules.ear/ThemeModules.war/modules/asa/js/nls/asa_layer_en_us.js
- If you use Tagging and Rating *PortalServer_root*/theme/wp.theme.modules/webapp/installedApps/ThemeModules.ear/ThemeModules.war/modules/portalclient/js/nls/tagging_rating_en_us.js

3. In the language_*vi_vn*.js file, replace all instances of:

   ```
   en_us")
   ```

   with:

   ```
   vi_vn")
   ```

   and all instances of:

   ```
   .en_us=
   ```

   with:

   ```
   .vi_vn=
   ```

4. Place the language_*vi_vn*.js file into the js folder of your custom theme. For example, dav:fs-type1/themes/*custom_theme*/js.
5. Create a theme module for the language_*vi_vn*.js file by creating a languages.json file with the following contents:

   ```
   {
    "modules":[{
     "id":"custom_languages",
     "prereqs":[{
      "id":"dojo"
     }],
     "contributions":[{
      "type":"head",
      "sub-contributions":[{
       "type":"js",
       "uris":[{
        "value":"/js/language_vi_vn.js",
        "lang":"vi_vn"
       }]
      }]
     }]
    }]
   }
   ```

   For more information about theme modules, see Registering theme modules.
6. Place languages.json into the contributions folder of your custom theme. For example, dav:fs-type1/themes/*custom_theme*/contributions.
7. Add custom_languages as the first module in the section that includes Dojo for each profile in your custom theme. For example, in the Portal theme, the custom_languages module would be added to the **moduleIDs** section of the Lightweight profile and the **deferredModuleIDs** section of the Deferred profile. For more information, see *Adding or removing a ready-to-use module to a theme*.
8. Restart your portal to pick up the new language and module contribution.

Related tasks:

"Defining theme modules" on page 2547
You can define theme modules in XML or JSON.

"Adding or removing a module from a profile" on page 2656
To add or remove a module, update the profile that is used to render a page for the theme.

Adding a new language to render localized content

You can add new languages to the portlet to render localized content in different languages and reach a larger audience.

About this task

The Web Content Viewer portlet supports the same set of default languages as IBM WebSphere Portal Express To render localized web content in a new language, you need to extend the supported languages of the Web Content Viewer portlet.

Procedure

1. Click the **Administration menu** icon. Then, click **Portlet Management** > **Portlets**.
2. Search for **Web Content Viewer**.
3. Click **Configure portlet** icon.
4. In the **New Preference** field, enter `ibm.portal.wcm.locales.extension`.
5. In the **New value** field, enter a list of new locales that are separated by commas. For example, to add Australian, British, and American English, enter `en_AU,en_GB,en_US`.
6. Click **Add**.
7. Click **OK**.

Related concepts:

"Portal administration portlets" on page 1047
Administration portlets are supplied with IBM WebSphere Portal Express. Use them to perform administration tasks and actions on portal resources, give other users limited access rights on selected resources, and deploy custom portlets, themes, or skins.

"The XML configuration interface" on page 1054
Use the XML configuration interface (XML Access) for exchanging portal configurations.

"Localized rendering" on page 2459
Localized rendering is provided by either automatically matching the user locale with the content locale, or by providing a navigation option in the site to allow the user to choose the locale for themselves. These two strategies might also be used together in some cases.

Adding JSPs for a new language

For the new language in your portal, you also need to add JSPs. Some JSPs that contain mostly text, such as help JSPs, are translated directly which means that the text is contained in the JSP and not in a resource bundle. For JSPs that do not use resource bundles, you need to copy and translate an existing JSP and store it in the appropriate location.

About this task

The location of JSPs can be, for example, jsp/[mime-type]/[language]/[country]/[variant]/files.jsp. For instance, existing help JSPs are already translated in WebSphere Portal Express and placed in the relevant [language]and [country] subdirectories. When deciding where to store new JSPs, you need to consider how the portal locates a JSP for rendering its content.

The following is an example of the order in which directories are searched, where path1 is a user-defined path, ie5 is the markup version (here: Internet Explorer 5), and the locale is en_US:

1. /html/path1/ie5/en_US/mytemplate.jsp
2. /html/path1/ie5/en/mytemplate.jsp
3. /html/path1/ie5/mytemplate.jsp
4. /html/path1/en_US/mytemplate.jsp
5. /html/path1/en/mytemplate.jsp
6. /html/path1/mytemplate.jsp
7. /html/en_US/mytemplate.jsp
8. /html/en/mytemplate.jsp
9. /html/mytemplate.jsp
10. /mytemplate.jsp

This search order means that if the user language is not supported, the portal will choose the file in the locale independent location, which in the example is the English file.

Globalization for People Finder fields

All fields of the People Finder portlet must have associated language strings that are defined in each language property file, PeopleFinderUI_*language_code*.properties. The field names are the names of the corresponding attributes in Member Manager.

For each People Finder field, the following three strings are required:

- One string for the field name, which is the attribute name
- One string for the field long name
- One string for the field description as it appears in the tasks of People Finder configuration mode

Example:

```
displayName = Name
displayName_Long = Preferred Name
displayName_Desc = Display name
```

The resource key for each field refers to the appropriate language property file, /nls/PeopleFinderUI_*language_code*.properties. Language translations of People Finder fields must be stored in the appropriate language property file.

Language properties files are in the following location on the WebSphere Portal Express server:

PortalServer_root/people/people.impl/peoplefinder/portlet/*nnnnnnn*.ear/lwp_peoplefinder_war.ear/lwp.peoplefinder.jsr168.war/WEB-INF/lib

The variable *nnnnnnn* represents a random number that is generated by the installation process when the `lwppeoplefinder.jar` file is installed.

XML samples for creating or removing language definitions

You can modify these XML samples and use them to create or remove language definitions from your portal.

The following XML sample shows how you use the XML configuration interface to create Japanese language in your portal:

```
<request xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" type="update"
         xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd">
     <portal action="locate">
          <language action="update" domain="rel" locale="ja">
          <localedata locale="ja">
           <title>Japanese</title>
          </localedata>
          </language>
     </portal>
</request>
```

The following XML sample shows how you use the XML configuration interface to remove Japanese language in your portal:

```
<request xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" type="update"
         xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd">
    <portal action="locate">
         <language action="delete" domain="rel" locale="ja">
         <localedata locale="ja">
           <title>Japanese</title>
         </localedata>
         </language>
    </portal>
</request>
```

Related information:

"Working with the XML configuration interface" on page 1061
You can use the XML configuration interface to export and import IBM WebSphere Portal Express configurations. This way you can configure selected features or areas of your portal. You can also transfer a complete configuration from one portal to another.

Changing the character set for a language

The character set is stored in the database. This is the character set used for the response to the user. You can change the character set for a language.

To change the character set for a language, use the **Supported Markups** portlet. Proceed as follows:

1. Click the **Administration menu** icon..
2. Click **Portal settings** and then click **Supported markups**.
3. Select the markup for which you want to change the character set.
4. Click **Edit selected markup**.
5. Click **Set locale-specific settings**.
6. Select the language for which you want to make the change.
7. Click **Edit setting for selected language**.
8. Change the character set for the selected language in the selected markup.
9. Click **OK** to save your changes, or click **Cancel** to return without saving.

10. Again, on the panel with the list of languages and on the panel for editing the markup, click **OK** to save your changes, or click **Cancel** to return without saving.

For details about how to perform these tasks refer to the Supported Markups portlet help.

Note: For a portlet to be rendered correctly, the language of the portlet must be supported by the character set of the portal.

To help the user's browser to render content correctly, the used character set is written to the HTTP header of the response stream. The default encoding is UTF-8. If it set to another encoding, you can force the default encoding by setting the JVM parameter as follows `default.client.encoding=UTF-8` .

Dynamically changing the language during the user session

Allow users to change the language while they are logged in to the portal.

About this task

If you want your users to be able to change the language during the session, use the following command provided by IBM WebSphere Portal Express:

```
<portal-navigation:url command="ChangeLanguage">
   <portal-navigation:urlParam name="locale" value="language"/>
</portal-navigation:url>
```

where `language` is the two character code for the required language, such as `en`, `de`, or `fr`. For a list of the available languages and their two character codes read *Language support*.

For users to be able to dynamically change the language for the session, add a link to the portal theme with the following text and link reference:

- The text displayed with the link specifies the language to which the user can change.
- The link reference calls the command described previously with the locale parameter corresponding to the specified language.

Users can then click this link to change to the language specified by the locale parameter with the command. If you want to make more than one language available to users, you create a separate link for each language.

Example: To create links for English and German, add the lines shown in the following example to the banner area of your theme:

```
<!-- add these lines -->
<a href="<portal-navigation:url command="ChangeLanguage"><portal-navigation:urlParam name="locale"
     value="en"/></portal-navigation:url>">English</a>
<a href="<portal-navigation:url command="ChangeLanguage"><portal-navigation:urlParam name="locale"
     value="de"/></portal-navigation:url>">Deutsch</a>

<%-- logout button --%>
```

The banner area can be defined in different files, depending on the different themes. Themes in recent portal versions commonly define the banner area within the `Default.jsp`, whereas older themes can include a separate JSP, such as `banner_toolbar.jsp`. For more information about locating the files for your themes refer to the topic about the Location of theme resources.

Notes:

- The changed setting applies only for the duration of the current session. When the user logs out and back in again, the portal applies the default language as determined by the steps described under Selecting and changing the language.
- The previous examples use the `portal:` prefix to designate JSP tags from the portal tag library in `portal.tld`. Your custom JSPs might use a different tag prefix. Refer to Tags used by the portal JSPs for more information.
- Important for every operating system: Touch the *Default.jsp* file after editing any JSP files and before any restart. This updates the timestamp on the file to the current time and will signal a recompile of *Default.jsp* to incorporate the edit changes from other JSP files. Enter:

  ```
  touch Default.jsp
  ```

  An alternative is to edit (open and save) *Default.jsp*, which has the same effect as the touch command. After updating theme JSPs, you must restart WebSphere Portal Express unless JSP reloading is enabled.

Related concepts:

"Understanding the Portal Version 8.5 modularized theme" on page 2521
Modern websites and browsers enable incredible new capabilities that can greatly enhance your user's web experiences. However, these capabilities are not without cost in terms of large page sizes and more processing in the browser when each page is rendered. These capabilities are worth it when you need them, but removing them for an entire site or including them only on pages that take advantage of these capabilities provides for more flexibility.

Selecting and changing the language

You can control the multiple language-specific settings within the portal.

Changing the default portal language

After the installation, you can change the default language of the portal. To change the language, use the **Global Settings** portlet. Click the **Administration menu** icon. Then, click **Portal Settings** > **Global Settings**. From the drop-down list, select the required default language for the portal. This option can be, for example, `en` for English. For a list of languages that are supported by the portal, refer to the topic about Language support.

Note: The Global Settings portlet does not work in portal cluster configurations. For portal clusters, set the portal default language in the portal Localizer service by using the WebSphere Integrated Solutions Console. For details about how to set the language refer to the topic about Setting service configuration properties.

Portlets

A portlet can support one or more locales. All portlets must have their own default language that is specified in the deployment descriptor. Otherwise, the portlet cannot be installed.

Changing titles for pages

You can edit titles for pages in the portlet for Managing Pages by using the configure option for the locale-specific settings. To open the **Manage Pages** portlet, click the **Administration menu** icon. Then, click **Portal User Interface** > **Manage Pages**. Click the **Edit Page Properties** icon, expand the Advanced options, and select the option for setting page titles and descriptions. You can enter a different title for each available language.

Language selection by the user

The user can select the preferred language for rendering portal content during the enrollment process. The user can select from a list of available languages. If required, the user can later change the selected language in the self-care portlet by selecting **Edit My Profile**. The selection list that is shown to the user for choosing a language shows all available portal languages.

Note: The user's language selection does not become effective until after the user logs in.

Language determined by the portal

The portal determines the language for rendering the portal content by a search process along the following sequence at login time:

1. The language that is encoded in the URL by the value for the `locale` parameter takes highest priority. The portal does not encode a locale into the URL by default. However, you can add code to the JSPs to support dynamic language selection. For more information, read *Dynamically changing the language during the user session*.
2. The language that is encoded in the navigational state by the locale tag: `<locale> . . . </locale>`.
3. The language that is stored in the `com.ibm.wps.state.preprocessors.locale.CookieSupportedLanguagePreProcessor` in the portal State Manager Service. For more information, read *State Manager Service*.
4. If the user logged in, the portal displays in the preferred language that is selected and stored in the user repository by the user.
5. If no preferred user language can be found, the portal looks for the language that is defined in the user's browser. If the portal supports that language, it displays the content in that language. If the browser has more than one language that is defined, the portal uses the first language in the list to display the content.
6. If no browser language can be found, for example if the browser used does not send a language or if the portal does not support the language that is set in the browser, the portal resorts to its own default language.
7. If the user has a portlet that does not support the language that was determined by the previous steps, that portlet is shown in its own default language.

This sequence describes the language selection process that is applied *for each user* at logon time. For pages viewed by anonymous users only, the last three steps for determining the language apply. This step applies, for example, before login and after logoff.

The language that is determined by this selection process is applied to the complete portal. If the portal or one component does not find the appropriate resources for the language as selected by this sequence, it tries to find the resources in a similar language. For example, if the determined language was US English (`en_US`), the next closest option is English (`en`).

This search sequence applies to all portal components individually including portlets. For example, if a portlet does not support the language that is selected by the portal, it is shown in default language of the portlet. This way, the portal can show individual portlets in different languages.

If a page does not support any of the languages that are determined by the steps that are given in the preceding list, then the navigation displays the object ID of the page rather than the page title. Such an object ID can be, for example, `7_0_5T`.

Preserving the language of the browser session

A users's choice of language is lost when the navigational state is cleared. For example, the language information is lost if users use bookmarks to friendly URLs for navigation or if the navigational state is cleared intentionally. You can preserve the language choice of the user's browser session. To do so, use the `com.ibm.wps.state.preprocessors.locale.CookieSupportedLanguagePreProcessor` preprocessor in the portal State Manager Service. It stores the language information to a cookie.

You can also determine the maximum lifetime of the cookie that holds the language information. To do so, use the `com.ibm.wps.state.preprocessors.locale.CookieSupportedLanguagePreProcessor.cookie.maxage` property in the portal State Manager Service.

For more detailed information, read *State Manager Service*

"State Manager Service" on page 347
The portal State Manager Service is the access point for managing the navigational state of the portal. The navigational state represents the current view of portal resources as displayed to a user.

How to control the behavior of the language fallback filter

You can manage the language fallback behavior of IBM WebSphere Portal Express by a built-in servlet filter. This way, you control the way by which the portal determines the language for rendering portlets.

By default, IBM WebSphere Portal Express Version 8.5 recognizes whether a general language code is secondary or farther down in the browser priority list. It ignores all regional variations that do not directly match a language that is defined by the portal. For example, if the browser locale list specifies `"ja-JP", "de", "ja"`, the portal ignores the entry `"ja-JP"` and falls back to the second entry of `"de"`. It recognizes that `"ja-JP"` does not have a match among the portal defined locales and that the more generic version `"ja"` of this locale is further down in the list after `"de"`. This behavior conforms to the HTTP specification.

The built-in language fallback servlet filter supports a mode that extends the language fallback behavior. If you enable this extended language fallback mode, the portal runs a fallback for all entries and removes duplicates of the fallback locales that are later in the list. In the example browser locale list of "ja-JP", "de", "ja" as given before, the portal recognizes that "ja-JP" does not match any of the portal defined locales. Therefore, it runs a fallback to the portal defined locale "ja". It uses "ja" as the locale of choice and ignores the third entry "ja" from the list. The resulting locale list that the portal uses is "ja", "de". This fallback mechanism bypasses strict adherence to the HTTP specification of accepting and showing languages and uses the fallback option instead. It also makes your WebSphere Portal Express Version 8.5 behave the same way as earlier portal versions.

You set the extended mode in the custom properties of the WP Configuration Service Resource environment provider by adding the property engine.enableExtendedLanguageFallback=true. Proceed by the following steps:

1. Open the WebSphere Integrated Solutions Console.
2. Select the Resource Environment Provider WP ConfigService.
3. In the Custom Properties section, add the property engine.enableExtendedLanguageFallback and set it to the value true.
4. Save your changes.
5. Restart your WebSphere Portal Express for your changes to take effect.

Example: Assume that the browser sends the Accept-Language header "DE_de, en". This combination means that the user prefers German as spoken in Germany as first priority, then English, but not German in general. In a portal scenario, these preferences would result in serving resources in "en", even though "de" would be supported (but is not acceptable according to the header). The default language fallback mode adds all fallback locales to the header, preserving the relative order of the original locales in the header. The result would be "DE_de, en, de", with the fallback to "de" showing after "en" to match the user preference.

In contrast, the extended language fallback mode gives fallbacks precedence over the original order of locales in the header. For "DE_de, en", the filter would generate "DE_de, de, en", giving all fallbacks for "DE_de" the same relative priority as "DE_de".

You can write your own filters and apply your own locale fallback logic. WebSphere Portal Express uses the value of the Accept-Language header for further processing. To replace the Language fallback servlet filter, proceed as follows:

1. Edit the file *wp_profile_root*/config/cells/node-name/applications/wps.ear/deployments/wps/wps.war/WEB-INF/web.xml.
2. Locate the following section:

```
<filter>
    <filter-name>Locale Filter</filter-name>
    <filter-class>com.ibm.wps.engine.ExtendedLocaleFilter</filter-class>
</filter>
```

3. Replace the filter class com.ibm.wps.engine.ExtendedLocaleFilter by the class name of your custom language filter.
4. Save the file.
5. Restart your WebSphere Portal Express for your changes to take effect.

Notes:

- If you remove a language from the portal, both filters rely on the locales that were defined last. For example, if you remove Japanese (`"ja-JP"`, `"ja"`) from the locales that are defined in the portal, then the browser locale list specifies `"ja-JP,de,ja"`. In this case, the portal recognizes that `"ja-JP"` and `"ja"` do not have a match among the portal defined locales. Therefore, it ignores these entries `"ja-JP"` and `"ja"`. Instead, it falls back to the second entry named `"de"`.
- IBM Web Content Manager does not use portlets and therefore cannot apply the filter that the portal uses for portlets. Therefore, if your portal installation includes Web Content Manager, you must set the custom filter in the Web Content Manager `web.xml` under the directory location *wp_profile_root*`/config/cells/`*node-name*`/applications/wcm.ear/deployments/wcm/ilwwcm.war/WEB-INF/`. Replace the extended filter as shown previously and restart the portal.

  If you use servlet delivery instead of portlet delivery, then you must edit `web.xml` under the directory location *wp_profile_root*`/config/cells/`*node-name*`/applications/PA_WCM_Authoring_UI.ear/deployments/PA_WCM_Authoring_UI/ilwwcm-authoring.war/WEB-INF/`.

You can modify these XML samples and use them to create or remove language definitions from your portal.

WSRP services

IBM WebSphere Portal Express supports the Web Services for Remote Portlets (WSRP) standard. By using this standard, portals can provide portlets, applications, and content as WSRP services. Other portals can then integrate the WSRP services as remote portlets for their users.

The WSRP standard and specification is provided by OASIS. It defines a web service communication interface for interactive presentation-oriented web services. This standard simplifies the integration of remote portlets, applications, and content into portals. Producers and Consumers use this interface for providing and consuming portlets. Users can work with WSRP in the following ways:

- Producers can provide portlets as presentation-oriented WSRP services and make them available to Consumers who want to use these services.
- Consumers can select from a rich choice of available remote portlets and integrate them into their portal.
- Portal site visitors can then access the integrated remote portlets. They can work and interact with them in the same way as they do with local portlets. The integrated remote portlets appear and operate to portal site visitors the same way as local portlets.

The WSRP implementation of WebSphere Portal Express Version 8.5 is built on the JAX-WS based web service stack of IBM WebSphere Application Server. The WSRP implementation in earlier versions of WebSphere Portal Express was based on the web service stack that is based on the JAX-RPC standard.

The information that is given in this WSRP section assumes that you are already familiar with WebSphere Portal Express and with the WSRP specification. If you want more detailed information about the OASIS WSRP specification, refer to the OASIS WSRP Standard website at http://oasis-open.org/committees/wsrp.

Before you start working with WSRP in your portal, read the relevant topics about WSRP carefully:

- In all cases, read the topics about planning, security considerations, and hints and tips for using WSRP with your portal.
- Depending on how you want to use WSRP, read the topics about Producers or Consumers.

Currently, there are two versions of the WSRP standard, WSRP 1.0 and WSRP 2.0. WebSphere Portal Express supports both versions of the WSRP standard.

The following topics provide information about WSRP Producers and Consumers and about how they communicate with each other.

"What is new in WSRP"
WSRP in IBM WebSphere Portal Express Version 8.5 is now based on the JAX-WS standard for Java based web services. It takes advantage of the improvements of the current JAX-WS based web services stack that is part of IBM WebSphere Application Server. The WSRP services are implemented as JAX-WS compliant service providers and service clients. To configure web service security and quality of service, you can manage them in the WebSphere Integrated Solutions Console by using policy sets.

"Learning about WSRP" on page 1435
Web Services for Remote Portlets (WSRP) allows easy integration of remote portlets, applications, and content into portal.

"Planning for WSRP" on page 1437
Before you work with WSRP, plan your configuration based on the information in the following topics.

"Using your portal as a WSRP Producer" on page 1444
Learn about the tasks that you perform when you use your portal to provide WSRP services as a WSRP Producer portal.

"Using your portal as a WSRP Consumer" on page 1457
Learn about the tasks that you perform when you use your portal as a WSRP Consumer portal to consume remote portlets. You can consume portlets from a IBM WebSphere Portal Express or from a different WSRP Producer such as the IBM WSRP Version 2.0 Producer for IBM WebSphere Application Server.

"Using handlers for WSRP web services" on page 1494
You can extend your WSRP Producer or WSRP Consumer portal by handlers that comply with JAX-WS.

"Reference for using WSRP with the portal" on page 1498
Reference information about using WSRP with the portal includes WSRP markup caching and Known limitations.

Related information:

OASIS WSRP Standard

What is new in WSRP

WSRP in IBM WebSphere Portal Express Version 8.5 is now based on the JAX-WS standard for Java based web services. It takes advantage of the improvements of the current JAX-WS based web services stack that is part of IBM WebSphere Application Server. The WSRP services are implemented as JAX-WS compliant service providers and service clients. To configure web service security and quality of service, you can manage them in the WebSphere Integrated Solutions Console by using policy sets.

WebSphere Portal Express now offers an extra security mechanism for WSRP. Besides, web services security, WSRP also supports HTTP-cookie-based Single Sign

On (SSO). This security mechanism does not require web service configuration and allows the WSRP Producer to process both authenticated and unauthenticated requests. The WSRP Producer works with WSRP Consumer portals that are built either on JAX-WS or on other web service stacks, such as JAX-RPC. In particular, WSRP in WebSphere Portal Express Version 8.5 works with WSRP counterparts in earlier versions of WebSphere Portal Express. The WSRP implementation in earlier versions of WebSphere Portal Express was based on the JAX-RPC API and the JAX-RPC web service stack.

New in CF 05

The WSRP Consumer markup caching feature now offers better performance. You can now use WSRP markup caching without enabling the portlet container fragment caching. With a new configuration parameter, you can enable and disable markup caching specifically for selected remote portlets or for all remote portlets of a Consumer portal.

The WSRP Consumer provides multiple new configuration parameters for defining two-phase rendering behavior, WSRP response timeouts, and a limit for the size of file uploads.

New in CF 06

You can now configure the WSRP Consumer to invalidate the remote session when a user explicitly logs out of the Consumer portal.

Learning about WSRP

Web Services for Remote Portlets (WSRP) allows easy integration of remote portlets, applications, and content into portal.

Related information

For information about the WSRP standard refer to the OASIS WSRP Standard website: http://oasis-open.org/committees/wsrp.

For more information about how WSRP works with the portal, read the following topics.

"WSRP Producer"
WSRP Producers provide portlets for Consumers who integrate them into their portal for their users.

"WSRP Consumer" on page 1436
WSRP Consumers consume the portlets that Producers provide.

"How Producer and Consumer portals communicate" on page 1436
The WSRP standard defines the interfaces and the protocol for communication between the Producer portal and the Consumer portal.

"Abbreviations" on page 1437
These topics about WSRP and the portal use some abbreviations.

Related information:

 OASIS WSRP Standard

WSRP Producer

WSRP Producers provide portlets for Consumers who integrate them into their portal for their users.

A WSRP Producer is a portal that provides WSRP services. These WSRP services make it possible for Consumers to access and call portlets on the Producer portal. Consumer portals can then consume portlets from the Producer portal as remote portlets by calling these WSRP services. The Producer works as the "server" of the WSRP communication.

A WSRP Producer provides one or more portlets through WSRP services for invocation by Consumer applications from remote sites. The Producer portal receives the requests from the Consumer portal to the WSRP service. The Producer portal generates the markup as required and sends it to the Consumer portal, where it is displayed for the user who started the request.

To allow communication between the Producer portal and the Consumer portal, the Producer provides a set of web service interfaces to the Consumers. These interfaces are defined by the WSRP standard. The Producer can make some or all of these interfaces available to the Consumers as appropriate. The Producer provides a description for the WSRP service interfaces and WSRP services in a service description document. The format of the service description document is defined in the Web Services Description Language (WSDL) standard. This WSDL service description also provides general technical information, for example, the endpoint addresses of the WSRP services.

WSRP Consumer

WSRP Consumers consume the portlets that Producers provide.

A WSRP Consumer is a portal that calls WSRP services on Producer portals and consumes portlets from Producer portals that provide them as remote portlets.

The Consumer part of the WSRP implementation in the portal enables the portal to consume portlets by calling WSRP services from remote Producer portals. The Consumer works as the "client" of the WSRP communication.

A WSRP Consumer integrates selected portlets into the Consumer portal as remote portlets. The Consumer portal requests and receives the markup from the remote WSRP service at the Producer portal and presents it to its users. This way, the Consumer portal can consume one or more remote portlets through the WSRP services.

How Producer and Consumer portals communicate

The WSRP standard defines the interfaces and the protocol for communication between the Producer portal and the Consumer portal.

To set up communication with a Producer portal, the Consumer portal requires the following information from the Producer portal:

- The WSDL (Web Services Description Language) service description document, which provides the following information:
  - Descriptions of the WSRP interfaces and WSRP services that the Producer provides.
  - Technical information, such as the service endpoint addresses.
- Information about the quality of service and security configuration of the WSRP services on the Producer portal.

When the Consumer has this information, the administrator of the Consumer portal can configure the Consumer portal accordingly. After this configuration, the Consumer can consume remote portlets from the Producer portal.

Depending on the overall WSRP setup, the Consumer might in turn provide information to the Producer. For example, if the Producer portal has security configured, the Consumer can send user IDs of Consumer portal users to the Producer. The Producer can then give these users access to the provided portlets. The Consumer portal users can then work with the portlets that the Consumer portal consumes from the Producer.

Planning for WSRP

Before you work with WSRP, plan your configuration based on the information in the following topics.

You can consume portlets from a IBM WebSphere Portal Express or from a different WSRP Producer such as the IBM WSRP Version 2.0 Producer for IBM WebSphere Application Server.

Prerequisites for WSRP in the portal

If you want to use WSRP with your portal, you must have the appropriate level of IBM WebSphere Application Server installed. Refer to WebSphere Portal detailed system requirements to determine the WebSphere Application Server version that is required by your version of WebSphere Portal Express.

"Supported portlet APIs"

Supported portlet APIs

Learn about how the WSRP implementation in WebSphere Portal Express Version 8.5 supports different portlet APIs.

Currently, there are two versions of the WSRP standard, WSRP 1.0 and WSRP 2.0. WebSphere Portal Express supports both versions of the WSRP standard.

You can use the WSRP implementation in WebSphere Portal Express Version 8.5 to do the following with your portal:

For Producer portals:

The WebSphere Portal Express WSRP Producer can provide a portlet through WSRP 1.0, or 2.0, or both, depending on the API version of the portlet:

- The Producer can provide JSR 168 portlets through both WSRP V 1.0 and V 2.0.
- The Producer can provide JSR 286 portlets only through WSRP V 2.0.

The following table shows which provided portlets on a WSRP Producer are available in which WSRP version:

Table 176. . Which API type portlets the Producer can provide through the WSRP versions.

API to which the portlet complies	Provided by WSRP V 1.0	Provided by WSRP V 2.0
JSR 168 standard API	X	X
JSR 286 standard API	JSR 286 portlets cannot be provided by WSRP V 1.0.	X

For Consumer portals:

The WebSphere Portal Express WSRP Consumer supports both WSRP V 1.0 and WSRP V 2.0 Producer portals. It can therefore consume all two types of portlets: JSR 168 and JSR 286.

Note: Currently, the WSRP Producer implementation in the portal does not support the Registration interface of the WSRP specification. This interface is optional. However, the Consumer portal can handle Producers that support WSRP registration interfaces.

Exchanging the required information between Producer and Consumer portals

The WSRP standard defines the interfaces and the protocol for communication between the Producer portal and the Consumer portal. The Producer portals provide WSRP services that can be called to invoke provided portlets. The Consumer portals request WSRP services to call the remote portlets.

Currently, there are two versions of the WSRP standard, WSRP 1.0 and WSRP 2.0. WebSphere Portal Express supports both versions of the WSRP standard.

WSRP builds upon existing web service technology and web service standards. The WSRP implementation of WebSphere Portal Express Version 8.5 is built on the JAX-WS based web service stack of IBM WebSphere Application Server. The WSRP implementation in earlier versions of WebSphere Portal Express was based on the web service stack that is based on the JAX-RPC standard. WSRP in WebSphere Portal Express Version 8.5 can interoperate with WSRP counterparts that are built on other web service stacks, such as JAX-RPC. In particular, WSRP in WebSphere Portal Express Version 8.5 can communicate and interoperate with WSRP counterparts in WebSphere Portal Express Version 8.0 and earlier versions.

WSRP defines a set of four web service interfaces. Two of these web service interfaces are mandatory and two are optional. The following table shows how the WSRP Producer and the WSRP Consumer support the interfaces:

Table 177. The four WSRP web service interfaces and how the WSRP Producer and Consumer support them

Web service interface	Supported by WebSphere Portal Express WSRP Producer	Supported by WebSphere Portal Express WSRP Consumer
Service Description	Yes	Yes
Markup	Yes	Yes
Registration (optional)	No	Yes
Portlet Management (optional)	Yes	Yes

Currently, the WSRP Producer implementation of the portal does not support the Registration interface of the WSRP specification. However, the Consumer implementation of the portal can interoperate with Producers that support WSRP Registration interfaces.

To set up communication with a Producer portal, the Consumer portal requires the following information from the Producer portal:

- The WSDL (Web Services Description Language) service description document, which provides the following information:
  - Descriptions of the WSRP interfaces and WSRP services that the Producer provides.
  - Technical information, such as the service endpoint addresses.

- Information about the quality of service and security configuration of the WSRP services on the Producer portal.

When the Consumer has this information, the administrator of the Consumer portal can configure the Consumer portal accordingly. After this configuration, the Consumer can consume remote portlets from the Producer portal.

Depending on the overall WSRP setup, the Consumer might in turn provide information to the Producer. For example, if the Producer portal has security configured, the Consumer can send user IDs of Consumer portal users to the Producer. The Producer can then give these users access to the provided portlets. The Consumer portal users can then work with the portlets that the Consumer portal consumes from the Producer.

The information that follows here describes details of the WSRP Producer and the WSRP Consumer. These details are relevant for the administrators of their respective portals. For example, an administrator of the WSRP Producer must know which service providers the WSRP Producer supports. An administrator of the WSRP Consumer normally does not need to know about the implementation details of a WSRP Producer.

Service providers of the WSRP Producer

To comply with the JAX-WS standard, the WSRP Producer of WebSphere Portal Express provides a set of service providers that implement the WSRP web service interfaces. The following table lists the supported service providers:

Table 178. WSRP Producer service providers that provide the web service interfaces for the two WSRP versions

Web service interface	WSRP 1.0 service provider	WSRP 2.0 service provider	WSRP 2.0 service provider for portal-internal WSRP communication
Service Description	WSRPServiceDescriptionService	WSRPServiceDescriptionService_v2	WSRPServiceDescriptionService_v2_internal
Markup	WSRPBaseService	WSRPBaseService_v2	WSRPBaseService_v2_internal
Portlet Management	WSRPPortletManagementService	WSRPPortletManagementService_v2	WSRPPortletManagementService_v2_internal

You can administer and configure each of the WSRP 1.0 and 2.0 service providers separately. You administer and configure them by using the administration clients of WebSphere Application Server. For example, you can use the WebSphere Integrated Solutions Console.

Note: Do not change the configuration of the WSRP 2.0 service providers for portal-internal WSRP communication. These service providers are used internally by WebSphere Portal Express during client side aggregation. Remote consumer portals cannot access these service providers.

Service clients and references of the WSRP Consumer

The WSRP Consumer of WebSphere Portal Express provides a set of service clients and default service references. The set includes two service clients, one each to support WSRP 1.0 and WSRP 2.0 and the respective port types or web service interfaces. There is one default service reference per service client. You can configure and administer the service clients and service references by using the WebSphere Integrated Solutions Console. For example, you can use the WebSphere Integrated Solutions Console to configure WSRP service providers and WSRP service clients by attaching policy sets. You can configure each service client and service reference separately.

The following table lists the supported service clients and service references:

Table 179. WSRP Consumer service clients and service references for the two WSRP versions

	WSRP 1.0	**WSRP 2.0**
Service client	`WSRPService`	`WSRPService_v2`
Service reference	`service/wsrp/WSRPService`	`service/wsrp/WSRPService_v2`

The service clients support all WSRP service interfaces: Service Description, Markup, Portlet Management, and Registration.

Note: The configuration of the WSRP service clients is managed outside WebSphere Portal Express. The portal WSRP Consumer supports all service client configurations that are configured in WebSphere Application Server. This support includes message level security, transport level security, and other quality of service configuration. However, the service client configuration of the WSRP Consumer must be compatible with the web service configuration of the WSRP Producer. Example: If the service providers of the Producer portal are configured for WS-Security, the service references of the Consumer portal must also be configured for WS-Security. Otherwise, the WSRP communication fails.

Related concepts:

"Information that the Producer exchanges with the Consumer" on page 1452
As a WSRP Producer, you must provide information to Consumers of your WSRP services so that they can prepare for consuming them as remote portlets. Depending on the configuration, you might also need information from the Consumer.

"Information that the Consumer exchanges with the Producer" on page 1458
Before a Consumer can consume portlets from a Producer, the Consumer needs specific information about the Producer. Depending on your configuration, you might also need to provide information about your Consumer portal to the Producer.

Security for WSRP services

IBM WebSphere Portal Express supports two security mechanisms for WSRP.

You can configure security for WSRP in your WebSphere Portal Express, but you do not need to configure security.

If security is configured for both the WSRP Producer and the WSRP Consumer, the WSRP Consumer sends a security token to the WSRP Producer as part of the WSRP request message. The security token represents the identity of the current user of the Consumer portal. The WSRP Producer uses this security token to authenticate and identify the user. The WSRP Producer processes the WSRP request under this user identity and performs access control for the provided portlets. If the WSRP Producer cannot process the security token or cannot authenticate the user on the WSRP Consumer side, the WSRP Producer rejects the WSRP request.

WebSphere Portal Express supports the following security mechanisms:

HTTP-cookie-based single sign-on

You can configure the WSRP Consumer to forward LTPA V2 cookies to the WSRP Producer as part of the WSRP request messages. The WSRP Producer uses these cookies to authenticate and identify the user and establish the security context for processing the WSRP request. This security option has the following advantages:

- It does not require configuration of the WSRP web services.
- It makes it possible for the WSRP Producer to accept and process both unauthenticated and authenticated requests. The Producer processes unauthenticated requests that do not contain an LTPA V2 cookie without establishing an individual security context. This way, it can serve requests from anonymous users.

Web Services Security (WSS)
You can configure the WSRP Consumer and WSRP Producer for Web Services Security according to the WS-Security standard. With a WS Security configuration, the WSRP Consumer sends a header that complies with the WS-Security standard as part of the WSRP request messages. The header contains credentials that identify and authenticate the user. For this option, both the WSRP Consumer and the WSRP Producer must be configured for Web Services Security.

For a WSRP Producer, security configuration is optional. A WSRP Consumer must use the same security configuration as the WSRP Producer from which it consumes portlets. If the request message that is sent by the WSRP Consumer does not comply to the security configuration of the WSRP Producer, the WSRP Producer does not accept the message. If the request message from the WSRP Consumer contains the security token that the WSRP Producer expects, the Producer processes the request under the appropriate user identity. If the WSRP Producer is not configured for security, it processes WSRP requests under the anonymous user identity.

Considerations for configuring security:

For Producer portals:
For a Producer portal, security for WSRP services is **optional**. You can configure securityt if required, but you do not have to do so.

When you configure security, you must also configure Portal Access Control and assign access rights for the Consumer portal users on the Producer portal. Assign the access rights based on the security configuration information as follows:

- If you use security, assign access rights on the Producer portal to the actual Consumer portal users.
- If you do not use security, assign access rights to the anonymous user, or disable Portal Access Control for the WSRP Producer.

By default, Portal Access Control is enabled for the WSRP Producer. For details about how to disable and enable Portal Access Control for the WSRP Producer, read *Configuring Portal Access Control for a WSRP Producer portal*.

For Consumer portals:
- For a Consumer portal, you must define a security configuration that is compatible with the security configuration of the Producer portal from which you consume WSRP services. This configuration must include all the appropriate security aspects.
- On the Consumer portal, the consumed portlets behave like local portlets. Therefore, you can configure Portal Access Control for the remote portlets on the Consumer portal the in same way as for local portlets. If you use Web Services Security, do not make the affected remote portlets available to anonymous users on the Consumer portal.

Instead, configure Portal Access Control to make the affected remote portlets available to authenticated users only.

For portals that work as both a Producer and a Consumer portal:

- If you use your portal as both a Producer and a Consumer portal, the security configurations for both these roles are independent of each other.

For more detailed information about Portal Access Control, read the sections about *Configuring Portal Access Control for a WSRP Producer portal* and *Managing Access Control*.

 WebSphere Application Server product documentation V 8.5

How you work with WSRP in your portal

To work with WSRP in your portal, you perform different administrative tasks. Some of these tasks depend on whether you use your portal as a Producer or Consumer portal.

Producer tasks

When Producers work with WSRP, they perform the following tasks:

1. Planning for WSRP
2. Using your portal as a WSRP Producer:
   a. Preparing security for a WSRP Producer portal and configuring the WSRP service providers. Preparing security is optional, depending on your setup.
   b. Exchanging the required information with Consumers of your WSRP services. This exchange includes information about the WSRP interfaces and the configuration of the WSRP services.
   c. Working with WSRP:
      1) Providing the local portlets in your Producer portal as WSRP services so that Consumer portals can consume and call them as remote portlets.
      2) Withdrawing a portlet. If you withdraw a portlet, Consumers can no longer consume this portlet remotely.
      3) If you do not use message authentication, assign anonymous users the Privileged User role for the provided portlets.

      To perform these tasks, you use the **Manage Portlets** portlet. Alternatively, you can use the XML configuration interface.
   d. Customizing the WSRP configuration of your Producer portal.

Consumer tasks

When Consumers work with WSRP, they perform the following tasks:

1. Planning for WSRP
2. Using your portal as a WSRP Consumer:
   a. Exchanging the required information for the WSRP communication with the Producer. This exchange includes information about the WSRP interfaces and the configuration of the WSRP services.
   b. Configuring the WSRP service clients, especially the security aspects. Whether you must perform this task depends on the Producer portal security setup.
   c. Creating and configuring one or more Producer definitions for the Producer portals from whom you want to consume WSRP services. To work with Producer definitions, use the portal administration portlet **Web Service Configuration**. You can also use the XML configuration interface.
   d. Consuming WSRP services, that is integrating and using the WSRP services in your portal as remote portlets. To consume WSRP services, use the portal administration portlet **Manage Web Modules**. You can also use the XML configuration interface.

Using your portal as a WSRP Producer

Learn about the tasks that you perform when you use your portal to provide WSRP services as a WSRP Producer portal.

About this task

1. "How to access the Producer WSDL" on page 1445
   As a Producer you must provide the URL for the Producer WSDL service description document to the Consumer.
2. "Securing a WSRP Producer portal" on page 1447
   To secure provided portlets, you can configure the WSRP Producer for web service message security, for example, for message authentication. If you configure message authentication, you must also configure Portal Access Control.
3. "Information that the Producer exchanges with the Consumer" on page 1452
   As a WSRP Producer, you must provide information to Consumers of your WSRP services so that they can prepare for consuming them as remote portlets. Depending on the configuration, you might also need information from the Consumer.
4. "Providing WSRP services as a Producer" on page 1454
   After you prepared your portal as a Producer portal, you can provide your portlets through WSRP. Providing portlets makes them available to Consumers. They can integrate them into their Consumer portals and use them as remote portlets. You can also withdraw portlets from being provided through WSRP. Consumer portals can then no longer use them.
5. "Exporting customized WSRP portlet instances by using the XML configuration interface" on page 1456
   If consumed portlets are customized on the Consumers portal, then the Producer can export the customized instances of those portlets by using the XML configuration interface.
6. "Changing the WSRP Producer context root" on page 1457
   The context root for the WSRP Producer references the context root for the WSRP Producer facade servlet. This context root is the entry point for all WSRP

protocol traffic, and you can change the context root as required to support your environment. This customization is optional.

How to access the Producer WSDL

As a Producer you must provide the URL for the Producer WSDL service description document to the Consumer.

The basic WSDL document is available under the following URL:

`http://producer_portal_host:producer_port/WpsContextRoot/wsdl/wsrp_service.wsdl`

where *WpsContextRoot* is the portal context root that was set at installation time. You can find its value in the file `wkplc.properties`.

This URL refers to a WSDL file with the WSRP 2.0 services. When a Consumer portal administrator configures the Consumer portal to interact with the Producer, the Consumer administrator must specify the WSDL URL. The Consumer accesses this URL and reads the contents of the WSDL document, which provides the endpoint addresses of the WSRP 2.0 services. Consumers use these endpoint addresses to communicate with the Producer through the WSRP protocol.

The URL format of the WSRP service endpoint addresses is as follows:

protocol`://`*host_name*`:`*port_number*`/`*wsrp_context_root*`/`*wsrp_port_name*

wsrp_context_root references the context root for the WSRP Producer facade servlet. The facade servlet is provided with the `wps.ear` enterprise application in the WebSphere Portal Server WSRP Facade web module `wps_facade.war` and controls access to the WSRP web service engine.

You can change the context root for the WSRP Producer with the `modify-servlet-path` configuration task, as described in *Changing the portal URI*

In addition, you can configure and override various settings to manipulate the contents of the WSDL document. To do so, you specify the appropriate parameters in the URL for the WSDL service description document:

- The WSRP version: WSRP Version 1.0, WSRP Version 2.0, or both
- The host name for the endpoint addresses
- The transfer protocol: HTTP, HTTPS, or both
- The port number for HTTP URLs
- The port number for HTTP**S** URLs.

To generate the WSDL service description document, the Producer portal uses the following parameters:

1. Parameters from the URL of the request for the service description document
2. Settings in the portal Configuration Service
3. Settings that result from the request for the service description document.

As a result, the portal provides a fallback mechanism for selecting the parameters from the WSDL service description document, depending on which parameters you specify:

1. If the administrator of the Consumer portal adds parameters as URL parameters to the URL for requesting the service description document, then the Producer portal uses these parameters. For example, it can use the parameters for creating the endpoint addresses of the WSRP web services that are contained in the WSDL document.

2. If you do not define such a parameter as a URL parameter in the service description document request, then the Producer looks for entries in the portal Configuration Service.
3. If you do not specify the parameter in the Configuration Service, then the Producer uses the host name and port of the incoming request to generate the endpoint addresses of the WSRP web services that are contained in the WSDL document.

URL parameters

The administrator of the Consumer portal can request a modified WSDL service description document from the Producer. In this document, the Producer modifies the endpoint addresses of the WSRP web services according to URL parameters that the Consumer provided. These parameters that are listed and described in the following table. Here is an example of the supported URL syntax:

```
http://producer_portal_host:producer_port/wp_contextRoot/wsdl/wsrp_service.wsdl
       ?protocol=<protocolValue>&port=<httpPort>&securePort=<httpsPort>
       &version=<WSRPVersion>&hostname=<hostname>
```

The following table lists possible values for URL parameters:

Table 180. Values for URL parameters:

URL parameter	Possible values	Results in WSDL file
`protocol`	`http`	WSRP endpoint addresses with HTTP protocol
	`https`	WSRP endpoint addresses with HTTP**s** protocol
	mixed	WSRP endpoint addresses with HTTP and with HTTP**s** protocol
`version`	`v1`	WSRP services for WSRP Version 1.0
	`v2`	WSRP services for WSRP Version 2.0
`port`	Integer, for example `80`	Port number for HTTP endpoint addresses
`portSecure`	Integer, for example `443`	Port number for HTTP**s** endpoint addresses
`hostname`	Name of the host, for example `localhost`	The host name that is used for endpoint addresses

Note: The URL parameters do not modify the Producer settings and bindings. They manipulate only the content of the WSDL service description document, for example, for debugging and tracing purposes.

Settings in the portal Config Service

To control the default output for the WSDL document, you set the following parameters in the portal configuration service:

wsrp.hostname = localhost
: Use this property to specify a host name for the endpoint addresses in the WSRP service WSDL document of the Producer.

wsrp.port.http = 80
Use this property to specify the HTTP port that is used for the endpoint addresses in the WSRP service WSDL document of the Producer.

wsrp.port.https = 443
Use this property to specify the HTTP**S** port that is used for the endpoint addresses in the WSRP service WSDL document of the Producer.

Related tasks:

"Changing the portal URI after an installation" on page 368
You can change the default portal Uniform Resource Identifier (URI) any time after you install IBM WebSphere Portal Express. Some applications have a fixed context root that cannot be changed.

Securing a WSRP Producer portal

To secure provided portlets, you can configure the WSRP Producer for web service message security, for example, for message authentication. If you configure message authentication, you must also configure Portal Access Control.

"Configuring security on the Producer portal"
You can configure security for the WSRP Producer portal and the provided portlets. If you enable security, the WSRP Producer processes the WSRP requests from the WSRP Consumer under the user identity that is associated with the WSRP request that the Consumer sent. This user identity is represented by a security credential that is included in the WSRP request message. The security credential is provided by the WSRP Consumer. Normally, it represents the identity of the user who is logged in to the Consumer Portal.

"Configuring Portal Access Control for a WSRP Producer portal" on page 1452
If you configure security for WSRP services, you must also configure Portal Access Control for the Producer.

Configuring security on the Producer portal:

You can configure security for the WSRP Producer portal and the provided portlets. If you enable security, the WSRP Producer processes the WSRP requests from the WSRP Consumer under the user identity that is associated with the WSRP request that the Consumer sent. This user identity is represented by a security credential that is included in the WSRP request message. The security credential is provided by the WSRP Consumer. Normally, it represents the identity of the user who is logged in to the Consumer Portal.

About this task

Note: For the WSRP Producer, security for WSRP services is optional. You can configure it if required, but you do not have to provide security. If you provide security for your WSRP services, the WSRP Consumer must be configured to use the same security mechanism as the WSRP Producer from which the Consumer consumes portlets.
You can configure security for the WSRP Producer by using either of the following two authentication mechanisms:

HTTP-cookie-based single sign-on
This security option is newly available with WebSphere Portal Express Version 8.5. To authenticate and identify the user and establish the security context for processing the WSRP request, the WSRP Producer uses LTPA V2 HTTP cookies that the WSRP Consumer sends as part of the WSRP request messages. The WSRP Producer receives the cookie and establishes

the corresponding security context on the Producer side. This option requires configuration of the WSRP Consumer to forward HTTP cookies. It has the following advantages:

- It does not require configuration of the WSRP web services. It makes it possible for the WSRP Producer to accept and process both unauthenticated and authenticated requests.
- The Producer processes unauthenticated requests that do not contain an LTPA V2 cookie without establishing an individual security context.

Web Service Security

You can configure the WSRP web service providers for Web Service Security according to the WS-Security standard. The WSRP Consumer sends a header that complies with the WS-Security standard as part of the WSRP request messages. The header contains credentials that identify and authenticate the user. For example, you can configure the Consumer portal to include Lightweight Third-Party Authentication (LTPA) version 1 or version 2 tokens or Username tokens in the WS-Security header. For this option, both the WSRP Consumer and the WSRP Producer must be configured for Web Services Security.

The Web Service Security configuration is based on policy sets. IBM WebSphere Portal Express provides a set of default policy sets and provider policy set bindings that can be attached to the WSRP service providers. If you configure your WSRP Producer for WS-Security, the Producer accepts and processes only authenticated requests. It rejects unauthenticated requests that do not contain a WS-Security compliant header.

For both security setup options, the WSRP Producer and the WSRP Consumer must be configured for Single Sign-On (SSO). The requirements for SSO depend on the authentication method that is used. For example, if you use LTPA version 1 or version 2, the WSRP Consumer and the WSRP Producer must use the same user registry or use the same realm. In addition, the WSRP Producer and the WSRP Consumer must exchange shared keys that are used to sign the security credentials.

If you use the Web Services Security option, the WSRP Producer accepts only authenticated request messages and rejects request messages that do not contain a suitable security header. In contrast, if you use the HTTP-cookie-based single sign-on security option, the WSRP Producer accepts both authenticated and unauthenticated request messages. If the message does not contain a security credential, the WSRP Producer does not establish a security context for processing the request. By default, the WSRP Producer performs access control for provided portlets.

You can choose to not set up security for the WSRP Producer and Consumer portals. In this case, the WSRP Producer does not process the WSRP requests from the Consumer under a specific user identity. Instead, the Producer processes the WSRP requests anonymously. In this case, the Consumer must not be configured for Web Service Security.

"Securing the WSRP Producer by HTTP-cookie-based single sign-on" on page 1449

You can provide security for your WSRP Producer by using HTTP-cookie-based single sign-on (SSO). For using this security option, the WSRP Producer

requires no configuration. The WSRP Consumer must be configured to send or forward LTPA V2 single sign-on cookies as part of the WSRP request message to the WSRP Producer.

"Securing the WSRP Producer by WS-Security" on page 1450
You can configure Web Services Security according to the WS-Security standard for your WSRP Producer and the provided web services.

WebSphere Application Server product documentation V 8.5

Securing the WSRP Producer by HTTP-cookie-based single sign-on:

You can provide security for your WSRP Producer by using HTTP-cookie-based single sign-on (SSO). For using this security option, the WSRP Producer requires no configuration. The WSRP Consumer must be configured to send or forward LTPA V2 single sign-on cookies as part of the WSRP request message to the WSRP Producer.

About this task

The single sign-on cookie represents a security credential that can be understood both by the WSRP Consumer and the WSRP Producer. The WSRP Producer receives the cookie and establishes the corresponding security context for the user on the Producer side.

For using HTTP-cookie-based single sign-on, the WSRP Producer must not be configured for Web Services Security.

Prerequisites for using HTTP-cookie-based single sign-on:

For using HTTP-cookie-based single sign-on (SSO), single sign-on must be configured between the WSRP Consumer and the WSRP Producer. This configuration requires the following two prerequisites:

- The WSRP Consumer and the WSRP Producer must be configured to use a shared user registry.
- The LTPA keys must be exchanged between WSRP Consumer and WSRP Producer.

Required WSRP Consumer configuration:

For using HTTP-cookie-based single sign-on, the WSRP Consumer must be configured to forward single sign-on cookies to the WSRP Producer. For more information, read *Securing the WSRP Consumer by HTTP-cookie-based single sign-on*.

Related tasks:

"Securing the WSRP Consumer by HTTP-cookie-based single sign-on" on page 1463
You can configure your WSRP Consumer for using HTTP-cookie-based single sign-on. For this option, you must configure the WSRP Consumer to send or forward LTPA V2 single sign-on cookies as part of the WSRP request message to the WSRP Producer.

Securing the WSRP Producer by WS-Security:

You can configure Web Services Security according to the WS-Security standard for your WSRP Producer and the provided web services.

About this task

The WSRP Producer in IBM WebSphere Portal Express provides a set of JAX-WS compliant service providers. You can manage the configuration of the WSRP service providers in IBM WebSphere Application Server through the concept of policy sets. You might want to configure the service providers of the WSRP Producer for WS-Security-based authentication and caller identification. You can do so by attaching an appropriate policy set to the service provider, for example by using the WebSphere Integrated Solutions Console.

The WebSphere Application Server ensures message security and quality of service according to the configuration that you defined. The WSRP Producer provides a set of default policy sets and default provider policy set bindings. You can use them for configuring WSRP service providers. You do not have to create your own policy set and provider policy set binding.

The following table describes the provided WSRP application policy sets and the provided WSRP provider policy set bindings:

Table 181. Provided WSRP application policy sets and provided WSRP provider policy set bindings

	WSRP application policy sets	**WSRP provider policy set bindings**
LTPA based	**LTPA-based message authentication policy set** This policy set defines LTPA token-based message authentication. It does not define other security mechanisms such as message confidentiality, or other web service mechanisms such as WS-Addressing.	**LTPA-based message authentication provider binding** You must use this provider policy set binding with the LTPA-based message authentication policy set. It defines the corresponding provider binding, including caller identification.
Username based	**Username-based message authentication policy set** This policy set defines Username token-based message authentication. It does not define other security mechanisms such as message confidentiality, or other web service mechanisms such as WS-Addressing.	**Username-based message authentication provider binding** You must use this provider policy set binding with the Username-based message authentication policy set. It defines the corresponding provider binding, including caller identification.

The WSRP application policy sets and client policy set bindings are contained in

compressed format in the directory `PortalServer/doc/policy-sets-samples` of the portal installation. For instructions about how to import and attach policy sets and provider policy set bindings, read the WebSphere Application Server documentation.

To use the WSRP policy sets and provider policy set bindings for service configuration, use the procedure given later in this topic.

Note: You are not limited to using the default policy sets and provider policy set bindings. Instead, you can also create and use a policy set and provider policy set binding of your choice. The WSRP Producer supports all service configurations that WebSphere Application ServerWebSphere Application Server supports. Therefore, you can use all security tokens that WebSphere Application Server supports. Some token types might require a specific setup. For more detailed information about web service configuration, read the WebSphere Application Server product documentation. Note that it is necessary to define a compatible web service configuration on the WSRP Consumer portals.

Procedure

1. Import the WSRP policy sets and provider policy set bindings. To do so, use a WebSphere Application Server administrative client, such as the WebSphere Integrated Solutions Console:
   a. Open the **Application policy sets** panel.
   b. Select **Import (From Selected Location)**.
   c. Select the LTPA-based message authentication policy `set.zip` file or the username-based message authentication policy `set.zip` file that you want to import.
   d. Open the **General provider policy set bindings** panel.
   e. Select **Import (From Selected Location)**.
   f. Select the LTPA-based message authentication provider `binding.zip` file or username-based message authentication provider `binding.zip` file that you want to import.
2. Attach the policy set and provider policy set binding to a WSRP service provider. Proceed as follows:
   a. Open the **Service providers** panel.
   b. Open the service provider that you want to configure. Do not select one of the internal service providers, such as `WSRPBaseService_v2_internal`, `WSRPPortletManagementService_v2_internal`, or `WSRPServiceDescriptionService_v2_internal`.
   c. Select the service. The service is the first resource listed.
   d. Use the **Attach** option to select and attach the LTPA-based message authentication policy set or the username-based message authentication policy set.
   e. Select the service. The service is the first resource listed.
   f. Use the **Assign Binding** option to select and assign the LTPA-based message authentication provider binding file or username-based message authentication provider binding.
   g. Save your changes to the master configuration.
3. After you have completed this configuration, restart your portal.

WebSphere Application Server product documentation V 8.5

Configuring Portal Access Control for a WSRP Producer portal:

If you configure security for WSRP services, you must also configure Portal Access Control for the Producer.

Before you begin

By default Portal Access Control is enabled for the Producer portal. You might want to disable Portal Access Control for using WSRP with WebSphere Portal. You can disable the WSRP security by setting the portal configuration parameter `wsrp.security.enabled` in the portal WP Configuration Service to `false`. You complete this step in the WebSphere Integrated Solutions Console. With this setting all portlets that your Producer portal provides can be accessed through the WSRP protocol without any authentication.

To enable Portal Access Control for the Producer portal again, set the portal configuration parameter `wsrp.security.enabled` in the portal WP Configuration Service to `true`.

Procedure

1. Activate the WSRP security by setting the property `wsrp.security.enabled` to `true` in the portal WP Configuration Service in the WebSphere Integrated Solutions Console.
2. Assign access rights based on the authentication information:
   - If you use security, assign access rights to the actual Consumer portal users. Get the user information from the Consumer.
   - If you do not use security, assign access rights to the anonymous user.

Information that the Producer exchanges with the Consumer

As a WSRP Producer, you must provide information to Consumers of your WSRP services so that they can prepare for consuming them as remote portlets. Depending on the configuration, you might also need information from the Consumer.

The exchange between Producers and Consumers includes the following information:

- "WSRP service description"
- "WSRP services configuration" on page 1453
- "Information about portal users" on page 1453
- "Registration information" on page 1453

WSRP service description

WSRP Consumers need information about how to bind to the WSRP services that the Producer provides. This information is described in the Web Service Description Language (WSDL) document of the Producer. The WSDL document provides general technical information about how the Consumer connects to the Producer and about the related infrastructure. The Consumer can use the information in the WSDL document to bind to the Producer and retrieve the Producer's service description for further details about the Producer.

The WSDL document provides information about various aspects and properties of the Producer:

- The WSRP services that the Producer provides

- The end-point addresses of the WSRP services.

As a Producer you can customize the content of the WSDL service document that you provide to WSRP Consumer portals.

WSRP services configuration

The Producer must provide information about the configuration of the WSRP web services to the Consumer. The Producer web service configuration is not described in the WSDL service description document. For WSRP communication to be successful, the WSRP producer web service configuration and the WSRP Consumer web service configuration must be compatible. The administrator of the WSRP Consumer portal must ensure that the WSRP Consumer portal uses a web services configuration that is compatible with the configuration of the Producer portal.

Example: The Producer configures web service security by using LTPA V2 tokens for WSRP services. If the Consumer sends messages that are secured by a different mechanism or not secured at all, the Producer cannot accept the messages.

Depending on the mechanism that is used for security, the Producer and Consumer portals must be set up specifically. For example, a security mechanism can require a user repository that is shared between the Consumer and Producer portals. Other security mechanisms can also require an exchange of certificates or public keys between the Consumer and Producer portals. For details about the prerequisites and implications of web service configuration and security, read the WebSphere Application Server product documentation.

Information about portal users

If the Producer portal has security for its WSRP services set up, the administrator of the Producer portal must assign access permissions to the users of the Consumer portal by using Portal Access Control. In this case, the Producer must obtain the required user information from the Consumer.

Registration information

If the Producer requires registration by the Consumer portal, the Producer must provide the required registration information to the Consumer.

"Producer checklist for exchanging information with a Consumer"
Use this list to check whether you provided and obtained all required information that you must exchange with the Consumer.

Producer checklist for exchanging information with a Consumer:

Use this list to check whether you provided and obtained all required information that you must exchange with the Consumer.

Information that a Producer provides to a Consumer

Mandatory information:

The WSDL service description document that contains the WSRP service description of the Producer.

The following information can be required.

Whether this information is required depends on the setup of the Producer portal:

The service configuration of the Producer portal.

If the Producer has set up a specific WSRP configuration, the Consumer needs this information. For example, a security mechanism can require a user repository that is shared between the Consumer and Producer portals. Other security mechanisms can also require an exchange of certificates or public keys between the Consumer and Producer portals.

Registration information.

The Consumer needs this information if the Producer requires registration.

Group IDs and handles of portlets.

If the Consumer administrator consumes a remote portlet from a Producer portal by using the XML configuration interface, the Consumer needs the group IDs and the portlet handles of the remote portlets at the Producer portal.

Information that a Producer obtains from a Consumer

The following information can be required.

Whether this information is required depends on the security setup of the Producer portal:

User information about users of the Consumer portal who uses the remote portlets.

If the Producer portal has security configured, the Producer needs this information to give the users of the Consumer portal access permission to the provided WSRP services.

Providing WSRP services as a Producer

After you prepared your portal as a Producer portal, you can provide your portlets through WSRP. Providing portlets makes them available to Consumers. They can integrate them into their Consumer portals and use them as remote portlets. You can also withdraw portlets from being provided through WSRP. Consumer portals can then no longer use them.

About this task

To provide or withdraw a portlet for WSRP services, you can use either of the following options:

- The portal administration portlet **Manage Portlets**.
- The portal XML configuration interface. For more information about the XML configuration interface (XMLAccess), read the topics about the XML configuration interface.

Notes:

1. A Producer provides portlets, not portlet instances. Therefore, only settings that are made in the Configure mode of the portlet on the Producer portal are available at the consumed remote portlet. Adding a remote portlet to a page on the Consumer side might create a new instance of the provided portlet on the Producer side. This portlet instance can be modified only on the Consumer portal. It is not available for use on the Producer portal.

2. Customization of the Producer portlets by Consumer portal users can be exported by using the XML configuration interface.

Proceed by selecting the appropriate topic from the following links:

"Using the Manage Portlets portlet to provide portlets through WSRP"
To provide portlets through WSRP, you use the **Manage Portlets** portlet. You can also use this portlet to withdraw the portlet from being available through WSRP.

"Using the XML configuration interface to provide or withdraw a portlet"
A WSRP Producer can provide or withdraw portlets by using the XML configuration interface.

Related concepts:

"The XML configuration interface" on page 1054
Use the XML configuration interface (XML Access) for exchanging portal configurations.

Related information:

"Working with the XML configuration interface" on page 1061
You can use the XML configuration interface to export and import IBM WebSphere Portal Express configurations. This way you can configure selected features or areas of your portal. You can also transfer a complete configuration from one portal to another.

Using the Manage Portlets portlet to provide portlets through WSRP:

To provide portlets through WSRP, you use the **Manage Portlets** portlet. You can also use this portlet to withdraw the portlet from being available through WSRP.

About this task

Click the **Administration menu** icon. Then, click **Portlet Management** > **Portlets**. Then, click **Manage Portlets**.

For details about how to work with the portlet, refer to the portlet help.

Using the XML configuration interface to provide or withdraw a portlet:

A WSRP Producer can provide or withdraw portlets by using the XML configuration interface.

Before you begin

To provide or withdraw the portlet by using the XML configuration interface, specify the `provided` attribute to the `portlet` tag:

provided = "true | false"

Use this attribute with the `portlet` tag to specify providing or withdrawing a portlet:

true To provide the portlet as a WSRP service, you set the `provided` attribute to `true`. When you run the XML script, the portlet is provided through WSRP. The portlet can now be consumed as a remote portlet by Consumer portals.

false To withdraw the portlet, set the `provided` attribute to `false`. The portlet is withdrawn. It is no longer available for Consumer portals to consume.

Example

XML script examples:

The following two XML samples show you how to use the XML configuration interface to provide a portlet that complies with the standard portlet API. The examples show the **provided** attribute highlighted. If you want to withdraw a portlet by using the XML configuration interface, specify `false` instead of `true` for the **provided** tag.

Providing a standard API portlet:

The following XML sample shows you how to provide a portlet that complies with the standard portlet API:

```
<?xml version="1.0" encoding="UTF-8" ?>
<request type="update" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xsi:noNamespaceSchemaLocation="PortalConfig_1.4.xsd">
      <!--
          Sample for providing a standard API compliant portlet as a WSRP producer.
          Be aware that this sample is provided as a sample only.
    It might or might not work, depending on the configuration of your portal.
      -->
   <portal action="locate">
      <!--
          uid must match the uid of the portlet application appended with .webmod
      -->
      <web-app action="locate" active="true"
         uid="stdTestsuite.war.webmod">
            <!--
                uid must match the optional portlet-app id attribute from the portlet.xml.
                If this is not set, the .war file name must be supplied here.
            -->
         <portlet-app action="update" uid="stdTestsuite.war">
            <!--
                Name must match the portlet-name tag in the portlet.xml file.
            -->
            <portlet action="update" name="TestPortlet1" provided="true" />
         </portlet-app>
      </web-app>
   </portal>
</request>
```

Use the XML configuration interface (XML Access) for exchanging portal configurations.

Related information:

"Working with the XML configuration interface" on page 1061
You can use the XML configuration interface to export and import IBM WebSphere Portal Express configurations. This way you can configure selected features or areas of your portal. You can also transfer a complete configuration from one portal to another.

Exporting customized WSRP portlet instances by using the XML configuration interface

If consumed portlets are customized on the Consumers portal, then the Producer can export the customized instances of those portlets by using the XML configuration interface.

Users of the Consumer portal can customize the consumed portlets, if the Producer gave them the required access rights. The customized portlet instances are created on the Producer portal. The Producer portal administrator can export the customized portlet instances by using the XML configuration interface for later import into another portal.

Here is an example XML script for exporting all customized WSRP portlet instances:

```
<request
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd"
    type="export">

    <!-- Sample for exporting the customized portlet instances of a WSRP Producer -->
    <portal action="locate">

        <wsrp-customized-portletinstance objectid="*" action="export"/>

    </portal>
</request>
```

Related concepts:

You can use the XML configuration interface to export and import IBM WebSphere Portal Express configurations. This way you can configure selected features or areas of your portal. You can also transfer a complete configuration from one portal to another.

Changing the WSRP Producer context root

The context root for the WSRP Producer references the context root for the WSRP Producer facade servlet. This context root is the entry point for all WSRP protocol traffic, and you can change the context root as required to support your environment. This customization is optional.

About this task

The facade servlet is provided with the `wps.ear` enterprise application in the `WebSphere Portal Server WSRP Facade` web module `wps_facade.war` and controls access to the WSRP Web Service engine.

Procedure

To change the context root for the WSRP Producer, run the `modify-servlet-path` configuration task, as described in *Changing the portal URI*.

Related tasks:

"Changing the portal URI after an installation" on page 368
You can change the default portal Uniform Resource Identifier (URI) any time after you install IBM WebSphere Portal Express. Some applications have a fixed context root that cannot be changed.

Using your portal as a WSRP Consumer

Learn about the tasks that you perform when you use your portal as a WSRP Consumer portal to consume remote portlets. You can consume portlets from a IBM WebSphere Portal Express or from a different WSRP Producer such as the IBM WSRP Version 2.0 Producer for IBM WebSphere Application Server.

1. "Information that the Consumer exchanges with the Producer" on page 1458
   Before a Consumer can consume portlets from a Producer, the Consumer needs

specific information about the Producer. Depending on your configuration, you might also need to provide information about your Consumer portal to the Producer.

2. "Working with Producer definitions" on page 1473
   To make a WSRP Producer known to your Consumer portal, you create a Producer definition for that WSRP Producer in your Consumer portal. You can also configure the Producer definition.
3. "Consuming portlets in a Consumer portal" on page 1483
   After you create a Producer definition, you can proceed to consume the portlets that are provided by that Producer. This way, you integrate them into your Consumer portal as remote portlets.
4. "Customizing the WSRP configuration of your Consumer portal" on page 1486
   You can customize some aspects of you WSRP Consumer portal.

Related information:

 IBM WSRP 2.0 Producer for WebSphere Application Server documentation

Information that the Consumer exchanges with the Producer

Before a Consumer can consume portlets from a Producer, the Consumer needs specific information about the Producer. Depending on your configuration, you might also need to provide information about your Consumer portal to the Producer.

The information that Producers and Consumers exchange includes the following items:

- "WSRP service description"
- "WSRP interfaces" on page 1459. They are included in the WSDL service description document.
- "WSRP web service configuration and user information" on page 1459
- "Registration information" on page 1460
- "Group IDs and handles of portlets" on page 1460.

WSRP service description

WSRP Consumers need technical information about the WSRP services that the Producer provides. This information is described in the Web Service Description Language (WSDL) document of the Producer. The Consumer can use the information in the WSDL document to set up communication with the Producer.

The WSDL document provides information about various aspects and properties of the Producer:

- The WSRP services that the Producer provides
- The WSRP interfaces that the Producer supports
- The end-point addresses of the WSRP services.

If the WSRP Producer is an IBM WebSphere Portal Express, then Consumers of WSRP services can access the WSDL document of the Producer at the following URL:

`http://producer_portal_host:producer_port/wp_contextRoot/wsdl/wsrp_service.wsdl`

Notes:

1. The host and port and the *wp_contextRoot* directory must match the host and port of the Producer WebSphere Portal Express installation.

2. If the communication with the Producer is set up to use Secure Socket Layer communication, the Consumer must use **HTTPs** to address this URL:

```
https://producer_portal_host:producer_port/wp_contextRoot/wsdl/wsrp_service.wsdl
```

If the WSRP service Producer is *not* a WebSphere Portal Express, then the owner or administrator of the Producer portal must provide the information to the Consumer.

WSRP interfaces

The WSRP standard defines a set of four web service interfaces. The interfaces are listed here:

Service Description
This interface is mandatory. It provides the self-description of the Producer and a description of the available portlets.

Markup
This interface is mandatory. It is an interface for requesting and interacting with markup fragments.

Portlet Management
This interface is optional. It provides operations for managing the lifecycle of the hosted portlets and their persistent state.

Registration
This interface is optional. It is not supported by the current implementation of the WSRP Producer in WebSphere Portal Express. However, the WebSphere Portal Express Consumer can handle Producers that support WSRP registration interfaces.

The Producer can provide some or all of these interfaces to the Consumers as appropriate. The Producer describes these WSRP interfaces in the Web Services Description Language (WSDL) document as described under "WSRP service description" on page 1458. The WSDL document provides general technical information about the web services that the Producer provides.

WSRP web service configuration and user information

The Producer can use a specific security or web service configuration for the provided WSRP services. This configuration can include a specific web service security configuration. The configuration of the WSRP web services on the Consumer portal must be compatible with the web service configuration of the Producer portal. For example, the Producer might configure message authentication according to the WS-Security standard for the WSRP services. In this case, the WSRP Consumer web services must also be configured for message authentication. Depending on the actual web service configuration, the Producer and Consumer portals might have to use the same user registry.

If the Producer portal has security configured for its WSRP services, the administrator of the Producer portal must assign access permissions for the provided portlets to the users of the Consumer portal. to do so, the Producer uses Portal Access Control. In this case, the Producer must obtain the required user information from the Consumer.

Registration information

If the Producer requires registration by the Consumer portal, the Producer must provide the required registration information to the Consumer.

Group IDs and handles of portlets

A Consumer portal can consume a remote portlet from a Producer portal by using the XML configuration interface. In this case, the Consumer portal administrator must specify the `handle` and `groupid` of the remote portlet. Therefore, the Producer must provide this information to the Consumer.

The portlet handle and group ID are listed in the WSRP service description of the Producer. The portlet handle for each portlet that the Producer provides is listed in a `portletHandle` tag. The group ID for each portlet that the Producer provides is listed in the `groupID` tag of the service description.

"Consumer checklist for exchanging information with a Producer"
Use this list to check whether you have obtained and provided all required information that you must exchange with the Producer.

"Configuring security on the Consumer portal" on page 1461
You can configure security for the WSRP Consumer. If you enable security, the WSRP Consumer sends a security token as part of the WSRP request message to the WSRP producer. The security token represents the identity of the user who is logged in to the Consumer Portal. The WSRP Producer uses the security token to process the WSRP requests under the user identity that is represented by the security token.

Consumer checklist for exchanging information with a Producer:

Use this list to check whether you have obtained and provided all required information that you must exchange with the Producer.

Information that a Consumer obtains from the Producer

Mandatory information:

The WSDL document that contains the service description of the Producer.
The WSDL document must include a description of the **two mandatory WSRP interfaces: Service Description and Markup**. The WSDL document can contain a description of the two optional WSRP interfaces: Portlet Management and Registration.

Information that can be required
Depending on the setup of the Producer portal, the following information can be required:

The web service configuration of the WSRP services of the Producer portal. The Consumer needs the web service configuration if the Producer has set up a specific web service configuration for the WSRP services.

The user registry information.
The Consumer might need this information if the Producer has configured message authentication that is based on token forwarding.

Registration information.
The Consumer needs this information if the Producer requires registration.

Group IDs and handles of portlets.
The Consumer needs these IDs and handles if the Consumer administrator consumes a remote portlet from a Producer portal by using the XML configuration interface.

Information that a Consumer provides to the Producer

Information that can be required.
The information that can be required depends on the security setup of the Producer portal.

User information about users of the Consumer portal who will use the remote portlets.
If the Producer portal has message authentication configured, the Producer must grant the users of the Consumer portal access permission to the provided portlets.

Configuring security on the Consumer portal:

You can configure security for the WSRP Consumer. If you enable security, the WSRP Consumer sends a security token as part of the WSRP request message to the WSRP producer. The security token represents the identity of the user who is logged in to the Consumer Portal. The WSRP Producer uses the security token to process the WSRP requests under the user identity that is represented by the security token.

About this task

For a WSRP Producer, security for WSRP services is optional. If a WSRP Producer requires security, the WSRP Consumer must be configured to use the same security mechanism as the WSRP Producer. Otherwise, the Consumer cannot consume the portlets that the Producer provides.

Example: A Producer might configure message authentication Web Service Security for the WSRP services by using a particular security token type according to the WS-Security standard. In this case, the WSRP Consumer web services must also be configured for web service security, and they must use the same security token type message authentication. You can configure security for the WSRP Consumer by using either of the following two authentication mechanisms:

HTTP-cookie-based single sign-on
The WSRP Consumer forwards LTPA v2 HTTP cookies that it receives from the client to the Producer as part of the WSRP request messages. The WSRP Producer receives the cookie and establishes the corresponding security context on the Producer side. This option requires configuration of the WSRP Consumer to forward HTTP cookies. It has the following advantages:

- It does not require configuration of the WSRP web services. It makes it possible for the WSRP Producer to accept and process both unauthenticated and authenticated requests.
- The Producer processes unauthenticated requests that do not contain an LTPA V2 cookie without establishing an individual security context.

Web Services Security

You can configure the WSRP Consumer to use Web Service Security according to the WS-Security standard. The WSRP Consumer sends a header that complies with the WS-Security standard as part of the WSRP request messages. The header contains credentials that identify and authenticate the user. For example, you can configure the Consumer portal to include Lightweight Third-Party Authentication (LTPA) tokens or Username tokens in the WS-Security header. For this option, both the WSRP Consumer and the WSRP Producer must be configured for Web Services Security.

When you configure the WSRP Consumer for Web Service Security, you can choose the security token type for the WSRP ports of a Producer definition. If you configured the security token type, the WSRP Consumer portal creates a security token of the selected type when it sends a request to the respective WSRP port of the Producer.

By alternative, you can manage the configuration of the WSRP service clients in IBM WebSphere Application Server by using policy sets. This type of management includes the security-related aspects and the quality of service related aspects of the service configuration. You configure the service clients and service references of the WSRP Consumer by attaching an appropriate policy set to the service client. IBM WebSphere Portal Express WebSphere Portal provides a set of default policy sets and client policy set bindings. To configure them, you use the WebSphere Application Server administration functions.

For both setup options, the WSRP Producer and the WSRP Consumer must be configured for Single Sign-On (SSO). The requirements for SSO depend on the authentication method that is used. For example, if you use LTPA V2, the WSRP Consumer and the WSRP Producer must use the same user registry or use the same realm. In addition, the WSRP Producer and the WSRP Consumer must exchange shared keys that they use to sign the security credentials.

"Securing the WSRP Consumer by HTTP-cookie-based single sign-on" on page 1463
You can configure your WSRP Consumer for using HTTP-cookie-based single sign-on. For this option, you must configure the WSRP Consumer to send or forward LTPA V2 single sign-on cookies as part of the WSRP request message to the WSRP Producer.

"Configuring WSRP Producer ports for Web Service Security on the Consumer portal" on page 1464
You can configure each WSRP port of a particular Producer definition for web service security by using LTPA or username tokens.

"Configuring WSRP web service clients" on page 1466
You might want to set up a specific and complex service configuration. In this case, you can configure the WSRP service clients and service references of the WSRP Consumer by using the concept of policy sets. If you intend to configure web service security by using LTPA or username tokens, do not configure the WSRP service clients and service references. In this case, you do not need to read this topic and its subtopics, but follow the procedure described in Configuring WSRP Producer ports for web service security on the Consumer portal.

"Enabling Portal Access Control for a WSRP Consumer portal" on page 1473
You can configure Portal Access Control for the remote portlets that you consume on your Consumer portal.

Securing the WSRP Consumer by HTTP-cookie-based single sign-on:

You can configure your WSRP Consumer for using HTTP-cookie-based single sign-on. For this option, you must configure the WSRP Consumer to send or forward LTPA V2 single sign-on cookies as part of the WSRP request message to the WSRP Producer.

About this task

The single sign-on cookie represents a security credential that both by the WSRP Consumer and the WSRP Producer understand. The WSRP Producer receives the cookie and establishes the corresponding security context for the user on the Producer side. For using HTTP-cookie-based single sign-on, the WSRP Consumer must not use Web Services Security. In particular, if you plan to use this security option, you must not configure Web Services Security for the respective Producer definition.

Prerequisites for using HTTP-cookie-based single sign-on:

For using HTTP-cookie-based single sign-on (SSO), single sign-on must be configured between the WSRP Consumer and the WSRP Producer. This configuration requires the following two prerequisites:

- The WSRP Consumer and the WSRP Producer must be configured to use a shared user registry.
- The LTPA keys must be exchanged between WSRP Consumer and WSRP Producer.

Configuring the WSRP Consumer for HTTP-cookie-based single sign-on:

For cookie forwarding of the LTPA v2 cookie, follow the description given in *Customizing client cookie forwarding*. You need to create a cookie forwarding rule for the cookie named LtpaToken2. To include the Producer host and the hosts of all resources that are linked by the remote portlets, choose the `hostdomainname` parameter.

The following example properties contain cookie forwarding rules for using HTTP-cookie-based single sign-on:

`wsrp.consumer.cookieforward.LtpaToken2 = alpha.domain.com`
`wsrp.consumer.cookieforward.LtpaToken = alpha.domain.com`

With these settings, the WSRP Consumer forwards the LTPA v1 and LTPA v2 cookies that it received from the clients to the Producers and resources on host `alpha.domain.com`.

`wsrp.consumer.cookieforward.LtpaToken2 = .domain1.com,.domain2.com`

With this setting, the WSRP Consumer forwards the LTPA v2 cookie that it received from the clients to all Producers and resources on hosts in the domains `domain1.com` and `domain2.com`

Related tasks:

"Securing the WSRP Producer by HTTP-cookie-based single sign-on" on page 1449
You can provide security for your WSRP Producer by using HTTP-cookie-based single sign-on (SSO). For using this security option, the WSRP Producer requires no configuration. The WSRP Consumer must be configured to send or forward LTPA V2 single sign-on cookies as part of the WSRP request message to the WSRP Producer.

"Customizing Client Cookie Forwarding" on page 1492
A client can send cookies to the WSRP Consumer as part of an HTTP request. You can customize the WSRP Consumer to forward specific client cookies to the Producer ports or to other resources that are served by the WSRP Consumer as a

proxy.

Configuring WSRP Producer ports for Web Service Security on the Consumer portal:

You can configure each WSRP port of a particular Producer definition for web service security by using LTPA or username tokens.

About this task

If you configure web service security for a Producer port, the WSRP Consumer creates a WS-Security-compliant header. The header contains a security token. When the Producer receives a WSRP request message that contains a WS-Security header, it processes the request under the user identity that is represented by the security token and performs access control for provided portlets.

IBM WebSphere Portal Express Version 8.5 provides three security token types for the most common scenarios. The following list describes these scenarios. In a default portal installation, none of the Producer ports is configured for message authentication or a token type. If your setup does not require security, you do not need to configure the Producer ports.

LTPAv2_Token
The Consumer portal provides an LTPA version 2 token in the WS-Security message header. This token type requires that Consumer and Producer portals share their user registry and LTPA configuration.

LTPA_Token
The Consumer portal provides an LTPA version 1 token in the WS-Security message header. This token type requires that the Consumer and Producer portals share their user registry and LTPA configuration.

Note:

IBM WebSphere Application Server Version 8.5 supports the LTPA v2 token by default. Use the LTPA_Token only if a Producer requires an LTPA v1 token and cannot be configured to use LTPA v2 tokens. A WebSphere Portal Express Version 8.5 Producer does not require LTPA v1 tokens. If you use a WebSphere Portal Express V 8.5 Producer, do not use this token type.

As WebSphere Application Server Version 8.5 does not support LTPA v1 by default, you need to enable the single sign-on interoperability mode in WebSphere Application Server to use LTP v1. To do so, use the single sign-on (SSO) panel within the WebSphere Integrated Solutions Console. For more information about this option, read the documentation about single sign-on settings in the WebSphere Application Server product documentation. If you select this token type and did not enable LTPA v1 tokens before, the WSRP Consumer throws an exception when trying to create the security token for a WSRP request message.

Username_Token
The Consumer portal provides a username token in the WS-Security message header. The username token specifies the user name in clear text.

You can set the token types by either of the following two ways:

Procedure

- You can use the portal administration portlet Web Service Configuration. Proceed as follows:
  1. In the portlet, go to the section for the port settings of the specific Producer for which you want to set the token types.
  2. From the list of service references and token types, select the token type for each port. By default, this list offers the three security token types. If you have defined custom service references, the list also offers these services. You can select either of the token types and custom service references from this list:
     - If you select a token type, the WSRP Consumer uses the default WSRP service reference for this port. Additionally, it includes a security token of the specified type in the WS-Security header of the WSRP request messages.
     - If a custom service reference is available and you select it, the WSRP Consumer uses this service reference. It does not generate extra security tokens.
     - If you do not select anything from this list, the WSRP Consumer uses the default WSRP service reference. It does not generate security tokens.
- You can use the portal XML configuration interface (XMLAccess) to set port specific settings, for example token types. For information about the XML configuration interface and how to use it, read the information about the *XML configuration interface*.

Results

The WSRP Consumer provides a token of the selected type in the WS-Security header of WSRP request messages that are sent to the appropriate Producer port. No further security mechanism, such as message integrity or message confidentiality, is used. If you plan a more complex service configuration or if you plan to use another token type, read *Configuring WSRP web service clients*.

The token types correspond to the default WSRP policy sets and provider policy bindings that are available for the configuration of Producers. The tokens are also compatible to a corresponding WebSphere Portal Express Version 7 or 8 Producer security configuration.

Related tasks:

"Configuring WSRP web service clients" on page 1466
You might want to set up a specific and complex service configuration. In this case, you can configure the WSRP service clients and service references of the WSRP Consumer by using the concept of policy sets. If you intend to configure web service security by using LTPA or username tokens, do not configure the WSRP service clients and service references. In this case, you do not need to read this topic and its subtopics, but follow the procedure described in Configuring WSRP Producer ports for web service security on the Consumer portal.

Related information:

"Working with the XML configuration interface" on page 1061
You can use the XML configuration interface to export and import IBM WebSphere Portal Express configurations. This way you can configure selected features or areas of your portal. You can also transfer a complete configuration from one portal to another.

Configuring WSRP web service clients:

You might want to set up a specific and complex service configuration. In this case, you can configure the WSRP service clients and service references of the WSRP Consumer by using the concept of policy sets. If you intend to configure web service security by using LTPA or username tokens, do not configure the WSRP service clients and service references. In this case, you do not need to read this topic and its subtopics, but follow the procedure described in Configuring WSRP Producer ports for web service security on the Consumer portal.

About this task

The WSRP Consumer of WebSphere Portal Express provides a set of service clients and default service references. The set includes two service clients, one each to support WSRP 1.0 and WSRP 2.0 and the respective port types or web service interfaces. There is one default service reference per service client. You can configure and administer the service clients and service references by using the WebSphere Integrated Solutions Console. For example, you can use the WebSphere Integrated Solutions Console to configure WSRP service providers and WSRP service clients by attaching policy sets. You can configure each service client and service reference separately. If your Consumer portal communicates with Producer portals with different web service configurations, you can also use extra service client references.

The service clients realize the communication with the remote WSRP Producers. They comply to the JAX-WS standard and build upon the JAX-WS web service stack.

The following table lists the supported service clients and service references:

Table 182. WSRP Consumer service clients and service references for the two WSRP versions

	WSRP 1.0	**WSRP 2.0**
Service client	`WSRPService`	`WSRPService_v2`
Service reference	`service/wsrp/WSRPService`	`service/wsrp/ WSRPService_v2`

The service clients support all WSRP service interfaces: Service Description, Markup, Portlet Management, and Registration.

WebSphere Portal Express provides a set of default WSRP policy sets and client policy set bindings. You can use them to configure the WSRP service clients and service references. In this case, you do not have to create your own policy sets and client policy set bindings. By alternative, you can create and use a policy set and client policy set binding of your choice.

For more detailed information about configuring the JAX-WS compliant web service clients, read the WebSphere Application Server product documentation.

Note: The configuration of the WSRP service clients is managed outside WebSphere Portal Express. The portal WSRP Consumer supports all service client configurations that are configured in WebSphere Application Server. This support includes message level security, transport level security, and other quality of service configuration. However, the service client configuration of the WSRP Consumer must be compatible with the web service configuration of the WSRP Producer. Example: If the service providers of the Producer portal are configured for WS-Security, the service references of the Consumer portal must also be configured for WS-Security. Otherwise, the WSRP communication fails.

You can configure your WSRP Consumer portal to consume portlets from Producer portals that have different web service configurations. To do so, you deploy extra service references for the WSRP service clients. You can assign the service references to the ports of a Producer definition. This way, you can configure multiple WSRP Consumer side web service configurations. You can configure each service reference separately. Use this option only if your WSRP Consumer portal communicates with multiple Producer portals that have different web service configurations. For more detailed information, read the following topics.

1. "Communicating with Producer portals with different web service configurations"
   You can use your Consumer portal to communicate with Producer portals that have different web service configurations.
2. "Using the WSRP policy sets and client policy set bindings" on page 1468

Communicating with Producer portals with different web service configurations:

You can use your Consumer portal to communicate with Producer portals that have different web service configurations.

About this task

For example, such a configuration can be necessary if your WSRP Consumer portal communicates with two separate remote WSRP Producer portals with different web services configurations:

- One of the Producers does not configure Web Services Security for the WSRP web services.
- The other Producer requires WSeb Services Security for its WSRP web services by using a token type that is different from LTPA and username.

In such a case, you deploy an extra service client reference on your WSRP Consumer portal.

This option to deploy extra service references makes it possible to manage multiple WSRP Consumer side web service configurations. If your WSRP Consumer portal does not communicate with multiple Producers that have different web service configurations, you do not need to deploy extra service client references.

If the Producers require web service security based on LTPA or username tokens and do not require further service configuration, you do not need to deploy extra service references. In this case, configure the token type for web service security by following the description in If the Producers require web service security based on LTPA or Username tokens and do not require further service configuration, you do not need to deploy extra service references. In this case, it is recommended to configure the token type for web service security by following the description in*Configuring WSRP Producer ports for message authentication*.

To deploy an extra service client reference for communication with Producers with different web service configurations, proceed as follows:

Procedure

1. Configure the service references separately:
   - Leave the default service reference as it is. Do not configure Web Service Security for the default service reference.
   - Deploy an extra custom service reference and configure it for WS-Security compliant Web Service Security.
2. When you create or edit the Producer definitions that represent the WSRP Producers, you can select the appropriate custom service references for the Producer ports:
   - Select the additional service reference for all ports of the Producer definition that represents the secure Producer.
   - For the non-secure ports of the Producer definition, you do not need to select a service reference. If no specific service reference is selected for a Producer port, the WSRP Consumer portal uses the default service reference.

Related tasks:

"Configuring WSRP Producer ports for Web Service Security on the Consumer portal" on page 1464
You can configure each WSRP port of a particular Producer definition for web service security by using LTPA or username tokens.

Using the WSRP policy sets and client policy set bindings:

WebSphere Portal Express provides a set of default WSRP policy sets and client policy set bindings. You can use them to configure the WSRP service clients and service references. In this case, you do not have to create your own policy sets and client policy set bindings. By alternative, you can create and use a policy set and client policy set binding of your choice.

About this task

The following table describes the provided WSRP application policy sets and the provided WSRP client policy set bindings:

Table 183. Provided WSRP application policy sets and provided WSRP client policy set bindings

	WSRP application policy sets	WSRP client policy set bindings
LTPA based	**LTPA-based message authentication policy set** This policy set defines LTPA token-based message authentication. It does not define other security mechanisms such as message confidentiality, or other web service mechanisms such as WS-Addressing.	**Username and LTPA-based message authentication client binding** You must use this client policy set binding with each of the two WSRP policy sets. It defines the corresponding client binding.
Username based	**Username-based message authentication policy set** This policy set defines Username token-based message authentication. It does not define other security mechanisms such as message confidentiality, or other web service mechanisms such as WS-Addressing.	

The WSRP application policy sets and client policy set bindings are contained in compressed format in the directory `PortalServer/doc/policy-sets-samples` of the portal installation.

For instructions about how to import and attach policy sets and client policy set bindings, read the IBM WebSphere Application Server documentation.

To use the WSRP policy sets and client policy set bindings for service configuration, proceed as follows:

Procedure

1. Import the WSRP policy sets and client policy set bindings. To do so, use a WebSphere Application Server administrative client, such as the WebSphere Integrated Solutions Console:
   a. Open the **Application policy sets** panel.
   b. Select **Import (From Selected Location)**.
   c. Select the LTPA-based message authentication policy `set.zip` file or the username-based message authentication policy `set.zip` file that you want to import.
   d. Open the **General client policy set bindings** panel.
   e. Select **Import (From Selected Location)**.
   f. Select the LTPA-based message authentication client `binding.zip` file or username-based message authentication client `binding.zip` file that you want to import.
2. Attach the policy set and client policy set binding to a WSRP service client or service reference. Proceed as follows:
   a. Open the **Service clients** panel.

b. Open the service reference that you want to configure. Do not select one of the default service references, such as `service/wsrp/WSRPService` or `service/wsrp/WSRPService_v2`.
c. Select the service reference.
d. Select the **Override** option.
e. Use the **Attach Client Policy Set** option to select and attach the LTPA-based message authentication policy set or the username-based message authentication policy set.
f. Select the service reference.
g. Use the **Assign Binding** option to select and assign the username and LTPA-based message authentication client binding.
h. Save your changes to the master configuration.

3. After you have completed this configuration, restart your portal.

Creating and deploying custom service references:

In your WSRP Consumer portal, you can deploy extra service references for the WSRP service clients.

About this task

The service clients and service references are defined in the `web.xml` deployment descriptor of the `wps.war` web application that is contained in the portal enterprise application archive `wps.ear`. To add service references, you export the portal enterprise application, modify the `web.xml` deployment descriptor, and update the portal enterprise application. To add service references for your WSRP Consumer portal, proceed by the steps that are given in the following.

Procedure

1. Export the portal application EAR file. You start with this step so that you can later add the service references in the `web.xml` deployment descriptor. To export the portal application `wps.ear` to a temporary portal EAR file, use a WebSphere Application Server administrative client, for example, the WebSphere Integrated Solutions Console. For details about exporting an enterprise application, read the WebSphere Application Server documentation.
2. Modify the `web.xml` deployment descriptor. To import the portal EAR file and to edit the `web.xml` deployment descriptor, you can either use an assembly tool, or you can extract or open the portal EAR file and edit the `web.xml` deployment descriptor file directly.
3. Add service references to the `web.xml` deployment descriptor. You can add one or multiple service references for the WSRP service clients to the `web.xml`. For more information, read the following topic about *Adding service references to the `wps.war` web application*.
4. Update the portal application. After you modified the `web.xml` deployment descriptor, proceed by one of the following options:
   - Export the portal EAR file from the assembly tool.
   - Save the modified `web.xml` file, and save or compress the portal EAR file. Then, update the portal application from the modified portal EAR file. To do so, you use a WebSphere Application Server administrative client, for example, the WebSphere Integrated Solutions Console. For details about updating an enterprise application, read the WebSphere Application Server documentation.

5. Restart your portal. In a stand-alone installation, restart the portal server. In a cluster configuration, restart the portal on each node.

   "Adding service references to the wps.war web application"
   The WSRP service clients and service references are defined in the web.xml deployment descriptor of the wps.war web application. That web application that is contained in the portal enterprise application archive wps.ear. To add service references, you modify the web.xml deployment descriptor.

Adding service references to the wps.war web application:

The WSRP service clients and service references are defined in the web.xml deployment descriptor of the wps.war web application. That web application that is contained in the portal enterprise application archive wps.ear. To add service references, you modify the web.xml deployment descriptor.

About this task

The following excerpt from file web.xml shows the definition of the default WSRP service references:

```
<service-ref>
    <description>WSRP 1.0 Default Service Reference</description>
    <service-ref-name>service/wsrp/WSRPService</service-ref-name>
    <service-interface>javax.xml.ws.Service</service-interface>
    <service-qname xmlns:pfx="http://www.ibm.com/xmlns/prod/websphere/portal/wsrp/wsdl/v1">
        pfx:WSRPService
    </service-qname>
</service-ref>
<service-ref>
    <description>WSRP 2.0 Default Service Reference</description>
    <service-ref-name>service/wsrp/WSRPService_v2</service-ref-name>
    <service-interface>javax.xml.ws.Service</service-interface>
    <service-qname xmlns:pfx="http://www.ibm.com/xmlns/prod/websphere/portal/wsrp/wsdl/v2">
        pfx:WSRPService_v2
    </service-qname>
</service-ref>
```

You can define extra service references by adding one or more service-ref elements. The following list shows the subelements that a new service-ref element must define:

description
The value for this subelement is user-defined. Specify a text string of your choice.

service-ref-name
The value for this subelement is partly user-defined. Specify service/wsrp/*service-ref-id* , where the prefix service/wsrp/ is fix, and service-ref-id is the user-defined ID of the service reference.

service-interface
The value for this subelement is fix. Specify javax.xml.ws.Service.

service-qname
For the value of this subelement, you can specify one of two options. Depending on your requirements, specify the service Qname for WSRP 1.0 or 2.0 as in one of the examples that are given here:

```
<service-qname xmlns:pfx="http://www.ibm.com/xmlns/prod/websphere/portal/wsrp/wsdl/v1">
   pfx:WSRPService
</service-qname>
```

or:

```
<service-qname xmlns:pfx="http://www.ibm.com/xmlns/prod/websphere/portal/wsrp/wsdl/v2">
   pfx:WSRPService_v2
</service-qname>
```

The following code sample shows how you can add two new service references to the `web.xml` file. Note the position of the new `service-ref` elements immediately after the default service references:

```
service-ref>
    <description>WSRP 1.0 Default Service Reference</description>
    <service-ref-name>service/wsrp/WSRPService</service-ref-name>
    <service-interface>javax.xml.ws.Service</service-interface>
    <service-qname xmlns:pfx="http://www.ibm.com/xmlns/prod/websphere/portal/wsrp/wsdl/v1">
        pfx:WSRPService
    </service-qname>
</service-ref>
    <service-ref>
    <description>WSRP 2.0 Default Service Reference</description>
    <service-ref-name>service/wsrp/WSRPService_v2</service-ref-name>
    <service-interface>javax.xml.ws.Service</service-interface>
    <service-qname xmlns:pfx="http://www.ibm.com/xmlns/prod/websphere/portal/wsrp/wsdl/v2">
        pfx:WSRPService_v2
    </service-qname>
</service-ref>
    <service-ref>
    <description>WSRP 2.0 Alternative Service Reference 1</description>
    <service-ref-name>service/wsrp/AlternativeWSRPService_v2</service-ref-name>
    <service-interface>javax.xml.ws.Service</service-interface>
    <service-qname xmlns:pfx="http://www.ibm.com/xmlns/prod/websphere/portal/wsrp/wsdl/v2">
        pfx:WSRPService_v2
    </service-qname>
</service-ref>
    <service-ref>
    <description>WSRP 2.0 Alternative Service Reference 2</description>
    <service-ref-name>service/wsrp/WSRPService_v2_Second_Alternative</service-ref-name>
    <service-interface>javax.xml.ws.Service</service-interface>
    <service-qname xmlns:pfx="http://www.ibm.com/xmlns/prod/websphere/portal/wsrp/wsdl/v2">
        pfx:WSRPService_v2
    </service-qname>
</service-ref>
```

The example defines two new service references: `service/wsrp/AlternativeWSRPService_v2` and `service/wsrp/WSRPService_v2_Second_Alternative`. After you updated the portal application, you can configure the new service references in a WebSphere Application Server administrative client. After you restart your portal, the WSRP Consumer can find the service references. When you create or edit a Producer definition, you can assign the new service references to Producer ports. For the WSRP Consumer to find the service references, you must name the service reference name according to the following syntax:

service/wsrp/*service-ref-id*
: where the prefix `service/wsrp/` is fixed, and the `service-ref-id` is user-defined.

As the administrator of the Consumer portal, you can assign a service reference to a Producer port of a Producer definition. Use the `service-ref-id` as the identifier for selecting that service reference. If a service reference name of a new service reference does not contain the prefix `service/wsrp/`, the WSRP Consumer cannot find the service reference. When you assign a service reference to a Producer port, the Web Services Configuration portlet shows the list of all defined service references. The list shows only the service reference IDs of the service reference

without the common prefix `service/wsrp`.

Enabling Portal Access Control for a WSRP Consumer portal:

You can configure Portal Access Control for the remote portlets that you consume on your Consumer portal.

Before you begin

When you consume portlets from a Producer portal in your Consumer portal, these remote portlets behave just like local portlets in your portal. You can assign access permissions to users on these portlets by using Portal Access Control.

Working with Producer definitions

To make a WSRP Producer known to your Consumer portal, you create a Producer definition for that WSRP Producer in your Consumer portal. You can also configure the Producer definition.

About this task

When you create a Producer definition, you use the information that you obtained from the Producer to configure the WSRP connection to the Producer. If required, you also register with the Producer.

There are different scenarios for creating a Producer definition:

1. You can use either the Web Service Configuration portlet or the XML configuration interface to create the Producer definition, depending on whether you work online or offline:
   a. If you can connect to the Producer portal and access all files that the Producer's WSDL service definition references, you can work online when you create the Producer definition. In this case, you can use either the Web Service Configuration portlet or the XML configuration interface to create the Producer definition. For example, this can be the case if you want to consume WSRP services in your current portal.
   b. If you cannot connect to the Producer portal and access all files that the Producer's WSDL service definition references, you work offline. In this case, you can use only the XML configuration interface to create the Producer definition. For example, this case can occur if you prepare your Consumer portal in a staging environment and do not connect to the Producer portal to consume WSRP services until you transfer your portal to the next stage.
2. There are three types of Producers. The type of Producer that you create determines which information you must provide with the Producer definition and whether you can create the Producer definition online or offline:
   a. The Producer does not require registration. In this case, you specify the information that you obtained from the Producer. You can create this type of Producer definition in online or offline mode. The IBM WebSphere Portal Express Producer is of this type.
   b. The Producer requires registration and is enabled for WSRP registration. Such a Producer provides a registration port. In this case, you can specify extra registration properties when you create the Producer definition in your Consumer portal. You can create this type of Producers only in online mode.

c. The Producer requires registration and is not enabled for WSRP registration. In this case, you must provide a registration handle that you obtained from the Producer. You can create this type of Producer definition in online or offline mode.

You can create all three types of Producers by using either the Web Service Configuration portlet or the XML configuration interface.

Table 184. Scenarios for creating a Producer definition

Type of Producer	Creating the Producer definition online by using . . .	Creating the Producer definition offline . . .
The Producer does not require registration. In this case you specify the information that you obtained from the Producer.	. . . the Web Service Configuration portlet or the XML configuration interface.	. . . by using the XML configuration interface.
The Producer requires registration and is enabled for WSRP registration. In this case the Producer provides a registration port. In this case, you can specify extra registration properties when you create the Producer definition in your Consumer portal.	. . . the Web Service Configuration portlet or the XML configuration interface.	. . . is not a valid scenario.
The Producer requires registration and is not enabled for WSRP registration. In this case you must provide a registration handle that you obtained from the Producer.	. . . the Web Service Configuration portlet or the XML configuration interface.	. . . by using the XML configuration interface.

Notes:

1. The current implementation of the WSRP Producer in the portal does not support the WSRP registration interface. However, the WSRP Consumer in the portal can handle Producers that support WSRP registration interfaces.
2. When you specify user attributes, make sure to avoid that any of the following events occur:
   - Sending security relevant attributes, such as passwords, over unsecured network connections
   - Passing sensitive data about your users to the Producer.

   "Different types of Producers"
   The information that you must provide with the Producer definition depends on the type of Producer.

   "Using the Web Service Configuration portlet to work with Producer definitions online" on page 1476
   If you work online, you can use the Web Service Configuration portlet to create a Producer definition.

   "Using the XML configuration interface to work with Producer definitions" on page 1477
   You can use the XML configuration interface to work with Producer definitions in different ways.

Different types of Producers:

The information that you must provide with the Producer definition depends on the type of Producer.

There are three different types of Producers. The Producer type influences how you create the Producer definition in your Consumer portals and what information you must provide:

The Producer does not require registration.

The IBM WebSphere Portal Express Producer is of this type. In this case you specify the following information when you create the Producer in your Consumer portal:

- The URL for the WSDL service definitions of the Producer. This item of information is mandatory.
- A name. This item of information is mandatory.
- A description. This item of information is optional.
- User attributes. This item of information is optional. The values for the selected user attributes are later passed on to the Producer when your portal users use the Producer's web service. For example, if you select the attribute for user name, then the Producer's web service can address your portal users by their name. By selecting specific attributes, you prevent sensitive data about your users from being passed to the Producer.

The registration handle and registration properties are not required.

The Producer requires registration and is enabled for WSRP registration.

In this case, the Producer provides a registration port. As a Consumer, you specify the following information when you create the Producer in your portal:

- The URL for the WSDL service definitions of the Producer. This item of information is mandatory.
- A name. This item of information is mandatory.
- A description. This item of information is optional.
- Registration properties. This item of information is optional. The registration properties are passed on to the Producer during your registration. For example, they can provide information about your geographical location, such as the postal code. The Producer can then adapt the web service to your location. If you live near the mountains, the Producer might then provide information or offers for ski vacation or hiking.
- User attributes. This item of information is optional.

The registration handle is not required in this case. After the Consumer completes the registration with the Producer, the Producer passes the registration handle to the Consumer, where it is stored in the Consumer portal database.

The Producer requires registration, but is not enabled for WSRP registration.

In this case, the registration consists of the following steps:

1. The owner of the Consumer portal registers with the owner of the Producer portal by separate communication, for example by email. The Consumer portal owner can provide registration properties. The Consumer portal owner receives the registration handle from the Producer portal owner.
2. The Consumer portal administrator creates the Producer and provides the following information:
   - The URL for the WSDL service definitions of the Producer. This item of information is mandatory.

- A name. This item of information is mandatory.
- A description. This item of information is optional.
- The registration handle that the Consumer received from the Producer by outside communication. This item of information is mandatory.
- User attributes. This item of information is optional.

The Consumer provides no registration properties during creation because the Producer personnel already received this information during the registration by outside communication.

Using the Web Service Configuration portlet to work with Producer definitions online:

If you work online, you can use the Web Service Configuration portlet to create a Producer definition.

Before you begin

Note: Creating the Producer definition by using the Web Service Configuration portlet works only if both the Producer portal and the Consumer portal are online. Under this condition, the Consumer portal can connect to the Producer portal and to all files that are referenced in the Producer's WSDL service definition. If one of the portals is offline and you want to create a Producer definition on the Consumer portal, you must use the XML configuration interface. For example, this case can occur if you prepare your Consumer portal in a staging environment and do not connect to the Producer portal to use WSRP services until you transfer your portal to the next stage.

About this task

When you create a new Producer definition, you do the following tasks:

1. Define the name for the new Producer definition.
2. Give a description for the Producer definition.
3. Specify the URL for the WSDL service description document of the Producer portal.
4. Specify the registration handle for the Producer.

What to do next

Optionally, you can also do the following tasks:

- Set `registration properties` for the Producer definition.
- Set `user attributes` that you want to be passed on to the Producer.
- Set `language-specific names and descriptions` for the Producer definition.
- Assign access permission to your portal users on a Producer definition.
- Delete a Producer definition from your portal.

After you create a Producer definition, you can proceed to using the portlets that are provided by that Producer, that is, integrating them into your Consumer portal as remote portlets.

To work with the **Web Service Configuration** portlet, click the **Administration menu** icon. Then, click **Portlet Management** > **Web Services**.

For details about how to work with the portlet refer to the portlet help.

Using the XML configuration interface to work with Producer definitions:

You can use the XML configuration interface to work with Producer definitions in different ways.

Before you begin

About this task

If you use the XML configuration interface to create a Producer definition, you can work online or offline. Depending on these scenarios, you must consider some differences.

You can also use the XML configuration interface to export a Producer definition, and to create a Producer definition and consume a portlet from that Producer by using a single XML script.

"Creating a Producer definition offline"
When you create a Producer definition offline, be aware which information you must provide.

"Using the XML configuration interface to create a Producer definition" on page 1478
You can use the XML configuration interface to create a Producer definition online or offline.

"Exporting a Producer definition by using the XML configuration interface" on page 1482
You can use the XML configuration interface to export a Producer definition. You might, for example, export the Producer from a test portal to update your production portal with it later.

"Creating a Producer definition and consuming a portlet by a single XML script" on page 1482
You can use a single XML script to create a Producer definition and then consume portlets from that same Producer.

Related concepts:

"The XML configuration interface" on page 1054
Use the XML configuration interface (XML Access) for exchanging portal configurations.

Related information:

"Working with the XML configuration interface" on page 1061
You can use the XML configuration interface to export and import IBM WebSphere Portal Express configurations. This way you can configure selected features or areas of your portal. You can also transfer a complete configuration from one portal to another.

Creating a Producer definition offline:

When you create a Producer definition offline, be aware which information you must provide.

About this task

If you work offline, that is you cannot connect from your Consumer portal to the Producer portal, you can use only the XML configuration interface to create the Producer definition. In this case you specify the following information:

- The endpoint address URLs to the Service Description and the Markup interfaces of the Producer.
- If the Producer supports the two optional WSRP interfaces Portlet Management and Registration, you specify them as well.

If the Producer requires certain registration properties or a registration handle with the registration by the Consumer, you must specify this information as well.

The XML configuration interface writes all parameters that you provide into the portal database. This includes all of the following information:

- The URL for the Producer's WSDL service definitions
- A name for the Producer definition
- A description for the Producer definition
- The registration handle that you received from the Producer by outside communication
- The registration properties
- The user attributes.

The portal transfers the user attributes and the registration handle to the Producer later when **both** of the following conditions apply:

1. You work online, that is you can connect to the Producer portal.
2. You update the portal configuration with an XML script that includes the scripting code for consuming a portlet.

The user attributes are sent to the Producer with every markup or action request, that is every time when a user interacts with a remote portlet of that Producer.

Using the XML configuration interface to create a Producer definition:

You can use the XML configuration interface to create a Producer definition online or offline.

About this task

The main tag to specify when you use the XML configuration interface to create a Producer is the `wsrp-producer` tag. The following table lists possible **subtags** that you can specify with the `wsrp-producer` tag:

Table 185. Tags for creating a Producer definition

Possible subtag for the `wsrp-producer` tag	Description
`wsdl-url`	This subtag describes the URL to the Producer's WSDL document. This subtag is the only tag that is required for creating a Producer when you use an online connection. The other URLs are extracted from this WSDL file.
`port-type`	Each of the Producer ports (Service Description, Markup, Portlet Management, and Registration) can be described by one tag. These tags are required for offline creation.
`parameter`	This subtag is used for registration properties.

Table 185. Tags for creating a Producer definition (continued)

Possible subtag for the wsrp-producer tag	Description
preferences	This subtag is used for user attributes.
localedata	This subtag is used to specify globalization names and titles.
access-control	This subtag is used to specify access control.

The following table lists possible attributes that you can specify with the wsrp-producer tag:

Table 186. Attributes for creating a Producer definition

Possible attributes for the wsrp-producer tag	Possible values	Description
registration-required	true|false	This attribute indicates whether the Producer requires registration.
force	true|false	This attribute forces creation of the Producer.
default	true|false	Set this attribute to true if this Producer is the default Producer.

Use the following subtags to specify the Producer ports.

Table 187. Subtags for creating a Producer definition

Subtag	Description
secure-url	Specifies the secure URL of the port (HTTPs).
unsecure-url	Specifies the unsecure URL of the port (HTTP).
ws-security-profile	Specifies the Web Service Security token type or service reference that is assigned to the port. The value of the subtag must refer to a defined WSRP service or to one of the defined token types.

Use the following attributes to specify the Producer ports.

Table 188. Attributes for creating a Producer definition

Attribute	Possible values	Description
type	Specify one of the following values: service-description markup portlet-management registration	Defines the port to which the tag applies.

Table 188. Attributes for creating a Producer definition (continued)

Attribute	Possible values	Description
`defaultbinding`	Specify one of the following values: `secure` `unsecure` `onrequest` `undefined`	Defines whether to use the secure or unsecure URL. The value `onrequest` applies to the Markup port only.

The following attributes are listed for the sake of completeness only. Do not change them.

Table 189. Attributes for creating a Producer definition that are not to be changed. These attributes are listed for completeness only. Do not change them.

Possible attribute for the `wsrp-producer` tag	Possible values	Description
`state`	(binary data)	The Producer's state. This attribute is specified as Base64 encoded binary data. It is only used during export and update by the XML configuration interface.
`cookiepolicy`	One of: `none per_user per_group undefined`	The Producer's cookie policy. The policy and possible values are defined in the WSRP specification.
`wsrpversion`	`V1 | V2`	This attribute indicates the WSRP protocol version that is used for communication between consumer and producer.

"XML samples for creating Producer definitions"
You can modify use these XML samples and use them to create Producer definitions,

XML samples for creating Producer definitions:

You can modify use these XML samples and use them to create Producer definitions,

XML sample script for creating a Producer definition

You can use these samples to create the Producer definition online or offline.

The following XML sample shows how you use the XML configuration interface to create a Producer if you work offline:

```
<?xml version="1.0" encoding="UTF-8" ?>
<request type="update" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd" create-oids="true">
   <portal action="locate">
      <wsrp-producer action="update" uniquename="ibm.portal.MySampleProducer1">
         <porttype type="service-description" update="set">
             <unsecure-url> http://producer_portal_host:producer_port/wp_contextRoot/WSRPServiceDescriptionService</unsecure-url>
         </porttype>
         <porttype type="markup" update="set">
             <unsecure-url>http producer_portal_host:producer_port/wp_contextRoot/WSRPBaseService</unsecure-url>
         </porttype>
         <localedata locale="en">
             <title>My Sample Producer 1</title>
         </localedata>
      </wsrp-producer>
   </portal>
</request>
```

Replace `http://producer_portal_host:producer_port/wp_contextRoot` with the appropriate values for the environment of your Producer.

This sample specifies the minimum required mandatory WSRP interfaces Service Description and Markup.

XML sample script for creating a Producer definition for a Producer who requires registration

The following XML sample shows how you use the XML configuration interface to create a Producer who requires registration. You can use this sample if you work online and have access to the Producer's WSDL document.

```
<?xml version="1.0" encoding="UTF-8" ?>
<request type="update" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd" create-oids="true">
   <portal action="locate">
      <wsrp-producer action="update" registration-required="true" uniquename="ibm.portal.MySampleProducer2">
         <wsdl-url>  http://producer_portal_host:producer_port/wp_contextRoot/wsdl/wsrp_service.wsdl</wsdl-url>
         <parameter name="regprop1" type="string" update="set">value1</parameter>
         <parameter name="regprop2" type="string" update="set">value2</parameter>
         <preferences name="userattributes" update="set">
            <value>cn</value>
            <value>o</value>
            <value>uid</value>
         </preferences>
         <localedata locale="en">
            <title>Producer 2</title>
         </localedata>
      </wsrp-producer>
   </portal>
</request>
```

Replace `http://producer_portal_host:producer_port/wp_contextRoot/wsdl/wsrp_service.wsdl` with the appropriate values for the environment of your Producer.

This sample also includes specification of user attributes.

To use this sample with a WebSphere Portal Express Producer portal, set `registration-required="false"` and remove the parameter tags. This modification is necessary because the WebSphere Portal Express Producer does not support registration.

Creating a Producer definition and consuming a portlet by a single XML script:

You can use a single XML script to create a Producer definition and then consume portlets from that same Producer.

About this task

If you consume the portlet in an XML script that has already created the Producer in a previous step, you must specify the following items in the XML script:

1. A `locate` action on the Producer.
2. A `locate` action on the `web-app` tag with the `uid="com.ibm.wps.wsrp.proxyportletapp.webmod"` attribute.
3. The `servlet` subtag with the `remotehandle` and `wsrp-producerref` attributes.
4. A `locate` action on the `portlet-app` subtag with the `uid="com.ibm.wps.wsrp.proxyportletapp"` attribute.
5. The `portlet` subtag with the `servletref` attribute.

The following XML sample shows how you use the XML configuration interface to integrate a remote portlet:

```
<?xml version="1.0" encoding="UTF-8" ?>
<request type="update" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xsi:noNamespaceSchemaLocation="PortalConfig_8.5.0.xsd">
   <portal action="locate">
      <wsrp-producer action="locate" objectid="Producer_OID" uniquename="wps.myProducer1">
      <web-app action="locate" uid="com.ibm.wps.wsrp.proxyportletapp.webmod">
         <servlet action="update" objectid="Servlet_OID" remotehandle="Remote_handle"
             wsrp-producerref="Producer_OID"/>
         <portlet-app action="locate" uid="com.ibm.wps.wsrp.proxyportletapp">
            <portlet action="update" active="true" defaultlocale="en"
               servletref="Servlet_OID" name="Sample_Portlet">
               <localedata locale="en">
                  <title>Sample Portlet</title>
                  <description>Simple sample portlet as Web service</description>
               </localedata>
               <access-control externalized="false" owner="undefined" private="false"/>
            </portlet>
         </portlet-app>
      </web-app>
   </portal>
</request>
```

Related concepts:

Consuming portlets in a Consumer portal

After you create a Producer definition, you can proceed to consume the portlets that are provided by that Producer. This way, you integrate them into your Consumer portal as remote portlets.

About this task

To consume a remote portlet in your Consumer portal, you can use either of the following tools:

- The **Manage Web Modules** portlet.
- The portal XML configuration interface. For more information about the XML configuration interface, read the appropriate topics.

Notes:

1. On the Consumer side, all remote portlets behave like standard API-compliant portlets, independent of their implementation on the Producer side.
2. When a Producer provides a portlet, only settings that are made in the Configure mode of the portlet are available at the consumed remote portlet. Adding a remote portlet to a page on the Consumer side creates a new instance of the provided portlet on the Producer side. But this instance can be modified only on the Consumer and is not visible on the Producer portal.
3. Customization of the consumed portlets by Consumer portal users can be exported by using the XML configuration interface.

Proceed by selecting the appropriate topic from the following links:

"Using the Manage Web Modules portlet to consume portlets from a Producer portal"
To consume portlets from a Producer portal, you use the **Manage Web Modules** portlet and consume a web module.

"Using the XML configuration interface to consume portlets from a Producer portal"
You can use the XML configuration interface (XMLAccess) to consume portlets from a Producer portal.

Related concepts:

"The XML configuration interface" on page 1054
Use the XML configuration interface (XML Access) for exchanging portal configurations.

Related information:

"Working with the XML configuration interface" on page 1061
You can use the XML configuration interface to export and import IBM WebSphere Portal Express configurations. This way you can configure selected features or areas of your portal. You can also transfer a complete configuration from one portal to another.

Using the Manage Web Modules portlet to consume portlets from a Producer portal:

To consume portlets from a Producer portal, you use the **Manage Web Modules** portlet and consume a web module.

About this task

Click the **Administration menu** icon. Then, click **Portlet Management** > **Web Modules**.

For details about how to work with the portlet refer to the portlet help.

For the relevant topics of the portlet help refer to the following links:

Using the XML configuration interface to consume portlets from a Producer portal:

You can use the XML configuration interface (XMLAccess) to consume portlets from a Producer portal.

About this task

To consume a portlet by using the XML configuration interface, specify the handle of the remote portlet and the Producer portal that provides the remote portlet. Specify this information by using the attributes `remotehandle` and `wsrp-producerref` with the `servlet` subtag. Both values are required to use the remote portlet. The `remotehandle` attribute is defined by the owner of the Producer portal. The owner of the Producer portal provides the handle to you by appropriate means, such as email.

Producers with an IBM WebSphere Portal Express Producer can obtain this information by exporting all provided portlets on their Producer portal by using the XML configuration interface.

Table 190. Tags for integrating WSRP services

subtag	Attribute for the subtag	Description
`servlet`	`remotehandle`	As provided by the Producer
`servlet`	`wsrpproducerref`	ID of the Producer

After successful integration, the remote portlets are available in the portal administration. They are handled in the same manner as local portlets.

Notes:

- You can consume a portlet only if you work online and can access the Producer's WSDL document.
- To obtain a list and descriptions of the portlets that a specific Producer provides, the WSRP implementation of the portal uses the discovery mechanism that is defined in the WSRP standard.
- An integrated portlet is always treated as a standard API-compliant portlet.

To delete integrated remote portlets, use the Manage Web Modules portlet.

"Creating a Producer definition and consuming a portlet by one single XML script"

      <web-app action="locate" uid="com.ibm.wps.wsrp.proxyportletapp.webmod">
         <servlet action="update" objectid="Servlet_OID" remotehandle="Remote_handle"
             wsrp-producerref="Producer_OID"/>
         <portlet-app action="locate" uid="com.ibm.wps.wsrp.proxyportletapp">
            <portlet action="update" active="true" defaultlocale="en"
               servletref="Servlet_OID" name="Sample_Portlet">
               <localedata locale="en">
                  <title>Sample Portlet</title>
                  <description>Simple sample portlet as Web service</description>
               </localedata>
               <access-control externalized="false" owner="undefined" private="false"/>
            </portlet>
         </portlet-app>
      </web-app>
   </portal>
</request>
```

Customizing the WSRP configuration of your Consumer portal

You can customize some aspects of you WSRP Consumer portal.

About this task

This customization is optional.

"Customizing the WSRP resource proxy"
The WSRP resource proxy is used by the WSRP Consumer to load resources that are referenced by remote portlets.

CF05 "Configure timeout properties for the WSRP communication" on page 1490
You can configure web service timeout properties for the WSRP communication on the Consumer. You can configure the timeout properties in the WP Configuration Service or as a preference specifically for remote portlets.

CF05 "Configure a limit for the size of file uploads" on page 1491
You can configure a limit for the size of file uploads during an action request. You can also configure the Consumer behavior if a file upload exceeds the defined limit.

CF05 "Switch off the caching of Producer service descriptions" on page 1491
By default, the Consumer portal caches the WSRP service descriptions that it receives from Producers. If required, you can switch off the caching.

"Customizing Client Cookie Forwarding" on page 1492
A client can send cookies to the WSRP Consumer as part of an HTTP request. You can customize the WSRP Consumer to forward specific client cookies to the Producer ports or to other resources that are served by the WSRP Consumer as a proxy.

CF06 "Configuring remote session invalidation" on page 1493
You can configure the WSRP Consumer to invalidate the remote session when a user explicitly logs out of the Consumer portal. If you enable remote session invalidation and a user logs out of the Consumer portal, the Consumer sends a `releaseSessions` WSRP request to all the Producers with which the user interacted. The Producers portals can then invalidate these sessions.

Customizing the WSRP resource proxy:

The WSRP resource proxy is used by the WSRP Consumer to load resources that are referenced by remote portlets.

About this task

Depending on your environment, it can be necessary to customize the resource proxy behavior with regards to the following aspects:

- SSL settings for secure connections to remote resources
- LTPA token forwarding for single sign-on scenarios
- Proxy server settings for outbound connections
- Support for relative URLs
- HTTP basic authentication for outbound connections
- HTTP headers that are not forwarded.

"Customizing the WSRP resource proxy SSL settings"
The WSRP resource proxy uses one SSL configuration for all secure outbound connections.

"Customizing the WSRP resource proxy for LTPA token forwarding" on page 1488
The WSRP resource proxy can forward single sign-on cookies (LTPA, LTPA2) from the client requests to resources in the same single sign-on domain.

"Customizing the WSRP resource proxy for proxy server support" on page 1488
The WSRP resource proxy supports HTTP proxy servers. It can connect directly to remote resources or to a proxy server that forwards the requests to remote resources.

"Disabling support for relative URLs for the WSRP resource proxy" on page 1489
By default, the WSRP resource proxy serves resources relative to the current resource proxy URI. You can disable the support for relative URLs.

"Customizing the WSRP resource proxy for basic authentication" on page 1489
You can customize the WSRP resource proxy for HTTP basic authentication.

"Customizing the WSRP resource proxy HTTP header forwarding behavior" on page 1490
By default, the WSRP resource proxy forwards all HTTP headers from the client request except for the host header and cookie headers. You can define further headers that you do not want to be forwarded.

Customizing the WSRP resource proxy SSL settings:

The WSRP resource proxy uses one SSL configuration for all secure outbound connections.

About this task

By default, the global SSL configuration as defined in the HTTP Client Service properties is taken for the WSRP resource proxy as well. To specify a different SSL configuration for the WSRP resource proxy only, you can overwrite the global configuration. To do so, proceed as follows:

Procedure

1. Set the following property in the HTTP Client Service:
   `wsrp.resourceproxy.ssl.configuration = SSL configuration name`. To specify the value, use the name of an SSL configuration as defined in the WebSphere Application Server security configuration that you want to use for the WSRP resource proxy.
2. Restart the portal or the cluster for the new setting to become active.

Customizing the WSRP resource proxy for LTPA token forwarding:

The WSRP resource proxy can forward single sign-on cookies (LTPA, LTPA2) from the client requests to resources in the same single sign-on domain.

About this task

You can influence the LTPA token forwarding behavior. To do so, proceed as follows:

Procedure

1. Set the following property in the HTTP Client Service: `wsrp.resourceproxy.sso.domain = Single sign-on domain`. Use this property to specify the single sign-on domain. If the WSRP resource proxy loads a resource from a host inside this domain and the client request contains LTPA or LTPA2 cookies, these cookies are forwarded to the remote resource.
2. Restart the portal or the cluster for the new setting to become active.

Related tasks:

"Enabling remote rendering with WSRP and the Web Content Viewer" on page 2069
To display web content on a portal that does not include IBM Web Content Manager, you can use the Web Content Viewer and the WSRP support in the portal. The Web Content Viewer can then retrieve and display content from a web content system on a different server.

Customizing the WSRP resource proxy for proxy server support:

The WSRP resource proxy supports HTTP proxy servers. It can connect directly to remote resources or to a proxy server that forwards the requests to remote resources.

About this task

By default, the global proxy configuration as defined in the HTTP Client Service properties is taken for the WSRP resource proxy as well. To specify a different proxy configuration for the WSRP resource proxy only, you can overwrite the global configuration by setting a combination of the following properties in the HTTP Client Service:

wsrp.resourceproxy.proxy.http.host
Use this property to specify a proxy host for HTTP URLs. If no proxy host is set, the portal tries to load all HTTP URLs directly.

wsrp.resourceproxy.proxy.http.port
Use this property to specify the port for the HTTP proxy. If no value is specified, 80 is used as the default value.

wsrp.resourceproxy.proxy.https.host
Use this property to specify a proxy host for HTTPs URLs. If no proxy host is set, WebSphere Portal tries to load all HTTPs URLs directly.

wsrp.resourceproxy.proxy.https.port
Use this property to specify the proxy port for HTTPs URLs. If no value is specified, 443 is used as the default value.

wsrp.resourceproxy.proxy.auth.credentialslot
Set this property if you want proxy authentication to be used for connections that use a proxy server. You must provide the user ID and

password in a credential slot of the portal credential vault. You then specify the name of this credential slot in this property. The credential must have the type `UserPasswordPassive`. Proxy authentication applies to the proxy server only, not to the target server of the outbound connection.

wsrp.resourceproxy.proxy.excludehost
Use this property to specify a particular host for which no proxy connection is used, even if a proxy is configured. You can set this property more than once. Specify one setting for each host that is excluded from proxy connections.

Note: You can explicitly set no value for a property that has a value in the global configuration. To do so, specify the value `none` to overwrite the global configuration value. Restart the portal or the cluster for the changes to take effect.

Disabling support for relative URLs for the WSRP resource proxy:

By default, the WSRP resource proxy serves resources relative to the current resource proxy URI. You can disable the support for relative URLs.

About this task

If you disable the support for relative URLs, the resource proxy accepts only requests for URLs that are rewritten and signed by the WSRP Consumer portal itself. URLs that are manipulated at the client side, for example by modifying URL parameters with JavaScript functions, are discarded.

To switch off the support for relative URLs, access the WebSphere Integrated Solutions Console and set the following property in the WP Configuration Service: `wsrp.resourceproxy.support.relative = false`. Restart the portal or the cluster for the changes to take effect.

Customizing the WSRP resource proxy for basic authentication:

You can customize the WSRP resource proxy for HTTP basic authentication.

About this task

To do so, set the following property in the WP Configuration Service:

wsrp.resourceproxy.basic.auth.credentialslot = *your_credential_slot*
Use this property to specify a credential vault slot that contains the user ID and password credentials. The resource proxy servlet uses the credentials from the credential vault slot when it fetches resources that are protected by HTTP basic authentication. The user ID and password are sent to all remote resources that are referenced in the markup of the remote WSRP portlet. By default no value is set for this property.

After you set the property, restart the portal or the cluster for your changes to take effect.

For details about creating a credential vault slot and about how to set configuration properties refer to the following links:

Customizing the WSRP resource proxy HTTP header forwarding behavior:

By default, the WSRP resource proxy forwards all HTTP headers from the client request except for the host header and cookie headers. You can define further headers that you do not want to be forwarded.

About this task

To do so, set the following property in the Configuration Service: `wsrp.resourceproxy.no.header.forwarding = comma-separated list of header names`. Use this property to specify the list of HTTP headers that are not forwarded from the client request in addition to the host header and cookie headers. The host header and cookie headers are never forwarded independent of how this property is set. The default behavior is that WSRP forwards all headers except for the host header and cookie headers. After you set this property, restart the portal or the cluster for the change to take effect.

Configure timeout properties for the WSRP communication:

You can configure web service timeout properties for the WSRP communication on the Consumer. You can configure the timeout properties in the WP Configuration Service or as a preference specifically for remote portlets.

For a description of the timeout properties and the respective default values, go to *JAX-WS timeout properties* in the WebSphere Application Server IBM Knowledge Center.

To define the timeout properties, configure the following configuration parameters on the Consumer:

```
wsrp.consumer.connectiontimeout = (timeout in seconds)

wsrp.consumer.writetimeout = (timeout in seconds)

wsrp.consumer.responsetimeout = (timeout in seconds)
```

By default each of these parameters is `undefined`. The default setting means that the Consumer does not set a timeout property on an outgoing WSRP request. In this case, WebSphere Application Server uses the default timeout properties as described in *JAX-WS timeout properties.*

If timeout properties are configured, the Consumer passes the timeout properties to WebSphere Application Server in the *MessageContext* of an outgoing WSRP request. You therefore do not need to configure timeout settings in WebSphere Application Server in a policy set.

You can set these parameters specifically for a remote portlet. To do so, set this parameter in the portal WP Configuration Service by using the WebSphere Integrated Solutions Console.

If you set a parameter both as a preference of a remote portlet and in the WP Configuration Service, the value that is defined in the preference of the remote portlet takes precedence.

Related information:

CF05 JAX-WS timeout properties

Configure a limit for the size of file uploads:

You can configure a limit for the size of file uploads during an action request. You can also configure the Consumer behavior if a file upload exceeds the defined limit.

To configure set the following configuration parameters on the Consumer:

wsrp.maxUploadDataLength = (the maximum size in Kilo Bytes, a integer value > 0)
Use this parameter to define a maximum size of upload data. By default this parameter is undefined. The default setting means that the Consumer does not limit the size of upload data. Also, if you specify a negative value, the Consumer does not limit the size of the upload data.

wsrp.uploadErrorHandledByProducer = (true,false)
Use this parameter to define the Consumer behavior if a file upload exceeds the defined limit. The default for this parameter is true. This default setting means that if the upload data exceeds the defined limit, the Consumer continues processing. The Consumer sends a WSRP request, which is cleared of all upload data, to the Producer. The remote portlet needs to handle this situation.

If this parameter has the value `false` and if upload data exceeds the defined limit, the Consumer stops processing this action request by throwing an exception. The Consumer does not send a WSRP request to the Producer.

You can set these parameters specifically for a remote portlet. To do so, set this parameter as a preference in the portlet definition of the remote portlet on the Consumer.

Alternatively, you can set this parameter for all remote portlets on the Consumer. To do so, set this parameter in the portal WP Configuration Service by using the WebSphere Integrated Solutions Console.

If you set a parameter both as a preference of a remote portlet and in the WP Configuration service, the value that is defined in the preference of the remote portlet takes precedence.

Switch off the caching of Producer service descriptions:

By default, the Consumer portal caches the WSRP service descriptions that it receives from Producers. If required, you can switch off the caching.

The caching of the WSRP service descriptions in the Consumer is determined by the portal Cache Manager Service property `cacheinstance.wsrp.cache.servicedescription.enabled`. The default setting is `true`. The caching increases performance and reduces network traffic.

If you encounter problems, or if you want to turn off caching of the service description for other reasons, switch off the caching. To do so, set the property `cacheinstance.wsrp.cache.servicedescription.enabled = false` in the WP Cache Manager Service. You set this parameter by using the WebSphere Integrated Solutions Console.

Customizing Client Cookie Forwarding:

A client can send cookies to the WSRP Consumer as part of an HTTP request. You can customize the WSRP Consumer to forward specific client cookies to the Producer ports or to other resources that are served by the WSRP Consumer as a proxy.

About this task

By default the WSRP Consumer does not forward client cookies to WSRP Producers or other resources. To customize the WSRP Consumer to forward specific client cookies, proceed as follows:

Procedure

1. Set the following property in the HTTP Client Service:
   `wsrp.consumer.cookieforward.`*`cookiename`* `=` *`hostdomainnames`* `[;` *`cookiepriority`*`]`

   Specify a separate property for each client cookie that you want to be forwarded.
2. Restart the portal or the cluster for the new setting to become active.

Results

Description:

wsrp.consumer.cookieforward.*cookiename* = *hostdomainnames* [; *cookiepriority*]
This property defines a cookie forwarding rule for the cookie that is identified by the value for *cookiename*. The cookie forwarding rule specifies a list of host names and domain names and optionally specifies the cookie priority.

cookiename
The value for *cookiename* must match the cookie name literally.

hostdomainname
This setting comprises a comma-separated list of host names and domain names. The cookie is forwarded to Producers whose WSRP endpoint address URLs match to entries in the host domain name list. The WSRP Consumer also forwards the client cookies to resources that are served by the WSRP Consumer as a proxy and whose URLs accord to the host domain name list. The host domain name can contain host names, such as `alpha.company.com`, or domain names that are identified by a leading period (`.`) such as `.sample.com`. The WSRP Consumer literally matches the host domain names to the Producer WSRP endpoint address URLs and resource URLs. It does not translate IP addresses into host domain names or vice versa.

cookiepriority
This setting is optional. You can use it to specify the cookie priority. The WSRP Consumer uses the cookie priority to control how priority conflicts between client cookies and producer set cookies with identical names are resolved. Valid values are as follows:

clientfirst
This priority setting directs the WSRP Consumer to prioritize a client cookie over an identically named cookie

that was set by the Producer. In other words, it instructs the WSRP Consumer to send the client cookie to the WSRP Producer or to the Producer resource, rather than to send the Producer cookie.

clientlast
This priority setting directs the WSRP Consumer to prioritize a cookie that was set by the WSRP Producer over a client cookie. In other words, it instructs the WSRP Consumer to send the cookie that was set by the WSRP Producer to the WSRP Producer or to the Producer resource, rather than to send the client cookie. This value is the default priority value. For example, it is applied if the cookie priority is not specified in the cookie forwarding rule.

Example properties that contain cookie forwarding rules are as follows:

wsrp.consumer.cookieforward.SAMPLECOOKIE = alpha.company.com,.sample.org
With this setting, the WSRP Consumer forwards the client cookie named `SAMPLECOOKIE` to the host `alpha.company.com` and to all hosts contained in the domain `sample.org`. It assumes the default cookie priority `clientlast` .

wsrp.consumer.cookieforward.COOKIE2 = .myorg.com,beta.sample.com;clientfirst
With this setting, the WSRP Consumer forwards the client cookie named `COOKIE2` to the host `beta.sample.com` and to all hosts in the domain `myorg.com`. It gives client cookies first priority.

Note: The WSRP Consumer does not send cookies when it requests the WSDL service description documents from a Producer.

Related concepts:

"Cookie support" on page 1500
The WSRP Consumer stores cookies that it receives from a WSRP Producer or from resources that the Consumer serves as a proxy. It forwards the cookies appropriately in subsequent requests to a Producer or other resources.

Configuring remote session invalidation: CF06

You can configure the WSRP Consumer to invalidate the remote session when a user explicitly logs out of the Consumer portal. If you enable remote session invalidation and a user logs out of the Consumer portal, the Consumer sends a `releaseSessions` WSRP request to all the Producers with which the user interacted. The Producers portals can then invalidate these sessions.

About this task

By default, remote session invalidation is disabled.

Before you enable remote session invalidation, carefully consider the performance impact:

- Remote session invalidation allows the Producer portal to invalidate unused sessions. This way, the Producer can free resources when the users log out.
- However, remote session invalidation creates extra WSRP communication during logout. There is at least one WSRP roundtrip to each Producer with which the user interacted. In some cases, the Consumer needs to send multiple `releaseSessions` requests to one Producer.

To configure remote session invalidation, set the following configuration property on the Consumer portal:

`wsrp.consumer.releaseSessions.enabled = (false|true)`
Use this property to enable or disable remote session invalidation. The default for this property is `false`. This default setting means that the Consumer does not invalidate remote sessions.

You set this property in the portal WP Configuration Service by using the WebSphere Integrated Solutions Console. For details about portal service configuration properties and how to set them, read Portal service configuration and Setting service configuration properties.

Using handlers for WSRP web services

You can extend your WSRP Producer or WSRP Consumer portal by handlers that comply with JAX-WS.

About this task

The WSRP web services conform to the JAX-WS standard. To create and process custom extensions of WSRP messages, you can create and deploy JAX-WS compliant handlers for the WSRP web services.

By default, the WSRP Producer and WSRP Consumer do not use any handler.

Migration note: Up to WebSphere Portal Express Version 8.0, WSRP was based on the JAX-RPC standard. If you upgrade your WebSphere Portal Express from Version 8.0 to Version 8.5, you must reimplement your existing JAX-RPC compliant handlers to comply with JAX-WS.
Before you can use a custom handler, you must first create a handler implementation according to the JAX-WS specification. For details about the handler framework, read the JAX-WS specification. For information about how to use handlers with JAX-WS web services, read the appropriate information in the WebSphere Application Server documentation.

Related information:

JAX-WS specification

Using handlers in JAX-WS web services

Using a handler on a WSRP Producer portal

Find the procedure for configuring and using a handler on a WSRP Producer portal.

About this task

You can configure handlers for the WSRP Producer in the `wps.ear` portal application.

CF05 Starting with CF05, you can register handlers that implement the SOAPHandler interface as an extension of a WSRP extension point. In this case, you do not need to modify the portal application. For details, read the information in a later section.

To configure a JAX-WS handler in the portal application, use the following procedure:

Procedure

1. Create a handler implementation according to the JAX-WS specification. For details about the handler framework, read the JAX-WS specification. For information about using handlers with JAX-WS web services, read the appropriate information in the WebSphere Application Server documentation.
2. Provide the handler implementation in the class path of the `wps.ear` portal application, for example in the portal shared application directory.
3. Export the `wps.ear` portal application. The exported `wps.ear` file contains a `wps.war`. The `WEB-INF/classes` directory in the `wps.war` file contains two files `wp.wsrp.producer-v1-handlerchain.xml` and `wp.wsrp.producer-v2-handlerchain.xml`.
4. Modify either one of the files `wp.wsrp.producer-v1-handlerchain.xml` or `wp.wsrp.producer-v2-handlerchain.xml`. Update the default `handler-chains` element by adding one or more `handler` elements.
5. Update the `wps.ear` portal application.
6. Restart your WSRP Producer portal.

Results

You can now use the handler in your Producer portal

Example

The following samples show excerpts from the file `wp.wsrp.producer-v2-handlerchain.xml`. The samples contain a handler definition for the WSRP Producer.

Before CF 05:

```
<?xml version="1.0" encoding="UTF-8"?>
<ns:handler-chains xmlns:ns="http://java.sun.com/xml/ns/javaee">
    <ns:handler-chain name="wp.wsrp.producer-v2-handlerchain">
        <ns:handler>
            <ns:handler-class>sample.handler.ProducerHandler</ns:handler-class>
        </ns:handler>
    </ns:handler-chain>
</ns:handler-chains>
```

CF05 With CF 05 and later fix packs, you must not modify the default handler definition for the handler class `com.ibm.wps.wsrp.producer.handler.ProducerHandlerChain`. You can add more handlers as shown in the following example:

```
<?xml version="1.0" encoding="UTF-8"?>
<ns:handler-chains xmlns:ns="http://java.sun.com/xml/ns/javaee">
    <ns:handler-chain name="wp.wsrp.producer-v2-handlerchain">
        <ns:handler>
            <ns:handler-class>com.ibm.wps.wsrp.producer.handler.ProducerHandlerChain</ns:handler-class>
        </ns:handler>
        <ns:handler>
            <ns:handler-class>sample.handler.ProducerHandler</ns:handler-class>
        </ns:handler>
    </ns:handler-chain>
</ns:handler-chains>
```

JAX-WS specification

Using handlers in JAX-WS web services

Registering a SOAPHandler as a WSRP extension: CF05

About this task

CF05 To register a handler that implements the SOAPHandler interface, you can use a WSRP extension point. In this case, you do not need to modify the portal application. To do so, provide a JAR file that contains the handler implementation and a `plugin.xml` file that defines an extension of extension point `com.ibm.portal.wsrp.producer.SOAPHandler`. You can also define multiple handlers inside one `plugin.xml` file as shown in the following example. The class attribute must specify the handler implementation class.

```
<?xml version="1.0" encoding="UTF-8"?>
<plugin
    id="sample.handler"
    name="Sample WSRP Handlers"
    version="1.0.0">

    <extension point="com.ibm.portal.wsrp.producer.SOAPHandler" id="SampleProducerHandler1">
        <impl class="com.ibm.wps.wsrp.test.handler.ProducerHandler1" weight="100"/>
    </extension>
    <extension point=" com.ibm.portal.wsrp.producer.SOAPHandler" id="SampleProducerHandler2">
        <impl class="com.ibm.wps.wsrp.test.handler.ProducerHandler2" weight="110"/>
    </extension>
</plugin>
```

Using a handler on a WSRP Consumer portal

Find the procedure for configuring and using a handler on a WSRP Consumer portal.

About this task

You can configure handlers for the WSRP Consumer in the `web.xml` file of the `wps.ear` portal application.

CF05 Starting with CF05, you can register handlers that implement the SOAPHandler interface as an extension of a WSRP extension point. In this case, you do not need to modify the `web.xml` file of the portal application. For details, read the information in a later section.

To configure a JAX-WS handler in the `web.xml` file of the portal application, use the following procedure:

Procedure

1. Create a handler implementation according to the JAX-WS specification. For details about the handler framework, read the JAX-WS specification. For information about using handlers with JAX-WS web services, read the appropriate information in the WebSphere Application Server documentation.
2. Provide the handler implementation in the class path of the `wps.ear` portal application, for example in the portal shared application directory.
3. Export the `wps.ear` portal application. The exported `wps.ear` file contains a `wps.war` file, which in turn contains a file that is named `web.xml`.
4. Modify the `web.xml` file by adding a `handler-chains` element to the service reference for which you want to deploy the handler.
5. Update the `wps.ear` portal application.
6. Restart your WSRP Consumer portal.

Results

You can now use the handler in your Consumer portal

Example

The following samples show excerpts from the file `web.xml`. The samples contain a handler definition for the WSRP Consumer.

Before CF 05:

```
<service-ref>
   <description>WSRP 2.0 Default Service Reference</description>
   <service-ref-name>service/wsrp/WSRPService_v2</service-ref-name>
   <service-interface>javax.xml.ws.Service</service-interface>
   <service-qname
      xmlns:pfx="http://www.ibm.com/xmlns/prod/websphere/portal/wsrp/wsdl/v2">pfx:WSRPService_v2</service-qname>
   <handler-chains>
      <handler-chain>
         <handler>
            <handler-name>sample handler</handler-name>
            <handler-class>sample.handler.ConsumerHandler</handler-class>
         </handler>
      </handler-chain>
   </handler-chains>
</service-ref>
```

CF05 With CF 05 and later fix packs, you must not modify the default handler definition named `WSRP 2.0 Default Consumer Handler`. You can add more handlers as shown in the following example:

```
<service-ref>
   <description>WSRP 2.0 Default Service Reference</description>
   <service-ref-name>service/wsrp/WSRPService_v2</service-ref-name>
   <service-interface>javax.xml.ws.Service</service-interface>
   <service-qname
```

```
      xmlns:pfx="http://www.ibm.com/xmlns/prod/websphere/portal/wsrp/wsdl/v2">pfx:WSRPService_v2</service-qname>
   <handler-chains>
      <handler-chain>
         <handler>
            <handler-name>WSRP 2.0 Default Consumer Handler</handler-name>
            <handler-class>com.ibm.wps.wsrp.consumer.handler.ConsumerHandlerChain</handler-class>
         </handler>
         <handler>
            <handler-name>sample handler</handler-name>
            <handler-class>sample.handler.ConsumerHandler</handler-class>
         </handler>
      </handler-chain>
   </handler-chains>
</service-ref>
```

   name="Sample WSRP Handlers"
   version="1.0.0">

   <extension point="com.ibm.portal.wsrp.consumer.SOAPHandler" id="SampleConsumerHandler1">
      <impl class="com.ibm.wps.wsrp.test.handler.ConsumerHandler1" weight="100"/>
   </extension>
   <extension point=" com.ibm.portal.wsrp.consumer.SOAPHandler" id="SampleConsumerHandler2">
      <impl class="com.ibm.wps.wsrp.test.handler.ConsumerHandler2" weight="110/>
   </extension>
</plugin>
```

Reference for using WSRP with the portal

Reference information about using WSRP with the portal includes WSRP markup caching and Known limitations.

"WSRP Markup Caching" on page 1499
To improve performance, the WSRP implementation in the portal can use expiry-based markup caching for remote portlets. This caching reduces the number of interactions between the Consumer and the Producer. The Consumer caches remote portlet content, based on the cache-control data structure that the Producer provides as part of its response. You can enable markup caching on the Consumer for all remote portlets or specifically for selected remote portlets.

"Cookie support" on page 1500
The WSRP Consumer stores cookies that it receives from a WSRP Producer or from resources that the Consumer serves as a proxy. It forwards the cookies appropriately in subsequent requests to a Producer or other resources.

"WSRP two-phase rendering" on page 1501
The WSRP Consumer and the WSRP Producer in the portal support two-phase rendering for JSR 286 portlets. Two-phase rendering allows a remote portlet to set headers and cookies and to modify the HTML head section.

"Handling HTTP headers" on page 1502
You can configure both the WSRP Producer and the Consumer to ignore headers.

"Hints and tips for using WSRP with the portal" on page 1502
Here are some hints and tips for using WSRP with IBM WebSphere Portal Express.

"Troubleshooting WSRP" on page 1504
You can troubleshoot WSRP by using different methods such as logging and tracing, debugging, and monitoring.

WSRP Markup Caching

To improve performance, the WSRP implementation in the portal can use expiry-based markup caching for remote portlets. This caching reduces the number of interactions between the Consumer and the Producer. The Consumer caches remote portlet content, based on the cache-control data structure that the Producer provides as part of its response. You can enable markup caching on the Consumer for all remote portlets or specifically for selected remote portlets.

To enable the use of remote caches, the Consumer can use the cache control data structure to set the HTTP cache control header of a resource response or a render response during the render headers phase.

CF05 Starting with Portal 8.5 CF05, markup caching is no longer based on the portlet container's fragment caching feature. You can now use WSRP markup caching without enabling fragment caching. The WSRP Consumer uses the Portal cache `wsrp.cache.markup` to store WSRP *getMarkup* responses according to the cache control.

The Producer derives the WSRP cache control from the cache settings of the local standard API portlet. These settings are specified statically in the portlet definition or dynamically through the Portlet API during run time. They comprise the following information:

- **`Expiration`** specifies the duration in seconds that markup fragment remains valid. A value of `-1` indicates that the markup fragment never expires.

  Note: If an expiration value of `-1` is specified, the Consumer and all remote caches cache the content for unlimited time. This way, the content is never updated.
- **`Scope`** specifies a string that indicates when the cached markup can be used by various users. The markup is either cached specifically for one user or for all users. This parameter is relevant for remote caching. For more information, read the section about tuning your portal.

If the local portlet is not a standard API portlet, the Producer does not return any cache control information. It disables caching for this portlet.

The Consumer can configure WSRP markup caching by using the following configuration parameters:

CF05 **`wsrp.markupcaching.enabled = (false,true)`**
Use this parameter to enable or disable WSRP markup caching. The default for this parameter is `false`. This default setting means that WSRP markup caching is disabled, if no value is specified for this parameter.

Note: If the parameter **wsrp.requiresSeparateRenderPhase** is enabled, the Consumer automatically disables WSRP markup caching for the corresponding portlet and does not consider this parameter.

wsrp.caching.enabled = (true, false)
Use this parameter to enable or disable setting the HTTP cache control header in a resource response or in a render response during the render headers phase. The default for this parameter is `true`.

CF05 You can set these parameters specifically for a remote portlet. To do so, set this parameter as a preference in the portlet definition of the remote portlet on the Consumer.

Alternatively, you can set these parameters for all remote portlets on the Consumer. To do so, set this parameter in the portal WP Configuration Service by using the WebSphere Integrated Solutions Console.

CF05 If you set a parameter both as a preference of a remote portlet and in the WP Configuration Service, the value that is defined in the preference of the remote portlet takes precedence.

Cookie support

The WSRP Consumer stores cookies that it receives from a WSRP Producer or from resources that the Consumer serves as a proxy. It forwards the cookies appropriately in subsequent requests to a Producer or other resources.

The following list gives an overview of the supported use cases of the WSRP Consumer cookie handling.

Cookies that the Consumer receives from the Producer during session context initialization for a remote portlet:
If the Consumer receives a cookie from the Producer during session context initialization for a remote portlet, the Consumer forwards that cookie to remote portlets of the same Producer or of the same group. The forwarding target depends on the Producer initialization cookie policy. Additionally, the Consumer forwards the cookie to resources that the Consumer serves as a proxy and that the remote portlet addresses.

Cookies that the Consumer receives from a remote JSR 286 portlet:
If the Consumer receives a cookie from a remote JSR 286 portlet, the Consumer forwards that cookie to remote portlets and resources that the Consumer serves as a proxy, if the cookie domain and path match.

Cookies that the Consumer receives from resources that the Consumer serves as a proxy:
If the Consumer receives a cookie from resources that the Consumer serves as a proxy, the Consumer forwards that cookie to remote portlets and resources that the WSRP Consumer serves as a proxy, if the cookie domain and path match.

Cookies that the client sends to the Consumer:
A client can send cookies to the WSRP Consumer. You can customize the Consumer to forward these cookies to the WSRP Producer or to other resources that the WSRP Consumer serves as a proxy. By default, the Consumer does not forward any cookies that the client sends to the WSRP Consumer.

Related tasks:

"Customizing Client Cookie Forwarding" on page 1492
A client can send cookies to the WSRP Consumer as part of an HTTP request. You can customize the WSRP Consumer to forward specific client cookies to the Producer ports or to other resources that are served by the WSRP Consumer as a proxy.

"Customizing the WSRP resource proxy" on page 1486
The WSRP resource proxy is used by the WSRP Consumer to load resources that are referenced by remote portlets.

WSRP two-phase rendering

The WSRP Consumer and the WSRP Producer in the portal support two-phase rendering for JSR 286 portlets. Two-phase rendering allows a remote portlet to set headers and cookies and to modify the HTML head section.

CF05 The Consumer and Producer determine whether a JSR 286 portlet requires two-phase rendering. The following description explains how the Consumer and Producer process a portlet that supports two-phase rendering:

CF05 By default, the Consumer and Producer process both render phases during one WSRP *getMarkup* request. The default process is advantageous since the two-phase rendering requires only one WSRP request/response roundtrip. Here the Consumer sends a WSRP *getMarkup* request only during the render headers phase and uses the WSRP response for processing both the render headers phase and the render markup phase. The Producer starts the portlet's render method both in the render headers and the render markup phases.

CF05 Starting with Portal CF 05, you can configure WSRP to use separate WSRP requests for processing the render headers and the render markup phases. This configuration enables the use of portlets, which depend on increased separation between the render phases over WSRP. Here the Consumer sends separate WSRP *getMarkup* requests during the render headers phase and the render markup phase and uses the corresponding WSRP response during each phase.

To configure WSRP two phase rendering, configure the following configuration parameters on the Consumer:

wsrp.requiresSeparateRenderPhases=(false,true)
Use this parameter to define whether WSRP uses separate WSRP requests to process the render headers and the render markup phases. The default for this parameter is *false*. This default setting means that WSRP uses one WSRP request to process both render phases, if no value is specified for this parameter.

You can set this parameter specifically for a remote portlet. To do so, set this parameter as a preference in the portlet definition of the remote portlet on the Consumer.

Alternatively, you can set this parameter for all remote portlets on the Consumer. To do so, set this parameter in the portal WP ConfigurationService by using the WebSphere Integrated Solutions Console.

If you set the parameter as a preference for both a remote portlet and the WP Configuration Service, the value that is defined in the preference of the remote portlet takes precedence.

Note: Enabling this parameter automatically disables WSRP markup caching.

Related tasks:

"Using two-phase rendering with JSR 286 portlets" on page 2935
For portlets conforming to JSR 286, IBM WebSphere Portal Express includes support for two-phase rendering, which allows portlets to set cookies and the HTTP headers and to change the portal page title dynamically.

Handling HTTP headers

You can configure both the WSRP Producer and the Consumer to ignore headers.

To do so, use the following portal service configuration parameter in the portal Configuration Service:

wsrp.ignore.headers = (comma-separated list of headers)
Use this parameter to specify one or more headers that you want to be ignored by WSRP. The Producer portal does not pass any headers that are contained in this list to the Consumer. The Consumer portal does not pass any headers that are contained in this list to the Producer. The Consumer portal also ignores headers that are contained in this list if it receives them from the Producer portal. By default this parameter is not set. You can set this parameter in the portal WP Configuration Service by using the WebSphere Integrated Solutions Console. for details about how to do so, read Setting service configuration properties.

Hints and tips for using WSRP with the portal

Here are some hints and tips for using WSRP with IBM WebSphere Portal Express.

Consuming remote portlets with your portal

If you use WebSphere Portal Express to consume remote portlets, you must set the following JVM property for the portal JVMs:

com.ibm.ws.websvcs.useMultipleSetCookie = true
Use this property to enable the WSRP Consumer to process multiple Set-Cookie headers that are contained in a WSRP response.

This property was introduced with IBM WebSphere Application Server APAR PM91361. The APAR is contained in WebSphere Application Server Version 8.5.5.1 and later.

To set this JVM property, use the WebSphere Integrated Solutions Console. After you set this JVM property, restart your Portal server.

Consuming remote portlets from IBM WSRP Producer for WebSphere Application Server

If you use WebSphere Portal Express Version 8.5 to consume remote portlets from an IBM WSRP Producer for WebSphere Application Server that you own, use the July 2015 update of that Producer. If your Producer is an earlier version, update the Producer to the July 2015 update. You can obtain the IBM WSRP Producer for WebSphere Application Server from the IBM Collaboration Solutions Catalog.

Consuming remote portlets from an earlier version IBM WSRP Producer for WebSphere Application Server might not work properly under individual environments and scenarios.

Registration

The WSRP Producer for IBM WebSphere Portal Express does not support the WSRP Registration interface.

Remote portlets on unauthenticated pages

If you add remote portlets to unauthenticated pages that have public sessions turned off, you get the following two consequences:

1. Session data is lost for each request.
2. An extra request to the Producer is submitted to establish a session.

If you add remote portlets to unauthenticated pages, turn on public sessions. This way, you can benefit portal performance and avoid unexpected behavior that results from the lost session data.

Rendering URLs for forms

Submitting data to a portlet through forms is semantically an `action` request, as this request changes the state of the portlet. WSRP strongly enforces the separation of `action` and `render` requests according to the corresponding semantics. It prevents the submission of form data through `render` requests. As a result, portlets that use `render` URLs to submit form data do not work remotely.

Portlets cannot use portal internals

With WSRP, you cannot use portal internals in portlets, such as engine objects or engine tags. Portlets that use such internals do not work remotely as WSRP does not supply the infrastructure that is required for portlets to use portal internals.

Compatibility of portlets with WSRP

The following restrictions apply to the Compatibility of portlets with WSRP:

Some of the portlets that are included with WebSphere Portal Express cannot be provided as WSRP services.

The reason is that some additional and more advanced WebSphere Portal Express concepts and features are not reflected by the current WSRP standard yet. This group includes all portal administration portlets, the Portal Search portlets Manage Search and Search Center, and some other portlets that are provided with the portal.

If portlets contain URLs to other resources, the URLs must be encoded according to the Java portlet specification to work with WSRP.

You might have portlets that serve or link to resources such as images, CSS files, JavaScript files, or servlets that are packaged with the portlet. To work in a distributed environment such as WSRP, these portlets must handle the URLs correctly. The WebSphere Portal Express WSRP Producer runtime hooks into the URL generation code that is used by the Java Portlet Specification APIs. In such cases, the portal can generate WSRP-compliant URLs to allow resources to be proxied by the WRSP Consumer server. Therefore, URLs in the browser can point to a resource

proxy that the WSRP Consumer provides and that routes the request to the appropriate resource that the WSRP Producer host provides. For example, portlets might contain URLs that include CSS or JavaScript files, and you want to provide these portlets by WSRP. In such a case, you must make sure that the URLs point to the correct locations by encoding them in compliance with the Java portlet specification. If you do not encode the URLs by using the JSR API calls, the portlets might not work properly.

Note: The WebSphere Portal Express resource proxy implementation also supports the serving of relative URLs. Example: A URL points to a CSS file and is encoded by using the Java Portlet Specification API. The CSS file in turn contains relative links to further resources such as images. In such a case, requests for those images are also routed and served through the WSRP Consumer resource proxy.

WSRP does not support Consumer-side configuration of remote portlets that do not support shared configuration

The configuration of the `edit_defaults_compatibility` portlet mode is not supported for portlets that are consumed by using WSRP.

The PUMA SPI cannot be used with WSRP

The PUMA SPI does not allow use with remote portlets.

Tag Cloud, Tag Center, and Results List portlets do not support WSRP

The Tag Cloud and Tag Center portlets, including the Result List portlet, do not support WSRP. Therefore, a Producer portal cannot provide these portlets as remote web services, or for a Consumer portal to consume them so that its users can use them.

Troubleshooting WSRP

You can troubleshoot WSRP by using different methods such as logging and tracing, debugging, and monitoring.

- "Setting traces and using the portal run time log file for WSRP diagnosis"
- "Debugging and monitoring the WSRP protocol flow" on page 1505
- "Monitoring WSRP messages between the Consumer and Producer by using TCPMon" on page 1505

Setting traces and using the portal run time log file for WSRP diagnosis

You can diagnose problems that might occur during the use of WSRP. To do so, you set WSRP-specific traces and enable run time logs for the Consumer, Producer, and administration components of the WSRP implementation. Use the administration portlet Enable Tracing.

You can enable the following trace loggers for the WSRP implementation:

Table 191. WSRP trace loggers

Component	Trace string
Administration	com.ibm.wps.command.wsrp.*=all com.ibm.wps.wsrp.cmd.*=allcom.ibm.wps.wsrp.common.*=all com.ibm.ws.websvcs.trace.MessageTrace=all
Consumer	com.ibm.wps.wsrp.consumer.*=all com.ibm.wps.wsrp.common.*=all com.ibm.ws.websvcs.trace.MessageTrace=all
Producer	com.ibm.wps.wsrp.producer.*=all com.ibm.wps.wsrp.common.*=all com.ibm.ws.websvcs.trace.MessageTrace=all
XMLAccess	com.ibm.wps.command.xml.*=all com.ibm.wps.wsrp.common.*=all com.ibm.ws.websvcs.trace.MessageTrace=all

Debugging and monitoring the WSRP protocol flow

You can trace SOAP messages that are exchanged between a WSRP Consumer and a WSRP Producer. To do so, you use a monitor or sniffer application to capture network traffic between the two points. You can use the utility **TCPMon** that is shipped with the WebSphere Application Server. As an alternative, most Linux operating systems provide suitable utilities, for example, **tcpdump**. You can run **tcpdump** on either side and record network traffic that is captured by a network interface. There are also free tools available.

Monitoring WSRP messages between the Consumer and Producer by using TCPMon

You can use the TCPMon tool to monitor the WSRP messages between the Consumer and Producer. For information about how to do so, read the WebSphere Application Server Information Center topic about Tracing web services messages. The TCPMon application uses the man-in-the-middle approach. TCPMon listens on a TCP port, logs the HTTP or SOAP traffic, and forwards the request to the designated server and TCP port. Therefore, you must redirect the communication from the Consumer to the TCPMon application and have TCPMon forward the request to the WSRP Producer.

If you already have a Producer configuration on your Consumer portal, you can modify the host and port for each WSRP end point address URL that you want to monitor. You can change the WSRP endpoint address URLs that the Consumer uses to communicate with the integrated Producer. To do so, you can use either the portal administration user interface or the XML configuration interface.

Alternatively, to debug a certain scenario, you can also create a new Producer definition on the Consumer with a WSDL that contains WSRP endpoint address URLs that point to the TCPMon host and port.

In WebSphere Portal Express, you can manipulate the WSDL contents by adding URL parameters to the WSDL URL.

After you redirect the traffic, configure the TCPMon tool to listen on the port that you specified on the Consumer side to communicate with the Producer portal. Also, set the target port to the actual port values of the Producer WSRP interfaces.

For the WebSphere Portal Express Producer, these target ports are the ports that the WSDL file contains when you request the WSDL file without the `port` parameter.

To run the TCPMonitor tool, follow the instructions that are given in the WebSphere Application Server information center under *Tracing SOAP messages with tcpmon*.

Browser behavior and scenarios

Browser behavior for the back button, bookmarks and history affect user interaction and cause unexpected results.

"Back button behavior"
Learn how the behavior of the web browser Back button can affect portal navigation.

"Back button limitations" on page 1512
The following restrictions apply to backward navigability of portal pages.

"Configuring history expiration limits" on page 1513
You can configure how far back the WebSphere Portal Express tracks the history of the navigational state of pages. This allows you to control the balance between the performance of your portal and the retrievability of previously visited pages for users.

Back button behavior

Learn how the behavior of the web browser Back button can affect portal navigation.

With IBM WebSphere Portal Express users can use the Back button of the browser to navigate back through the recent history of the **views** of the pages that they visited.

When a user navigates backwards by using the browser Back button, the portal restores the views of pages that the user visited recently. This behavior of the portal might affect the following aspects of the pages:

- The sequence by which the user navigated through the portal and selected the pages.
- The expanded or collapsed state of the tree hierarchy that the navigation shows.
- The lateral scrolling position of the register tabs that users can use to switch between pages.
- The information of the user's default selection for a label. For example, this can be the information which page is selected for a label by default for that user. If the user selects a different page from that label, the portal displays that page as the default page for that label from then on.
- The portlet window information that distinguishes between different instances of the same portlet on different pages.
- Modifications of the view or window state of a portlet, such as the minimized, maximized, or normal or default state. For example, if a user views a portlet in its default view state, and then maximizes the portlet, clicking the Back button returns the portlet to its previous state, that is the portlet is displayed with its default size.

- The portlet mode selection options, such as View, Personalize, Edit Shared Settings, or Configure.
- The information as to whether a portlet is displayed in solo state, and the information which portlet is displayed in solo state.
- The information as to whether the link for toggling between **Show layout tools** and **Hide layout tools** is displayed. For example these tools include options for moving portlets on a page.
- If the portlet complies with the standard portlet API, the view state of the portlet is preserved as it is determined by the render parameters of the portlet. For detail about state changes to standard API compliant portlets, refer to Using the Back button with standard API portlets.

Terminology: The following terminology conventions are used for this topic:

1. The terms **view** state and **navigational** state are used synonymously here. **`Render parameters`** in the sense of the standard portlet API also refers to the same.
2. Everything that is said about the browser Back button here applies to the browser Forward button respectively.
3. The browser Back button does not have an undo function. It interacts with the view or navigational state only, not with the application state.

User experience

Users can click the Back button of the browser as many times as the browser history mechanism allows. In such cases the markup comes from the history cache of the browser and is served without an additional request to the server. Users see exactly the same markup as they saw when they visited the page previously.

When users use the Back button to return to a page, they can use any link on that previously visited page to navigate further as follows:

- If the link is only a render link and does not result in a portlet action, then no special case applies.
- If the link is an action link and includes a portlet action, the behavior differs, depending on whether the user had already clicked the same action link during a previous visit to the page in the same session:
  - If the user has not clicked the action link previously, the portal performs the action.
  - If the user has already clicked the action link previously, then the portal displays the markup of the state that resulted from the last invocation of the action link. In other words, the portal does not perform the same action twice.

From a user point of view the consequences of considering these parameters as view state are as follows:

- Each different combination of states is part of the address of the page, that is its URL, and can be bookmarked. Users can set separate bookmarks for different states of the same page.
- Users can use the Back button to navigate through modifications of the view states. For example, if a user maximized a portlet, the user can use the browser Back button to switch back to the previous window state of this portlet.
- The effect of the Back button on interactions with individual portlets strongly depends on the implementation of the portlet. If the portlet implements its links as render links by changing render parameters on a per-link basis, then the Back

button can be used to navigate through the history of the interactions with the portlet. This however is only possible for portlets written against the standard portlet API.

Example scenarios

Example scenario 1: Maximizing or minimizing portlets

1. The user views a page A with two portlets A1 and A2, both in their normal default window state.
2. The user maximizes portlet A1.
3. The user clicks the Back button. Portlet A1 is displayed in normal state again.

Example scenario 2: Switching between pages

1. The user views a page A with two portlets A1 and A2, both in their normal default window state.
2. The user maximizes portlet A1.
3. The user selects page B. The portal displays page B.
4. The user clicks the Back button. The portal returns to page A. Portlet A1 is displayed in maximized state.
5. The user clicks the Back button once more. Portlet A1 is displayed in normal state again.

Example scenario 3: Different user action leads to same result.

Initial scenario and user actions:

1. The user views a page A with a number of portlets on this page.
2. The user interacts with the portlets.
3. The user puts portlet A1 into edit mode.
4. The user clicks A2 into minimized state.
5. The user makes the document viewer portlet A3, which is a standard API portlet, display page 2 of the document that it shows.
6. Now the user switches to page B with portlet B1. Portlet B1 is displayed in normal state, view mode and in its default application state.
7. The user minimizes portlet B1.

Despite different subsequent user actions, the following sub-scenarios have the same final outcome:

Scenario 3a: Using the Back button

1. The user clicks the Back button. The portal displays portlet B1 in normal state.
2. The user clicks the Back button once more. The portal changes to page A. It displays portlet A1 in edit mode and portlet A2 in minimized state. Portlet A3 shows page 2 of the document.

Scenario 3b: Making a new selection

1. The user clicks page A *in the navigation* to "return" to page A. Conceptually this change is not considered a change *back* to page A, but *forward* to page A. As a result, the portal displays page A. It shows portlet A1 in edit mode and portlet A2 in minimized state. Portlet A3 shows page 2 of the document.

Setting bookmarks

All state information except the portlet application state is bookmarked, for example render parameters, window states, and modes. The invocation of a bookmark resets the application state to the default state as defined by that bookmark.

Note: The user can set several independent bookmarks for different windows of the same page. Therefore the result of the previous example scenario is independent of other bookmarks that the user might have set on different window states of the same page.

Example scenario: Setting bookmarks

1. The user selects a page A with portlets A1 and A2.
2. The user maximizes portlet A1 and minimizes portlet A2.
3. The user sets a bookmark on the page. The user names the bookmark `A1min_A2max`.
4. The user logs out and logs back in.
5. The user selects the bookmark A1min_A2max. The portal displays page A with portlet A1 maximized and portlet A2 minimized.

The user can set another separate bookmark `A1Edit_A2Default` on the same page A with portlet A1 in Edit mode and portlet A2 in its default state. Both bookmark will work independently of each other.

Considerations for administrators about Back button behavior

The Back button behavior of the portal is internally achieved by coding the combination of all states into the address of the view, that is into its URL. Thus each different combination of navigational states results in a different URL. This has the following additional advantages:

- Users can set separate bookmarks for different states of the same page.
- You can have pages cached by configuring specific requirements.

However, make no assumptions about the syntax or structure of portal URLs. For example, you cannot create valid URLs by simple concatenation. This will automatically be true if only the public API is used to create URLs.

Using the Back button with standard API portlets

If a portlet complies to the standard portlet API, users can use the Back button to navigate backwards through the view states of that portlet as determined by the render parameters of the portlet. When the user clicks the Back button after working with that type of portlet, all information defined by the render parameters is reversed. There is no general rule as to which information is stored in cache as render parameters for a portlet. The effect of the Back button on interactions with individual portlets depends on the implementation of the portlet. This is determined by the person who developed the portlet.

If the portlet implements its links as render links by changing render parameters on a per-link basis, then users can use the Back button to navigate through the history of the interactions with the portlet. However, this is only possible for portlets written against the standard portlet API.

As a general rule, all information that influences the *view* of the portlet rather than its application state should be implemented as render parameters. For more details about how to develop standard API compliant portlets for WebSphere Portal Express, refer to Best practices: Developing portlets using JSR 168 and WebSphere Portal Express.

Configuring the history expiration limit for portal pages

You can configure the portal so that it discards the render parameters for pages that the user has not visited recently within the same session. The purpose of this setting is to limit the URL length which might benefit your portal performance. The portal discards the navigational state of the portlet application of standard API portlets on pages that are too far back in the history.

You can specify the number of different page visits after which the history mechanism can discard the render parameters of the portlet. Your setting determines how far backwards users can at least navigate in the recent history of portal pages that they visited. The number that you specify defines the minimum number of different pages selected by the user after which the portal can discard the render parameters of a page. (The decision whether the render parameters of the page are actually discarded depends on the expiration policy of the internal cache that stores the render parameters of those pages.) If the user returns to a page after visiting the specified number of other pages *and* if the render parameters of that page have expired, the portal displays that page in its default state.

You configure this expiration limit by setting the value for the property `keymanager.lru.size= (integer)`. You set this property in the `StateManagerService`.

You can specify by which circumstances the render parameters of a page are stored or discarded:

1
: Each time that the user selects a different page, the render parameters of the portlets on the previously selected page can be discarded.

A positive integer
: Specify the required number of pages. The render parameters of a given page can be discarded after the user has visited that number of other pages.

0
: Render parameters are always stored in the portal session memory and never discarded.

Note: Do not specify a value smaller than zero (**0**). Negative values are considered to be not valid.

Example scenario: Configuring a limit to the history of viewed pages

1. The configuration setting is set to a history value of 2.
2. The portal pages A, B, and C contain separate instances of the standard portlet API compliant document viewer portlet A1, B1, and C1. Each of the portlets display page 1 of the same document on each page A, B, and C. This is the default for the portlet.
3. The user selects portal page A and navigates to page 2 of the document in portlet A1.

4. The user selects portal page B and navigates to page 3 of the document in portlet B1.
5. The user selects portal page C and navigates to page 4 of the document in portlet C1.
6. The user selects portal page B. Portlet B1 displays page 3 of the document as before.
7. The user selects portal page C. Portlet C1 displays page 4 of the document as before.
8. The user selects portal page A. Portlet A1 displays page 1 of the document because this is the default state for this portlet. The previous state has been discarded because it is back in the view history by 3 pages already, and thereby exceeds the configuration setting of only 2 pages.
9. The user selects page C. Portlet C1 still displays page 4 as before as it is within the configured history value of two stored pages.

Configuring the history setting might result in an inconsistent user experience, depending on the browser cache. If the user uses the Back button to navigate backwards rather than use explicit navigation, the user experience can be inconsistent if the user exceeds the configured view history size on the server. In this case the browser might display the portlets in their previous application state rather than the default state, because the markup is served from the client browser cache without a request to the server. However, if the view history has been exceeded, the server resets the portlet state to its default. Refreshing such a page displays the affected portlet in its default state rather than in the state that was displayed before the refresh operation. If you do not want to accept this behavior, set the size of the view history to the value `0` . This means that the portlet application state never expires.

View history limit influences only the navigational state of the application

The configured limit to the view history influences only the navigational state of portlet applications. It does not influence any of the following:

- The **portal** view or navigational state.
- The **session** state of a portlet application, that is any actions or transactions performed with the portlet.

Example scenario: View history limit influences only the navigational state of the application

1. The configuration setting is set to a history value of 3.
2. The user navigates to a shopping site.
3. The user navigates through several views of pages and looks at various products.
4. On a page X the user picks an item and puts it in the virtual shopping cart.
5. The user navigates through four more page views and looks at more products.
6. The user clicks the browser Back button four times to navigate backward to where the user placed the item in the shopping cart. The portal displays page X in its default state and not in the state in which it was when the user navigated to the next page. The reason is that the page view is back in the history by 4 navigational steps already and thereby exceeds the configuration setting of 3 views. However, the product that the user wants to purchase is not removed from the shopping cart as that information is part of the session state of the application.

Related concepts:

"Caching" on page 267
Caching affects the performance of your IBM WebSphere Portal Express environment. Learn about some simple ways to improve the caching performance. After you have reviewed this content, you should also review the WebSphere Portal Express and Web Content Manager Performance Tuning Guide which provides more information about caches for both WebSphere Portal Express and Web Content Manager.

http://www.ibm.com/developerworks/websphere/library/techarticles/0403_hepper/0403_hepper.html

Back button limitations

The following restrictions apply to backward navigability of portal pages.

The administration portlets do not officially support the browser 'Back' or 'Refresh' functions.

For a listing and description of the administration portlets, refer to "Portal administration portlets" on page 1047.

The Back and Forward buttons have no undo or redo function

The browser Back and Forward buttons do not have an undo or redo function for actions or transactions performed by users. The portal marks completed actions by an internal identifier. If a user performs an action in a portlet and then navigates back to the same portlet panel by the Back or Forward buttons of the browser, the action is not performed once more.

For example, if a user initiates a money transfer or payment of a bill and then navigates further, clicking the Back and Forward buttons of the browser does not repeat the money transfer once again. An action is only performed once.

If a user wants to perform the same action again, the user can do so after refreshing the page. That portal marks that action with a different internal identifier. The protection against repeating the same action applies only to actions within the same markup fragment.

URL length limitation

In a browser, the possible length of a URL is limited to 2048 characters. This depends on the browser and its implementation. Reverse proxies usually have a length limit of 1024 characters for URLs. To circumvent this limit, you can keep the URLs shorter by configuring an expiration limit for pages that are too far back in the navigation history.

URL length limit on small devices

Small devices have a more severe length limit for URLs than browsers and proxies. For such small devices the complete view state is kept in the session on the server

and is referenced by an ID in the URL. Therefore users cannot bookmark pages with their view state. However, they can use the Back button the same way as described previously to navigate back to the same state of a page.

Structure of portal URLs

Do not make any assumptions about the syntax or structure of portal URLs. For example, you cannot create valid URLs by simple concatenation. This will automatically be true if only the public API is used to create URLs.

Bookmarks from previous versions of WebSphere Portal Express do not work

Browser bookmarks to pages from WebSphere Portal Express Version 7.0 do not work for Version 8.5. Users need to create their bookmarks new.

Server side bookmarks of the WebSphere Portal Express Favorites portlet are migrated automatically as you migrate to WebSphere Portal Express Version 8.5.

Related concepts:

"Portal administration portlets" on page 1047
Administration portlets are supplied with IBM WebSphere Portal Express. Use them to perform administration tasks and actions on portal resources, give other users limited access rights on selected resources, and deploy custom portlets, themes, or skins.

Configuring history expiration limits

You can configure how far back the WebSphere Portal Express tracks the history of the navigational state of pages. This allows you to control the balance between the performance of your portal and the retrievability of previously visited pages for users.

About this task

The further back your portal tracks the history of portal pages, the further back your users can go in their browsing history of pages that they visited before. However, this also increases the URL length of your portal pages, as the navigational history is stored in the page URL. Therefore limiting the page history might be of benefit for the performance of your portal.

WebSphere Portal Express provides two different approaches for controlling the page history in the navigational state:

1. The **history manager** allows you to control the number of previously visited pages for which the portal tracks the navigational state.
2. The history expiration limit for swapped render parameters

   "History manager for pages" on page 1514
   The history manager allows you to control for how many visited pages navigational state you want to tracked. In other words it controls the maximum number of pages whose state is contained in the portal URLs. The visited pages are tracked within the navigational state in a LRU algorithm based way.

   "History expiration limit for render parameters" on page 1515
   You can configure the portal so that it discards the render parameters for pages

that the user has not visited recently within the same session. The purpose of this setting is to limit the URL length. This might be of benefit for the performance of your portal. The portal discards the navigational state of the portlet application of standard API portlets on pages that are too far back in the history.

History manager for pages

The history manager allows you to control for how many visited pages navigational state you want to tracked. In other words it controls the maximum number of pages whose state is contained in the portal URLs. The visited pages are tracked within the navigational state in a LRU algorithm based way.

The history manager provides a configurable threshold to define the maximum number of pages that are tracked. If the number of different tracked pages exceeds that threshold, the history manager discards the page that was visited the longest time ago is dropped out. With this page the portal also drops the state of the portlets on this page. Furthermore, the history manager this functionality allows you to define strategies for how to proceed with public render parameters. Limiting the navigational state to a maximum number of pages can reduce the length of the portal URLs.

Notes:

1. The history manager applies to both anonymous and authenticated users, in other words it works on public and protected pages.
2. The history manager is independent of the history expiration limit for swapped render parameters, which determines how long render parameters are kept for swapping into the session.

Configuration of the history manager

The history manager provides the configuration settings listed in the following. You configure them in the WP State Manager Service in the WebSphere Integrated Solutions Console. For details about this service and how to configure these settings see the topics about Setting service configuration properties and the State Manager Service.

historymanager.enabled = (true)
: This parameter allows you to disable (`false`) or enable (`true`) the history manager. The default value is `true`, that is the history manager is enabled.

historymanager.threshold = (10)
: This parameter allows you to configure the maximum number of different pages for which the navigational state is tracked. Set this parameter to a positive integer value. The default value is `10` .

historymanager.prp.removalstrategy = [no_removal | wcm_id | explicit_bucket_assignment]
: This parameter allows you to specify a strategy that defines how to proceed with public render parameters if the history manager removes the state of a page and the portlets on this page. As public render parameters might be used by portlets on different pages, the removal of public render parameters needs special handling. The possible values have the following meaning:

no_removal
Public render parameters are not removed. This means that only the portlet specific state is removed, for example private render parameters.

wcm_id
Public render parameters are removed if the expired page has an explicit shared state bucket assigned that starts with the String `ibm.wcm.` .

explicit_bucket_assignment
Public render parameters are removed if the expired page has an explicit shared state bucket assigned, regardless of a prefix. This is a more general strategy than `wcm_id` . This is the default value.

Example scenarios

The following examples can help explain the history manager functionality. For all examples the maximum configured number of pages that are tracked in the navigational state is set to `3` .

Example 1:
A user visits portal pages in the following order: P1, P2, P3, P4. When the user navigates to page P4, the history manager removes the navigational state of page P1 and the states of all portlets on that page from the state.

Example 2:
A user visits portal pages in the following order: P1, P1, P2, P3, P2, P3, P1. The history manager removes no state.

Example 3:
A user visits portal pages in the following order: P1, P2, P3, P1, P4. When the user navigates to page P4, the history manager removes the navigational state of page P2 and the states of all portlets on that page.

History expiration limit for render parameters

You can configure the portal so that it discards the render parameters for pages that the user has not visited recently within the same session. The purpose of this setting is to limit the URL length. This might be of benefit for the performance of your portal. The portal discards the navigational state of the portlet application of standard API portlets on pages that are too far back in the history.

You can specify the number of different page visits after which the history mechanism can discard the render parameters of the portlet. Your setting determines how far backwards users can at least navigate in the recent history of portal pages that they visited. The number that you specify defines the minimum number of different pages selected by the user after which the portal can discard the render parameters of a page. The decision whether the render parameters of the page are actually discarded depends on the expiration policy of the internal cache that stores the render parameters of those pages. If the user returns to a page after visiting the specified number of other pages *and* if the render parameters of that page have expired, the portal displays that page in its default state.

You configure the expiration limit for render parameters by setting the following property to an integer in the WP State Manager Service in the WebSphere Integrated Solutions Console. For details about this service and how to configure these settings see the topics about Setting service configuration properties and the State Manager Service. You can specify by which circumstances the render parameters of a page are stored or discarded.

keymanager.lru.size

Specify one of the following values:

1 Each time that the user selects a different page, the render parameters of the portlets on the previously selected page can be discarded.

A positive integer

Specify the required number of pages. The render parameters of a given page can be discarded after the user has visited that number of other pages.

0 Render parameters are always stored in the portal session memory and never discarded.

Note: Do not specify a value less than zero (**0**). Negative values are considered to be not valid.

Example scenario: Configuring a limit to the history of viewed pages

1. The configuration setting is set to a history value of 2.
2. The portal pages A, B, and C contain separate instances of the standard portlet API compliant document viewer portlet A1, B1, and C1. Each of the portlets display page 1 of the same document on each page A, B, and C. This is the default for the portlet.
3. The user selects portal page A and navigates to page 2 of the document in portlet A1.
4. The user selects portal page B and navigates to page 3 of the document in portlet B1.
5. The user selects portal page C and navigates to page 4 of the document in portlet C1.
6. The user selects portal page B. Portlet B1 displays page 3 of the document as before.
7. The user selects portal page C. Portlet C1 displays page 4 of the document as before.
8. The user selects portal page A. Portlet A1 displays page 1 of the document because this is the default state for this portlet. The previous state has been discarded because it is back in the view history by 3 pages already, and thereby exceeds the configuration setting of only 2 pages.
9. The user selects page C. Portlet C1 still displays page 4 as before as it is within the configured history value of two stored pages.

Chapter 12. Securing

Security tasks include setting up property extension databases and custom user repositories, configuring and activating SSL, and configuring authentication. In addition, tasks such as activating Federal Information Processing Standards (FIPS) and NIST SP800-131a security modules and configuring external security managers such as Security Access Manager might be required to secure your portal environment.

If you have not configured your user registry yet, go to the Installing section, select the appropriate operating system, and then choose the appropriate deployment scenario. Then, select the Configuring portal to use a user registry topic.

"Configuring SSL" on page 1595
Secure socket layers (SSL) encrypt traffic between the client browser and the server to secure information exchanged over the network between the browser and IBM WebSphere Portal Express. You will need to configure your environment for SSL to activate this additional security feature.

"Enabling FIPS and (NIST) SP800-131a" on page 1608
IBM WebSphere Portal Express tolerates IBM WebSphere Application Server support of Federal Information Processing Standards (FIPS) and National Institute of Standards and Technology (NIST) SP800-131a. You can configure WebSphere Application Server to activate FIPS 140-2 compliant security modules. When you enable FIPS, you can use only FIPS to securely encrypt data. For this reason, you must also configure FIPS for systems that require secure transactions, which can include HTTP servers and LDAP servers.

"Configuring Session Security Integration" on page 1609
IBM WebSphere Application Server protects your session from access by other users.

"Enabling HTTP Basic Authentication for simple clients" on page 1610
IBM WebSphere Portal Express provides an HTTP Basic Authentication Trust Association Interceptor that can be enabled to allow specific clients to log into the portal by using HTTP Basic Authentication instead of HTTP Form Based Authentication.

"Setting up custom user repositories" on page 1615
A custom user repository is any repository that WebSphere Portal Express does not support out-of-box. However, you can configure WebSphere Portal Express to support any type of repository in a federated or stand-alone user registry, whether an LDAP directory, database, file system, and so on. Setting up custom user repositories involves tasks such as defining additional repositories to the default federated user registry, creating a custom stand-alone user repository, and updating your user repository to reflect changes in your environment. Learn what steps are required to create and update custom user repositories and what specific interfaces you must implement to enable communication between WebSphere Portal Express and a repository.

"External security managers" on page 1619
Use external security managers such as IBM Security Access Manager to perform authentication and authorization for IBM WebSphere Portal Express. You can use an external security manager for authentication only or for both authentication and authorization. Using an external security manager to perform only authorization is not supported at this time.

"Deleting passwords from properties files" on page 1669
The configuration tasks might require you to write security-sensitive information, such as passwords, into multiple properties files. When you no longer need this security-sensitive information for your configuration, you should remove them and move the files to a safe place or set the file permissions so that only authorized users can read them.

"Updating user ID and passwords" on page 1670
IBM WebSphere Portal Express and IBM WebSphere Application Server use some accounts from the registry (for example, the LDAP server) including administrative and bind IDs for authenticated access to databases and LDAP severs respectively, as well as the WebSphere Portal Express and WebSphere Application Server administrative IDs. Often this means that the account passwords are stored in the WebSphere Portal Express and WebSphere Application Server bootstraps configuration files, which allows the authentication process to work.

Security and authentication considerations

Security and authentication are key elements of a production environment. Learn about single sign-on, credential vaults and external security managers.

Related information:

WebSphere Application Server V7.0 Security Guide

Authentication

Authentication requires users to identify themselves to gain access to a system or resources. The combination of a user ID and a password is the most common method of authentication. Users can identify themselves immediately upon entry to the system or the system can prompt users to identify themselves before accessing protected resources. After users successfully authenticate, the system identifies which resources-specific users have sufficient authorization to access.

Note: You can have simultaneous, multiple log ins with the same user ID and password. However, this method can result in a non-reliable behavior depending on the client or authentication method. For this reason, IBM WebSphere Portal Express does not support simultaneous, multiple log ins.

WebSphere Portal Express supports the following methods for login and authentication:

Form-based authentication
WebSphere Portal Express uses the IBM WebSphere Application Server Custom Form-based Authentication mechanism to prompt for identities. Users type their user ID and password in the Login portlet.

SSL client certificate authentication
You can configure authentication with certificates that are stored in the browser or on a smart card. The certificates are stored through a Secure Sockets Layer (SSL) client certificate authentication. The authentication is done for the users when they access the protected area of the portal.

Third-party authentication
You can also configure third-party authentication. An external security manager, such as IBM Security Access Manager, is an example. With this method the portal trusts that the authentication was done by the third-party product.

Federal Information Processing Standards and and (NIST) SP800-131a

Federal Information Processing Standards (FIPS) and NIST SP800-131a are standards and guidelines issued by the United States National Institute of Standards and Technology (NIST) for federal government computer systems. FIPS and SP800-131a are developed when there are compelling federal government requirements for standards, such as for security and interoperability, but acceptable industry standards or solutions do not exist.

WebSphere Portal Express tolerates WebSphere Application Server's support of FIPS 140-2 and SP800-131a. WebSphere Application Server integrates cryptographic modules such as Java Secure Socket Extension (JSSE) and Java Cryptography Extension (JCE), which are FIPS 140-2 certified. Throughout the documentation and the product, the FIPS 140-2 certified IBM JSSE and JCE modules are called as IBMJSSEFIPS and IBMJCEFIPS, which distinguishes the FIPS-certified modules from the prior, non-certified IBM JSSE and IBM JCE modules.

The FIPS 140-2 compliant toleration means that WebSphere Portal Express will continue to work after WebSphere Application Server is configured to activate FIPS 140-2 compliant security modules. The WebSphere Portal Express product has no self-contained Cryptographic Support and as a result is unaware of the module differences. Functions in WebSphere Portal Express that use encryption include:

- Secure Sockets Layer (SSL) connections inbound from clients (but this is basically the WebSphere Application Server and HTTP Server support for SSL connections, and is not apparent to WebSphere Portal Express)
- Internal connections between WebSphere Portal Express administrative functions and WebSphere Application Server administrative services (started, for example, when deploying a portlet which must create a web application in WebSphere Application Server)

All connections listed in this document are carried over SSL using FIPS-compliant encryption. Without FIPS 140-2 support, connections might not be encrypted.

Limitations

There are some restrictions in the level of support that WebSphere Portal Express provides in using FIPS-certified modules:

- By default, Microsoft Internet Explorer might not have TLS enabled. To enable TLS, open the **Internet Explorer browser** and click **Tools** > **Internet Options**. On the **Advanced** tab, select the **Use TLS 1.0** check box.
- The IBM Tivoli Directory Server provides the Use FIPS certified implementation option, which enables the directory server the FIPS-certified encryption algorithms uses. For information, see "Setting the level of encryption" within the IBM Tivoli Directory Server Administration Guide.
- You can use FIPS-certified JSSE providers if your servers and clients are using WebSphere Application Server.
- If you are trying to enable FIPS processing mode with GSKit bundled with ITDS, see technote 1578181.

Related tasks:

“Enabling FIPS and (NIST) SP800-131a” on page 1608
IBM WebSphere Portal Express tolerates IBM WebSphere Application Server support of Federal Information Processing Standards (FIPS) and National Institute of Standards and Technology (NIST) SP800-131a. You can configure WebSphere Application Server to activate FIPS 140-2 compliant security modules. When you enable FIPS, you can use only FIPS to securely encrypt data. Support for NIST SP 800-131 and NAS Suite B

Planning for single sign-on

Single sign-on provides a secure method of authenticating a user one time within an environment and using that authentication (for the duration of the session) to access other applications, systems, and networks. In the context of IBM WebSphere Portal Express there are two single sign-on realms; one realm from the client to the portal and other web applications and the other realm from the portal to the backend applications.

Single sign-on for the client realm is established using the IBM WebSphere Application Server Lightweight Third Party Authentication (LTPA) token functionality or an Authentication Proxy. The LTPA token can also establish

backend single sign-on if the backend application accepts it through the Credential Vault portlet or the Java Connector architecture.

WebSphere Portal Express and Java Authentication and Authorization Services

Single sign-on uses only the authentication portion of Java Authentication and Authorization Services (JAAS). WebSphere Portal Express builds a JAAS Subject for each logged on user. The Subject consists of Principals and Credentials. A Principal is a piece of data, such as the user ID or the distinguished name that gives the Subject's identity. A Credential is a piece of data, such as a password or a CORBA Credential that can be used to authenticate a subject. The Subject carries around the Principals and Credentials that the portlet can use directly or through the credential service.

Related information:

Lightweight Third Party Authentication

Secure communications using SSL

Configuring IBM WebSphere Portal Express for SSL adds security to the client-portal exchange. It encrypts all traffic between the client browser and the server, so that no one can "eavesdrop" on the information that is exchanged over the network between the client browser and WebSphere Portal Express. In addition, assuming that the IBM WebSphere Application Server is also configured to accept or require SSL connections, the LTPA Token and other security and session information can be protected against hijack and replay attacks.

Configuring WebSphere Portal Express for SSL is a multistep process that involves configuring the following components:

- Web (HTTP) server running in front of WebSphere Application Server
- WebSphere Application Server
- WebSphere Portal Express

In general, the web server must be configured to accept inbound SSL traffic. The WebSphere Application Server plug-in for the web server must be configured to forward traffic on that port to WebSphere Application Server and WebSphere Portal Express. Then, you must configure the virtual host information. Finally, WebSphere Portal Express must be configured to generate self-referencing URLs using SSL as the transport.

Note: This procedure might be slightly different if a front-end security proxy server such as Security Access Manager WebSEAL is used. In that case, the front-end security server handles the client SSL connections. The web server receives connections from the front-end security proxy server. Mutually authenticated SSL can be configured in the web server and the front-end security proxy server if needed. It is highly dependent on the security requirements of each deployment.

WebSphere Application Server Security Guide: Chapter 5

Credential Vault

The Credential Vault is a service that stores credentials that allow portlets to log in to applications outside the realm on behalf of the user. It manages multiple identities for portlets and users.

Using Credential Vault, a portlet can retrieve a user's authentication identity and then pass the information to a backend application. The Credential Vault features the following level of sign-on:

Passive Credentials
Passive Credentials retrieve stored secret data such as user ID and password or certificates. This option is more flexible. However, it requires portlet writers to manage their own connections and authentication to backend applications with the credentials they retrieved from the Credential Vault.

Credential objects can also pass IBM Security Access Manager or Computer Associates eTrust SiteMinder single sign-on tokens to backend applications.

IBM WebSphere Portal Express provides one simple database vault implementation for mappings to secrets for other enterprise applications. By default, the Credential Vault contains an administrator-managed vault segment and a user-managed vault segment. Administrator-managed vaults allow users to update mappings; however, users cannot add new applications to this vault. The user-managed vault segment allows users to add application definitions, such as a POP3 mail account, under the user vault and store a mapping there. By default, the vault uses an encryption plug-in that encodes the passwords in Base 64.

WebSphere Portal Express initially provides two vault adapter configurations that write to the database:

- A default vault for administrator-managed vault segments that stores credentials in the release domain: default-release
- And a default vault for user-managed vault segments that stores credentials in the customization domain: default-customization

WebSphere Portal also supports the storage and retrieval of credentials from other vault services, such as Security Access Manager. WebSphere Portal includes a Credential Vault adapter for Security Access Manager. This plug-in works on the following operating systems:

- Windows

Caching considerations

Information that is protected by access control and is therefore restricted to a limited set of people needs special consideration when served from an access control agnostic cache. These considerations especially apply to server side caches but you also need to consider local browser caches.

Browser caches usually have no issues unless the computers are shared between multiple users with different levels of access. If you access WebSphere Portal Express from a shared computer, it is important to realize that all users who have access to the computer can access content that is cached in the local browser cache. To prevent this from happening, do not enable public or private caching of the content. Caching is disabled by default.

Depending on the type of browser you are using, you can still experience information leakage from shared computers, even if caching is completely disabled, because some browsers serve content that is accessed by clicking the browser's Back button from a separate history cache that is not affected by HTTP caching directives. As a result, if you click the Back button, you may see content generated from the previous user even if the previous user performed a logout. To prevent this from happening, the markup that is rendered on logout should explicitly clear the browser's history cache, which typically requires browser-specific script coding, or display a message to close all browser windows after logout. History cache can typically be disabled in the browser but it may be activated by default.

The WebSphere Portal Performance Tuning Guide provides information about caches for WebSphere Portal Express and Web Content Manager. After you have setup your environment, review the tuning guide to learn more about stand-alone and cluster tuning and then read about both WebSphere Portal Express and Web Content Manager caches.

Essential tuning and performance resources

Controlling access

After creating users and groups, you can assign them different levels of access to specific resources, roles, and policies. This access controls what actions they can perform on various pages, portlets, and applications.

Review the following information and perform the following tasks to control access within IBM WebSphere Portal Express:

"Managing Access Control" on page 1525
Get familiar with concepts related to administering IBM WebSphere Portal Express access control. To administer access control, use the Resource Permissions portlet, the User and Group Permissions portlet, the Manage Users and Groups portlet, the XML configuration interface, or the Portal Scripting Interface.

"Resources, roles, access rights, and initial access control settings" on page 1526
In order to fine-tune the security measures of your IBM WebSphere Portal Express environment, the administrator creates resources, roles, and access rights, which allows the administrator to control who has access to various information based on their roles and the access rights to that information.

"Access control scenarios" on page 1553
These scenarios provide helpful illustrations on how access control can be set up.

"Access control" on page 1556
You can restrict access to selected users and groups to the views within an authoring portlet, the items that are managed by the authoring portlet, and to elements and pages that are displayed within a website.

"Setting user and group permissions" on page 1567
The User and Group Permissions portlet lets you view and modify the roles that users and groups have on resources.

"Setting resource permissions" on page 1568
Assign and control access for different types of resources.

"Delegated Access Control Administration" on page 1569
IBM WebSphere Portal Express supports delegated access control administration.

"Access Control Caching" on page 1570
Access Control internally uses several caches to improve the access control decision times. You can improve access control performance for special scenarios by setting the lifetime and size properties of these caches in the Cache Manager Service. In most cases, WebSphere Portal Express will run smoothly with the default cache settings. However, if you have a large number of resources or a large number of customized resources, you may want to adjust cache settings and conduct some tests to find the best performance trade-offs.

Managing Access Control

Get familiar with concepts related to administering IBM WebSphere Portal Express access control. To administer access control, use the Resource Permissions portlet, the User and Group Permissions portlet, the Manage Users and Groups portlet, the XML configuration interface, or the Portal Scripting Interface.

Authorization

Authorization is sometimes referred to as access control. Authorization determines what interactions a user is permitted to have with a resource or a service. Administrators configure access to resources or services by assigning roles to users and groups.

WebSphere Portal Express supports fine-grained access control over resources. Users can select and view only those resources for which they have appropriate access rights. When rendering a resource, WebSphere Portal Express verifies that the user has appropriate rights to use the requested resource. You can administer access rights by using the following portal tools:

- Dedicated access control administration portlets called **User and Group Permissions** and **Resource Permissions**
- The group membership portlet called **Manage Users and Groups**
- The Portal Scripting Interface
- The XML configuration interface (XML Access)
- The Manage Pages portlet
- The Portal 8.5 theme.

Access control information is accessible through the XML configuration interface. By default access control data is stored in the WebSphere Portal Express database. Alternately, you can configure an external security manager, such as IBM Security Access Manager, to host parts of the access control data and to manage role assignments.

All unauthenticated users are considered anonymous users. The access control component provides a dedicated virtual principal called Anonymous Portal User to represent such users. Prior to authenticating, an anonymous user, represented by this virtual principal, has specific access to a resource or service. In order for users to benefit from user and group specific privileges, they must be successfully authenticated by the system. Access control is dependent on the authentication of actual users.

WebSphere Portal Express only protects resources and services. WebSphere Application Server protects J2EE artifacts (for example servlet URLs and Enterprise Java Beans™ methods) and its artifacts (like server or node configurations).

WebSphere Portal Express Administrator and Security Administrator

The `Administrator@Portal` and `Security Administrator@Portal` roles contain a special permission that is not available to any other role. This permission allows the Administrator or Security Administrator to make arbitrary changes to the access control configuration of all resources. The Administrator and Security Administrator can create and delete roles, role assignments, and role blocks. If the configuration allows an external security manager such as IBM Security Access Manager to manage role assignments, additional privileges need to be set to allow arbitrary changes to the access control configuration. To change the access control configuration for resources that are externally managed, you must have the `Administrator@External Access Control` or the `Security Administrator@External Access Control` role.

Resources, roles, access rights, and initial access control settings

In order to fine-tune the security measures of your IBM WebSphere Portal Express environment, the administrator creates resources, roles, and access rights, which allows the administrator to control who has access to various information based on their roles and the access rights to that information.

Review the following information to learn more about resources, roles, access rights, and initial access control settings:

"Resources"
Resources are organized in a hierarchy. Resources in the hierarchy propagate their access control configuration to all of their child resources. If a user has the Editor role on the Market News page, then that user also has the Editor role on child pages of the Market News page. Resource instances are specific resources, such as a single portlet or page. Each resource instance belongs to only one resource type. For example, the resource instance Market News Page would belong to the Content Nodes resource type.

"Roles" on page 1533
Roles provide task permissions for users on resources. For example, Editor is a role that allows users to view, modify, and create resources. Roles are denoted as `Role@`*`Resource`*; for example, `Editor@`*`Portal Page`*.

"Access permissions" on page 1537
Learn about sensitive operations for resources and the roles that are required to perform those operations. Sensitive operations include common tasks such as viewing portlets on specific pages and complex, high-risk tasks like running XML configuration interface scripts.

"Initial Access Control Settings" on page 1550
The administrative user who installs IBM WebSphere Portal Express has a default set of access rights.

Resources

Resources are organized in a hierarchy. Resources in the hierarchy propagate their access control configuration to all of their child resources. If a user has the Editor role on the Market News page, then that user also has the Editor role on child pages of the Market News page. Resource instances are specific resources, such as a single portlet or page. Each resource instance belongs to only one resource type. For example, the resource instance Market News Page would belong to the Content Nodes resource type.

Virtual resources are a unique resource type. Virtual resources have two functions:

- They protect sensitive operations that affect the entire portal or specific services in the portal. For example, the virtual resource XMLAccess protects the ability to run XML configuration interface scripts.
- They are parent resources for all resource instances. For example, the **Web Modules** virtual resource is the root node of all web modules instances. So by default role assignments on the **Web Modules** virtual resource are propagated to all individual **Web Modules** resources through inheritance.

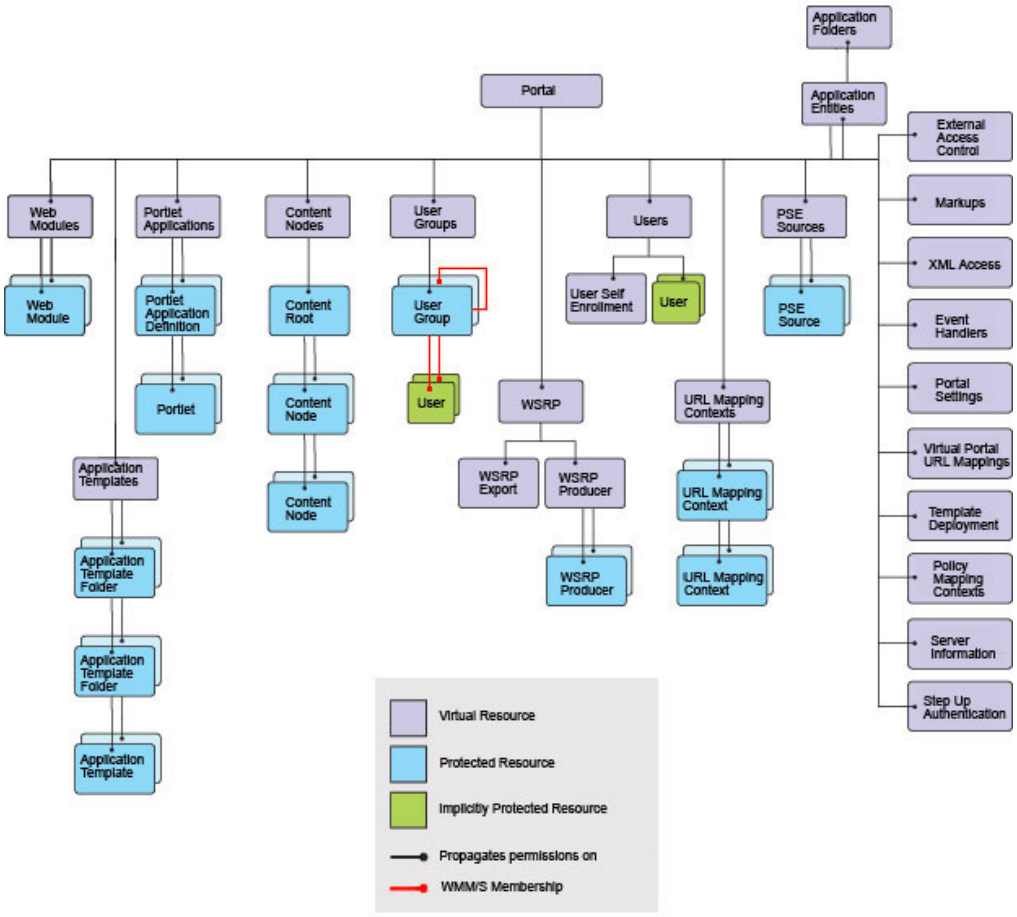
Resource data is stored in one of four different database domains. To have a consistent database back-up and restore, the access control data protecting individual resources is stored in the same database domain as the resource data. In each of the four domains, the protected resources are stored in a hierarchy as a single tree of resources. They are also known as the protected resource hierarchy.

Resources might be in different domains depending on the type of resource. JCR nodes are exclusively contained in the JCR domain. User customization data represented by private resources are exclusively contained in the customization domain. The community domain contains resources related to collaborative applications, and the release domain contains all remaining resources. Resources can be administered in the following ways:

- Protected Resources of the release domain can be managed through the access control administration portlets and through the XML Configuration interface
- Policy resources are stored in the JCR domain and can also be managed through the access control administration portlets and through the XML Configuration interface
- Resources in the community domain can be managed only through collaboration application-specific administrative portlets. Resources in this domain are not shown in the access control administration portlets
- The customization domain holds private resources for users only. No role assignments are possible in this domain, so resources in this domain are also not shown in the access control administration portlets

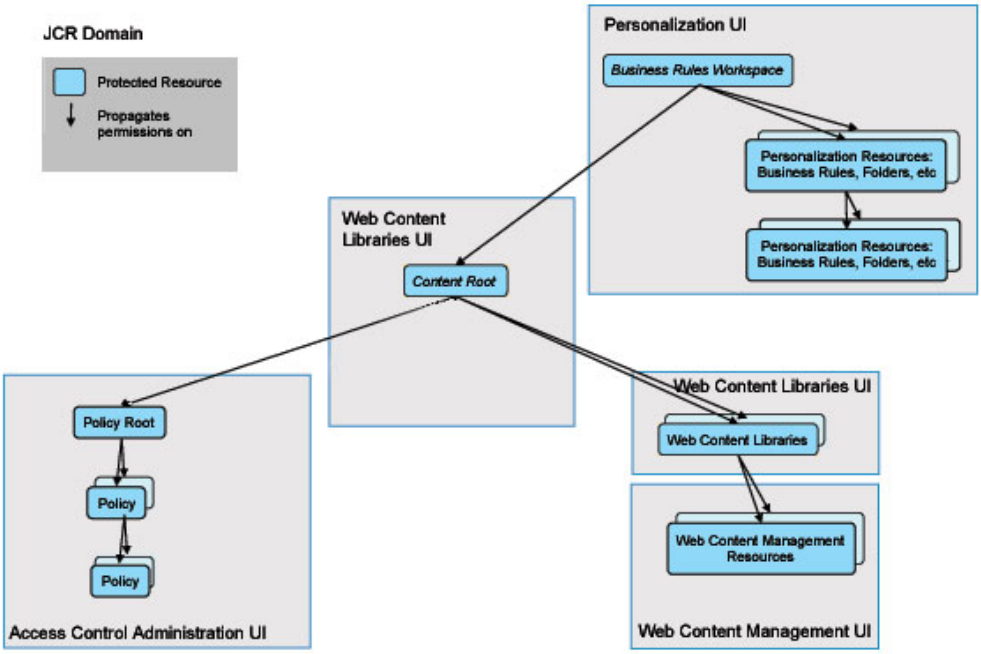
Note: Role inheritance never crosses domain boundaries, thus limiting the inheritance scope. A role assignment for a user on the Content Nodes virtual resource in the release domain grants access only to Content Nodes resources (pages) in the release domain.

Next are illustrations of the available resources tree, first for the release domain, and second for the JCR domain.



The following illustration shows the hierarchy of resources in the JCR domain. These resources are related to Personalization, Web Content Manager, and Resources Policies.

Note: This image represents an access control-specific view of resources in the JCR domain. It is not intended to show how the resources are stored and organized in the JCR domain.
Resource Permission inheritance applies to this hierarchy and to the release domain. Permission granted on the JCR Content Root node are propagated to all children in the hierarchy. Use Policies, Web Content Manager Libraries, Inheritance, and Propagation role blocks to reduce this propagation of permissions to children in the hierarchy.



A different user interface is provided to administer access control for each type of resource in the JCR domain. The following list shows the path to take within WebSphere Portal Express to reach the access control portlet for each resource stored in the JCR domain:

- Access Control Administration User Interface (UI):
  - Click the **Administration menu** icon. Then, click **Access** > **Resource Permissions**.
  - Click the **Administration menu** icon. Then, click **Access** > **User and Group Permissions**.
- Personalization user interface: **Personalization** > **Business Rules** > **Personalization Navigator portlet**
- Web Content Libraries user interface: Click the **Administration menu** icon. Then, click **Portal Content** > **Web Content Libraries**.
- Web Content Manager user interface: **Applications** > **Content** > **Web Content Management** > **Authoring portlet**

You can assign roles on virtual resources and on resource instances. Assigning roles on virtual resources reduces the time required to administer access control. All child resources inherit roles that are assigned to the parent resource by default. Assigning roles to specific resource instances offers more granular access control. You can assign roles to specific resource instances to override role blocks that block inheritance. For more information about role blocks, see the Roles topic.

The following information describes virtual resources. The resources listed might be different depending on other products that are installed with WebSphere Portal Express.

Administrative Slots

The root node of all administrative vault slots. It protects the administrative slot access and therefore the access to the credentials the slot holds.

Content Nodes
The root node of all pages, labels, and external URLs. Pages contain the content that determines the portal navigation hierarchy. If a new top-level page is created, it is automatically a child resource of the Pages virtual resource. If a new page is created beneath an existing page, the new page is automatically child of the existing page. Pages inherit access control configuration from their parent page unless role blocks are used.

Designer Deployment Service
Protects the ability to run the automatic deployment feature of IBM Workplace Designer.

Event Handlers
Protects management of Event Handlers. This virtual resource has no child resources.

External Access Control
Protects modifying access control configuration for resources that are controlled externally by a security manager such as Security Access Manager. Also protects the ability to externalize or internalize a resource. This virtual resource has no child resources.

Markups
Protects the ability to control markups for the portal. This virtual resource has no child resources.

Portal This resource is the root node of all resources in the release domain. Roles on this resource affect all other resources in the release domain by default through inheritance unless role blocks are used. Resources in other domains like Templates and Policies are not affected through role mappings on this resource.

Portal Settings
Protects portal settings that can be modified through the Portal Settings Portlet or the XML configuration interface. This virtual resource has no child resources.

Portlet Applications
The root node of all installed portlet applications. Portlet applications are the parent containers for portlets. If a new web module is installed, the applications that are contained within that module become child resources of the Portlet Applications virtual resource. Portlets that are contained within a portlet application are child nodes of that portlet application. Thus a two-layer hierarchy consisting of portlet applications and the corresponding portlets exists beneath the Portlet Applications virtual resource. Portlets inherit access control configuration from their parent portlet applications unless role blocks are used.

PSE Sources
The root node of all search collections. If a new search collection is created, it is automatically a child of this virtual resource. Roles on this resource affect all defined search collections unless role blocks are used.

URL Mapping Contexts
The root node of all URL mapping contexts. URL mapping contexts are user-defined definitions of URL spaces that map to portal content. If a new top-level URL mapping context is created, it is automatically a child resource of the URL Mapping Contexts virtual resource. If a new URL mapping context is created beneath an existing context, the new context is

automatically a child of the existing context. URL mapping contexts inherit access control configuration from their parent context unless role blocks are used.

User Groups
The root node of all user groups. Each user group in the portal inherits its access control configuration from the User Groups virtual resource. It is not possible to create role blocks on individual user groups.

User Self Enrollment
Protects the Selfcare and User Enrollment facilities (sign up and Edit My Profile). This virtual resource has no child resources.

Users This virtual resource has no child resources. The Users virtual resource protects sensitive operations that deal with user management. For example, in order to add a user to a user group, you must have the `Security Administrator@Users` role. Users are implicitly protected resources. Users cannot be protected individually, but only through their group membership. As a result, it is not possible to have a role assignment on a specific user. Roles must be on user groups instead. So, you can edit the user profile of Mary if you have a role assignment on some user group to which Mary belongs.

VP URL Mappings
Protects the ability to modify a URL Mapping linked to a virtual portal.

Web Modules
The root node of all **Web Modules**. **Web Modules** are portlet WAR files that are installed on WebSphere Application Server. **Web Modules** can contain multiple portlet applications. If a new **Web Modules** is installed, it is automatically a child of the **Web Modules** virtual resource. Roles on this resource affect all child resources (all installed **Web Modules**) unless role blocks are used.

WSRP This resource is the parent resource of the virtual resources `WSRP Export` and `WSRP Producers`. By default, roles on the `WSRP` resource affect the other two virtual WSRP resources and all WSRP resource instances through inheritance. If there are no role blocks in between, users who have role assignments on the `WSRP` resource have access rights on *all* WSRP resources.

WSRP export
This virtual resource controls the ability of a user to provide and withdraw portlets as a WSRP Service.

WSRP Producers
This resource is the root node of all registered Producer instances. Each Producer that is registered in the portal inherits its access control configuration from the `WSRP Producers` virtual resource unless role blocks are used.

XML configuration interface
Protects the ability to run XML configuration interface scripts. This virtual resource has no child resources.

ADMIN_SLOTS
The root node of all shared administrative credential vault slots that contain a system credential. This node controls access to modify and delete such vault slots and to retrieve its credentials.

POLICY MAPPING CONTEXTS
Identifies the Root node to all Policy items. This virtual resource is independent of the Mapping of a Policy.

SERVER INFORMATION
Protects the ability to create/modify/delete Mappings between a remote server information used for Federation and this WebSphere Portal Express server instance.

STEP UP AUTHENTICATION
Protects the ability to modify the binding of resources such as Portlets or Pages to an authentication level.

TAGS Users can apply keywords to describe, classify, or label web content resources.

RATINGS
Users can assign numeric values to web content resources for evaluation.

THEME MANAGEMENT
Users can update and modify the portal theme.

"Role blocks for resources"
Role blocks prevent inheritance and propagation through the resource hierarchy. This topic describes role blocks and provides examples of how role blocks affect resources.

Role blocks for resources:

Role blocks prevent inheritance and propagation through the resource hierarchy. This topic describes role blocks and provides examples of how role blocks affect resources.

Role blocks

There are two types of role blocks:

Inheritance blocks
Prevent child resources from acquiring role assignments from parent resources.

Propagation blocks
Prevent parent resources from extending role assignments to child resources.

Inheritance blocks and propagation blocks are similar in that they prevent parent resources from affecting child resources. You apply inheritance blocks to prevent parent resources from affecting only specific child resources. You apply propagation blocks to prevent parent resources from affecting all child resources.

Role blocks apply to specific resources. For example, the Market News page is the parent of the Europe Market News page and the USA Market News page. An inheritance block exists for the Editor role on the Europe Market News page. No inheritance blocks exist for the USA Market News page. All users with the Editor role on the Market News page (`Editor@Market News Page`) inherit the Editor role for the USA Market News page (`Editor@USA Market News Page`), but do not inherit the Editor role for the Europe Market News page.

Role blocks apply to specific roles. For example, an inheritance block exists for the Editor role on the Europe Market News page. This role block prevents the Europe

Market News page from acquiring any Editor role assignments from the Market News page. However, this role block does not affect inheritance of other roles. For example, no inheritance blocks exist for the Manager role. For this reason, all users with the Manager role on the Market News Page (`Manager@Market News Page`) inherit the Manager role on the Europe News Page (`Manager@Europe Market News Page`).

Creating and deleting role blocks

Use the following to create and delete role blocks:

XML configuration interface
Create and delete role blocks for all roles.

Portal scripting interface
Create and delete role blocks for all roles, except for Administrator and Security Administrator.
